Weight Loss and Maintenance

Epidemiologic studies show a lower body mass in subjects who eat a high-fiber diet and greater incidence of obesity in those with low intake of dietary fiber.^{31,40} Interventional studies show mixed results with high-fiber diets and weight loss, although less weight gain over time is associated with higher intake of whole grains.⁵⁰ Research suggests that fiber intake may influence body weight through various mechanisms, such as delayed gastric emptying, prolonged small bowel transit time and subsequent effects on peptides associated with satiety and gut function, activation of the “ileal brake” feedback mechanism, and stimulation of colonic cells, resulting in production of appetite-regulating hormones.⁵¹

Assessment of Functional Food Use: A Case-Based Approach

FF play a role in preventing disease and optimizing health. For patients who have mild signs of or are at risk for CHD, these foods may be a viable alternative to pharmacotherapy, as Case 24–1 illustrates.

Case 24–1

Relevant Evaluation	Scenario/Model Outcome

Criteria	
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has no symptoms but recently had a health assessment at work and was told that she is at risk for coronary heart disease because of her family history. She says she does not feel sick, but she does not want to end up taking a "bunch of pills every day" like her mother and oldest brother. She wants to do what she can to avoid heart disease and is particularly interested in "functional foods" because of a healthy lifestyle program she recently watched.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	n/a
c. Description of the patient's efforts to relieve the symptoms	n/a
d. Patient's identity	Angela Barcelona
e. Patient's age, gender, height, and weight	30 years, female, 5 ft 4 in., 190 lb
f. Patient's occupation	Third-grade teacher

g. Patient's dietary habits	Eats breakfast most mornings: typically a cup of tea and cereal bar from home or a fast food English muffin with egg and sausage.
	Lunch: usually has a sandwich with potato chips and soft drink from the cafeteria.
	Afternoon snack: typically has a candy bar or granola bar.
	Dinner: Usually has meat (beef, pork, or chicken mostly) and fish "every once in a while when someone has gone fishing"; rice or pasta most nights; fresh, frozen, or canned vegetable 4-5 times per week; sweet dessert (cake, pie, baked goods) or ice cream 5-6 times a week; typically has a soft drink with dinner and occasionally an alcoholic drink.
h. Patient's sleep habits	Usually sleeps about 8 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No medical conditions. She takes a birth control pill and multivitamin with folate daily.
j. Allergies	NKDA
k. History of other adverse reactions to medications	None
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms and correctly identify the patient's	Mrs. Barcelona has no signs or symptoms of disease but wants to follow a preventive strategy of a healthy diet.

primary problem(s).	
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mrs. Barcelona to her regular health care provider for a more thorough assessment for heart disease and evaluation of her risk. (2) Refer Mrs. Barcelona to a registered dietitian for comprehensive nutritional assessment and counseling. (3) Inform Mrs. Barcelona about foods that have health claims associated with reduced risk of heart disease. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	A combination of the options is appropriate.(1) Provide basic information and counseling related to functional foods with health claims associated with heart disease. Emphasize authorized and authoritative health claims (Table 24-1), because these are supported by strong scientific evidence. The limited evidence for qualified claims and structure-function claims can be presented along with a discussion of where they fit, if at all, in the patient's overall plan.(2) Refer Mrs. Barcelona for cholesterol screening (or perform screening in the pharmacy) and assessment for heart disease.(3) Refer Mrs. Barcelona to a dietitian if her daughter feels she needs more than basic counseling on nutrition, or have her request a referral from her primary care provider (may be necessary for insurance coverage).(4) Weight control and heart disease should be discussed with Mrs. Barcelona, or these issues should be suggested as part of her discussion with her primary care provider or a dietitian.
6. Describe the recommended therapeutic	"A number of foods with health claims are associated with decreased risk of heart disease. For several foods, there is significant scientific agreement regarding their potential benefits. Using these foods in place of some of

approach to the patient or caregiver.	your current foods may reduce your risk of heart disease. However, it also would be helpful to know what your risks are, including your cholesterol level.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Given your family history, you should have your cholesterol checked periodically and be evaluated for other risk factors for heart disease. Your weight is a risk factor for heart disease for you.”“I can provide you with basic information on foods that have health claims related to heart disease and that may be of benefit in maintaining heart health. Dietitians are the food and nutrition experts; they can do a comprehensive assessment of your diet and provide more in-depth dietary counseling if you want that.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	(1) “Decrease the saturated fat and cholesterol in your diet. No more than 10% of your calories should come from saturated fat, and you should limit cholesterol in your diet to no more than 300 mg cholesterol a day, but less is better. When you drink milk, you might want to try 1% milk; most people find that to be more acceptable than nonfat (skim) milk, and it is lower in fat than 2% milk. Or you could try soy or almond milk. Low-fat yogurt also is another good calcium source and usually is tolerated by people with lactose intolerance.”(2) “Eat fruits, vegetables, and grain products that contain fiber, particularly soluble fiber. Replace white breads and pasta with whole-grain products. Total dietary fiber should be at least 25 g daily.” [AI for women 19–50 years of age](3) “You also can get soluble fiber from oat bran, rolled oats, or whole oat flour in certain foods, or from barley. Incorporate these products into the diet as replacement for breads and cereals that are not whole grain.”(4) “Plant sterol and stanol esters also help to reduce the risk of heart disease. Total intake is at least 1.3 g daily of sterol esters or 3.4 g daily of stanol esters, as part of a diet low in saturated fat and cholesterol. You usually need to eat the products at least twice a day to get the recommended amount. Some margarines and orange juice have added plant sterol/stanol esters.”
	(5) “The health benefits of eating whole-grain foods overlap somewhat with those for grain products containing fiber, as noted earlier, but not limited to soluble fiber only. Insoluble fibers also are important in health. Look for whole grains, such as whole wheat, as the first ingredient on labels.”
	“To make these health claims, foods must generally contain a certain amount of the desired component. Check food labels for these claims and for ingredient amounts.”

	“There are also other foods that are considered healthy but do not yet have strong evidence to suggest they help to reduce the risk of heart disease. Therefore, the health claims may not be as effective or the claims might be changed if new studies are reported. Because the following foods are otherwise healthy foods when used in moderation, they can still be safely incorporated into your diet.”
	(1) “Walnuts and several other types of nuts: 1.5 ounces a day; remember that nuts are a concentrated source of calories, so use judiciously.”
	(2) “Omega-3 fatty acids: specifically eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA), found in salmon, lake trout, herring, and other oily fish.”
	(3) “Monounsaturated fats from olive oil: 23 g daily (2 tablespoons) in place of a similar amount of saturated fat. A number of salad dressings and a few soft margarines now include olive oil.”
	(4) “Canola oil, unsaturated fatty acids: 19 g daily (1.5 tablespoons) in place of a similar amount of saturated fat. Some cooking oil, a number of salad dressings, a few soft margarines, and some baked goods include canola oil.”
	(5) Oleic acid: 20 g daily (1.5 tablespoons) in place of fats and oils higher in saturated fat. A number of cooking oils, including olive oil, nuts, and avocado, include oleic acid.
	(6) Soybean oil: 20.5 g daily (1.5 tablespoons) in place of a similar amount of saturated fat. Soybean oil is now a popular oil to use for cooking.
Solicit follow-up questions from the patient or caregiver.	(1) “Are there any things I need to be aware of as I add these foods into my diet?”
	(2) “Are there any side effects from changing my diet?”
	(3) “Where can I find more information on dietary changes and diet plans to prevent heart disease?”
	(4) “May I use dietary supplements instead of changing to functional foods? Most information on the Internet is advertising for dietary supplements.”
Answer the patient’s or	(1) “These foods should replace other foods in your diet so that the total calories do not increase. The more ‘healthful’ fats must replace saturated

caregiver's questions.	fats and not increase the total fat intake. You will need to read food labels carefully to be sure you are getting whole grains, low saturated fats, low cholesterol, and sterol/stanol esters in the product. Also look for the amount of soy or soluble fiber."
	(2) "Rapid increases in fiber content of the diet can cause gas and bloating, so it is best to gradually increase the fiber in your diet. Replace 1-2 servings of white bread and pasta with whole-grain products every few days until the refined foods are totally replaced. Also add extra fiber by gradually replacing the low-fiber cereals with a whole-grain cereal or oatmeal. Fruits and vegetables can be increased gradually as well to replace snacks and desserts. Be sure to drink plenty of water when eating a high-fiber diet."
	(3) "The U.S. Food and Drug Administration website (www.fda.gov) includes information on health claims and food labels that you might find helpful. You could consider making an appointment with a registered dietitian, who could help develop some menus that incorporate foods you like and provide more specific plans for substituting healthier foods. Your health insurance plan may contract with a dietitian for coverage. If not, the Academy of Nutrition and Dietetics can provide the name(s) of private consultants and the contact information for a dietitian. The phone number for referrals is on their website (www.eatright.org)."
	(4) "In general, foods are better than supplements. Many studies have shown beneficial effects from a diet containing fiber-rich foods and whole grains but not with isolated supplements. Psyllium, found in products like Metamucil, fits criteria for a health claim related to soluble fiber and risk of congestive heart disease and could be used to increase soluble fiber. It also has the added benefit of reducing constipation, as do fibers from whole grains."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	"May we talk about the changes you have made in your diet when you pick up your prescription refills next month?"

Medical Foods and Meal Replacement Foods

Traditional medical foods include products developed for patients with inborn

errors of metabolism (“metabolics”). Product descriptions are available on manufacturer websites, and such products may be available from the federally funded Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), because this program is often involved in distribution of products and patient monitoring. Enteral nutrition formulas, specialty formulas in particular, may meet the definition of a medical food; however, many such products are better classified as food for “special dietary use,” because they are readily available for purchase without a medical recommendation or prescription and are marketed directly to consumers as regular foods, often as meal replacement products. Enteral formulas typically are semisynthetic liquid formulas intended for oral consumption or administration through a feeding tube. Certain liquid diets designed for use in medically supervised very-low-calorie diets or bariatric programs are classified as medical foods. Various puddings, shakes, and other solid or semisolid food forms specially formulated and processed to meet *distinctive* nutritional requirements of the disease or condition for which they are intended also can be classified as medical foods. Both liquid and solid medical foods may replace regular meals or enhance nutrient intake to meet the distinctive nutritional requirements of patients. However, these products also are frequently used to meet general nutritional needs.

Health care providers involved with self-care counseling should determine when a product is used as a medical food to meet truly distinctive nutritional requirements, as determined by scientific studies, and when it is used as meal replacement or enhancement to meet *general* nutritional requirements. Foods intended to meet general nutritional requirements do not need medical oversight and can be used safely for self-care. By contrast, FDA regulations state that use of medical foods requires recommendation or prescription by a physician or other authorized prescriber *and* ongoing medical supervision.^{4,16} Referral to a dietitian generally is appropriate for patients with distinctive nutritional requirements. When enteral formulas are used to meet general nutritional requirements, however, third party providers may refuse to cover the cost under insurance benefits, leaving patients with self-care responsibility.

Enteral Formula Uses

Tube Feeding

Enteral formulas are best known as complete nutritional replacements for patients requiring a feeding tube to meet their nutritional needs, such as persons with severe dysphagia subsequent to a stroke. Patients who cannot, should not, or will not take adequate nutrients by mouth are candidates for tube feeding and should be under medical care; tube feeding is not a condition conducive to a safe and effective self-care approach. Unfortunately, little if any support is provided by most suppliers of adult enteral formulas in today's health care environment, even if the formula itself is covered by insurance benefits. Patients in this situation may benefit from referral to a Certified Nutrition Support Clinician (CNSC) or Board Certified Nutrition Support Pharmacist (BCNSP) if they are experiencing any difficulty with their feedings. For information related to tube feeding, the reader is referred to one of the many specialized references available; to the Oley Foundation (www.oley.org), a consumer-oriented organization for support of people requiring intravenous or tube feeding; or to the American Society for Parenteral and Enteral Nutrition (ASPEN). In addition to topics related to enteral and parenteral nutrition, the ASPEN website (www.nutritioncare.org) contains literature and other resources related to malnutrition.

Many enteral preparations are currently available. Most formulas provide nutritional support consistent with general dietary guidelines and are safe for use in self-care. Formulas intended for patients with impaired digestion and those designed for specific metabolic or clinical conditions require oversight by a qualified health care provider. Characteristics that are likely to result in the use of a formula as a true medical food requiring medical supervision are listed in **Table 24–8**, along with a few representative products. The patient's overall health condition also influences the need for medical supervision. For example, formulas with >25% of calories from protein should be used with medical supervision in patients with compromised renal function, but the potential for adverse effects is of less concern when these products are used occasionally by people with normal renal function.

Table 24–8 Enteral Formula Characteristics Consistent With Need for Medical Supervision

Characteristic	Example(s)
Protein as peptides and/or free amino acids	Peptamen, Crucial, Vital

Characteristic	Example(s)
Alteration of amino acid content by addition of individual amino acids, such as glutamine, arginine, or branched-chain amino acids	Juven, Impact, Perative
Addition of specific fatty acids to alter the inflammatory response	Oxepa
Addition of significant amounts of medium-chain triglycerides to alter absorption	Portagen, Enfaport
High percentage (>50%) of calories from fat	Pulmocare
Very high protein content (≥25% of calories as protein)	Nutren Replete, Promote
Intended for patients with organ failure	Renalcal, Nepro, Suplena with Carbsteady, NutriHep

Supplementation of Nutrient Intake

Liquid food preparations, including enteral products initially developed for tube feeding, are often used as oral supplements. They frequently are marketed directly to consumers as supplements to the usual diet and as convenience foods to meet general nutrient goals, most commonly for protein, calories, or both. Older adults tend to be a major target for use of such products because of changes related to aging ([Table 24–9](#)) that may contribute to reduced oral intake and increased risk for malnutrition.^{52–55} Products also are marketed as “meal replacement” alternatives that are healthier than eating “fast foods” or skipping meals and that serve as a method of portion control. Persons participating in sports activities are targeted for selective products (see [Chapter 25](#)).

Oral nutritional supplements (ONS) benefit hospitalized patients who are undernourished at baseline; use of such products also is recognized to reduce hospital readmissions.^{53,55,56} A systematic review and meta-analysis conducted in the United Kingdom reported a reduction in readmissions from 33.8% to 23.9% with use of ONS compared with standard care; the number needed to treat was 10.⁵⁵ Benefit from routine ONS use at home or for persons who are well nourished in any setting is more difficult to demonstrate. However, reported prevalence rates for malnutrition among community-dwelling older adults living in industrialized nations vary, with a range of 7%–35%, depending on the criteria used to define malnutrition and the settings included.⁵⁴ Of chronically ill community-dwelling patients in the United States, 10% have

disease-associated malnutrition.⁵⁷ The cost of community-based disease-associated malnutrition in the United States is estimated to be \$157 billion based on 2010 dollars, with more than 75% of expenditures associated with increased morbidity. In addition, evidence is mounting for the need for higher protein intake among all older adults to maintain physical function and mitigate risk for sarcopenia, osteoporosis, and impaired immune response.⁵³ Unfortunately, physicians and other health care providers typically receive minimal training in nutrition, and malnutrition often is not addressed until patients are significantly malnourished. Patients and families may therefore seek self-care alternatives, including ONS, to improve nutritional intake and mitigate or prevent malnutrition. Growing evidence indicates that ONS can be useful to prevent malnutrition.^{53,55,56} These ONS products may or may not be complete (i.e., contain all necessary nutrients, including vitamins and trace elements) and balanced (i.e., contain appropriate ratios of nutrients) in their nutritional content. Users of such products should carefully review labels to ensure that their overall diet is complete and balanced.

Table 24–9 Changes With Aging and Other Factors That May Contribute to Poor Oral Intake and Malnutrition

Gastrointestinal Tract Changes
Reduced taste threshold
Motility dysfunction of lower esophageal sphincter
Slowed gastric emptying
Reduced gastric acid production
Decreased number and density of nerve fibers in the myenteric plexus
Impaired renewal and regeneration of intestinal epithelial tissue
Decreased number of Brunner glands in the duodenum resulting in a lower pH, which impairs pancreatic enzyme function
Colonic motility dysfunction resulting in either constipation or fecal incontinence
Structural changes in the pancreas
Decreased pancreatic lipase
Reduced gut-associated lymphoid tissue (GALT) immune response

Changes That Affect Protein Requirement and Intake
Reduced anabolic response to ingested protein
Impaired antiproteolytic response to insulin
High splanchnic protein extraction
Increased inflammatory and catabolic conditions
Other Factors
Poor appetite
Edentulousness
Self-reported poor health
Hospitalization

Classification of Enteral Nutrition Products

Enteral products are classified as polymeric formulas, oligomeric formulas, and modular components. In addition, a growing segment of meal supplement and meal replacement products, including beverages, bars, and puddings, are designed to assist in meeting nutrient goals within an appropriate caloric intake.

Polymeric Formulas

Polymeric formulas are used most often. They are for people with normal digestive capability and contain macronutrients in the form of intact (whole) proteins, carbohydrates, and fatty acids or oils. Most persons who require alternative nutrition support will tolerate and do well with standard polymeric formulas. The standard formulas usually (1) supply 1 kcal/mL unless concentrated to provide less free water; (2) feature a macronutrient composition typical of the American diet (carbohydrate: 45%–70%; protein: 10%–18%; fat: 20%–40%); and (3) are isotonic to slightly hypertonic with respect

to body fluids (300–450 mOsm/kg); however, the osmolality of flavored products often ranges from 500 to 700 mOsm/kg. Polymeric formulas are listed as being generally safe for self-care when taken orally ([Table 24–10](#)).

Table 24–10 Examples of Meal Replacement Products/Liquid Formulas Suitable for Self-Care^a

Product Name	Energy (kcal/mL)	Protein (g [% kcal])^b	CHO (g [% kcal])	Fat (g [% kcal])	Fiber (g)	Use as Sole Source of Nutrition?	Comments

Modular Components^d							
Bene-protein	25	6 (100%)	None	None	None	No	Listed content per 7 g packet or 1 scoop
ProMod Liquid Protein	100 (3.33)	10 (40%)	14 (60%)	None	None	No	Listed content per ounce (30 mL); curdles when mixed with enteral formula
Bene-calorie	330 (7.5)	7.5 (9%)	None	33 (91%)	None	No	Content per 1.5-ounce serving (44 mL)
Micro-lipid	67.5 (4.5)	None	None	7.5 (100%)	None	No	Content per 15 mL; 50% fat emulsion; safflower oil
Nutri-Source Fiber	15	None	4 (100%)	None	3	No	Content per 4 g serving; 100% soluble fiber

Note: The most current and detailed information is available at manufacturer websites, including Abbott Nutrition (www.abbottnutrition.com/brands) and Nestlé Nutrition (<https://www.nestlehealthscience.us/>).

^a Amounts are for an 8-ounce serving unless otherwise indicated. Some products are listed for use under medical care; however, the products meet nutritional content

consistent with general dietary guidelines, unless otherwise indicated, and can be used for self-care. The products can be obtained in consumer-size single-serving packages (8–12 ounces) without a prescription and are available through the Internet or retail businesses.

^b Protein content over 25% of calories should generally be used as a supplement to oral intake. Use as a sole source of nutrition should be under medical supervision even when a formula is listed as complete.

^c Use sparingly for self-care, because the fat content is relatively high compared with that in studies of high-fat/low-carbohydrate diets and is higher than that recommended by general dietary guidelines. In accordance with recommendations from the American Diabetes Association (www.diabetes.org; see American Diabetes Association, Bantle JP, Wylie-Rosett J, et al. Nutrition recommendations and interventions for diabetes: a position statement of the American Diabetes Association. *Diabetes Care*. 2008;31(Suppl 1):S61–78), monounsaturated fatty acid content tends to be higher than in many standard formulas, and saturated fat content is low. Products should be used as part of a diabetes management plan, which does require medical supervision.

^d Modular components can be added to food or mixed with water and flushed through a feeding tube. Modular components generally should not be added directly to the enteral formula.

Key: CHO = Carbohydrate.

Oligomeric Formulas

Oligomeric products require minimal digestion and also are known as predigested, peptide, or elemental formulas. They contain free amino acids, hydrolyzed or partially hydrolyzed protein, and less-complex carbohydrates. In these formulas, the fat content frequently is altered to improve absorption if impaired. Oligomeric formulas most often are used in the acute care setting when a polymeric formula has proved inadequate or for initial nutritional support for patients in whom malabsorption is likely because of critical illness, recent surgery, severe malnutrition, or exacerbation of gastrointestinal disease (e.g., Crohn disease). They are rarely consumed orally because of poor palatability. In general, use of oligomeric formulas requires medical supervision.

Modular Products

Modular products supplement a single macronutrient. Examples are protein powder, medium-chain triglyceride oil; emulsified oils, and powdered, flavorless glucose polymers. These products can be incorporated into food to increase protein and calorie content. For example, a protein powder may be of benefit in an older adult who is having difficulty meeting protein requirements with the usual oral diet.

Specialty Formulas

Specialty formulas may be either polymeric or oligomeric. They are designed to optimize nutrient intake and improve disease management for patients with specific disease states such as renal insufficiency, diabetes mellitus, hepatic dysfunction, and carbon dioxide–retaining pulmonary dysfunction. The use of specialty formulas is controversial; data supporting improved outcomes are limited. In general, use of such formulas requires medical supervision. Consultation with a registered dietitian, CNSC, or BCNSP may be warranted.

Immune-modulating formulas contain components such as arginine, glutamine, omega-3 fatty acids, dietary nucleotides, and/or antioxidants. They most often are used perioperatively in the acute care setting; however, oral consumption of an immune-modulating formula may be recommended for a specific period before and after major elective surgery in some patients. This use does not qualify as ordinary self-care and should be monitored by a qualified health care provider. Further information and guidelines related to immune-modulating formulas are available from nutrition support organizations, such as ASPEN ([nutritioncare.org](https://www.nutritioncare.org)).

Some specialty formulas, such as certain pulmonary and diabetic formulas, supply different ratios of fat and carbohydrate but contain no special dietary components. Although technically such products are medical foods, most people who use them could replace a few meals per week with little concern for adverse effects. However, patients must be encouraged to limit their use unless otherwise advised by a qualified health care provider or a specialist in nutritional management of their condition. In any case, meal replacement with such products should be reported to the primary care provider, because management of the underlying disease itself requires medical oversight. [Table 24–10](#) includes a few examples of pulmonary and diabetic formulas.

Product Use for Self-Care

All products recommended for self-care, whether initially marketed for tube feeding or intended for oral ingestion, should contain basic nutrition labeling, including serving size, calories, protein, fat, and other components consistent with food labeling so that nutrient intake can be determined in the same manner as for regular foods. Many formulas are available in a variety of flavors to reduce taste fatigue; nutrient content may differ slightly among the flavors.

Administration and Monitoring Guidelines for Enteral Nutrition

For products taken orally, the patient should be encouraged to vary flavors to avoid taste fatigue and to consume the product after an attempt to eat a well-balanced meal or a between-meal snack. Chilling may improve palatability. Once opened, the container should be kept refrigerated to prevent bacterial growth, and all open or prepared products should be discarded after 24 hours.

When products are given as tube feedings, medical supervision is recommended. Enteral nutrition practice recommendations are available at the ASPEN website (www.nutritioncare.org). Referral to a nutrition support provider may be appropriate. Medical referral is appropriate for patients in whom consumption of meal replacement formulas leads to development of diarrhea, nausea, or abdominal distention. Formula-related diarrhea is an osmotic diarrhea that usually stops within 24 hours of discontinuing the formula; diarrhea that persists longer is unlikely to be caused by the formula per se. Lactose intolerance is seldom an issue with enteral formulas; most formulas, except powders prepared with milk, are lactose-free. Other products not intended for tube feeding, however, may contain lactose. Many high-protein products marketed for oral consumption by the general population contain milk proteins (whey and/or casein), although they are lactose-free. High-fat products can delay gastric emptying, resulting in nausea and/or abdominal bloating.

Food–Medication Interactions

Interactions between medications and enteral formulas often are complex and

poorly understood. Interactions involving a formula component have the potential to occur with either oral administration or feeding tube administration. The health care provider is advised to consult specialty references for a more complete listing and explanation of such interactions. Although controversial, general practice with administration of certain medications (including phenytoin, carbamazepine, and warfarin) is to withhold the tube feeding formula for 1 or 2 hours before and after giving the medication, especially when therapeutic levels are not achieved with typical doses. It is reasonable to suggest this same precaution of separating drug administration by 1 or 2 hours when formula is taken by mouth and to advise supervision of the medication response by a primary care provider. Vitamin K content of the formula also should be checked for patients on warfarin. Although most formulas provide no more vitamin K than that of a typical diet, a few contain this vitamin in amounts that could interfere with anticoagulation. Manufacturers' websites, such as those listed in the footnotes in [Table 24–10](#), provide detailed, up-to-date information on the nutrient content of formulas.

Other Medical Foods and Meal Replacement Foods

In recent years, several medical foods have become available for a range of common diseases treated in the ambulatory care setting ([Table 24–11](#)). Foods used in weight loss and bariatric programs also are medical foods for which medical supervision is required with use as intended, because of the significant risks associated with rapid weight loss. Meal replacement foods such as Slim Fast, Weight Watchers, and Jenny Craig products are not medical foods. They can be used safely without medical supervision to help control portion size and to balance nutrient intake; however, they should be used as part of an overall weight loss plan (see [Chapter 27](#)).

Assessment of Enteral Nutrition and Meal Replacements: A Case-Based Approach

The first step in assessing the type of meal replacement (or supplement) to

recommend is to determine the presence of any of the exclusions for self-care listed in [Table 24–12](#). If self-care is permissible, the provider should ascertain the reason for a meal replacement or supplement so that the most appropriate product can be selected. For instance, an older adult with early satiety may benefit from a concentrated formula that provides 1.5 or 2 kcal/mL, whereas for a young person seeking a meal supplement for use with weight lifting, a higher protein formula may be more appropriate. The selected formula should meet the patient’s specific nutritional needs according to health status while avoiding excessive or contraindicated macronutrients and micronutrients.

Table 24–11 Examples of Products Marketed as Medical Foods for Common Conditions

Condition	Product(s) [Alternate Name] (Manufacturer)
Alzheimer disease	Axona (Accera, Inc.)
	Cerefoli Nac [metafolbicplus] (Alphasigma USA, Inc.)
Attention deficit hyperactivity disorder (ADHD)	Vayarin (VAYA Pharma, Inc.)
Depression	Deplin [levomefolate] (Alphasigma USA, Inc.)
Depression-associated sleep disorders	Sentra PM (Targeted Medical Pharma)
	GABAdone (Targeted Medical Pharma)
Diabetic neuropathy	Foltanx (Breckenridge, Inc.)
	Metanx (Alphasigma USA, Inc.)
Dyslipidemia	UltrMeal Cardio 360° (Metagenics)
Fatigue and cognitive disorders	Sentra AM (Targeted Medical Pharma)
Inflammatory bowel disease–associated gut dysfunction	UltrInflamX Plus 360° (Metagenics)
Irritable bowel syndrome	VSL#3 probiotic (Sigma-Tau Pharmaceuticals)
	Enteragam (Entera Health, Inc.)
Osteoarthritis	Limbrel (Primus Pharmaceuticals)

Condition	Product(s) [Alternate Name] (Manufacturer)
Osteopenia/osteoporosis	Fosteum Plus (Primus Pharmaceuticals)
Pain and inflammation	Theramine, for chronic pain (Targeted Medical Pharma),
	Trepadone, for joint disorders (Targeted Medical Pharma)
	Percura, for peripheral neuropathy-associated pain and loss of sensation (Targeted Medical Pharma)
Sarcopenia	UltraMeal Advanced Protein (Metagenics)
Ulcerative colitis	VSL#3 probiotic (Sigma-Tau Pharmaceuticals)

Table 24–12 Exclusions for Self-Care With Enteral Formulas

Condition	Example/Comments
Organ dysfunction requiring diet modification	Renal insufficiency requiring restriction of protein and electrolytes eliminated through the kidneys (potassium, phosphorus, magnesium)
Gastrointestinal dysfunction	Poor motility: Dietary modification may be required to avoid bowel obstructions; enteral formula may be appropriate under the supervision of a PCP or nutrition specialist; use for self-care is not appropriate.
	Reduced absorption: Hydrolyzed protein, modified fats, and/or relatively simple carbohydrates may be necessary for adequate absorption; monitoring for nutrient deficiencies is required.
	Dysphagia: Referral for medical evaluation is required.
	Bariatric surgery: Medical supervision is required; recommendations of a PCP or nutrition specialist should be followed.
Significant unintended weight loss	Refer for medical evaluation to determine the underlying cause.
	Life-threatening fluid and electrolyte abnormalities can occur when refeeding affected persons; medical supervision and monitoring are required.
Disease state affected by diet, such as diabetes	Enteral formula may be appropriate to meet nutritional requirements; use should be under the supervision of a PCP or

Condition	Example/Comments
mellitus, chronic obstructive pulmonary disease	nutrition specialist; use for self-care is not appropriate.

Key: PCP = Primary care provider.

Meal replacement products can have efficacy for the treatment of many health concerns. Traditionally, meal replacement has been considered a therapeutic intervention needed to maintain adequate nutrition in malnourished patients; to completely replace nutritional intake in patients with a physical limitation that interferes with nutritional intake (e.g., dysphagia); or to precisely control intake of specific dietary components (calories for obesity and phenylalanine in phenylketonuria). Increasingly, nutrition products are used as lifestyle choices of self-directed therapy. This practice is particularly true of the meal replacement products used by working people who are too busy to prepare or eat a proper meal or who perceive these products as healthier alternatives to fast foods.

Case 24–2 illustrates assessment of a patient with Alzheimer disease for whom a food/liquid meal product seems indicated.

Case 24–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	

a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is an older adult with progressive Alzheimer dementia symptoms. Her daughter reports that the patient is easily frustrated and demanding of attention.
	The daughter also describes her as being very forgetful, asking the same question every 5 minutes and being very upset that she is not getting an answer despite her daughter's answering each time. Signs of dementia have worsened in the past month. At the Alzheimer family support meeting last week, the daughter heard about a food/liquid meal that is helpful in slowing the disease's progression, and she is requesting this product for her mother.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	n/a
c. Description of the patient's efforts to relieve the symptoms	Patient is currently taking a combination product containing donepezil and memantine (changed a month ago from donepezil). She also takes a "senior" multivitamin/mineral supplement.
d. Patient's identity	Sophia Valdez
e. Patient's age, gender, height, and weight	82 years, female, 5 ft 1 in., 100 lb
f. Patient's occupation	Homemaker
g. Patient's dietary habits	Usually has two meals daily and a couple of snacks. Must be reminded to eat and encouraged to eat more than one food off her plate; sometimes she refuses to eat anything.
h. Patient's sleep habits	Sleeps about 6 hours at night but also naps during the day.
i. Concurrent medical conditions, prescription and	Hydrochlorothiazide for hypertension; multivitamin/mineral supplement

nonprescription medications, and dietary supplements	
j. Allergies	No known medical allergies
k. History of other adverse reactions to medications	Ataxia with metronidazole
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient's daughter is requesting a medical food for use in Alzheimer dementia.
3. Identify exclusions for self-treatment (Table 24-12).	Medical foods require medical supervision.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer patient to her regular health care provider to discuss use of the medical food and to obtain a recommendation. (2) Recommend self-care with a general supplement to improve nutrient intake. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into	Patient's daughter should consult with her mother's primary care provider regarding the medical food.

account patient preferences.	
6. Describe the recommended therapeutic approach to the patient or caregiver.	“You are requesting a product that requires medical supervision for use. The pharmacy can order the product for you once you have discussed this with your mother’s health care provider and you have a recommendation.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“In addition to verifying that your mother has medical supervision for using the product, a prescription may make the product eligible for coverage by your mother’s insurance, although such products typically are not covered.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“Do you know how this product works, and could I just change what I cook for my mother rather than discussing her eating problem with her provider? I thought this product would also help with her calorie intake, as she has lost 7 or 8 pounds in the last couple months, because she often refuses to eat at mealtime. She will drink a milk shake when I’m home to make one in the afternoon, but I’m at work most afternoons. Is there a product that I could use instead that would also increase her daily calories?”
Answer the patient’s or caregiver’s questions.	“The medical food product for Alzheimer disease is based on a specific type of fat that is absorbed and metabolized differently than the typical oils found in the grocery store. It must be given in an appropriate amount with a proper balance of other nutrients to achieve the desired effect. Your mother’s weight loss is concerning

	and should be evaluated by her primary care provider to be certain the weight loss is related only to not eating enough; it could be related to a medical condition that requires treatment.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	“Let me know when you have discussed these issues with your mother’s primary care provider. If you decide to try the medical food for Alzheimer disease, I can order the product once you obtain the recommendation, and preferably a prescription for documentation of medical supervision. If you want more information on the product, you also can check the product manufacturer’s website (www.about-axona.com). The Alzheimer’s Association website (www.alz.org) also has information on current research, alternative therapies, and their evaluation of various types of products marketed for Alzheimer disease.”
	“A prescription is not required for most liquid meal products intended to supplement calories, and I can help you select a product if your mother’s regular health care provider thinks her weight loss is primarily due to inadequate food intake. You also may want to ask your mother’s provider about a nutrition consultation, because a dietitian or nutrition support specialist could provide a more complete nutritional assessment as well as more comprehensive recommendations related to her diet.”

Patient Counseling for Enteral Nutrition and Meal Replacements

Advancements in home infusion therapy, along with development of an increased range of enteral products, are allowing more people with serious, even terminal, illnesses to be cared for at home. Enteral products also are appropriate for ambulatory patients with metabolic or digestive diseases and for persons who want to ensure adequate nutrition for their life stage. Providers serve a pivotal role in helping patients to select the optimal product for their nutritional needs and to assist them in its proper use, under medical supervision when indicated. The box “Patient Education for Enteral and Meal Replacement Products” lists specific information to provide patients and

Patient Education for Enteral and Meal Replacement Products

The objective of self-treatment is to provide the appropriate amounts and types of specific micronutrients and macronutrients to meet the person's nutritional needs. For most people, the product instructions and self-care measures listed here will help ensure optimal therapeutic outcomes.

- Typical products provide 1 Kcal/mL; higher-calorie products are available if you must limit your fluid intake or can drink only a small amount at a time.
- When drinking the formula, take about ½–1 can/container at a time. You can drink the formula at room temperature, but it may taste better if chilled or semifrozen as a slush-type drink.
- Varying the flavor of the formula may reduce taste fatigue.
- For tube feeding, the product should be used as directed by your primary care or nutrition care provider. The Oley Foundation (www.oley.org) provides consumer information on tube feeding.
- Keep opened containers refrigerated and covered to prevent bacterial growth; discard all remaining prepared products after 24 hours. Unopened product can be stored at room temperature.
- Use of meal replacement products as the sole or primary source of nutrition for longer periods of time (>3 weeks) requires medical supervision and should be discussed with your primary care provider. Periodic laboratory testing may be appropriate to detect electrolyte abnormalities in this situation.

When to Seek Medical Attention

- Monitor blood glucose (sugar) levels if you have diabetes or have had high blood glucose levels. Talk to your primary care provider if your blood glucose levels are high or low.

Key Points for Functional and Meal Replacement Foods

- The definition of FF typically includes providing “health benefits beyond those of basic nutrition.”
- Health claims are statements describing an association between a food, food component, dietary ingredient, or dietary supplement and the risk of a disease or health-related condition.
- Authorized and authoritative health claims meet the significant scientific agreement level of evidence. These claims should be routinely incorporated into counseling for lifestyle changes associated with health benefits and, when appropriate, included as part of an overall plan for management of diseases associated with these claims.
- Qualified health claims do not meet the significant scientific agreement level of evidence; a claim statement must include language that indicates the qualified nature of the health claim.
- Structure–function claims lack the significant scientific agreement level of evidence and make no association between the product and the risk of a disease or health-related condition; they do not require validation or authorization by FDA.
- Health care providers should understand the limitations of qualified health claims and structure–function claims. In counseling for lifestyle changes, the limited scientific evidence for these claims should be clearly delineated so that patients can understand the role, or lack thereof, for these products in a healthy lifestyle.
- Foods for special dietary use meet particular dietary needs related to physical, physiologic, pathologic, or other conditions, such as disease, convalescence, pregnancy, lactation, underweight, overweight, infancy, or need for sodium restriction, or are used to supplement or fortify the usual diet. They are subject to general

labeling requirements for foods and do not require use under medical supervision.

- Medical foods are specially formulated and processed to meet distinctive nutritional requirements (established by medical evaluation based on recognized scientific principles) of the disease or condition for which they are intended. These foods are to be recommended and used under medical supervision.
- Conventional foods classified as FF typically are associated with health benefits in epidemiologic studies; evidence supporting a functional role for these foods is weak–moderate, with clinical trials often lacking.
- Fiber is associated with improved laxation, cholesterol reduction, satiety, and probably glucose control for select fiber sources.
- Enteral nutrition products may be classified as medical foods; however, many polymeric enteral formulas are readily available and often can be used safely as a meal replacement product.
- Specialty enteral formulas should be used with medical supervision, not for self-treatment.
- Semisynthetic liquid formulas intended for oral consumption may or may not be complete and balanced nutritional products.
- Nutrient content of meal replacement products should be considered in evaluating dietary intake to ensure that the overall dietary content is complete and balanced.

Chapter 25: Sports Nutrition and Performance-Enhancing Nutrients and Supplements

Authors: Mark Newnham

Recreational athletes exercise at a variety of intensities but usually target general health, wellness, or stress reduction as an intended outcome. Such recreationally active people typically perform less than 1 hour of activity per session and usually engage in only 3–4 sessions each week. The Academy of Nutrition and Dietetics would classify this group of athletes, who are active less than 7 hours per week, as low-volume exercisers.¹ Diet alone should meet their nutritional needs. By comparison, athletes in a program of moderate training for 7–20 hours per week or high-volume intense training for greater than 20 hours per week may require specific nutritional intake to maintain or enhance performance.¹ This chapter provides an introduction to the effects of products that contain macronutrients and nutritional supplements on physical activity and performance for both the recreational athlete and the more aggressive competitor.

Certain food supplements and natural products are marketed as ergogenic aids to athletes and other active people for three primary purposes: (1) to improve strength and power, (2) to prolong the duration of exercise by providing fuel for continued effort, and (3) to replace water and electrolytes lost in sweat with exercise, thus preventing dehydration and supporting normal muscle contractions. Detailed discussions on this topic are available in published guidelines from both the International Society of Sports Nutrition (ISSN) Exercise and Sport Nutrition Review² and a joint statement of the Academy of Nutrition and Dietetics, the Dietitians of Canada, and the American College of Sports Medicine (this collaboration is referred to collectively as “the Academy” in the remainder of this chapter).¹ Sports nutrition is a complex field. Highly competitive and elite athletes who seek advice about sport-specific nutrition or ergogenic aids should be referred to a clinical dietitian with a subspecialty in sports nutrition.

Popularity of Sports Nutrition Products

Sports nutrition products and performance-enhancing supplements have gained wide acceptance in both highly trained athletes and mildly to moderately active people. Increasing numbers of consumers are choosing sports nutrition products as lifestyle alternatives to traditional beverages and snacks. In 2015, the sports nutrition market was estimated to reach \$16 billion in sales worldwide.³ The market segment includes traditional carbohydrate and electrolyte sports drinks, along with energy drinks with supplemental caffeine; recovery drinks; and other nutrient-enhanced soft drinks, juices, and waters. The market for solid forms includes meal replacement bars and easy-to-digest carbohydrate gels. Tablets, capsules, and powders that contain macronutrients, electrolytes, and herbal supplements also are included in the supplement market.

Use and Regulation of Performance-Enhancing Supplements: Labeling and Antidoping Considerations

The U.S. Food and Drug Administration (FDA) does not approve dietary supplements or validate claims of athletic performance enhancement. Reports of nutritional supplement misbranding are common, however, and use of misbranded supplements can result in doping violations within a sport.⁴⁻⁶ *Misbranding* is a lack of correlation between ingredient claims and the actual contents. Misbranded products may contain an ingredient that is not listed on the nutrition facts, or a listed ingredient may not even be present. Misbranded products may also occur when the quantity of an ingredient is significantly more, or less, than the labeled quantity. Unlabeled doping substances, including stimulants and anabolic steroids, were found in 19% of vitamin and creatine supplements submitted for voluntary testing by Olympic athletes in 2002.⁴ An even higher percentage of misbranding was reported in “black market” supplements confiscated by Norwegian authorities and tested by the Norwegian Control Doping Laboratory.⁵ Of the 296 products seized, 80% contained prohibited substances, including anabolic-androgenic steroids, glucocorticoids, antiestrogens, cannabinoids, and other drugs. A recent summary of publications from the period 2000–2017 found frequent misbranding among the supplements tested, with reported contamination rates of 12.5%–58%.⁶ This large review included observational studies in which

human volunteers underwent blood and urine testing after ingestion of various nutritional supplements. In several instances, prohibited substances were identified in the blood and urine samples. These findings suggest that the use of misbranded substances while in competition may lead to doping violations.⁶

The World Anti-Doping Agency states clearly in its Anti-Doping Code that “*Athletes are responsible for any Prohibited Substance or its Metabolites or Markers found to be present in their Samples.*”⁷ A positive test result is a violation regardless of the athlete’s intent or the package label, even when the source can be traced to a nutritional supplement.⁷ Nutritional products are tested at independent laboratories such as ConsumerLab.com, which provides reports for a fee. A list of banned substances and antidoping resources is available from both the U.S. Anti-Doping Agency (at www.usantidoping.org) and the World Anti-Doping Agency (at www.wada-ama.org). Results of independent product testing for banned substances and misbranding are reported by ConsumerLab.com (at www.consumerlab.com), which receives no industry funding. Chapter 50 provides a more detailed discussion of dietary supplement regulation.

Dietary supplements and prescription drugs are used and shared among college and high school athletes, possibly for performance gains. In 2017, the National Collegiate Athletic Association (NCAA) surveyed 23,000 athletes who participated in sports at division I, II, and III levels.⁸ The NCAA survey reported that student athletes were just as likely to use a protein supplement (41%) as they were to take a general multivitamin supplement (41%) in the past 12 months. The report also indicated that 31% of student athletes were using energy boosters (e.g., energy drinks, energy shots) and 13% were using creatine products. Many of today’s high school athletes also are occasional or regular consumers of nutritional supplements.⁹ A survey of American high school athletes published in 2007 noted a high rate of nutritional supplement use: 62.1% used a daily multivitamin, 31.2% used energy drinks, 21.8% used protein powders, and 12.2% used creatine. Among female athletes, 18.6% of seniors reported using a thermogenic substance or “fat burner,” to boost metabolism and lose weight. Of the male students, 5.9% reported using an anabolic steroid. High school athletes reported greater use of these substances compared with college-age students; accordingly, education on the safe and effective use of nutritional intervention, supplements, and performance-enhancing products is needed as early as the high school years.

The American Academy of Pediatrics (AAP) has determined that the average child engaged in routine physical activity should drink water for hydration. AAP has taken the position that carbohydrate-containing sports drinks are not necessary in school sport activities, and that caffeine-containing “energy drinks” should not be consumed by children and adolescents.¹⁰

Macronutrient Use for Athletic Performance—Basic Concepts

Macronutrients (carbohydrates, fats, proteins) play pivotal roles in athletic performance and muscle development, but each type of macronutrient has unique properties and use. Even during competition, the primary drive is to preserve muscle glycogen for “fight or flight” responses. Four primary concepts explain sports nutrition macronutrient intake and its contribution to energy provision for athletic performance. First, when the athlete is not exercising, unused energy from ingested macronutrients are stored for later use. If muscle glycogen stores are full, the remainder is converted to and stored as fat. Second, during exercise, stored macronutrients are used slowly according to the exerciser’s aerobic capacity to burn fats rather than glycogen, thus preserving glycogen. The oxidation of fatty acids is the primary mode of energy release and consumption for aerobically intense activity. Third, muscle glycogen is depleted slowly at lower intensities or when the athlete is aerobically adapted to use fats. By comparison, muscle glycogen is depleted rapidly at high intensities, particularly when the athlete is trained to use carbohydrates as fuel or expects carbohydrate availability during the event. Finally, at the highest intensities, an anaerobic energy system contributes energy from muscle phosphocreatine (i.e., creatine phosphate) directly to depleted adenosine diphosphate (ADP), permitting restoration of muscle adenosine triphosphate (ATP).

The first concept of energy use in exercise is that of glycogen preservation and preferential fatty acid oxidation in aerobic environments. Humans are biologically designed to maintain a full reserve of glycogen as an immediate energy source for short-duration, high-intensity activity, such as fight or flight. At the lowest level of exercise intensity, a walking state, calorie utilization per minute is minimal, with 80% of the calories obtained from fatty acid oxidation and the remaining 20% derived from carbohydrates.^{11,12} As exercise intensity

increases on progression from walking to aerobic jogging, calorie consumption per minute increases, and fatty acid oxidation continues to provide about 80% of the fuel.^{11,12} Conversion of fatty acids to energy is slow and rate-limited, and the conversion rate varies for different athletes. Fatty acid oxidation is increased by low carbohydrate availability in the diet and by adaptation to aerobic physical exercise.¹³ No proposed ergogenic supplements have been shown to consistently improve the rate of fatty acid metabolism.^{1,2} A detailed discussion of fatty-acid metabolism is beyond the scope of this chapter and can be found elsewhere in the literature.^{12,13}

Second, calories burned per minute from fats are limited and reach a plateau; at that point, athletic performance will be impaired without additional calories from other sources such as carbohydrates.¹¹⁻¹³ At the intensity of a fast run, such as a 10-km race, fatty acid oxidation cannot meet all energy requirements, and energy from carbohydrate utilization is added to that derived from fats. At this level of intensity, carbohydrate utilization increases to 30% of total calorie expenditure.¹⁴ The percentage of energy from carbohydrate oxidation rises to 50% and 70%, respectively, for sprint events of 400 m and 200 m.¹⁴ Progression of exercise intensity from walking to running to sprinting is a component of many sports activities, and some sports, such as soccer and field hockey, involve a combination of extreme high-intensity effort intermixed with efforts at a more aerobic pace. The oxidation of fatty acids is the predominant mode of fuel generation until exercise intensity requires the faster energy conversion from carbohydrates.

Third, glycogen depletion is mediated by both intensity and duration of activity. Marathon runners refer to the subjective experience of muscle glycogen depletion as “hitting the wall.” A similar term, “bonking,” references the cognitive and mental attention deficits incurred when glycogen depletion leads to hypoglycemia. Limited storage capacity exists for glucose as glycogen within the liver and skeletal muscle; an average 150-pound person stores only about 2000 total calories of glycogen. High-intensity exercise over time depletes glycogen stores.^{11,12} Muscle glycogen is burned initially, and as this resource is depleted, the liver releases glucose from stored glycogen to maintain serum glucose levels. When both muscle and liver glycogen stores are depleted, serum glucose decreases and athletic performance declines. Sudden drops in blood glucose levels affect the athlete’s mental acuity, attention, and focus.^{11,12} Endurance athletes slow to an aerobic effort in which fatty acid mobilization predominates, but they are less competitive at that

level of exercise intensity. Athletes participating in sports that require high-level cognitive skills, such as shooting sports, archery, and automobile racing, experience lower performance and brain activity as their serum glucose levels decrease.^{1,2} The rate of glycogen depletion is dependent on the intensity and duration of exercise, as well as the fitness level of the athlete.^{10,11}

Endurance runners can deplete muscle glycogen in about 2–2.5 hours at a marathon run training pace; they do not require carbohydrate intake unless they exercise for that duration or longer at lower intensities (see the later section “Carbohydrate-Based Products” for recommended carbohydrate intake).^{1,2} Carbohydrate intake during the race can delay the onset of muscle glycogen depletion when running at the higher intensity of a marathon race pace. The same runners may deplete glycogen in 60 minutes when running at the faster intensity of a 10-km run, but they generally do not require carbohydrate supplements, because they complete the event in less time (30–40 minutes) than it takes to deplete muscle glycogen.^{1,2} Team sports such as football, lacrosse, field hockey, and basketball have official game time durations of 60 minutes or less, as well as time-outs, half-times, and player substitutions that allow for periods of aerobic recovery. With mandated durations for these sports, glycogen depletion is not expected to occur unless the athlete is consistently on the field playing at a high intensity. Compared with undertrained athletes, very fit athletes adapt over time to a state of efficient fatty acid utilization and require less glycogen; their carbohydrate stores are available in later stages of an event.^{11,12}

A fourth concept is that the highest intensity sports, those requiring short bursts of power lasting less than 30 seconds to 1 minute, use the phosphagen system and energy stored primarily as ATP.¹⁵ Examples are track and field events and weight lifting. Energy stored in phosphate bonds is depleted in a matter of seconds and then regenerates with rest. This energy system is discussed further in the section “Creatine.” Intermittent high-intensity sports such as football, soccer, basketball, tennis, and ice hockey use both very short (phosphagen and ATP) energy systems and intermediate (glycogen) systems over the competition range of 30–60 minutes.

Sports Nutrition Market Basics

The sports nutrition market was developed for well-trained athletes competing

at high levels of intensity and for long-duration if activity. College football players, for example, may exercise for 4 hours daily and exceed 20 hours of exercise per week. These athletes may need to provide fuel during exercise to delay or prevent glycogen depletion, or they may require rapid muscle glycogen restoration between morning and afternoon practices. Sports drinks can be consumed during practice or competition, and on-the-go fueling has replaced the concept of carbohydrate loading before long-duration events. Most marathon runners and triathletes consume carbohydrates during their events, which typically last 90–240 minutes or longer.^{1,2} Sports products also contain electrolytes to prevent deficiencies from sweat loss.

By comparison, moderate physical activity such as daily exercise for health and wellness usually occurs at a lower intensity and typically lasts 60 minutes or less per day.^{1,2} Glycogen depletion is unlikely for recreational athletes, even if they exercise 7 hours per week; consequently, carbohydrate- and electrolyte-containing sports products are unnecessary for health and wellness athletes or sedentary persons who do not participate in prolonged exercise.^{1,2}

Carbohydrate-Based Products

Carbohydrate-based sports nutrition products contain monosaccharides (e.g., glucose, fructose, galactose) as well as the disaccharide sucrose (glucose + fructose); these sugars provide rapid absorption and availability of carbohydrates. Maltodextrin (glucose + glucose as a polymer) is used in endurance formulas and is marketed as having slower absorption; maltodextrin also is tasteless, which is preferred by many athletes. Lactose (glucose + galactose), or milk sugar, also can be used as a recovery fuel after exercise.^{1,2}

The Academy guidelines for carbohydrate intake by athletes are broken down by exercise intensity and planned duration of exercise. Carbohydrate intake is not needed during exercise for events lasting less than 45 minutes regardless of intensity. For highly intense exercise lasting 45–75 minutes, the Academy considers rinsing the mouth with a sports drink during the activity as possibly performance-enhancing, although evidence for a performance benefit of this brief mouth rinse is inconsistent.^{2,16} Observations are limited to well-trained cyclists exercising for around 60 minutes and show small 1%–3% improvements in watts of energy produced, or in time trial distance covered.¹⁶ No improvements have been shown in other activities such as weight lifting or

sprinting.¹⁶ For prolonged exercise and “start and stop” sports activities that exceed 60–150 minutes, the Academy recommends intake of 30–60 g of carbohydrate per hour.¹ This recommendation translates to intake of 8–15 g of carbohydrates or 4–8 ounces of a sports drink every 15 minutes.

Most sports nutrition drinks contain 6%–8% carbohydrates for optimal absorption and gastrointestinal (GI) tolerance.^{1,2} The amount of carbohydrates is small and should be used up rapidly during continuing exercise; however, the fluid volume is relatively large. Energy gel packets are lighter and easier to carry, but they contain 20%–25% carbohydrate and should be consumed with water for dissolution. These products should be used in practice and under simulated competition to determine the athlete’s tolerance of different preparations. Research suggests that pre-exercise carbohydrate consumption may stimulate the release of insulin, potentially resulting in hypoglycemic symptoms with reduced performance in some athletes, whereas this practice has been recognized to improve performance in others.¹⁷ Ultra-endurance athletes who compete for 2.5 hours and longer may require greater than 90 g of carbohydrate intake per hour to meet energy expenditure rates even though their exercise intensity is lower.¹ The additional carbohydrate allows for longer durations (24 hours or longer) of continuous exercise. These athletes have trained to tolerate greater amounts of food during sustained exercise. Their food choices include energy-dense fats as well as protein and carbohydrate. The various carbohydrate forms (i.e., drinks, gels, bars) do not differ in their effectiveness, although individual athletes’ tolerances to various forms may differ. However, these products do vary in amounts of water and electrolytes and specific sugar sources. Bars and gels are lighter and easier to carry than an equivalent amount of calories in the form of a sports drink; however, bars and gels require a water source for proper dissolution, absorption, and GI tolerance. In addition, compared with sports drinks, the bars tend to contain other macronutrients, such as fats, proteins, and vitamins, making them better suited for lower intensity exercise or exercise that does not involve as much jostling, such as cycling. Bars also are convenient for recovery after exercise.

Although the original intent of these products was to provide fuel on the go, the market has evolved to provide meal replacements for active people in a hurry. These products are misunderstood by the public as healthier than soft drinks, candy bars, or even regular meals, despite their high sugar and caloric content. Health care providers should be prepared to read and interpret the

nutrition label with patients and to calculate total calories if the package offers multiple servings. These products are not required by active adults or children who exercise 60–90 minutes in any one session.^{1,10} Recreational athletes and sedentary persons should be discouraged from using these products before, during, or after exercise that lasts less than 90 minutes.^{1,10} The Academy and AAP recommend eating a meal after exercise as a suitable glycogen recovery method.^{1,10} Examples of bars, gels, and drinks are presented in [Table 25–1](#).

^a Composition per serving. In a brand name product that is available in different flavors and formulations, the quantity of nutrients differs slightly among the product line extensions. (See product nutrition label or the manufacturer's website for the most current information.)

^b Intended as a healthy, low-calorie alternative to carbohydrate sports drinks. For rehydration and electrolyte replacement after exercise lasting 1 hour or less when glycogen depletion is not a concern. Performance benefits are unproved.

^c Intended for use during exercise to provide carbohydrates for energy and glycogen sparing, as well as electrolytes and water for rehydration.

^d Intended for use after exercise of prolonged duration when glycogen depletion is expected.

^e Intended for use during exercise to provide electrolytes as well as carbohydrates for energy and glycogen sparing. Require a water source for proper dissolution and absorption. Not intended for rehydration.

^f Intended for post-exercise recovery after exercise of prolonged duration when glycogen depletion is expected. Can serve as a meal replacement product. Often contain added vitamins and minerals.

Fats: Triglyceride-Containing Products

Fats are an important source of energy, fat-soluble vitamins, and essential fatty acids for athletes, and their consumption should not be severely restricted.¹ Many athletes minimize fat consumption, because they are calorie dense, and because they seek weight loss as a performance benefit. This benefit needs to be balanced with the risk of vitamin deficiency and the alteration of physiologic functions such as menstruation and pregnancy in female athletes.¹ The timing of fat intake prior to exercise is very important.¹ Long-chain triglycerides, found in typical fats and oils, should be avoided in sports nutrition products that will be used 1–2 hours before and during exercise, because they tend to slow gastric emptying and may cause discomfort, bloating, and GI intolerance during intense exercise. Medium-chain triglycerides (MCTs) are packaged into sports drinks and powders to provide an alternative fuel to glucose and to reduce muscle glycogen utilization.¹³ The moderate length (8–12 carbons) of MCTs results in absorption from the GI tract directly into the bloodstream, allowing more rapid utilization than with long-chain triglycerides, which are absorbed through the lymphatic system. Some MCT beverages are marketed to strength and conditioning athletes on low-carbohydrate diets. Clinical data in athletes suggest that MCTs are utilized metabolically within 30 minutes of ingestion, but evidence is lacking for improved performance or muscle glycogen sparing ([Table 25–1](#)).^{1,13}

Protein Products for Muscle Mass Gain

Athletes and those who exercise according to health standard recommendations may train with weights or their own body weight to maintain or build muscle. This approach allows the exerciser to perform their sport, improve performance, and prevent chronic disease such as sarcopenia and osteoporosis. Many athletes believe they need to consume large quantities of protein to provide substrates for muscle development. Dietary sources of protein include meat and dairy; vegetarian sources such as legumes, beans, and nuts; and prepackaged protein sources, such as protein powders, amino acid supplements, and various protein-containing bars, gels, and drinks.

Many variables affect nutrient requirements; in general, however, compared with less active persons, athletes who exercise for 10 or more hours per week have increased protein and calorie requirements.¹⁸ The Academy guidelines recommend protein intake of 1.2–2.0 g/kg daily in highly active adults who

participate in endurance exercise and in those who are attempting to increase body mass; this recommendation is in addition to an increased overall caloric intake to meet higher metabolic demands.¹ The Academy no longer offers a specific daily target for kilocalories per kilogram (kcal/kg) but rather uses a complicated formula to calculate an individual athlete's energy availability, whereby energy intake and energy expenditure are balanced with specific goals for body image and energy training. Determination of planned exercise expenditure will allow proper balance with energy intake, thereby avoiding ingestion of too many calories and risking unintentional weight gain.¹ (A review of the Academy guidelines is recommended for readers who seek more detailed understanding of this topic.¹) By comparison, the ISSN guidelines recommend 25 kcal/kg daily for sedentary persons and 25–35 kcal/kg daily for more casual athletes who choose a moderate exercise duration of 90–120 minutes weekly.² Competitive athletes training 15–30 hours per week may expend 600–1200 kcal per hour of intense exercise. Meeting these increased energy needs may require up to 40–70 kcal/kg daily.^{1,2} Athletes competing at this level should be referred to a clinical dietitian with a subspecialty in sports nutrition.^{1,2}

Athletes attempting to gain muscle mass may require an increased total calorie intake to balance their increased energy needs with exercise and to provide protein for muscle building.¹ For those who wish to build muscle, an important consideration is not to exceed reasonable total calorie goals, because energy intake that exceeds energy expenditure may lead to an accumulation of body fat, defeating the intent of training for a leaner body. In anecdotal reports, ingestion of 2.0–2.5 g/kg daily of protein has been described, although data supporting the effectiveness of such high intake are lacking.^{1,18,19} The marketplace offers a large number of protein supplements that provide specific protein sources, namely essential amino acids or branched-chain amino acids (BCAAs). ISSN and Academy guidelines indicate that simple adjustments to the athlete's diet can provide sufficient protein to meet dietary intake goals for increasing muscle mass.^{1,2,18} The available evidence is insufficient to support packaged protein supplements or specific amino acid mixtures as more effective for increasing body mass than eating whole foods that contain equivalent amounts of high-quality protein.^{1,2,18} The Academy recognizes, however, that the use of protein supplements may be reasonable for their convenience.²

Clinical Evidence of Protein Needs for Muscle Building

Muscle protein is in a constant state of synthesis and breakdown. Resistance exercise induces changes in muscle that effectively stimulate muscle remodeling and growth, provided that the diet offers an adequate quality of protein, with appropriate timing of intake, for that growth.¹⁸ The process is slow and requires repeated exercise stimulus, optimal nutrition, and several months to produce weight gain. Protein intake recommendations from the Academy and ISSN are similar at 1.2–2.0 and 1.4–2.0 g/kg daily, respectively.^{1,2,18} Both guidelines recommend that this protein intake be spread throughout the day, with small amounts of protein consumed every 3–4 hours.^{1,2} Well-designed studies of protein intake at 2 g/kg daily or greater have not shown consistent increases in lean body mass in comparison with the control group and indicate only increased protein oxidation for energy.¹⁸ Both the Academy and ISSN recommend consumption of a small dose of protein within 30 minutes after exercise to optimize metabolic adaption and muscle rebuilding. The Academy recommends a post-exercise protein dose of 0.25–0.3 g/kg body weight, which translates into 15–25 g of protein for a person of average body size.¹ A lack of information prevents specific recommendations for athletes on the extreme ends of the weight spectrum. Yogurt, cottage cheese, and almonds are readily available foods that provide adequate protein. Both guidelines recommend that athletes consume whole protein sources, because these will contain an appropriate amount of both essential and non-essential amino acids.^{1,2} Limited data suggest that BCAAs, particularly leucine, should be included in the protein source. Supplements and protein powders, particularly whey-based proteins, constitute a reasonable alternative to meet this need.^{1,2,18} Protein derived from rice and insect sources may prove beneficial as well, but data on these emerging markets are limited.²

Adverse Effects of Protein Supplement Use and High Protein Intake

The Academy and ISSN have concluded that protein intake up to 2.0 g/kg daily is effective and safe in healthy exercising adults.^{1,2,18} These agencies have similarly concluded that insufficient evidence is available to support the claim that high-protein diets, defined as exceeding 2.0 g/kg daily, are unsafe in the same healthy population.^{1,2,18,19} Concerns over kidney damage and bone osteoporosis have been raised but remain unproved.¹⁹ Minor adverse effects,

such as GI distress and diarrhea, have been reported. GI distress may be related to the osmolality of the final product as mixed by the user or to individual athlete tolerance to the product. More concerning are case reports of hypertension, abdominal pain, hepatitis, and renal insufficiency in military servicemen who reported using protein supplements, although the origin, quantity, and duration of protein use are not specified and testing for misbranding of the supplements was not performed.²⁰ The quantity of protein supplement contents, compared with the product label ingredients, is regularly tested and reported on websites such as that of [ConsumerLab.com](https://www.ConsumerLab.com), although no testing program validates all lot numbers. The most recent tests of protein powders found that the quantity of protein present was consistent with the label value but did find variations between test and label values for sodium and cholesterol content for a few products.²¹

Water and Electrolytes

Water and electrolytes are essential to performance. The Academy and ISSN recommend that athletes monitor their water balance and attempt to avoid dehydration, defined as a 2% decrease in total body weight, which has been shown to affect physical and mental performance.^{1,2,22} Dehydration is not just the loss of body water and corresponding body weight. Physical exercise during dehydration has multiple adverse effects, including an increase in electrolyte loss, impaired evaporative heat loss, and increased peripheral vasodilation, all of which contribute to cardiac effort and physical strain. Physical effects can be measured by elevations in core body temperature, heart rate, and perceived exertion. The greater the body water deficit, the greater the strain for a given task. Dehydration also can affect cognitive performance, such as mental concentration and focus on skilled tasks. Of note, however, an even greater degree of dehydration (with loss of 3%–5% of body weight) does not appear to affect anaerobic performance and muscle strength.²² Readers are referred to the position statement of the American College of Sports Medicine for guidelines and detailed discussion of this topic.²²

Dehydration involves water loss and electrolyte concentrations as separate issues. Athletes generate heat from exercise-related muscle contractions in proportion to the intensity and duration of exercise. This heat generation is transferred to the blood and then to the body core. Blood circulation through peripheral blood vessels and the skin allows radiant heat exchange with the

environment. Sweating, albeit with a variable degree of fluid and electrolyte loss, facilitates evaporative cooling at the skin surface. Environmental conditions such as temperature, humidity, air motion, helmets, and layers of clothing influence the success of evaporative cooling. If sweat-related water and electrolyte losses are not replaced, the athlete experiences dehydration.

The significance of dehydration depends on environmental conditions, exercise intensity, and duration of the activity. For example, compared with a recreational runner, an elite marathon runner may demonstrate a higher sweat rate, as measured by sweat loss in kilograms per hour, but both athletes will have similar total sweat losses owing to the prolonged time that the recreational athlete needs to complete the event. By comparison, when practicing under identical conditions, American football players have significantly greater sweat rates than those of soccer players.²² A higher sweat rate may be related to the layers of clothing and use of helmets, which contribute to greater heat accumulation and increased sweat and electrolyte losses, while preventing evaporative cooling.²² The risk of dehydration in any sport is further influenced by participation in twice-daily practice sessions, which may not allow adequate time between sessions for water and electrolyte replacement.¹

Health Conditions Related to Hydration and Electrolytes

Hydration can affect health status through water loss or water gain (overdrinking) and can alter serum sodium levels sufficiently to endanger health. In general, dehydration is more common, but overhydration resulting in hyponatremia can be equally life-threatening. Signs of dehydration include fatigue, confusion, irritability, and increased risk of heat illness, with symptoms of muscle cramps, heat exhaustion, heat stroke, and exertional rhabdomyolysis.²² Rhabdomyolysis has been reported as a result of dehydration, heat stress, and novel training. *Novel training* involves the introduction of new exercise patterns in athletes who have not been acclimated to such activity, such as with military recruits at boot camp or high school students attending preseason football camps.

Prevention of Dehydration

Meal consumption is an important aspect of maintaining optimal hydration status between exercise sessions.^{1,22} Eating promotes fluid intake and

retention of water, provided the meal is a sufficient source of sodium.²² Water alone is sufficient for rehydration during events lasting 60 minutes or less.^{1,10} Sports drinks can provide water and electrolytes after exercise, but on assessment the morning following a workout of 60 minutes or less, the drinks have not proved superior to a meal with water consumed after exercise.^{1,2,22}

Hyponatremia Risk From Drinking Excessive Free Water

Most laboratory-based studies of dehydration have occurred on stationary treadmills in climate-controlled rooms with little to no convective airflow to help sweat evaporation.²² On the basis of such studies, athletes have been taught to drink as much water as possible to prevent dehydration. However, liberal water intake has been called into question, particularly for endurance athletes, following clinical observations of weight gain, severe hyponatremia, cerebral edema, and death in athletes who consumed water without added electrolytes during athletic events lasting longer than 4 hours.²²⁻²⁴ Improved water availability to athletes competing in marathons has not resulted in a lower rate for seeking post-race medical care.^{23,24} The original research was directed at elite-level athletes competing for 60–150 minutes who consumed small sips of water while running very fast and generating significant body heat with high sweat rates. Unfortunately, this description does not apply to average athletes, who complete the same marathon races at a much slower pace, generate less heat accumulation, and have lower sweat rates.

Observations from actual marathon race conditions resulted in an advisory statement from the International Marathon Medical Directors Association (IMMDA).²⁴ Heat production by athletes is significantly affected by the effort expended (the combination of duration and intensity or speed of the exercise); a 10-km race effort will therefore generate more heat than a marathon effort (42.2 km). Average athletes run more slowly than elite athletes, so they are at lower risk for heat illness and have more time to consume water offered at aid stations. The result is that clinical hyponatremia occurs more frequently in nonelite athletes, particularly women, who typically require more than 4 hours to finish a marathon, and in long-course triathletes, who require 13–17 hours to complete their events.²²⁻²⁵ IMMDA recommends that fluid consumption during a race be based on the trigger of actual thirst, rather than on a set volume of fluid intake. As subjective thirst increases, the athlete can increase fluid intake from sips of water to match the previously calculated sweat rate. IMMDA strongly recommends that the athlete choose an electrolyte

replacement drink instead of free water, however, to avoid the risk of hyponatremia when competing in events that last 4 hours or longer.²⁴

Athletes competing for 2 or more hours can calculate their individual sweat rates by determining their total body weight before and after prolonged exercise. For example, an athlete who takes a 2-hour run on a hot afternoon may drop 2 kg of body weight, demonstrating a sweat rate of 1 kg per hour. Each 1-kg change in body weight is associated with a 1000-mL water deficit, so in this example, the athlete's decrease in body weight translates to a loss of 2000 mL of body water. The athlete can therefore target a drinking rate of 1000 mL per hour, or 240 mL (8 ounces) every 15 minutes, during prolonged exercise.

Appropriate athlete education before the event and provision of electrolyte-containing sports drinks during the event has resulted in a reduction in the occurrence of hyponatremia in triathletes²⁵ but not in experienced marathon runners.²²⁻²⁴ Other potential contributing factors include environmental conditions and duration of competition, as well as pharmacokinetic effects. For example, clinical observations indicate that exercise-induced hyponatremia may be more frequent with concurrent use of nonsteroidal anti-inflammatory drugs (NSAIDs) in marathon runners²³ and long-course triathletes.²⁵ An exact mechanism is unknown; however, NSAIDs may interfere with normal prostaglandin-mediated regulation of glomerular filtration and renal blood flow. Triathletes with significant hyponatremia have been observed to have elevated nitrogen and potassium levels, suggestive of reduced glomerular filtration.²⁵

Postural hypotension, rather than heat-related illness or dehydration, has been recognized as a health risk in endurance running that is not directly related to fluid intake. When a runner crosses the finish line and then stops, the sudden cessation of leg muscle contractions allows pooling of blood in the lower limbs, with consequent decreased venous return. The resulting drop in cardiac output may leave the brain under perfused with oxygenated blood, causing the affected athlete to black out.²⁴ To prevent this reaction, the athlete should continue walking past the finish line.

Only athletes demonstrating a rectal temperature higher than 104°F (40°C) should be treated for heat illness.²⁴

Carbonated and Oxygen-Enhanced Water

Available research does not substantiate a performance benefit of oxygenated water or carbonated water in humans.^{22,26} Dissolved gases from consumption of such products can accumulate, with consequent GI distress and bloating, resulting in decreased total fluid consumption.²² According to purveyors of oxygenated water, it contains 30% or higher dissolved oxygen; when marketed in plastic bottles, however, it may contain no more dissolved oxygen than tap water, and 12 ounces of oxygenated water in glass bottles contains less oxygen than that in a single breath of room air.²⁶

Electrolytes and Water Without Added Carbohydrates

Several carbohydrate-free products that offer water, electrolytes, and vitamins have been developed; they contain an artificial sweetener to replace most or all carbohydrates typically found in a carbohydrate-containing sports drink. Low-calorie carbohydrate-containing sports drinks provide as little as 3–8 g of carbohydrates per 8-ounce serving, or just 12–32 kcal, contrasting with 11–18 g of carbohydrates and 44–72 kcal per 8-ounce serving of most carbohydrate-containing sports drinks. These low-calorie and no-calorie electrolyte waters have not been evaluated for performance benefits. An alternative to carbohydrate-containing sports drinks is artificially sweetened electrolyte drinks, but they offer no more performance benefits than water does, other than the observation that a small amount of added sweetness to offset the sodium may encourage consumption of a greater volume of fluid.^{1,22}

Electrolytes, Carbohydrates, and Water

Addition of carbohydrates to sports drinks benefits athletes competing longer than 60–90 minutes by replacing muscle glycogen lost during periods of intense or prolonged effort. Carbohydrate supplementation during exercise provides exercising muscles with fuel for energy while allowing muscles to conserve stored carbohydrate energy as glycogen. This strategy of providing fuel during exercise at a rate of 30–60 g per hour for events lasting longer than 60 minutes has been shown to prolong the time to exhaustion in football and soccer players, as well as in long-distance endurance athletes such as runners and cyclists.¹ Carbohydrate-containing sports drinks appropriate for consumption during exercise provide 6%–7% carbohydrate concentration. To meet the target of 30–60 g of carbohydrate per hour, the athlete would drink

500–1000 mL per hour. Many triathletes and runners use a combination of carbohydrate-containing drinks and gels or chews, which must be consumed with water or another fluid to assist in dissolution and absorption of the carbohydrate.

Electrolytes, Carbohydrates, Protein, and Water

Several sports nutrition drinks combine an electrolyte– carbohydrate solution with added protein. The protein provides an additional metabolic fuel for ATP production.^{27,28} These products are marketed to endurance athletes competing at aerobic intensities for long-duration events, including marathon runners (2.5–5 hours), long-distance triathletes (2–17 hours), and adventure racers (12 hours to 5 days). Only a few studies have compared carbohydrate-only with carbohydrate plus added protein products. The studies that carefully controlled for equal caloric consumption between two groups of subjects have consistently demonstrated equivalent performance effects on cycling exercise duration.^{27,28} However, the group of subjects who drank the carbohydrate–protein solution showed significantly lower creatine kinase levels and perceived less muscle soreness on the day after the exercise. Unfortunately, these studies did not measure cycling performance on subsequent days and cannot be used to show an association between the observed muscle soreness and its effect on future exercise performance.^{27,28}

Although ready-to-drink options are available, some protein-containing drinks are powders that require reconstitution and can release significant amounts of gas when mixed with water. Bubbles and foam appear in the hydrated powder, which can influence GI tolerance in athletes. Protein-containing sports drinks should be introduced during the training regimen so that athletes can determine their tolerance to the products and the products' impact on performance before using such drinks during an event. Of note, because hydrolysis can affect stability of some proteins once they are mixed with water, protein-containing dry-powder drinks should never be prepared the night before an event. Optimal protein potency and effect may require athletes to carry unmixed powder and add water during the race, a potentially unsafe practice. For example, a triathlon participant attempting to prepare such a drink could lose control during the bicycling portion of the event. Once mixed, all sports drinks should be consumed or stored in the refrigerator within 2 hours to prevent bacterial growth.

Pre-exercise Nutrition and Hydration

The Academy guidelines recommend that a hydration fluid of 5–10 mL/kg of body weight be consumed 2–4 hours before exercise.¹ As an example, for a 59-kg athlete, appropriate early hydration would consist of 295–590 mL of fluid. This timing allows for the excretion of excess fluid in the urine before exercise begins. Hyperhydration with glycerol increases the risk of needing to void during competition, provides minimal performance advantage, and is discouraged.^{22,29}

The timing of pre-exercise carbohydrates is controversial. Eating a meal before exercising or competition can affect the athlete's performance through GI intolerance and the body's metabolic response to nutrient intake. Athletes are encouraged to allow several hours between a meal and exercise to allow for digestion and absorption of foods consumed, as well as to permit stabilization of metabolic responses such as insulin release and serum glucose levels before exercise.^{30,31} Carbohydrate intake before exercise is intended to ensure optimal muscle glycogen for competition. However, studies of pre-exercise carbohydrate intake in the 60 minutes before exercise have shown varied effects on performance.^{30,31} A carbohydrate load is known to stimulate insulin release, which has been measured after pre-exercise doses of 25–125 g.³¹ The release of insulin signals carbohydrate availability beyond what is needed for immediate use, and thus insulin signals for carbohydrate storage. When carbohydrates are abundant, fatty acid oxidation is not needed, and we see that insulin inhibits the release of the enzyme lipoprotein lipase.

Lipoprotein lipase is responsible for the hydrolysis of a triglyceride molecule into free fatty acids, and one glycerol molecule.^{11,13} Cellular uptake of the free fatty acids for oxidation is increased in the presence of lipoprotein lipase, and inhibited by the presence of insulin.^{11,13} The effect of insulin on the inhibition of lipoprotein lipase is evidenced by the dramatic drop in serum glycerol following a carbohydrate load.³¹ The metabolic result of the pre-exercise glucose load is that the athlete is inhibited from the efficient use fatty acid oxidation for energy and becomes more dependent on carbohydrate energy sources.

Introducing exercise after these metabolic changes is associated with serum glucose depletion and observations of hypoglycemia in as little as 15 minutes of exercise at moderate to high intensity (>70% of maximal oxygen

consumption—i.e., $\text{Vo}_{2\text{max}}$).³¹ Observational studies of hypoglycemia risk in the laboratory have been highly variable and inconclusive in that not all athlete's experience a clinical hypoglycemia.^{13,31}

The performance impact of pre-exercise nutrition is affected by many variables, such as the type, intensity, and duration of activity and the availability of additional carbohydrate during exercise. What is known is that the athlete will disproportionately use serum glucose for energy, because the insulin effect inhibits glycogen breakdown from the liver and dramatically reduces the energy provision from fatty acid oxidation. American football and soccer athletes who train with carbohydrate loading and continued carbohydrate maintenance doses during sustained exercise are essentially unaffected. By comparison, a long-distance runner who trains in a fasted state has adapted to aerobic fatty acid oxidation as a primary means of fuel generation. The long-distance runner is more likely to experience an unintended reduction in performance on introducing a carbohydrate load immediately (<60 minutes) before a prolonged running event.

The Academy guidelines state that optimal performance depends on individually determined distribution of macronutrient intake before exercise, because of variations in athlete body habitus, the energy demands of different sports, overall daily calorie needs, and the timing of macronutrient intake before the practice or event. Individual athletes should consider nutrition a part of their training regimen, with attention to timing, quality, and quantity of intake for establishing their own tolerance and timing.

Nutrition and Hydration During Exercise

As detailed previously, for competitions lasting longer than 60–90 minutes, athletes are recommended to determine a sweat rate by measuring pre- and post-exercise body weights. A reasonable goal is to drink 16–24 fluid ounces of a sports drink for every 0.5 kg of body weight lost during exercise.¹ Similarly, the Academy recommends carbohydrate provision during exercise lasting longer than 60–90 minutes as a method to preserve muscle glycogen. The Academy guideline recommends consuming 30–60 g of carbohydrate (from food and/or fluids) per hour during exercise to maintain blood glucose levels.² A carbohydrate drink concentration of 6%–8% is recommended, because concentrations greater than 8% are associated with adverse GI effects.¹ Athletes who intend to consume carbohydrates in the 60 minutes prior to

exercise or during prolonged exercise should train with carbohydrate provision, to assess their individual exercise tolerance to these carbohydrates.

Post-exercise Nutrition and Recovery Drinks

Goals of post-exercise recovery nutrition are to rehydrate, to restore muscle glycogen, and to provide protein to repair muscle damage and synthesize new muscle tissue, thereby preparing the athlete for another period of activity. The choice of recovery nutrition depends on how much time is available until the next session of intense activity. When the athlete's recovery time between bouts of exercise will be 4 hours or longer, the Academy recommends consumption of a balanced meal or snack after exercise for glycogen restoration, optimal rehydration, and correction of electrolyte imbalances.¹ No benefits are recognized for consumption of sports nutrition products compared with eating a meal in this setting.

Several studies have compared a carbohydrate-only sports drink with consuming low-fat milk containing an equal number of calories from low concentrations of fat, carbohydrate, and protein.³²⁻³⁴ Consumption of low-fat milk was associated with a greater degree of rehydration, lower urine output, and improved body weight recovery when measured 4 hours after dehydration-inducing exercise.³² In addition, low-fat milk was associated with a longer time to exhaustion in subsequent exercise sessions.^{33,34} Milk is an effective after-exercise option and is better for recovery than a carbohydrate-only sports drink. Of note, low-fat and skim milk should not be confused with products such as Muscle Milk, which is advertised as a nondairy product despite containing milk protein isolate, and calcium and sodium caseinates from milk. Compared with low-fat or skim milk, each serving of Muscle Milk contains considerably more calories in the form of added fats and high-glycemic-index carbohydrate.

When recovery time will be less than 4 hours, drinking a carbohydrate sports drink improves muscle glycogen recovery better than drinking water. The sooner the carbohydrate is consumed after exercise, the sooner muscle glycogen is replaced. The Academy guidelines recommend carbohydrate consumption of 1.0–1.2 g/kg per hour for the first 4 hours after a glycogen-depleting exercise.¹

Safety and Efficacy of Specific Ergogenic Supplements

This section discusses evidence that supports the safety and efficacy of specific nutritional supplements and micronutrients for sports performance—namely, herbs, plant extracts, antioxidants, and other supplements purported to improve sports performance. These nutritional supplements are marketed as “foods” and are not regulated as drugs by FDA. Accordingly, manufacturers of such foods are not required to provide safety and efficacy data in humans to prove their effectiveness on the playing field, nor is testing required to prove the labeled content of such foods. As noted previously, abundant evidence has accrued for misbranding and the frequent inclusion of substances banned by antidoping agencies in these products.^{4–6} **Table 25–2**^{1,2,35–45} lists substances for which available evidence does not support claimed effectiveness. Athletes should be reminded that extreme caution is warranted with use of nutritional supplements to enhance sports performance: Misbranding of these supplements may lead to doping infractions, and serious adverse effects and deaths have been reported from supplement use.

Table 25–2 Selected Products Marketed as Ergogenic Supplements

Ingredient	Marketed Claim	Conclusion/Evidence
Antioxidants ^{1,2,35}	Claims for antioxidants include ability to reduce oxidative stress from exercise and/or to speed recovery after exercise. Many antioxidants have been included in sports nutrition supplements, including alpha-lipoic acid, carotenoids, glutathione, <i>N</i> -acetylcysteine, ubiquinones (coenzyme Q10), vitamin B complex, vitamin C, and vitamin E.	Evidence does not support an effect on reducing oxidative damage or enhancing performance. Frequent exercise is associated with an enhanced antioxidant system.
Arginine ²	Arginine has been promoted to improve muscle building and cardiovascular functioning through the production of nitrous oxide, which causes cardiac vasodilation and increased oxygen delivery to the heart.	Evidence does not support an effect on performance enhancement.
Branched-chain amino acids	BCAAs are isoleucine, leucine, and valine. Skeletal muscle cells use BCAAs to supply energy during	Evidence does not consistently support an

Ingredient	Marketed Claim	Conclusion/Evidence
(BCAAs) ^{1,2}	exercise. Supplementation may reduce fatigue and increase exercise time to exhaustion by reducing serum levels of L-tryptophan and its effect on serotonin levels in the brain.	effect on endurance performance.
Beta-alanine ³⁶	Beta-alanine supplementation improves muscle carnosine concentrations. Work capacity may improve in short efforts (<120 seconds) but not in longer efforts.	The primary literature does not consistently support an effect on performance.
Carnitine ²	Carnitine is an essential cofactor for the transport of long-chain fatty acids into the mitochondria. Product is proposed to improve fatty acid oxidation, fat burning, and oxygen absorption as well as to reduce lactic acid accumulation.	Evidence does not support an effect on performance.
Chromium ²	Chromium is marketed to enhance carbohydrate utilization in the body, promoting fat burning and dietary protein sparing for muscle building.	Evidence does not support an effect on performance.
Citrulline ²	L-Citrulline is a metabolic precursor to arginine. Citrulline is not affected by first-pass hepatic metabolism and is converted by the kidneys to arginine. Product is proposed to improve oxygen consumption and time to exhaustion in treadmill running.	Evidence does not support an effect on performance.
Conjugated linoleic acid (CLA) ²	CLA is promoted to endurance athletes as a thermogenic aid, body fat reducer, and ergogenic aid that enhances fat metabolism. CLA may increase cardiac risk by lowering high-density lipoprotein and increasing lipoprotein(a) concentrations.	Evidence does not support an effect on performance or body composition.
<i>Cordyceps sinensis</i> ³⁷⁻³⁹	<i>Cordyceps sinensis</i> is used in Chinese medicine to treat lung disease and fatigue. Products claim that this mushroom can decrease oxygen consumption and improve endurance. Product is frequently combined with <i>Rhodiola</i> .	Evidence does not consistently support an effect on performance.
Eleuthero ⁴⁰	Extracts of Siberian ginseng have been reported to affect cardiorespiratory performance, fat metabolism, and improved endurance.	Evidence does not support an effect on performance.
Ginseng ⁴¹	Extracts of <i>Panax ginseng</i> have been reported to improve lactate clearance and delay the onset of	Evidence does not support an effect on

Ingredient	Marketed Claim	Conclusion/Evidence
	fatigue.	performance.
Glycerol ^{1,42}	Glycerol is reported to act as an osmotic agent to promote hyperhydration before exercise, thereby reducing the risk of dehydration from intensive exercise in the heat.	Evidence does not support an effect on performance.
Hydroxy-methylbutyrate (HMB) ^{1,2,43}	Beta-HMB is a metabolite of leucine metabolism, purported to increase fat-free mass by reducing muscle protein breakdown after a workout and to increase protein synthesis. HMB also has been proposed to improve aerobic performance.	Evidence supports an increase in fat-free mass but does not consistently support effects on performance. Untrained subjects appear to receive greater benefit than trained athletes.
Lecithin ⁴⁴	Lecithin is a source of choline and a precursor to acetylcholine. Decreased plasma choline and acetylcholine levels have been reported in marathon runners. Supplementation of lecithin before a marathon does prevent the decline in serum acetylcholine levels but does not affect finishing times.	Evidence does not support an effect on performance.
<i>Rhodiola</i> sp. ^{37-39,45}	<i>Rhodiola rosea</i> and <i>Rhodiola crenulata</i> are Chinese herbs used to stimulate the nervous system, improve aerobic work performance, and reduce fatigue. <i>Rhodiola</i> is reported to improve oxygenation at high altitudes and to elevate the lactate threshold. Endurance athletes have seen 1%-2% reductions in cycling time trials and running events.	Evidence suggests small improvements in endurance exercise that are minimal enough to question the herbs' performance value.

Caffeine and Caffeine-Supplemented Energy Drinks

Caffeine supplementation has shown effects in some, but not all, anaerobic resistance exercises (weight lifting).^{2,46} Pre-exercise caffeine doses of 2 mg/kg have improved duration of endurance exercise but not measured oxygen uptake.⁴⁶ Caffeine has no effect on high-intensity sprints or on agility tests.^{2,46} It does improve alertness in very-long-duration endurance races, such as 24-hour bicycle races, because it may counteract sleep deprivation. Caffeine

doses affecting sports performance (2–6 mg/kg) are similar to doses that can be obtained from foods and beverages that are unrelated to exercise or performance. Doses exceeding 9 mg/kg do not add benefit.⁴⁶ Incidental exposure to caffeine is common, and complete avoidance is unrealistic. WADA does not list caffeine as a problematic substance, and many questions regarding the effective use of caffeine for ergogenic benefit are still unanswered.

The class of products labeled as providing “energy” is broad and increasingly popular, although the vast majority of consumption is recreational and unrelated to sports.^{3,47} Although the composition of sports drinks is similar to that of energy drinks (EDs) and energy shots (ESs), both EDs and ESs contain caffeine in addition to water and electrolytes. EDs may contain carbohydrates or be labeled as “calorie free.” They usually contain a blend of other nutrients and herbal additives such as taurine or guarana that are proposed to affect exercise performance or mental performance during exercise. These additives have not been proved to affect sports performance or weight loss.⁴⁸

EDs are not without risk of unintended adverse effects. The additional caloric load may affect blood glucose and insulin levels and consequently promote weight gain.⁴⁸ Weight gain and increases in body mass index have been reported in sedentary children who drink EDs.⁴⁹ EDs are more acidic than sports drinks, and have been associated with a faster rate of enamel loss when teeth are exposed to both products in a controlled lab environment.⁵⁰ Users of EDs also are cautioned to consider the possible adverse effects from cumulative daily doses of caffeine. Limits on the amount of caffeine present in EDs are not enforced within the United States at this time. Caffeine content of U.S. products varies, with a reported range of 100–286 mg per serving, whereas Canada has limited EDs to 180 mg of caffeine per drink.⁴⁸ This quantity of caffeine is similar to that in a 16-ounce serving of coffee. In addition to GI intolerance, adverse effects include insomnia, nervousness, tachycardia, tremors, and anxiety. A recent clinical observation in healthy college-age adults showed that a single dose of an ES can increase systolic and diastolic blood pressure by 5 mm Hg from baseline, although none of the healthy subjects were reported to have reached a level of prehypertension.⁵¹ More severe adverse effects from EDs have been recorded for emergency department visits related to the indiscriminate use of EDs mixed with alcohol.⁵² A more recent meta-analysis, however, contradicts earlier research and concludes that users of ED mixed with alcohol are not more likely to abuse

alcohol or to engage in risky behaviors such as drinking and driving as compared with users of ED alone.⁵³

AAP has concluded that children and school-age athletes should not consume EDs or ESs and that they have no place in sports competition.⁹ ISSN further states that diabetics and persons with preexisting cardiovascular, neurologic, or metabolic disorders should avoid these products.⁴⁸ Avoiding the use of EDs and ESs for sports performance generally is appropriate advice for any age group.

Creatine

Creatine is the most widely used ergogenic aid among athletes, and it has the most consistent data.¹⁵ Creatine, a naturally occurring substance, is synthesized in the body by the combining of arginine and glycine, or it is absorbed intact after ingestion of red meat and fish.¹⁵ Creatine is found in all skeletal muscle as free creatine or high-energy phosphorylated creatine (PCr). PCr functions as an energy buffer, transferring a phosphate group to ADP, thereby rapidly regenerating ATP during periods of exercise. Skeletal muscle contains limited amounts of energy stored as ATP at rest; exercise depletes this stored ATP energy quickly. The body must oxidize macronutrients through the Krebs cycle to restore ADP to the high-energy ATP state for continuous or repeated efforts. PCr transfers its energy to ADP in seconds, acting as a secondary fuel. However, the total amount of PCr energy in muscles lasts for only 20–30 seconds.¹⁵

Performance gains with creatine are limited to laboratory-based studies of short bursts of anaerobic activity lasting 30 seconds or less. Creatine supplementation attenuates normal decreases in the force associated with repeated work applications.¹⁵ For example, a weight lifter may perform three sets of a bench press, with a goal of 10 lifts, or repetitions, per set. The lifter takes 30 seconds of rest between each set. Ordinarily, the lifter may be able to move a certain amount of weight for 10 repetitions in the first set, 8 repetitions in the second set, and only 6 repetitions in the third set. The decrease in number of possible lifts is called *attenuation* and is related to decreased energy (ATP) in the muscles. Creatine can improve the amount of ATP energy available to lift the weight, allowing the same athlete to complete more repetitions in each subsequent set (e.g., 10, 10, and 8 repetitions rather than 10, 8, and 6).¹⁵ Similar improvements in maximum weight in a single lift also have

been reported.¹⁵ Creatine is useful for athletes participating in events that require repeated, short, explosive bursts of power, such as sprinting and jumping as seen in American football, soccer, and track and field events. By comparison, creatine does not benefit athletes in sports that require more than 20–30 seconds of high-intensity activity. Thus, with aerobic activities as short as 800-m (2-minute) and 1600-m (5-minute) runs on a track, no performance benefit has been shown with use of creatine.¹⁵

Current evidence does not support that creatine can induce structural changes in muscle fibers. The muscles may be larger and weigh more, owing to the presence of creatine and water in complex with creatine. The athlete may gain mass and appear stronger in the gym, but this change is dependent on maintenance supplementation. Short-term studies show a return to normal muscle creatine concentrations and depletion of the extra PCr energy on cessation of creatine supplementation. Creatine itself does not appear to cause permanent alteration of muscle fiber types.^{54,55} Poor study design and inappropriate statistical analysis will affect interpretation of existing studies. An observation of an increased number of satellite cells after 8 weeks of supplementation was not validated when observed again after 12 weeks nor was it confirmed as permanent after cessation of supplement use.⁵⁴ Muscle satellite cells can form or repair myofibers in skeletal muscle. A similar observation of increased myosin heavy chain expression and an increase in “fast twitch” type IIx muscle fibers was not properly evaluated between groups or confirmed as a permanent change by reassessment of the muscle after cessation of use and “washout” of the supplement.⁵⁵

Loading doses of creatine are not required if performance benefits are not desired within 10–14 days.¹⁵ A maintenance dose of 5–6 g daily is adequate to boost muscle creatine levels and is associated with fewer GI adverse effects. If an immediate improvement in strength is required, benefits can be detected at 5 days after a loading dose of creatine at 20 g daily (or 0.3 g/kg daily).¹⁵ This loading dose usually is divided into 4 doses to reduce GI adverse effects of stomach upset and nausea. Nausea may be related to osmotic effects or to malabsorption. Muscle cramping has been reported, but dehydration and heat-related illness have not been associated with long-term studies of creatine supplementation.¹⁵ However, creatine supplements have been reported to be misbranded and to contain substances banned by antidoping agencies.^{4,6}

All athletes should be discouraged from using creatine supplements until regulated testing of such products is required. They should be encouraged to seek natural creatine sources from food rather than from supplements. When the athlete insists on using creatine, health care providers should emphasize that supplementation should be used only as long as necessary (e.g., only during the competitive season). No reason exists to continue the supplements during the off season. Health care providers also should recommend appropriate additional hydration during creatine exposure, because creatine is a protein that is filtered through the kidneys. For an athlete who becomes significantly dehydrated, it is best to temporarily hold creatine use until proper fluid balance is restored.

Dimethylamylamine

Dimethylamylamine (DMAA), also known as methylhexanamine, was previously marketed as a sympathomimetic to treat nasal congestion. DMAA appeared in nutritional supplements following the FDA ban on ephedra, with product labeling claims that include increased muscle mass and thermogenesis to reduce body weight. Product claims also imply that the chemical was derived from a natural source, such as geranium extract. Use of these products has been associated with multiple cases of cardiac toxicity, acute hepatic failure, liver transplantation, and death from cardiogenic shock.^{56,57} A report from the Centers for Disease Control and Prevention (CDC) noted 29 cases of hepatic failure, with 40% of affected users requiring hospitalization. In this report, 24 people had used a DMAA-containing supplement in the 60 days before onset of hepatic injury, and 12 of these denied taking any other supplement besides the DMAA-containing product.⁵⁶ Dimethylamylamine is currently banned by the FDA but may appear in supplements from outside of the United States or as a misbranded ingredient in marketed products.

Ephedra and Pseudoephedrine

Pseudoephedrine is available without a prescription, but even when it is taken temporarily for appropriate medical reasons, its use may be troublesome for elite athletes, because it may be detected in random drug testing. Urine concentrations of pseudoephedrine greater than 150 mcg/mL are flagged as prohibited use by WADA. No evidence supports performance enhancement with pseudoephedrine at nonprescription doses (120 mg daily).⁵⁸ However,

when pseudoephedrine was taken at 2.5 mg/kg, roughly 5 times the recommended nonprescription dose, one study of 7 runners showed an average 6-second improvement in 1500-m time.⁵⁹ Reports that ephedra was associated with hypertension, cardiac arrhythmias, and seizures in otherwise healthy young adults were used to determine that ephedra was unsafe for human consumption, and ephedrine alkaloids were banned from U.S. markets in 2004.⁶⁰ No data support ephedra as useful for athletic performance.⁵⁸ Athletes and consumers should be aware that plant alkaloids related to ephedra may appear in nutritional supplements (e.g., ma huang, Mormon tea, some weight loss supplements). Ephedra continues to be available in foreign markets and through internet sales.

Steroidal Precursors, Dehydroepiandrosterone, and Aromatization Inhibitors

The Anabolic Steroid Control Act of 2004 classified hormone substances that are pharmacologically related to testosterone as legend, or prescription-only, drugs. Androstenedione and prohormone precursors to testosterone were sold as nutritional supplements before passage of the Act, but more recently they have been identified as misbranded ingredients in nutritional supplements sold through the Internet. Dehydroepiandrosterone (DHEA) is a precursor to more potent androgens such as testosterone. In well-designed studies, DHEA supplementation resulted in significant elevations in estradiol and estrone, but no elevations in serum testosterone, in men who took the supplement.⁶¹ Aromatase inhibitors prevent the conversion of testosterone to estrone, and their use is specifically prohibited by the antidoping agencies. Many body-building supplements claim to include substances, such as *Tribulus terrestris*, that act as aromatase inhibitors. No data support these claims; however, some supplements have been misbranded with the legend drug tamoxifen.^{5,6} Products with claims (implied or otherwise) to boost testosterone or provide aromatase inhibition should not be recommended as performance-enhancing supplements.

Stacking Products and Use of Proprietary Blends

Sports nutrition products often combine several agents into a single product, a process known as “stacking,” with the implication that they work better together than separately. In a similar fashion, sports nutrition products provide

a blend of ingredients but label these ingredient amounts as “proprietary” to avoid having full disclosure on the label.⁶² Blended ingredients may include vitamins, minerals, metabolites, amino acids, or herbal supplements. Advertising for these ingredient blends indicates that they are added to improve muscle strength, to reduce oxidative stress, or to enhance fat metabolism. The quantity of each ingredient should be included on the label. A recent investigation of 100 sports performance products sold over the counter found that these products had an average of 8.1 ingredients with undisclosed quantities.⁶² When quantities per serving were properly labeled, it was common for ingredients such as caffeine to be present in a less-than-efficacious dose.⁶² Ingredients for which available data are insufficient to support a clear positive effect on performance are reviewed in [Table 25–2](#).^{1,2,35–45}

Assessment of Performance-Enhancing Nutrients: A Case-Based Approach

Performance enhancers run the gamut from electrolyte solutions to energy bars to herbal supplements. To help in selecting an appropriate product, the health care provider should determine the type of exercise or physical activity in which the athlete engages, the expected intensity and duration of activity, and any products previously tried. The person also should be asked about any ill effects experienced after physical activity or after using a performance enhancer.

Cases 25–1 and 25–2 illustrate basic assessment of two different athletes who wish to use a performance-enhancing product.

Sales of sports nutrition products designed to enhance or improve performance are increasing every year. The most common self-treatments are use of creatine to improve muscle power and ingestion of carbohydrates during exercise to preserve muscle glycogen and to prolong time to fatigue across all sports. Several herbal supplements claim to enhance performance, but evidence to support these claims is currently lacking. Although these natural herbal products are touted as safe, evidence suggests that some may have detrimental effects on long-term health in that they increase cardiovascular risk by reducing levels of high-density lipoprotein.

Case 25–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient is a recreational runner and father of three children who wishes to lose weight and improve his running endurance so that he can complete a marathon. He reports feeling confident through 10 miles of running, but then his pace declines around mile 9 and he is not able to sustain the 10 minutes per mile pace beyond 90 minutes. He also complains of muscle soreness for 2 days after his long runs. The muscle soreness affects his movement at work, which can be significant during 12-hour shifts.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Mr. Platt started running again 6 months ago and has completed several 10k races. Initially, he could barely run for 20 minutes at a pace of 12 minutes/mile, primarily owing to deconditioning and weight gain. His initial weight and BMI were 86 kg and 27.8 kg/m ² , respectively. He has seen his endurance and pace improve with training and a loss of 5 kg total body weight. He has reached a plateau of endurance, with performance declines starting around 60–70 minutes into his runs. The fatigue he experiences also is less common on cool morning runs and is more significant on warm humid days, when he sweats more.
c. Description of the patient's efforts to relieve the symptoms	The patient believes that weight loss is needed, because he ran half-marathons at a pace of 8 minutes per mile when he served in the Army 5 years previously. His weight and BMI were 74 kg and 24.1 kg/m ² at his discharge, and he associates his weight with his performance. He has avoided the sports nutrition products used by his training partners, considering them to be calorie-dense. However, he knows to avoid hyponatremia and adds a dash of salt to his water bottle. He currently drinks less than 120 mL of water per hour. He has taken his bathroom scale to the park where he trains. In his last 120-minute run, he measured a

	3-pound (1.6-kg) weight loss.
d. Patient's identity	Paul Platt
e. Patient's age, gender, height, and weight	37 years, male, 5 ft 9 in., 178 lb (81 kg)
f. Patient's occupation	Critical care ICU nurse
g. Patient's dietary habits	Mr. Platt works 12-hour shifts in the surgical ICU of a teaching hospital. He has been making poor decisions on food selection from the cafeteria, which serves hamburgers, hot dogs, and fried chicken wings.
h. Patient's sleep habits	Mr. Platt sleeps no more than 7 hours on nights when he helps his children with homework. He usually goes to bed at 11 pm and awakens at 6 am for work or to help get the children off to school.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	An annual medical examination identified a vitamin D deficiency. His blood pressure and fasting glucose levels are normal, but his father and grandfather both had type 2 diabetes that eventually required insulin. He takes a daily multivitamin supplement that contains 800 IU of vitamin D ₃ .
j. Allergies	NKA
k. History of other adverse reactions to medications	Penicillin skin reaction as a child
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary	Mr. Platt is a reasonably healthy man, although he is still overweight with a BMI of 26.3 kg/m ² . He desires to lose weight and hopes to improve his running endurance so that he can complete a 26-mile marathon.

problem(s).	
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Calculate a sweat rate. Mr. Platt's target marathon is planned for November. Dehydration risk should be minimal. His current sweat rate is 0.8 kg per hour in warm conditions. With his marathon in cooler conditions, he can train to replace half of his fluid losses by drinking 360 ml of fluid per hour. He can target 90 mL (3 oz) of water every 15–20 minutes. Mr. Platt will wear a waist belt with a small pouch and a detachable 8 oz bottle that he can refill from water stations. (2) The marathon will provide water and Gatorade sports drink. Mr. Platt can prepare a calorie-free electrolyte drink from an easy-to-carry wafer (Nuun) mixed with water available on the course. His goal is to drink 360 mL (12 oz) per hour, so he will prepare a bottle with $\frac{1}{2}$ of a wafer added to 6 ounces (180 mL) of water every 30 minutes. Mr. Platt can sip on this drink while running, rather than drinking larger volumes at each water station. Each wafer (2 bottles) will provide 360 mg sodium and 100 mg potassium per hour. These amounts are greater than the sports drink provides. (3) Mr. Platt can consider a mixed approach where he trains for 90–120 minutes in his aerobic zone without carbohydrate intake before introducing small amounts of carbohydrate in the later stages of training. He can train with the carbohydrate–electrolyte sports drink the race will provide. Following the same fluid consumption rate (360 mL per hour) will provide 22 g carbohydrate per hour. This is less than the guideline recommendations for 30–60 g per hour, but his primary goals are finishing the marathon distance while improving his body weight. (4) Mr. Platt can follow the original calorie-free electrolyte water plan but introduce a carbohydrate–electrolyte with added protein source such as Accel-Gel. Each gel packet provides 20 g of carbohydrate and 5 g of protein as a secondary fuel for the exercising muscle. Mr. Platt can plan

	to use ½ of a gel packet every 15 minutes starting 90–120 minutes into the marathon. This will provide 40 g carbohydrate and 200 mEq sodium per hour. When introducing the gel, he should switch to plain water at a goal rate of 360 mL per hour.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Platt should train for 90 minutes using a water–electrolyte solution and then introduce a gel that provides carbohydrate and electrolytes with added protein starting around 90 minutes.
6. Describe the recommended therapeutic approach to the patient or caregiver.	“Your training plan indicates that your longest training runs will be 3.5 hours in duration. You can train the first 90 minutes using a noncalorie sports drink, and then add carbohydrates and protein to help sustain your efforts and support endurance. Your primary goal will be to optimize fat utilization as a primary fuel in all of your runs long runs. Taking ½ of a gel packet every 15 minutes will provide 40 g of carbohydrate and 200 kcal per hour. You will need water available at the race course to dilute the concentrated gel. The gel also will deliver sodium (200 mEq per hour), so you can switch your hydration to plain water at 360 mL per hour. The packets are lightweight and easily carried in a pouch that is attached to the same belt that holds the refillable water bottle. You should introduce the gel packets into your training now, so that you can evaluate your tolerance to the gel in training conditions.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“For the first 90 minutes of your long training runs, the focus is on fatty acid oxidation and its effect on weight reduction. After 90 minutes, you can introduce a carbohydrate and protein source as additional fuels for continued effective muscle contraction. The amount of calories consumed is around 200 kcal per hour, which is less than the anticipated caloric burn rate for running at 8–10 miles per hour. The goal is to burn primarily fat for energy, while providing some energy to support your ability to finish. The carbohydrate doses are small and should not have a negative effect on fatty acid oxidation since your pace will remain within your aerobic threshold. The calories in the sports gel will not impair your primary weight loss plan. A secondary benefit may be a reduction in muscle soreness the

	day after long training runs by introducing a protein source as a noncarbohydrate source of energy.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	“Current guidelines recommend an intake of 30–60 g of carbohydrate per hour. Consumption of 2 packets of sports gel will provide 40 g of carbohydrate per hour.”
b. Maximum number of days the therapy should be employed	“You only need to use the carbohydrate-electrolyte with added protein sports gel on your long-run training days that will exceed 90 minutes. In general, this is only one run per week. The other runs should start in a fasted state to optimize fatty acid metabolism. You should carry a gel product on shorter runs (45–90 minutes) to address any symptoms of a low blood sugar.”
c. Product administration procedures	“Several calorie-free electrolyte drinks are available, but the most convenient method may be to carry a wafer that dissolves in water. This product can be used in your routine training (less than 90 minutes) so that you grow accustomed to its taste, tolerance, and mixing process. The tablets can be cut in half in advance. They come in a plastic tube that will prevent them from breaking down while running.”
d. Expected time to onset of relief	“Continued training without carbohydrate intake should be associated with additional weight loss. Training benefits should be seen as your total body weight decreases, although this process takes months. The inclusion of a carbohydrate sports gel, starting after 90 minutes of training, is likely to produce a subjective feeling of additional energy from the first dose. Repeated doses will be needed to provide additional carbohydrate calories as they are used. Despite the feeling of additional energy, the actual impact on performance measures such as pace per mile or total miles run will be

	difficult to prove. The intent is to focus on the goals to complete the full distance of each long training run (up to 18 miles) in anticipation of finishing the marathon, rather than being concerned about how fast it is finished.”
e. Degree of relief that can be reasonably expected	“Finishing the marathon is one primary objective, but losing weight to a healthier BMI is an equally important objective. The addition of carbohydrate and protein only on long runs should help you reach both objectives. The additional calorie sources on long runs will help your body extend endurance and improve the total duration and length of these runs. A reasonable expectation is to increase total distance run per week by 5%–10% each week.”
f. Most common adverse effects	“Consuming calories during continued exercise takes practice but most endurance athletes can adapt. Gastrointestinal discomfort such as bloating and cramping are common during early experiences with sports drinks and gels. Nausea and diarrhea have been reported. Be sure to drink plenty of fluids to allow the nitrogen waste from the protein to be eliminated through your kidneys.”
g. Adverse effects that warrant medical intervention should they occur	“During any period of increased training, you should always tell your coach or training partner if you are not feeling well. Any signs of heat illness, muscle cramping, or pain on urination should be reported immediately.”
h. Patient options in the event that condition worsens or persists	“If you are unable to tolerate the sports gel with protein, consider a similar gel that provides only carbohydrate.”
i. Product storage requirements	“Electrolyte wafers and unopened gel packets can be stored at room temperature. A reconstituted electrolyte drink and any open gel packets should be used within 2 hours, or discarded. Electrolyte wafers are hygroscopic and can absorb water from the air over time, although it takes weeks for them to degrade. If you live in a humid environment, the wafers will last longer when stored in environmentally controlled conditions.”
Solicit follow-up questions from the patient or caregiver.	“Why are you recommending a sports gel that includes protein? None of my training partners are using it. They drink Muscle Milk after their long runs. Why are you not recommending that product?”

Answer the patient's or caregiver's questions.	"Sports drinks with added protein may be associated with less muscle discomfort the day following each long athletic effort. You have commented on muscle soreness at work the day after long training runs. Comparison studies were conducted in long-distance cyclists riding for several hours on stationary bikes. When carefully controlled to provide equal calories, the protein-included sports drink did not affect performance but was associated with lower creatine kinase levels in the blood and subjective reports of less muscle soreness the day after the trial. You may perceive a benefit if your next-day muscle soreness is reduced. Muscle Milk is advertised as a recovery drink. This product is manufactured to contain whey protein from milk with small amounts of added sugar and fat for taste. The nutrition content label will indicate more protein and less carbohydrate and sugar than for equal volumes of low-fat milk, although its price can be 3-4 times higher. Muscle Milk was not tested by Consumer Lab.com in its last protein drink review. Low-fat milk as part of a meal, however, is an evidence-based choice for rehydration and recovery."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Platt within 2-3 weeks to review his progress with the training plan and tolerance for the recommended products. Consider referral to an RD or RDN if any additional questions arise regarding Mr. Platt's diet and nutritional requirements.

Key: BMI = Body mass index; ICU = intensive care unit; n/a = Not applicable; NKA = no known allergies; RD = registered dietitian; RDN = registered dietitian nutritionist.

Case 25-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	

1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient is a high school football player who complains of fatigue and tired legs, starting about 30–40 minutes into his team workouts. He is currently participating in summertime preseason workouts and has 9 practices a week, with 2 workouts daily on Mondays, Wednesdays, and Fridays. He reports a decrease in leg strength, particularly when asked to push a heavy blocking sled. He also notes a decrease in running speed when doing 40-yard shuttle runs on the field. He comments that white lines of salt are visible on his clothing when it dries. Despite this observation, he thinks that he cannot be dehydrated, because he has to urinate frequently and he wakes from sleep at least once a night to urinate.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Summer workouts take place in high temperatures and humidity. For this patient, the fatigue sets in earlier under direct sunlight. Rehydration halfway through practice improves leg strength for 10–15 minutes. By comparison, air-conditioned training does not result in fatigue. The indoor workout focuses on strength and balance as well as walking through plays, so the intensity and energy expenditure are lower. When asked, he says that he does not drink a sports drink before indoor workouts, because he does not anticipate the same level of thirst.
c. Description of the patient's efforts to relieve the symptoms	The athletic trainer at the school is active in weighing the athletes before and after practice. The patient had a 4-pound weight loss over 2 practices, and the athletic trainer calculated a fluid replacement goal of 1800 mL (60 ounces) per day. On the advice of his coach, the patient drinks a full 20-ounce bottle of carbohydrate–electrolyte drink 3–5 times a day (1800–3000 mL daily). He drinks half of the bottle (10 ounces) at the start of practice and the rest during a 10-minute break halfway through practice. He drinks a second bottle immediately after the workout. On days with 2 workouts, he drinks 4 bottles. He finishes each day with an additional bottle before bed.
d. Patient's identity	Ryan Ladone
e. Patient's age, gender, height, and weight	17 years, male, 6 ft 0 in., 220 lb

f. Patient's occupation	High school student
g. Patient's dietary habits	Ryan has been eating larger portion sizes to gain weight for football season. The family eats some sort of fast food for dinner at least 3 nights a week. When meals are cooked at home, they are healthy meals.
h. Patient's sleep habits	He gets 8 hours of sleep each school night but complains of sleep interruptions for urination.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Ryan's preseason laboratory results included a fasting blood glucose of 110 mg/dL and HbA _{1c} of 6.1%, which suggest that he may have glucose intolerance. His current BMI is 29.8 kg/m ² , which is approaching obesity. Ryan is at risk for adult-onset diabetes. His blood pressure was 105/70 mm Hg at his primary care provider's office. Ryan takes no scheduled medications or supplements.
j. Allergies	NKA
k. History of other adverse reactions to medications	None reported.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Ryan is experiencing a decline in muscle endurance (over 90 minutes) associated with a post-exercise loss of 1.8% of his body weight. He is likely feeling the effects of dehydration. He also may be experiencing the metabolic effects of a pre-exercise carbohydrate load. The resulting insulin release may be causing a reduction in fatty acid oxidation, leaving Ryan more dependent on carbohydrate energy during the long workout. His fatigue is temporally associated with rapid glucose utilization and is relieved after midsession rehydration with additional carbohydrates.
3. Identify exclusions for self-treatment.	Ryan's father has type 2 diabetes. A family history of diabetes may complicate Ryan's decision to use a sports drink, and he is drinking a large quantity of carbohydrate-containing product per day.
4. Formulate a comprehensive list of therapeutic	Options include (1) Take no action. Symptoms may abate when school starts and the number of practices is reduced to once per day.

alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Dehydration also is less likely with cooler weather and less direct sunlight in late September and October. (2) To monitor dehydration, a simple daily weight taken in the morning (before any exercise or nutrition intake) can assist in monitoring for changes in body weight. Changes in weight are a secondary marker of hydration status. The goal is to start each day with a stable weight and hydration status. (3) Increase dietary salt intake during the training season, with appropriate amounts of free water to replace sweat losses. The targeted fluid replacement of 60 ounces (1800 mL) was based on a day with 2 outdoor workouts of roughly 4 hours. Consider drinking 12 ounces (360 mL) of water per hour of continued exercise and an additional 12 ounces after exercise. Sodium can be provided with his regular meals along with salty snacks after workouts. (4) Consider using noncaloric Nuun wafers or low-calorie G2-Gatorade during workouts. One wafer mixed in 12 ounces of water will provide 160 mEq of sodium without carbohydrate. G2 will provide a similar amount of sodium with only 8 g of carbohydrate. (5) After each workout, consider drinking low-fat milk rather than a sports drink. Consuming low-fat milk for recovery has been associated with better rehydration during the 4 hours after a workout, as evidenced by less urine output when compared to the sports drink and improved replacement of body weight loss to dehydration.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Taking 1–2 days off from practice (Saturday and Sunday) will allow time to help reestablish normal hydration and a baseline body weight. Monitor weight daily, first thing in the morning, as a secondary measure of hydration status. Weight loss of 1 kg (2.2 lb) in a day is suggestive of water loss of 1000 mL. Attempt to start each day at about the same body weight. Monitor urine for a light yellow color. Dark yellow to brown urine is suggestive of dehydration. Mix a no-calorie electrolyte sports drink using an electrolyte wafer. The wafers are lightweight and portable and are dissolved in water available during practice. The wafer provides an appropriate product to use before and during the first hour of practice. If

	fatigue sets in after 60–90 minutes of practice, a carbohydrate sports drink is reasonable to assist in completing the workout. For recovery after practice, 8–16 ounces (240–480 mL) of low-fat milk with a meal or salty snack is better for recovery than a sports drink. Ryan should not consume an additional 20-ounce sports drink before bed.
6. Describe the recommended therapeutic approach to the patient or caregiver.	“Your weight loss during practice is 1.8% of your total body weight. Clinical dehydration with reduced performance is common in athletes who lose 2% of their body weight per exercise session. Focusing on post exercise recovery, rehydration, and glycogen replacement is reasonable.”
	“A salty meal or snack has been recognized to assist in recovery and rehydration after exercise. Consuming a meal that is balanced with protein, fat, and carbohydrate, preferably complex carbohydrate, generally is superior to sports drinks.”
	“Low-fat milk is an excellent source of all three macronutrients as well as sodium and potassium in quantities exceeding that of sports drinks. Low-fat milk also has been superior to sports drink in replacing body weight lost due to exercise-induced dehydration. The volume of urine output following a sports drink is considerably larger than the volume of urine produced by an equal volume of milk. You have commented on sleep interruption related to drinking a sports drink at night before bed. Milk may be a better choice to retain fluid, with fewer trips to the bathroom.”
	“The sports drink that you are using is a significant source of high-glycemic-index carbohydrate. A daily total of 60 ounces from three bottles will provide 105 g of carbohydrate. You are consuming even more carbohydrate after twice-daily practices. Your current weight and BMI suggest that you are overweight. Your fasting glucose levels indicate that you are at risk for developing insulin resistance and type 2 diabetes. Minimizing exposure to high-glycemic carbohydrates is reasonable.”
	“You should avoid carbohydrate intake in the 2 hours before exercise to allow your body to optimize its ability to use fatty acids for energy during aerobic exercise. Your workouts have long periods of aerobic recovery between short, high-intensity bursts. You may find that your endurance is improved by optimizing fat burning over carbohydrate dependence. Use of a sports drink after 60–90 minutes of practice is reasonable if your total workout time exceeds 10–15 hours per week.”
	“A carbohydrate dose before exercise is known to stimulate insulin release, which moves the carbohydrates into the exercising muscle cells. This insulin release inhibits the enzymes that help to break down serum

	triglycerides, significantly reducing your ability to oxidize fatty acids. Normally, aerobic oxidation of fats contributes at least 50% of your energy needs on the field of play. Drinking a carbohydrate sports drink before exercise may be reducing your ability to use fats for energy and may be influencing your muscles to use carbohydrates for all energy needed on the field. This may explain why you get fatigued quickly, and why a carbohydrate drink during the break may lead to a short recovery. This reaction to carbohydrates can occur in certain athletes who are more sensitive to carbohydrate doses, but it is not the case for all athletes.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Providing a healthy meal within 2 hours after exercise is the optimal way to replace muscle glycogen and restore hydration balance. The typical American diet has sufficient salt for replacement of salt losses. Your experience of poor performance occurs after drinking a carbohydrate sports drink and participating in mixed aerobic/anaerobic activity of variable intensity. You have noted a loss of performance over time (60 minutes) and a recovery after a supplemental dose of carbohydrate at mid-practice. The recovery lasts only 15–20 minutes. This suggests that your performance is affected by carbohydrate availability, rather than fatty acid oxidation, during sustained exercise.”
	“Low-fat milk is an excellent source of all three macronutrients as well as sodium and potassium in quantities exceeding that of sports drinks. Low-fat milk also is superior to sports drinks in replacing body weight lost with exercise-induced dehydration. The volume of urine output after consuming a sports drink is considerably larger than the volume of urine produced after drinking an equal volume of milk.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate	“A 12-ounce bottle of water with an electrolyte wafer added will provide

dose and frequency of administration	360 mg of sodium to support hydration during the first hour of practice. Drinking 3 ounces (90 mL) every 15 minutes ensures that the sodium is available slowly during practice. Additional water is permitted if you are thirsty."
	"Sports nutrition guidelines recommend the use of a carbohydrate sports drink only when exercise time exceeds 60-90 minutes. If fatigue sets in after 60 minutes, you can switch to drinking 150 mL (4 ounces) every 15 minutes using a carbohydrate sports drink like Gatorade. This strategy will provide 36 g of carbohydrate for each hour of sustained practice. Gatorade Thirst Quencher is available in a 20-ounce bottle that provides this specific amount of carbohydrate and fluid."
b. Maximum number of days the therapy should be employed	"Dehydration will be most common on days of multiple workouts, and glucose for energy will be needed mostly during the preseason, when workouts last several hours. A sports drink will be less necessary when school starts, workouts are shorter in duration, and the season changes, bringing cooler weather. There is no reason to use a sports drink during the off season."
c. Product administration procedures	n/a
d. Expected time to onset of relief	n/a
e. Degree of relief that can be reasonably expected	"Some athletes have higher sensitivity to insulin release than others. Avoiding carbohydrates in the 2 hours before practice will allow you to start each practice in a metabolic state optimized for use of fatty acids for your primary fuel at aerobic intensities. When intensity increases, you will have adequate stores of muscle glycogen to provide fuel for 60-90 minutes of the workout and maybe longer. It is possible you will feel some difference in the first few workouts on the new fueling strategy. However, adaption to fatty acid metabolism as a primary fuel will take multiple workouts and possible several weeks of sustained training."
f. Most common adverse effects	"It is unlikely that the electrolyte wafer will cause any adverse effects that you have not experienced from drinking a carbohydrate sports drink during practice. The wafers are effervescent and release a very small amount of carbon dioxide gas while they dissolve. The gas can be vented off by not sealing the bottle during the 5 minutes of tablet dissolution. Failure to allow the gas to release may lead to slight stomach bloating from the wafer product. Otherwise, the wafer is not expected to cause adverse effects that are different from what you have experienced from the sports drink."

g. Adverse effects that warrant medical intervention should they occur	“You should see your regular health care provider if you are unable to return to your usual morning weight, or if you experience muscle cramping that persists despite adequate salt intake. You mention lines of sweat on your clothes. If cramping occurs frequently or is severe enough to interrupt practice, it would be reasonable to see your provider for measuring serum levels of calcium and magnesium as well as testing kidney function. Similarly, if you notice that your urine is significantly darker than usual or has a new foul odor, first assess your hydration status. If the urine changes are persistent despite proper hydration, you will want to follow up with your regular health care provider.”
h. Patient options in the event that condition worsens or persists	“If you observe a dark urine that is not normalizing with proper hydration, you can elect to reduce the protein in your diet for a few days. If the color or odor persists, then consider seeing your regular health care provider.”
i. Product storage requirements	“Electrolyte wafers and unopened sports drinks can be stored at room temperature. A reconstituted electrolyte drink and any open sports drinks should be used within 2 hours or discarded. Electrolyte wafers are hygroscopic, so they can absorb water from the air over time. The wafers will last longer in storage conditions that are environmentally controlled.”
Solicit follow-up questions from the patient or caregiver.	“I have read that creatine is natural and safe. Do you think that creatine would improve my performance?”
Answer the patient's or caregiver's questions.	“Creatine is a naturally occurring compound found in red meats and fish. Choosing natural sources of creatine from dietary protein is ideal, particularly, because taking creatine supplements has been associated with unintended adverse effects. Creatine supplements have not been proved to be more effective than natural dietary creatine in building muscle mass. In addition, misbranding of nutrition supplements has occurred, by either intentional or unintentional formulation. You should use natural protein sources when possible. If you choose to use a supplement, at least narrow your choice of supplement to a product that has undergone quality assurance testing by an independent laboratory.”
Follow-up: Monitor and Evaluate	
9. Assess	Contact Ryan and his parents within 1 week to determine whether he has

patient outcome.	made an appointment with his primary care provider.

Patient Counseling for Performance-Enhancing Nutrients

The quest for enhanced physical performance has resulted in serious health consequences for some athletes. Clinical studies of many botanical and hormonal dietary supplements touted as performance-enhancing products reveal significant adverse effects and little or no enhancement in physical performance. Health care providers should discourage use of performance-enhancing products, because none except creatine has been found to be effective. The box “Patient Education for Performance-Enhancing Nutrients” lists specific information to provide in patient counseling.

Registered dietitians with national board certification as Certified Specialist in Sports Dietetics are uniquely qualified to assist athletes of all levels in evaluating their nutritional needs and to work with them on hydration needs, as well as the quality, quantity, and timing of foods and supplements for optimal performance. Accredited sports dietitians can be found on the Sports, Cardiovascular and Wellness Nutrition web site (www.scandpg.org).

Patient Education for Performance-Enhancing Nutrients

The objective in selecting a performance enhancer is to choose a product

that is safe and appropriate for the type, intensity, and duration of the physical activity. Following the recommendations of an appropriate health care provider and other sports nutrition specialists, as well as carefully following product instructions and the self-care measures listed here, will help ensure optimal therapeutic outcomes.

Muscle Glycogen Preservation

- Carbohydrate-containing sports drinks contain one or more forms of sugar and the electrolytes sodium and potassium. These drinks are optimal for practice or training sessions that last longer than 90 minutes and are generally not needed during the first 60–90 minutes of training. Small doses repeated every 15–20 minutes may be necessary for sustained energy over longer events to maintain glucose levels for performance energy, thereby delaying the time to fatigue.
- Athletes with diabetes should seek the advice of a knowledgeable health care provider or sports dietitian before beginning an exercise program to ensure that they are prepared to avoid hypoglycemia while exercising.
- Note that sports bars often contain other macronutrients, such as fats and proteins. Many of these bars are more appropriate for after-exercise recovery than for use during athletic events. If a well-balanced meal is unavailable within 2 hours of exercise completion, many of these bars may be an appropriate after-exercise fuel replenishment source. (Table 25–1 lists specific products.)
- Long-chain triglycerides can cause discomfort and bloating during intense exercise; therefore, avoid consuming meals that contain large amounts of fat at least 2 hours before exercise.

Enhancement of Muscle Mass

- Athletes do not need to exceed the recommended daily intake of 2.0 g of protein per kg of body weight to increase body mass. Available data indicate that higher intakes do not produce additional muscle mass or strength.
- Athletes who ingest high amounts of protein, either through their

foods or protein supplements, should discuss this practice with their regular health care provider or sports dietitian. Blood urea nitrogen and serum creatinine levels may be monitored to ascertain whether high-protein intake is affecting kidney function.

Hydration and Electrolytes

- For athletes exercising less than 60–90 minutes, water intake alone is sufficient to complete the exercise.
- Athletes exercising longer than 60 minutes may consider incorporating a carbohydrate- and electrolyte-containing sports drink into the exercise program for optimal performance.
- Endurance athletes exercising for 4 hours and longer are discouraged from drinking only free (regular) water owing to the risk of dilutional hyponatremia. Exercise of this duration (e.g., marathon running, long-distance triathlons) will require electrolyte and carbohydrate replacement for optimal performance.
- Athletes should not target a set quantity of water to consume during exercise; rather, they should drink according to the trigger of thirst. Slower runners and walkers exercising in cool conditions can consume water at a lower rate (sips), whereas faster and heavier athletes and those exercising in heat and humidity should be prepared to drink a large volume. Individual calculations of sweat rate for fluid needs during exercise and an additional calculation for recovery fluids can be made to better meet the athlete's needs.
- Athletes should consume 6–12 ounces of plain water if exercise lasts less than 60 minutes. If exercise lasts longer than 60 minutes, they should consider a carbohydrate- and electrolyte-containing sports drink. (See *Fluid Tips for Training and Competition*, available at <http://arizona.openrepository.com/arizona/bitstream/10150/146640/1/az1387-2006.pdf>.)
- Carbonated water may cause gastrointestinal distress and bloating; avoid drinking carbonated water before or during an athletic event.

Ergogenic Supplements

- Little or no clinical evidence supports the performance-enhancing

claims of most herbal supplements. Quality concerns, misbranding, and contamination with heavy metals have occurred with sufficient frequency to suggest that risk outweighs benefit and that such supplements should be avoided.

- Creatine may help increase muscle strength and power in events that require short bursts of power, but gastrointestinal discomfort may occur. To avoid this problem, do not take loading doses. The same benefits occur within 7–14 days of taking a daily maintenance dose of 5 g daily. Maintain proper hydration to assist in the elimination of metabolic waste and to avoid dehydration.
- Long-term use of creatine has no known benefit. The strength improvements achieved with creatine are not maintained beyond the period of supplementation; on cessation of creatine intake, “washout” will occur, with reversion to baseline values. Athletes should consider optimizing their nutritional intake rather than using creatine.

Key Points for Sports Nutrition and Performance-Enhancing Nutrients

- Training regularly and eating a well-balanced diet are consistently shown to benefit sports performance and activity. Most athletes do not require sports nutrition products.
- Despite marketing claims, the benefits of most performance-enhancing nutritional products and ergogenic aids are unproved, and several may be unsafe.
- Misbranding of nutritional supplements has occurred and can lead to unintentional safety risks and to positive results on screening tests performed by antidoping agencies.
- Most sports nutrition drinks, gels, and bars are significant sources of carbohydrate calories. AAP has developed a position that these

carbohydrate and energy drinks should not be used in adolescents and children. They should similarly be avoided in adults who are not engaging in prolonged bouts of exercise (>60–90 minutes).

- Dehydration can significantly affect performance. However, no evidence supports sports nutrition drinks as beneficial when used during events lasting 60 minutes or less. For activity longer than 60 minutes, electrolytes in carbohydrate-containing sports drinks are encouraged and may enhance fluid absorption.
- Sports nutrition drinks containing carbohydrates and electrolytes can prolong the time to fatigue (glycogen depletion) in events or practices lasting 60–90 minutes or longer. Use of such sports drinks may therefore be considered when exercise duration is anticipated to exceed this duration.
- To minimize the risk of dehydration or hyponatremia related to the intake of salt-free fluids, athletes exercising for very long periods of time should use sports drinks that contain electrolytes and carbohydrates rather than plain water.
- Creatine supplementation can increase muscle phosphocreatine concentrations, thus increasing the amount of stored energy in muscles. Phosphocreatine can lend its high-energy phosphate bond to ADP to rapidly restore ATP, allowing increased power for single bursts and repeated activities of high intensity for 30 seconds or less.
- Pseudoephedrine is monitored by the U.S. Anti-Doping Agency, and athletes subject to testing for banned substances should be warned about any product containing this substance. A similar warning should be given for any cough and cold product that includes a sympathomimetic amine as a decongestant, such as oxymetazoline nasal spray.

Chapter 26: Infant Nutrition and Special Nutritional Needs of Children

Authors: M. Petrea Cober

Human milk is most physiologically suited to infants and is their optimal milk source up to the age of 12 months. The American Academy of Pediatrics (AAP) recommends that human milk be used as the sole source of nutrition for infants during the first 6 months of life. For infants whose mothers choose not to breastfeed, the nutritional quality, safety, and convenience of infant formulas make such products an appropriate alternative. Variations among formulas allow for product selection to meet a specific infant's nutritional needs, along with considerations of palatability, digestibility, nutrient sources, convenience, and cost.

In the area of infant nutrition, an important role for today's pharmacist is as an additional information resource for parents or other caregivers to promote successful breastfeeding. In addition, in consultation with the child's parents and primary care provider, the pharmacist also can evaluate indications, advise on formula selection, and help ensure its appropriate use. This service requires in-depth knowledge about infant and child nutrition needs, breastfeeding issues and practices, and commercially prepared infant and pediatric formulas, including differences in formula composition and specific uses for therapeutic formulas.

Some children may require specialized enteral formulas after the age of 1 year because of various disease states and conditions. Familiarity with these products and their appropriate use is essential to allow the pharmacist to answer related caregiver questions, facilitate their procurement, and perform an assessment for associated complications.

Organ Maturation and Infant Growth

Knowledge of the development of the gastrointestinal (GI) tract and the kidney is crucial to understanding infant nutrition. Different aspects of maturation are reflected in physiologic parameters and events of digestive function, as reviewed in this section.

In clinical practice, monitoring growth and growth rate using World Health Organization (WHO) growth charts is important for assessing the infant for possible abnormal or unhealthy growth. WHO growth charts are recommended for use in children younger than 24 months of age, and the Centers for Disease Control and Prevention (CDC) growth charts are recommended for use in children 24 months and older.¹

Gastrointestinal Maturation

By the completion of 27 weeks of gestation (or 27 weeks after the woman's last menstrual period), all segments of the fetal GI tract are formed and display some physiologic function. From 28 weeks of gestation onward, however, maximal GI tract growth and differentiation occur. Therefore, premature infants—those born before 37 weeks of gestation—often have reduced GI tract function, especially those born before 32 weeks. Transition from intrauterine nutrition delivered through the maternal–fetal unit (i.e., the placenta) to extrauterine nutrition derived from mother's milk or infant formula requires the maturation of many physiologic processes. These processes include effective sucking, swallowing, gastric emptying, intestinal peristalsis, and defecation; production of salivary, gastric, pancreatic, and hepatobiliary secretions; and development of intestinal brush border enzymes and transport systems ([Table 26–1](#)).²

Table 26–1 Gastrointestinal Maturation

Function	Weeks of Gestation When First Detectable	Comments
Sucking and swallowing	16	16weeks: swallowing of amniotic fluid
		26 weeks: sucking
		33–35 weeks: mature, coordinated sucking, swallowing, and breathing
Gastric motility and secretion	13	Gastric emptying delayed in first few days of life; affected by caloric density, carbohydrate concentration, pathologic conditions
Intestinal motility	20	26–30 weeks: disorganized contractile activity

		30–34 weeks: repetitive groups of contractions
		34–35 weeks: more mature migrating motor complexes
Digestion and Absorption		
Important Factors	Weeks of Gestation When First Detectable	Proportion of Adult Values
Protein		
Enterokinase	24–26	30 weeks: 20%
		Term: 10%–25%
Hydrochloric acid	At birth	30 weeks: <20%
		Term: <30%
		First 3 months: 50%
Peptidases	<12	30 weeks: 15%
		Term: nearly 100%
Trypsinogen/ chymotrypsinogen	20	Term: 10%–60%
Amino acid transport	ND	Term: nearly 100%
Macromolecule absorption	ND	Term: nearly 100%
Fat		
Lingual lipase	30	Term: nearly 100%
Pancreatic lipase	16–20	Term: 5%–10%
Bile acids	22	32 weeks: 25%
		Term: 50%
Medium-chain triglyceride uptake	ND	100% (absorption occurs in the stomach)

Long-chain triglyceride uptake	ND	<i>Term:</i> 10%–90%
Carbohydrate		
Pancreatic alpha-amylase	22–30	<i>Term:</i> 0%
		<i>6 months of age:</i> secretion begins
Salivary alpha-amylase	16	<i>30 weeks:</i> 0%
		<i>Term:</i> 10%–20%
Lactase	11	<i>28–34 weeks:</i> 30%
		<i>Term:</i> nearly 100%
Monosaccharide absorption	11–19	<i>Term:</i> glucose absorption: 50%–60%

Key: ND = Not determined.

Silver Spring, MD: American Society for Parenteral and Enteral Nutrition; 2015:23–29.

Nutritive sucking develops at approximately 33–34 weeks of gestation. In term infants born at 37–42 weeks' gestational age, a mature, efficient pattern of sucking is seen within a few days after birth. In premature infants, an immature, inefficient pattern may persist for a month or longer. Infants born before they attain a gestational age of 34 weeks cannot coordinate sucking, swallowing, and breathing and may therefore require tube feedings for several

weeks to months until these reflexes mature. Liquid nutrition is appropriate for all infants until complex tongue movements and swallowing reflexes mature. Maturation of these reflexes typically occurs by the age of 4–6 months, and it is at this time that solid foods can be safely added to the infant's diet.² For infants born prematurely, corrected gestational age should be used to determine these developmental milestones. *Corrected gestational age* is calculated by adding chronologic age to gestational age at birth. Once premature infants reach 40 weeks corrected gestational age, their growth and developmental parameters are assessed using an age adjusted for gestational age (i.e., chronologic age in weeks minus number of weeks premature). For example, for an infant born at 23 weeks' gestational age who is currently 25 weeks old, the corrected gestational age would be 48 weeks, with a maturation age of 2 months (or 8 weeks) corrected age. This patient would therefore be developmentally equivalent to a term infant at 2 months of age.

Early in life, frequent feedings (every 2–3 hours) are necessary, because the stomach capacity of a term newborn with a birth weight greater than 2500 g (5 pounds 8 ounces) is only 20–90 mL (equivalent to approximately 0.7–3 ounces). Gastric capacity increases to 90–150 mL (3–5 ounces) by 1 month of age, at which time longer periods between feedings are possible, enabling the infant to sleep for longer periods of time (i.e., through the night). Human milk empties more rapidly from the stomach than infant formula; therefore, human milk–fed infants typically eat more often than their formula-fed peers.

In term infants, gastric acid and pepsin secretion peak in the first 10 days of life, decrease between 10 and 30 days of life, and then increase to adult levels by the age of 3 months. In premature infants, basal acid output is lower than that in term infants but increases with postnatal age. Milk in the infant's stomach causes a sharp increase in the pH of the gastric contents and a slower return to lower pH values than in older children and adults. Gastric acidity in the newborn is unsuitable for optimal pepsin action. Because of this low pepsin activity, little protein digestion occurs in the stomach. The extent of protein absorption, however, is similar to that seen in children and adults. Amino acids and peptides produced by protein digestion are absorbed passively or by active transport mechanisms that reach adult capacity by the age of 14 weeks.

Premature and full-term infants can digest most carbohydrates, because the production of intestinal enzymes such as sucrase, maltase, isomaltase, and

glucoamylase is sufficiently mature at birth. Lactase activity increases relatively late in fetal life and begins to decline after the age of 3 years, especially in African American children and those of Asian ancestry. By adulthood, approximately 15% of Whites, 40% of Asian Americans, and 85% of African Americans are deficient in intestinal lactase.³ Pancreatic amylase secretion does not reach adult levels until the age of approximately 1 year. Salivary amylase may help compensate for this relative lactase and amylase deficiency in early infancy. Despite this relative lactase deficiency, most term and preterm infants tolerate lactose-containing formulas, with negligible unabsorbed carbohydrate output in the stool. Unabsorbed lactose that enters the colon undergoes bacterial fermentation (colonic salvage) to short-chain fatty acids, thereby creating an acidic environment that favors growth of acidophilic bacterial flora (lactobacilli) and suppresses growth of more pathogenic organisms. This acidity also promotes water absorption and prevents osmotic diarrhea. Because of the relative abundance of glucoamylase compared with lactase in the premature infant's intestine, glucose polymers are digested and absorbed better than lactose is.²

Newborns exhibit low concentrations of pancreatic lipase and slow rates of synthesis of bile acid. Both pancreatic lipase and bile acids are important for fat absorption. The rate of bile acid synthesis increases throughout gestation and with increasing postnatal age. The bile acid pool in a premature infant is one-fourth that in an adult, whereas a term infant's is one-half that in an adult. However, fat malabsorption is not a major problem in preterm or term infants, because lingual and gastric lipases are present. Infants born earlier than 34 weeks' gestational age, however, may exhibit steatorrhea.

Intestinal length also may affect nutrient absorption. At birth, a term infant's small intestine is approximately 270 cm (106 inches) long. From 28 weeks' gestational age, the intestinal length approximately doubles. Infants born prematurely, therefore, have less small intestine and consequently a decreased surface area for absorption. Adult intestinal length of 4–5 m (13–16.5 feet) is reached by the age of approximately 4 years.

Kidney Maturation

Maturation of the kidney also is important in nutrition because it determines the ability of the kidney to excrete a solute load. Glomerular filtration begins around week 9 of fetal life; however, kidney function does not appear to be

necessary for normal intrauterine homeostasis, because the placenta serves as the major excretory organ. After birth, the rate of glomerular filtration increases until growth stops, toward the end of the second decade of life. Even after correction for body surface area, the glomerular filtration rate in children does not approximate adult values until the third year of life.

Growth

Birth weight is determined primarily by maternal prepregnancy weight and pregnancy weight changes. The average birth weight of a term infant is approximately 3500 g (7 pounds 11 ounces). Premature infants are categorized by birth weight as follows: *low-birth-weight* infants weigh less than 2500 g (5 pounds 8 ounces); *very low-birth-weight* infants weigh less than 1500 g (3 pounds 4 ounces); *extremely low-birth-weight* infants weigh less than 1000 g (2 pounds 3 ounces); and so-called *micropreemies* weigh less than 750 g (1 pound 10 ounces).

Water weight loss (6%–10% of body weight) occurs immediately after birth over a period of 1–2 weeks. Subsequently, the average weight gain throughout the first 12 months of life is 26–31 g daily for the first 3 months; 17–18 g daily for months 3–6; 12–13 g daily for months 6–9; 9 g daily for months 9–12; and 7–9 g daily from 12 months of age.⁴ Most term infants double their birth weight by 4–6 months of age and triple it by 12 months. Premature infants may reach these milestones sooner than predicted by their corrected gestational age. From the age of 2 years to approximately 10 years, the growth rate is fairly constant at approximately 2.3 kg (5 pounds) each year. Growth velocity increases, and a major growth spurt occurs during adolescence. Height shows a growth pattern similar to that of weight; most infants increase their length by 50% in the first year, 100% in the first 4 years, and 300% by the age of 13 years. Changes in body composition accompany height and weight changes. Most notably, total body water decreases as adipose tissue increases. Total body water accounts for approximately 90% of total body weight at 24 weeks of gestation, 70% at term, and 60% by the age of 1 year.

Normal values for weight, length/height, and head circumference (until 3 years of age) in infants and children generally are expressed in terms of percentile-for-age; the reference standards most commonly used are WHO growth standards for infants and children younger than 2 years of age and the CDC growth charts developed by the National Center for Health Statistics (NCHS)

for children 2 years of age and older. As determined by CDC, the National Institutes of Health (NIH), and AAP, use of the WHO growth standards is recommended in the United States for patients younger than 2 years of age (https://www.cdc.gov/growthcharts/who_charts.htm). Three primary benefits of WHO growth standards for these patients cited as the reason for their use are establishing growth of the breastfed infant as the norm for growth, providing a better description of physiologic growth in infancy, and basing information on a high-quality study designed explicitly for creating growth charts. For children 2 years of age and older, the CDC growth charts should still be used, because the methods used to create both the CDC and WHO growth charts were similar for 2- to 5-year-olds, and WHO growth charts are based only on data for children up to 5 years of age.¹ Charts can be downloaded free of charge on the CDC website (www.cdc.gov/growthcharts). The infant charts are intended for use in term infants. In premature infants, growth parameters should be plotted on these charts using an age corrected for gestational age, as discussed previously, until the age of 18 months for weight, 40 months for length/height, and 18 months for head circumference.⁴ Charts for premature infants younger than 40 weeks' gestational age are available and should be used when appropriate. Specialized growth charts for children with certain pathologic conditions such as Down syndrome also are available. Although debate continues regarding the use of these charts versus standard charts for age, specialized growth charts may be helpful in assessing growth within these populations.^{5,6} Clinicians should be aware that limitations to the use of these charts exist and that not all children with a given condition may be accurately represented by the data presented. CDC provides information on the Down syndrome-specific growth charts on its website (<https://www.cdc.gov/ncbddd/birthdefects/downsyndrome/growth-charts.html>). The most commonly used charts for premature infants are the Fenton and Olsen charts (available at www.ucalgary.ca/fenton/2013chart and <https://www.aap.org/en-us/Documents/GrowthCurves.pdf>, respectively).

Most infants' growth parameters will fall between the 3rd and 97th percentiles on the gender-specific weight-for-age, length/height-for-age, weight-for-length, and head circumference-for-age charts. In children younger than 2 years of age, a recumbent length measurement is obtained in the primary care office, whereas in children 2 years of age or older, a standing height is measured. Most children grow along a percentile established shortly after birth, but spurts and plateaus are common. *Failure to thrive* was historically defined as a fall of 2 or more growth percentiles from a previously established

percentile in 6 months or less but now is defined as growth that is significantly lower than the norms for the affected child's age and gender.⁴ If growth is not progressing as expected, particularly in the first year of life, when growth should be rapid, the infant's diet and other potential contributory factors (e.g., environment, diseases, syndromes) should be evaluated. The four most commonly associated factors for failure to thrive are medical, nutritional, developmental, and social.⁴ Satisfactory growth is the most sensitive indicator of whether nutritional needs are being met.

For children 2 years and older, body mass index (BMI)-for-age charts can be useful in assessing obesity risk. BMI, a measure of body weight adjusted for height, is a useful tool to assess body fat. BMI is calculated as weight in kilograms divided by height in meters squared. The use of BMI was recommended by an expert committee consisting of members from the American Medical Association, the Health Resources and Services Administration and CDC (https://www.cdc.gov/healthyweight/assessing/bmi/childrens_bmi/about_childrens_bmi.html). The committee's nomenclature changes were intended to make it easier to discuss children's weight issues with parents and children and to affect the transition to adult assessments. According to these recommendations, a child whose BMI is at or above the 85th percentile but below the 95th percentile or 30 kg/m², whichever is smaller, should be classified as *overweight*. A child whose BMI is at or above the 95th percentile or 30 kg/m², whichever is smaller, should be classified as *obese*.⁷ In 2011–2012, 8.1% of infants and toddlers from birth to 2 years of age had BMIs at or above the 97th percentile on WHO growth charts, whereas 18.5% of children and adolescents 2–19 years of age in 2015–2016 had values at or above the 95th percentile on the CDC growth charts.^{8,9} The prevalence of obesity in children and adolescents 2–19 years of age has not statistically changed since 2013–2014 (17.2% in 2013–2014 versus 18.5% in 2015–2016) but still is higher than the *Healthy People 2020: National Health Promotion and Disease Prevention Objectives* goal of 14.5%.^{9,10} The incidence of obesity remains high. However, the proportion of obesity prevalence differs among various ethnic groups, with 25.8% of Hispanics, 22% of non-Hispanic Blacks, 14.1% of non-Hispanic Whites, and 11% of non-Hispanic Asians between 2 and 19 years of age classified as obese.⁹

A BMI below the 5th percentile is indicative of *underweight*. In applying these definitions, however, pharmacists and other health care providers should keep in mind that because of the way the growth charts were developed, values for

5% of normally growing and healthy children will fall below the 5th percentile and those for another 5% will fall above the 95th percentile on the weight-for-age or height-for-age charts. These children should not be branded as “malnourished” and “obese,” respectively.

Energy Requirements and Growth

Acceptable growth is achievable only with adequate intake, absorption, and utilization of energy, protein, carbohydrates, minerals, and vitamins. The Food and Nutrition Board of the National Research Council has established dietary reference intakes (DRIs) as reference values for nutrient intake sufficiency and safety. The DRIs for micronutrients are discussed in detail in [Chapter 23](#), and tables in that chapter list the current established recommended dietary allowances (RDAs) and adequate intakes (AIs) for healthy infants and children. [Table 26–2](#) lists the daily DRIs of macronutrients for healthy infants and children.¹¹ Children with various diseases and syndromes may have different needs. An example is the need for “catch-up” calories in infants and children recovering from failure to thrive. Calorie requirements for catch-up growth are often 1.25 times those of age-matched peers, depending on the degree of catch-up growth needed. The average rate of weight gain for corrected age for prematurely born infants is up to 2–3 times more.⁴ In patients with fat malabsorption (e.g., from cystic fibrosis or other cause of pancreatic insufficiency, bile acid deficiency, or short bowel syndrome), calories for catch-up growth may be 1.5 times or more those of age-matched peers.

Table 26–2 Daily Dietary Reference Intakes of Macronutrients for Full-Term Infants and Children^{a,b}

Nutrient	0–6Months	7–12Months	1–3Years	4–8Years	9–13Years
Energy ^c (kcal)	M: 570	M: 743	M: 1046	M: 1742	M: 2279
	F: 520	F: 676	F: 992	F: 1642	F: 2071
Protein ^c					
(g/kg)	1.5	1.2 ^d	1.1 ^d	0.95 ^d	0.95 ^d
(g)	9.1	13.5 ^d	13 ^d	19 ^d	34 ^d

Nutrient	0–6Months	7–12Months	1–3Years	4–8Years	9–13Years
Carbohydrate (g)	60	95	130 ^d	130 ^d	130 ^d
Water (L) ^e	0.7	0.8	1.3	1.7	M: 2.4
					F: 2.1
Fat (g)	31	30	ND	ND	ND
Alpha-linolenic acid (g)	0.5	0.5	0.7	0.9	M: 1.2
					F: 1
Linoleic acid (g)	4.4	4.6	7	10	M: 12
					F: 10
Fiber (g) ^f	ND	ND	14	M: 19.6	M: 25.2
				F: 16.8	F: 22.4

^a Expressed as AIs unless noted otherwise.

^b DRIs have not been established for premature infants.

^c Estimated requirements; include needs associated with growth (i.e., energy expenditure plus energy deposition). The assumed normal body weight and length used for the DRIs are as follows: 0–6 months: 6 kg, 62 cm; 7–12 months: 9 kg, 71 cm; 1–3 years: 12 kg, 86 cm; 4–8 years: 20 kg, 115 cm; and 9–13 years: 36 kg, 144 cm for males, 37 kg, 144 cm for females.

^d Expressed as RDA.

^e Water from all sources including formula, human milk, foods, beverages, and drinking water.

^f Fiber guidelines are provided for adolescents and include goals of 30.8 g for males 14–18 years of age and 25.2 g for females 14–18 years of age.

Key: AI = Adequate intake; DRI = dietary reference intake; F = female; M = male; ND = not determined; RDA = recommended dietary allowance.

December 2015. Available at: <https://health.gov/our-work/food-and-nutrition/2015-2020-dietary-guidelines/>. Accessed July 26, 2020.

Energy requirements vary with age and clinical condition. Total energy expenditure is a combination of basal energy needs: the energy required to digest food (thermic effect of feeding, also called “specific dynamic action of food”), thermoregulation, and activity. Estimates of energy requirements for infants and children are based on meeting total energy expenditure plus promoting growth. An infant’s energy requirement is higher in relation to body mass than that of an adult or older child because of the rapid growth experienced during infancy. Estimated energy requirements for term infants and children are shown in [Table 26–2](#).¹¹ Although no RDA has been established, premature infants require 110–130 kcal/kg/day for enteral nutrition before hospital discharge and 100–120 kcal/kg/day after discharge.¹² In some cases, as much as 120–150 kcal/kg/day or more is needed for adequate growth.

Infant Nutritional Standards

An amendment to the Food, Drug, and Cosmetic Act (Infant Formula Act of 1980, amended 1986) gives the U.S. Food and Drug Administration (FDA) the authority to revise nutrient levels for infant formulas, establish quality control, and require adequate labeling. FDA sets specifications for minimum amounts of 29 nutrients and maximum amounts of 9 of those nutrients. All formulas marketed in the United States must meet these requirements. Parents should be cautioned against using any infant formula not manufactured in the United States. FDA alerts have warned of the dangers of using infant formulas from China whose contents fall well below FDA standards. Formulas granted exemption from FDA-established nutrient specifications must be labeled for use in infants with specific indications, such as inborn errors of metabolism, low birth weight, or other, unusual medical problems or dietary needs. A list of exempt formulas can be obtained at the FDA website (www.fda.gov). In addition, FDA has published guidance documents to clarify certain requirements for industry on labeling of infant formula, including nutrient content claims, health claims, and qualified health claims, and requirements

for preparation directions and a statement regarding the need to add or not add water. The September 2016 guidance document is available at <http://www.fda.gov/FoodGuidances>.

Components of a Healthy Diet

Infants require the same dietary components as for adults: fluid, carbohydrates, proteins, fats, and micronutrients. However, the desired proportions of these components in the infant diet differ from those recommended for adults.

Fluid

Water is an important part of an infant's diet in that it makes up a larger proportion of the infant's body weight than that of older children or adults. The Holliday–Segar method is most often used to estimate maintenance water needs: 100 mL/kg/day for the first 10 kg of body weight, plus 50 mL/kg/day for each kilogram between 10 and 20 kg, and 20 mL/kg/day for each kilogram over 20 kg. Body surface area also may be used to estimate daily fluid requirements; fluid requirements are approximately 1500 mL/m²/day. These methods, however, will underestimate the needs of premature infants, whose requirements are in general much higher (i.e., 120–170 mL/kg/day, or as high as 200 mL/kg/day based on specific patient circumstances). Adequate water intake in the first 6 months of life can be derived from human milk or formula. Both contain sufficient amounts of water, so the normal, healthy infant does not need supplemental water. At the age of 6–12 months, when solid foods are introduced, water intake remains high, because most infant foods contain at least 60%–70% more water than other foods, and formula or human milk intake also should still be high.

Renal excretion, evaporation from the skin and lungs, and, to a lesser extent, elimination of feces are the major routes of fluid loss. Increased water loss caused by diarrhea, fever, or unusually rapid breathing, particularly in concert with decreased water intake, may result in significant dehydration and electrolyte imbalance and must be offset by fluid intake in excess of maintenance needs. (Refer to [Chapter 19](#) for information on the diagnosis and management of dehydration in pediatric patients.)

Carbohydrates

An AI for carbohydrates has been established for infants ([Table 26–2](#)).¹¹ Under normal circumstances, an infant can efficiently use a diet with 40%–50% of total calories from a carbohydrate source. Carbohydrate intake should be balanced with adequate fat intake to allow proper neurologic development. A carbohydrate-free diet generally is undesirable because it may lead to metabolic modifications favoring fatty acid breakdown, dehydration, and tissue protein and cation loss. However, children with seizure disorders may receive an essentially carbohydrate-free diet—the ketogenic diet—because these metabolic effects may facilitate seizure control. Use of a ketogenic diet should be under direct, strict medical supervision, with additional management as appropriate by a registered dietitian or other qualified health care provider.

Lactose, the primary carbohydrate source in human milk and most milk-based formulas, is hydrolyzed to its monosaccharide components, glucose and galactose, by gastric acid and the enzyme lactase. Congenital lactase deficiency is a rare type of lactose intolerance resulting from an inborn error of metabolism. Infants born prematurely, before the maturation of significant lactase activity (before approximately 36 weeks' gestational age), are relatively lactase-deficient. Secondary lactase deficiency is a temporary reduction in intestinal lactase caused by gastroenteritis or significant malnutrition. Because of low lactase activity, infants with congenital lactase deficiency, premature infants, and infants recovering from diarrhea or severe malnutrition may be unable to completely metabolize the lactose found in human milk or milk-based infant formulas, with consequent development of lactose intolerance resulting in diarrhea, abdominal pain or distention, bloating, gas, and cramping.

Fiber intake is of considerable interest, because in adults, high-fiber diets have been associated with the prevention of diverticular disease, colon cancer, and coronary heart disease. (See [Chapter 24](#) for further discussion of fiber.) AAP recommends following the Dietary Guidelines 2015–2020 for Americans from the U.S. Departments of Health and Human Services and Agriculture (<https://health.gov/dietaryguidelines/2015/resources/2015-2020-Dietary-Guidelines.pdf>). An AI for fiber for infants 0–12 months of age has not been established. Infants rarely require added fiber to maintain normal bowel function. Starting from the age of 6–12 months, however, whole cereals, green

vegetables, and legumes typically are introduced to provide a source of fiber in the infant's diet. The fiber AI for older children is shown in [Table 26–2](#). Adult values are reached by the teenage years.

Protein and Amino Acid

The most recent revision of the DRIs established new AIs for protein in term infants and children ([Table 26–2](#)).¹¹ Total body protein increases by an average of 3.5 g daily in the first 4 months of life and by 3.1 g daily over the next 8 months, representing an overall increase in body protein composition from 11% to 15% of total body weight.

A specific protein's amino acid composition (i.e., chemical makeup) also is important. Amino acids are classified as essential (or indispensable), nonessential, or conditionally essential. The amino acids cysteine, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan, tyrosine, and valine are considered essential for infants, because the human body cannot synthesize them from other amino acid and carbohydrate precursors. In the neonate and young infant, immature biochemical pathways for synthesis or conversion of select amino acids may prevent adequate synthesis for normal growth and development.

Taurine is an especially important amino acid in infancy. Quantities in human milk are high, and all infant formulas are supplemented during the manufacturing process to provide the same margin of physiologic safety as for human milk.¹³ Taurine is not an energy source and is not used for protein synthesis, but it serves as a cell membrane protector by attenuating toxic substances (e.g., oxidants, secondary bile acids, excess retinoids) and acting as an osmoregulator. Additionally, the conjugation of bile acids requires taurine. Taurine deficiency can result in reduced bile acid secretion, leading to accumulation of toxic bile acids, retinal dysfunction, slow development of auditory brainstem evoked response in preterm infants, and poor fat absorption in preterm infants and children with cystic fibrosis. Substantial clinical or physiologic improvement can be obtained with use of taurine supplements in these conditions.

Despite similar amino acid densities and milk intakes in formula-fed and human milk-fed infants, serum concentrations of some amino acids measured in formula-fed infants tend to exceed those measured in human milk-fed

infants; however, both groups exhibit comparable growth. The protein content of human milk evolves with the growing infant's needs, but the high protein requirements of preterm infants are not completely met by early human milk. Fortification with commercially available powders or liquids is required for the preterm infant to achieve reasonable amino acid profiles and to meet requirements for expected growth rates. In evaluating the adequacy of an infant's protein intake, it is important to consider not only the absolute amount of protein ingested but also the *linear growth velocity* (i.e., rate of linear growth over a defined period of time), the quantity of nonprotein calories and other nutrients necessary for protein synthesis, and the quality of the protein itself.

Fat and Essential Fatty Acids

Fat is the most calorically dense component in the diet, providing 9 kcal/g, compared with 4 kcal/g for both protein and carbohydrates. Fat accounts for approximately 50% of the nonprotein energy in both human milk and infant formula. Infant feeding choices, especially fat and calorie intake, are increasingly being linked to obesity and other diseases (e.g., diabetes, cardiovascular disease [CVD]) in adulthood. Despite these concerns, children younger than 2 years of age (the time of most rapid growth and development requiring high energy intakes) should not receive a fat- or cholesterol-restricted diet unless medically prescribed. Children between 12 months and 2 years of age who are at increased risk for subsequent early development of CVD because of a family history of obesity, dyslipidemia, or CVD may be candidates for reduced-fat milk products.¹⁴ AAP supports this position, with attention to appropriate fat intake, on account of the recognized need for adequate fatty acids for normal neurologic development and adequate calories for growth.¹⁴ Parents of children with or without hypercholesterolemia should be encouraged to adopt a diet that contains no more than 30% of total calories from fat, with 7%–10% of calories from saturated fats and dietary cholesterol (≤ 300 mg daily).¹⁴

The diet also must contain small amounts of the two essential polyunsaturated fatty acids (PUFAs): linolenic acid, an omega-3 (n-3) fatty acid, and linoleic acid, an omega-6 (n-6) fatty acid. These fatty acids are precursors for the n-3 and n-6 long-chain PUFAs—docosahexaenoic acid (DHA) and arachidonic acid (ARA), respectively. Essential fatty acid deficiency, rarely seen in the United States, can manifest as increased metabolic rate, failure to thrive, hair loss, dry flaky skin, thrombocytopenia, and impaired wound healing. Because of substantial

fat stores, overt clinical manifestations of essential fatty acid deficiency generally are delayed for weeks in older children and adults; however, rapid onset (within days) may occur in premature infants with inadequate linoleic acid in their diets. Linoleic acid represents the bulk of PUFAs in infant formulas. Generally, an intake of at least 10% of total calories from fat and linoleic acid equal to at least 2%–4% of total dietary calories is adequate to prevent essential fatty acid deficiency; 3%–7% is the amount found in human milk.¹⁵ Providers also should ensure an adequate provision of carnitine in at-risk patients. Carnitine is required for the transport of long-chain fatty acids across the mitochondrial membrane for oxidation. Preterm infants are at risk for carnitine deficiency, because its accrual from the mother occurs late, during the third trimester. AIs for the essential PUFAs are shown in [Table 26-2](#).¹¹

Historically, infant formulas contained only the precursor PUFAs: linoleic and linolenic acid. Nowadays, most infant formulas are supplemented during manufacturing with DHA and ARA. In fact, more than 60 countries permit the addition of these fatty acids to infant formulas. AAP has not taken an official stand on whether infant formulas should be supplemented with DHA and ARA. However, the current European recommendations supported by the World Association of Perinatal Medicine, the Early Nutrition Academy, and the Child Health Foundation are for the addition of 0.2%–0.5% DHA to all infant formulas.¹⁶ These long-chain PUFAs, which are abundant in human milk but not in cow milk, are not considered essential but are thought to provide extra nutritional benefits. Increased amounts of DHA beyond what is currently being added to term infant formulas to mimic term human milk levels are being recommended for some preterm infants.^{17,18} DHA is important in both brain and eye development; a direct role for ARA is less clear. However, supplementation of DHA without ARA may lead to ARA deficiency and possible growth suppression.¹⁹

Whether the addition of DHA and ARA to infant formulas improves visual and cognitive function remains controversial. Some studies have shown benefit for visual function, cognitive and behavioral development, and growth with DHA and ARA supplementation in infants; other studies have shown no differences in supplemented versus control infants.²⁰⁻²² Benefits such as a decreased prevalence of allergies and a reduced incidence of common respiratory illnesses also have been suggested, but studies have had mixed results.²³⁻²⁵ No adverse effects have been noted in infants receiving DHA- and ARA-supplemented formulas; however, two studies in which the formula was

supplemented with only DHA reported growth suppression, stressing the importance of supplementation with both DHA and ARA.²² Several studies have examined the long-term benefits, particularly cognitive, of DHA supplementation and have not found sustained effects.^{26,27} However, significant benefits were observed in selected cognitive components in a more recent study conducted in children 3–6 years of age.²⁸

FDA has issued a “generally recognized as safe” (GRAS) notification to Martek Biosciences Corporation for its patented plant-based fatty acid blends DHASCO (DHA-rich single cell oil), extracted from *Cryptothecodinium cohnii*, and ARASCO (ARA-rich single cell oil), extracted from *Mortierella alpina*, both of which are currently used to supplement infant formulas during manufacturing.

Some evidence also indicates that maternal diet can affect fatty acid concentrations in the infant, both in utero and during lactation for human milk-fed infants, but supplementation has not been shown to significantly improve neurodevelopmental outcomes, visual acuity, or growth and only weakly favors supplementation.²⁹ Many prenatal vitamins, as both prescription (e.g., Nexa Plus, Duet DHA Balanced) and nonprescription (e.g., Similac Prenatal Vitamin, various store brands) products, currently are available, with an additional softgel capsule containing either DHA or DHA with eicosapentaenoic acid (EPA). The sources of DHA and EPA range from fish-based products to plant-derived sources. Enfamil Expecta Prenatal Dietary Supplement, softgel capsules containing 200 mg DHA, is marketed as a non-fish-based (algae) supplement for pregnant and lactating women to increase maternal dietary DHA and potentially increase DHA concentrations in their infants. These capsules may have less aftertaste than other sources of DHA. Additionally, selecting “burpless” products and freezing the product before administration may help to decrease the aftertaste of the fish-derived products. Routine supplementation during pregnancy and lactation remains controversial and should be discussed with a knowledgeable health care provider.

Micronutrients

DRIs for term infants (given as RDAs if defined or as AIs if RDAs are not defined) for vitamins and minerals, including trace elements, are shown in Tables 23–3 and 23–4 in [Chapter 23](#). Precise needs are difficult to define and

depend on energy, protein, and fat intakes as well as absorption and nutrient stores. Infant formulas are supplemented with adequate amounts of vitamins and minerals to meet the needs of most term and premature infants when the appropriate formula is chosen. As with protein fortification, human milk must be fortified to meet the micronutrient needs of most premature infants. Appropriate supplementation is included in the discussion of specific milks and formulas.

Infant Food Sources

Human milk– and cow milk–based formulas are the primary food sources for most infants in the United States. Soy protein–based formulas and goat milk are alternatives. A variety of formulas are available to feed infants with special nutritional needs, including those unable to consume a regular oral diet, those with inborn errors of metabolism, and those with various malabsorptive conditions. Most infants and children receive either human milk or an enteral formula by mouth; however, some children will receive nutrition through feeding tubes such as naso- or orogastric, nasoduodenal, gastrostomy, or jejunostomy tubes. A discussion of these feeding techniques is beyond the scope of this chapter. More information on enteral feeding tubes and potential complications is available on the following websites: www.nutritioncare.org and www.oley.org.

Human Milk

Both WHO and AAP recommend that infants be breastfed without supplemental foods or liquids for approximately the first 6 months (i.e., exclusive breastfeeding) and be encouraged to breastfeed for the first year of life or longer if desired by mother and child.^{30–32} Breastfeeding initiation rates worldwide have increased steadily since 1990, with the rate at hospital discharge increasing from a low of 24.7% in 1971 to 83.2% in 2015. However, in 2015, the reported rates of any breastfeeding in infants 6 and 12 months of age were only 57.6% and 35.9%, respectively. Sociodemographic factors affect breastfeeding rates. Black women are less likely than White, Hispanic, and Asian women to breastfeed. Poor, unmarried, and poorly educated women also are less likely to breastfeed their infants. [Table 26–3a](#) shows breastfeeding rates in the United States for infants born in 2015 based on various ethnicities.^{33–35}

Table 26–3 Breastfeeding Rates in the United States, 2015

a. Ethnicity-Based					
	All Ethnic Groups (%)	Asian (%)	Black (%)	Hispanic (%)	White (%)
Breastfeeding at					
Any time after birth	83.2	89.3	69.4	84.6	85.9
6 months	57.6	72.2	44.7	54.1	62
12 months	35.9	50.3	24	32.6	39.8
b. Compared With Healthy People 2020 Goals					
	Healthy People 2020 Goal (%)	Observed Rate (%)			
Breastfeeding at					
Birth	82	83.2			
6 months	61	57.6			
1 year	34	35.9			
Exclusive breastfeeding at					
3 months	46	46.9			
6 months	25	24.9			
Formula supplementation within first 2 days of life	14	17.2			

Source: [References 10, 33, and 34.](#)

Because breastfeeding is a major public health issue, breastfeeding goals were included in *Healthy People 2020: National Health Promotion and Disease Prevention Objectives*, the national plan to improve the health of the American people.¹⁰ Objectives of *Healthy People 2020* are provided in [Table 26–3b](#),

including data from 2015 (the year of last official reporting of information). All values showed improvement from the 2006 baseline levels, and goals were met for any breastfeeding at birth, any breastfeeding at 1 year, and exclusive breastfeeding at 3 months. The proposed breastfeeding goal for *Healthy People 2030* will involve only exclusive breastfeeding at 6 months, which aligns with the recommendations of WHO and CDC (www.healthypeople.gov). AAP recommends support for breastfeeding through the first year of life. The AAP policy statement on breastfeeding and the use of human milk was updated in 2012 and includes reinforcement of breastfeeding and human milk as the reference normative standards for infant feeding and nutrition and reaffirmation of the recommendation for exclusive breastfeeding for 6 months, followed by continued breastfeeding for 1 year or longer as mutually desired by mother and infant. AAP cautions that medical contraindications to breastfeeding are rare in the United States (e.g., positive maternal human immunodeficiency virus [HIV] serostatus, active tuberculosis without at least 2 weeks of prior treatment, infant galactosemia, or need for maternal medication not compatible with breastfeeding).³⁶ Moreover, AAP recommends (1) the use of WHO growth charts to avoid mislabeling of infants as underweight and with failure-to-thrive status, (2) hospital initiatives to encourage and support the initiation and sustaining of exclusive breastfeeding, (3) support by pediatricians as advocates of breastfeeding, and (4) acknowledgment of the economic benefits to society of breastfeeding.³¹

Breastfeeding not only offers an optimal source of nutrition for the infant but also provides other benefits, such as improved mother–child bonding and advantages for the infant’s general health, growth, and development. Strong evidence indicates that a human milk–based diet decreases the incidence and severity of various infections (e.g., nonspecific gastrointestinal tract infections, respiratory tract infections, otitis media) in infants and necrotizing enterocolitis in premature infants.³⁰ Other proposed benefits of human milk include decreased rates of sudden infant death syndrome, type 1 and type 2 diabetes, leukemia, overweight, obesity, hypercholesterolemia, asthma, atopic dermatitis, eczema, celiac disease, and childhood inflammatory bowel disease. Breastfeeding also has been associated with slightly enhanced performance on tests of cognitive development; however, the effect of genetic and socioenvironmental factors on intelligence is difficult to measure separately from that of breastfeeding.³¹ Among premature infants, improvement also is seen in clinical feeding tolerance, quicker attainment of full enteral feeding, and more favorable neurodevelopmental outcomes. With recognition of these

benefits, AAP recommends use of human milk for all preterm infants. If the mother's own milk cannot be provided, pasteurized donor milk, term or preterm as appropriate, should be used.³¹

Besides enhanced mother–child bonding, maternal benefits of breastfeeding include decreased postpartum bleeding, more rapid uterine involution, decreased menstrual blood loss, increased spacing between children, earlier return to prepregnancy weight, decreased risk of breast and ovarian cancer, decreased risk of rheumatoid arthritis, and decreased rates of hip fracture and osteoporosis in the postmenopausal period.

A savings of more than \$13 billion per year (\$3.7 billion in direct and indirect pediatric health costs, with \$10.1 billion in premature death from pediatric diseases) could be realized if 90% of mothers in the United States would exclusively breastfeed for 6 months. If only 80% chose to exclusively breastfeed for 6 months, \$10.5 billion per year would be saved. More important, 911 deaths annually would be prevented if a 90% exclusive breastfeeding rate was achieved (741 deaths with an 80% achievement rate).^{37,38} In the business environment, the case for breastfeeding is an economic one. For every \$1 a business spends on creating and supporting lactation support programs at the worksite, a \$2–\$3 return on investment is achieved.³⁹ An economic analysis of estimated direct health care costs for diarrhea, lower respiratory tract infections, and otitis media in the first year of life found that costs for infants who were never breastfed were \$300 more than for infants exclusively breastfed for at least 3 months.⁴⁰

Many unanswered questions regarding the protective effects of breastfeeding remain: What is the duration of such protection after breastfeeding has been discontinued? What influence does maternal age have on the protective effect? How great is the interactive effect of social and demographic variables? How does the addition of solid foods (complementary feeding) to the diet of a human milk–fed infant influence the protective effect? What consequence does partial formula feeding have for the protective effect? Well-designed studies are needed to answer these questions.

The impact of the use of breast pumps also should be considered. The 2005–2007 Infant Feeding Practices Study II (IFPS II) assessed the use of expressed human milk among breastfeeding mothers of infants 1.5–4.5 months of age.⁴¹ Of these mothers, 85% had expressed their own milk some time during their child's infancy, and 5.6% of mothers had exclusively fed their

infants expressed human milk. As with breastfeeding rates in general, the use of expressed human milk is more common among women with a higher level of education and a higher household income. The primary reason reported in IFPS II for the use of expressed human milk is the ability to have someone else feed the infant, allowing many mothers to continue to provide breast milk while working outside of the home. Unfortunately, the use of expressed human milk is not always an elective decision. When women express milk for nonelective reasons (i.e., to alleviate sore nipples, to increase milk supply, or to allow later feedings when the baby is unable to nurse owing to sickness or when the mother is working), a concern is that breastfeeding duration may be adversely affected. Mothers thought to be less likely to continue to breastfeed, with consequent shorter duration of human milk feedings for their infants, include those who are pumping because of either employment or a recognized difficulty with infant feeding at the breast.⁴²

Although breast milk pumping can provide many of the same benefits to infant and mother, some potential problems have been noted. If an electric breast pump is used improperly, the mother can incur mastitis, pain, trauma, and nipple wounds. With respect to the infant, the expressed milk can become contaminated with bacteria if it is expressed or stored improperly.⁴³

Recommendations and protocols for handling and storing human milk have been established by CDC and the Academy of Breastfeeding Medicine.^{44,45}

Storage of human milk in nonglass containers is associated with destruction of some key milk components, and storing milk at either refrigerator or freezer temperatures can reduce levels of key milk components (i.e., vitamin C, lipids, and immunologic cells). Finally, the composition of human milk changes throughout a single feeding and with the infant's age. For example, most mothers who pump their milk breastfeed the infant first and then express the remainder for later use. This method separates the foremilk, which is high in carbohydrate content, from the hindmilk, which is high in fat content. Such separation of the macronutrient components within a feeding of mother's milk can lead to adverse GI effects in the infant, such as diarrhea. Well-designed research is needed in this area to assess the true impact of the use of breast pumps on maternal health and infant nutrition.⁴¹

Very few contraindications to the use of human breast milk have been recognized. In developed countries, such as the United States, one reason for not breastfeeding is a maternal diagnosis of HIV infection, which can be transmitted through human milk. Women with HIV-seropositive status in

underdeveloped countries, however, are encouraged to breastfeed, because the risk of infant morbidity and death with formula use (from inadequate sanitation or refrigeration and illiteracy-associated errors in preparation) is greater than the risk of HIV transmission.³¹ Other reasons for not breastfeeding in women in developed countries, either temporarily or permanently, include the following medical disorders and conditions: classic galactosemia in the infant, active maternal untreated tuberculosis, maternal human T cell lymphotropic virus type I or II infection, presence of a herpes simplex lesion on the breast (although use of the other breast may be possible), and the maternal use of drugs not compatible with breastfeeding. Several excellent textbooks provide information regarding the use of drugs during lactation and pregnancy (e.g., Briggs' *Drugs in Pregnancy and Lactation*, Hale's *Medications & Mother's Milk*; see also the Preface of this book for a detailed explanation of the pregnancy data).

In addition, a comprehensive database of available information on drugs in lactation (LactMed) is maintained by the National Library of Medicine (<http://toxnet.nlm.nih.gov/newtoxnet/lactmed.htm>) and is currently recommended as a definitive source by AAP.⁴⁶ Further questions can be directed to the poison control center hotline (800-222-1222) or the National Breastfeeding Helpline (800-994-9662) or website (<http://www.womenshealth.gov/breastfeeding/>).

The overall risk of an adverse reaction to a drug in a breastfed infant depends on the concentration in the infant's blood and the effects of the drug on the infant (<http://www.infantrisk.com/content/drug-entry-human-milk>). Feeding immediately before the mother's dose may help minimize exposure, because the concentration in milk is likely to be lowest toward the end of the dosing interval. This may not be the case with lipid-soluble drugs. Alternating breast and bottle feedings or discarding the pumped breast milk during drug therapy is an option if the need for a particular drug is short term.

In the United States and other countries, human milk donor banks have been established, with 28 member banks in the Human Milk Banking Association of North America (HMBANA). Another source of human donor milk is preparations available from private companies such as Prolacta Bioscience: Human milk from carefully screened donors undergoes Holder pasteurization to eliminate potential viral and bacterial contaminants while maintaining most of the milk's unique immunologic factors.^{47,48} An estimated 20%–62% of the

immunoglobulin A (IgA) is lost in processing;⁴⁹ however, because cow milk contains no IgA at all, infants who receive donor human milk still benefit from its presence at lower levels. The cost is approximately \$4 per ounce plus shipping and handling. More information about donor milk banks, including how to be a donor or to receive donor milk, can be obtained on the HMBANA and Prolacta websites (www.hmbana.org and www.prolacta.com, respectively). A positive impact on decreased rates of necrotizing enterocolitis, a severe inflammation of the intestinal mucosa, with the use of donor milk when maternal human milk is either unavailable or insufficient has been shown for very low-birth-weight infants.⁵⁰

Cow Milk

Cow milk is the primary nutrient source for commercially prepared milk-based infant formulas. In both human milk and cow milk, more than 200 constituent factors have been identified in the fat- and water-soluble fractions. Estimates of the major nutrients contained in pooled mature human milk, preterm human milk, and whole cow milk are listed in [Table 26–4](#).

Table 26–4 Average Composition of Mature Human Milk, Preterm Milk, and Whole Cow Milk

Component	Mature Human Milk ^a	Preterm Milk	Whole Cow Milk
Water (mL/100 mL)	87.1	–	87.2
Energy			
(kcal/100 mL)	65–70	67	66–68

Whole Cow Milk

Whole cow milk is not suitable for providing nutrition to infants younger than 1 year. Because of the low concentration and poor bioavailability of iron, a whole cow milk–based diet has been associated with iron-deficiency anemia.^{51,52}

Sensitivity to dietary proteins, most commonly cow or soy milk proteins, can manifest as occult GI bleeding, further increasing the risk of anemia. In the past decade, convincing evidence has accumulated to indicate that iron deficiency impairs psychomotor development and cognitive function in infants, even those with relatively mild anemia. Milk protein intolerance and/or allergy also can result in rash, wheezing, diarrhea, vomiting, colic, and anaphylaxis when whole cow milk is used. Moreover, when whole cow milk is fed with solid food, infants receive unnecessarily high intakes of protein and electrolytes, resulting in a high renal solute load (RSL)⁵³ (Table 26–5). The implications of a high RSL are discussed later in the chapter. The current position of the AAP Committee on Nutrition (AAP-CON) is that iron-fortified infant formula is the only acceptable alternative to human milk. The use of cow milk is not recommended during the first year of life.⁵⁴

Table 26–5 Potential Renal Solute Load (PRSL) for Selected Milks and Infant Formulas

Milk/Formula	PRSL	
	mOsm/L	mOsm/100 kcal
Human milk	93	14
Milk-based formula	135–260	20–39
Soy protein-based formula	160	24
Whole cow milk	308	46
Skim cow milk	326	93
FDA upper limit	277	41
Beikost ^a	153	23

^a *Beikost* is foods other than milk or formula.

Key: FDA = U.S. Food and Drug Administration.

Source: Reference 53.

Reduced-Fat Cow Milk

Consumption of reduced-fat cow milk, such as skim milk (0.1% fat), low-fat milk (1% fat), and reduced-fat milk (2% fat), has been advocated to prevent obesity and atherosclerosis as part of a “heart-healthy diet.” However, when the low-fat diet recommended for adults is imposed on children younger than 2 years of age, it puts them at risk for failure to thrive and impaired neurologic development. Infants who receive a major percentage of their caloric intake from reduced-fat milk may receive an exceedingly high protein intake and an inadequate intake of essential fatty acids. The maximum protein concentration allowed by FDA in infant formulas is 4.5 g/100 kcal, but skim milk and 2% milk provide approximately 8–10 g/100 kcal and 7–10 g/100 kcal, respectively. Therefore, using reduced-fat cow milk for infant nutrition will provide an unbalanced percentage of calories supplied from protein, fat, and carbohydrates.

Per unit volume, skim milk has a slightly higher potential RSL (PRSL) than that of whole cow milk ([Table 26–5](#)). The solute concentration is further increased by water loss during processing. Reduced-fat milk is not recommended during episodes of diarrhea because of the possibility of hypertonic dehydration. As stated earlier, AAP does not recommend the use of low-fat diets during the first 2 years of life, except in children between 12 months and 2 years of age with a family history of CVD.

Evaporated Milk

Evaporated milk is a sterile, convenient source of cow milk with standardized concentrations of protein, fat, and carbohydrate. However, it is not recommended for infant feeding.

Goat Milk

Although goat milk is the primary milk source for more than 50% of the world’s population, it is rarely used in the United States for infants with intolerance to cow milk. Goat milk is commercially available in powdered and evaporated forms. It contains primarily medium- and short-chain fatty acids, so the fat is more readily digested than that in cow milk. The use of unfortified goat milk is not recommended by AAP, because it is deficient in folate and low in iron and vitamin D.⁵⁵ The evaporated and powdered whole milk forms of Meiyenber

goat milk, however, are supplemented with vitamin D and folic acid. Because goat milk is not a complete formula, vitamin supplementation is required if it is used for infant nutrition.

Commercial Infant Formulas

When provision of human milk to an infant is not possible (e.g., with lack of maternal supply, positive maternal HIV serostatus, or need for maternal medication contraindicated with breastfeeding) or not desired by the mother, then commercially supplied infant formulas constitute an acceptable alternative (Table 26–6). Differences in palatability, digestibility, sources of nutrients, convenience of administration, and cost among these formulas allow individualization for the infant’s special nutrient needs and the family’s resources.

Formula Properties

The International Formula Council is a voluntary, nonprofit trade association composed of the five companies that manufacture and market infant formulas and adult nutritionals: Abbott Nutrition, Mead Johnson Nutrition, Nestlé Infant Nutrition, Perrigo Nutritionals, and Pfizer Nutrition. This association has established guidelines requiring liquid formulations to be free of all viable pathogens, including spores, and other organisms that may cause product degradation. In addition, infant formula constituents must meet certain concentrations to ensure optimum nutrition. In accordance with the FDA's Infant Formula Act of 1980, standards have been established to ensure safety and efficacy of infant formulas.

Microbiologic Safety

Manufacturers sterilize liquid formulas using heat treatment, and the product is free of microbes so long as the container remains intact. Powdered formulas are not required or guaranteed to be sterile; however, coliforms and other

pathogens are absent, and levels of contamination with other microorganisms are below acceptable government standards. If clinically significant microbiologic contamination occurs, an infant ingesting the formula could develop diarrhea with subsequent fluid and electrolyte losses. In 2002, FDA issued an alert after the death of an infant in a neonatal intensive care unit after consumption of powdered formula contaminated with *Cronobacter* (formerly *Enterobacter*) *sakazakii* at the manufacturing site. Information regarding potential contamination can be found on the CDC website (www.cdc.gov/features/cronobacter).

Risk for infection after exposure to contaminated formula is likely to depend on a number of factors, including the infant's immune status. Accordingly, for premature and immunocompromised infants, use of ready-to-feed or liquid concentrates is recommended unless no suitable alternative to a powdered formula is available.

Physical Characteristics

Infant formulas are emulsions of edible oils in aqueous solutions, but fat separation rarely occurs. If it does, shaking the container usually will redisperse the fat. Redispersion may not be achievable if stabilizers are lacking or if the formula was stored beyond its shelf life. Liquid infant formulas may contain thickening agents, stabilizers, and emulsifiers to provide uniform consistency and prolong stability. Protein agglomeration may occur, however, if storage time is excessive. Evidence of such agglomeration ranges from development of a slightly grainy consistency through increased viscosity and gel formation to eventual protein precipitation. Agglomeration and separation do not affect a formula's safety or nutritional value; however, the formula's appearance may deter caregivers from using it.

Caloric Density

The standard caloric density for infant formulas is 20 kcal/oz, or approximately 67 kcal/100 mL, which mimics the historical average caloric density of human milk. One exception is selected standard infant formulas manufactured by Abbott Nutrition that, if prepared according to standard preparation instructions, provide 19 kcal/oz, or approximately 65 kcal/100 mL ([Table 26–6](#)). According to the manufacturer, this change reflected newer information indicating that the caloric density of term breast milk is closer to 19 kcal/oz.

Subsequently, however, Abbott decided to convert all of its infant formulas back to a standard 20 kcal/oz, beginning in 2019 with the Similac Advance milk-based formula products and continuing with the other infant formulas throughout 2020 (www.nutritionnews.abbott).

A healthy term infant should have no difficulty consuming enough formula to meet both energy (calorie) and fluid needs with the standard caloric density of 20 kcal/oz. Premature, malnourished, volume-restricted (e.g., for cardiac or liver disease or from poor oral feeding), or severely ill infants may require more calories (130–150 kcal/kg/day or higher) or formulas with higher caloric densities (e.g., 22, 24, or 27 kcal/oz) to meet their energy needs. Infant formulas with caloric densities significantly lower or higher than 20 kcal/oz are regarded as *therapeutic formulas* to be used in managing special clinical conditions (Tables 26–6 and 26–7). Concentrated formulas should be used only under close medical supervision, especially with monitoring for dehydration caused by the reduction in free water consumed.

Osmolality and Osmolarity

Osmolality is the preferred term for reporting the osmotic activity of infant formulas. Osmolality represents the number of osmoles of solute per kilogram of solvent (Osm/kg). Any dietary component soluble in water contributes to osmolality. Osmolality is directly related to the concentration of molecular or ionic particles in the solution (i.e., amino acids, small peptides, electrolytes, and simple sugars) and inversely proportional to the concentration of water in the formula. The osmolality of human milk is approximately 295 mOsm/kg; osmolality of standard-caloric-density formulas is 200–300 mOsm/kg.

The *osmolarity* of an infant formula may be expressed as the concentration of solute per unit of total volume of solution, or as the number of osmoles of solute per liter of solution (Osm/L). The osmolarity of human milk is approximately 273 mOsm/L. Formulas for infants should have osmolarities no higher than 400 mOsm/L. Unless the formula is very concentrated, there is no meaningful difference between osmolality and osmolarity of infant formulas.

The osmolality of a formula increases with increasing caloric density. The relationship between osmolality and caloric density is reasonably linear within the range of caloric concentrations usually fed to infants. Thus, if the osmolality of a 20 kcal/oz formula is known, the same formula with any other caloric

density can be calculated, assuming a direct proportion between osmolality and caloric density. For example, if a 20 kcal/oz formula has an osmolality of 283 mOsm/kg, then the same formula concentrated to 24 kcal/oz would have an osmolality of approximately 340 mOsm/kg.

No clinically meaningful differences in osmolality have been noted for the various 20 kcal/oz, ready-to-use formulas in common use. In addition, when concentrated products are diluted to yield a formula providing 20 kcal/oz, no meaningful difference in osmolality is seen relative to the similar ready-to-use product. However, directions for diluting concentrated and powdered formulas must be followed exactly. Soy protein-based formulas have somewhat lower osmolalities than milk-based formulas because of the difference in carbohydrate source.

Potential Renal Solute Load

The PRSL is the solute load derived from the diet that must be excreted by the kidney if the amino acids from protein digestion are not used for growth or eliminated by nonrenal routes. The PRSL for an infant formula can be calculated using the following equation: $\text{PRSL (mOsm)} = \text{N}/28 + \text{sodium} + \text{chloride} + \text{potassium} + \text{phosphorus(available)}$, where N is total nitrogen content in milligrams, and concentrations of sodium, chloride, potassium, and phosphorus(available) (P_a) are expressed in millimoles (or milliosmoles), typically measured per liter of formula. The P_a is assumed to be the total phosphorus content except in soy-based formulas, in which it represents only two thirds of the total phosphorus. [Table 26–5](#) lists PRSLs for various milks and infant formulas compared with the FDA-recommended upper PRSL limit.⁵³ Excretion of 1 mOsm of ingested solute requires 1 mL of water intake. Standard 20 kcal/oz infant formulas supply approximately 1.5 mL of water per kilocalorie ingested, an adequate amount of water to provide usual needs. Accordingly, when the infant is healthy, the PRSL generally is not a consideration in hydration; however, during illnesses associated with water loss, such as vomiting, diarrhea, and fever, or in infants with compromised renal function or diabetes insipidus, the formula's PRSL becomes a factor in maintaining fluid balance. Feeding a formula with a high PRSL (i.e., high protein content or concentrated to more than 24 kcal/oz) may produce a hypertonic urine, leading to increased renal water losses and dehydration.

Types, Uses, and Selection of Commercial Infant

Formulas

Standard formulas for term infants are milk-based, or milk-based with added whey protein (whey-predominant). Other formulas are available for infants and children with specific dietary needs and should be used only under medical supervision.

Milk-Based Formulas

Milk-based formulas ([Table 26–6](#)) are prepared from nonfat cow milk, vegetable oils, and added carbohydrate (lactose). The added carbohydrate is necessary, because the ratio of carbohydrate to protein in nonfat cow milk solids is less than desirable for infant formulas. The most widely used vegetable oils are corn, coconut, safflower, sunflower, palm olein, and soy. Replacement of the butterfat with vegetable oils allows for better fat absorption. Although Similac Sensitive and Similac Total Comfort are milk-based formulas, they contain sucrose with corn maltodextrin, rather than lactose, as the carbohydrate source and may be used for infants with lactose intolerance. Enfamil Gentlease and Gerber Good Start Soothe contain decreased lactose amounts (20% and 30%, respectively) when compared with the relevant product line's standard milk-based formulas, and both are marketed for infant colic.

Therapeutic Formulas

Therapeutic infant formulas are used for infants with conditions requiring dietary adjustment and should be used with medical supervision, rather than being self-selected by parents. [Table 26–7](#) lists indications for various therapeutic formulas, including soy protein-based, casein-based, casein hydrolysate-based, and whey hydrolysate-based formulas and low-electrolyte and low-mineral formulas. Formulas intended for use in premature infants and those formulated specifically for children 1–10 years of age also are considered therapeutic formulas.

Table 26–7 Indications for Therapeutic Infant Formulas^a

Problem/ Indication	Suggested Therapeutic Formula(s)	Comments
Allergy or	EleCare (for Infants), Neocate	Protein hydrolysate or free amino acid

Problem/ Indication	Suggested Therapeutic Formula(s)	Comments
sensitivity to cow milk or soy protein	Infant DHA & ARA, Nutramigen, PurAmino, Pregestimil, Similac Alimentum, Gerber Extensive HA	formula is best.
		Up to 50% cross-sensitivity between cow milk and soy protein allergies is possible.
Biliary atresia, cholestatic liver disease	EleCare (for Infants), Enfaport, Pregestimil, Similac Alimentum	Impaired digestion and absorption of long-chain fats; higher percentage of MCTs may improve absorption.
Carbohydrate intolerance (severe)	3232A, RCF	These are carbohydrate-free products.
		A patient-tolerated carbohydrate source is added gradually (e.g., dextrose, glucose, sucrose, fructose).
Cardiac disease	No therapeutic formula generally necessary	Low electrolyte content (Similac PM 60/40) is indicated if infant has renal insufficiency.
		Electrolyte supplementation may be needed in patients receiving diuretics.
		Calorically dense, standard formulas often used in cases of failure to thrive and for volume restriction.
Celiac disease	EleCare (for Infants), Neocate Infant DHA & ARA, Nutramigen, PurAmino, Pregestimil, Similac for Diarrhea	Advance to standard formulas as intestinal epithelium returns to normal; diet must be gluten-free.
Chylothorax or chylous ascites	Enfaport	High MCT intake decreases flow through the lymphatic system.
Constipation	No therapeutic formula necessary	Continue routine formula; increase water; refer cases of severe constipation.
Cystic fibrosis	EleCare (for Infants), Pregestimil, Similac Alimentum, Gerber	Impaired digestion and absorption of long-chain fats; cow milk-based formula

Problem/ Indication	Suggested Therapeutic Formula(s)	Comments
	Extensive HA	or human milk may be used with appropriate pancreatic enzyme supplementation.
		Enzyme supplementation may be required even with predigested therapeutic formulas; soy protein-based formulas are contraindicated.
Diarrhea, chronic nonspecific	Enfamil ProSobee, Nutramigen, Similac Soy Isomil, Gerber Good Start Soy	Trial of lactose-free cow milk or soy protein-based formula may be needed; avoid fruit juices.
Diarrhea, intractable	3232A, EleCare (for Infants), PurAmino, Pregestimil, RCF, Similac Alimentum	Hydrolyzed protein is needed because of impaired digestion of intact protein, long-chain fats, and disaccharides.
		Similac Alimentum contains sucrose and may not be appropriate for all cases.
Diarrhea, antibiotic-associated	Similac for Diarrhea	Contains added dietary fiber from soy and was specifically formulated for infants with diarrhea secondary to antibiotics; use short term until diarrhea resolves.
Failure to thrive	No therapeutic formula generally necessary	Most cases related to inadequate intake.
		Start with standard formula; may need more calorically dense formula for catch-up growth; change to predigested formula only if malabsorption is present.
Galactosemia	Enfamil ProSobee, Similac Soy Isomil, Gerber Good Start Soy, Nutramigen, Pregestimil	Formulas without lactose or sucrose; cow and human milk are contraindicated.
Gastroesophageal reflux	Enfamil A.R., Similac For Spit-Up	Recommend use of thickened commercial formulas as first line therapy. If using standard formula thickened with rice cereal, start with 1–2 teaspoons/oz of formula and increase to a maximum of 1 tablespoon/oz as

Problem/ Indication	Suggested Therapeutic Formula(s)	Comments
		tolerated.
		Thickening formula with rice cereal increases the caloric density, may cause constipation, results in delivery of less volume, and usually requires enlarging the nipple, which increases risk for aspiration.
		Some infants may have an allergic-type reaction to rice cereal; oatmeal may be used in such cases.
		Attempt small, frequent feedings; avoid using products like Thick-It and SimplyThick to thicken formula (these products are intended for patients with dysphagia or swallowing difficulties); use more calorically dense formula if decreased volume or catch-up growth is needed.
Hepatitis without liver failure	No therapeutic formula necessary	Impaired digestion or absorption of long-chain fats is uncommon.
Hepatitis with liver failure	EleCare (for Infants), Enfaport, Pregestimil, Similac Alimentum	Digestion or absorption of long-chain fats may be impaired.
Increased ostomy output	Similac for Diarrhea, Elecare (for Infants), Neocate Infant DHA & ARA	Improve consistency in term infants without malabsorption (e.g., Hirschsprung disease, imperforate anus, necrotizing enterocolitis, intestinal atresias).
		More elemental formulas may be required for malabsorption.
Lactose intolerance (primary or secondary)	Enfamil ProSobee, Similac Soy Isomil, Gerber Good Start Soy	Remove lactose from diet; use lactose-free formula.
Necrotizing enterocolitis (during recovery	EleCare (for Infants), Neocate Infant DHA & ARA, Pregestimil, Similac Alimentum	Impaired digestion or absorption requires a hydrolysate or free amino acid formula.

Problem/ Indication	Suggested Therapeutic Formula(s)	Comments
or postresection)		
Prematurity	Fortified human milk (preferred); Enfamil Premature 20 Cal, Similac Special Care 20, or transition infant formula (Enfamil EnfaCare or Similac NeoSure); may use more concentrated premature formulas during hospitalization (24–30 kcal/oz)	Human milk fortifier needed; transition formula (see Suggested Therapeutic Formula(s) column) can be added to human milk to increase caloric density after hospital discharge to home (1 teaspoon/90 mL of milk makes 24 kcal/oz).
Refractory seizure disorder	KetoCal, RCF	Dietary management of intractable epilepsy (fat/carbohydrate + protein ratio).
Renal insufficiency	Similac PM 60/40	Formula is low phosphate.

^a Products are listed alphabetically. List is not all-inclusive; other products may be acceptable.

Key: MCT = Medium-chain triglyceride.

Prethickened Milk-Based Formulas. Enfamil A.R. and Similac For Spit-Up were developed specifically for infants with gastroesophageal reflux. These iron-fortified formulas contain rice starch. Before ingestion, the viscosity of Enfamil A.R. or Similac For Spit-Up is much lower than that of a standard infant formula thickened with rice cereal. Therefore, these formulas flow better through a nipple than standard infant formula thickened with rice cereal. Once they are ingested, however, the viscosity increases dramatically in the stomach's acidic pH, reaching a viscosity equal to that for the combination of standard infant formula plus rice cereal. This effect may be minimized in infants receiving a

histamine type 2 receptor antagonist (e.g., famotidine) or proton pump inhibitor (e.g., omeprazole, lansoprazole, pantoprazole, esomeprazole) for treatment of their gastroesophageal reflux, if the gastric pH is greater than 5.4. Also, Similac For Spit-Up is a lactose-free formula. Neither Enfamil A.R. nor Similac For Spit-Up is recommended for use in premature infants, because neither product will adequately meet their nutritional needs, especially for protein, calcium, and phosphorus. In May 2011, FDA cautioned parents against using thickening agents such as SimplyThick and Thick-It in premature infants because of reports of associated necrotizing enterocolitis. This cautionary statement was expanded to apply in infants of all ages in September 2012 (www.fda.gov).

Soy Protein–Based Formulas. Despite relatively few true indications for soy protein–based formulas, approximately 20% of formulas sold in the United States are soy protein–based, suggesting that these formulas are being selected by parents rather than being prescribed by health care providers.^{35,40} Soy protein–based formulas (Table 26–6) contain a soy isolate fortified with L-methionine; none contain lactose. Soy formulas are a safe and nutritionally sound alternative for achieving normal growth and development in infants who are not fed human milk, who do not tolerate cow milk–based formula, or have galactosemia, or whose parents choose such products for other reasons (e.g., to follow a vegetarian diet). However, because soy formulas have insufficient amounts of calcium, phosphorus, and vitamin D for meeting the increased needs of some children, they are not recommended for infants weighing less than 1800 g. Additionally, even after the infant attains a weight of 1800 g, these formulas may not be adequate to provide optimal growth and to prevent osteopenia of prematurity in the long term.⁵⁶

Food allergy develops in infants, because the immature digestive and metabolic processes may not be completely effective in converting dietary proteins into nonallergenic amino acids. Cow milk protein allergy occurs in 2%–3% of infants and is defined as symptomatology involving the respiratory tract (wheezing), skin (rash), or GI tract (diarrhea and bloody stools) that resolves when cow milk is removed from the diet. The disappearance of symptoms may take up to 2 weeks. To confirm a cow milk allergy, two separate challenges of reintroduction of cow milk are conducted during a symptom-free period; reappearance of the symptoms on both tests is diagnostic. Symptoms of cow milk protein intolerance generally regress within 3–4 years in most children.

Soy protein–based formulas are appropriate for infants with lactose intolerance resulting from lactase deficiency and with documented immunoglobulin E (IgE)–mediated allergy to cow milk protein. However, infants with cow milk protein–induced enteropathy or enterocolitis also are frequently sensitive to soy protein (with cross-sensitivity rates of up to 50%); therefore, AAP-CON recommends protein hydrolysate formulas for these infants.⁵⁶ Most infants suspected of having adverse reactions to milk-based formulas have not experienced life-threatening manifestations. These infants appear to tolerate soy protein–based formulas, which are less expensive and better-tasting than the protein hydrolysate formulas. Routine use of soy protein–based formulas has no proven value in prevention of atopic disease.⁵⁷ Some infants with moderate to severe gastroenteritis will exhibit intolerance to lactose and sucrose because of a temporary lactase and sucrase deficiency. After rehydration, however, most infants with diarrhea or recovering from a diarrhea illness can be managed by continuing their usual nutrition regimen, whether milk-based or soy protein–based.

In addition, soy protein–based formulas are not recommended for infants with cystic fibrosis, because these children do not use soy protein adequately, will lose substantial nitrogen in their stools, and are prone to the development of hypoproteinemia or even anasarca (generalized infiltration of fluid into subcutaneous connective tissue). Formula-fed infants with cystic fibrosis do well nutritionally when given an easily digested formula that contains semi-elemental protein and medium-chain triglycerides (MCTs) (e.g., a casein hydrolysate–based formula). However, studies have shown that infants with cystic fibrosis grow equally well on a regular cow milk–based formula and on human milk so long as adequate pancreatic enzyme supplementation is given.⁵⁸

RCF (historically, Ross Carbohydrate Free) is a soy protein–based formula that contains no carbohydrates and is currently marketed as the only infant formula available for patients requiring the ketogenic diet. Use of this formula is limited to infants unable to tolerate the type or amount of carbohydrates in human milk or infant formulas. A carbohydrate source (sucrose, dextrose, fructose, or glucose polymers) is added gradually in increasing amounts to improve carbohydrate tolerance over time.

Casein Hydrolysate–Based Formulas. Protein in casein hydrolysate–based formulas is supplied by enzymatically hydrolyzed, charcoal-treated casein,

rather than by whole protein. Available products include Pregestimil, Nutramigen, and Similac Alimentum ([Table 26–6](#)). These formulas are classified as semi-elemental and contain nonantigenic polypeptides with molecular masses less than 1200 daltons; therefore, they can be fed to infants who are sensitive to intact milk protein. Casein hydrolysate–based formulas are supplemented with L-cysteine, L-tyrosine, and L-tryptophan, because the concentrations of these amino acids are reduced during the charcoal treatment.

Carbohydrate sources in casein hydrolysate–based formulas vary and include corn syrup solids, modified corn and tapioca starch, corn maltodextrin, and sucrose ([Table 26–6](#)). Glucose polymers found in corn syrup solids, modified corn starch, or corn maltodextrin are particularly useful in infants who have malabsorption disorders and are frequently intolerant of high concentrations of lactose, sucrose, and glucose. In addition, glucose polymers contribute little to the total osmolar load. Low osmolality is an advantage in intestinal disorders in which the osmolar load of disaccharide- or glucose-containing elemental diets may not be tolerated. The formula 3232A is an extensively hydrolyzed casein–based formula with added amino acids that is intended, like RCF, to be used with small amounts of added carbohydrate to gradually improve tolerance. This product contains modified tapioca starch and fat, 82% of which is MCTs.

Hydrolysate formulas usually contain modified fat sources. MCTs typically are included, because they do not require emulsification with bile and are more easily digested and absorbed than long-chain fats. Shorter-chain fatty acids and MCTs are directly absorbed into the portal system, not into the lacteals of the lymphatic system. In addition, MCTs enhance the absorption of long-chain triglycerides and do not require carnitine for transport into the mitochondria, where oxidation and energy production occur. MCTs cannot be the sole source of dietary fat, however, because they do not provide essential fatty acids—an important consideration in prevention of essential fatty acid deficiency. Pregestimil and Similac Alimentum contain DHA and ARA as long-chain fatty acids. Diarrhea can result from MCT malabsorption caused by overfeeding or intestinal mucosal disease.

Use of casein hydrolysate–based formulas for allergy prophylaxis is controversial. The AAP policy statement on hypoallergenic formulas notes that infants at high risk for development of allergy identified by a strong family

history (in both parents or in one parent and a sibling) may benefit from a hypoallergenic formula, but studies are not conclusive.⁵⁶ Currently, no evidence has emerged to support the use of hydrolysate formulas for treating colic, irritability, or gastroesophageal reflux. Although these problems are common in infants, they are rarely a result of an IgE-mediated allergic reaction to cow milk protein.

Extensively hydrolyzed casein formulas are less palatable than standard formulas. If the formula is rejected by the infant when first offered, it should be tried again after a few hours. These products are designed to provide a sole source of nutrition for infants up to 4–6 months of age and a primary source of nutrition for children up to 12 months of age, when indicated. Extended use of hydrolysate formulas as a sole source of nutrition in children older than 6 months requires close medical supervision and monitoring.

Whey Hydrolysate–Based Formulas. Enzymatically hydrolyzed whey protein is another protein source used in infant formulas. Infants who have GI intolerance to cow milk but are not allergic to it often tolerate whey hydrolysate–based formula. The product with this formulation, Gerber Good Start Gentle, is promoted as having a pleasant taste, smell, and appearance. It may be better accepted than casein hydrolysate–based formulas, which parents (and infants) find to differ noticeably from cow milk– and soy protein–based formulas in both appearance and taste. No specific indications are recognized for these products, so they may be chosen according to parent, patient, or nutritional program preference.

Amino Acid–Based Formulas. Occasionally, infants are intolerant of even hydrolyzed casein and require a free amino acid–based formula. Neocate Infant DHA & ARA, EleCare (for infants), and PurAmino contain 100% free amino acids and are considered hypoallergenic. They are used for infants with cow milk protein allergy, multiple food protein allergies, or intolerance to casein hydrolysate formulas.

High MCT Formulas. Enfaport and Portagen are unique formulas because of their high MCT content (i.e., 83% and 87% of the fat content, respectively). They also contain higher concentrations of both lipid- and water-soluble vitamins than those found in casein hydrolysate–based formulas. The higher concentrations of MCTs and vitamins in these formulas help compensate for the impaired digestion and absorption of long-chain fatty acids in patients with pancreatic insufficiency (e.g., cystic fibrosis) or bile acid deficiency (e.g.,

biliary atresia, cholestatic jaundice), or with inability to utilize long-chain fatty acids as with long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) deficiency, and those who have undergone intestinal resection. Another use is to decrease lymphatic flow in patients with lymphatic anomalies such as chylothorax and chylous ascites. Since it contains the essential fatty acids of alpha-linolenic and alpha-linoleic acid, Enfaport can be used as the sole dietary source for infants, whereas Portagen can be used as the sole dietary source for children and adults or can be given as a beverage to be consumed with each meal as a supplement. Children with fat malabsorption who receive Portagen are at risk for development of essential fatty acid deficiency. Linoleic acid (e.g., corn or safflower oil, Microlipid) can be given in the diet, either by mixing with the formula if a sterile mixing environment is available or delivered by syringe through a feeding tube for home use, to prevent essential fatty acid deficiency.

Low PRSL Formulas. Similac PM 60/40 is an infant formula with lower mineral (potassium and phosphorus) and protein (1.5 g/100 mL) content and, consequently, lower PRSL than in standard infant formulas. It is most appropriately used for infants with renal insufficiency. Similac PM 60/40 also contains less calcium and iron than in standard infant formulas; supplementation of these minerals may be necessary.

Premature Infant Formulas. The current AAP recommendation is for all premature infants to receive maternal human milk or donor human milk.³⁰ Nutrient intake can be inadequate in human milk-fed premature infants, however, because unfortified human milk does not meet the needs of this population. Because of their increased nutrient needs and somewhat decreased ability to consume an adequate volume, premature infants (especially those born before 34 weeks' gestational age) often need feedings providing a higher caloric density, as well as increased protein, calcium, phosphorus, and other nutrients. The nutritional goal for a preterm infant is to achieve a postnatal growth rate approximating the intrauterine growth rate of a normal fetus of the same corrected gestational age.

No commercially available formula is completely satisfactory for premature infants. Formulas for premature infants ([Table 26–6](#)) share features such as whey-predominant proteins, carbohydrate mixtures of lactose and corn syrup solids, and fat mixtures containing both MCTs and long-chain triglycerides. They differ in electrolyte, vitamin, mineral, protein, and caloric content. When given in sufficient volume, these formulas promote adequate growth in

preterm infants. An isotonic osmolality (approximately 300 mOsm/kg of water) is maintained at a caloric density of 24 kcal/oz or 80 kcal/100 mL.

Calcium and phosphorus are crucial to the development and maintenance of the human skeleton. In addition, calcium and phosphorus are integral components of many biochemical reactions. Calcium requirements are affected by protein and phosphorus intake in that these nutrients interact with the renal tubular reabsorption of calcium. Calcium-to-phosphorus weight ratios vary significantly for human milk (2:1) and cow milk (1.2:1). This ratio also varies in commercial infant formulas. Formulas designed for term infants will not meet the calcium and phosphorus needs of premature infants. For these infants, the additional calcium and phosphorus found in premature infant formulas is necessary for normal bone growth and mineralization. Typical amounts of calcium and phosphorus found in 20 kcal/oz infant formulas are 112–122 mg calcium/100 mL and 61–68 mg phosphorus/100 mL for preterm formulas versus 53–65 mg calcium/100 mL and 28–36 mg phosphorus/100 mL for term formulas. Human milk fed to premature infants requires calcium and phosphorus supplementation with either a human milk fortifier or addition of a transitional premature formula, as discussed later.

Nutrient-enriched transition or post-discharge formulas are designed specifically to provide for continued catch-up growth in premature infants after hospital discharge. Similac NeoSure and Enfamil EnfaCare (both milk-based formulas) contain MCTs as part of the fat source. The caloric (22 kcal/oz), protein, vitamin, and mineral contents of these formulas exceed those of standard term formulas but are less than those of 24 kcal/oz premature infant formulas. Use of these formulas in preterm infants until 9 months of postnatal age results in greater linear growth, weight gain, and bone mineral content than those achieved with the use of standard, term infant formulas.⁵⁹

Human Milk Fortifiers. Mothers who give birth to premature infants produce milk that is higher in protein, sodium, potassium, chloride, and iron, and possibly other nutrients than the milk of mothers who deliver at full term. However, these nutrients decline to the amounts found in mature human milk by 4–8 weeks after delivery. From 28 weeks' gestational age, the fetus receives 125–150 mg of calcium and 65–80 mg of phosphorus daily, with 80% being deposited in bone during this time. Without supplementation, human milk, whether preterm or mature, cannot supply the amounts of calcium and phosphorus needed to prevent osteopenia of prematurity. Human milk must

therefore be fortified for premature infants to achieve adequate growth.⁶⁰

Commercial products have been developed to supplement the nutrient content of human milk to meet the needs of most preterm infants. Enfamil Human Milk Fortifier Acidified Liquid, Similac Special Care 30, Similac Human Milk Fortifier Concentrated Liquid, Similac Human Milk Fortifier Hydrolyzed Protein Concentrated Liquid, and Prolact+ H²MF all are liquids that add nutrients to human milk without displacing a significant amount of volume. Enfamil Human Milk Fortifier Acidified Liquid, Similac Special Care 30, Similac Human Milk Fortifier Concentrated Liquid, and Similac Human Milk Fortifier Hydrolyzed Protein Concentrated Liquid are made from cow milk supplemented with whey protein to provide a whey/casein ratio of 60:40 and a fat mixture to provide MCTs. When added to human milk, fortifiers increase the osmolality by 85 mOsm/kg. Prolact+ H²MF is made from concentrated 100% human milk. It provides extra protein, calories, vitamins, and minerals and is specifically indicated for preterm infants weighing less than 1500 g. This product does not meet all nutritional goals, however, because it is human milk-based, necessitating added vitamin and mineral supplementation (e.g., vitamin D, iron). [Table 26–8](#) summarizes the composition of the human milk fortifiers. Studies support adequate weight gain and nutrient retention in infants when either fortified human milk or commercial preterm formulas are ingested.⁶¹ However, human milk has been shown to provide various immunologic benefits, as well as to improve the intelligence quotient (IQ) in infants born small for gestational age and very low-birth-weight infants.⁶² The use of these products will result in weight gain equivalent to that with intrauterine growth rates in most premature infants. Product selection will therefore be dictated by cost and clinical preference.

Note: Changes are made periodically in human milk fortifier composition; for the most up-to-date information, refer to the manufacturer's website.

^a Amount per 4 vials; generally mixed with 100 mL human milk to yield 120 mL, with a caloric density of 24 kcal/oz.

^b Amount per 60 mL; generally mixed with 60 mL human milk to yield 120 mL, with a caloric density of 25 kcal/oz.

^c Amount per 5 mL; 5 mL packet with 50 mL human milk to yield 55 mL, with a caloric density of 22 kcal/oz, or 5 mL packet with 25 mL human milk to yield 30 mL, with a caloric density of 24 kcal/oz.

^d Amount per 20 mL of Prolact + 4; generally mixed with 80 mL human milk to yield 100 mL, with a caloric density of 24 kcal/oz. Nutrient contribution from Prolact + 4 based on target values for macronutrients and minerals and on averages of three lots for vitamins.

Key: IU = International units.

Source: Abbott Nutrition (www.abbottnutrition.com); Mead Johnson Nutrition (www.meadjohnson.com); and Prolacta Bioscience (www.prolacta.com). Accessed October 26, 2019.

These products are expensive. Enfamil Human Milk Fortifier Acidified Liquid costs between \$2.56 and \$3.10 per vial (depending on purchasing as a case of 100 vials versus 200 vials), and one vial is generally added to each 25 mL of human milk to yield a 24 kcal/oz concentration. Moreover, this product comes only in cartons of 100 or 200 vials. Similac Special Care 30 costs as much as \$0.90 per ounce and, when added in equal parts (2 ounces of human milk to 2 ounces of Similac Special Care 30), yields a 25 kcal/oz concentration. Similac Human Milk Fortifier Concentrated Liquid and Similac Human Milk Fortifier Hydrolyzed Protein Concentrated Liquid both come in 5 mL packets, and addition of one packet to 50 mL of human milk yields a 22 kcal/oz concentration. When 5 mL is added to 25 mL of human milk, a 24 kcal/oz concentration is obtained. These two human milk fortifier products from Similac differ primarily in the amount of additional protein provided and cost approximately \$0.95/5 mL packet. They are sold in packages of 6 boxes of 24 packets each (total 144 packets). Prolact+ H²MF is the most expensive, at a cost of approximately \$6.25/mL, and the addition of 20 mL of Prolact+4 H²MF to 80 mL of human milk is required to yield a 24 kcal/oz concentration.

The strongest evidence supporting the financial benefit of human milk as a sole source of nutrition is in relation to decreased incidence of necrotizing enterocolitis.^{50,63} Once the infant is ready for discharge from the hospital or has reached a weight of 2.5 kg, one of the transition or post-discharge formulas can be added to human milk to increase the caloric density (1 teaspoon of powder added to 90 mL of formula yields 24 kcal/oz) and to promote delivery of other nutrients. Assessment of vitamin and mineral composition should be

determined before discharge to ensure that no further supplementation is required.

Metabolic Formulas. Infants with various inherited inborn errors of metabolism require specific formulas tailored to their particular condition and must be under the care of a specialist, usually a pediatric endocrinologist or geneticist. Information about these formulas is available on the various manufacturers' websites. These formulas, as well as formulas intended for use in low-birth-weight infants or in patients with specific medical conditions or dietary needs, are classified by FDA as exempt formulas—that is, exempt from FDA nutrient content and labeling requirements.⁶⁴

Concentrated Formulas. A child with caloric needs exceeding normal requirements may be given concentrated formula under medical supervision. A few ready-to-use formulas made from cow milk are available in a caloric density of 22 or 24 kcal/oz (Table 26–6). Various concentrations can be prepared from liquid concentrates or powders by varying the amount of water added (Tables 26–9 and 26–10). Increasing caloric density by adding less water also increases delivery of all nutrients, including protein and electrolytes, and decreases free water delivery. Increased concentration of protein and electrolytes (i.e., PRSL) in conjunction with decreased fluid intake may result in dehydration and electrolyte imbalances. Careful monitoring of the infant's fluid intake and output, weight, serum electrolytes, blood urea nitrogen, serum creatinine, and urine specific gravity and osmolality is recommended, especially on initiation of the concentrated formula.

Table 26–9 Dilution of Concentrated Liquid Infant Formulas^a

Caloric Concentration Desired (kcal/oz)	Liquid Formula Concentrate (oz)	Added Water (oz)
20	1	1
22 (actual 21.8)	3	2.5
24	3	2
26–27 (actual 26.7)	3	1.5
28–29 (actual 28.6)	5	2

^a Commercial concentrates of infant formula generally contain 40 kcal/oz before dilution with water.

Table 26–10 Dilution of Powdered Term Infant Formulas^a

Caloric Concentration Desired (kcal/oz)	Formula Powder (scoop)^b	Added Water (oz)
20	1	2
24	3	5
28	4	5.5
28	7	10.0

^a Powdered infant formulas generally contain 44 kcal per one level, unpacked scoop before dilution. If a large volume of formula is to be prepared, add powder necessary to supply desired calories; then add water to achieve the final volume desired. Directions for preparation may vary; check manufacturer's information.

^b Historically, the conversion of 1 scoop = 1 tablespoon of powder has been used. However, this scoop-equivalent measurement varies between powders. For improved accuracy, parents and caregivers should be instructed always to use the manufacturer's provided scoop for preparing formula products.

Modular macronutrient components ([Table 26–11](#)) can be added to either human milk or infant formula and are available as alternatives to concentrated formulas. Adding carbohydrates as glucose polymers can result in diarrhea. Protein supplementation may increase the PRSL. Fat may be added as MCTs (MCT Oil, Nestlé Nutrition; Liquigen, Nutricia) or Microlipid (Nestlé Nutrition) for infants with fat malabsorption or intolerance. Microlipid is an emulsion made from safflower oil that provides long-chain fatty acids and mixes well with formula. Addition of fat to milk or formula can lead to diarrhea, steatorrhea, delayed gastric emptying, vomiting, and gastroesophageal reflux. Adding modular components is more expensive and time-consuming than simply concentrating the formula; these components should be reserved for situations in which a single nutrient is needed or further concentration of the

formula is not appropriate.

Toddler Formulas. Toddler formulas (see under Older Infants/Toddler Milk-Based Formulas in [Table 26–6](#)) (e.g., Gerber Good Start Gentle 2, Go & Grow by Similac Toddler Drink, Enfagrow Toddler Transitions) are designed for infants and children 9–24 months of age. AAP, however, has stated that these formulas offer no nutritional advantages; standard formulas are appropriate for infants up to 12 months of age, and cow milk is appropriate for children 12 months of age and older.⁵¹

Table 26–11 Modular Additives

Additive^a(Mfr)	Nutrient(s) Provided	Amount of Nutrient(s)	Calories
Carbohydrate			
Polycal (Nut)	Maltodextrin	Per 5 g scoop: carbohydrate ~4.8 g	~20 kcal/ scoop
Protein			
Beneprotein (Nes)	Whey protein isolate (milk), soy lecithin	Per 7 g scoop or packet: protein 6 g	25 kcal/ scoop
Complete Amino Acid Mix ^b (Nutr)	Essential and nonessential amino acids ^c	4 g of protein in 5 g mix	3.16 kcal/g
Essential Amino Acid Mix ^b (Nutr)	Essential amino acids ^d	4 g of protein in 5 g mix	3.28 kcal/g
Liquid Protein Fortifier (A) (liquid)	Casein hydrolysate	0.17 g protein/ mL	0.67 kcal/ mL
Procel (GHP)	Whey protein concentrate (milk), soy lecithin	Per 6.6 g scoop: protein 5 g; fat 0.5 g	25 kcal/ scoop
ProMod Liquid Protein (A) (liquid)	Hydrolyzed beef collagen	0.33 g protein/ mL	3.3 kcal/ mL

Additive^a(Mfr)	Nutrient(s) Provided	Amount of Nutrient(s)	Calories
Fat			
Liquigen (Nut) (liquid)	MCTs (50%, palm kernel/coconut oils)	Per mL: fat 0.5 g	4.5 kcal/mL
MCT Oil (Nes) (liquid)	MCTs (coconut/palm kernel oils)	Per mL: fat 0.93 g	7.7 kcal/mL
Microlipid (Nes) (liquid)	Long-chain fats (safflower oil)	Per mL: fat 0.5 g	4.5 kcal/mL
Combined			
Benecalorie (Nes) (liquid)	Calcium caseinate (milk); high oleic sunflower oil, sucralose	Per 44 mL package: protein 7; fat 33 g	7.5 kcal/mL
Duocal (Nut)	Hydrolyzed cornstarch; blend of refined vegetable oils (corn, coconut), MCT (coconut/palm kernel oils)	Per scoop: carbohydrate 3.6 g; fat 1.1 g	25 kcal/scoop (5 g) 42 kcal/tablespoon
LiquaCal Liquid Protein (GHP) (liquid)	Hydrolyzed collagen protein, L-arginine, whey protein isolate, sucralose	Per 30 mL: carbohydrate 9 g; protein 16 g	3 kcal/mL

^a Products listed are powders unless specified otherwise.

^b Recommended mixing concentration of 5% w/v (5 g of powder to 100 mL of water)

^c Contains the following essential and nonessential amino acids: lysine, glutamate, leucine, arginine, proline, valine, aspartic acid, glycine, isoleucine, threonine, phenylalanine, histidine, serine, tyrosine, alanine, tryptophan, methionine, glutamine, and glutamic acid.

^d Contains the following essential amino acids: lysine, leucine, valine, threonine, isoleucine, tyrosine, phenylalanine, histidine, methionine, and tryptophan.

Formulas for Children 1–13 Years of Age. Nutritionally complete, isotonic, virtually lactose-free enteral formulas designed for young children who cannot tolerate a normal diet or eat solid food are available (see under Children's Formulas in [Table 26–6](#)) (e.g., PediaSure Enteral Formula, Nutren Junior, Boost Kid Essentials). Flavored products contain sucrose, have a pleasant taste, and can be used as oral supplements. These formulas also are appropriate to use as tube feedings regardless of delivery mode (e.g., gastric, duodenal, jejunal). They contain adequate amounts of calcium, phosphorus, iron, and vitamin D for this age group; the amounts contained in adult enteral products typically are inadequate.

Several therapeutic formulas also have been developed for children 1–13 years of age ([Table 26–6](#)). Peptamen Junior and PediaSure Peptide are peptide-based, semi-elemental formulas. Vivonex Pediatric, Neocate Junior, Neocate Splash (unflavored), and EleCare Jr are amino acid–based elemental formulas. These products are intended for use in children with altered digestive or absorptive capabilities caused by a number of conditions, including severe protein allergy and eosinophilic esophagitis ([Table 26–7](#)). Another area of infant feeding and nutrition of increasing popularity is home-prepared blenderized diets and whole food formulas (e.g., Kate Farms, PediaSure Harvest, Compleat Pediatric, Nourish, Liquid Hope). A discussion of these feeding modalities is beyond the scope of this chapter, however.

Nutritional Problems in Infancy

GI problems, especially diarrhea, can occur with the use of infant formulas, as well as with human milk or any food. Tooth decay and nutritional deficiencies are other potential problems.

Diarrhea

Diarrhea can lead to failure to thrive (with chronic diarrhea) and dehydration (with acute diarrhea). Infants are particularly susceptible to dehydration

because of their high metabolic rate and relatively higher ratio of surface area to weight and height. (See [Chapter 19](#) for information on dehydration.) Fluid depletion by diarrhea or vomiting may quickly (within 24 hours) produce severe dehydration with fluid and electrolyte imbalances, shock, and possible death. A potential formula-related cause of diarrhea and vomiting is the improper dilution of a concentrated liquid or powdered formula or the incorrect addition of a modular product.

If diarrhea develops, the pharmacist or other health care provider should ascertain the severity and duration, stool frequency, and formula preparation method. If the diarrhea appears to be severe (i.e., with many more stools per day than normal) or has continued for more than 72 hours, or if the infant is clinically ill (exhibiting fever, lethargy, anorexia, irritability, dry mucous membranes, or decreased urine output), referral for medical attention is warranted. (Diarrhea is discussed in [Chapter 16](#).)

Mild diarrhea will usually resolve without the need for medical intervention, but the infant should be observed closely for signs of dehydration. Temporarily discontinuing usual dietary intake is not recommended except during a 4- to 6-hour period of oral rehydration if the infant is dehydrated. Oral electrolyte replacement solutions manufactured especially for infants (e.g., Pedialyte, Enfamil Enfalyte) may be used for short-term replacement of fluid and electrolyte losses in mild to moderate dehydration to augment fluid intake, but these solutions should not replace formula or human milk intake.⁶⁵ Prevention of dehydration by replacement of ongoing losses with a glucose–electrolyte solution in liquid or frozen form is the best intervention for diarrhea in infants and children.

Lactose-free formulas or a lactose-free diet may be considered for infants and children with moderate to severe diarrheal illness, but full-strength lactose-containing formulas, human milk, or a regular diet can be used in most infants. Parents should be advised that diarrhea is likely to continue for 3–7 days regardless of the type of formula, and seeking medical consultation is warranted if a sudden increase in stool output occurs with resumption of feeding.⁶⁵

Other Gastrointestinal Issues

Adverse GI effects of formula include mechanical obstruction (from

inspissated milk curds) and hypersensitivity to specific milk protein. Cow milk intolerance is associated most often with an inability to digest lactose or milk proteins. Feeding hyperosmolar formulas may adversely affect premature infants during the early neonatal period and may be a contributing factor in the development of necrotizing enterocolitis. For this reason, initiation of feedings in these infants is most often done with unfortified human milk or a 20 kcal/oz premature infant formula. Typically, after the infant has reached an intake of 80–100 mL/kg/day of enteral feedings, the caloric density can be advanced, but one study suggests that earlier fortification at 20 mL/kg/day to improve the provision of protein is possible.^{54,66} Initiation and advancement of formula for premature infants should occur under medical supervision and do not constitute an appropriate strategy for self-care.

Tooth Decay

“Baby bottle” tooth decay can occur in children who are bottle-fed beyond the typical weaning period (1 year) and who go to sleep with a bottle. It also can occur if the infant is allowed to sip on a bottle or from a training cup frequently during the day. Caries can be seen in children younger than 2 years and may involve the maxillary incisors, maxillary and mandibular first molars, or maxillary and mandibular canines. Restorative dentistry is often required, with the potential for difficulty in speech development without prompt and appropriate repair. Methods for prevention once teeth start to erupt include substituting plain water for carbohydrate-containing formula or other drinks given in a bottle until the infant is weaned from the bottle, encouraging the use of a cup for high-sugar drinks such as juice, providing either infant juices that contain a higher proportion of water or standard juices diluted with additional water, ensuring adequate fluoride intake, and cleaning the baby’s mouth at least once daily.⁶⁷ Going to sleep with a bottle should be actively discouraged for all infants.

Nutritional Deficiencies or Toxicities

Generally, age- and condition-appropriate commercial infant formulas are nutritionally adequate and safe for most infants and children. Nutritional deficiencies reported historically with commercial infant formulas are unlikely today with appropriate supplementation procedures and technologic advances in processing.

Because of a concern about possible aluminum contamination of infant formulas, the Food and Agriculture Organization of the United Nations has identified a provisional tolerable aluminum intake of 1 mg/kg/day. Aluminum in toxic amounts can interfere with cellular and metabolic processes in the nervous system as well as negatively affect bone and liver tissue.⁶⁸ Aluminum toxicity is primarily a concern in patients with decreased or immature renal function, such as premature infants, and in those receiving intravenous therapies. If an infant were to ingest as much as 200 mL/kg/day of a formula known to have the highest aluminum content, the amount of aluminum received per day would still be less than 0.5 mg/kg/day. The highest aluminum concentrations in infant formulas (500–2400 mg/L) have been reported for soy protein–based formulas, because plants readily absorb aluminum from soil.

Infant Formula Preparation

Most formulas are available as a ready-to-use liquid or as a liquid concentrate or powder for reconstitution mixed with water. Ready-to-use formulas should *never* be diluted. They are convenient but usually more expensive. By contrast, concentrated liquids *must* be diluted, typically by mixing equal amounts of water and concentrated liquid (e.g., a 13-ounce can of formula with a 13-ounce can of water) to prepare a 20 kcal/oz formula ([Table 26–10](#)). Powdered term and preterm transition or post-discharge formulas provide a measuring scoop in the can and require addition of 1 unpacked, level scoop of powder to each 2 ounces of water for a 20 kcal/oz term formula and a 22 kcal/oz preterm post-discharge formula. Directions for preparation may vary between products, and the caregiver should always prepare the formula according to the manufacturer's or health care provider's directions. If parents or caregivers are given alternative directions from those printed on the can, these should be given in writing and explained thoroughly. Directions should be provided in the appropriate language for non–English-speaking parents. Before use, infant formula containers should be inspected for the expiration date and any damage. Unopened formula containers, cans, or bottles can be stored at room temperature but must not be subjected to extreme temperature changes.

Preparation Techniques

Each infant formula has specific instructions for preparation, and most formulas have symbols on the containers that can be used as guidelines for preparation. Because infants may be more susceptible to infection, various

sterilization methods have been recommended for preparation of formula for this age group. **Table 26–12** reviews sterilization methods for different types of formulas. Studies have shown that the “clean” method of preparing formula (i.e., without boiling the water) is as safe as terminal sterilization (i.e., boiling the water); therefore, some providers do not recommend boiling water. WHO and AAP currently recommend that all water for formula preparation be boiled, because of reports of municipal water supply contamination in some areas. If well or pond water is used or if the geographic watershed area is prone to flooding, the water must be boiled.^{69,70} If tap water is used, cold water should be run for at least 2 minutes before use to clear any lead or leached chemicals that might be in the pipes and thereby decrease toxin exposure. If bottled water is used in infant formula preparation, it should be treated the same as for tap or well water (i.e., it is boiled and cooled before use) unless the water is labeled as sterile.

Table 26–12 Sterilization Method for Infant Formula Preparation

General Preparation

- Always wash hands before preparing formula or handling bottles and nipples; repeat washing if interrupted.
- Sterilize bottles and other equipment (e.g., glass measuring cup, spoons, nipples, rings, disks) separately from the formula. Many pediatricians and other primary care providers now consider the use of a dishwasher with a heated drying cycle as adequate for sterilization of infant feeding supplies.
- Using tongs, place all equipment in a deep pan or sterilizer, cover all equipment with cold tap water, bring to a boil, and continue boiling for 5 minutes.
- Both tap water and bottled water should be heated until it reaches a rolling boil, allowed to continue to boil for 1–2 minutes, and then allowed to cool to room temperature for 30 minutes. Boiling for a longer period of time may concentrate impurities (e.g., lead) in the water.
- Using tongs, remove all items from the pan or sterilizer and place on a clean towel. Place bottles and nipples on the towel with their open ends facing down.

Concentrated Liquid Formula

- For cans, wash top of can with hot water and detergent, rinse in hot running water, and dry. Shake can well and open it with a clean punch-type can opener.
- For bottles, the protective cap must be removed. Shake bottle well and open.
- Mix appropriate amounts of concentrated liquid and sterilized water (according to product label or health care provider instructions). For accuracy, use a measuring cup for all measurements of formula and water.
- Pour formula into sterilized bottles; place nipples, rings, and disks on bottles.
- Tightly cover any unused formula and store in refrigerator. Use formula within 48 hours of

preparation or discard.

Powdered Formula

- Wash top of can with hot water and detergent, rinse in hot running water, and dry.
- Open can and mix appropriate amounts of powder and sterilized water (according to product label or health care provider instructions). For accuracy, use the scoop provided.
- Pour formula into sterilized bottles; place nipples, rings, and disks on the bottles.
- Tightly cover any unused prepared formula and store in the refrigerator. Use this formula within 24 hours of preparation.
- Cover any formula remaining in the can with the plastic top. Write the date on the opened can. Store in a cool, dry place for up to 1 month.

Ready-to-Use Formula

Ready-to-Use Cans

- Wash top of can with hot water and detergent, rinse in hot running water, and dry.
- Shake can well, and open it with a clean punch-type can opener.
- Add the amount of formula needed for a single feeding to one sterilized bottle or to the number of bottles needed for a full day's feedings.
- Do *not* add water.
- Prepared bottles and any formula left in the can should be tightly covered and refrigerated for up to 48 hours after the can was opened.

Ready-to-Use Bottles

- The protective cap must be removed, and a sterile nipple cap must be screwed onto the bottle before feeding.
- Shake each bottle well to ensure mixing of formula.

All Types of Formulas

- Warm bottle to desired temperature by immersing in hot water bath or holding under hot running water.
- Heating bottles in the microwave is not recommended owing to potential for creation of "hot" spots, which may burn the infant's mouth.
- Never boil or overheat formula.
- Shake each bottle well before feeding infant.
- Test formula temperature before feeding infant.
- After feeding, discard any formula left in bottle, and immediately rinse bottle and nipple in cool water.

^a If disposable bottle liners are used, only nipples, rings, and screw tops of bottles need to be sterilized; the bottle liners provided by the manufacturer are sterile.

Table 26–12 provides handling instructions and recommendations for storage of infant formulas once the original container has been opened. Expressed human milk should be stored in glass or plastic airtight containers, refrigerated, and used within 96 hours. Human milk can be frozen, preferably up to 6 months but as long as 12 months when the freezer's temperature is at least 0°F (–18°C) or colder, in accordance with CDC recommendations (https://www.cdc.gov/breastfeeding/recommendations/handling_breastmilk.htm). Frozen milk should be rapidly thawed by holding the container under tepid running water or placing it in a tepid water bath. Thawed human milk should always be used within 24 hours of thawing and never refrozen.

Adverse Effects of Improperly Prepared and/or Administered Formulas

As stated previously, failure to properly dilute a concentrated infant formula can result in a hypertonic solution with the potential for adverse effects of diarrhea and dehydration. In extreme cases, the ingestion of an overly concentrated formula can lead to hypernatremic dehydration (induced by water deficit), metabolic acidosis, and renal failure. Excessive formula dilution can lead to water intoxication, which can result in irritability, hyponatremia, coma, brain damage, or death. Such a situation may arise when a caregiver misunderstands the instructions for preparing a concentrated formula, dilutes a ready-to-use formula, or tries to make the baby's formula last longer by diluting it.

Parents or other caregivers may have questions about how much infant formula their child should receive. Typically, a health care provider at the hospital will have given parents feeding instructions before mother and infant are discharged home. When a formula change is made after hospital discharge, however, adequate information may not be provided in some health care settings. Generally, the required daily formula intake depends on the infant's age and weight and individual considerations such as the need for catch-up growth (**Table 26–13**). During the first year of life, a normal, healthy formula-fed term infant usually eats every 3–5 hours (average of 4 hours). Small or weak infants may eat every 2–3 hours, because they have smaller stomach capacity or shorter gastric emptying time, or tire easily during feedings.

Breastfed infants or those receiving human milk from a bottle also will nurse or eat more often, reflecting that human milk empties from the stomach more rapidly than formula.

Table 26–13 Average Age-Appropriate Number of Daily Feedings and Volume per Feeding

Age	Average Number of Daily Feedings	Average Volume per Feeding (oz)
Birth–2 weeks	6–10	2–3
2 weeks–1 month	6–8	3–5
1–3 months	5–6	4–6
3–4 months	4–5	6–7
4–12 months	3–5	7–8

Most term infants will tolerate longer intervals between feedings of up to 4 hours by the age of 3–4 weeks. Premature infants may continue to require frequent feedings past 6–8 weeks of age, depending on birth weight, corrected gestational age, and growth. Some infants begin to stop nighttime feedings after the age of 1–2 months, whereas others take as long as 4–6 months to cease such feedings. The process is highly variable and may depend more on weight attained than on a specific age; most infants are able to sleep through the night when they reach approximately 11 pounds.

The amount of formula offered to a bottle-fed infant should be consistent with the DRI for energy according to age and weight ([Table 26–2](#)). [Table 26–13](#) lists typical quantities of feedings for various age groups. The infant should be fed on demand and not forced to take more formula than is desired at any one feeding. If the infant finishes a bottle and still seems hungry, more formula should be offered. Parents also should be aware that a newborn typically loses weight (mostly water) during the first week of life, but by 2 weeks of age, the infant should be gaining weight. Healthy weight gain usually indicates that the infant is receiving an appropriate amount of formula. WHO standardized growth charts are used to determine whether an infant is growing appropriately. Weight, length/height, and head circumference should be determined at each medical visit.

Both underfeeding and overfeeding are potential problems. Infants who like to “graze” all day can take in too much milk and gain too much weight. However, this behavior also can be a sign of inadequate intake in breastfed infants, with consequent failure to thrive. Other problems associated with overfeeding are regurgitation, gastroesophageal reflux, vomiting, loose stools, constipation, and colic. Spitting up a small amount of formula, even after every feeding, is not usually a cause for concern. If the infant is regurgitating or vomiting significant amounts, a primary care provider should be consulted. Bilious emesis (with green-tinged vomitus) is always a reason for prompt medical evaluation.

Loose stools are normal for some infants, especially those receiving human milk or hydrolyzed formulas. A loose stool consistency also may be the result of an improperly concentrated formula or overfeeding. Rarely, loose stools may be the result of the administration of contaminated formula, as mentioned previously. The contaminated formula results in pathologic changes in the gut, leading to loose stools. Human milk-fed infants may have only 1 stool every 1–3 days; however, some infants will have 10–12 stools each day. Formula-fed infants usually have 1–3 stools per day. *Diarrhea*, defined as increased stool volume and frequency that differ from the usual volume and frequency, warrants medical attention when it persists for more than 3 days or when the infant appears dehydrated. Constipation is rare in human milk- or formula-fed infants; it most often results from inadequate formula (fluid) intake. Severe or prolonged constipation with straining and blood streaks on the stool warrants a visit to the primary care provider.

Product Selection Guidelines

For healthy term infants, a milk-based formula with or without added whey protein is indicated, except in patients who require a therapeutic formula. Recommendations for a formula should be based on ease of preparation or administration, the parent’s or caregiver’s ability to follow product directions, parental attitudes and preferences, availability of sanitary conditions and refrigeration facilities, and cost. Before assisting parents in selecting a therapeutic formula, the pharmacist should confirm that their primary care provider recommended its use.

For many parents, cost may be a critical factor in formula selection. Concentrated liquids and powders typically are less expensive than ready-to-

use products. Convenience also is a consideration. The preparation of powdered and concentrated liquid formulas requires more manipulative functions and more attention to clean technique. The formula selected should be one that is well tolerated by the infant, convenient for parents and caregivers, and priced to fit the family's budget. To simplify formula preparation away from home, parents can select products available in unit-of-use packaging for ready-to-use liquids, or they can place a powder packet or powder in an empty bottle and add water whenever needed.

The federal grant program Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) helps ensure that all infants, children (up to 5 years of age), and pregnant, postpartum, and breastfeeding women have access to adequate nutrition. State health departments and other agencies regulate and allocate funds in the federal grant program (i.e., approximately \$5.4 billion in fiscal year 2018). Formula and preventive services are subsidized for eligible participants but often require a prescription and previous authorization. More than 6.8 million persons received WIC benefits each month in 2018, most of them infants and children.⁷¹

Vitamin and Mineral Supplementation

Routine multivitamin and mineral supplementation generally is unnecessary for most formula- or human milk-fed term infants. However, some infants may be at risk for deficiency and require appropriate supplementation. Cases of vitamin D-deficiency rickets continue to be reported in the United States, and the prevalence of iron-deficiency anemia among children 1–3 years of age is 2.1% in the general population.^{52,72} Accordingly, particular care is warranted to ensure that children in this age group get adequate dietary iron. AAP does not, however, endorse routine iron supplementation in children 1–3 years of age unless the child's diet is low in iron-containing foods.⁵² With likelihood of deficiency or recognition of risk factors, the child should be referred to the family's regular health care provider for further evaluation.

Vitamin and mineral supplementation may be needed for preterm and human milk-fed infants whose nutrition is inadequate^{73–75} (Table 26–14). These infants and those with other nutritional deficiencies, malabsorptive and other chronic diseases, rare vitamin-dependent conditions, inborn errors of vitamin or mineral metabolism, or deficiencies related to the intake of certain medications will need a medically supervised regimen of vitamin and mineral

supplementation.

Table 26–14 Guidelines for Use of Vitamin and Mineral Supplements in Healthy Infants^a					
Age Group	Multivitamin/Mineral	Vitamin D^b	Vitamin E	Folate	Iron^c
Full-Term Infants					
Human milk-fed	0	+	0	0	±
Formula-fed	0	± ^d	0	0	0
Preterm Infants					
Human milk-fed ^e	+	+	0	0	+
Formula-fed ^e	+	+	0	0	+
Older Infants (>6 Months)					
Normal	0	0	0	0	±
High-risk ^f	+	0	0	0	±

^a Not shown is vitamin K for newborn infants and fluoride in areas with insufficient fluoride in drinking water supply ([Table 26–15](#)).

^b All infants should have a minimum daily intake of 400 international units of vitamin D beginning during the first few days of life; this intake should be continued throughout childhood and adolescence.

^c Iron-fortified formula and infant cereals are more convenient and reliable sources of iron than a supplement.

^d Supplement typically is indicated if infant is receiving less than 1000 mL daily of formula. An exception is Enfamil Premium Newborn, which is indicated for use from birth to the age of 3 months and provides 400 international units of vitamin D in 810 mL (27 fluid ounces).

^e Multivitamin supplements (plus added folate) are needed primarily when calorie intake is below approximately 300 kcal daily or when the infant weighs less than 2.5 kg; vitamin D should be supplied at least until the age of 6 months in human milk-fed infants. Iron should be started by the age of 2 months.

^f Multivitamin/mineral preparations including iron are preferred to supplements containing iron alone.

Key: + = Supplement usually indicated; ± = supplement sometimes indicated; 0 = supplement not usually indicated.

Source: [References 10](#) and [73–75](#).

Human Milk–Fed, Full-Term Infants

The healthy, full-term, human milk–fed infant requires little to no special supplementation for the first 4–6 months of life except for vitamin D and iron. AAP recommends vitamin D supplementation (400 international units per day) for all human milk–fed infants unless they are weaned to at least 1000 mL daily of vitamin D–fortified formula. Risk factors for vitamin D deficiency include higher birth order (third child or later), dark skin, cultural or sociogeographic factors that minimize maternal skin exposure to sunlight, and delayed intake of dairy products in the infant or mother because of intolerance or other factors.⁷⁶ Mothers should be encouraged to maintain a balanced diet and to drink 3–5 8-ounce glasses of milk each day while breastfeeding. If the mother cannot tolerate milk because of lactose intolerance, lactose digestion aids (e.g., Lactaid, Dairy Ease, various store brands) and lactose-free milk are available. Mothers who do not drink milk should be encouraged to increase vitamin D and calcium intake through other dietary sources or by taking supplements. Furthermore, if the infant is showing signs or symptoms of being excessively colicky, the primary care provider should consider a “milk” sensitivity. If sensitivity is confirmed, the breastfeeding mother should decrease her dairy consumption and seek nondairy sources of calcium and vitamin D. Some primary care providers recommend complete removal of dairy products from the diet, whereas others suggest a more moderate approach that allows better-tolerated foods such as yogurt and cottage cheese.

Human milk–fed infants rarely develop iron-deficiency anemia before the age of 4–6 months.⁵² Although the iron concentration in human milk averages only 0.3–0.5 mg/L, the form of iron present is well absorbed. At the age of 4–6 months and beyond, the iron stores in infants fed human milk exclusively may become exhausted, necessitating a supplemental source. The addition of iron-

enriched foods such as fortified infant cereals will usually meet needs, or alternatively, an iron supplement (as elemental iron at a dosage of 1 mg/kg/day) can be given.⁵² However, one study reported an association between increased duration of breastfeeding and decreased iron stores in the body.⁷⁷ Term infants who are small for gestational age are likely to have higher requirements, but the necessity for supplementation in this population is unclear.

The first iron-enriched food introduced into the infant's diet typically is infant cereal. Bioavailability of the large-particle, electrolytic iron powder used to fortify dry infant cereals is substantially less than that of ferrous sulfate iron used in milk- or soy protein-based formulas. Cereals also contain potent inhibitors of iron absorption and constitute an unreliable source of iron sufficient to prevent deficiency for infants who receive minimal iron from other sources. With iron-fortified, wet-packed cereal and fruit combinations marketed in jars, the ferrous sulfate is not exposed to oxygen until the jar is opened; therefore, iron absorption is improved. Consuming fruit juices and other products containing ascorbic acid along with iron-fortified cereals has been shown to enhance iron absorption.⁷⁸

Formula-Fed, Full-Term Infants

Full-term infants who consume adequate amounts of an iron-fortified, milk-based formula do not need vitamin and mineral supplementation in the first 6 months of life. An iron-fortified formula is preferred to ensure adequate iron stores for growing infants. Infants fed iron-fortified formulas do not demonstrate a difference in stool consistency, fussiness, colic, or regurgitation compared with infants fed low-iron formulas. Vitamin and mineral supplements are not needed for infants older than 6 months who receive a diet consisting of formula and increasing amounts of infant and table foods. A multivitamin with minerals may be needed, however, if the infant is at special nutritional risk secondary to a metabolic syndrome or other medical condition.

Preterm Infants

Preterm infants fed with either human milk or formula need vitamin and mineral supplementation. Their nutrient needs are greater than those of full-term infants because of their more rapid growth rate, relative inability to ingest an adequate volume of formula or human milk, decreased intestinal

absorption, and lower body stores. Premature infants often require a multivitamin supplement to provide the equivalent of the recommended intakes for full-term infants while receiving maternal breast milk, inadequate daily volume totals (less than 1000 mL daily), or certain formulas (e.g., Similac Alimentum), or before reaching a body weight of 2.5 kg.

Premature infants are especially susceptible to iron-deficiency anemia because of their marginal iron stores at birth. Without iron supplementation or blood transfusions given for clinically significant low hemoglobin/hematocrit, iron stores will be depleted by the age of 2 months, in contrast with depletion at 4–6 months in full-term infants.

Originally the AAP-CON recommendations included supplementation with elemental iron at a dosage of 2 mg/kg daily for premature infants with birth weights between 1500 and 2500 g once they were 2 months old or had doubled their birth weight.^{52,59} AAP currently recommends that preterm infants who receive human milk should receive elemental iron supplementation (2 mg of elemental iron/kg/day minimum, with up to 4–6 mg of elemental iron/kg/day in cases of deficiency) earlier, within 1 month, through 12 months of age. If these preterm infants are switched from human milk to formula, they will most likely not require iron supplementation once they are consuming 150 mL/kg/day. However, reports have shown that approximately 14% of preterm infants receiving appropriate formula will still need a supplement at 4–8 months of age because of decreased iron stores.⁵² To address this deficit, some clinicians advocate even earlier initiation of iron supplementation in preterm infants born at less than 30 weeks of gestational age by starting supplementation as early as 2 weeks of chronologic age with elemental iron doses of 2–4 mg/kg/day.⁷⁹ Infants receiving erythropoietin should receive elemental iron 6 mg/kg daily. To minimize the possibility of hemolytic anemia related to insufficient vitamin E absorption, iron supplements should be withheld until the preterm infant is 2 weeks old. However, with adequate vitamin E supplementation in the formula, the risk of hemolytic anemia is minimal.

Supplementation of calcium, phosphorus, and vitamin D in preterm infant formulas is necessary to ensure adequate bone mineralization and to prevent osteopenia and rickets. The prevention of severe bone disease in preterm infants appears to depend on both high oral intakes of calcium and phosphorus and the intake of at least 400 international units (12.5 mg) of

vitamin D per day.⁵⁹ Therefore, preterm infants should receive specialized formulas, tailored to their needs, containing appropriate amounts of calcium, phosphorus, and vitamin D. Depending on the volume of formula consumed, vitamin D supplementation may be necessary, along with a premature formula, to provide 400–800 international units daily. Additionally, if patients are receiving either furosemide for congestive heart failure or bronchopulmonary dysplasia or phenobarbital for seizure disorders, increased vitamin D supplementation may be required.⁸⁰

Fluoride Supplementation

When used appropriately, fluoride is both safe and effective in preventing and controlling dental caries. Fluoride helps prevent dental decay by reducing the solubility of enamel, limiting the ability of bacteria to produce acid, and promoting remineralization. Systemic fluoride, such as that obtained from fluoridated water, primarily provides a topical benefit to teeth: Fluoride is secreted from the salivary glands, for near-constant contact with tooth surfaces.⁸¹ In 2014, CDC reported that 75% of the U.S. population for whom the water supply comes from a fluoridated community water system receive adequate fluoride.⁸²

Fluoride supplementation currently is not recommended from birth to the age of 6 months. Furthermore, the recommended supplementation for children 6 months to 16 years of age whose drinking water is inadequately fluoridated and who do not receive adequate fluoride from other sources has been decreased from previous recommendations because of an increased incidence of fluorosis.⁸³ Fluorosis, which affects approximately 22% of U.S. children, is manifested in the dentition as changes ranging from minor white lines running across the teeth to a very chalky appearance resulting from too much fluoride. Infants who are being fed powdered or concentrated formula should be given fluoride supplements only if the community's drinking water, or bottled water used for making formula, contains less than 0.3 ppm of fluoride. Bottled water often is free of fluoride, and its use for reconstituting formula mandates appropriate supplementation. **Table 26–15** can be used to determine the proper fluoride supplementation for a child, depending on the fluoride level in the drinking water. Ready-to-use formulas are manufactured with defluoridated water and contain less than 0.3 ppm of fluoride. The primary care provider may recommend a fluoride supplement for infants not receiving adequate fluoride.

Table 26–15 Recommended Fluoride Supplementation

	Daily Supplementation (mg)^a Indicated for Fluoride Concentration in Drinking Water		
Age Group	<10.3 ppm	0.3–0.6 ppm	>0.6 ppm
Birth–6 months	0	0	0
6 months– 3 years	0.25	0	0
3–6 years	0.50	0.25	0
6–16 years	1.00	0.50	0

^a Sodium fluoride 2.2 mg contains fluoride 1 mg.

Assessment of Infant Nutrition: A Case-Based Approach

Body weight, length (height), and head circumference are the growth parameters for determining whether infants are receiving appropriate nutrients, are digesting and absorbing ingested nutrients, or both. If an infant appears to be underweight or underdeveloped, the pharmacist should advise the parent that further medical evaluation is warranted.

The pharmacist's primary role in infant nutrition is to provide information about breastfeeding and infant formula products, including assistance with product selection and preparation instructions.

Cases 26–1 and 26–2 are examples of assessment of infant nutrition in two different patients.

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A mother is worried about her 4-week-old daughter spitting up formula after every feeding, almost always with a little force. Although some emesis has occurred since birth, the amount and frequency have increased over the past few days. The mother thinks her daughter seems colicky, often crying from "gas pains." The infant has always been a "good burper," so her mother feels that the gas pains are not related to too much air in the stomach. The infant appears to be well hydrated, and according to her mother, she has no fever.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Emesis occurs only after feedings. The infant appears to be more comfortable after each episode of emesis. Irritability associated with gas pains appears to be relieved by simethicone.
c. Description of the patient's efforts to relieve the symptoms	The mother has been giving the infant simethicone for gas. Nothing specific has been done for the emesis.
d. Patient's identity	Lydia Smith

e. Patient's age, gender, length/height, and weight	4 weeks, female, 21.5 in., 10 lb 9 oz (4.8 kg)
f. Patient's dietary habits	Lydia was receiving primarily breast milk until 7 days ago, when her mother switched her to formula because of inadequate breast milk supply. The infant's feedings were changed to Similac Advance. Per Mrs. Smith's report, the formula is being mixed to a standard 20 kcal/oz concentration according to the instructions on the container. The infant takes approximately 165 mL (5.5 ounces) every 3 hours. No extra water or juice is given during the day.
g. Patient's sleep habits	Lydia has not yet started sleeping through the night.
h. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Lydia is a healthy term infant without any significant medical conditions or past medical history. Her mother is currently giving her simethicone 20 mg up to 4 times a day as needed for apparent gas pains. She says that she usually gives approximately 2-3 doses per day.
i. Allergies	NKA
j. History of other adverse reactions to medications	None
k. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary	<i>Primary problem:</i> emesis with feedings
	<i>Secondary problem:</i> increased intestinal gas

problem(s).	
3. Identify exclusions for self-treatment.	Bloody or bilious emesis
	Signs of dehydration: sunken fontanelle, dry mucous membranes, decreased number of wet diapers, dark urine, decreased oral intake
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required and share this information with the patient or caregiver.	Options include (1) Refer Lydia for immediate medical attention/PCP management. (2) Review preparation of infant formula with Mrs. Smith. (3) Monitor Lydia's symptoms and recommend nondrug measures only. (4) Recommend a medication alone or combined with nondrug measures. (5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient/caregiver preferences.	Lydia's current feeding schedule, 165 mL of 20 kcal/oz of formula every 3 hours, provides 183 kcal/kg/day in a volume of 275 mL/kg/day. Both exceed the usual recommended intakes for a healthy term newborn (Tables 26-2 and 26-12). Because the emesis and gas pain have increased since Lydia's transition from breast milk to infant formula, Lydia most likely is not tolerating the volume of the formula provided every 3 hours. Unlike when Lydia was breastfed, the formula provided in a bottle can be visually seen by the caregiver, and the infant is often encouraged to complete ingestion of the bottle contents. If the caregiver is providing an excessive volume of formula, the infant may consume the entire volume but may regurgitate the additional quantity owing to a much smaller tolerated gastric volume. In addition to limiting the volume of formula, use of a slow-flow nipple to regulate the flow of milk may be of benefit. Explain to Mrs. Smith the correlation between the increased emesis and volume of formula provided. Also describe how she can assess the appropriateness of the volume fed to Lydia by appropriate weight gain and Lydia's satisfaction

	when full. Remind her not to feed Lydia beyond what she desires. Recommend that Mrs. Smith contact Lydia's PCP to discuss appropriate advancement of infant formula as she grows. If Lydia continues to have problems after a change in volume, her mother should follow up with her PCP for further management.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Simethicone should be stopped. The increased emesis and gas pain are caused by an excessive volume of formula provided every 3 hours. Providing a smaller volume of infant formula at each feeding should relieve Lydia's symptoms. If the symptoms persist after the change in volume, Lydia should be seen again by her pediatrician or other primary care provider."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Because the symptoms started (or acutely worsened) with the change from breast milk to infant formula and the caloric density but not the volume of the infant formula is appropriate for a healthy term infant, excessive volume of formula at each feeding is the most likely cause of Lydia's emesis and irritability. If the volume is the major issue, changing the volume should produce relief of symptoms within several days."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Product storage requirements	"Infant formula should be used soon after mixing or kept tightly covered in the refrigerator and used within 24 hours of preparation. If the infant has already consumed some of the formula out of the bottle, the rest should either be consumed within 1 hour or discarded. See the product information insert for any specific storage requirements."

b. Specific nondrug measures	n/a
Solicit follow-up questions from the patient or caregiver.	"What if Lydia continues to have emesis and gas pain after seeing the primary care provider and decreasing the volume of formula provided?"
Answer the patient's or caregiver's questions.	"From the history, it sounds like Lydia might be receiving too much formula at each feeding. If she receives less volume at each feeding, her emesis and gas pains should noticeably lessen. If a change in volume does not help relieve her symptoms, her primary care provider will further assess her gastrointestinal intolerance."
Follow-up: Evaluate and Monitor	
9. Assess patient outcome.	Ask Mrs. Smith to call in 2-3 days to update you on Lydia's response to your recommendations, or you could call her in a few days to evaluate the response. If no improvement has occurred, ensure that she has made an appointment with Lydia's PCP for further evaluation.

Key: GI = Gastrointestinal; n/a = not applicable; NKA = no known allergies; PCP = primary care provider.

Case 26-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and	

medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The mother of a healthy-appearing 4-month-old term infant comes to the pharmacy for advice on whether she should start to give him vitamins, because he is exclusively breastfed. His pediatrician suggested this at his recent well child checkup. The mother asks specifically if she should have her child take the multivitamin Poly-Vi-Flor, which her friend's 11-month-old son takes, because he is still breastfeeding.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None
c. Description of the patient's efforts to relieve the symptoms	n/a
d. Patient's identity	Aaron Adams
e. Patient's age, gender, length/height, and weight	4 months (born at 40 weeks' gestational age), male, 24.5 in., 15 lb 13.5 oz (7.2 kg)
f. Patient's occupation	n/a
g. Patient's dietary habits	Mrs. Adams is still on maternity leave. Aaron is exclusively breastfed, eating approximately every 3–4 hours during the day.
h. Patient's sleep habits	He sleeps from 10 pm to 6 am.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Aaron is a healthy term infant with no preexisting medical conditions. He currently takes no prescription or nonprescription medications and no dietary supplements.
j. Allergies	NKA
k. History of other adverse reactions to medications	None

1. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Potential for vitamin D and iron deficiency due to age and exclusive breast milk diet. No current need exists for fluoride supplementation, because the patient is younger than 6 months of age.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer this patient to the PCP. (2) Recommend a nonprescription multivitamin with iron but without fluoride supplementation. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient/caregiver preferences.	Recommend a standard infant multivitamin containing ferrous sulfate.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your primary care provider suggested a multivitamin, because Aaron is now 4 months of age and is exclusively breastfed. I would recommend a standard infant multivitamin containing iron as ferrous sulfate."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Term infants have approximately a 4- to 6-month store of iron reserves in their bodies. Human milk is very low in iron but meets most infants' needs for the first 4-6 months. However, Aaron's need for adequate vitamin D currently exceeds the amount provided in breast milk. Aaron is younger than 6 months old, so he currently does not require fluoride supplementation, which is present in Poly-Vi-Flor. For these reasons, your primary care

	provider suggested you start giving a daily multivitamin containing iron, not fluoride.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	“Give Aaron an infant multivitamin with iron (e.g., Enfamil Poly-Vi-Sol with Iron Drops) 1 mL by mouth daily.”
b. Maximum number of days the therapy should be employed	“Until recommended to discontinue per Aaron’s pediatrician or regular health care provider.”
c. Product administration procedures	“Measure liquid using the dropper that comes with the medication and have Aaron swallow the liquid.”
d. Expected time to onset of relief	n/a
e. Degree of relief that can be reasonably expected	n/a
f. Most common adverse effects	“Adverse effects are rare, but gastrointestinal symptoms are possible. Give the iron drops with food if these effects occur.”
g. Adverse effects that warrant medical attention	“Contact a health care provider if signs of an allergic reaction, such as a rash or trouble breathing, occur after a dose is given.”
h. Patient’s/caregiver’s options in the event that condition worsens or persists	n/a
i. Product storage	“Keep all medications in a tightly secured container away from any

requirements	extreme temperature and out of children's reach."
j. Specific nondrug measures	n/a
Solicit follow-up questions from the patient or caregiver.	"What do I do if Aaron spits out a dose of the multivitamin product?"
Answer the patient's or caregiver's questions.	"If Aaron spits out a dose of the multivitamin product, do not try to give the dose again. The medication is not so vital that it must be given each day for a medical condition, and Aaron could potentially receive too much iron if he is given multiple doses. Be aware of the potential for the multivitamin product to stain clothing."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mrs. Adams to call after 1 week with an update on her son's response to your recommendations, or you could call her in a week to evaluate Aaron's response.

Key: n/a = Not applicable; NKA = no known allergies; PCP = primary care provider.

Patient Counseling for Infant Nutrition

The number and variety of infant formulas available may bewilder some parents. Once the formula type recommended or prescribed by the baby's primary care provider is known, the parents can be directed to an appropriate product. If the parents need further assistance with product selection, the pharmacist can make a recommendation to accommodate their preferences. At these encounters, the parents should demonstrate that they know how to properly prepare their baby's formula and how much formula to give at each feeding. The box "Patient Education for Infant Nutrition" lists specific information to include in patient counseling for parents and caregivers. In addition, families who may qualify for the WIC program but are not enrolled can be advised of its availability and benefits.

Patient Education for Infant Nutrition

Optimal nutrition is critical in infants and children to ensure normal growth and development. Parents who carefully follow product instructions for formula preparation and the measures listed here will help ensure optimal nutrition-related outcomes.

- Check unopened formula containers for damage. Do not use products if the container is significantly dented or if the expiration date has passed.
- When preparing formula from powder or liquid concentrate, carefully follow instructions for dilution to the desired caloric density ([Tables 26–8](#) and [26–9](#)). If the formula is too concentrated, the baby may have diarrhea or become dehydrated. If it is too dilute, the baby can become water-intoxicated, which can lead to irritability, seizures, coma, or brain damage.
- When preparing formula from powder or liquid concentrate, follow the technique for aseptic processing and sterilization. Be sure to sterilize the bottles (or use sterile liners) and other equipment, and boil the water used to make the formula ([Table 26–11](#)).
- When preparing ready-to-use formulas, do not add water to the formula. Follow the instructions in [Table 26–11](#). Be sure to sterilize the bottles (or use sterile liners) and other equipment.
- Use prepared or opened ready-to-use formula within 48 hours. Keep refrigerated.
- Feed your baby according to the frequency and quantities listed in [Table 26–12](#) unless instructed otherwise by the baby's primary care provider. Paying careful attention to your infant's hunger and fullness cues is important to avoid over- and underfeeding. Discuss any concerns with your infant's primary care provider.
- Heating formula in a microwave is not recommended. However, if formula or human milk is warmed in a microwave, follow these instructions to prevent a container explosion incident or scalds or burns to the baby's mouth:
 - Remove the bottle's lid to allow heat to escape.

- Heat only 4 ounces or more of refrigerated milk; do not thaw frozen human milk in a microwave. Place frozen human milk in a tepid water bath to thaw.
- Heat 4 ounces of refrigerated formula on full power for no longer than 30 seconds; heat 8 ounces of refrigerated formula for 45 seconds.
- After heating the formula, replace the nipple assembly and invert the bottle a minimum of 10 times.
- Test the formula's temperature by putting a few drops on your tongue or the top part of your hand or the underside of the wrist. Do not feed the baby the formula unless it feels cool to the touch.

When to Seek Medical Attention

- Seek medical attention if
 - Your baby is regurgitating or vomiting significant amounts of formula. A small amount of spitting up is normal. Projectile vomiting or bilious emesis (with green-tinged vomitus) always warrants immediate medical attention.
 - Your baby has severe diarrhea or diarrhea that persists for more than 3 days.
 - Your baby appears dehydrated (e.g., decreased number of wet diapers, dark urine, limp body tone, no tears, lethargic appearance).
 - Your baby's stools have blood in them.

Key Points for Infant Nutrition and Special Nutritional Needs of Children

- Human milk is the optimal food for infants younger than 12 months of age, and its use should be encouraged for nearly all infants. When breastfeeding or provision of human milk is not possible or desired, commercial infant formulas provide a safe,

nutritionally adequate substitute.

- Commercial formulas are available in a variety of types to meet the needs of most infants, as well as children with special nutritional requirements, such as for a feeding tube.
- Therapeutic formulas designed for infants and children with altered requirements dictated by disease or other conditions, including prematurity, vary in content and are not generically equivalent. These formulas should be used under medical supervision and are not self-selected.
- Accurate preparation of formula is critical to ensure optimal nutritional outcomes. Parents and caregivers should be counseled on proper preparation techniques.
- Some infants will require vitamin and/or mineral supplementation when their needs are not adequately met by their formula intake.
- Parents should be referred to their regular health care provider if the child has persistent vomiting or if at any time the emesis fluid is bilious (green-tinged).
- Parents should be referred to an appropriate health care provider if the child has diarrhea lasting more than 3 days, especially if dehydration develops, if the child looks clinically ill, or if blood is present in the stool.

Chapter 27: Overweight and Obesity

Authors: Sarah J. Miller, Sherrill Brown

Obesity rates in the United States have increased dramatically since the mid-1970s. Overweight and obesity are significant health factors because they are associated with increased morbidity from various conditions, including cardiovascular disease (CVD), type 2 diabetes, gallbladder disease, osteoarthritis, and several cancers.¹

The National Health and Nutrition Examination Survey (NHANES) studies of the U.S. population have tracked prevalence rates for overweight and obesity in adults from 1960 to the present. NHANES data have demonstrated a marked increase in obesity in both men and women across all age and ethnic groups. As of 2016, nearly 40% of U.S. adults were obese ([Figure 27-1](#)), and more than 70% were either overweight or obese.² In the same dataset, prevalence of overweight remained more stable over time compared with the rising prevalence of obesity.² More males than females fell into the overweight but not obese category, whereas more females than males were obese.²

Figure 27-1 Overweight and obesity among adults. (Source: [Reference 2.](#))

Prevalence of obesity during childhood and adolescence also is a public health concern ([Figure 27-2](#)).³ NHANES data for 2013–2016 show obesity in 18% of youths 2–19 years of age; the prevalence was much lower at 5%–7% in the 1960s.³ Obese children, especially those in adolescence, are likely to enter adulthood still exhibiting obesity and are at increased risk for developing chronic conditions such as diabetes mellitus and cardiovascular disease at earlier ages.

Figure 27-2 Obesity among children and adolescents aged 2–19 years, by sex and race and Hispanic origin: United States 2013–2016. (Source: [Reference 3](#).)

The economic impact of overweight and obesity is substantial. The Milken Institute estimates that in the United States in 2016, obesity-related chronic diseases accounted for nearly half a trillion dollars in direct health care costs.⁴ In further estimates, obesity was responsible for more than \$1.2 trillion in productivity costs. Quantification of costs that are directly due to obesity is difficult, because many comorbid conditions associated with obesity have other possible causes.

Americans spend billions of dollars on weight control products and services

annually. Use of nonprescription or dietary supplement weight loss products is common. For maximum effectiveness in counseling patients with weight loss concerns, today’s pharmacists as health care providers need to be knowledgeable regarding benefits as well as limitations and potential harm of weight loss products, and they should be comfortable in recommending appropriate nonpharmacologic lifestyle changes, such as diet and exercise. Patients who need additional strategies can be referred for medical evaluation; considerations may include prescription weight loss therapies, weight loss devices, and weight loss surgery.

Clinical Indicators of Overweight and Obesity

The 2013 systematic review *Managing Overweight and Obesity in Adults*, prepared by the U.S. Department of Health and Human Services (USDHHS), defines overweight and obesity in adults by *body mass index* (BMI), a parameter that takes into account both height and weight.¹ BMI is calculated by dividing body weight in kilograms by height in meters, squared (kg/m²). The U.S. Preventive Services Task Force (USPSTF) on screening for and management of obesity also recommends the use of BMI for screening of obesity.⁵[Table 27–1](#) shows BMI values for persons of various heights and weights and also provides formulas for calculation of BMI. *Overweight* is defined in adults as a BMI of 25–29.9, which corresponds with Grade 1 overweight, and *obesity* as a BMI of 30 or greater. Severe or morbid obesity refers to a BMI greater than 40, corresponding with Grade 3 overweight; BMI between 30 and 40 accords with Grade 2 overweight.

Table 27–1 BMI Corresponding to Height and Body Weight^a

Table 27–1 BMI Corresponding to Height and Body Weight^a

BMI^{b,c}

	19	20	21	22	23	24	25	26	27	28	29	30	35	40

^a To determine BMI, find the height in the left-hand column; then move across the row to a given weight. The number above the weight column is the BMI for that height and weight.

^a To determine BMI, find the height in the left-hand column; then move across the row to a given weight. The number above the weight column is the BMI for that height and weight.

^b **Weight** calculations: weight (kg)/height (m)² or (weight [lb]/height [in.²]) × 703.

^b **BMI** 30-34.9 defines Class I obesity, BMI 35-39.9 defines Class II obesity, BMI ≥40 defines Class III obesity.

Key: BMI = Body mass index. BMI 30–34.9 defines Class I obesity; BMI 35–39.9 defines Class II obesity; BMI ≥40 defines Class III obesity.

Key: BMI = Body mass index.

Exclusive use of BMI as an indicator of overweight and obesity has limitations in that it does not consider extreme variation in body composition. Very muscular subjects, for example, may be classified by BMI as overweight or obese when, in fact, they are not carrying excessive adipose tissue. Alternatively, some persons with BMI in the desirable range may have less than optimal muscle mass and a high percentage of body fat. Finally, the optimal BMI range for minimizing the risk of obesity-related CVD may differ among ethnic groups and age categories.⁶ A controversial finding is that of the “obesity paradox”: Several epidemiologic studies indicated a survival benefit for being overweight or mildly obese in some cases of CVD; a 2016 meta-analysis, however, does not support this contention.⁷

The importance of the distribution of body fat to risk for obesity-associated disease and death has been described. Central fat around the waist and deep visceral adipose surrounding internal organs are associated with greater health risk than inert subcutaneous adipose in regions such as the buttock or thigh. Fat cells in the viscera of the abdomen are associated with chronic inflammation, which in turn can contribute to chronic diseases such as CVD, type 2 diabetes, and cancer.⁸ A waist circumference greater than 40 inches for men or 35 inches for women has been considered a risk factor for development of type 2 diabetes and CVD; however, the 2013 review from the USDHHS indicated that use of these cutoffs requires further study.¹ In an effort to better identify and address obesity and its related risks, health care providers are encouraged to take measurements of height, weight, and waist circumference; performance of these physical assessment techniques can be realistically accomplished even in a busy clinical setting.

Metabolic syndrome is characterized by the presence of certain metabolic risk factors and has been associated with increased risk of coronary artery disease, other vascular diseases, and type 2 diabetes. Patients with three or more of the following risk factors are said to have metabolic syndrome:

- Waist circumference greater than 40 inches in men or 35 inches in women (numbers may vary among different ethnic groups)
- Serum triglyceride levels of 150 mg/dL or greater
- High-density lipoprotein (HDL) cholesterol level less than 40 mg/dL in men or less than 50 mg/dL in women
- Blood pressure of 130 mm Hg systolic or 85 mm Hg diastolic or higher
- Fasting serum glucose level of 100 mg/dL or greater

Subjects with metabolic syndrome are likely to demonstrate insulin resistance and may benefit more from weight loss to reduce morbidity and mortality than would overweight or obese subjects without the syndrome. In addition, increased muscle mass is associated with improved insulin sensitivity. Therefore, physical activity promoting increased muscle mass may result in improved insulin sensitivity even in the absence of weight loss.

The Endocrine Society has published guidelines for obesity in children and adolescents that are based on Centers for Disease Control and Prevention growth charts.⁹ These guidelines define a BMI “percentile for age” between the 85th and 95th percentiles as *overweight* and the 95th percentile or greater as *obese*.

Pathophysiology of Overweight and Obesity

Weight gain is, to some extent, a reflection of energy intake exceeding energy expenditure. The physiology of energy intake and expenditure is complex, however, and involves numerous body systems, including the hypothalamic–pituitary axis, autonomic nervous system, central nervous system, endocrine system, gastrointestinal (GI) tract, and adipose tissue.

Both genetic and environmental factors are important in the etiology of overweight and obesity, and a complex interplay between these factors is recognized. The rapid increase in obesity over the past few decades argues for a strong environmental role. Increased portion sizes and caloric intakes no doubt contribute to recent trends in obesity rates. Today’s lifestyle and environment are likely modulating genetic expression of obesity in many susceptible persons. For example, studies have shown that higher intakes of sugar-sweetened beverages and fried foods may predispose people with certain genetic traits to risk for developing obesity.^{10,11} However, consumers

should be cautioned about commercial weight management programs offering genetic analysis as part of their packages; these programs may be beneficial, but marketing may overstate the evidence for their proven utility.

Researchers studying obesity have identified several different hormones and proteins potentially involved in energy balance.¹² Studies are ongoing to determine whether excess or deficiency of or resistance to specific substances may be related to weight homeostasis. Compounds of interest include leptin, peptide YY, ghrelin, and glucagon-like peptide 1. An in-depth discussion of this topic, however, is beyond the scope of this chapter.

Environmental factors contributing to recent increases in obesity include decreased physical activity coupled with increased food availability and consumption, especially calorie-dense foods. Guidelines for regular moderate physical activity are met by only a minority of adults and children in the United States.^{13,14} Initiation of even modest amounts of exercise by sedentary persons can have multiple health benefits, including maintenance of current weight instead of continued weight gain.

Significant increases in portion sizes of food and increased sedentary working hours may be environmental factors contributing to increasing rates of obesity. (See [Chapter 23](#) for a discussion of a healthy diet.)

Another factor of interest in the etiology of overweight and obesity is sleep, with respect to both duration and quality. Several mechanisms have been postulated and studied regarding this association.¹⁵ Sleep deprivation has been associated with decreased leptin and increased ghrelin levels in some studies; these hormonal alterations may potentially lead to increased appetite. People who do not sleep well or who sleep for only short periods each night may engage in more sedentary screen-based activities (e.g., television and computer viewing), which may encourage unhealthy snacking.

Still another concept in the etiology of obesity relates to the gut microbiome.¹⁶ Lean and obese subjects have been found to have different proportions of certain bacteria. Furthermore, these proportions have been shown to change with weight loss. These findings may lead to investigation of prebiotics, probiotics, and antibiotics as tools for weight maintenance and weight loss. (See [Chapter 20](#) for a discussion of prebiotics and probiotics.)

Use of some medications can lead to weight gain.¹⁷ As clearly shown by

abundant evidence, a majority of the second-generation antipsychotics contribute to significant weight gain and related metabolic disorders. Older antidepressants (tricyclics and monoamine oxidase inhibitors) may be associated with modest weight gain (10–15 pounds). Although some of the selective serotonin reuptake inhibitors may produce weight loss, this loss usually is short-lived, and weight gain can eventually occur. Other important groups of medications contributing to significant weight gain are hormonal contraceptives, systemic corticosteroids, certain anticonvulsants, certain sulfonylureas, thiazolidinediones, and insulins. The latter three groups are noteworthy because patients with type 2 diabetes for whom these medications are prescribed frequently are already overweight.

Obesity and Chronic Health Problems

Overweight and obesity are associated with myriad chronic health problems.¹ Many of these problems can be ameliorated with even modest weight loss, defined as about 5% of initial body weight.

Obese persons experience more difficulties in performing activities of daily living, such as walking, climbing stairs, or bending and kneeling. Weight loss can result in improved comfort, safety, and mobility during kneeling.

Obesity is closely associated with cerebrovascular disease. Overweight and obesity are associated with both hemorrhagic and ischemic stroke.¹ Fatal and nonfatal stroke risk increases with increasing BMI.¹ Overweight and obesity are linked to increased risk for hypertension, dyslipidemia, coronary artery disease, and arrhythmias.¹⁸ Prevalence of hypertension begins to increase at relatively low levels of overweight. Weight loss in obese subjects is associated with significant reductions in blood pressure.¹

A correlation between increasing BMI and increasing triglyceride and low-density lipoprotein (LDL) cholesterol levels has been recognized and investigated in some detail. Beneficial HDL cholesterol levels tend to be lower in both men and women with higher BMI values. Modest weight loss of 3–8 kg can have beneficial effects on blood lipid levels, although these effects generally are much less robust than those achieved by greater weight loss and particularly statin therapy.¹

The relationship between overweight and obesity and type 2 diabetes is well documented. Visceral adiposity (large waist circumference) has been shown to be a risk factor for development of type 2 diabetes. Patients who initially are insulin-resistant, typically evidenced by high plasma triglycerides and low HDL cholesterol, are most likely to benefit in terms of reduced morbidity and mortality risk after weight loss. Modest weight loss is effective in improving blood glucose control in patients with type 2 diabetes; addition of orlistat, a weight control drug, may accentuate this effect.¹ Modest weight loss also may help prevent development of type 2 diabetes in persons at risk.^{1,19}

A specific challenge in the management of obesity is combating the effects of widespread negative attitudes toward obese people, leading to social stigmatization and discrimination. The recognition of obesity as a disease by the American Medical Association was a step toward addressing such stigmatization and bias within the medical community. Obese persons may demonstrate self-isolation that leads to constraints in their pursuit of beneficial health care. Overweight children may develop psychosocial difficulties including emotional disorders, depression, and self-esteem issues.

Obesity appears to increase the risk for a number of other disorders, including gallbladder disease, nonalcoholic fatty liver disease, osteoarthritis, sleep apnea, asthma, certain types of cancer, and disorders of female reproductive function.¹ Obesity is a risk factor for hyperuricemia and gout.¹ Overweight is believed to contribute to a significant proportion of certain cancers and increased mortality from cancer.¹ Of particular concern are cancers with a hormonal basis, such as cancers of the breast, prostate, or endometrium, as well as cancers of the colon, rectum, and gallbladder. Hypertension and gestational diabetes are more likely in obese women who become pregnant.

Algorithm: Overweight and Obesity

Figure 27–3 Self-care for overweight and obesity. Key: ACC = American College of Cardiology; AHA = American Heart Association; BMI = body mass index; CVD = cardiovascular disease; DS = dietary supplement; HTN = hypertension; PCP = primary care provider; TOS = The Obesity Society.

Management of Overweight and Obesity

Management Goals and General Management Approach

The three major approaches to weight management are adoption of a healthy lifestyle (i.e., diet and exercise habits), pharmacologic therapy (nonprescription and prescription medications, dietary supplements), and bariatric surgery. A combination of these approaches may sometimes be used. Treatment goals of weight loss can be classified into three main categories: (1) improved control of comorbid conditions and chronic diseases associated with overweight and obesity, such as type 2 diabetes and CVD; (2) improvement in psychological health and feelings of well-being; and (3) cosmetic benefit.

For many people, losing weight or maintaining weight loss is a lifelong challenge. Successful weight loss and subsequent weight maintenance require significant behavioral modification. Pharmacologic therapy with nonprescription agents should be only a short-term measure unless overseen by a health care provider. Long-term use of prescription therapies with appropriate medical supervision may be an option for patients with a BMI of 30 or higher or a BMI of 27 or higher with comorbid conditions.¹⁹ Pharmacologic interventions, however, often result in only modest weight loss that is regained after drug discontinuation. Bariatric surgery may be considered for patients with a BMI of 40 or higher or a BMI of 35 or higher with comorbid conditions, including hypertension and hyperlipidemia.¹⁹ In patients with type 2 diabetes, bariatric surgery is sometimes considered with BMI of 30 to 35. Surgery is effective for helping many patients to achieve weight loss, although success following surgery also requires lifestyle changes. The procedures carry their own significant risks. In addition, weight loss devices (hydrogel capsules, aspiration devices, and endoscopic balloon and sleeve devices) are currently available.

Many chronic diseases and conditions respond favorably to weight loss. In many instances, however, weight loss goals set by the patient are unrealistic and based on desired cosmetic rather than health benefits. Weight loss (and maintenance of that loss) of 5%–10% of initial weight can have positive health effects in persons with hypertension and type 2 diabetes. Guidelines prepared

by the American Heart Association/American College of Cardiology/The Obesity Society state that the initial goal of weight loss is to reduce body weight by about 5%–10% over 6 months.¹⁹ If this goal is achieved and further weight loss is indicated, it can be attempted. The first 10% loss carries the greatest health benefits; it also is easiest to attain, because a decreased basal metabolic rate often causes weight loss to plateau after about 6 months. In many patients, it is more important to maintain the 10% weight loss than to pursue further weight loss, and most patients find weight maintenance to be more difficult than initial modest weight loss. An approach often overlooked may be to prevent further weight gain in people who have slowly but steadily gained weight over a period of years. [Figure 27–3](#) is a guide for the health care provider in recommending weight loss measures.

Nonpharmacologic Therapy: Lifestyle Intervention

Dietary modification or restriction is the mainstay of weight loss therapy. Physical activity is less effective in producing weight loss initially but is important in maintaining weight loss and improving overall fitness. The term *lifestyle intervention* describes a strategy of dietary change, physical activity, and behavior therapy.¹ One major key to weight loss and maintenance of that loss is implementing lifestyle interventions that are sustained over a long period of time. Support for and directed access to lifestyle intervention programs should be included in the array of services available from today's health care providers.

Dietary Change

Dietary change is the most commonly used weight loss strategy. Diet strategies include caloric restriction; changes in dietary proportions of fat, protein, and carbohydrate; use of macronutrient substitutes (i.e., sugar and fat substitutes); and changes in timing or frequency of meals. Short-term success for many methods has been documented; however, data on longer-term effectiveness and safety are less encouraging. Weight loss at the end of relatively short-term programs can exceed 10% of initial body weight. However, a strong tendency to regain weight has been well documented. A relatively small portion of participants do maintain weight loss over more extended periods. The National Weight Control Registry tracks persons who have

maintained weight loss of at least 30 pounds for at least 1 year.²⁰ To initially lose weight, subjects in this registry used a variety of methods; about one half were self-directed methods and half were some type of program. Most participants reported maintaining weight loss through a combination of a low-calorie, low-fat diet and exercise.

Even small changes in dietary patterns can have a positive effect. Cutting portion sizes, switching to water or diet soda rather than sugar-sweetened beverages, using smaller plates for meals, and keeping healthy snacks such as fruits and vegetables on hand are useful, sustainable strategies. Trying to eat foods with low energy density (i.e., low calories per weight of food) may be helpful in that these foods tend to promote satiety. Because lifestyle changes need to be made for the long term, patients should be encouraged to make realistic, smaller changes, rather than opting for more radical fad diets that are difficult to adhere to over time. (See [Chapter 23](#) for more details about healthy diets.)

Caloric Restriction

Daily caloric allowances for moderately active persons vary with age, gender, and body weight. Overall, the U.S. population suffers from “portion distortion,” and people need to relearn appropriate food portion sizes based on age and activity levels. Daily caloric intake allowances for a reference 30-year-old man (weight, 154 lb; height, 5 ft 10 in.) in a temperate climate are approximately 2400–3000 kcal/day, depending on activity level. Corresponding figures for a reference 30-year-old woman (weight, 126 lb; height, 5 ft 4 in.) are approximately 1800–2400 kcal/day.²¹ These figures are lower for older adults and higher for younger adults. Caloric requirements for women increase during pregnancy and lactation (see [Chapter 23](#)).²¹ Self-initiated weight loss during pregnancy is not generally recommended.

A diet that is individually planned and designed to create a deficit of 500 kcal/day or more should be an integral part of any weight loss program.¹ A low-calorie diet (LCD) of approximately 1200–1800 kcal/day may involve a structured commercial program, or it may involve guidelines for selecting conventional foods, including careful attention to portion sizes. Initial weight loss with an LCD typically is 1–2 pounds per week. A very-low-calorie diet (VLCD) of 800 or fewer calories per day, as indicated in certain circumstances, should be monitored under medical supervision and accompanied by high-

intensity lifestyle intervention.¹ VLCDs frequently consist of liquid formulas given several times a day. Although weight loss with VLCDs over 12–16 weeks typically is double that with LCDs, long-term results are often no better. A multivitamin and multimineral preparation should be recommended for patients consuming fewer than 1200 kcal/day for prolonged periods.

Another strategy for weight loss and maintenance receiving increasing attention is fasting and time-restricted eating. Various approaches have been described, including eating only within a time frame of 6–10 hours each day, eating regularly for 5 days a week and consuming restricted calories 2 days a week, and alternate-day fasting. Preliminary evidence has given the signal that such approaches may have beneficial effects on weight control and metabolic and cardiovascular risk factors.²² However, further randomized controlled trials with clinical outcomes are needed. These approaches generally have been associated with only minor adverse events so long as the fasting is short term.

Altered Proportions of Food Groups

The 2010 Dietary Guidelines for Americans recommended a diet supplying no more than 35% of total calories from fat, of which no more than 10% of total calories come from saturated fat.²³ The 2015–2020 Dietary Guidelines still recommend a diet low in saturated fat but do not state a ceiling for percentage of overall fat in the diet.²¹ A low-fat diet alone is inadequate for weight loss; the diet must also reduce total calories.

Very-low-fat vegetarian diets in the context of other lifestyle changes have been advocated. Although such programs can result in regression of coronary atherosclerosis and improvement of endothelial function in some patients with moderate to severe coronary heart disease, their applicability to larger populations remains questionable with regard to compliance. Dietary fats must be carefully chosen for a very-low-fat diet to prevent essential fatty acid deficiency. Such diets increase triglyceride levels and lower HDL cholesterol in the short term because of the high carbohydrate content.

A spectrum of popular high-protein, higher-fat, and low-carbohydrate diets have been described. Some contain very low amounts of carbohydrates (supplying approximately 5%–15% of total calories; e.g., the Atkins diet) and are ketogenic, whereas others are considered moderate-carbohydrate diets (supplying approximately 35%–50% of calories from carbohydrate; e.g., the

Zone diet). People often start out on the “ultralow” form of the diet, with subsequent transition to a more moderate form. Part of the success of low-carbohydrate diets may lie in the fact that they simplify food choices, thus facilitating dietary adherence.

Very-low-carbohydrate diets prevent the elevated insulin levels that promote storage of body fat. Much of the weight loss seen with these diets is a result of decreased caloric intake from avoiding high-carbohydrate foods. Initial weight loss results in part from a diuretic effect and glycogen depletion. Low-carbohydrate diets result in significant weight loss over 6–24 months. Long-term effects of these diets on CVD risk are still largely speculative.¹ Low-carbohydrate diets generally have more favorable effects on triglycerides and HDL cholesterol levels, whereas low-fat diets have more favorable effects on LDL and total cholesterol.¹ Some research has indicated that weight loss associated with low-carbohydrate diets is associated with smaller decreases in resting energy expenditure compared with weight loss achieved with low-fat diets; this might help with maintenance of the weight loss.²⁴

Potential adverse effects of low-carbohydrate diets include lack of essential nutrients such as potassium, calcium, and magnesium. High-protein foods consumed in large quantities on these diets could increase uric acid levels and precipitate gout, although this problem has not been common in studies with up to a year of follow-up. High animal protein content promotes calcium excretion in the urine, which could be deleterious to bone health. Restriction of fruits, vegetables, whole grains, and milk products may potentially increase the risk for various cancers by depleting essential vitamins, minerals, and fiber and also lead to constipation. High protein content may predispose the dieter to dehydration and hyperfiltration by the kidneys, leading to eventual kidney damage, particularly in diabetic patients. Headache, muscle weakness, and fatigue are other adverse events reported by some persons on low-carbohydrate diets.

Several published randomized trials of these diets demonstrated relative safety of the low-carbohydrate, higher-fat, high-protein diets for 2–24 months, with greatest weight loss seen in the first 6 months.²⁵ In the Women’s Health Initiative trial, reduction in total fat intake for 8 years did not reduce risk for CVD.²⁶ This finding may be related to the observation that when compared with fat-restricted diets, carbohydrate-restricted diets have more favorable effects, not only on triglyceride and HDL cholesterol levels but also on small

dense LDL cholesterol mass.²⁶

Low-glycemic-index food products are promoted commercially. *Glycemic index* refers to the amount of blood glucose rise seen over a set period of time after ingestion of a standardized amount of a food. Many high-carbohydrate, low-fat diets are associated with a high glycemic index for the foods ingested. Through careful selection of dietary carbohydrates, a lower glycemic response can be obtained. Low-glycemic-index diets could be expected to promote satiety and prevent large fluctuations in insulin concentrations and may help maintain insulin sensitivity. Studies have not consistently supported the usefulness of low-glycemic-index diets in weight control, and the methods used to classify foods with this system are controversial.

Use of Food Additives

Some patients may use food additives such as artificial sweeteners and fat substitutes to reduce caloric intake. Although theoretically the use of these agents should help decrease caloric intake, existing data and recommendations are conflicted regarding the beneficial and detrimental effects of these products. [Table 27–2](#) outlines information related to sugar and fat substitutes.

Table 27–2 Common Sugar and Fat Substitutes	
Substitute (With Selected Trade Name)	Comments
Sugar Substitutes	
Saccharin (Sweet'n Low) ^a	Has bitter taste; has been replaced largely by newer sweeteners
Aspartame (NutraSweet) ^a	Contains phenylalanine, so contraindicated in patients with phenylketonuria; not for use in cooking or baking as heat breaks it down into free amino acids, which impart a bitter taste
Fructose	Nutritive sweetener that should not be viewed as sugar free; insulin not required for fructose utilization in the body; contains approximately 10 calories when supplied in an amount providing the equivalent sweetness of about 1 teaspoon of sucrose

Substitute (With Selected Trade Name)	Comments
Sorbitol	Nutritive sweetener that should not be viewed as sugar free; does not cause tooth decay but can cause osmotic diarrhea when ingested in large quantities; contains approximately 10 calories when supplied in an amount providing the equivalent sweetness of about 1 teaspoon of sucrose
Xylitol	Nutritive sweetener that should not be viewed as sugar free; does not cause tooth decay; contains approximately 10 calories when supplied in an amount providing the equivalent sweetness of about 1 teaspoon of sucrose
Acesulfame potassium (Sweet One) ^a	May be substituted for sucrose in cooking; may be combined with aspartame, because some people detect a metallic aftertaste with acesulfame potassium alone
Sucralose (Splenda) ^a	May be used in cooking
Neotame ^a	Chemically similar to aspartame; may be used in cooking
Cyclamates ^a	Banned by FDA in 1969 because of association with cancer in animals; applicability of this finding to humans has been challenged; remains available in many countries
Advantame ^a	Approved by FDA in United States as of 2014; 20,000 times sweeter than sugar; not commonly used
Stevia (Truvia) ^a	Approved by FDA in United States as of 2008 as a food additive in a specific purified form
Fat Substitutes^b	
Microparticulated protein (Simplese)	Used in frozen desserts, salad dressing; unstable if heated
Soluble fiber (Oatrim)	Derived from oats and designed to replace fat in meats, cheeses, baked goods, and frozen desserts
Sucrose polyester (Olean)	Also known as olestra; is not absorbed; can cause malabsorption of fat-soluble vitamins; possible GI adverse effects with ingestion of large quantities; can be used for cooking and frying

^a Can be labeled as noncaloric based on FDA labeling regulations; cyclamates no

longer approved by FDA for use as sugar substitute.

^b Use of these fat substitutes in food products in place of fat typically decreases caloric content of the foods by about half, unless extra sugars are added to the products.

Key: FDA = U.S. Food and Drug Administration; GI = gastrointestinal.

Meal Replacement Therapy

Diets that use meal replacement foods typically involve replacing up to 2 meals a day with a liquid drink, snack bar, or measured frozen meal, with the dieter encouraged to eat a “reasonable” third meal each day. The main advantage to this approach is portion control. Products typically contain about 200–300 kcal per serving and are low-fat foods, although low-carbohydrate options also are available. The challenge with this approach is that dieters enter their third meal extremely hungry and may consume excessive calories by overeating at this time. Early weight loss with these products, part of which may be a result of low sodium content leading to water loss, can give a psychological boost to adhere to the program. Meal replacement products are discussed further in [Chapter 24](#).

Commercial Weight Loss Programs

Structured commercial weight loss programs such as Weight Watchers, Jenny Craig, and Take Off Pounds Sensibly (TOPS) are very popular in the United States. Women tend to gravitate to these programs more frequently than men do. Participation in structured commercial programs may be expensive if subjects are required to purchase program-specific tools as well as specially packaged snacks or meals. The success seen with these programs is likely at least partially due to the social support that develops with periodic meetings. Online tools such as diet and exercise diaries and support groups are increasingly available; these resources may be less expensive than community-based structured commercial programs.

Physical Activity

Encouragement of physical activity for preventing overweight and obesity is an important public health strategy for all age groups, including children. The

U.S. Department of Health and Human Services outlines the physical activity recommendations shown in [Table 27–3](#).²⁷ For older adults, regular exercise can reduce functional declines that occur with aging.

Table 27–3 Physical Activity Recommendations^a	
Children and Adolescents	
<i>Aerobic:</i>	≥60 minutes of moderate or vigorous aerobic activity a day, including vigorous activity at least 3 days a week
<i>Muscle and bone:</i>	Strengthening physical activity should occur at least 3 times a week
Adults	
<i>Aerobic:</i>	150–300 minutes of moderate aerobic activity or 75–150 minutes of vigorous physical activity a week, performed in ≥10-minute episodes ^b
<i>Muscle:</i>	Strengthening activities involving major muscle groups should occur at least twice a week

^a As proposed by the U.S. Department of Health and Human Services in *Physical Activity Guidelines for Americans, 2018*.²⁷

^b More activity than is outlined here is necessary to promote weight loss in most people. Exercise should be used in combination with dietary restriction to promote weight loss.

Increased physical activity is an important component of weight loss therapy and is even more important in weight maintenance after weight loss. Persons who regularly exercise may, in general, be more committed to a healthy lifestyle. Exercise builds muscle, which has a higher metabolic rate than a corresponding amount of fat. Weight loss that can be achieved by an exercise program is modest; combining a reduced-calorie diet with increased physical activity produces greater weight loss and reduction in abdominal fat than can be achieved with either approach alone. Patients who have restrictions as to types of exercise should have a medical evaluation before starting an exercise regimen. Regardless of presence of concomitant diseases, current recommendations call for men older than age 40 and women older than age 50 to undergo a medical evaluation before starting an exercise program.

For sedentary patients, a walking program often is a good place to begin. A pedometer or other inexpensive activity tracker may be an aid to increasing activity in some persons. Patients can start by walking 30 minutes each day for 3 days a week, building up to at least 60 minutes of moderate-intensity physical activity most days of the week. The 60-minute activity periods can be accrued in multiple smaller increments throughout the day with similar benefit. Patients should be encouraged to participate in activities that they enjoy and are therefore more likely to continue.

Behavioral Therapy

Behavioral therapy used in combination with other strategies, such as diet, exercise, and medications, can improve the outcome of weight loss programs. Behavioral interventions are most effective when patients participate in sessions at least once or twice a month.⁵ Behavioral therapy may be administered in either an individual or a group setting by professionals or lay leaders. Remote coaching and mobile technologies are increasingly being explored as less expensive methods for encouraging adherence to lifestyle modifications. Behavioral techniques include self-monitoring of weight; use of tools such as pedometers and food scales; and problem solving to identify barriers to weight loss and maintenance.⁵

Public Health Initiatives

In an era when federal and state governments bear an increasing percentage of the cost of health care in the United States, interest in public health initiatives to decrease overweight and obesity has increased. Efforts at all levels of government to require dietary information in restaurant menus, to limit portion sizes of sugar-sweetened beverages, to eliminate trans-fat content in commercial foods, and to levy taxes on certain unhealthy foods are just a few examples of initiatives that have been considered or actually implemented. Many schools have banned the sale of sugar-sweetened beverages and high-fat snacks on their premises. These measures are controversial, and positive benefits on public health are not consistently shown at this time.

Pharmacologic Therapy

Pharmacologic therapy is generally not recommended for weight loss. In recent years, many more weight loss products have been removed from the

market for safety reasons than were approved. The ideal weight loss drug, which would provide fast and permanent weight loss with no adverse effects, does not exist despite the billions of research and consumer dollars spent on weight loss products every year.

Guidelines for obesity and overweight management recommend weight loss medications only for adjunct therapy to lifestyle interventions in patients with either a BMI of 30 or greater or a BMI of 27 or greater associated with concomitant diseases or risk factors.¹⁹ Recent guidelines on overweight and obesity treatments did not specifically address medication therapy for weight management because of the scarcity of medications approved for chronic management of obesity. Since publication of updated guidelines, additional medications have been approved for weight loss.¹⁹ These guidelines should apply to all weight loss products (prescription or nonprescription drugs and dietary supplements), although nonprescription orlistat (allī) can be used in patients with a BMI of at least 25, as discussed in the following section. Weight loss medications and supplements should be used in conjunction with lifestyle intervention and should be continually assessed for efficacy, safety, and tolerability.

Status of Nonprescription Weight Loss Products

Since 1991, FDA has banned more than 100 weight control ingredients in nonprescription drug products, including phenylpropanolamine, ephedrine, aloe, and cascara sagrada.²⁸ Ephedrine alkaloids are contained in several botanicals, including sea grape, yellow horse, joint fir, popotillo, ma huang, and country mallow. Although these products are banned from sale in the United States, other substances that may pose similar risks are still included in dietary supplements and often are found as components of weight loss products.

In the period 2013–2015, FDA sent warning letters to several manufacturers of products containing BMPEA (beta-methylphenethylamine), DMBA (1,3-dimethylbutylamine), and DMAA (1,3-dimethylamylamine).^{29–31} FDA does not consider BMPEA, DMBA, and DMAA to meet the legal definition of a dietary ingredient, primarily because these substances are not from botanical sources, regardless of the manufacturers' claims. FDA warns consumers to avoid products containing these ingredients because of potentially dangerous adverse effects, such as hypertension and cardiovascular problems.

Dietary supplements are distinct entities from nonprescription drugs. They include herbal and other products meant to supplement the diet and are regulated under the Dietary Supplement Health and Education Act of 1994 (see [Chapter 50](#)).

A majority of drugs currently considered safe and efficacious for weight loss have prescription-only status and include benzphetamine (Didrex), diethylpropion (Tenuate), methamphetamine (Desoxyn), orlistat (Xenical), phendimetrazine (Bontril), phentermine (Ionamin), phentermine/topiramate (Qsymia), lorcaserin (Belviq), naltrexone/bupropion (Contrave), and liraglutide (Saxenda). Another agent, sibutramine (Meridia), was withdrawn from the U.S. market in 2010. Standard pharmaceutical references can be consulted for more information about these drugs.

Orlistat was approved by FDA as a prescription weight loss medication (Xenical) in 1999 and as a nonprescription weight loss medication (allī) in 2007.³² The prescription strength of orlistat (120 mg) is approved for use in patients ages 12 years and older; however, the nonprescription strength (60 mg) is approved only for patients 18 years and older.

Orlistat aids in weight loss by decreasing absorption of dietary fats. It inhibits gastric and pancreatic lipases and specifically reduces absorption of fat by inhibiting hydrolysis of triglycerides.³³ Orlistat should be used in conjunction with a reduced-calorie, low-fat diet and exercise program. The labeling for the prescription product states that the drug is indicated for obese patients with a BMI of at least 30 or for patients with a BMI of 27 or higher who also have risk factors such as diabetes, hypertension, or dyslipidemia. The labeling for the nonprescription product simply states that the drug is indicated for use in overweight adults, which by the standard definition would be persons with a BMI of 25 or greater.³²

The recommended dosage of prescription-strength orlistat is 120 mg taken 3 times a day before meals containing fat; at this dosage, it inhibits dietary fat absorption by about 30%.³³ The nonprescription form of the drug is recommended at a dosage of 60 mg taken 3 times a day before meals containing fat; its inhibition of fat absorption is approximately 25%.³⁴ With either dosage of orlistat, the risk of greasy diarrhea increases as the amount of fat increases in a meal. Because of its mechanism of action, the drug need not be given with a fat-free meal.

Most studies have used the 120-mg dosage in combination with a reduced-calorie diet and have reported modest weight losses, especially during the first 6 months of therapy. In one study with the 60-mg nonprescription dose, weight loss after 16 weeks in the active drug group was significantly greater than in subjects receiving placebo (3.05 kg versus 1.90 kg; $P < .001$).³⁵ In another study, patients on orlistat 60 mg lost an average of 8.5 kg after 1 year of treatment.³⁶ The nonprescription product labeling notes that most patients lost 5–10 pounds (about 2–5 kg) over 6 months in clinical trials.³⁷ Patients receiving orlistat have had significantly greater reductions in LDL cholesterol and blood pressure compared with placebo.³³ Effects on lipid levels may be independent of weight loss, whereas the changes in blood pressure probably are largely due to weight loss. Orlistat 120 mg has been shown to be effective in preventing and delaying development of type 2 diabetes over a 4-year period in patients with impaired glucose tolerance.³⁸

Although the 120-mg dose of prescription orlistat also is indicated for weight maintenance, nonprescription orlistat is indicated only for weight loss and should be discontinued once the patient's BMI has reached 25 or less.

Nonprescription orlistat may be of benefit as an adjunct to lifestyle changes in helping patients lose a modest amount of weight. Results will be more favorable when use of this agent is combined with a reduced-calorie, low-fat diet and increased physical activity. With appropriate patient education, orlistat has the ability to promote change in eating habits, both to optimize the drug's effect on fat absorption and to minimize its adverse effects. Rather than suppressing the appetite, an effect that goes away once the drug is discontinued, orlistat is of benefit in that the patient knows to choose food with lower fat content. Once orlistat is discontinued, adherence to healthier food choices can be maintained.

Patients should be made aware that the adverse GI effects of the medication are likely to be exacerbated by concomitant ingestion of a low-carbohydrate, high-fat diet. Some concern has been raised that this nonprescription agent may be misused, particularly by adolescents; in clinical practice, it would be prudent to watch for repeated purchases of the preparation by patients in this age group.

Orlistat may decrease absorption of fat-soluble vitamins (A, D, E, and K). It is recommended that patients taking this medication take a multivitamin once daily at bedtime or separated by at least 2 hours from an orlistat dose. Orlistat

is minimally absorbed and therefore exhibits little systemic toxicity. Common GI adverse effects are caused by the increased unmetabolized fat present in the GI tract and include flatulence with oily spotting, loose and frequent stools, fatty stools, and fecal urgency and incontinence. Decreasing the amount of ingested fat can minimize these effects. These adverse effects are expected to be less common with the nonprescription dosage, and they generally subside within a few weeks of initiating therapy.

Drug interactions with orlistat are unlikely because of the drug's limited absorption. [Table 27–4](#) lists potential or documented drug interactions with orlistat. Patients with malabsorption disorders should avoid taking orlistat, and patients with a history of thyroid disease, cholelithiasis, nephrolithiasis, or pancreatitis should consult their primary care provider before taking orlistat. Both the prescription and nonprescription strengths of orlistat contain warnings regarding potential liver injury. These warnings are based on rare cases of severe liver injury with orlistat, including one case associated with the nonprescription strength preparation.

Table 27–4 Potential Drug–Drug Interactions With Orlistat	
Drug	Interaction
Cyclosporine	Reductions in cyclosporine concentration may be seen.
Fat-soluble vitamins	Absorption of these vitamins (A, D, E, K) may be decreased.
Levothyroxine	Levothyroxine concentrations may be decreased, leading to hypothyroidism.
Warfarin	Malabsorption of vitamin K may lead to over anticoagulation.
Amiodarone	Starting oral amiodarone during orlistat therapy may result in decreased concentrations of amiodarone.
Antiepileptic drugs	Orlistat could decrease concentrations of various antiepileptic drugs; thiopental, fosphenytoin, and pentobarbital are exceptions.
Antiretroviral drugs	Orlistat may lower the effectiveness of antiretroviral drugs used to treat HIV, possibly owing to inhibition of absorption.

Source: [Reference 33](#).

Orlistat is contraindicated in pregnancy because weight loss offers little potential benefit to a pregnant woman and may result in fetal harm.³³ (See the Preface for a detailed explanation of the pregnancy data.) It is not known if orlistat is excreted into human milk, so caution should be exercised when orlistat is administered to a nursing mother. The safety and effectiveness of the nonprescription orlistat product have not been established for patients younger than 12 years of age. Clinical studies of orlistat did not include sufficient numbers of patients ages 65 years and older to determine whether they show a different response from that seen in younger patients. No dosage adjustment is recommended in patients with renal or hepatic dysfunction.

Use of Inappropriate Medications for Weight Loss

Persons seeking to lose weight will sometimes turn to inappropriate, potentially dangerous methods to induce loss, such as use of diuretics or laxatives. The risks associated with diuretics and laxatives are discussed in [Chapters 9](#) and [15](#), respectively.

Complementary Therapies

Botanicals and Other Preparations

A summary of botanicals commonly used in weight loss supplements is presented in [Table 27–5](#).^{39–43} [Chapter 51](#) provides an in-depth discussion of the more common dietary supplements. Many of these supplements also contain vitamins and minerals, presumably to ensure adequate intake of these essential nutrients by patients on low-caloric diets. In addition, a majority of these supplements contain multiple ingredients with several purported actions. To further complicate the issue, many of the supplements contain “proprietary blends.” Ingredients of proprietary blends must be listed, but their amounts do not have to be specified. Of note, however, for many of these ingredients, scientific evidence for usefulness in weight loss is lacking. To confuse matters further, many herbal extracts are listed by common or not-so-common names (e.g., bitter orange, Seville orange, and sour orange are all common names for *Citrus aurantium*). Many products do not list the botanical name, making it difficult to determine exactly what the herbal product contains. A majority of these products have not been clearly demonstrated to

be effective or safe, and many have been associated with serious adverse effects. Health care providers are advised to carefully review the labels of all dietary supplement weight loss products to determine the risk for adverse reactions and drug–supplement interactions. Broadly speaking, the ingredients of weight loss supplements can be categorized as outlined in [Tables 27–5](#) and [27–6](#).

Table 27–5 Complementary Therapy Agents Commonly Used for Weight Loss	
Agent	Associated Risks
Stimulants, Energy Boosters, and Thermogenic Aids	
Bitter orange (<i>Citrus aurantium</i>)	Synephrine may cause hypertension, cardiovascular toxicity, myocardial infarction, stroke, and seizure.
Caffeine: cola nut (<i>Cola acuminata</i> , <i>Cola nitida</i>); green tea (<i>Camellia sinensis</i>); guarana (<i>Paullinia cupana</i> , <i>Paullinia sorbilis</i>); maté (<i>Ilex paraguariensis</i>)	Caffeine may cause GI distress, nausea, dehydration, headaches, insomnia, nervousness, anxiety, muscle tension, heart palpitations, hypertension, addiction, decreased appetite, and vertigo; avoid in patients with gastric ulcers.
	Use with caution in patients with renal disease, panic disorder, hyperthyroidism, anxiety, or susceptibility to spasm; use only under medical supervision in patients with peptic ulcers, cardiovascular disease, or blood-clotting abnormalities; discontinue use at least 24 hours before surgery; may alter effects of anticoagulant medications.
Forskolin (<i>Coleus forskohlii</i>)	Forskolin is generally well tolerated.
Fat and Carbohydrate Modulators	
Chromium	Chromium is generally well tolerated at low doses.
	Rhabdomyolysis and renal failure may occur with large doses.
	May cause mood and sleep changes, headaches, and cognitive and perception dysfunction.
Cinnamon (<i>Cinnamomum</i> spp.)	Cinnamon is usually well tolerated.
	Allergic reactions, such as dermatitis and gingivitis, may occur with external application and with use of flavored chewing gums, mints, or toothpastes.

Agent	Associated Risks
Conjugated linoleic acid (CLA)	CLA causes GI upset.
Garcinia or brindleberry (<i>Garcinia cambogia</i>)	Garcinia may cause GI distress; acute liver toxicity has been reported
Green coffee	Green coffee is generally well tolerated. Green coffee extract contains caffeine (see Caffeine, listed above).
Green tea (<i>Camellia sinensis</i>)	See Caffeine, listed above.
Licorice (<i>Glycyrrhiza glabra</i>)	Pseudoaldosteronism, hypertension, and hypokalemia may occur.
Pyruvate	GI upset may occur.
Turmeric or curcumin	Curcumin causes GI upset.
	Increased bleeding risk may occur with high doses of curcumin.
Appetite Suppressants and Satiety Promoters	
Damiana (<i>Turnera diffusa</i>)	Damiana may cause diarrhea, headache, insomnia, and hallucinations.
Glucomannan (<i>Amorphophallus konjac</i>)	GI upset may occur; avoid powder or capsule formulations.
Guar gum (<i>Cyamopsis tetragonolobus</i>)	GI upset may occur.
Hoodia (<i>Hoodia gordonii</i>)	No risks have been reported.
Plantain or psyllium (<i>Plantago lanceolata</i> , <i>Plantago major</i> , <i>Plantago psyllium</i> , <i>Plantago arenaria</i>)	Flatulence, GI distress, nausea, and vomiting may occur; ensure adequate water intake to decrease risk of choking and GI obstruction; plantain may reduce absorption of drugs including lithium and carbamazepine.
Fat Absorption Blockers	
Chitosan	Chitosan is generally well tolerated; may cause GI upset, flatulence, nausea, increased stool bulk, constipation; cross-sensitivity may occur in patients with shellfish allergies.
Green coffee	See comments under Fat and Carbohydrate Modulators, listed above.

Agent	Associated Risks
Raspberry ketones extract (<i>Rubus idaeus</i>)	No reliable information about adverse effects of raspberry extract is available. The active ingredient is structurally similar to synephrine; see Bitter orange, listed above.
Carbohydrate Absorption Blockers	
Ginseng (<i>Panax</i> sp.)	Ginseng may cause nervousness, excitement, inability to concentrate, estrogenic effects, Stevens–Johnson syndrome, allergy, and hypoglycemic effects; may interact with several drugs including warfarin, digoxin, and alcohol.
Laxatives and Diuretics	
Cascara sagrada (<i>Rhamnus purshiana</i>)	Abdominal pain, cramps, and diarrhea may occur; chronic use can lead to potassium depletion, disturbed heart function, and muscle weakness; avoid in patients taking digoxin or potassium-depleting diuretics.
Dandelion (<i>Taraxacum officinale</i>)	Avoid use in patients with allergies to ragweed or marigolds (or other members of the Asteraceae/Compositae family); contraindicated in patients with gallbladder or bile duct obstruction, or with bowel obstruction.
Miscellaneous	
Calcium	Constipation, nausea, and vomiting may occur; possibly effective when ingested as naturally occurring calcium in foods, but not when used as a dietary supplement.
Guggul (<i>Commiphora mukul</i>)	GI distress, diarrhea, nausea, and skin rash may occur; use only under medical supervision in patients with hyperthyroidism; may alter effects of thyroid medications, cholesterol-lowering medications, anticoagulants, antiplatelet medications, propranolol, and diltiazem.
Willow bark (<i>Salix alba</i>)	Willow bark is a salicin source; may cause GI upset; avoid in kidney disease owing to potential for reduction in renal blood flow.

Key: GI = Gastrointestinal.

Source: [References 39–42](#). (See also [Chapter 51](#) for additional related information.)

Table 27–6 Categories of Ingredients in Weight Loss Dietary Supplements

Category	Purported Mechanism(s)	Selected Ingredient(s)
Stimulants/energy boosters/ thermogenic aids	Increase basal metabolism, increase energy, counteract fatigue	Caffeine, bitter orange
Fat and carbohydrate modulators	Alter fat or carbohydrate metabolism, resulting in decreased body fat mass and increased lean muscle mass	Green tea, chromium, garcinia
Appetite suppressants and satiety promoters	Reduce caloric intake by suppressing appetite or promoting satiety	Guar gum, glucomannan, psyllium
Fat absorption blockers	Block intestinal absorption of dietary fat	Chitosan
Carbohydrate absorption blockers	Block intestinal absorption of dietary carbohydrate	Kidney bean extract, mung bean extract
Cortisol blockers	Block stress-induced release of cortisol to avoid cortisol-induced increased appetite and fat storage	Beta-sitosterol, phosphatidylserine, theanine
Laxatives	Promote weight loss by increasing fecal loss	Cascara sagrada, psyllium
Diuretics	Promote weight loss by increasing urination and fluid loss	Dandelion, caffeine

Herbal laxatives and diuretics often are included in multiple-ingredient dietary supplements marketed for weight loss. For example, so-called dieter's or "slimming" teas contain a variety of botanical laxatives and diuretics. Diuretics, whether herbal or drug, may result in an initial transient weight loss, but this effect lasts only a few days. Herbal or drug laxatives typically act in the colon and will therefore not decrease caloric absorption in the small intestine, which is the primary site of food absorption. Many of these botanicals are stimulant laxatives that should be used for only 1–2 weeks at a time. Prolonged use may lead to electrolyte imbalances and dependence on the laxative for regular

bowel movements (*cathartic colon*), as discussed in [Chapter 15](#).

Herbal sources of caffeine often have been used in combination with ephedra and willow bark (a source of salicin) for weight loss because of purported synergistic effects. This combination is often referred to as a “fat-burning stack” or ECA (ephedrine-caffeine-aspirin), with claims of additive thermogenic or heat-producing effects.^{42,43} However, adverse reactions to these products, either alone or in combination, have been reported, ranging from relatively mild symptoms, such as headache, nervousness, or hypertension, to more severe afflictions including stroke, myocardial infarction, and sudden death. In several cases, significant adverse events occurred in otherwise healthy young or middle-aged adults, and many such events followed consumption of relatively low doses for short periods.^{42,43}

Since FDA banned ephedra-containing dietary supplements in 2004, many weight loss medications now contain bitter orange (*Citrus aurantium*), often in combination with sources of caffeine such as cola nut (*Cola acuminata* or *Cola nitida*), guarana (*Paullinia cupana* or *Paulinia sorbilis*), or maté (*Ilex paraguariensis*). Bitter orange contains synephrine, which is structurally similar to epinephrine, and octopamine, which is similar to norepinephrine. Bitter orange is touted as a safe alternative to ephedra in many herbal weight loss products. Although adrenergic effects of synephrine and octopamine may suppress appetite and increase lipolysis, these products have the same potential health risks as for ephedra. In a study of healthy adults, a single dose of *C. aurantium* increased heart rate and blood pressure significantly compared with placebo. However, those effects may have been due to the combination of *C. aurantium* with caffeine and other stimulants in the multicomponent product used in the study.⁴⁴ Clinical trials of *C. aurantium* for weight loss have failed to support efficacy for this indication.

Economically Motivated Adulteration

Although adulteration of medications is not a new concept, it is of increasing concern in the dietary supplement industry. A working definition of *economically motivated adulteration* proposed by FDA is the “fraudulent, intentional substitution or addition of a substance in a product for the purpose of increasing the apparent value of the product or reducing the cost of its production, i.e., for economic gain.”⁴⁵ FDA tracks tainted supplements; the most common issue related to weight loss supplements is the undisclosed

inclusion of sibutramine, a prescription weight loss medication that was voluntarily withdrawn from U.S. and Canadian markets because of an associated increased risk of heart attack and stroke in patients with concomitant CVD.⁴⁶ Such adulteration, whether intentional or unintentional, is of particular concern in the weight loss dietary supplement industry, because increasing numbers of cases characterized by the potential for serious adverse events are appearing in the literature.

Assessment of Overweight and Obesity: A Case-Based Approach

Before recommending a weight loss method or product, the health care provider should first determine the patient's motivation for weight loss. The reason may be immediately obvious with some patients; others may want to lose a few pounds to improve their appearance or to enhance their perception of good health (or to comply with medical recommendations for management of a chronic condition). The initial assessment should include measurement of the patient's waist circumference and calculation of the patient's BMI. A careful review of the patient's current medication history (prescription and nonprescription), including use of herbal products and other dietary supplements, is essential. A family history of overweight and obesity is important to recognize, and eating habits (e.g., food types, number and timing of meals) should be identified.

The assessment also should ascertain what weight loss strategies were used previously and whether the attempts were successful. Such strategies may include dietary counseling or physical activity training the patient may have received in the past or is currently receiving. The patient's support system should be considered; support from family and friends is a critical component for success. Similarly, cultural background should be considered because cultural and social factors have a strong effect on food decisions. Such factors should not be seen as insurmountable obstacles. The health care provider can serve an important role to motivate and encourage the patient in weight loss.

Using all information obtained during the assessment, the health care provider can determine whether weight loss is indicated and, if so, can help select a weight loss program of appropriate type, intensity, and duration. Patients with

significant comorbid conditions in addition to obesity should be discouraged from using dietary supplements. For persons within the normal height and weight range who want to lose weight for other reasons (e.g., improved appearance, enhanced sense of well-being), the difficulties involved and the potential for adverse physical and psychological effects with certain interventions should be underscored; often the focus on diet to achieve reduction in body weight can be redirected to a commitment to healthy exercise to attain the desired results.

Cases 27–1 and 27–2 illustrate assessment of two different patients who seek assistance with weight control.

Case 27–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has been overweight since the age of about 30 years. He was a jockey in his teens and 20s, so he had to restrict his eating to keep his body weight below specified limits. After "retiring" from racing, however, he gained weight.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient is a rancher and eats when stressed, particularly at harvest and calving time.
c. Description of the patient's efforts to relieve the symptoms	Patient has not really tried formal diet programs. He is very active in his vocation, but this has not prevented him from gaining weight.
d. Patient's identity	Don Smart
e. Patient's age, gender, height, and weight	42 years, male, 5 ft 4 in., 170 lb

f. Patient's occupation	Rancher
g. Patient's dietary habits	Usually eats eggs, bacon, and toast for breakfast. Usually eats a couple of roast beef or ham sandwiches for lunch. Dinner typically consists of a steak, potatoes, bread, and dessert eaten while watching television with his wife. He drinks a lot of sweetened tea and soft drinks during the day. He also consumes, on average, 2 to 3 beers each evening.
h. Patient's sleep habits	Goes to bed late and gets up early; averages about 6 hours of sleep per night throughout the week.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Takes lisinopril for hypertension, which is currently well controlled. Takes aspirin or ibuprofen occasionally for aches and pains, and lansoprazole as needed for heartburn.
j. Food/drug allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Mr. Smart's BMI is 29, placing him in the overweight category (Table 27-1). Poor dietary habits and inadequate sleep probably contribute.
3. Identify exclusions for self-treatment (Figure 27-3).	None identified.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mr. Smart to a dietitian for dietary advice. (2) Refer Mr. Smart to reputable websites such as myfitnesspal.com for tracking food intake. (3) Refer Mr. Smart to a support group such as Weight Watchers.

	(4) Counsel on diet. (5) Recommend a dietary supplement for weight loss. (6) Recommend orlistat. (7) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Smart chooses to try to get his wife, who also is overweight, on board for them to lose weight together. She is the primary cook, so she will need advice on healthy, lower calorie meal preparation. Mr. Smart also agrees to switch to water as his primary beverage throughout the day, and to cut back on his beer consumption.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Cut back on calorically dense beverages. Reduce portion sizes. Eat mindfully; eating dinner while watching television may contribute to overeating."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Your exercise level is adequate. Your emphasis should be on making healthy diet choices that are enjoyable to you and to establish eating habits that are sustainable."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	n/a
b. Maximum number of days the therapy should be employed	n/a

c. Product administration procedures	n/a
d. Expected time to onset of relief	n/a
e. Degree of relief that can be reasonably expected	“Loss of 1–2 pounds per week is a robust goal of dieting. Loss of even 10 pounds can be beneficial for lowering blood pressure. Maintenance of weight loss can be difficult but is important.”
f. Most common adverse effects	“The more weight you lose, the harder it becomes to lose more weight, because your energy expenditure level drops. Try not to become discouraged when you reach a plateau of weight loss.”
g. Adverse effects that warrant medical intervention should they occur	Criterion does not apply in this case.
h. Patient options in the event that condition worsens or persists	“Consult a dietitian for diet advice. The nonprescription drug orlistat may be an option to help lose weight, although it can have adverse gastrointestinal effects in persons consuming high-fat diets such as yours.”
i. Product storage requirements	None
j. Specific nondrug requirements	“Dietary caloric restriction and exercise are of greatest importance in losing weight. Attempt to reduce stress and thus stress eating. Keep healthy snacks such as fruits and vegetables close at hand during the day. Too little sleep has been associated with increased body weight, so sleep hygiene measures may be helpful.” (See Chapter 46 .)
Solicit follow-up questions from the patient or caregiver.	“Are nuts a good thing for me to snack on?”
Answer the patient’s or caregiver’s questions.	“Nuts are an excellent source of many micronutrients and healthy fats. They do tend to be calorically dense, so portion sizes should be controlled.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mr. Smart to weigh himself twice a week and to record these values. He should return to you in a month

to report on his progress and to discuss his diet. A weight loss of a few pounds over the first month should be considered a success.

Key: BMI = Body mass index; n/a = not applicable; NKA = no known allergies.

Case 27-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	An adolescent girl accompanied by her mother is concerned about her weight. She has been considered overweight since preschool. She would like to lose weight to avoid being teased at school.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient spends most of her day reading and watching television. She has a limited diet consisting mostly of pizza, macaroni and cheese, hot dogs, potato chips, and sweets.
c. Description of the patient's efforts to relieve the symptoms	The patient has tried eating less but has not formally tried to diet since her parents think her weight is normal and healthy.
d. Patient's identity	Taylor Wolfe
e. Patient's age, gender, height, and weight	12 years, female, 4 ft 10 in., 110 lb
f. Patient's occupation	Seventh-grade student

g. Patient's dietary habits	She eats cereal and 2% milk for breakfast with orange juice. She eats lunch in the cafeteria at school. She has a snack after school, usually potato chips or cookies. She eats dinner, including dessert, with her family every night.
h. Patient's sleep habits	Averages about 9 hours of sleep a night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Food/drug allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Patient participates in physical education classes at school every day. She has no other regular exercise activity. Both parents and her older sister and brother are overweight.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Taylor's BMI is 23, placing her in the 90th BMI percentile for age and thus in the overweight category. Her current weight status is associated with increased risk for type 2 diabetes, high cholesterol, hypertension, sleep apnea, and orthopedic problems during adolescence and adulthood. Regular consumption of high-fat and salty snacks and lack of adequate physical activity are contributing to her weight problem.
3. Identify exclusions for self-treatment (Figure 27-3).	Age younger than 18 years is an exclusion for self-treatment.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Taylor to a health care provider for a health screen. (2) Refer Taylor to a dietitian and a personal trainer for diet and exercise advice, respectively. (3) Recommend a dietary supplement weight loss product.

	(4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer Taylor to a health care provider for a health screen.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your health care provider may refer you to a dietitian and/or a personal trainer, or the provider could also offer prescription-strength orlistat."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You need to see your health care provider to determine whether a diet and exercise program is appropriate. Healthy eating habits and exercise are the mainstays of successful weight loss, and these should be a lifelong goal."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Is there a nonprescription medication that might work?"
Answer the patient's or caregiver's questions.	"No nonprescription medications are approved or appropriate to recommend in a patient younger than age 18 without referral from a primary care provider."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Taylor's parents within the next week to ensure she has an appointment for further medical evaluation.

Key: BMI = Body mass index; NKA = no known allergies.

Patient Counseling for Overweight and Obesity

The main objective in counseling patients who want to lose weight is to foster realistic goals for weight loss while also promoting a healthy restricted-calorie diet and increased physical activity. The ultimate goal for the patient is to achieve a healthy weight and maintain that weight over the long term. For patients unable to lose weight, the objective is to prevent further weight gain. The box “Patient Education for Overweight and Obesity” lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Overweight and Obesity

Successful weight loss generally requires a lifelong commitment to an approach that combines healthy eating and exercise patterns. Realistic weight loss expectations might be loss of 5%–10% of the initial weight over 6 months, or 1–2 pounds per week. The patient should be counseled that weight management is a lifelong process and that regain after loss is typical if good lifestyle habits are not continued. During any weight loss program, the patient should be monitored for healthy eating and exercise patterns; at a minimum, blood pressure should be routinely measured. More extensive physical examination and laboratory measures may be indicated, particularly in patients with comorbid conditions such as hypertension or type 2 diabetes. Follow-up with patients attempting weight loss should be encouraged, preferably monthly or more frequently. In addition to measuring weight at follow-up visits, the health care provider should explore eating habits and exercise patterns with the patient, especially if weight loss is not being achieved. Also indicated is reexamination of the previously determined goals,

along with follow-up on the patient's progress; new goals can be selected or modifications introduced, as appropriate. Referral to a dietitian or personal trainer may be helpful. After the desired weight loss has been achieved, the importance of maintaining healthful dietary and exercise habits should be emphasized in the subsequent evaluation. Referral for pharmacologic therapy or consideration of bariatric surgery may be an option for patients with more significant obesity who fail to lose weight through lifestyle interventions.

Patient Education for Overweight and Obesity

The objectives of self-treatment are (1) to foster realistic weight loss and exercise goals, (2) to maintain a healthy weight, and (3) to prevent further weight gain. Carefully following the self-care measures listed here, together with continued adherence to a safe and effective weight loss program, will help ensure optimal therapeutic outcomes.

Objectives of Self-Treatment:

Prevention of Health Risks of Obesity

- Health risks related to overweight and obesity include the following:
 - Coronary heart disease
 - Type 2 diabetes
 - Sleep apnea
 - Elevated serum triglycerides and dyslipidemia
 - Hypertension
 - Stroke
 - Gallbladder disease
 - Osteoarthritis
 - Certain types of cancers

Nondrug Treatment Guidelines

- Focus on small, gradual changes in eating and exercise patterns.
- Maintain realistic goals for weight loss and increased activity levels.
- Eat a low-calorie balanced diet.

- Eat meals at the table, and do nothing else while eating (e.g., no television, texting, or social media interactions).
- Set a regular eating schedule, and avoid skipping meals.
- Eat slowly and enjoy the food.
- Put down your fork or spoon between bites.
- Try to leave some food on your plate each time you eat.
- Wait 5 minutes before going back for extra helpings of food.
- Remove serving dishes from the table after the first servings have been made.
- Leave the table, or at least clear food from the table after eating.
- Use smaller plates so that moderate servings do not appear too small.
- Start a meal with a broth-based soup (low salt) to help you feel fuller.
- Strive to consume at least 5 servings a day of fruits and vegetables.
- Keep on hand healthful snacks such as fruits and vegetables, low-fat cheese and yogurt, and frozen fruit juice bars.
- Drink at least 8 glasses of noncaloric beverages each day to help you feel full.
- When you experience a craving, try doing something else, such as going for a walk; cravings generally pass within minutes.
- Avoid eating after dinner.
- Shop for food immediately after a meal, and use a prepared list.
- Gradually increase your activity level, with the goal of engaging in 60 minutes of moderate-intensity physical activity most days of the week.
- Increase your lifestyle activity: Walk and stand more, climb stairs, and park farther from your destination.
- Limit the amount of time spent watching television, playing video games, or using the Internet.
- Keep a diary of your weight, physical activity, and caloric intake so that you can see your progress and success.

Drug Management Guidelines

- Avoid taking nonprescription drugs and supplements marketed for weight loss, with the exception of orlistat. They are not proved to

work, and they can cause significant adverse effects.

- If you do decide to take one of these products, make sure to notify your primary care provider and pharmacist so that you can be adequately monitored for potential adverse effects and drug interactions.
- Both prescription and nonprescription formulations of orlistat are available; be sure you do not take both forms concurrently.

Key Points for Overweight and Obesity

- A reasonable goal for weight loss in most overweight and obese subjects is a 5%–10% loss over 6 months.
- Although this amount of weight loss may not result in the cosmetic effect desired by the dieter, it is associated with a reduction in risk for chronic disease.
- The safest approach to losing weight entails combining a reduced-calorie diet with increased physical activity.
- Physical activity typically needs to be something the dieter enjoys if it is to be sustained over time.
- A key to sustained weight loss is modification of behavior related to eating and exercise.
- If nonprescription or dietary supplement products for weight loss are used, ongoing assessment for efficacy, safety, and tolerance is warranted. It is essential for patients to report all such products used to the health care provider. Labels of nonprescription or dietary supplement weight loss products should be carefully reviewed to determine the risk for adverse reactions and drug–supplement interactions.

Chapter 28: Ophthalmic Disorders

Authors: Richard Fiscella, Michael K. Jensen

The nonprescription ophthalmic products market offers preparations that treat a wide range of eye-related disorders. Limited population-based data are available on the epidemiology of such disorders. People with ocular complaints commonly are first seen in clinical settings including primary care provider practices, hospital emergency departments, and ophthalmologist or optometrist (i.e., eye care specialist) offices; often, however, they initially consult a pharmacist for specific management recommendations.

Ocular discomfort associated with dry eye disease may be the most common condition for which use of nonprescription ophthalmic products is appropriate. In the United States, dry eye disease may affect as many as 5 million people 50 years of age and older.¹⁻⁵

Many common conditions that cause ocular discomfort are minor and self-limiting. In some instances, however, relatively mild symptoms may be associated with severe, potentially vision-threatening conditions. Health care providers, including today's pharmacists, should be well versed in eye anatomy and physiology, as well as in common ocular conditions and disorders. This knowledge will enable them to offer the best possible guidance for patients who seek help in choosing between self-treatment and professional medical care.

Self-treatable ophthalmic disorders primarily are those affecting the eyelids; a few disorders and conditions involving the eye surface, however, also may be responsive to self-treatment. The latter group includes dry eye, pinguecula, pterygium, allergic conjunctivitis, corneal edema of known etiology, presence of loose foreign debris, minor ocular irritation, and use of an artificial eye requiring cleaning and lubricating. *Careful assessment is important*, especially with evolving or persistent symptoms, to rule out more complicated disorders or conditions that may necessitate referral to an eye care specialist.

Role of Eye Anatomy in Ocular Drug Pharmacokinetics

The external location of the eye, with concomitant exposure of vulnerable tissues, makes it susceptible to environmental and microbiologic contamination. The eye has many natural defense mechanisms to protect it against contamination, however, and the eyelid is one of its major protective elements (Figure 28–1).

Figure 28–1 Anatomy of the eyelid and eye surface.

The *eyelid* consists of a multilayer tissue comprising an external skin covering and an internal thin, mucocutaneous epithelial layer called the palpebral conjunctiva. The eyelids also contain the meibomian and smaller accessory glands. The middle layer of the eyelid contains glandular tissue and muscles for lid movement. This specialized glandular tissue, along with conjunctival goblet cells, secretes the bulk of nonstimulated tears.

The eyelids primarily protect the anterior surface of the eye and, through the blink reflex, spread the tears produced by the glandular tissue over the ocular

surface. The lids force the flow of tears toward the nose and into the drainage canals located in the upper and lower eyelids that form what is known as the puncta. The drainage canals converge, forming the lacrimal sac between the inner eyelid and the nose. The lacrimal sac is drained by a canal opening just below the inferior turbinate of the nasal cavity. A highly vascularized epithelium lines the lacrimal drainage system, and absorption into the systemic circulation along this pathway is the means by which topically administered eye medications can produce systemic effects.^{2,3,6}

The *tear layer* keeps the ocular surface lubricated, provides a mechanism for removing debris that touches the ocular surface, and has potent antimicrobial activity conferred by specific enzymes and a number of immunoglobulin proteins (including the most prevalent, immunoglobulin A). The tear layer is a complex, multilayer film. The outermost, lipid layer, which is secreted from the meibomian and accessory glands (i.e., glands of Moll and Zeis) in the eyelid, maintains the optical properties of the eye and reduces evaporation. The middle, aqueous layer is largely responsible for the wetting properties of the tear film. The innermost, mucinous layer allows the lipid and aqueous layers to maintain constant adhesion across the cornea and conjunctiva. Abnormalities within any one of the tear layers can result in ocular discomfort. Commercial artificial tear products often are formulated to mimic the properties of natural tears, to provide effects that are as physiologic as possible.⁷⁻¹⁸

Tears are produced at a rate of 1–2 μL /minute, with a turnover of approximately 16% of the total volume each minute.^{2,3} As much as 25% of the total tear volume is lost to evaporation.^{2,3} An ambient tear volume of approximately 7–10 μL is found on the ocular surface at any given moment.^{2,3} During episodes of ocular irritation, reflex tearing is stimulated by the lacrimal gland found underneath the outer portion of the upper eyelid, and tear production increases to greater than 300% of the non-stimulated production rate.^{2,3} Reflex tearing occurs immediately on instillation of a drug into the eye, diluting the drug's concentration. Drug penetration into the eye is reduced because of this increase in tear production and lacrimal drainage, sufficient to release teardrops that fall down the cheek. Studies have shown that as much as 90% of an instilled dose of a drug administered to the eye may be lost.^{2,3,6}

The visible external portion of the eye is composed of the normally white, noninnervated sclera, and the normally clear, innervated cornea. The *sclera* is a tough, collagenous layer that gives the eye rigidity and encases the internal

eye structures. The visible sclera is covered by two epithelial layers: the episclera and the bulbar conjunctiva. The bulbar conjunctiva is contiguous with the palpebral conjunctiva at the junction between the eyelid and the ocular surface (the fornix). The episcleral and bulbar conjunctival layers (which contain the vascular and lymphatic systems of the anterior eye surface) are the affected tissues in eye redness from ocular irritation or inflammation.

The *cornea* is dome shaped in contour and consists of an avascular tissue that is the principal refractive element of the eye. The cornea is approximately 12 mm wide and 0.5 mm thick and comprises five distinct layers. The pharmacokinetics of ocularly administered drugs is mediated by three of these layers: the outermost epithelium layer, the middle and most abundant stromal layer, and the innermost endothelial layer. The corneal epithelium is lipophilic and facilitates the passage of fat-soluble drugs. However, if a drug is too lipophilic, it may become entrapped in the corneal epithelium. This epithelial sequestering often is the rate-limiting step in absorption of medication into the anterior chamber. The corneal stroma is hydrophilic and allows the passage of water-soluble drugs. Although the single corneal endothelium layer also is lipophilic, it is not considered a barrier to drug penetration.¹⁸

Damage to the corneal epithelium may often increase drug absorption rates. Comparative studies with intact and compromised epithelium have shown that drug penetration into the aqueous humor may be increased as much as threefold in corneas with compromised epithelium.⁷ Corneal epithelium can be compromised by trauma, routine contact lens wear, topical ocular anesthetics, preservatives, or thermal or ultraviolet (UV) light exposure. Compromise of any layer of the cornea can result in significant vision loss and/or scarring.

Directly behind the cornea is the *anterior chamber*, a cavity filled with aqueous humor. The aqueous humor maintains the normal intraocular pressure (IOP) and provides nutritional support for the cornea and crystalline lens. The aqueous humor is produced by the ciliary body and is drained from the anterior chamber through the uveoscleral tract and the trabecular meshwork. The *trabecular meshwork*, which is located at the junction of the cornea and iris, accounts for approximately 80%–90% of aqueous drainage from the anterior chamber. The *uveoscleral tract* (located posterior to the iris and comprising the sclera, ciliary body, and choroid areas) accounts for approximately 10%–20% of aqueous drainage, although this percentage may

vary with age and disease state.

During episodes of internal eye inflammation, inflammatory cells may block the drainage system, causing the IOP to rise. Increased IOP is one of the most significant risk factors for all types of glaucoma, including primary open-angle glaucoma, primary angle-closure glaucoma, secondary glaucoma, and developmental glaucoma. Similarly, during episodes of primary angle-closure glaucoma, the iris physically blocks the trabecular meshwork, which also results in an increase in IOP. Dilating the pupil with mydriatic drugs may precipitate an acute angle-closure attack. These attacks often occur as the pupil is returning to its normal state several hours after the mydriatic drug has been instilled. Any agent with anticholinergic or dilating effects has the potential to cause angle closure. The most common manifestations of this pathologic event are blurred or hazy vision with perception of halos around lights, brow ache, and headache, often accompanied by nausea and vomiting. These symptoms typically are severe enough to cause affected persons to visit an eye care provider.

The visible, colored portion of the eye, the *iris*, is located in the anterior segment of the eye, behind the cornea. It functions in much the same way as for an aperture on a camera by regulating the amount of light striking the retina. The central opening in the iris is the *pupil*. The pupillary diameter is controlled by two opposing muscles within the iris: the sphincter and the dilator. The sphincter muscle runs along circular arcs parallel to the pupillary border and exerts a miotic (closing) effect through parasympathetic stimulation. The dilator muscles are radial from the pupillary border and exert a mydriatic (opening) effect through sympathetic stimulation. Prostaglandins released by the iris during episodes of inflammation may affect the sphincter muscle, resulting in constriction of the pupil.

The *ciliary body* is bordered anteriorly by the iris and is continuous posteriorly with the choroid. In addition to producing aqueous humor, the ciliary body participates in focusing the optical apparatus (lens) for near viewing—a process known as accommodation. During episodes of ocular inflammation, the ciliary muscle may go into spasm, resulting in fluctuating vision and pain. Therefore, inhibition of the ciliary muscle (cycloplegia) with anticholinergic agents is a frequently used approach to treatment of internal ocular inflammation.

The *vitreous cavity*, located in the posterior segment of the eye, is the largest

portion of the eye and is filled with vitreous humor. Floating spots in the visual field, or “floaters,” have their origin here. Floaters are deposits of various shapes, sizes, and motility in the vitreous humor; they may be related to degenerative changes in gel that is normally transparent. Problems in this area are not amenable to self-treatment and require medical evaluation because of the possibility of concurrent retinal problems.

The *retina* is responsible for the initial processing and transmission of light signals. The optic disc, where the optic nerve (cranial nerve II) exits the eye, transmits visual information from the retina to the brain. The macula is an oval-shaped pigmented area near the center of the retina and is responsible for optimal visual acuity. Several inflammatory conditions of the retina can occur, and most are associated with prominent symptoms. Some, however, cause relatively mild symptoms, mimicking common irritative conditions. Trauma, even minor, may cause the retina to separate from its underlying layer (the pigment epithelium)—that is, retinal detachment. The retinal pigment epithelium provides vital “electrical” support to the retina. Macular degeneration, the leading cause of blindness in the United States, is directly related to atrophy in the pigment epithelium and choroidal neovascularization. Diabetic retinopathy and diabetic macular edema also are major causes of vision loss. Potential manifestations of retinal disease that warrant immediate referral to an eye care specialist include subjective perceptions described as “flickering lights” or “a black curtain coming down” and presence of new large or multiple floaters, as well as sudden loss of vision,

Considerations With Use of Topical Ophthalmic Products

Beyond the specific effects of topical ophthalmic products, other factors to consider in the use of these agents include pH, sterility, stability, and expiration date.¹⁸ The pH of the tear film is approximately 7.4 (i.e., physiologically neutral). Of note, however, topical products such as eye drops may be formulated with a lower or a higher pH because of stability and solubility issues. Fortunately, the eye can respond immediately through reflex tearing to help neutralize any pH deviation. A low concentration of buffer in the drug vehicle also has been used to allow the eye’s natural buffering system to reestablish a normal tear pH.

Pharmacologic agents given topically or systemically can affect uptake of topical ophthalmic agents because of their effects on tissue permeability, fluid secretion, and blood flow. Preservatives, buffers, and vehicles may have some effects on drug absorption (see the section “Pharmacologic Therapy” under “Dry Eye Disease”). Systemic agents such as antihistamines may decrease tear film production, thereby also affecting absorption of topical ophthalmic products.

Sterile products are required for topical ophthalmic formulations to be used in the eyes, whether manufactured or compounded. The determination of drug stability is of importance for commercial ophthalmic products.¹⁸ The U.S. Food and Drug Administration (FDA) requires the manufacturer to demonstrate that at least 90% of the labeled concentration of a drug is present in the active form after storage at room temperature for the specified shelf life. A shelf life of more than 18 months usually is recommended for practical considerations, including warehousing and drug distribution, unless consumer demand for the product is high and rapid turnover can be expected. Once a sealed bottle is opened, the contents are subject to the risk of microbial contamination or oxidation from light exposure. Preservatives (see the section “Pharmacologic Therapy” under “Dry Eye Disease”) are essential in multidose topical products to prevent contamination. Some new ophthalmic medication bottles have filtration systems that may allow the contents of the bottle to be preservative free.

The combination of active drug, vehicle, and preservative may result in a hypotonic formulation (<290 mOsm). Buffering agents, salts, and certain sugars often are added to adjust osmolarity of the solution. The tear film has a wide tolerance to osmotic pressure variation. Of interest, hypotonic solutions may be used to relieve dry eye symptoms by helping reduce high tear osmolarity values often reported in dry eye disease.

Dry Eye Disease

Pathophysiology and Clinical Presentation of Dry Eye Disease

Dry eye disease is among the most common disorders affecting the anterior eye.¹ Most often associated with the aging process (especially in postmenopausal women), dry eye also can be the result of lid or corneal defects, loss of lid tissue turgor, Sjögren syndrome, Bell's palsy, thyroid disorder–related eye disease, or various collagen diseases (e.g., rheumatoid arthritis) and has been associated with use of certain ocular and systemic medications.^{7–13} Dry eye disease has been generally classified by severity for a stepwise system of staged management and treatment recommendations, as follows: mild, for which step 1 (lower-level) interventions are appropriate; moderate, best managed with step 2 options; and severe, with step 3 and step 4 interventions (**Table 28–1**). This classification is imprecise, however, because characteristics of different severity levels can overlap, in accordance with the nature of this disease.^{10,11}

Table 28–1 Staged Management and Treatment Recommendations for Dry Eye Disease^{a–c}

Step 1: Mild Disease

- Education regarding the condition and its management, treatment, and prognosis
- Modification of local environment
- Education regarding potential dietary modifications, including use of systemic omega-3 fatty acid supplements (e.g., flaxseed oil)
- Identification and potential modification/elimination of offending systemic and topical medications
- Presence of ocular lubricants of various types (if MGD is present, consider lipid-containing supplements)
- Lid hygiene and use of warm compresses of various types

Step 2: Moderately Severe Disease

- If above options are inadequate, consider:
- Preservative-free ocular lubricants to minimize preservative-induced toxicity
- Tea tree oil treatment for *Demodex* infection (if present)
- Tear conservation
- Punctal occlusion
- Moisture chamber spectacles/goggles
- Overnight treatments (such as ointment or moisture chamber devices)
- In-office, physical heating and expression of the meibomian glands (including device-assisted therapies such as LipiFlow)
- In-office intense pulsed light therapy for MGD
- Prescription drugs to manage dry eye disease^d
- Topical antibiotic or antibiotic/steroid combination applied to the lid margins for anterior blepharitis (if present)
- Topical corticosteroid (limited duration)

- Topical secretagogues
- Topical nonglucocorticoid immunomodulatory drugs (such as cyclosporine)
- Topical LFA-1 antagonist drugs (such as lifitegrast)
- Oral macrolide or tetracycline antibiotics

Step 3: Severe Disease

If above options are inadequate, consider:

- Oral secretagogues
- Autologous/allogeneic serum eye drops
- Therapeutic contact lens options
 - Soft bandage lenses
 - Rigid scleral lenses

Step 4: Treatment-Resistant Disease

If above options are inadequate, consider:

- Topical corticosteroid for longer duration
- Amniotic membrane grafts
- Surgical punctal occlusion
- Other surgical approaches (e.g., tarsorrhaphy, salivary gland transplantation)

^a Potential variations within the disease spectrum are acknowledged to exist between patients, and the listed management options are not intended to be exclusive. Disease severity and etiology will dictate the range and number of management options selected from one or more step categories. Severity stages are relatively associated with the steps and are guidelines for treatment.

^b One or more options within a step category can be considered concurrently for each stage of disease. Options within a category are not ranked according to importance, and all may be equally valid.

^c Of note, the levels of evidence available to support the various management options differ and will inevitably be lower for newer management options. Thus, each treatment option should be considered in accordance with the level of evidence available at the time management is instigated.

^d The use of prescription drugs needs to be considered in the context of the specific clinical presentation and the relative level of evidence supporting their use for that indication, because these agents differ widely in mechanism of action.

Key: LFA-1 = Lymphocyte function–associated antigen-1; MGD = meibomian gland dysfunction.

Source: Reproduced with minor modifications from Jones L, Downie LE, Korb D, et al. TFOS DEWS II Management and Therapy Report. *Ocul Surf*. 2017;15:575–628. doi: 10.1016/j.jtos.2017.05.006.

The TFOS DEWS II report defines dry eye disease as “a multifactorial disease of the ocular surface characterized by a loss of homeostasis of the tear film, and accompanied by ocular symptoms, in which tear film instability and hyperosmolarity, ocular surface inflammation and damage, and neurosensory abnormalities play etiologic roles.” Most people with symptoms related to ocular surface disease (OSD) suffer from a combination of abnormal meibomian gland physiology (i.e., evaporative dry eye disease) and tear underproduction (i.e., aqueous-deficient dry eye disease).¹⁰

Patients who have undergone refractive surgery may complain of transient dry eyes for weeks to months after the procedure. This effect usually is mild if it does occur, but it can be more pronounced in some patients. Drugs with anticholinergic properties (e.g., antihistamines, antidepressants), decongestants, diuretics, and beta blockers are some of the more common pharmacologic agents that may cause dry eye. The condition may be exacerbated by allergens or other environmental conditions (e.g., dry or dusty working situations), or by exposure to heating and air conditioning systems that reduce relative humidity, thereby increasing the evaporation of tears.

Dry eye disease typically is characterized by a normal-appearing white sclera or a mildly red eye, often associated with patient complaints of a sandy, gritty feeling or a sensation that something is in the eye. Contrary to what its name suggests, this condition often may manifest with excessive tearing initially. Abnormalities in the tear layer cause less-than-optimal lubrication of the ocular surface, with subsequent inadequate tear production and initiation of a vicious circle. Without proper and timely diagnosis and treatment, dry eye disease can eventuate in severe damage to ocular tissues, particularly the corneal surface (see [Color Plates](#), photograph 7). Evidence demonstrates that dry eye disease can be linked to a T cell-mediated inflammatory process, which can respond to treatment with immunomodulatory agents (e.g., cyclosporine).^{8–11}

Treatment of Dry Eye Disease

Early stages of dry eye disease often lend themselves to self-treatment, but as disease severity increases, medical intervention is required. Of note, however, patients with worsening disease often will continue with self-management interventions for step 1 as well as certain step 2 options, as listed in [Table 28–1](#), so the pharmacist should be aware of the potential for dangerous overtreatment in such instances.

Treatment Goals

The goal in treating dry eye disease is to alleviate the dryness of the ocular surface, thereby relieving the symptoms of irritation and preventing possible corneal and noncorneal tissue damage. Although this disorder also has been referred to as “dysfunctional tear syndrome” and “keratoconjunctivitis sicca,” the International Dry Eye Workshop (DEWS) has accepted *dry eye disease* as the most appropriate term.^{1,9} The DEWS I and the updated DEWS II reports, and the recently published preferred practice patterns from the American Academy of Ophthalmology have introduced an accompanying set of guidelines for treatment of dry eye disease.^{9–11}

General Treatment Approach

The primary modality of self-treatment for dry eye disease is the use of ocular lubricants. With disease of mild to moderate severity, however, treatment also may include other pharmacologic and nonpharmacologic recommendations, including patient education, environmental modifications, eyelid-specific therapies, elimination of offending topical or systemic medications, and use of systemic omega-3 fatty acid supplements (e.g., flaxseed oil) ([Table 28–1](#)). The availability of synthetic chemicals suitable for topical application to the eye led to the development of various solutions, so-called artificial tears, to help alleviate dryness of the ocular surface.

Artificial tears products vary by viscosity in accordance with the ingredients used in their preparation. With these products, higher viscosity allows more prolonged ocular contact time and greater resistance to tear dilution. Mild cases of dry eye disease may show improvement with less viscous products,

whereas more severe cases may require more viscous products. Bland (i.e., nonmedicated) ophthalmic ointments (e.g., petrolatum) or gels constitute another type of ocular lubricant. Because ointment preparations tend to cause blurred vision, they typically are reserved for use only at bedtime or for severe cases of dry eye. As with ointments, the more viscous the artificial tears are, the greater their blurring effect becomes. Vitamin A preparations also are available for treating dry eye disease. Specific guidelines for topical ophthalmic vitamin A require further study.

Nonpharmacologic measures (e.g., applying warm compresses, discontinuing any offending agents, maintaining good eyelid hygiene) also may increase eye comfort for patients with this disorder. Dietary modification including supplementation with omega-3 oils or flaxseed oil in the normal doses recommended by the manufacturer is thought to improve lid function, possibly because the products have some anti-inflammatory properties.⁹⁻¹¹

Eye care providers treat the most severe cases of dry eye disease with punctal plugs, which occlude the lacrimal drainage system to increase the available tear pool. Advances in understanding of the underlying pathophysiology of dry eye disease point to potential benefit from treatment with topical nonglucocorticoid immunomodulatory drugs (e.g., topical cyclosporine), topical lymphocyte function–associated antigen-1 (LFA-1) antagonist drugs (e.g., lifitegrast), topical corticosteroid (limited duration), and topical secretagogues.^{8,11} Whereas patients with mild dry eye disease may require only relief of ocular surface dryness, patients with moderate to severe disease may benefit from a combined approach incorporating immunomodulating agents (e.g., topical cyclosporine in conjunction with ocular surface lubrication). Accordingly, signs and symptoms suggestive of moderate to severe dry eye disease dictate referral to an eye care specialist.

Nonpharmacologic Therapy

The primary nondrug measure in self-care for dry eye disease is avoiding environments that increase evaporation of the tear film. If possible, patients should avoid dry or dusty places. Using humidifiers or repositioning workstations away from heating and air conditioning vents may help alleviate dry eye symptoms. In addition, avoiding prolonged use of computer screens and wearing eye protection (e.g., sunglasses, goggles) in windy, outdoor environments may further help alleviate dry eye problems.

Pharmacologic Therapy

Nonmedicated ointments are commonly used in treating minor ophthalmic disorders, including dry eye. Because ointments can cause blurred vision (resulting in severe visual limitations), combination therapy with a nonmedicated ointment plus artificial tears to help offset this undesired effect usually is recommended. Gels offer some clinical advantage in that they disturb vision less compared with ointments and are better tolerated by the patient. The effectiveness of retinol solutions for treating dry eye remains speculative.

Artificial Tear Solutions

Although many advances have been made in elucidating the mechanisms involved in tear film formation, the role of tears in maintaining a normal conjunctival and corneal surface is still not completely understood. Lubricants that are formulated as artificial tear solutions consist of preservatives, inorganic electrolytes to achieve tonicity and maintain pH, and water-soluble polymeric systems. The lubricating agents in artificial tears products are similar in palliative effect in that they all provide ocular lubrication, but buffering agents, preservatives, pH, and other formulation components may vary ([Table 28–2](#)). The newer artificial tear substitutes have important properties, including the ability to stabilize the tear film, protect the corneal and conjunctival cells, reduce tear evaporation with the incorporation of lipids, and enhance wound healing and lubrication of the ocular surface.^{1–3}

Table 28–2 Commonly Used Nonprescription Ophthalmic Lubricants

Trade Name	Primary Ingredient(s)
Artificial Tear Solutions	
Blink Tears, Mild to Moderate	Glycerin 0.3%; propylene glycol 1.0%; EDTA; hydrochloric acid; sodium hydroxide; BAK 0.01%
Bion Tears ^a	Hydroxypropyl methylcellulose 0.3%; dextran 70 0.1%
Clear Eyes Contact Lens Relief Drops	Sorbic acid 0.25%; EDTA 0.1%; NaCl; hydroxypropyl methylcellulose; glycerin
FreshKote PF	Polyvinyl alcohol 2.7%; povidone 2.0%

Trade Name	Primary Ingredient(s)
Lubricant Drops	
GenTeal Lubricant Eye Drops, Mild and Mild to Moderate	CMC; boric acid; phosphonic acid; NaCl; sodium perborate
Moisture Eyes ^b	Propylene glycol 1%; glycerin 0.3%; BAK 0.01%
Murine Tears Lubricant	Povidone 0.6%; PVA 0.5%; BAK
Nature's Tears Eyemist	Hydroxypropyl methylcellulose 2906 0.4%; KCl; NaCl; sodium phosphate; BAK 0.01%; EDTA
Oasis Tears	Glycerin 0.22%; EDTA; potassium sorbate; sodium chloride
Oasis Tears PF, Oasis Tears Plus	Glycerin (0.22%); sodium chloride; sodium hyaluronate
Ocucoat Lubricating ^b	Hydroxypropyl methylcellulose 0.8%; dextran 70 0.1%; BAK 0.01%
Preservative-Free Moisture Eyes ^a	Propylene glycol 0.95%; boric acid; NaCl; KCl; sodium borate; EDTA
Refresh Optive	CMC sodium 0.5%; glycerin 0.9%
Refresh Optive Advanced	CMC sodium 0.5%; glycerin 1%; polysorbate 80 0.5%
Refresh Optive Mega-3 PF	CMC 0.5%; glycerin 1.0%; polysorbate 80 0.5%; castor oil; flaxseed oil
Refresh Optive Repair	CMC sodium; glycerin 0.9%
Refresh Relieva Drops	CMC 0.5%; glycerin 0.9%
Refresh Tears	CMC sodium 0.5%; Purite ^c
Retaine HPMC Drops PF	Hypromellose (hydroxypropyl methylcellulose) 0.3%; citric acid; sodium citrate; sorbitol; water
Retaine MGD Emulsion	Novasorb; light mineral oil 0.5%; mineral oil 0.5%; tyloxapol USP; poloxamer 188; tromethamine; glycerol

Trade Name	Primary Ingredient(s)
Soothe	Restoryl (Drakeol-15 1.0% and Drakeol-35 4.5%); polysorbate 80 0.4%; octoxynol 40; NaCl; sodium phosphate; EDTA; polyhexamethylene biguanide preservative
Soothe PF	Restoryl (Drakeol-15 1.0% and Drakeol-35 4.5%); polysorbate 80 0.4%; octoxynol 40; NaCl; sodium phosphate; EDTA
Soothe XP, Soothe XP Preservative Free	Light mineral oil 1.0% emollient; mineral oil 4.5% emollient
Systane Complete	Propylene glycol 0.6%; boric acid; dimyristoyl phosphatidylglycerol; edetate disodium; hydroxypropyl guar; mineral oil; polyoxyl 40 stearate; Polyquad (polyquaternium-1) 0.001% preservative
Systane Balance	Propylene glycol 0.6%; boric acid; dimyristoyl phosphatidylglycerol; EDTA; hydroxypropyl guar; mineral oil; polyoxyl 40 stearate; Polyquad (polyquaternium-1) 0.001% preservative
Systane Lubricant Drops	PEG-400 0.4%; propylene glycol 0.3%; boric acid; calcium chloride; hydroxypropyl guar; Polyquad (polyquaternium-1) preservative
Tears Again	PVA 1.4%; dibasic sodium phosphate; EDTA; BAK 0.01%
Tears Naturale Forte	Dextran 70 0.1%; hydroxypropyl methylcellulose 0.3%; glycerin 0.2%; polyquaternium-1 0.001%; NaCl; KCl; sodium borate
Tears Naturale Free ^a	Hydroxypropyl methylcellulose 0.3%; dextran 70 0.1%
Tears Naturale II	Hydroxypropyl methylcellulose 0.3%; dextran 70 0.1%; Polyquad 0.001%
TheraTears PF ^a	CMC 0.25%
Nonmedicated Ointments	
Refresh Lacri-Lube ^a	White petrolatum 57.3%; mineral oil 42.5%; lanolin alcohols
Refresh PM ^a	White petrolatum 56.8%; mineral oil 41.5%; lanolin alcohols
Soothe Eye Ointment	Mineral oil 20%; white petrolatum 80%
Systane Lubricant Ointment	Mineral oil 3.0%; white petrolatum 94%; lanolin 3%
Nonmedicated Gels	

Trade Name	Primary Ingredient(s)
Blink Gel Tears	PEG 400 0.25%; boric acid; sodium chloride (OcuPure Brand) as a preservative; sodium hyaluronate
GenTeal Lubricant Eye Gel	Hydroxypropyl methylcellulose 0.3%; sodium perborate 0.028%; carbopol 980; phosphoric acid; sorbitol
TheraTears Gel	CMC 1%, KCl; sodium bicarbonate; NaCl; sodium phosphate
Refresh Celluvisc	CMC 1.0% single-use container
Refresh Liquigel	CMC 1.0%
Refresh Optive Gel	CMC 1.0%; glycerin 0.9%
Systane Gel Drops	PEG 400 0.4%; propylene glycol 0.3%; aminomethylpropanol; boric acid; edetate disodium; hydroxypropyl guar; Polyquad (polyquaternium-1) 0.001% preservative
Systane Lubricant Gel	Hypromellose (hydroxypropyl methylcellulose) 0.3%; carbopol 980; phosphonic acid; purified water; sodium perborate; sorbitol

^a Preservative-free product.

^b Preservative-free formulation available.

^c Stabilized oxychloro complex.

Key: BAK = Benzalkonium chloride; CMC = carboxymethylcellulose; EDTA = ethylenediaminetetraacetic acid; KCl = potassium chloride; NaCl = sodium chloride; PEG = polyethylene glycol; PVA = polyvinyl alcohol; USP = United States Pharmacopoeia.

One class of ophthalmic vehicles or ocular lubricants, in their commonly used ophthalmic formulation concentrations, is the substituted cellulose ethers, which include hydroxypropyl methylcellulose 0.3%–0.8% and carboxymethylcellulose (CMC) 0.5% and 1.0%. CMC 1% often is classified as a “gel” because of its higher viscosity. These solutions are colorless and vary in viscosity depending on the grade and concentration of the cellulose ether. Polyvinyl alcohol (PVA) 1.4%, povidone 0.6%–2.0%, polyethylene glycol 400,

propylene glycol 0.3%–0.6%, and glycerin 0.5%–1.0% are other vehicles commonly used as ocular lubricants.^{14–21} Carbomer polymers (e.g., Carbopol 980) often are added as inactive ingredients but may contribute to increasing viscosity, providing the “gel” component of artificial tears (e.g., GenTeal Severe Dry Eye). Sodium hyaluronate also is classified as an inactive ingredient, although some research suggests that it may promote healing of the corneal epithelium.¹⁴

Combining drugs with these vehicles increases overall viscosity, with consequent enhancement of the pharmacologic effects. The increased viscosity retards drainage of the active ingredient from the eye, thereby increasing the retention time of the active drug and enhancing bioavailability at the external ocular tissues. These effects generally are not accompanied by irritation or toxicity to the ocular tissues. Like the cellulose ethers, PVA also enhances stability of the tear film without causing ocular irritation or toxicity.

Povidone has surface-active properties similar to those of cellulose ethers. This compound is believed to form a hydrophilic layer on the corneal surface, mimicking natural conjunctival mucin. This mucomimetic property has firmly established the usefulness of povidone as an artificial tears formulation. Because this agent promotes wetting of the ocular surface, mucin- and aqueous-deficient dry eyes appear to benefit from its use.

An example of the most commonly recommended and newer products on the market is Refresh Optive Advanced Lubricant Eye Drops, which contains glycerin (0.9%), polysorbate 80 (0.5%), CMC 0.5%, boric acid, castor oil, erythritol, levocarnitine, and carbomer copolymer type A. This product is reported to be a lipid-based, triple-action preparation that helps lubricate and hydrate dry eyes and protects against evaporation of natural tears. Another product, Soothe, is an artificial tear solution that contains a lipid restorative layer, which provides a barrier to prevent loss of the aqueous component of the tears.

Many Systane products combine lubricants such as propylene glycol and/or polyethylene glycol with a gelling and polymer system. Hydroxypropyl guar binds to the hydrophobic corneal surface, forming a glycocalyx or gel-like environment that stays in contact with the ocular surface for a longer period. Systane is said to create an ocular shield, allowing epithelial repair that promotes patient comfort and relief of symptoms. Refresh Optive, a combination of CMC and glycerin, is believed to help protect the corneal epithelium through an osmotic protective effect.

Refresh Optive Mega-3 contains a blend of flaxseed and castor oils in addition to polysorbate 80, CMC, and osmoprotectants (glycerin, L-carnitine, erythritol, and trehalose) for corneal epithelial cell protection. Retaine MGD, Systane Balance, and Soothe XP all contain mineral oil for their lipid layers in addition to other lubricants.

Studies have shown that formulations of artificial tears products without preservatives are less likely than those with preservatives to irritate the ocular surface.^{7,10,13} Providers and patients should be aware, however, that preservative-free products should be discarded immediately after being opened and used. This precaution is needed because the remaining product in the opened container can readily become contaminated, potentially causing infection if applied to the ocular surface.

In most mild cases of dry eye disease, the patient instills drops of artificial tears once or twice a day, typically on arising in the morning and/or before retiring at night ([Table 28–3](#)).¹¹ A regimen of at least twice-daily drops is a good starting point. The viscosity of the drops and amount used can then be adjusted according to the patient's clinical response. For more severe cases, the dosage can be increased to 3–4 times daily. If the patient's clinical needs and response to therapy indicate the need for more frequent use, these solutions may be given as often as hourly. In many cases, use of artificial tears may be continued indefinitely, depending on patient response. Preservative-free products or those with less toxic preservatives (e.g., Purite [sodium perborate]) (see the section “Ophthalmic Preservatives”) are preferred in patients with moderate to severe dry eye disease or those who are sensitive to such agents.

Table 28–3 Administration Guidelines for Eye Drops

1. If you have difficulty determining whether eye drops have been successfully instilled into your eye, refrigerate the solution before administering it—the cold drops on the eye surface are easily detected. Do not refrigerate suspensions, however. Always check the expiration date.
2. Wash hands thoroughly. Wash areas of the face around the eyes. Contact lenses should be removed unless the product is designed specifically for use with contact lenses.
3. Tilt head back. When administering drops to children, have the patient lie down before placing drops in the eyes.
4. Gently grasp lower outer eyelid below lashes and pull eyelid away from eye to create a pouch.
5. Position dropper over eye by looking directly at it, as shown in the drawing.

6. Just before applying a single drop, look up.
7. As soon as the drop is applied, release the eyelid slowly. Close eyes gently for 3 minutes and position the head downward as though looking at the floor (using gravity to pull the drop onto the cornea). Minimize blinking or squeezing of the eyelid.
8. Use a finger to put gentle pressure over the opening of the tear duct.
9. Blot excessive solution from around the eye.
10. If multiple medications are indicated, wait at least 5 minutes before instilling the next eye drop preparation. This pause helps ensure that the first drop is not flushed away by the second and that the second drop is not diluted by the first.
11. If using a suspension, shake the container well before instilling. If using the suspension with another solution dosage form, place the suspension drop last because it has prolonged retention time in the tear film.
12. If both drop and ointment/gel therapy are indicated, instill the drops at least 10 minutes before the ointment/gel so that the ointment/gel does not present a barrier to the drops' penetration of the tear film or cornea.

FDA has warned the public about eye drop bottles with loose plastic safety seals or tamper-evident rings (i.e., collar or band), located below the bottle cap, which may fall onto the eye when the product is used. These devices are supposed to stay connected to the bottle neck. In some instances, a safety seal has dropped onto the user's eye when the bottle was tilted or squeezed. Such rings or seals should not be removed because of the potential to contaminate the tip of the dropper. FDA is identifying all relevant products and requires a revision to the packaging design that recommends a tamper-evident ring.²²

Use of ocular lubricants requires balancing the number of instillations (i.e., drops) per day with the viscosity of the recommended solution and the presence of a preservative. Specifically, as the daily dosage increases, toxicity from preservatives becomes more likely.^{7,13,16}

Although PVA is compatible with many commonly used drugs and preservatives, certain compounds—such as sodium bicarbonate, sodium borate, and the sulfates of sodium, potassium, or zinc— can cause solutions containing PVA to thicken or gel. For example, sodium borate is found in some extraocular irrigating solutions or irrigants and may react with contact lens wetting solutions that contain PVA.¹⁷ Therefore, a certain degree of caution is warranted in recommending solutions containing PVA.

Nonmedicated Ophthalmic Ointments

The primary ingredients in commercial nonprescription ophthalmic ointments ([Table 28–2](#)) are white petrolatum 60% (which contains a lubricant and an ointment base), mineral oil 40% (which helps the ointment melt at body temperature), and lanolin (which facilitates incorporation of water-soluble medications and also prevents evaporation).

The principal advantage of nonmedicated (bland) ointments is their longer retention time in the eye, which appears to enhance the integrity of the tear film. Therefore, mucin- and aqueous-deficient eyes can benefit from the application of lubricating ointments.

Ointment formulations usually are administered twice daily ([Table 28–4](#)). However, depending on the patient's clinical needs and therapeutic response, ointments may be administered as often as every few hours or only occasionally, as needed. Many patients prefer to instill the ointment at bedtime, to keep the eyes moist during sleep and to help prevent morning symptoms of dry eye.

Table 28–4 Administration Guidelines for Eye Ointments/Gels

1. Wash hands thoroughly. Wash areas of the face around the eyes.
2. If both drop and ointment/gel therapy are indicated, instill the drops at least 10 minutes before the ointment so that the ointment does not present a barrier to the drops' penetration of the tear film or cornea.
3. Tilt head back.
4. Gently grasp lower outer eyelid below lashes, and pull eyelid away from eye, as shown in the drawing.
5. Position ointment/gel tube over eye by looking directly at it.
6. With a sweeping motion, place a strip of ointment/gel, $\frac{1}{4}$ to $\frac{1}{2}$ inch wide, inside the lower eyelid by gently squeezing the tube, but avoid touching the tube tip to any tissue surface.
7. Release the eyelid slowly.
8. Close eyes gently for 1–2 minutes.
9. Blot excessive ointment/gel from around the eye.
10. Vision may be blurred temporarily. Avoid activities that require good visual ability until vision clears.

Because of the viscosity of the melted ointment base in the tear film, many patients complain of blurred vision with use of these products. This problem usually can be managed by decreasing the amount of ointment instilled or by administering the ointment at bedtime. Providers should routinely counsel patients to expect blurring of vision with use of eye ointments.

Ointment preparations generally are nonirritating, but preservatives can be toxic to ocular tissues. Some patients develop hypersensitivity reactions, which may prompt them to discontinue therapy. Changing to a single-use and/or preservative-free formulation (e.g., Systane Nighttime, Soothe Nighttime, Refresh PM) may eliminate symptoms associated with use of preservative-containing ointments. Preservative-free products are particularly helpful for use in long-term treatment. As a rule, pharmacists should recommend preservative-free, nonmedicated ointments for the treatment of dry eye to avoid the potential problems associated with preservatives. (See “Preservative-Free Formulations” under “Product Selection Guidelines.”)

Formulation Considerations for Ocular Lubricants and Other Ophthalmic Products

Ocular lubricants and other nonprescription ophthalmic products are formulated to reduce the stinging, burning, and other adverse effects commonly associated with some conventional ophthalmic drugs. With these products, lack of (or minimal) ocular discomfort on instillation is a major advantage, deriving from carefully controlled pH and the presence of buffers, tonicity adjusters, and preservative systems; patients are therefore more likely to adhere to recommended self-treatment regimens. Drug vehicle and preservative systems are among the most important inactive ingredients of these products. Other commonly used vehicles are dextran 70, gelatin, glycerin, hydroxyethylcellulose, methylcellulose, polyethylene glycol, and propylene glycol. Various other ingredients often are included as excipients (i.e., agents to improve tolerability and solubility of artificial tears).

Ophthalmic Preservatives

Preservatives are incorporated into multidose ophthalmic products. These components are intended to destroy or limit the growth of microorganisms inadvertently introduced into the product. Surfactants, one of two distinct groups of preservatives, usually are bactericidal, meaning that they disrupt the

bacterial plasma membrane. Of the quaternary surfactants, benzalkonium chloride (BAK) and benzethonium chloride are preferred by many manufacturers because of their stability, excellent antimicrobial activity, and long shelf-lives. Unfortunately, both agents can have toxic effects on the tear film and the corneal epithelium.^{7,18,19} Long-term use of topical products containing BAK can lead to damage of conjunctival and corneal epithelial cells. Complications associated with use of BAK-containing products include allergy, fibrosis, dry eye disease, and increased risk of failure of glaucoma surgery.^{7,20} Although only a small percentage of patients with dry eye disease experience BAK toxicity, this drawback may become quite problematic for those exhibiting symptoms. Polyquad, a high-molecular-weight quaternary compound, does not bind to contact lenses and may be less toxic than BAK.

Chlorhexidine is useful as an antimicrobial agent in the same range of concentrations as for BAK, yet it is used at lower concentrations in commercial ophthalmic formulations. Because it does not alter corneal permeability to the same extent as with BAK, chlorhexidine is not as toxic to the eye.

The second distinct group of preservatives includes the metals mercury and iodine, their derivatives, and alcohols. With the mercury-based preservatives, patients who become sensitized to thimerosal can develop contact blepharitis or conjunctivitis after several weeks of exposure and must discontinue the use of products that contain it. These products are rapidly disappearing from the marketplace.

Chlorobutanol is less effective than BAK as an antimicrobial preservative and, in fact, tends to break down in bottles during prolonged storage.^{17,18} However, prolonged use of chlorobutanol does not appear to produce allergic reactions. This preservative often is used in 0.5% concentrations and has both antifungal and antibacterial properties.

Methylparaben and propylparaben, both *p*-hydroxybenzoic acid derivatives, have a long history of use in some ophthalmic medications (especially in artificial tears and nonmedicated ointments). However, these preservatives are unstable at high pH and can sometimes induce allergic reactions.

Ethylenediaminetetraacetic acid (EDTA) is a chelating agent that preferentially binds and sequesters divalent cations. EDTA assists the action of thimerosal, BAK, and other agents but can sometimes induce contact allergic reactions.^{17,18}

Sodium perborate (e.g., GenAqua), which has been used extensively as a tooth-bleaching agent, has found a new use as an ophthalmic preservative. The first of two so-called disappearing preservatives, sodium perborate dissociates on contact with the eye to form hydrogen peroxide, which in turn rapidly dissociates to oxygen and water. The amount of hydrogen peroxide formed is so small that it does not produce eye irritation. The second disappearing preservative, a stabilized oxychloro complex (e.g., Purite, OcuPure), also is designed to dissociate on contact with the eye. After exposure to long-wavelength UV light, Purite breaks down quickly to water and sodium chloride. These disappearing preservatives have the advantage of microbial protection while potentially limiting preservative toxicity.

Other, less commonly used ophthalmic preservatives include cetylpyridinium chloride, phenylethyl alcohol, sodium propionate, and sorbic acid.

Ophthalmic Excipients

Other useful excipients are antioxidants, wetting agents, buffers, and tonicity adjusters. Antioxidants prevent or delay deterioration of products that are exposed to oxygen. Wetting agents reduce surface tension, allowing the drug solution to spread more easily over the ocular surface. Buffers are added to help maintain a pH range of 6.0–8.0, thereby preventing ocular discomfort on product instillation. Tonicity adjusters allow the medication to be isotonic with the physiologic tear film. Products in the sodium chloride equivalence range of 0.9%–1.2% are considered isotonic; use of these products helps limit ocular irritation and tissue damage. Solutions in the tonicity range of 0.6%–1.8% usually cause no discomfort when instilled in the human eye. Hypertonic solutions used for corneal edema are not well tolerated.

Product Selection Guidelines

Clinical results and patient acceptance remain the final criteria for determining a product's efficacy in the treatment of dry eye. Of importance, no single formulation has yet been identified that will universally relieve clinical signs and symptoms while maintaining patient comfort and acceptance.^{16,17} If symptoms do not subside after 72 hours of treatment, the patient should be encouraged to seek further assessment from an eye care specialist.

Preservative-Free Formulations

In recent years, artificial tears preparations have been introduced in preservative-free formulations and, more recently, in disappearing-preservative formulations. These preparations are beneficial for patients who are sensitive to preservatives such as BAK and thimerosal, those who use drops frequently, and those with compromised corneas. Products such as GenTeal (Mild to Moderate or Moderate to Severe), Refresh Optive, Refresh Tears, and lubricant gels such as Systane Lubricant Eye Gel and Tears Again Liquid Gel, are uniquely formulated to allow the preservative to rapidly dissociate into nontoxic components on the ocular surface. True preservative-free artificial tears preparations (e.g., Refresh Optive Advanced Preservative Free, Soothe Preservative Free, Blink Tears Preservative Free) are available in a variety of unit-dose dispensers. Some of these products are formulated to provide electrolyte support to the damaged surface epithelium of the eye. Preservative-free formulations not only are more expensive than preserved artificial tear solutions but also are easily contaminated during use. Therefore, patient counseling should emphasize the need to follow strict hygienic procedures for self-administration and to discard any unused product immediately after opening and using it.

Associated Lesions

Pingueculae are yellowish bumps, often located on the midportion of the sclera between the eyelids that is exposed to the sun. They are believed to be caused by UV light from the sun and exposure to dust and wind. Dry eye disease may contribute to enlargement or exacerbation of these lesions. Recommended treatment may include use of artificial tears to alleviate symptoms of dry eye, including itching, burning, and foreign body sensation. Wearing sunglasses to protect the eye from UV light, even on overcast days, also is recommended.

A *pterygium* is a benign, elevated growth, often triangular in shape, on the eye surface that typically starts on the sclera and continues to grow onto the cornea. These lesions also are believed to be caused by UV light from sun exposure, dust, and wind. Continued growth may cause ocular discomfort and blurry vision. Many patients may not experience symptoms or require treatment except in concert with symptoms seen with dry eye disease such as itching, burning, and dryness. Occasionally a pterygium can become inflamed,

with consequent hyperemia. Continued growth onto the cornea may even cause astigmatism and affect vision. Small pterygia often can be managed with use of artificial tears or lubricants. Reduced UV sunlight exposure with sunglasses and protection from dust and wind also are warranted. Larger lesions may be of concern because of their cosmetic appearance and/or may require surgical removal.

Allergic Conjunctivitis

Pathophysiology and Clinical Presentation of Allergic Conjunctivitis

The list of antigens that can cause ocular allergy is virtually endless, but the most common allergens include pollen, animal dander, and topical eye preparations. Patients with ocular allergy often report seasonal allergic rhinitis as well. Allergic conjunctivitis is characterized by a red eye with watery discharge (see [Color Plates](#), photograph 8). The hallmark symptom of ocular allergy is *pruritus* (itching). Vision usually is not impaired but may be blurred because of excessive tearing. Contact lenses should not be used until the allergic symptoms resolve.²³

Treatment of Allergic Conjunctivitis

Treatment Goals

The goals in treating allergic conjunctivitis are (1) to remove or avoid the allergen, (2) to limit or reduce the severity of the allergic reaction, (3) to provide symptomatic relief, and (4) to protect the ocular surface.²³

General Treatment Approach

Treatment often is directed at the root cause of the symptoms. Questioning the patient about exposure to allergens may help identify the offending substance. Removal or avoidance of the responsible allergen is the best

therapeutic strategy, but nonprescription ocular lubricants, ocular decongestants, ocular decongestant/antihistamine preparations, ocular antihistamine/mast cell stabilizer combination agents, oral antihistamines, and application of cold compresses will help relieve symptoms.^{24–28} Oral antihistamines often are used by patients with allergy symptoms; however, use of such agents has been associated with dry eye and can worsen the condition.

Nonpharmacologic Therapy

In addition to removing and/or avoiding exposure to the offending allergen, applying cold compresses to the eyes 3–4 times per day will help reduce redness and itching. Other important measures for avoiding the allergic response include checking the pollen count, keeping doors and windows closed, using hypoallergenic bedding, washing clothes frequently, bathing or showering just before bedtime, running the home's air conditioning system, using air filters, and so on. If eyes are itchy, cool compresses often provide some relief.^{24,29} Wearing sunglasses outdoors will shield eyes from the wind and allergens for many patients.

Pharmacologic Therapy

First-line treatment for allergic conjunctivitis is instillation of artificial tears (possibly refrigerated, in accordance with pharmacist recommendations) as needed (see [Tables 28–1](#) and [28–3](#)). Artificial tears may help wash out the allergens and provide some symptom relief.^{23,24} If symptoms persist, the patient should switch to an ophthalmic antihistamine/mast cell stabilizer or possibly a histamine type 1 (H₁) receptor antagonist product. The reclassification of products from prescription to nonprescription status has been a very favorable improvement for the treatment of allergic conjunctivitis. Ketotifen fumarate 0.025% (e.g., Zaditor, Alaway) is very safe and can be used in patients 3 years of age and older; it is dosed twice daily and is very effective in relieving the signs and symptoms of allergic conjunctivitis. As specified in the product name, Pataday Twice Daily Relief (olopatadine 0.1% solution) is dosed twice daily and Pataday Once Daily Relief (olopatadine 0.2% and 0.7% solution) once daily. Both are safely used in patients 2 years of age and older. Although a definite time period of treatment has not been well studied, the combination antihistamine/mast cell stabilizer products have been used for symptom management over many years. An oral antihistamine can be added to the

second treatment option, if needed. Medical referral is indicated if symptoms do not resolve after 72 hours of appropriate treatment.

Other nonprescription ophthalmic products designated specifically for treatment of allergic conjunctivitis include decongestants (often in combination with antihistamines) and, more recently, the antihistamine/mast cell stabilizer combination. (See [Chapter 11](#) for discussion of systemic nonprescription antihistamines and topical corticosteroids.)

Ophthalmic Decongestants/Alpha-Adrenergic Agonists

Five nonprescription decongestants are available for topical application to the eye: phenylephrine, naphazoline, tetrahydrozoline, oxymetazoline, and brimonidine. Decongestants reduce ocular redness by acting as local vasoconstrictors. In nonprescription ophthalmic products, phenylephrine is available in concentrations of 0.12% or lower. Higher concentrations of phenylephrine (2.5% and 10%) are prescription products and often are used for pupillary dilation. Naphazoline, tetrahydrozoline, and oxymetazoline are chemically classified as imidazoles. Higher concentrations of brimonidine at 0.1%–0.2% are used to lower intraocular pressure in open-angle glaucoma or ocular hypertension. These agents are available as solutions in a variety of concentrations ([Table 28–5](#)).

Phenylephrine acts primarily on alpha-adrenergic receptors of the ophthalmic vasculature to constrict conjunctival vessels, thereby reducing eye redness. The imidazoles also have greater alpha- than beta-receptor activity and are therefore clinically useful in constricting conjunctival blood vessels. These agents have only minimal effect on the underlying vessels of the episclera and sclera. Vasoconstrictors are effective in constricting conjunctival vessels, with consequent reduction in redness, vascular congestion, and eyelid edema, but they do not diminish the allergic response.^{24–28,30} [Table 28–6](#) lists dosages of ophthalmic decongestants.

When used as directed, ocular decongestants generally do not induce ocular or systemic adverse effects. However, presence of these products in households with young children and the use of such agents in this age group are risk factors that require patient education for prevention of adverse events. Ingestion of these agents can result in coronary emergencies and death. When used excessively or for other than brief periods, ocular decongestants

have the potential to produce rebound conjunctival hyperemia (i.e., rebound redness due to conjunctival congestion), allergic conjunctivitis, and allergic blepharitis.²⁵ Accordingly, they should not be used for more than 72 hours. Rebound congestion appears to be less likely with topical ocular use of naphazoline or tetrahydrozoline than with use of oxymetazoline or phenylephrine. Rebound congestion may be experienced within a few days of initiating treatment, and a case was reported within 8 hours of use.²⁵ Minimal rebound redness was reported with brimonidine 0.025% for 7 days on discontinuation after 4 weeks of treatment.²⁷ Patients with apparent rebound congestion should be referred to an eye care specialist for further evaluation and appropriate management.

Indiscriminate use of most decongestants in an irritated eye can induce papillary dilation and may precipitate angle-closure glaucoma in eyes that have narrow anterior chamber angles. Use of these products in angle-closure glaucoma is contraindicated, and health care providers should counsel patients with angle-closure glaucoma against using these products for treating allergic conjunctivitis.

Some patients may experience epithelial xerosis (abnormal dryness) from prolonged topical instillation of ocular decongestants, which may exacerbate the symptoms of irritation, pain, and dryness associated with allergic conjunctivitis.

Caution is warranted with use of ocular decongestants by patients with systemic hypertension, arteriosclerosis, other cardiovascular diseases, or diabetes. Adverse cardiovascular events also are possible when these agents are used in patients with hyperthyroidism.²⁶ Because of these possible adverse reactions, patients should not use phenylephrine and other ocular decongestants as ocular irrigants. During pregnancy, women should be advised to use ocular decongestants only sparingly, if at all. Instillation of solutions that have been stored at high temperatures has been associated with ocular reactions and severe mydriatic responses. In such cases, if signs or symptoms do not resolve within 72 hours, the patient should see an eye care specialist.

Brimonidine 0.025% (Lumify) is a recently approved nonprescription ocular decongestant for the treatment of ocular redness in adults and children older than 5 years. This selective alpha-2 adrenergic receptor agonist dosed at 4 times daily for 4 weeks was evaluated in a prospective, randomized, double-

masked, vehicle-controlled trial.²⁷ Brimonidine 0.025% was found to significantly reduce ocular redness, was not associated with tachyphylaxis, and exhibited rare rebound redness. Brimonidine 0.025% appears to be better tolerated than other decongestants, although controlled trials comparing the various agents have not been completed.

Ophthalmic Antihistamines and Ophthalmologic Antihistamine/Mast Cell Stabilizer Combinations

Two nonprescription antihistamines are available for topical ophthalmic use: pheniramine maleate and antazoline phosphate. Although either agent is effective alone, nonprescription products containing these antihistamines also contain a decongestant. The two combinations are pheniramine/naphazoline and antazoline/naphazoline ([Table 28–5](#)).

Table 28–5 Commonly Used Nonprescription Ophthalmic Products Containing Decongestants, Antihistamines, and/or Astringents

Trade Name	Primary Ingredient(s)
Decongestant Eye Drop Products	
Clear Eyes	Naphazoline HCl 0.012%; glycerin 0.25%; BAK
Clear Eyes Itchy Eye Relief	Naphazoline 0.012%; BAK; EDTA; zinc sulfate 0.25%; glycerin 0.2%
Lumify	Brimonidine tartrate 0.025%; BAK; boric acid; glycerin
Murine Plus for Dry Eyes	Tetrahydrozoline HCl 0.05%; povidone 0.6%; PVA 0.5%; BAK
Opti-Clear	Tetrahydrozoline 0.05%; BAK 0.01%; boric acid; EDTA; sodium borate; NaCl
Visine Advanced Relief	Tetrahydrozoline HCl 0.05%; PEG 400 1.0%; povidone 1.0%; BAK 0.01%; dextran 70, 1.0%

Trade Name	Primary Ingredient(s)
Visine Original	Tetrahydrozoline HCl 0.05%; BAK 0.01%
Antihistamine/Mast Cell Stabilizer Eye Drop Products	
Zaditor, Alaway	Ketotifen 0.025%; BAK 0.01%; glycerol; sodium hydroxide and/or hydrochloric acid; purified water
Pataday Twice Daily Relief	Olopatadine 0.1%; BAK 0.01%; dibasic sodium phosphate; HCl sodium hydroxide (adjust pH); purified water; sodium chloride
Pataday Once Daily Relief 0.2%	Olopatadine 0.2%; BAK chloride 0.01%; dibasic sodium phosphate; hydrochloric acid/sodium hydroxide (adjust pH); purified water; and sodium chloride
Pataday Once Daily Relief 0.7%	Olopatadine 0.7%; povidone; hydroxypropyl-gamma-cyclodextrin; polyethylene glycol 400; hydroxypropyl methylcellulose; boric acid; mannitol; BAK 0.015%; hydrochloric acid/sodium hydroxide (to adjust pH); purified water
Antihistamine/Decongestant Eye Drop Products	
Naphcon A	Pheniramine maleate 0.3%; naphazoline HCl 0.025%; BAK 0.01%
Opcon-A	Pheniramine maleate 0.315%; naphazoline HCl 0.02675%; hydroxypropyl methylcellulose 0.5%; BAK 0.01%
Visine-A	Pheniramine maleate 0.3%; naphazoline HCl 0.025%; BAK 0.01%
Decongestant/Astringent Eye Drop Products	
Clear Eyes ACR	Naphazoline HCl 0.012%; zinc sulfate 0.25%; glycerin 0.2%; BAK
Zincfrin	Phenylephrine HCl 0.12%; zinc sulfate 0.25%; BAK 0.01%
Zinc Sulfate Eye	Zinc sulfate 0.4%

Trade Name	Primary Ingredient(s)
Drops	

^a Preservative-free formulation.

Key: BAK = Benzalkonium chloride; EDTA = ethylenediaminetetraacetic acid; HCl = hydrochloride; NaCl = sodium chloride; PEG = polyethylene glycol; PVA = polyvinyl alcohol.

Pheniramine and antazoline are in different antihistamine classes, but both act as specific H₁ receptor antagonists.^{28–30} Topical antihistamines are used for rapid relief of symptoms associated with seasonal or atopic conjunctivitis. Using a decongestant with either of these topical antihistamines has been shown to be more effective than using either agent alone.^{28–30}

Ketotifen fumarate is a combination ophthalmic antihistamine/mast cell stabilizer. It has very potent H₁ receptor antagonist activity, thereby preventing acute histamine-mediated allergy symptoms. The mast cell stabilization activity inhibits mast cell degranulation, preventing the release of inflammatory mediators, including histamine. Ketotifen also inhibits eosinophils, which in turn inhibits the release of late-phase mediators. Ketotifen provides relief within minutes, its effects may last up to 12 hours from a single dose, and it does not contain a vasoconstrictor.^{24,28} It is therefore a very safe product, raising no concerns for vasoconstrictor overuse.

Another recently approved nonprescription combination antihistamine/mast cell stabilizer is olopatadine HCl. It is available in two formulations: Pataday Twice Daily Relief (olopatadine HCl ophthalmic solution 0.1%) is approved for the temporary relief of ocular itching and redness due to pollen, ragweed, grass, and animal hair or dander. Pataday Once Daily Relief (olopatadine HCl ophthalmic solution 0.2% and 0.7%) is approved for the temporary relief of ocular itching due to pollen, ragweed, grass, and animal hair or dander. These products were previously available for many years as prescription drugs and have proved to be very safe and effective.

Table 28–6 provides dosages of the antihistamine combination products. Burning, stinging, and discomfort on instillation are the most common adverse effects of ophthalmic antihistamines.^{24,28,30}

Table 28–6 Dosage Guidelines for Nonprescription Ophthalmic Decongestants and Antihistamines				
Agent	Nonprescription Concentration (%)	Dosage	Duration of Action (hours)	Duration of Use
Decongestant Products^a				
Phenylephrine	0.12	1–2 drops up to 4 times/day	0.5–1.5	72 hours
Naphazoline	0.1, 0.12, 0.02, 0.03	1–2 drops up to 4 times/day	3–4	72 hours
Oxymetazoline	0.025	1–2 drops every 6 hours	4–6	72 hours
Tetrahydrozoline	0.05	1–2 drops every 4 hours	1–4	72 hours
Brimonidine	0.025	1 drop up to 4 times daily	6–8	4 weeks
Antihistamine/Mast Cell Stabilizer^b Products				
Olopatadine	0.1/0.2	1 drop every 12 (0.1) or/24 (0.2) hours	12/24	>72 hours
Ketotifen	0.025	1 drop every 8–12 hours	8–12	>72 hours
Decongestant/Antihistamine Products				
Naphazoline/ pheniramine	0.025 (naphazoline)	1–2 drops 3–4 times/ day	3–4	72 hours
	0.3 (pheniramine)			
Naphazoline/ antazoline	0.05 (naphazoline)	1–2 drops 3–4 times/ day		72 hours
	0.5 (antazoline)

^b Zaditor [product insert]. Novartis Pharmaceuticals Corporation, East Hanover, NJ.

Ophthalmic antihistamines have anticholinergic properties and may cause pupillary dilation. This effect is seen most commonly in people with light-colored irises or compromised corneas (e.g., from contact lens wear).^{28–30} In susceptible patients, pupillary dilation can lead to angle-closure glaucoma. Therefore, these agents are contraindicated in persons recognized to be at risk for angle-closure glaucoma.^{28–30} Sensitivity to any of the components is another contraindication.

Product Selection Guidelines

After artificial tear solutions, ketotifen and olapatadine are the second safest and most effective products for the treatment of allergic conjunctivitis. Once- or twice-daily dosing and proven safety for use in children 2–3 years of age and older make either of these agents the primary option for self-treatment for signs and symptoms of allergic conjunctivitis.

Although product-to-product comparisons are available for decongestant and antihistamine ophthalmic products, definitive conclusions regarding clinical comparisons of the available nonprescription ocular decongestants are difficult to establish. Naphazoline 0.02%, however, is an excellent choice for nonprescription therapy for mild to moderate conjunctivitis of environmental, viral, or noninfectious origin because it can be soothing, reduces redness, and does not mask signs of infection if used for 72 hours or less.^{24,28,30}

Because rebound congestion appears to be less likely after topical ocular use of naphazoline or tetrahydrozoline, these agents generally should be recommended over phenylephrine or oxymetazoline.

Complementary Therapies

The homeopathic product known as Similasan Eye Drops #2 is indicated for

relief from itching and burning caused by allergic reactions. The active homeopathic ingredients are Apis, Euphrasia, and Sabadilla. The efficacy of this formulation has not been established in controlled clinical trials.

Corneal Edema

Pathophysiology and Clinical Presentation of Corneal Edema

Corneal edema may occur with any of a variety of conditions, including overwear of contact lenses, surgical damage to the cornea, and inherited corneal dystrophies. The edematous area of the cornea often is confined to the epithelium. Because the accumulated fluid distorts the optical properties of the cornea, subjective perception of halos or starbursts around lights (with or without reduced vision) is a hallmark symptom of corneal edema. An eye care specialist must diagnose this disorder before self-treatment is attempted.

Treatment of Corneal Edema

Treatment Goals

The goal in treating corneal edema is to draw fluid from the cornea, thereby relieving the associated symptoms.

General Treatment Approach

Once the diagnosis is established, patients can use topical hyperosmotic formulations to treat corneal edema. Of the topical ophthalmic hyperosmotic agents available, only sodium chloride can be obtained without a prescription in both solution and ointment formulations ([Table 28–7](#)). Sodium chloride is available as a 2% or 5% solution and as a 5% ointment. First-line treatment is instillation of a 2% solution 4 times per day. If symptoms persist for more than 1–2 weeks, nighttime use of a 5% hyperosmotic ointment should be added to the regimen.³¹ If symptoms do not abate after 1–2 weeks of the augmented

regimen, the patient should switch to a 5% hyperosmotic solution and continue nighttime use of the ointment. If symptoms still persist without relief after another 1–2 weeks, medical referral is necessary.³¹

Table 28–7 Commonly Used Miscellaneous Nonprescription Ophthalmic Products

Trade Name	Primary Ingredients
Hyperosmotics	
AK-NaCl Solution	NaCl 5%; methylparaben 0.023%; propylparaben 0.01%; boric acid; hypromellose (hydroxypropyl methylcellulose) 2906; propylene glycol
AK-NaCl Ointment ^a	NaCl 5%; lanolin oil; mineral oil; white petrolatum
Muro 128 Solution 2%	NaCl 2%; hydroxypropyl methylcellulose 2906; methylparaben 0.046%; propylparaben 0.02%; propylene glycol; boric acid
Muro 128 Solution 5%	NaCl 5%; boric acid; hydroxypropyl methylcellulose 2910; propylene glycol; methylparaben 0.023%; propylparaben 0.01%
Muro 128 Ointment ^a	Mineral oil; white petrolatum; lanolin
Irrigant Solutions	
Bausch + Lomb Eye Wash	Sodium borate; boric acid; NaCl; sorbic acid 0.1%; EDTA 0.025%
Bausch + Lomb Eye Wash Eye Irrigating Solution	Boric acid; sodium borate; NaCl; preserved with BAK chloride 0.01% in purified water
Collyrium for Fresh Eyes	Boric acid; sodium borate; BAK
Eye Stream	Sodium acetate 0.39%; sodium citrate 0.17%; sodium hydroxide and/or hydrochloric acid; BAK
Prosthesis Lubricant/Cleaner	
Enuclene Solution	Tyloxapol 0.25%; hydroxypropyl methylcellulose 0.85%; BAK 0.02%
TheraTears SteriLid Eyelid Cleanser	Water; PEG-80; sorbitan laurate; sodium trideceth sulfate

^a Preservative-free formulation.

Key: BAK = Benzalkonium chloride; EDTA = ethylenediamine tetraacetic acid; NaCl = sodium chloride; PEG = polyethylene glycol.

Pharmacologic Therapy

Hyperosmotics

Hyperosmotic agents increase the tonicity of the tear film, promoting movement of fluid from the cornea to the more highly osmotic tear film. Normal tear flow mechanisms then eliminate the excessive fluid. Many patients with mild to moderate corneal epithelial edema may experience subjective improvement in comfort and vision after appropriate use of these medications.

Usually, 1–2 drops of the solution are instilled every 3–4 hours ([Table 28–3](#)). The ointment formulation, however, requires less frequent instillation and usually is reserved for use at bedtime to minimize symptoms of blurred vision ([Table 28–4](#)). Because vision associated with corneal edema often is worse upon awakening, several instillations of the solution during the first few waking hours may be helpful.

In general, sodium chloride 5% in ointment form is the most effective product for reducing corneal edema and improving vision, but it tends to cause stinging and burning. For that reason, patients often prefer the 2% solution for long-term therapy. Hypertonic saline is nontoxic to the external ocular tissues, and allergic reactions are rare.³¹

The most important contraindication to the use of topical hyperosmotic sodium chloride is traumatic injury of the corneal epithelium. In such cases, this agent must not be given to treat associated corneal edema. The intact corneal epithelium permits only limited permeability to inorganic ions; therefore, an absent or compromised corneal epithelium will result in increased corneal penetration of the hyperosmotic product, reducing its osmotic effect.³¹ If the clinical history or the physical appearance of the eye suggests a damaged corneal epithelium, the affected person should be referred to an eye care specialist immediately. It is essential to warn patients

against preparation of homemade saline solutions for use in the eye because of the associated risk of infection.

Loose Foreign Substances in the Eye

Pathophysiology and Clinical Presentation of Loose Foreign Substances in the Eye

Despite the protective effect of the eyelids, foreign substances often contact the ocular surface. The immediate clinical manifestations are pain and watering (tearing). If exposure to the substance causes only minor irritation, with no abrasion of the eye surface, self-treatment is appropriate.³²

Treatment for Loose Foreign Substances in the Eye

Treatment Goals

The goal in treatment for loose foreign substances in the eye is to remove the irritant by copious irrigation. If a known foreign substance is a fragment of wood or metal, prompt attention from an eye care specialist is imperative because of the associated potential for penetrating injuries.

General Treatment Approach

If reflex tearing does not remove the foreign substance, the eye may need to be flushed. Lint, dust, and similar materials usually can be removed by rinsing the eye with sterile specific eyewash preparations (irrigants). Outside of a clinical setting, loose particles can be washed away by flushing the eyes with copious amounts of water from a sink faucet or even a garden hose. If needed, nonmedicated ophthalmic petrolatum ointment can be applied at bedtime.³² Ophthalmic petrolatum provides prolonged duration of protection, and the associated blurry vision does not pose a problem while the patient is sleeping.

Pharmacologic Therapy

Ocular Irrigants

An ocular irrigant is used to cleanse ocular tissues while maintaining their moisture; these solutions must be physiologically balanced with respect to pH and osmolality. Because the tissues that the irrigant contacts obtain nutrients (e.g., immunoglobulins, mucins) elsewhere, the role of irrigants is primarily to clear away unwanted materials or debris from the ocular surface. To reduce risk of contamination, patients should use ocular irrigants only on a short-term basis, and they should be alert to any further signs or symptoms that may point to other pathologic processes involving the eye. All ophthalmic irrigating solutions are available without a prescription ([Table 28–7](#)).

In the eye care provider's office, irrigating solutions are essential to certain clinical procedures, and they often are used to wash away mucous or purulent exudates from the eye. These solutions also are administered in the hospital setting to cleanse eye tissues between changes of ocular dressings.

Ocular irrigants should not be used for open wounds in or near the eyes. Patients should instead seek immediate medical attention and not place any solution in the eye. Although irrigating solutions may be used to wash out the eyes after contact lens wear, they have no particular value as contact lens wetting, cleansing, or cushioning solutions.

If the patient experiences unremitting eye pain, changes in vision, continued redness, irritation of the eye, or if the ocular condition persists or worsens, evaluation by an eye care specialist is strongly recommended. Irrigants may be packaged with an eyecup; however, because contamination of the eyecup is possible, it should never be used by anyone to rinse the eye.

Minor Eye Irritation

Pathophysiology and Clinical Presentation of Minor Eye Irritation

Nonallergic, minor eye irritation can be caused by a loose foreign substance in the eye, contact lens wear, or exposure of the eye to wind, sun (e.g., during snow skiing without protective eye goggles), smog, or chemical fumes including swimming pool chlorine. Redness of the eye is a common sign of minor irritation. In cases of snow blindness (i.e., temporary overexposure to light from the reflection off the snow), other burns from UV light (e.g., sunlamps), or arc welder's burns, common additional symptoms include pain and the subjective feeling of "sand in the eyes."

Treatment of Minor Eye Irritation

Minor irritation often responds well to instillations of artificial tear solutions or nonmedicated ointments (see "Treatment of Dry Eye Disease").

Zinc sulfate, a mild astringent, may be recommended for temporary relief of minor ocular irritation. The dosage is 1–2 drops up to 4 times daily.

The homeopathic product known as Similasan Eye Drops #1 is marketed to relieve dryness and redness caused by smog, contact lens wear, and other factors. The active homeopathic ingredients are Belladonna, Euphrasia, and Mercurius sublimatus. Controlled clinical trials have not demonstrated the efficacy of this formulation in the treatment of dry eye disease. This product is not approved by FDA.

Chemical Burn

Pathophysiology and Clinical Presentation of Chemical Burn

Chemical burns may occur from exposure to alkalis (e.g., oven cleaners, cement, lye), acids (e.g., battery acid, vinegar), detergents, and various solvents and irritants (e.g., tear gas, pepper spray, Mace). Chemical burns range in degree from mild to severe, depending on the inciting agent and/or exposure time. Patients complain of pain, irritation, photophobia, and tearing. Signs will vary according to the severity of injury. With less severe chemical burn injury,

clinical signs include superficial *punctate keratitis* (characterized by small pinpoint lesions associated with loss of epithelial cells in the cornea), perilimbal ischemia, chemosis, hyperemia, eyelid edema, hemorrhages, and concomitant first- or second-degree burns of the lid and outer skin. With more severe chemical burn injury, signs include corneal edema and opacification, anterior chamber inflammation, increased IOP, and retinal toxicity from scleral penetration. Alkali burns are more penetrating and potentially more damaging to eye tissues than acid burns. Alkali burns often are more resistant to irrigation and are associated with greater tissue destruction when they penetrate the deeper (stromal) layers of the cornea. If the burns are more superficial and only several layers of the corneal epithelium have been affected, the cells should be replenished within approximately 24 hours.³²

Emergency Treatment of Chemical Burn

Emergency treatment includes immediate copious irrigation with sterile ocular irrigants ([Table 28–7](#)), or with tap water if nothing else is available. Irrigation must be continued until an eye care specialist can be seen; if irrigation is stopped prematurely, residual material that may still be under the lid or in the inferior cul-de-sac may cause the pH of the tear film to revert to either acidic or alkaline.³² Further treatment after irrigation may include the use of cycloplegic agents, ophthalmic antibiotics, and analgesics. Most acid or alkali burns often are not treated with neutralizing solutions because it is difficult to determine the actual pH, which often continues to change; in such instances, overtreatment may cause even more severe injury. In more severe cases, if significant inflammation of the anterior chamber or cornea is present, ophthalmic steroids may be prescribed. Antiglaucoma medications also are used if the IOP is elevated. Follow-up evaluation and management by an eye care provider are required to prevent development of conjunctival adhesions and corneal complications. Chemical burns are considered ophthalmic emergencies, and patients with a history or clinical manifestations consistent with such injury should be immediately referred to an eye care specialist or hospital emergency department physician.

Artificial Eyes

Besides the obvious aesthetic benefits, clearing dried mucus or fluid secretions from the surfaces of artificial eyes eliminates a potential medium for bacterial growth. A sterile, isotonic buffered solution containing tyloxapol 0.25% and BAK 0.02% is available specifically for cleaning and lubricating ophthalmic prostheses. The primary method of preventing bacterial growth is routine hygiene with mild, nonallergenic soap and water.

Tyloxapol is a surfactant that softens solid matter on the prosthesis, and BAK aids tyloxapol in wetting the artificial eye. The solution is used in the same manner as for ordinary artificial tears. With the artificial eye in place, 1–2 drops of solution should be applied 3–4 times daily. In addition, the solution can be used as a cleanser to remove oil or mucus deposits; in this case, the artificial eye is removed, rubbed between the fingers and thumb, and then rinsed with tap water before reinsertion.

Contact Dermatitis of the Eyelid

Pathophysiology and Clinical Presentation of Contact Dermatitis of the Eyelid

Contact dermatitis of the eyelid can be a reaction to either an allergen or an irritant. Recognized etiologic factors include a change in cosmetics or soap, adverse effects of eye medications, and contact with other foreign substances. The involvement of both eyelids suggests allergy because such reactions typically follow general exposure rather than localized irritation. Common clinical manifestations include swelling, scaling, or redness of the eyelid, along with severe pruritus (itching). Sunburn of the eyelids and UV burn to the cornea (e.g., with recent sun exposure from beach or ski outings without eye protection; working in labs that use UV light; working with arc welding devices) should be ruled out.

Treatment of Contact Dermatitis of the Eyelid

Questioning the patient about the use of eye medications or new personal

care products (e.g., eyeliner, eye shadow) may help identify the offending substance quickly. Discontinuing use of the suspected product is the best treatment strategy. If swelling of the eyelid is marked, nonprescription oral antihistamines (e.g., diphenhydramine) along with application of cold compresses 3–4 times per day will help reduce the inflammation and itching.

Age-Related Macular Degeneration

Two types of age-related macular degeneration (AMD) are recognized: dry AMD and wet AMD. Dry AMD is more common, accounting for approximately 80% of all cases of this disorder. Wet AMD, of neovascular etiology, is significantly more sight-threatening and often is responsible for 80%–90% of those cases involving vision loss associated with AMD. Neovascularization, or new blood vessel growth, under the retina breaks through the retinal pigment epithelium (RPE) layer into the macula with consequent leakage of fluid and blood, causing macular edema and scarring. With the use of intravitreal anti-vascular endothelial growth factor (anti-VEGF) agents to treat wet AMD, vision loss has been significantly stabilized; in many cases, vision has improved. Research on dietary supplementation for AMD in the Age-Related Eye Disease Study (AREDS) trials from the National Eye Institute (NEI) is reviewed next.

Dry AMD often is associated with retinal drusen, or groups of yellowish protein and debris seen when RPE cells lose some of their ability to function properly. Whereas symptoms of wet AMD are reported as distorted and wavy vision, reduced vision in one eye, and haziness or blurriness, patients with dry AMD may not exhibit any symptoms. Patients with a family history of AMD, cigarette smoking, older age (>50), and high cholesterol levels and heart disease and those with lightly pigmented skin are at greater risk for development of AMD and should have regular eye examinations for early detection. The recommendations for treating dry AMD include improved cardiovascular diet with green leafy vegetables, smoking cessation, and eye protection from the sun with polarized sunglasses. Use of a supplement with specific vitamins and minerals has been studied in two large clinical trials, AREDS and AREDS2, and demonstrated benefit in patients with intermediate- and late-stage dry AMD. Patients with early dry AMD did not demonstrate clinical benefit from use of the AREDS formulations. The AREDS and AREDS2 trials used nutritional supplements that may delay progression of intermediate to more advanced

AMD.^{33,34}

The AREDS formulations include vitamins C and E, zinc, copper, and the carotenoids beta-carotene (AREDS) and lutein/zeaxanthin (AREDS2). **Table 28–8** lists the specific ingredients and amounts of the products used in both trials. The vitamin and mineral doses are higher than the recommended dietary allowances (RDAs). Carotenoids are present in abundance in green leafy vegetables and are found at relatively low levels in animal-based foods. Beta-carotene is used to make vitamin A, which is required by the retina to detect light and convert it into “electrical,” or neural, signals. Of note, smokers were excluded from the AREDS trial because of the increased risk of lung cancer in smokers taking beta-carotene. Lutein and zeaxanthin replaced beta-carotene in the AREDS2 trial because beta-carotene itself is not found in the eye. Lutein and zeaxanthin are found in the retina and lens, where they are believed to act as natural antioxidants to help absorb damaging ultraviolet and blue light. This use of lutein and zeaxanthin has not been associated with increased cancer risk.

Table 28–8 Commercially Available (Nonprescription) Preparations of AREDS/AREDS2 Nutrient Formulations

Nutrient	AREDS Formula^a	AREDS2 Formula^b
Vitamin C	400 mg	400 mg
Vitamin E	400 IU	400 IU
Beta-carotene	15 mg	–
Copper (cupric oxide) ^c	2 mg	2 mg
Lutein	–	10 mg
Zeaxanthin	–	2 mg
Zinc	80 mg	80 mg

^a Not recommended for current or former smokers.

^b The nutrients used in AREDS2 formulations were provided by Alcon, Bausch + Lomb, DSM Nutritional Products Inc., and Pfizer.

^c Added to avoid zinc-related copper deficiency.

Key: ASRED = Age-Related Eye Disease Study; NEI = National Eye Institute.

Source: Adapted from NEI data. Available at: <https://www.nei.nih.gov/research/clinical-trials/age-related-eye-disease-studies-aredsareds2/aredsareds2-frequently-asked-questions>. Accessed June 8, 2020.

Zinc 80 mg (alone or in combination with antioxidant vitamins) was found to be of benefit in patients with AMD compared with a placebo. High concentrations of zinc in the original AREDS formula were associated with some gastrointestinal complaints. A lower dose of zinc was an option in the AREDS2 trial. No difference in the effects of zinc 80 mg versus 25 mg was found. Copper (cupric oxide) was added to the AREDS formulations to reduce the risk of copper deficiency anemia associated with high levels of zinc intake.

The AREDS formula contains 400 IU of vitamin E, which is above the usual RDA. Both AREDS trials, however, found no adverse effects attributed to this dose. Previous studies have demonstrated that more than 1500 IU/day from natural vitamin E (1100 IU/day for synthetic vitamin E) may be associated with an increased risk of bleeding. Some potential for vitamin E interactions with medications such as blood thinners, lipid-lowering drugs, and chemotherapeutic agents has been recognized. The AREDS trials found no effect of high-dose vitamin E on increased risk of prostate cancer. NEI recommends consulting with a health care provider before taking vitamin E or other nutritional supplements.

AREDS and AREDS2 supplements reduced the risk of developing intermediate to advanced AMD by about 25%. Neither of these formulations prevented the onset of AMD, nor did they have any effect on cataract formation. In the AREDS2 trial, lutein plus zeaxanthin or omega-3 fatty acids added to the AREDS formula had no additional overall effect on the risk of advanced AMD. No significant changes in effectiveness were correlated with use of the lower zinc concentrations in the AREDS2 trial. Among former smokers who took a formulation with beta-carotene in the AREDS2 trial, a higher incidence of lung cancer was demonstrated. Accordingly, beta-carotene was removed from the

formulation, and no significant change was subsequently noted in its effectiveness. Therefore, former and current smokers should take the AREDS2 formula and avoid beta-carotene, which increases the risk for lung cancer.^{33,34}

Diet alone will not provide the necessary nutrients to confer the same benefit obtained from the AREDS nutritional supplements. Patients are still advised to eat diets rich in green, leafy vegetables, which are a good source of lutein and zeaxanthin. Of interest, however, patients in the AREDS2 trial who had low levels of these nutrients in their diet benefited most from the preparation containing lutein and zeaxanthin. Participants had a 26% lower risk for progression to advanced AMD compared with those taking the original AREDS formula. Lutein and zeaxanthin are believed to offer similar or better protective benefits against advanced AMD compared with beta-carotene. Patients taking the AREDS formulation containing lutein and zeaxanthin but lacking beta-carotene demonstrated an 18% lower risk for progression to advanced AMD compared with those taking a beta-carotene product.^{33,34}

Comprehensive dilated eye examinations provide the best way to determine the risk for AMD risk, and genetic testing available as of June 2020 adds little to identifying this risk. NEI analyses of AREDS trials indicate that these formulations are beneficial for patients of all tested genotypes. The American Academy of Ophthalmology, however, does not support the use of genetic testing to guide treatment for AMD. More information is available from NEI at <https://www.nei.nih.gov/research/clinical-trials/age-related-eye-disease-studies-aredsareds2/aredsareds2-frequently-asked-questions>.

Patients currently taking a multivitamin preparation should check with their pharmacist to be sure there is no potential for interaction or too much overlap with the AREDS formulations. High-dose nutritional supplements can sometimes interfere with medications and compete with other vital nutrients for absorption into the body. People who are considering taking an AREDS formulation should make a list of all of their medications to share with their health care provider. The list should include supplements and nonprescription drugs. Before initiating any AREDS regimen, patients should consult with their regular health care provider or eye care specialist about which supplement, if any, is right for them.

Assessment of Ophthalmic Disorders: A Case-

Based Approach

For patients who have not seen an eye care specialist, the pharmacist or the primary care provider must determine whether the ophthalmic disorder is amenable to self-treatment or requires medical referral. Great care must be taken in assessing a patient with a new-onset, acute problem. Ocular inflammation and irritation can be caused by many disorders and conditions, some of which can be treated safely and effectively with nonprescription ophthalmic products. These products are used primarily to relieve minor signs and symptoms of burning, stinging, itching, and watering. FDA has suggested that self-treatment may be indicated for tear insufficiency, corneal edema, and external inflammation or irritation.

Cases 28–1 and 28–2 are examples of the assessment of two different patients presenting with ophthalmic disorders.

Table 28–9 describes the major features of disorders that necessitate medical attention. Any self-treatable condition that does not resolve within 72 hours constitutes an indication for immediate referral to an eye care specialist for further assessment.

Table 28–9 Differentiation of Ophthalmic Disorders/Conditions That Warrant Medical Referral			
Disorder/ Condition	Potential Signs/ Symptoms	Complications	Treatment Approach
Blunt trauma	Ruptured blood vessels, bleeding into eyelid tissue space, swelling, ocular discomfort, facial drooping	Internal eye bleeding, secondary glaucoma, detached retina, periorbital bone fracture (blowout fracture)	Medical referral is appropriate.
Foreign particles	Reddened eyes,	Corneal abrasions/ scarring, chronic red	Medical referral for removal of particles is appropriate.

Disorder/ Condition	Potential Signs/ Symptoms	Complications	Treatment Approach
trapped/ embedded in the eye	profuse tearing, ocular discomfort	eye, intraocular penetration from metal striking metal at high speeds	
Ocular abrasions	Partial/ total loss of corneal epithelium, blurred vision, profuse tearing, difficulty opening eye	Risk of bacterial/fungal infection with eye exposure to organic material, corneal scarring, anterior chamber rupture	Medical referral is appropriate.
Infections of eyelid/eye surface	Red, thickened lids, scaling, ocular discharge and matting of the lashes	Scarring of lids, dry eye, corneal abrasion or scarring, loss of vision, hordeolum (stye), chalazion (risk of malignancy—i.e., basal cell or sebaceous cell carcinoma), and blepharitis (loss of lashes, corneal irritation)	Medical referral is appropriate. In most cases, <i>hordeolum</i> (stye, internal or external) does not require more than warm soaks. Recurrence of hordeolum necessitates medical follow-up evaluation. <i>Blepharitis</i> often is a chronic problem that requires self-management with scrubs and warm soaks. Recurrence warrants medical referral.
Eye exposure to chemical splash, solid chemical, or chemical fumes	Reddened eyes, watering, difficulty opening eye	Scarring of eyelids and eye surface, loss of vision	To prevent/reduce scarring of eyelids from chemical burns, flush eye immediately for at least 10 minutes, preferably with sterile saline or water. If neither is available, flush with tap water. After flushing eye, arrange immediate transportation to an emergency care facility. No recommendation is noted for chemical neutralization.
Thermal injury to eye (welder's arc burn)	Reddened eyes, pain, sensitivity to light	Corneal scarring, secondary infection	Medical referral for definitive care (including possible eye patching) is appropriate.

Disorder/ Condition	Potential Signs/ Symptoms	Complications	Treatment Approach
Bacterial conjunctivitis	Reddened eyes with purulent, colored (mucous) discharge, ocular discomfort, eyelids stuck together on awakening	Typically, self-limited, with resolution in 2 weeks	Medical referral for treatment with topical antibiotics to clear infection more quickly is appropriate; some infections will require systemic antibiotic treatment.
Viral conjunctivitis	Reddened eyes with watery, clear, or white discharge, ocular discomfort, hyperemia, matting of the lashes	Typically, self-limited, with resolution in 2-3 weeks	If unresolved or condition worsens, medical referral may be necessary. Eye care specialist will monitor for corneal involvement. Treatment with topical decongestants to provide comfort is appropriate; cold compresses can be applied.
Chlamydial conjunctivitis	Watery or white or yellow mucous discharge, ocular discomfort, low-grade fever, possible blurred vision	Scarring	If infection with <i>Chlamydia</i> spp. is likely or confirmed, or if symptoms are too vague to rule out viral or allergic conjunctivitis, medical referral is mandatory.

Source: [Reference 32](#).

Case 28–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient states that she may have dry eye disease but believes it to be mild. She notes that dryness in both eyes becomes more severe as the day goes on. She also notices that during spring and fall her symptoms seem to get worse. She had some allergies to pollen and flowers when she was in her early teens but claims she had "grown out" of those. She has not used any eye drops except for an occasional artificial tears product for her dry eyes.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms usually occur during the spring when trees and flowers start to bud. She previously had ascribed her symptoms to a flare-up of her dry eye disease. In the past week, however, she has noticed some nasal congestion in conjunction with her dry eyes.
c. Description of the patient's efforts to relieve the symptoms	Artificial tears 3–4 times a day throughout the day. She would like to use some decongestant eye drops to "get the red out" because she has many sales meetings for which appearance is important, and she feels that her eye redness "gives a bad impression."
d. Patient's identity	Susan Lee
e. Patient's age, gender, height, and weight	46 years, female, 5 ft 6 in., 118 lb
f. Patient's occupation	Vice president of sales for a pharmaceutical company
g. Patient's dietary habits	Normal healthy diet with mostly fish and chicken. Occasional social drinking; works out on treadmill 6 times weekly.
h. Patient's sleep habits	Sleep schedule varies according to how busy she is at work;

	usually 6–7 hours a night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Dry eye disease</i> (self-diagnosed), for which the patient uses an artificial tears product with lipid supplementation to mimic physiologic tears; tetrahydrozoline eye drops 3–4 times daily in both eyes.
j. Allergies	Previous history years ago of seasonal allergies to pollen and some flowers
k. History of other adverse reactions to medications	None
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Patient is experiencing exacerbation of her dry eye condition. She also has occasional ocular pruritus that is not being controlled by her current therapy.
3. Identify exclusions for self-treatment (Table 28–8 and Figure 28–2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required and share this information with the patient or caregiver.	Options include (1) Refer Mrs. Lee to an eye care specialist (optometrist or ophthalmologist). (2) Suggest that Mrs. Lee discontinue her topical decongestant eye drops. Continue with her artificial tears as needed. Possibly switch to ketotifen topical drops twice daily for suspected allergy flare-up, especially during peak seasonal times. Occasionally use a different agent to “get the red out” to reduce risk of rebound congestion. (3) Take no action.
Plan	

5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient prefers to discontinue her decongestant drops. She will increase her use of artificial tears to more frequent administration during the day as needed. She will start the new ocular antihistamine on days when her eyes are especially irritated. She did not realize that allergies can develop later in life. She will occasionally use a different agent to "get the red out" when she has a public presentation.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Instill 1 drop of the ketotifen product twice daily in both eyes." (See Table 28-3 .) "You do not need to use the drops if you do not notice any irritation, especially if you have not gone outside. Supplement throughout the day with the artificial tears product as needed, but wait at least 5 minutes after instilling the ketotifen eye drops." If she occasionally has a need for a topical agent for ocular redness, recommend instilling brimonidine 0.025% initially just before a meeting.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You may not need to see an eye care provider if you follow the recommended administration guidelines." (See Table 28-3 .)
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	See Table 28-6 .
b. Maximum number of days the therapy should be employed	See Table 28-6 .
c. Product administration procedures	See Table 28-3 .

d. Expected time to onset of relief	See Table 28–6 .
e. Degree of relief that can be reasonably expected	“Complete symptom control should be possible. Some minor symptoms likely will appear from time to time.”
f. Most common adverse effects	“Transient burning, stinging, and discomfort may occur on instillation of the drops.” This has been reported with artificial tears, ketotifen, and brimonidine.
g. Adverse effects that warrant medical intervention should they occur	“If the eye pain worsens and the redness continues, see your eye care provider.”
h. Patient options in the event that condition worsens or persists	“An eye care specialist should be consulted if the condition does not improve, or if irritation and pain become intolerable.” She may wish to consult with an eye care specialist regarding her self-diagnosis of dry eye disease.
i. Product storage requirements	“Store product under cool conditions at less than room temperature and away from heat and light. Observe product expiration date.”
j. Specific nondrug measures	“Remove and/or avoid exposure to the offending allergen. Helpful measures can include ‘checking pollen count to guide outdoor activity, keeping doors and windows closed, running the home’s air conditioning, and using air filters.’ In addition, ‘apply cold compresses to the eyes 3–4 times a day to help reduce redness and itching.’”
Solicit follow-up questions from the patient or caregiver.	(1) “If my eyes still bother me, may I use the drops that I was using previously to get the red out?”
	(2) “Also, my spouse has prednisolone acetate eye drops that he used previously after his cataract surgery, and they seemed to help him very quickly. May I try his eye drops?”
Answer the patient’s or caregiver’s questions.	(1) “No. The ‘get-the-red-out’ eye drops actually can cause rebound worsening of the eye redness and dryness.” Note: In addition to causing rebound hyperemia, such products also are not recommended for patients with dry eye disease; limited use on the days of the worst symptoms is suggested.
	(2) “No. The prednisolone acetate eye drops, which are a steroid

	preparation, can cause significant eye complications, such as secondary infection, glaucoma, and cataract.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Encourage Mrs. Lee to contact you if she has any further questions.
Key: n/a = Not applicable.	

Case 28–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient seeks your recommendation regarding her severe eye irritation. She states that about 30 minutes into a mountain hike on which she stopped to pick wildflowers, her left eye began to hurt and sting, with onset of light sensitivity. Also, a hiking companion noted that the eyelids looked swollen and red. Patient adds that about 30 minutes later, her right eye became affected with the same symptoms. The lids of both eyes are now swollen, and she is having trouble opening her eyes without stinging and pain on exposure to light. The pain and irritation in both eyes are significant. She wants to know what nonprescription product she could use to help relieve her symptoms and what other measures she should take for this problem.
b. Description of	The patient states that she experiences pain, tearing, and light sensitivity

any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	when she tries to open her eyes enough to see.
c. Description of the patient's efforts to relieve the symptoms	She just now returned from the mountain hike and has done nothing to relieve her symptoms. Patient expresses that she does not want to go to an "eye doctor" and requests your recommendations for appropriate self-care measures.
d. Patient's identity	Candice Bean
e. Patient's age, gender, height, and weight	20 years, female, 5 ft 5 in., 127 lb
f. Patient's occupation	Shoe store manager
g. Patient's dietary habits	Semivegetarian with limited meat consumption; generally chooses healthful foods.
h. Patient's sleep habits	Sleeps 6-8 hours a night; this varies with work duties.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) -----	Patient is an avid outdoor enthusiast; runs in marathons and sprint races.

Assess

2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Ms. Bean's eye symptoms are likely the result of an irritant or a foreign object that got into her eye during her hike.
3. Identify exclusions for self-treatment.	See Table 28–8 .
	<i>Ocular abrasions:</i> Partial/total loss of corneal epithelium, blurred vision, profuse tearing, difficulty opening eye. Risk of bacterial/fungal infection with eye exposure to organic material, corneal scarring, anterior chamber rupture. Medical referral may be appropriate if ocular irritant cannot be removed by self-treatment options or if symptoms are not relieved/worsen.
	<i>Foreign particles trapped/embedded:</i> Reddened eyes, profuse tearing, ocular discomfort. Risk of corneal abrasions/scarring, chronic red eye, intraocular penetration. Medical referral for possible removal of particles if present is appropriate.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required and share this information with the patient or caregiver.	Options include (1) Take no action; wait to see if symptoms resolve on their own. (2) Thoroughly rinse/irrigate eyes to remove potential irritants still on the eye surface or trapped under lids. (3) Apply cold compresses as needed to control pain. (4) Use artificial tears eye drops for symptom relief. (5) Use a nonprescription combination antihistamine/mast cell stabilizer as needed to relieve itching and other allergy-related symptoms. (6) Take ibuprofen for control of pain.

	(7) Seek medical care if symptoms do not subside or resolve.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. Bean is reluctant to see an eye care specialist. After being presented with a brief description of complications and risks, she decides to try a self-care approach, and then, if her eyes do not start to "feel better in a few hours," she will seek appropriate medical care.
6. Describe the recommended therapeutic approach to the patient or caregiver.	It is most likely that in touching the wildflowers, Ms. Bean experienced an irritant exposure to the left eye, followed by subsequent right eye exposure incurred by rubbing both eyes. She should rinse/irrigate both eyes with copious amounts of water to help remove possible irritants from the ocular surface. Additional self-treatment options include use of artificial tears, combination allergy drops, and ibuprofen and/or cold compresses for pain. If symptoms persist or do not resolve quickly, patient should seek medical attention for treatment, with the possibility of an embedded foreign particle.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Seeing an eye care provider is the best option in your case. This specialist can determine what the irritant may be, whether there is a foreign particle embedded in the eye, how much damage has been done, and if additional treatment is required. Initially, however, you can use self-treatment options as recommended for possible irritant exposure, but if your symptoms are not relieved or worsen after a few hours, you should see an eye care specialist."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug	

therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	See Table 28–6 .
b. Maximum number of days the therapy should be employed	See Table 28–6 .
c. Product administration procedures	See Table 28–3 .
d. Expected time to onset of relief	See Table 28–6 .
e. Degree of relief that can be reasonably expected	“Complete symptom control should be possible. Some minor symptoms likely will appear from time to time until the condition has resolved.”
f. Most common adverse effects	“Burning, stinging, and discomfort may occur on instillation of the drops.”
g. Adverse effects that warrant medical intervention should they occur	“If the eye pain worsens or symptoms are not relieved in a few hours, see an eye care specialist.”
h. Patient options in the event that condition worsens or persists	“An eye care specialist should be consulted if the condition does not improve, or if irritation and pain become intolerable.”
i. Product storage requirements	“Store under cool conditions at less than room temperature and away from heat and light. Observe the product expiration date.”

j. Specific nondrug measures	“Remove and/or avoid exposure to the offending allergen. Helpful measures can include ‘checking pollen count to guide outdoor activity, keeping doors and windows closed, running the home’s air conditioning, and using air filters.’ In addition, ‘apply cold compresses to the eyes 3–4 times a day to help reduce redness and itching.’”
Solicit follow-up questions from the patient or caregiver.	“Is there anything I should do to prevent this in the future?”
Answer the patient’s or caregiver’s questions.	“In the future, wear sunglasses outdoors, and avoid touching organic materials and then rubbing your eyes.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Ms. Bean to call you to report her status after initial self-treatment efforts. If she experiences no relief or worsening of symptoms, refer her immediately to an eye care provider.

Algorithm: Eye Surface Disorders

Figure 28–2 Self-care for eye surface disorders. Key: AH = Antihistamine; D/C = discontinue; MCS = mast cell stabilizer; OTC = over-the-counter.

Algorithm: Soft Lenses

Figure 28–3 Self-care for eyelid disorders. Key: AH = Antihistamine.

Patient Counseling for Ophthalmic Disorders

Before making treatment recommendations for a patient with an ophthalmic

disorder, the health care provider should carefully consider the nature and extent of the ocular involvement. In cases of acute and/or severe ocular disease, prompt evaluation (including establishing baseline visual acuity) for a specific diagnosis is essential before a self-management approach with use of nonprescription products can be considered. Some acute conditions (which may or may not involve ocular pain or blurred vision) can be appropriately treated with nonprescription agents, but a recent definitive diagnosis from an eye care specialist can give additional reassurance and confidence in recommending such treatment. Although the cost-effectiveness of ophthalmic care can be greatly improved using nonprescription agents, severe visual impairment—including blindness—can be a serious clinical and medicolegal complication if referral for evaluation and treatment is delayed. After careful consideration of the patient's history, the health care provider should always clearly identify the indications for and limitations of self-treatment. The algorithms in [Figures 28–2](#) and [28–3](#) can assist providers in recommending the appropriate measures for self-treatable disorders of the eye surface and eyelid, respectively.

Numerous nonprescription ophthalmic products for treating minor ocular irritations are available for self-administration by the patient with minimal or no supervision ([Tables 28–3](#) and [28–4](#)). These products also are adequate for treating certain clinical conditions diagnosed by primary care providers or eye care specialists. First-line therapy should always include counseling on nonpharmacologic treatment options. These interventions alone frequently are sufficient to relieve the ocular symptoms or are necessary as an adjunct to the ophthalmic drug therapy.

Proper drug instillation technique is critical if the target tissue (the eye) is to receive maximum benefit from the medication. Ophthalmic solutions and ointments often are used incorrectly. Carefully instructing patients in the proper self-administration procedures can help ensure maximum safety and effectiveness of these agents. Appropriate patient education and counseling must accompany dispensing of any ophthalmic product.

Although drug adverse effects and interactions are rare with topically applied ophthalmic products, the potential for such effects is well recognized. Accordingly, patients should be advised of the specific adverse effects, including the clinical signs of drug toxicity or allergy, associated with each of the products they are using.

The health care provider must actively assist patients in selecting the appropriate product, which will enhance compliance, minimize or avoid adverse effects, and reduce the attendant costs of therapy. The other major considerations in making therapeutic recommendations are whether the person has sensitivity to one of the product constituents, whether the product can be used with contact lenses, and whether the product has the potential to wash out prescription ophthalmic drugs the patient may be using. Except for ophthalmic antihistamines and decongestants, little product-to-product comparative research has been done for nonprescription ophthalmic preparations. Accordingly, therapy recommendations should be made on the basis of the patient's diagnosis and consideration of the products the patient is using. The box "Patient Education for Ophthalmic Disorders" lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Ophthalmic Disorders

Patients who initiate self-treatment for allergic conjunctivitis, dry eyes, loose foreign substances in the eye, or minor eye irritation should see an eye care specialist if symptoms persist after 72 hours of appropriate treatment. The pharmacist may wish to schedule a follow-up interview with the patient to determine if the recommended treatment has provided adequate relief. Dry eye disease often is a chronic disorder, requiring regular use of ophthalmic lubricants. Patients with corneal edema should consult an eye care specialist if symptoms persist or worsen despite adherence to the recommended treatment regimen for the causative disorder.

Symptoms of contact dermatitis should resolve quickly once exposure to the offending substance is terminated. If symptoms persist after 72 hours of antihistamine use, referral for medical evaluation is warranted.

Patient Education for Ophthalmic Disorders

The objectives of self-treatment are (1) to relieve the symptoms of minor

ophthalmic disorders using appropriate nonprescription products or nondrug measures and (2) to use nonprescription products as directed for adjunctive treatment of ophthalmic disorders diagnosed by an eye care specialist. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

- Remove the offending agent/irritant responsible for your ocular condition or disease.
- If *blunt trauma* to the eye occurs, visit an eye care specialist for further evaluation as soon as possible.
- When making recommendations for topical ophthalmic products, assess the patient's ability to administer eye drops. Difficulty placing a drop in the eye may be associated with various limiting factors such as visual field loss, arthritis, essential tremor, Parkinson's disease, or altered cognition.
- If you have *dry eye disease* and the ophthalmic lubricants used for initial treatment are not effective, ask your eye care provider or pharmacist about the following therapeutic strategies: increasing the dosage, switching to a product with increased viscosity, and/or switching to a preservative-free product ([Table 28–2](#)).
- When treating *allergic conjunctivitis*, do not exceed the recommended dosages for ophthalmic antihistamine/mast cell stabilizer, decongestant, or antihistamine/decongestant products ([Tables 28–5](#) and [28–6](#)). Consult an eye care specialist if symptoms persist after 72 hours of treatment.
- Discard or replace eye drop bottles 30 days after the sterility safety seal is opened. The manufacturer's expiration date does not apply once the seal is broken.
- If *eye exposure to chemicals* occurs, irrigate the eye continuously for 10 minutes with copious amounts of water or an eye irrigant ([Table 28–7](#)) and seek immediate medical care.
- If a *loose foreign substance* such as lint, dust, or pollen enters the eye, flush the substance from the eye using an ocular irrigant or water ([Table 28–7](#)).
- If a *foreign object or substance* becomes embedded in the eye or trapped under the eyelid, see an eye care specialist for removal.

Continued presence of the substance could lead to an eye infection or tissue damage.

- Consult an eye care specialist before initiating self-treatment for *corneal edema*. If hyperosmotic solutions ([Table 28–7](#)) are recommended, follow the recommended dosages even though the product may sting. Continued utilization of these products will depend on the eye care specialist's recommendations.
- Note that taking ophthalmic vitamin supplements for macular degeneration along with general multivitamins may result in gastrointestinal upset or vitamin toxicity.
- If *contact dermatitis of the eyelid* occurs, wash the surrounding areas of the face, identify the cause of the reaction, and try to avoid future contact with the substance. Consult an eye care specialist if symptoms persist after 72 hours of use of oral antihistamines.

Key Points for Ophthalmic Disorders

- The pharmacist is well positioned in the community to assess for and treat various ophthalmic disorders, including medical referral as appropriate, or to recommend self-management with one or more nonprescription drugs.
- Many ophthalmic products are available to manage the symptoms of minor acute or chronic disorders and conditions of the eye and eyelid.
- Familiarity with the pathophysiology of certain ocular conditions and proficiency in the assessment of patients who present with such conditions will allow the pharmacist to optimize the safe, appropriate, effective, and economical use of nonprescription drugs to manage selected conditions of the eye and eyelid.
- Nonprescription ophthalmic products should be used only in cases of minor pain or discomfort. If the nature of the problem is in doubt, the pharmacist should refer the patient for medical care.

- Nonprescription ocular medications should not be recommended to patients who have demonstrated an allergy to any of the active ingredients, preservatives, or other excipients in the product.
- Patients who are already using a prescription ophthalmic product should use nonprescription products only after consulting with an eye care specialist or a pharmacist.
- Patients with narrow anterior chamber angles or narrow-angle glaucoma should not use topical ocular decongestants because of the risk of angle-closure glaucoma.
- Drug administration should be conservative in patients with hyperemic conjunctiva because of the potential for increased systemic drug absorption and the risk of adverse effects.
- The lowest effective concentration and conservative dosage frequencies should be used, especially for ocular decongestants; overuse should be avoided.
- Ophthalmic products frequently are used incorrectly; therefore, counseling on appropriate application of products is crucial.
- Patients should be evaluated by an eye care specialist to determine if they are candidates for an AREDS preparation for dry AMD. Consultation with the pharmacist is important if patients are taking other vitamin preparations.

Chapter 29: Prevention of Contact Lens-Related Disorders

Authors: Aleda M.H. Chen, Andrew Straw

An estimated 40.9 million people use contact lenses in the United States, and more than \$8.5 billion is spent annually worldwide on contact lenses. Soft contact lenses, introduced in 1971, provide greater comfort than rigid lenses and account for >90% of lens purchases. In 2018, U.S. consumers spent \$3 billion on soft contact lenses.¹ The newest soft lens material, known as silicone hydrogel, continues to dominate this market category, being favored by 69% of soft lens wearers.¹

The types of lenses prescribed vary markedly among countries. Rigid gas-permeable (GP) lenses account for approximately 20% of prescribed contact lenses in some countries, such as France, New Zealand, and the Netherlands, and for 43% in Switzerland,² whereas only 6% of contact lenses prescribed in the United States are of the GP type.¹

Complications associated with contact lens wear are not uncommon, with reported rates of 23%–94%; this wide range is attributable in large part to variability in type of lens, wearing schedule, and adherence to the prescribed care regimen.³ Contact lenses, even when expertly fitted, induce local changes that alter ocular tissues and affect corneal metabolism. The prevention of contact lens–related disorders requires that both patients and health care providers understand the proper prescribing, fitting, and care regimens associated with safe contact lens wear. Failure to follow optimal practices can greatly increase the chances of development of corneal infection (with accompanying ulcers) and other ocular conditions that may result in permanent eye damage and blindness. Preventive measures aimed at improving patient hygiene and appropriate contact lens care and minimizing environmental factors, as well as adherence to recommended replacement frequency schedules, will reduce the overall risk of contact lens complications.^{3,4} Fortunately, most complications from contact lens wear are reversible, if attended to promptly. Approximately 23%–33% of patients discontinue wearing their contact lenses periodically or permanently, with lens discomfort or dryness cited as the most common reason.^{3,5,6} Silicone hydrogel contact lenses have the lowest discontinuation rates,⁶ and proper care and

fitting of lenses can help eliminate discomfort and encourage maintenance of an optimal wear schedule.

The fitting and dispensing of contact lenses, traditionally the sole domain of optometrists and ophthalmologists, underwent dramatic changes with passage of the Fairness to Contact Lens Consumers Act in 2003. This legislation requires that contact lens prescribers release a copy of the prescription to the patient at the conclusion of the fitting process, whether or not this information is requested.⁷ With prescription in hand, consumers can now purchase their contact lenses and related supplies from any of various authorized sources, including pharmacies—as well as nonprofessional sources for which appropriate training in eye care may be lacking. In 2018, 22% of all contact lens sales were conducted online.¹ It is unknown whether the source of contact lenses, such as online supplier versus eye care provider clinic, has an impact on the quality of eye care, including self-care. Some studies have found a lower likelihood of appropriate self-care^{8,9} and fewer eye exams when contact lenses are purchased online,¹⁰ whereas others have found no difference in complication rates.¹⁰ As detailed in this chapter, fitting and dispensing contact lenses involve more than specifying parameters for the lenses themselves. Additional considerations of importance include patient education regarding adherence to requirements for lens care systems, wearing schedules, and lens replacement schedules. Patient education also should incorporate proper lens handling and the signs and symptoms of complications as other essential aspects of a successful wear regimen. Another area of concern is the enforcement of expiration dates for lens prescriptions.

Use of Contact Lenses

Most people can wear one or more types of contact lenses without problems if certain precautions are taken. As detailed further on, however, in several specific instances the use of contact lenses is contraindicated.

Indications for Contact Lenses

Indications for the use of contact lenses include the correction of refractive errors such as myopia (nearsightedness), hyperopia (farsightedness), astigmatism, and presbyopia. In astigmatism, dissimilar curvatures of the refractive surface of the eye result in a blurred image. GP lenses or toric soft

lenses can be used to correct astigmatism.

The benefits of contact lens wear are widely known and include the convenience of freedom from eyeglasses, no obstruction to vision from eyeglass frames, no fogging of lenses caused by sudden temperature changes, improved optics and clarity of vision, wider peripheral field of vision, equal image sizes when refractive disparity exists between eyes, and better function during sports activities or exercise. Perhaps a significant reason for choosing contact lenses is the perceived improvement in self-image and personal appearance.¹¹

The decision to wear contact lenses rather than eyeglasses is sometimes based on therapeutic necessity or cosmetic interest. For example, in patients with keratoconus (a corneal dystrophy causing gradual protrusion of the central cornea), satisfactory vision usually is unattainable with ordinary eyeglasses but can be achieved with rigid contact lenses, which can favorably reshape the curvature of the cornea. Another example of therapeutic necessity is the use of soft contact lenses as “bandage” lenses in the case of severe corneal abrasions. Other, less common indications for contact lenses include aphakia (absence of the natural lens of the eye), corneal scarring, and disfigured eyes. In the first two conditions, patients typically see better with contact lenses, and for patients with disfigurement, tinted prosthetic soft contact lenses may improve cosmetic appearance by rendering defects from a variety of conditions virtually unnoticeable. Additionally, some patients utilize “special effects” contact lenses for cosmetic or occupational purposes, such as costume-related events, theatrical productions, or expression of personal style. These lenses often have a tint that hides the natural eye color and may add unique features to the appearance of the eye.

Contraindications and Warnings for Contact Lens Wear

Certain patients are poor candidates for contact lens wear—they either cannot or should not wear contact lenses. Contraindications often are based on lifestyle as well as on medical history. The following factors and conditions are relative contraindications that should be considered on an individual basis before the patient is fitted for contact lenses:

- Monocular vision. In persons with vision in only one eye, the risk of

complications such as inflammation or infection that can permanently scar the cornea in the seeing eye must be weighed against the need for optimal visual correction. Overnight wear of lenses should absolutely be avoided.

- Presence of an active pathologic process involving the lids, cornea, or conjunctiva. Such conditions include blepharitis, corneal infections (e.g., herpes, keratitis, *Staphylococcus aureus* infection, *Pseudomonas* infection), and conjunctivitis. Conjunctivitis associated with common colds or chronic allergic conditions such as hay fever and asthma also may make contact lens wear extremely uncomfortable or impossible.
- Presence of dry eye (keratitis sicca), except for use of “bandage” soft contact lenses for protection. Although this condition presents obvious difficulties for successful lens wear, it has been recognized that some patients with severe dry eye actually benefit from the use of bandage soft contact lenses to protect the ocular surface. In general, however, persons who have insufficient tear production, a deficiency or excess of mucin, or excessive lipid production and those who spend time in excessively dry environments may be unable to use contact lenses successfully. Poor blink rate or “incomplete” blinking (in which the eyelid does not completely close) also may contribute to difficulty with lens wear. Postmenopausal women may experience higher rates of dry eye, precluding successful contact lens wear.
- Pregnancy or use of oral contraceptives. The fluid-retaining effects of estrogen may lead to edema of the cornea, which will alter corneal topography and affect the fit of contact lenses.
- Diabetes. Patients with diabetes are advised against the use of continuous-wear contact lenses because of the retarded healing processes and reduced corneal sensitivity associated with their disease. These considerations probably are of lesser significance with daily-wear lenses, which often may be used unless specific problems arise (e.g., inflammation, infection, abrasion).
- Eye medications requiring frequent dosing (e.g., for treatment of glaucoma). The preservatives in multidose bottles can bind to soft contact lenses, with potential toxicity to the corneal epithelium.
- Personal habit, vocation, or hobby that is not conducive to lens wear (e.g., smoking, exposure to chemically toxic environments). Occupational conditions that may prohibit the wearing of contact lenses include exposures involving wind, glare, molten metals, irritants, dust and particulate matter, fur, dander, feathers, sand, tobacco smoke,

and chemicals and chemical fumes. Certain chemical fumes may be particularly hazardous because of the potential for concentration of irritants under a rigid lens or inside a soft lens. With lenses on the eye, contact of such substances with the cornea is potentially prolonged, which can lead to corneal toxicity.

- Medications that cause discoloration of fluids. Rifampin, used in therapy for tuberculosis, is a common offender.
- Activity (e.g., frequent air travel) that entails moving from a low to a high altitude. Such changes in altitude may induce hypoxia, with consequent edema of the cornea, or metabolic deficiency, resulting in irritation and corneal abrasions.
- A pattern of abusing lens wear or multiple episodes of ocular complications. The patient's medical history should be reviewed to identify potential problems.
- Inability to care for contact lenses appropriately. This restriction typically affects pediatric patients who are not properly supervised and older or impaired persons who lack cognitive skills or dexterity to handle contact lenses.

Soft Versus Rigid Contact Lenses

The three major categories of contact lenses are soft (hydrophilic), rigid gas-permeable (i.e., GP), and rigid non-gas-permeable (polymethylmethacrylate [PMMA]). PMMA lenses—often known as “hard” contact lenses—are rarely used today owing to their lack of oxygen permeability and are not discussed in this chapter. Soft and GP lenses are composed of single or multiple plastic monomers; soft lens materials contain water, but GP lens materials do not. Soft lenses are popular because of their excellent initial comfort on insertion. Rigid lenses, by contrast, have always provided the best optics, with consequent superior visual acuity. In the contact lens area of clinical practice, use of the term “hard lenses” during patient counseling is no longer acceptable because it creates a stigma about optimal lens designs for individual needs. Therefore, rigid lenses should simply be referred to as “gas-permeable lenses.” [Table 29–1](#) compares the advantages and disadvantages of soft and GP contact lenses with regard to lens properties, ease of care and handling, potential associated complications, and other characteristics.

TABLE 29–1 Advantages and Disadvantages of Soft and Gas-Permeable (GP) Contact Lenses

Soft Contact Lenses	GP Contact Lenses
Advantages	
Excellent initial lens comfort Rapid adaptation; well suited to intermittent lens wear Correction of nearly all forms of refractive error Ease of fitting Ease of care Trapping of foreign material under the lens unlikely Low likelihood of dislodging or falling out; well suited to use in sports activities Can be tinted for cosmetic or prosthetic purposes (many lenses have light tints to improve visibility when handling)	Excellent optics for optimal visual acuity Correction of nearly all forms of refractive error Improved vision for conditions with irregular corneas Fit customized to individual patient Economical Lower incidence of inflammatory/infectious complications
Disadvantages	
Less successful vision correction—achievement of excellent visual acuity not possible in all patients Fluctuations in vision due to variability in lens hydration with prolonged wear and changes in ambient temperature and humidity Lens fitting not customized to the patient's eye Greater likelihood of complications, especially from hypoxia Fragility and ripping (or tearing) of lenses during handling Susceptibility of lenses to adverse effects of preservatives in ophthalmic products Lack of surface markers on lens to verify correct eye once packaging is removed, with no means of distinguishing between lenses for left and right eyes	Longer initial adaptation period Capable of trapping foreign material beneath the lens, causing discomfort May dislodge from the eye More difficult to fit Subjective flare around the periphery that may be noticed at night, particularly with large pupils

Hydrophilic (Soft) Contact Lenses

First introduced in 1971, soft contact lenses have become the lens of choice from the standpoint of health care providers and patients alike, as mentioned previously. Soft contact lenses are now available in any spherical or cylindrical power, and they can correct for presbyopia, myopia, or hyperopia and astigmatism.¹²

In 1986, the U.S. Food and Drug Administration (FDA) classified soft hydrogel contact lenses into four categories according to water content and ionic properties: low water nonionic, high water nonionic, low water ionic, and high water ionic. Soft contact lenses with less than 50% water content are

considered to be in the low water categories. Less reactive surfaces are called nonionic, and more reactive materials are called ionic. Most eye care providers prescribe nonionic soft contact lenses because of their inherent chemical ability to deter the formation of charged protein and lipid deposits. Oxygen deprivation, or hypoxia, can be a common complication of contact lens use. The oxygen transmissibility of contact lenses is described by the term Dk/t ,¹² where D represents gas diffusion, k is the solubility coefficient, and t the contact lens oxygen transmissibility. A higher Dk/t value allows more oxygen to pass through the lens. As the water content increases, so does the k value, along with oxygen permeability. However, permeability also depends on lens thickness.

The original soft contact lenses were intended to be cleaned and disinfected daily and replaced on a yearly basis. Few patients could successfully wear these lenses, however, because of overall poor self-care compliance and higher complication rates.

Instead, today's disposable lenses represent greater than 97% of the soft lens market,¹ and having a fresh, clean lens available on a regular basis has lessened the incidence of complications from inadequate lens wear hygiene, such as contact lens-associated papillary conjunctivitis. These soft lenses are replaced monthly, biweekly, or daily, depending on how the specific lens is manufactured. The introduction of silicone hydrogel materials was a major factor in the emergence and availability of such continuous-wear lenses.

The eye care community was hopeful that frequent lens replacement would equate to improved general lens wear hygiene and sidestep the negative effects of biofilm development on the surface of lenses. Many eye care providers also believed that the use of silicone hydrogel materials would effectively eliminate inflammatory and infectious complications of contact lens wear, including microbial keratitis, by preventing or limiting hypoxia and its damaging effects on the corneal epithelium. Although years of clinical use have shown that these materials do in fact diminish the hypoxic effects of lens wear, such as redness, limbal neovascularization, and microcystic edema, they have failed to completely eliminate infectious and inflammatory complications.³ Continuous-wear contact lenses carry a higher risk of complications, such as corneal lesions.³ Patients should be made aware of these risks, and some prospective users may discover that they cannot tolerate continuous-wear regimens (for either 7 or 30 days, as approved by FDA for

specific products). None of the soft contact lenses on the market, including the silicone hydrogel types, can prevent or protect the eye from inflammatory and infectious complications. The importance of patient education regarding adherence to lens care regimens and wearing and replacement schedules, as well as awareness of more serious signs and symptoms, cannot be overemphasized to ensure safe contact lens wear.

Even a disposable, continuous-wear lens can be used on a daily-wear basis, and patients should replace lenses at the prescribed interval. When used on a daily-wear basis, these lenses must be cleaned and disinfected regularly. Patients looking to optimize convenience without exposing themselves to the risks associated with continuous wear should be directed toward daily disposable lenses. Daily disposables have the following advantages: (1) each lens is sterile before removal from its package for immediate insertion into the eye; (2) no cleaning regimen is necessary because the lens is discarded after wear for a day; (3) deposit formation is minimal; and (4) lens-related problems such as giant papillary conjunctivitis or allergic reactions to lens care solutions occur less frequently.

Hydrophilic Lens Fitting

Unlike with rigid contact lenses, which typically are custom-designed, the parameters of the most commonly used soft contact lenses are predetermined by the manufacturer and are proprietary in nature. Often, the lens diameter and base curve are limited to one or two choices at most, providing little flexibility for adjusting fit. Thus, if a lens does not fit correctly or causes some other complication, another lens design must be tried. Some exceptions are available, and custom-fitted soft lenses with a specified diameter, base curve, and power can be ordered.

Hydrophilic Contact Lenses as Therapeutic Devices

Aside from the cosmetic use of contact lenses, hydrophilic lenses have found wide application in the treatment of ocular disease and are being investigated for potential use as ocular drug delivery devices. Of note, hydrophilic lenses are employed as an “eye bandage” to protect the cornea and to promote corneal reepithelialization after corneal injury or various corneal surgical procedures. Some soft contact lenses are currently approved by FDA for use therapeutically as such bandage lenses in the treatment of corneal abrasions and other ocular

surface problems. It is important to counsel patients who are prescribed contact lenses for this purpose to be diligent in cleaning and disinfecting the lenses.¹³

Gas-Permeable Contact Lenses

Rigid contact lenses preceded soft lenses in the market but were quickly surpassed because of one primary factor: the greater initial awareness of rigid lenses on the eye. In terms of optical quality, rigid lenses are far superior to soft lenses. However, patients are willing to sacrifice clarity for comfort. In defense of rigid lenses, initial discomfort can dissipate over several weeks as adaptation occurs and nerve endings on the inner surface of the eyelids become desensitized to the presence of the lens.

Rigid GP lenses are made from monomer components of hydrophobic plastic compounds that allow oxygen to diffuse through the lens.¹² Advantages of GP lenses over soft contact lenses include increased oxygen transmissibility, reduced lipophilicity (e.g., less contamination from the environment), and sharper vision. These lenses also have less surface reactivity, thereby decreasing tear film deposits. Another significant advantage of GP lenses over soft contact lenses is a lower incidence of adverse inflammatory or infectious consequences. When properly cared for, GP lenses also are durable and can be reused repeatedly for months to years before replacement is necessary, making them more economical than soft lenses. Moreover, surface scratches and deposits can be removed with powerful cleaners or in-office polishing machines. The disadvantages of GP lenses include lesser surface wettability; a negative surface charge, which can attract lysozymes and other positively charged deposits; and greater mass, which can affect lens fit, depending on the specific type of lens.

GP lenses are the lens of choice for dealing with complicated corneal disorders such as keratoconus or corneal scarring from disease or trauma, and for use with transplanted corneas or those with high degrees of astigmatism. Unlike soft lenses, which drape over the surface of the cornea, even if it is irregular, rigid lenses create a new refracting surface, with a tear layer filling the gap between lens and cornea. GP lenses are available in a wide range of designs, including toric lenses for astigmatism and bifocals for presbyopia. Although far more limited in terms of choice, some GP materials also are FDA approved for either 7 or 30 days of continuous wear, depending on the material.

Gas-Permeable Lens Fitting

Most providers who prescribe contact lenses agree that compared with soft lenses, fitting GP lenses requires a higher level of both art and science. Unlike soft lenses, GP lenses are not mass-produced but rather are custom-designed and manufactured on demand, requiring the prescriber to specify the parameters of diameter, base curve, power, and material to order a lens.

Specialty Contact Lenses

Numerous companies manufacture soft contact lenses. The product offerings of many companies overlap to address the most common myopic, hyperopic, and astigmatic refractive errors. Many companies sell prepackaged, mass-produced lenses that consumers can buy in bulk with a prescription. Some offer customized lenses to address unusual needs. Several companies promote materials that absorb ultraviolet light. Corrective tinted lenses are available for easier handling and for cosmetic purposes. Translucent tints facilitate handling by increasing the visibility of the lens and also enhance eye color. Opaque lenses cover the iris and hide its natural color. These lenses also may be used as a prosthesis to mask corneal scarring. By contrast, all GP lenses are custom-made by laboratories that often use proprietary, computer-generated lens designs. These unique designs are aimed at specialty needs such as with keratoconus, post–corneal transplantation, corneal scarring, post–refractive surgery, aphakia, or high degrees of astigmatism.

Two specialty lenses worth mentioning are lenses for presbyopia and hybrid lenses. *Presbyopia* is the loss of accommodation in the aging eye, typically beginning around the age of 40 years, requiring the addition of plus power (i.e., adjustment for farsightedness) to improve the clarity of vision at a near reading distance. It affects people who are nearsighted or farsighted or who have an astigmatism and thus is common in contact lens wearers. In eyeglasses, a separate portion of the spectacle lens at the bottom of the lens provides this additional plus power for reading (bifocal glasses). This change in power is more difficult to accomplish with contact lenses. A common method of correcting presbyopia with contact lenses is monovision, a technique that uses standard lenses, fitted to the dominant eye corrected for distance and to the other eye corrected for near vision. Monovision can be effective, but it can affect depth perception, intermediate-distance vision, and night driving. Today, multifocal contact lenses are being designed to provide binocular vision for

patients, which provides a smooth transition among the near, intermediate, and far zones of the lens. The practitioner should discuss the options with the patient to determine what would work best for personal preferences or lifestyle requirements.¹⁴

A *hybrid contact lens* is a unique contact lens that combines GP and soft lens materials in the same lens. The overall advantages of this lens are excellent optics through the GP portion of the lens, improved comfort from the soft lens portion, greater oxygen permeability (compared with an earlier version of the lens), and accommodation for astigmatism and irregular corneas (e.g., with keratoconus or post–corneal transplantation). The disadvantages are expense, difficulty with insertion and removal, longer fitting time, and complications of lens wear. The care of these lenses follows the patterns described for soft contact lenses in later sections.

Algorithm: Soft Lenses

FIGURE 29–1 Basic care regimen for soft contact lenses. Key: UVR = Ultraviolet radiation.

Considerations for Lens Care

The manufacturing and marketing of contact lenses are regulated by the FDA ophthalmic devices division.¹⁵ Patients who wear contact lenses should use only lens care products that have been FDA-approved for use with their specific contact lenses.

The basic considerations for a well-formulated contact lens solution include pH, viscosity, isotonicity with tears, stability, sterility, and provisions for maintaining sterility (bactericidal action). The pH range of comfort is not well defined, because although normal tear pH is 7.4 (with a range of 6–8), values vary among individual patients. Accordingly, many contact lens solutions are formulated with pH values above or below 7.4 to prioritize stability and also to provide comfort. Solutions from different manufacturers should not be mixed because a precipitate may form.¹⁶

Soft Contact Lens Care

The goals of cleaning a contact lens are (1) to physically remove debris from the lens surface through the mechanical action of rubbing the lenses between the thumb and finger; (2) to prevent the accumulation of proteins from the tear layer on the lens; and (3) to disinfect the lens of organisms that can bind to the lens surface and potentially lead to infection. Lens disinfection is a crucial step, although all steps must be completed on a daily basis or after each wearing period to avoid ocular complications.¹⁷ The basic care regimen for soft lenses (Figure 29–1) differs from that for GP lenses.

Product Selection Guidelines

Since the early days of contact lens use, separate solutions have been available for each step of cleaning, rinsing, disinfecting, storing, and protein removal. These solutions include surfactants for cleaning the lens surface, saline solution for rinsing, disinfecting agents for sterilization, and enzyme-based products for protein removal, in addition to wetting drops for use while lenses are on the eye. To improve convenience and compliance, multipurpose products are available that combine these active ingredients in a biocompatible solution buffered for pH balance for use directly in the eye. Some of these solutions also contain demulcents to increase lubrication and comfort of the eye. Table 29–5 lists examples of products designed specifically for soft contact lenses

Tables 29–2 and 29–3 present detailed steps for cleaning soft contact lenses.

TABLE 29–2 General Cleaning Procedures for All Lens Types

- Before handling lenses, wash hands with noncosmetic soap and rinse thoroughly; then dry with a lint-free towel.
- Clean contact lenses only with commercially manufactured products made specifically for that type of lens. Homemade cleansers can scratch and contaminate the lenses or cause eye irritation, infection, or injury.
- Do not mix contact lens care products from different manufacturers unless an eye care provider confirms that the products are compatible.
- During cleaning, check lenses for scratches, chips, or tears and for the presence of foreign particles, warping, or discoloration. Also, ensure that lenses are clean and thoroughly rinsed of cleanser. Any residual impurities could cause eye discomfort.
- When cleaning a lens, rub it in a back-and-forth, rather than a circular, direction, even if

using a no-rub solution.

- Discard cleansers and other lens care products if the labeled expiration date has passed.
- Avoid touch contamination of open product bottle tips.

TABLE 29–3 Specific Cleaning Procedures for Soft Lenses

- Clean regular soft lenses daily with a surface-active cleaner at the end of daily wear.
- Clean continuous-wear soft lenses with a surface-active cleaner after each wearing.
- Place several drops of a cleaning product on the lens; gently rub the lens with the tip of the forefinger against the palm of the opposite hand, for 20–30 seconds, even if using a no-rub product, to ensure removal of protein deposits.
- Avoid cutting the lens with a fingernail or scratching the lens surface with grit or dirt on the hands.
- Rinse lenses with a sterile isotonic buffered solution. Never use tap water, because it is not isotonic and contains harmful microorganisms.
- Clean lenses at least weekly (or every day if using a daily product) with enzymatic cleaners, either separately from disinfection or as part of the disinfecting process.
- When combining enzymatic cleaning and disinfecting of the lenses as one step, see [Tables 29–5](#) and [29–8](#) for the appropriate products.
- Discard any enzyme cleaner that is discolored.

Soft Lens Disinfection

The lens care regimen must be built primarily around the use of a disinfecting system. In patient education, emphasis must be placed on hand hygiene and adherence to the manufacturer’s requirements for each disinfecting system, while stressing the minimum soaking time for disinfection.

Preservatives.

The most important point in considering contact lens disinfection pertains to the preservatives used both to keep multiuse solutions sterile and to disinfect the lens. A variety of preservatives that have effective antimicrobial properties are used. Daily use of the same bottle of any contact lens solution over a long period of time increases the risk of bacterial contamination. The solution must therefore contain a bactericidal agent that is both effective over the long term and nonirritating to the eye with daily use. Despite the presence of preservatives, once opened, any contact lens solution not used within the recommended time frame on the label, typically 1–3 months, must be

discarded. Touch contamination of the bottle tip also is a major concern, and if this occurs, it is imperative to dispose of the bottle. Patients should be directed to write the date on which the container is opened on the outside of the bottle.¹⁸

Disinfecting Methods.

FDA recommends disinfecting soft contact lenses before each reinsertion.^{17,18} Chemical-based disinfection is by far the most popular (Table 29–4). Thermal, or heat, disinfection is no longer a viable method of caring for today’s soft contact lenses. The alternative is an electronic system, PuriLens, that uses subsonic ultrasound agitation for cleaning and high-intensity ultraviolet light for disinfection. In chemical disinfection, lenses are stored for a specified period (usually 4–6 hours) in a solution containing bactericidal agents that are compatible with soft lens materials. Two basic chemical disinfection methods are available in the United States: chemical disinfectant systems and hydrogen peroxide–based systems.¹⁷ The first group uses the original chemical disinfecting solutions, which consisted of antimicrobial preservatives at sufficient concentration in storage solutions composed primarily of saline. Manufacturers currently are marketing solutions with less-sensitizing disinfectants for soft contact lens care. Examples are quaternary ammonium compounds (e.g., polyquaternium-1), biguanides (e.g., polyhexanide, polyaminopropyl biguanide), and amidoamine (e.g., myristamidopropyl dimethylamine). Modern chemical disinfectants have been found to be effective and are most commonly used.^{17,19}

TABLE 29–4 Guidelines for Disinfecting Gas-Permeable and Soft Lenses

Chemical Disinfection with Hydrogen Peroxide

- Using the cup provided with the hydrogen peroxide product, soak lenses for the length of time specified by the manufacturer. Do not use lens cups or cases supplied with other products.
- To disinfect and neutralize in one step, place platinum catalytic disk in lens case and leave the disk there until time to replace it. Add hydrogen peroxide, place lenses in the case, and leave for at least 6 hours.
- Never place neutralizing solution in a lens case with a catalytic disc. An unwanted chemical reaction may occur, or a gummy residue may form on the disc.
- Before inserting lenses in the eyes, make sure the hydrogen peroxide is completely neutralized by carefully following product instructions.

- Rinse lenses thoroughly with saline before inserting them.

Chemical Preservative Disinfection

- Store lenses for the prescribed period of time (usually a minimum of 4 hours) in a preservative disinfecting solution that is appropriate for the lens type.
- If you experience irritation, remove lenses and rinse them thoroughly with saline to remove any disinfecting solution.
- If not wearing lenses for prolonged periods after chemical disinfection, store the cleaned lenses in an appropriate multipurpose contact lens solution and change out the multipurpose solution in the storage container daily.

Combination Enzymatic Cleaning and Disinfection

- When combining enzymatic cleaning and disinfecting of the lenses as one step, select products compatible with your disinfecting system.
- Add appropriate solution (hydrogen peroxide or chemical disinfecting product) to the storage case of the disinfecting system.
- Place the lenses in the case and then add appropriate enzymatic cleaner.
- Follow directions for the appropriate disinfecting system listed previously.
- Rinse lenses thoroughly with saline to remove residual enzymes.

The second chemical disinfection method uses hydrogen peroxide as the antimicrobial agent. These products are good choices for patients with preservative allergies because they are preservative-free. Soft lenses are placed in purified hydrogen peroxide, and disinfection occurs with the liberation of oxygen from peroxide. Household hydrogen peroxide solution should not be used; its pH is too low, it is not sterile, and it may discolor lenses. After disinfection is completed, the peroxide is neutralized to trace levels by a neutralizing tablet that contains a delayed-release catalase or by the catalytic action of a platinum disc. This process takes approximately 6 hours.^{17,20}

One potential disadvantage of hydrogen peroxide disinfection is that patients may mistakenly insert the lens into the eye directly from the peroxide solution without neutralization. Patients must be warned not to perform a final rinse with the disinfecting solution before inserting their lenses, as they might do with a multipurpose chemical system. Emphasis on the neutralization step is

critical. A peroxide-soaked lens placed on the eye will likely cause a toxic keratitis, with manifestations of pain, photophobia, and redness. In this event, the patient should immediately remove the lens and flush the eye copiously with sterile saline solution or, if this is not available, even tap water. If signs and symptoms do not abate, prompt consultation with an eye care provider is warranted. Patients should be educated on appropriate replacement of the products and system components, such as the catalytic disc. An important point is that any sensation of discomfort or burning experienced by the patient when inserting contact lenses that have been disinfected with hydrogen peroxide is likely to mean incomplete neutralization, necessitating replacement of the disc. Hydrogen peroxide systems are not recommended for patients who wear lenses intermittently and leave their lenses in neutralized solution for extended days of storage. Patients with these wear habits should be advised to switch solutions after each peroxide cleaning to a multipurpose solution, or to change to daily disposable contact lenses. The hydrogen peroxide bottles also have a red cap to remind patients of the special handling required when in use.

Oxysept UltraCare is a catalase-based system. With this product, the user adds a delayed-release neutralizing tablet at the beginning of the 6-hour disinfecting cycle. Disinfection and neutralization then occur at the appropriate time intervals. This tablet contains catalase and cyanocobalamin; the latter ingredient turns the solution pink, reminding the user that the tablet has been added.²¹ The tablet is coated with hydroxypropyl methylcellulose, which helps lubricate the eye if the lens is not rinsed again between disinfection and insertion. It should not be used if crushed or cracked. A separate daily cleaning step is required. An enzymatic cleaner may be added weekly for protein removal.

When recommending a disinfecting method, the primary care provider should consider the patient's ability or reliability in adherence to the lens care regimen, wearing schedule, and convenience. Peroxide-based systems provide excellent disinfection against many organisms and essentially eliminate solution sensitivity issues. They are not well suited, however, for intermittent wear of disposable lenses or to adoption by the careless user, who may inadvertently instill peroxide in the eye. If the patient has a history of sensitivity reactions to lens solutions or is unsure whether sensitivity exists, it is best to recommend a product containing one of the nonsensitizing preservatives.

Multipurpose Products

Initially, manufacturers recommended three separate products for cleaning, removal of protein deposits, and disinfection in care regimens for soft contact lenses. More recently, a trend toward use of multipurpose solutions for all of these functions has emerged, in attempt to simplify lens care and improve adherence to optimal wear regimens. The original sequence for cleaning and disinfecting contact lenses was to rub, rinse, and soak the lens overnight. However, with promotion of the “no-rub” technique by manufacturers of multipurpose solutions, patients often are confused about proper lens care.^{22,23} Several studies have demonstrated that with multipurpose solutions, a no-rub technique does not adequately remove protein and other deposits and cosmetics compared with active rubbing of the lens with the fingertip. To reduce risk of infection, irritation, and other complications, proper rub, rinse, and soak technique should be recommended with use of all multipurpose solutions. This recommendation is shared by FDA, the American Optometric Association, and the American Academy of Ophthalmology.²⁴

The newest multipurpose solutions were made with due consideration of both disinfection and comfort and feature two significant chemical preservatives and agents to improve wettability. Biotrue contains a lubricant naturally found in the eye (hyaluronan), while matching the pH of healthy tears to improve the efficacy of the disinfectants.²⁵ OptiFree PureMoist features the HydraGlyde Moisture Matrix, which creates a moisture barrier on the surface of the lens and helps prevent protein and dirt buildup and aid in comfort. Blink RevitaLens solution is the only agent that contains the preservative alexidine, which provides broad antimicrobial coverage and often is found in mouthwashes.^{26,27} **Table 29–5** compares products made specifically for use with soft contact lenses.

TABLE 29–5 Selected Products for Use With Soft Lenses

Trade Name	Disinfectant(s)/Preservative(s)
Daily Cleaner	
Sensitive Eyes Daily Cleaner	Sorbic acid 0.25%, EDTA 0.5%
Preservative-Free Daily Cleaners	
Sof/Pro 2 Sterile Extra Strength Daily	n/a

Trade Name	Disinfectant(s)/Preservative(s)
Cleaner	
Sereine Extra Strength Daily Cleaner	n/a
Combination Hydrogen Peroxide Disinfecting Solutions and Rinsing/Neutralizing Products	
Clear Care	Hydrogen peroxide 3%
Clear Care Plus	Hydrogen peroxide 3%
Oxysept UltraCare	Hydrogen peroxide 3%
Refine One-Step	Hydrogen peroxide 3%
Enzymatic Cleaner	
Ultrazyme Enzymatic Cleaner	n/a
Preserved Saline Solutions	
Sensitive Eyes Plus Saline	Sorbic acid 0.1%, EDTA
Clear Care Rinse & Go	Polyquaternium 0.001%
Good Sense Saline Solution	Sorbic acid 0.1%, EDTA
Preservative-Free Saline Products	
PuriLens Plus ^a	n/a
LacriPure	n/a
Simply Saline	n/a
Rewetting/Lubricating Solutions	
Blink Contacts	Stabilized oxychloro complex 0.005% (OcuPure)
TheraTears Contact Lens Comfort Drops	Sodium perborate
Opti-Free Puremoist Rewetting Drops	Polyquaternium 0.001%, EDTA 0.05%
Opti-Free Express Rewetting Drops	Polyquaternium-1 0.001%,
Opti-Free Replenish Rewetting Drops	Polyquaternium-1 0.001%

Trade Name	Disinfectant(s)/Preservative(s)
Renu Rewetting Drops	Sorbic acid 0.15%, EDTA 0.1%
Renu MultiPlus Lubricating and Rewetting Drops	Sorbic acid 0.1%, EDTA 0.1%
Sensitive Eyes Rewetting Drops	Sorbic acid 0.1%, EDTA 0.025%
Multipurpose Solutions	
Biotrue	Polyaminopropyl biguanide (PHMB) 0.00013%, polyquaternium 0.0001%, EDTA
Complete Multi-Purpose Solution Easy Rub Formula	Polyhexamethylene biguanide 0.0001%, EDTA
OPTI-FREE Express	Polyquaternium-1 0.001%, myristamidopropyl dimethylamine 0.0005%, EDTA
OPTI-FREE PureMoist	Polyquaternium-1 0.001%, myristamidopropyl dimethylamine 0.0006%, EDTA
OPTI-FREE Replenish	Polyquaternium-1 0.001%, myristamidopropyl dimethylamine 0.0005%
Renu Fresh	Polyaminopropyl biguanide 0.0001%, EDTA
Renu Sensitive	Polyaminopropyl biguanide 0.00005%, EDTA
Blink RevitaLens	Alexidine dihydrochloride 0.00016%
	Polyquaternium-1 0.0003%, EDTA

^a To be used only with the PuriLens UV System.

Key: EDTA = Ethylenediaminetetraacetic acid; n/a = not applicable.

Reactions to solutions should always be considered in attempts to discern the cause of patient symptoms or findings of surface irritation during an eye examination. Most if not all of the chemicals listed as preservatives can cause irritation to the epithelium.²⁸ If signs and symptoms are related to solution use, a possible remedy is to use a final saline rinse before lens insertion or to

change to another formulation of multipurpose solution that uses a different preservative. Another alternative for patients who are sensitive to chemical-based care systems is the PuriLens system, as discussed earlier.

Cleaning Products

Daily use of separate cleaners and protein removal products, in addition to use of multipurpose solutions, generally is not necessary with disposable lenses that will be discarded after a few weeks of wear. These products should be recommended if patients have longer replacement schedules (>1 month) or demonstrate rapid formation of heavy deposits on lenses.²⁹ The nature of deposits varies, but they generally consist of proteins and lipids from lacrimal secretions. Environmental factors also can create deposits, such as tar and nicotine from tobacco products, pet dander, and dust.

Soft lens cleaning solutions generally contain a nonionic detergent, a wetting agent, a chelating agent, buffers, preservatives, and, in some cases, polymeric cleaning beads.²⁵ Cleaning with a surface-active cleaner can be done daily or, in the case of continuous-wear lenses, each time they are removed from the eyes. These products should be shaken before use. Care should be taken to ensure that no residue from the cleaning solution remains on the lens before insertion. Some surface-active cleaners (e.g., Bausch + Lomb Sensitive Eyes Daily Cleaner) have a lower viscosity, and such products may be a good choice for patients who have difficulty completely rinsing the cleaner off their lenses.

Although the surface-active cleaners generally are quite effective in removing lipid deposits, they remove tenacious protein debris less successfully. Enzymatic cleaners constitute an additional cleaning aid that can solve this problem.²⁹ The component enzymes hydrolyze polypeptide bonds of protein and dissolve the protein deposits. For the enzyme solution to work properly, however, the lens must be cleaned with a surface-active cleaner first; enzymes are ineffective on debris that covers or is mixed with protein.

An enzymatic cleaner is recommended in accordance with the disinfection system used by the patient. Ultrazyme contains the active ingredient subtilisin A and is used weekly with hydrogen peroxide cleaning systems. This product can be placed in the peroxide solution, thereby cleaning and disinfecting lenses at the same time.

Saline Solutions

A common source of confusion among patients is the use of saline solutions in lieu of disinfecting agents. At one point in the evolution of lens care, isotonic normal saline was the basic solution used for rinsing, thermally disinfecting, and storing soft contact lenses.^{25,29} It is now recognized, however, that saline used alone lacks disinfecting properties, and the health care provider should direct the patient toward a suitable multipurpose or hydrogen peroxide solution.

Saline still has a use as a final rinsing agent before insertion, especially for patients who experience eye irritation from the chemicals in multipurpose solutions. Prepared saline is available in either preserved or preservative-free forms. If preservative-free, the saline solutions can be used within a 30-day time period if they are in a multiuse bottle. Patients using nonpreserved saline should be counseled that only aerosolized solutions can be used to rinse lenses just before insertion into the eye. Other forms of saline, such as intravenous normal saline or saline nasal sprays, are not suitable for rinsing because these products usually are too acidic for use with soft contact lenses. Patients should not try to make their own saline solution, however, because it can become easily contaminated and cause infections.

Rewetting Solutions

Because dryness and discomfort with contact lens wear are common, additional lubricating or wetting drops are often recommended for use during lens wear. Exposure of lenses to wind and high temperature also causes some dehydration, even with the lens in the eye. Thus, encouraging patients to wear sunglasses to minimize exposure is beneficial to prevent these issues.

However, if dryness and discomfort occur, these accessory solutions permit lubricating and rewetting and, in some cases, cleaning of the soft lens while on the eye. Patients should be directed toward products for specific use with contact lenses, and to avoid drops preserved with benzalkonium chloride, which can cause irritation, discoloration of lenses, punctate keratopathy, and/or toxic ulcerative keratopathy.³⁰ Preservative-free lubricating drops also are a good alternative. The associated discomfort is sometimes relieved by instilling 1–2 drops of rewetting solution. To minimize risk of contamination, the tip of the applicator bottle should not touch the eye, eyelid, or any other surface.

Generic Solutions

Many generic versions of brand-name solutions are now available. However, patients who choose to buy generic (e.g., mass merchandiser–labeled) multipurpose lens solutions may be purchasing older, potentially obsolete formulas. Mass merchandisers generally acquire older formulations of nationally known brands of multipurpose solutions and then market them under their private label. In addition, the composition of a particular generic formulation can vary because the generic brand stores submit bids to manufacturers two or three times per year. Generally, patients should not use generic brands unless they carefully read the label and compare all ingredients with those of the product recommended by their eye care or other provider. Manufacturers are not required to use the same name for generic and brand-name ingredients, so comparing formulations may be difficult.³¹

Product Incompatibility

Several incompatibilities may be incurred during mixing of soft lens products. Most manufacturers test for compatibility within their own product lines; however, compatibility with other manufacturers' products usually is not determined. Generally, chemical disinfecting solutions should not be used interchangeably or concurrently, as discussed earlier.

Insertion and Removal

Table 29–6 provides instructions for inserting and removing soft lenses.

TABLE 29–6 Insertion and Removal of Soft Lenses

Insertion

- Wash your hands with noncosmetic soap and rinse thoroughly; dry hands with a lint-free towel.
- Remove one lens from its storage container.
- Rinse the lens with saline solution to dilute any preservatives left from disinfection (optional).
- Place the lens on the top of a finger, and examine it to be sure it is not inside out. This determination can be made by means of the “taco test”: Gently fold the lens at the apex (not the edges) between your thumb and forefinger. The edges should look like a taco shell with the edges pointed inward. If the edges roll out, the lens is inverted and must be reversed.

- Examine the lens for cleanliness. If necessary, clean it and rinse again.
- Place the lens on the eye using the procedure described for GP lenses (Table 29–9).
- Repeat all steps with the other lens.

Removal

- Before removing the lenses, wash hands with a noncosmetic soap; rinse hands thoroughly and dry them with a lint-free towel.
- Using the middle finger, pull down the lower lid of the right eye. Touch the index finger to the lens and slide the lens off the cornea, as shown in drawing A.
- Using the index finger and thumb, grasp the lens and remove it (drawing B).
- Repeat the procedure for the left eye.

Gas-Permeable Contact Lens Care

The care of GP contact lenses follows the same general guidelines as for soft lenses, but the solutions for GP and soft lenses are not interchangeable. The patient's eye care provider will recommend various products and regimens for the particular GP lens type, and lens wearers should be advised against substituting other products for those specifically recommended.

Rigid lens care involves the steps of cleaning, disinfecting, soaking, and wetting (Figure 29–2), which should be performed each time the lenses are removed from the eye, for optimal lens care.³² Modern solutions combine these steps in various formulations. Because GP lenses are replaced less frequently, allowing more time for deposits to accumulate, separate solutions for daily cleaning and protein removal are still popular. Oxidation systems (hydrogen peroxide) also can be used, but heat disinfection should not be used with GP lenses. Rinsing with tap water also is not recommended because of microorganisms in the water. Tables 29–2, 29–4, and 29–7 specify proper cleaning and disinfecting procedures for rigid contact lenses.

FIGURE 29–2 Basic care regimen for rigid contact lenses.

TABLE 29–7 Specific Cleaning Procedures for Gas-Permeable (GP) Lenses	
• Use the cleansing, soaking, and storage products recommended by your eye care provider for care of your lenses. • If you are unsure of your lens type, ask the eye care provider about proper cleaning procedures. • Upon removal of the lens, apply an appropriate cleaning solution to both lens surfaces. Then rub the lens with the tip of the forefinger against the palm of the opposite hand, using a back-and-forth motion, to avoid chipping an edge, which may occur if the lens is cleaned between the forefinger and the thumb. Do not apply too much pressure. If debris is still on the lens, soak a cotton swab in the surfactant cleaner, and use the swab to clean the lens. • Soak and store the lenses in a soaking or storage solution recommended by the eye care provider for the specified amount of time. Rewet lenses before inserting them in the eyes. • Enzymatic cleaning also may be recommended by your eye care provider and typically is performed weekly.

Product Selection Guidelines

With the abundance of combination wetting–disinfection solutions now on the market, the appropriate lens care regimen for GP lenses is fairly straightforward. Patients who wear GP lenses should be advised to purchase a surface-active cleaning product, an enzymatic product, and a conditioning or storage solution, depending on the type of lens worn.²⁵ A rewetting or reconditioning product also should be recommended. Table 29–8 lists examples of products for use with GP lenses.

Summary: July 2019 supplement to *Contact Lens Spectrum*, Pentavision LLC. Available at: https://www.clspectrum.com/resources/class-pdfs/7_19-class_final. Accessed April 15, 2020.

Cleaning Solutions

Cleaning solutions are used more often for GP lenses because of the longer wear time before disposal. Accumulated residue, primarily proteinaceous debris and lipids from tears and glandular secretions, acts as a growth medium for bacteria. If not routinely removed by daily cleaning, the residue

may harden to form coatings or tenacious deposits that decrease visual acuity and cause cloudiness of the lens. Cleaners contain silica gel, which acts to mechanically break the adhesive bonds that have formed between the lens and the deposits.

Storage Solutions

Storage solutions, also known as conditioning solutions, are used to store rigid contact lenses after removal. The stored lenses are maintained in a constant state of hydration for maximum comfort and visual acuity, and the conditioning agent also aids in removing deposits that accumulate on the lenses during wear. These solutions also increase comfort by providing cushioning and lubrication when the contact is reinserted into the eye.

Rewetting Solutions

Rewetting solutions are intended to clean and rewet the contact lens while it is in the eye. These solutions depend on the use of surfactants to loosen deposits; removal is assisted by the natural cleaning action of blinking. Although these products function well to recondition the lens, the cornea benefits more if the lens is actually removed, cleaned, and rewetted. Removing the lens for even a brief time allows the cornea to be resurfaced with a new proteinaceous or mucinaceous layer.

To maintain sterility in rewetting products, preservative levels are carefully selected in their formulation. Higher levels do not necessarily result in increased effectiveness and may lead to impaired wetting or corneal irritation because of the adsorption of preservatives onto the lens. Most rewetting agents are preserved, multidose products. Lens wearers who use these products frequently should be encouraged to use products that contain preservatives such as oxychloro complex or perborates. An important point to emphasize in patient counseling is that preserved artificial tears and rewetting agents are different; most preserved artificial tears are incompatible with contact lenses.³³

Enzymatic Solutions

As the silicone content of GP lenses increases, so does the amount of protein adherence. Silicone acrylate lenses have an active surface that promotes the binding of tear constituents. Protein deposits on a lens will decrease its oxygen

permeability and may contribute to wear discomfort. If daily cleaning is not sufficient, lenses of this type should be cleaned with an enzymatic product once weekly.³² Omission of this cleaning step may result in the need for professional polishing or replacement of the lens.

Insertion and Removal

Wearers of GP lenses should be counseled to follow proper insertion and removal procedures ([Table 29–9](#)).

TABLE 29–9 Insertion and Removal of Gas-Permeable Lenses

Insertion

- Wash your hands with noncosmetic soap and rinse thoroughly; dry hands with a lint-free towel.
- Remove one lens from its storage container.
- Rinse the lens with fresh storage or soaking solution, and inspect it for cleanliness and signs of damage (cracks or chips).
- If a wetting/storage solution is being used, place a few drops on the lens.
- Place the lens on the top of the index finger, as shown in drawing A.
- Place the middle finger of the same hand on the lower lid and pull it down (drawing B).
- With the other hand, use a finger to lift the upper lid, and then place the lens on the eye (drawing C).
- Release the lids and blink.
- Check vision immediately to see if the lens is in the proper position.
- If vision is blurred, blink three or four times. If vision is still blurred, the lens may be off center, on the wrong eye, or dirty.
 - Instill 1–3 drops of rewetting or reconditioning drops into the eye.
 - If vision is not improved, remove the lens, place several drops of wetting or storage solution onto both surfaces, and reinsert lens.
- Repeat all steps with the other lens.

Removal

- Before removing the lenses, wash hands with a noncosmetic soap; rinse hands thoroughly and dry them with a lint-free towel.
- Fill the storage cases with soaking or storage solution.
- Remove the top from the cleaning solution.
- Place a hand (or a towel) under the eye.
- Use one of the following methods to remove the lens from the eye.

Two-Finger Method of Removing Lenses

- Place the tip of the forefinger of one hand on the middle of the upper eyelid by the lashes, as shown in drawing D.
- Place the forefinger of the other hand on the center of the lower lid margin (drawing D).
- Push the lids inward and then together, as shown in drawing E. The lens should pop out.
- If the lens becomes displaced onto only the white part of the eye, recenter the lens and try again.

Temporal Pull/Blink Method of Removing Lenses

- Place an index finger on the temporal edge of the lower and upper lids. Initially, widen the eyelids a little (drawing F).
- Stretch the skin outward and slightly upward without allowing the lid to slide over the lens. Blink briskly, as shown in drawing G. The lens will pop out because of the pressure of the eyelids at the top and bottom of the lens. Blinking facilitates removal after the lids have been tightened around the lens.

Lens Storage Case

Patient education on the care of all contact lenses must include discussion of the proper care and cleaning of the contact lens storage case as well as the lens material. A dirty lens case can become contaminated with a biofilm that will attract pathogens, thereby increasing the risk of infection. The lens case should be cleaned daily. After lens insertion, the case (and case lid, if separate) must be emptied, rinsed with the same disinfecting solution, wiped, and air-dried between uses.³⁴ Tap water should not be used. All added solutions should be discarded daily. The case should not be used if cracked and should be replaced periodically, at least every 3 months.^{32,34}

Follow-up Care

Follow-up care is essential for the long-term success of contact lens wear. The minimum recommendation is 1 year between provider visits in the case of uncomplicated lens wear. These visits allow the prescriber to evaluate the integrity of the lenses worn and the condition of the cornea. Patient education content on the wearing schedule, replacement frequency, and lens care regimen also should be reviewed. Regular contact lens follow-up care is an important aspect of prevention of contact lens complications.

Contact Lens–Related Problems

Both soft and GP contact lenses provide good vision and safe, comfortable wear over years of use, provided that they are fitted properly and patients adhere to correct care regimens. Unfortunately, complications of contact lens wear have not been eradicated despite advances in material, lens design, and solutions. In general, soft contact lens wearers tend to have more complications because less tear exchange occurs beneath the lens and because wear times are longer, including overnight. Problems with GP lenses tend to be related to improper fit. Although occasional slight redness and mild discomfort are common with contact lens wear, health care providers likely to encounter patients with ocular complaints should be familiar with more severe symptoms that may herald significant complications, including threats to

vision. Whenever a patient presents with signs or symptoms that are believed to be related to contact lens wear, discontinuing lens wear is recommended until the underlying cause is diagnosed and treated. Therefore, every contact lens wearer should have eyeglasses available as a backup.

Evaluation of a contact lens–related complaint should begin with a thorough history of the problem. During the patient interview, the health care provider should determine what types of ocular signs and symptoms are present and for how long. Ascertaining whether the patient has a previous history of eye problems and identifying current medications will give a general sense of the etiology and urgency of the presenting problem. This information also will help to determine whether the problem is related to noncompliance with care regimens or to drug–lens interactions. Determining which type of contact lenses a patient is wearing and how long the patient has worn them is crucial in assessing problems that are related to improper lens care or deteriorated lenses. Patients should be asked to describe how they care for their lenses, which lens care products they use, and whether they have recently changed products.

Unfortunately, mild and severe complications of lens wear manifest with similar symptoms that overlap and vary in degree. For example, mild redness and irritation in both eyes occurring at the end of the day for several weeks or months are likely to reflect dryness that might resolve with a change in lens material, wearing schedule, or lubricating drops. However, a clinical presentation consisting of acute symptoms of marked, sectoral redness in one eye, accompanied by photophobia and pain that started 1 day earlier, suggests a more severe problem such as a corneal ulcer. This situation warrants immediate medical attention and should lead to referral to an urgent care center or a hospital emergency department.

The following signs and symptoms are common manifestations of lens-related problems:

- *Itching.* Patients usually are not allergic to lens materials, but they may have an allergy to solutions. Itching may also be a sign of allergic conjunctivitis unrelated to lens wear.
- *Blurred vision.* Mild blurring may suggest wrong lens power, accidental switching of lenses between eyes, an inside-out lens on the eye, or debris buildup on the lens. Blurring also accompanies problems with the ocular surface, such as superficial keratitis, corneal abrasion, and

corneal edema associated with infiltration or ulceration.

- *Redness.* Redness can occur as a response to any of numerous insults. The degree of redness typically, but not always, corresponds to the severity of the problem. Mild, diffuse redness can accompany end-of-day dryness, whereas severe redness, especially sectoral, can indicate a corneal problem. Ocular decongestants reduce the mild conjunctival hyperemia associated with prolonged lens wear. On cessation of use of these topical agents, however, a rebound hyperemia can result, especially with use for longer than 72 hours. Therefore, routine use of these products should be avoided, and if symptoms persist, the patient should be referred to an eye care provider.
- *Pain.* Pain is a significant finding because it is likely to be related to a pathologic process involving the eye's corneal nerve endings. Mild discomfort or irritation is not uncommon among wearers of all types of contact lenses. It may be related to the material, lens fit, or a torn or dirty lens. Severe pain or deep aching of the eye can signify corneal abrasions, infiltrates, or ulcers; if so, the pain typically persists even after removal of the lens. These latter symptoms are likely to represent urgent, sight-threatening conditions, and referral to an eye care provider is essential.
- *Fogging.* Misty or smoky vision can be caused by coatings or deposits on lens surfaces or by poor wetting of the lens while on the eye.
- *Photophobia (light sensitivity).* Similar to pain, photophobia suggests complications with the cornea or may be a symptom of iritis. This symptom necessitates referral to an eye care provider.
- *Excessive tearing.* Corneal nerves can start a feedback loop that promotes tearing; therefore, irritation to the corneal surface, such as a torn or dirty lens, will increase tearing.
- *Flare.* Point sources of light that have a sunburst or streaming quality can be caused by inadequate optic zone size or decentration of a poorly fitting lens.
- *Lens falling out of the eye.* Improper fit is usually the cause; however, even properly fitted rigid lenses may occasionally slide off the cornea or be blinked out of the eye. Soft lenses that dry out on the eye may move excessively and dislocate.
- *Squinting.* This reflexive maneuver is the result of excessive movement of a lens or a poorly fitted lens. The wearer will squint as an unconscious stratagem to center the optical portion of the lens over the pupil. Squinting also may indicate improper lens power.

Redness, discomfort, and dryness are the most common ocular complaints and the leading causes for discontinuing lens wear. Even with brand new contact lenses, mere presence of the lens disrupts the tear film and alters the environment of the anterior ocular surface, with corresponding clinical effects. A change in lens material or solution, alteration of lens fit, or use of lubricating drops usually leads to symptomatic improvement.

By contrast, microbial keratitis (leading to corneal ulceration) is the most serious complication of contact lens wear. The health care provider should be alert for signs and symptoms of this condition including blurred vision, redness, pain, light sensitivity, and watering that often worsen even after discontinuation of lens wear. A white infiltrate visible on the cornea necessitates urgent referral for evaluation by an eye care provider. Removal of contact lenses and prompt treatment are crucial to improve outcomes.

Overall, distinguishing common lens wear–associated complaints from signs of more severe inflammatory or infectious complications can be challenging. Considerations include whether one or both eyes are involved, the duration and severity of symptoms, and whether symptoms are isolated or found in conjunction with others. Even experienced health care providers have difficulty distinguishing inflammatory from infectious complications. Timely referral to an eye care provider is indicated if the clinical findings suggest more than lens wear–associated symptoms. [Chapter 28, Ophthalmic Disorders](#), addresses other problems that can be mistaken for contact lens issues.

Precautions for Contact Lens Wear

Adverse Effects of Drugs

Many undesired effects have been reported when a patient who wears contact lenses ingests, applies, or otherwise encounters certain drugs ([Table 29–10](#)). Wearers of soft hydrophilic contact lenses should be particularly cautious about exposure of the lenses to chemicals. Such chemicals, many of which penetrate and bind with the lens material, can come from cosmetics, environmental pollutants, and ophthalmic and systemic products. The health care provider must be fully cognizant of these potential drug-induced problems to counsel patients effectively.

TABLE 29–10 Drug–Contact Lens Interactions**Changes in Tear Film or Production*****Decreased Tear Volume***

Alcohol

Anticholinergic agents

Antihistamines

Antipsychotics

Beta blockers

Benzodiazepines

Botulinum toxin type A (Botox)

Conjugated estrogens

Diuretics/thiazides

Histamine type 2 (H₂) receptor antagonists

Oral contraceptives

Pain relievers—ibuprofen, acetaminophen-containing products

Phenothiazines

Proton pump inhibitors

Retinoids

Selective serotonin reuptake inhibitors

Sildenafil citrate

Statins

Timolol (topical)

Tricyclic antidepressants

Vardenafil HCl

Increased Tear Volume

Cholinergic agents
Garlic (dietary supplement)
Reserpine
Changes in Lens Color (Primarily With Soft Lenses)
Diagnostic dyes (e.g., fluorescein)
Epinephrine (topical)
Fluorescein (topical)
Nicotine
Nitrofurantoin
Phenazopyridine
Phenolphthalein
Phenothiazines
Phenylephrine
Rifampin
Sulfasalazine
Tetracycline
Tetrahydrozoline (topical)
Changes in Tear Tonicity
Pilocarpine (8%)
Sodium sulfacetamide (10%)
Lid/Corneal Edema
Chlorthalidone
Clomiphene
Conjugated estrogens
Oral contraceptives

Primidone
Ocular Inflammation/Irritation
Diclofenac (topical ophthalmic)
Garlic (dietary supplement)
Gold salts
Isotretinoin
Salicylates
Changes in Refractivity (Induction of Myopia)
Acetazolamide
Sulfadiazine
Sulfamethizole
Sulfamethoxazole
Sulfisoxazole
Changes in Pupil Size
<i>Pupillary Dilation</i>
Anticholinergic agents
Antidepressants
Antihistamines
CNS stimulants
Kava
Phenothiazines
<i>Pupillary Miosis</i>
Opiates
Miscellaneous Drug Effects
Digoxin—increased glare

Sedative-hypnotics/muscle relaxants—decreased blink rate
Ribavirin—cloudy lenses
Topical ciprofloxacin/prednisolone acetate—precipitate

Topical Medications

In general, patients should be warned not to use any ophthalmic solution, suspension, gel, or ointment in the eye when contact lenses are in place. A nonprescription ophthalmic product that is not specifically designed for compatibility with contact lenses also should not be used when lenses are in the eye. Soft lenses can absorb chemical compounds from topically administered ophthalmic products.³⁵ Topical administration of ophthalmic drugs also may have physiologic consequences or may modify pharmacologic responses to drugs. The use of solutions that may be considered benign, such as artificial tears, may reduce tear breakup time and alter the distribution of the mucoid, aqueous, and lipid components of tears, potentially causing initial discomfort on instillation of the drops. A topical drug administered while soft lenses are in place may have an exaggerated pharmacologic effect. The soft lens may absorb the drug and either release it over time, creating a sustained-release dosage form, or bind it tightly so that none of it is released into the eye. Furthermore, the presence of any kind of contact lens may increase the amount of time the medication is in contact with the eye. Finally, increased drug absorption may occur secondary to a compromised corneal epithelium from contact lens wear. The only exceptions to this rule are products specifically formulated to be used with contact lenses, such as rewetting drops, or those products that an eye care provider has specifically recommended for use with contact lenses.

After a drug solution has been instilled into the eye, insertion of a lens must wait until the solution has cleared from the lower eyelid's precorneal (conjunctival) pocket (approximately 5 minutes). Ideally, when topical ophthalmic ointments, gels, or suspensions are being used, the lenses should

not be worn at all.

Airborne Drugs and Particulate Matter

Some drugs that are present in indoor air may damage lenses, so caution is warranted in prescribing medications that are administered by inhalation for contact lens wearers. Similarly, lens wearers who have been exposed to a large amount of cigarette smoke have discovered a brown discoloration and nicotine deposits on their lenses. Other particulate matter, such as spray chemicals, smoke from grills, spattered cooking oil, pollen, animal dander, sawdust, or sand, also may create issues for contact lens wearers.

Systemic Medications

Use of a systemic medication often has far-reaching and unanticipated adverse effects aside from the expected pharmacodynamic actions. Perhaps the most common eye-related manifestation of such toxicity is the ocular discomfort or irritation and lens intolerance experienced by contact lens wearers taking certain systemic drugs. These patients often present with complaints of new-onset eye dryness or irritation and intolerance to previously well-established contact lens wear and request a nonprescription product to provide symptomatic relief. Although such symptoms are similar to those arising with other, more common underlying problems, such as improper contact lens hygiene, health care providers should always consider the pharmacology of specific systemic medications as well as potential relationships between medication initiation and onset of symptoms.³⁵

The effects of medications on the eye vary by drug class. As a general rule, compounds with anticholinergic effects can reduce tear volume and induce dry eye, with or without concomitant loss of accommodation and blurry vision.³⁶ Other classes of drugs, such as hormones (most notably birth control pills), also may alter tear volume and the contour of the corneal surface, resulting in blurring and contact lens intolerance. Some systemic medications are secreted into tears and may interact with the component material of the (primarily soft) lens. For example, rifampin will stain both lenses and tears orange. Drugs and dietary supplements such as gold salts and garlic are secreted into the tears, with consequent ocular irritation. Other drugs may affect tear production, the refractive properties of the eye, the shape of the cornea, or the actual lens ([Table 29–10](#)). Some medications may influence the

size of the pupil, leading to complaints of glare or flare when lenses are in place. Visual performance may be diminished, especially in patients who wear multifocal lenses or GP lenses, for which pupil size may determine placement of the reading segment or the optic zone of the lens, respectively.^{37,38}

Use of Cosmetics

Contact lens wearers should choose—and use—cosmetics with care. The patient should insert lenses before applying makeup and avoid touching the lens with eyeliner or mascara applicators. Cosmetics, moisturizers, and makeup removers with an aqueous base should be used, because oil-based products may cause blurred vision and irritation if they are deposited on the lens. Water-based products are always preferable, and when possible, users should choose makeup that has been specifically formulated for contact lens wearers. Lens wearers should avoid loose powders (e.g., face, eye) and instead use pressed or cream-based products, if available. Water-resistant mascara (as opposed to waterproof mascara, which requires an oil-based remover) should be applied only to the very tips of the lashes. Eyeliners should never be applied inside the eyelid margin; the liner material can clog glands in the eyelid and contaminate the contact lens. Eye makeup products should be discarded and replaced at least every 3 months.³⁹

Aerosol products, such as hair spray, body sprays, perfumes, sunscreens, and insect repellants, must be used with caution: Users should close the eyes when applying the product and step out of the mist before opening the eyes. Nail polish, hand creams, and perfumes also should be applied only after the lenses have been inserted. Men often contaminate their lenses with hair preparations and spray deodorants. Lens wearers should be reminded to take special care to clean the hands thoroughly before handling their lenses. Soaps that contain cold cream or deodorants should be avoided.

Exclusions for Self-Care

When the lens care regimen is appropriate but the lenses are old or, in the case of rigid lenses, chipped or scratched, the patient should see an eye care provider for replacement lenses. Other clinical scenarios that necessitate referral are those involving suspected vision changes, onset of deep aching of the eyes, overdue regular eye examination by more than 1 year, and suspected interaction between the lenses and systemic medications. Patients

experiencing lens problems related to any of the medical conditions or other factors discussed in the section “Contraindications and Warnings for Contact Lens Wear” also should be referred for further evaluation.

Cases 29–1 and 29–2 illustrate the assessment of two different patients with contact lens–related problems.

Case 29–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient is a contact lens wearer who complains of a “fogginess” in both eyes that is not present when she wears her glasses, as well as dry, itchy eyes. She has experienced these symptoms for the past week, but she states that they also typically occur toward the end of each month. She wears monthly disposable soft contact lenses. She reports changing her lenses on the first of each month and does not sleep in them. The patient’s lens care regimen includes soaking the lenses daily in fresh solution using the same multipurpose solution. She does not discard the solution at the end of the 90-day usability period. She also does not rub or rinse the contact lenses daily.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	Patient reports that she experiences less itching and redness when she first starts wearing a new pair of contact lenses and when she starts using a new bottle of solution.
c. Description of	Patient has not tried any measures to relieve her symptoms.

Relevant Evaluation Criteria	Scenario/Model Outcome
the patient's efforts to relieve the symptoms	
d. Patient's identity	Kate Smith
e. Patient's age, gender, height, and weight	30 years, female, 5 ft 6 in., 120 lb
f. Patient's occupation	Accountant
g. Patient's dietary habits	N/A
h. Patient's sleep habits	The patient gets about 7 hours of sleep per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe) -----	Ms. Smith is a nonsmoker who reports social alcohol use on the weekends.
She uses oil-based cosmetics.	
Assess	
2. Differentiate	Discomfort due to poor contact lens hygiene and care, as well as

Relevant Evaluation Criteria	Scenario/Model Outcome
patient's signs/symptoms, and correctly identify the patient's primary problem(s).	premature contact lens wear due to inadequate care, but the problem also could be due to oil-based cosmetic use.
3. Identify exclusions for self-treatment.	In view of the absence of any concurrent medical conditions or concomitant medications, Ms. Smith is a good candidate for self-care.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to an eye care provider. (2) Recommend self-treatment. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend using proper contact lens care and hygiene and switching to water-based cosmetics.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your symptoms suggest that you are not using an appropriate care regimen for your contacts. Not rinsing or rubbing your lenses daily can allow buildup of proteins on the lens, leading to fogginess. Also, wearing oil-based cosmetic products can lead to fogginess as well."
7. Explain to the	"Fogginess is a common contact lens complaint. Your symptoms are

Relevant Evaluation Criteria	Scenario/Model Outcome
patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	present only toward the end of a month of lens wear, when appropriate contact lens care has not been used, and may be exacerbated by your use of oil-based cosmetics. This is likely to be a self-care issue and does not require that you see an eye care provider at this time.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	“Discard the previous day’s solution and use new contact lens multipurpose solution daily. Rinse and rub contact lenses to remove proteins daily for at least 20 seconds. Use the recommended contact lens solutions from your eye care provider. Switch to water-based cosmetic products. Also be sure to discard the multipurpose solution at the end of the 90-day usability period. It might be helpful to write an ‘Opened on’ or ‘Discard’ date on the bottle as a reminder.”
b. Maximum number of days the therapy should be employed	“Perform appropriate lens care daily. You also should permanently switch to water-based cosmetics.”
c. Product administration procedures	“If your symptoms do not resolve, then return to your contact lens specialist for a refitting appointment and other options.”
d. Expected time	“Symptoms should resolve within the next day.”

Relevant Evaluation Criteria	Scenario/Model Outcome
to onset of relief	
e. Degree of relief that can be reasonably expected	"The fogginess should disappear with proper cleaning."
f. Most common adverse effects	n/a
g. Adverse effects that warrant medical intervention should they occur	"Fogginess that does not go away warrants medical attention."
h. Patient options in the event that condition worsens or persists	"See your eye care provider if the fogginess persists even after proper cleaning of the lenses, or if eye pain develops, because other issues may potentially be causing the problem."
i. Product storage requirements	"Solution should be stored at room temperature in a dry place. The contact lens case should be allowed to air dry while contact lenses are not in it."
j. Specific nondrug measures	n/a
Solicit follow-up questions from the patient or caregiver.	"What if I don't want to have to do this every day?"
Answer the patient's or caregiver's questions.	"You can call your eye care provider and discuss some options. The provider could potentially change your prescription to daily disposable contact lenses."
Monitor: Follow-up and Evaluate	
9. Assess patient	Call Ms. Smith in 2-3 days to assess how everything is going and if the

Relevant Evaluation Criteria	Scenario/Model Outcome
outcome.	suggestions worked for her. Also determine whether she has any questions.

Key: n/a = Not applicable; NKA = no known allergies.

Case 29–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient calls the pharmacy complaining of severe pain, redness, and blurry vision in both eyes after inserting his contact lenses this morning. He thought that the symptoms would dissipate in a few minutes, but they have persisted. Yesterday, he was switched to a peroxide-based disinfection system for his gas-permeable lenses at his yearly eye exam. Patient reports that he uses only a peroxide disinfecting solution and does not rinse lenses before insertion.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient reports that symptoms have subsided only slightly since removal of the lenses.
c. Description of the patient's efforts to relieve	The patient has not tried anything to address the situation other than removing the contacts shortly after insertion.

Relevant Evaluation Criteria	Scenario/Model Outcome
the symptoms	
d. Patient's identity	Thomas Chavez
e. Patient's age, gender, height, and weight	22 years, male, 6 ft 1 in., 200 lb
f. Patient's occupation	Web designer
g. Patient's dietary habits	Patient eats a balanced diet.
h. Patient's sleep habits	Mr. Chavez works long hours, getting about 5-6 hours of sleep per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No other conditions or medications
j. Allergies	Penicillin
k. History of other adverse reactions to medications	None
l. Other (describe) -----	Mr. Chavez is a nonsmoker and drinks socially.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Toxic keratitis, peroxide solution-induced
3. Identify exclusions for self-treatment.	Possible toxic keratitis
	Pain that does not subside with removal of contact lenses
4. Formulate a comprehensive list of	Options include

Relevant Evaluation Criteria	Scenario/Model Outcome
therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	(1) Refer the patient to an eye care provider.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Inform Mr. Chavez that he needs immediate medical care, either from his eye care provider or in a hospital emergency department, to identify the extent of the problem. He should not use self-care treatment at this time.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your symptoms suggest that you may have injured your eye, so you need to go to either your eye care provider or a hospital emergency department immediately."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"It is likely that your eye came into contact with un-neutralized peroxide solution from rinsing the contacts with peroxide solution or not allowing the contacts to neutralize overnight for at least 6 hours. Because eye contact with peroxide can cause significant damage, you need to go to either your eye care provider or a hospital emergency department immediately, to prevent any permanent damage, such as vision loss."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"I have a busy schedule today—do you think rinsing out my eye will be enough to solve the problem?"

Relevant Evaluation Criteria	Scenario/Model Outcome
Answer the patient's or caregiver's questions.	"Although you should rinse your eye with saline or tap water immediately, this will likely not be enough to ensure that no damage is done. Therefore, you need to be seen by your eye care provider or an emergency department physician as soon as possible. You could suffer permanent damage to your eye if it is not treated immediately."
Monitor: Follow-up and Evaluate	
9. Assess patient outcome.	Call Mr. Chavez in 2-3 days to determine whether he sought medical treatment and how the situation resolved. Ask if he has any further questions.

Patient Counseling for Prevention of Contact Lens–Related Disorders

Patient education on lens insertion and removal should always be provided at the time lenses are fitted. Patients also should be instructed on proper care techniques, with a specific recommendation for a lens care system. Often the prescriber's advice to use a particular product is ignored, and patients select products by price alone, especially with the availability of generic solutions. Similarity of product labels and lack of standardized labeling can lead to further confusion. Patients often ask whether it matters which solution they use. The correct answer is that it *does* matter, because incompatible solutions can be the cause of contact lens complications. Lens care products typically are formulated for use with either soft or GP lenses and, with a few exceptions, should not be used interchangeably. The box "Patient Education for Prevention of Contact Lens–Related Disorders" outlines the care regimen for each type of contact lens.

Patient Education for Prevention of Contact

Lens–Related Disorders

The objective of contact lens care is to prevent lens-related problems such as abrasions or infections of the cornea. For most patients, following the prescribed lens care regimen, product instructions, and self-care measures listed here will help ensure trouble-free use of contact lenses.

General Care Instructions for Most Contact Lens Types

- See [Table 29–2](#). Before handling or caring for contact lenses, wash hands with noncosmetic soap and rinse thoroughly; then dry them with a lint-free towel.
- Each time contact lenses are removed, clean, rinse, and disinfect them before wearing them again.
- Gently rub both surfaces of the contact lens, rinse thoroughly, and soak lenses overnight in the recommended solution according to the eye care provider’s instructions.
- For care of your lenses, use only those contact lens products recommended by the prescribing eye care provider.
- Do not change brands or products unless instructed to do so by the eye care provider. (Not all care systems are alike, and some may not be compatible with the contact lenses prescribed.)
- Do not “top off” a storage solution in the case after the solution has been used.
- Replace soaking or disinfecting solutions in the lens case after each use.
- Store contact lenses in fresh disinfecting solution overnight for the minimum soaking time recommended by the manufacturer to provide adequate disinfection.
- If lenses are worn intermittently, check and replace the solution weekly; consider daily disposable lens wear.
- Discard open bottles of solution if not used within the recommended time frame after being opened. Refer to the package labeling for individual products because “use within” time frames range from 1 up to 3 months, depending on the product. Write the date of first use of the solution on the outside of the

bottle.

- Store contact lenses in a proper lens case when not in use. Clean the contact lens case daily by rubbing with a disinfecting solution and allowing the case to air dry.
- Replace the contact lens case every 3 months.
- Saline solution is used only to rinse lenses; saline will not clean or disinfect contact lenses and should not be used as a storage solution.
- Do not use tap water to rinse contact lenses or to clean cases. Never store lenses in tap water.
- Do not place contact lenses in your mouth to clean or lubricate the lens. This practice can result in eye infections.
- To prevent contamination, do not touch dropper tip or the tip of lens care product containers.
- While lenses are in the eye, use only ophthalmic solutions specifically formulated for contact lens use.
- Avoid swimming, showering, bathing in hot tubs, or rafting or other activities in natural bodies of water while wearing contact lenses unless external eye protection, such as watertight goggles, is used.
- Follow prescribed wearing and replacement schedules.
- Avoid exposing contact lenses to extreme temperatures.
- Avoid use of oily cosmetics while wearing lenses. Bath oils or soaps with an oil or a cream base may leave a film on the hands that will be transferred to the lenses. Apply cosmetics *after* inserting contact lenses.
- To avoid mixing up the lenses, always insert or remove the same lens first. Check hard lenses for a dot in the lens periphery that identifies right from left.
- If a lens is not comfortable after insertion or vision is blurred, check to see if it is on the wrong eye or is inside out (inverted).
- To avoid damaging lenses, either apply aerosol cosmetics, hair products, and deodorants well before lens insertion or keep eyes closed until the air is completely clear of spray particles.
- Except for prescription continuous-wear lenses, do not wear lenses while sleeping.
- To avoid excessive dryness of the eyes, do not wear lenses while

- sitting under a hair dryer, overhead fans, or air ducts.
- When lenses are worn outside on windy days, protect the eyes from soot and other particles, which may become trapped under the lens and scratch the cornea, by wearing sunglasses or other protective eyewear.
 - Use eye protection in industry, sports, or any other occupation or hobby (such as cooking, when dangerous splatter may be an issue) that may be associated with the potential for eye damage.
 - Do not insert lenses in red or irritated eyes. If the eyes become irritated while lenses are being worn, remove the lenses until the irritation subsides. If irritation or redness does not subside, consult an eye care provider.
 - If an eye infection is suspected, see an eye care provider immediately.

Care Instructions for Soft Lenses

- See [Tables 29–2](#) and [29–3](#) for guidelines on cleaning and disinfecting soft lenses.
- Handle soft lenses carefully because they are very fragile and can be torn easily.
- Remove soft lenses before instilling any ophthalmic preparation not specifically intended for concurrent use with such lenses. Wait at least 20–30 minutes before reinserting the lenses, unless directed otherwise by an eye care provider.
- Do not wear lenses when a topical ophthalmic ointment is being used.
- Do not wear soft contact lenses in the presence of irritating fumes or chemicals.

Care Instructions for Gas-Permeable Lenses

- See [Tables 29–2](#) and [29–8](#) for guidelines on cleaning gas-permeable lenses.
- Do not use tap water to rinse off cleaner or to rewet lenses. If exposure to tap water occurs, disinfect lenses before inserting them in the eyes.

- See [Table 29–4](#) for guidelines on using disinfecting systems.

Care Instructions for Continuous-Wear Lenses (Gas-Permeable or Soft)

- Remove mascara before sleeping because it can flake off during sleep, with particles becoming trapped underneath the lens.
- If a lens appears to be lost on awakening, check to see whether the lens was displaced within the affected eye. Soft lenses can fold over on themselves and get lodged underneath the top or bottom eyelid.
- Each morning, check eyes carefully for unusual or persistent redness, discharge, or pain. If redness does not abate within 45 minutes, or if discharge or pain is present, remove the lens and call your eye care provider.
- Check vision after inserting lenses. (Some hazy vision is normal on awakening because of the corneal hypoxia that develops overnight.) Apply a few drops of rewetting solution to improve hydration of the lens and help correct the hypoxia. If the problem is not resolved, remove lenses, clean them, and reinsert. If vision is not improved within an hour, remove lenses and call your eye care prescriber.

Key Points for Prevention of Contact Lens–Related Disorders

- Following the prescribed lens care program is the best strategy for avoiding lens wear–related problems.
- The health care provider should explain the care regimen for the patient’s particular lens type and emphasize the importance of using only the products recommended for the prescribed lenses.
- Instructions on avoiding practices or situations that can cause eye irritation or lens damage also are important in educating the patient about successful wearing of contact lenses:

- Used contact lens solutions should not be “topped off” or reused.
- Even when using no-rub solutions, patients should be counseled to rub and rinse contact lenses to fully remove protein deposits.

- Patient counseling should identify signs and symptoms that indicate the need for medical care. Patients should be informed that if eye redness or pain or blurry vision occurs during wear of any form of contact lens, they should immediately remove the lens and see an eye care provider for evaluation before reinserting the lens.
- Patients should be reminded to have an annual check-up/evaluation by an eye care specialist.

Chapter 30: Otic Disorders

Authors: Deborah Zeitlin

Editor's Note: This chapter is based on the 19th edition chapter of the same title, written by Veronica T. Bandy.

Ear disorders are well-documented reasons for seeking health care in persons of all ages, with greater frequency noted in the pediatric and geriatric age groups than in adults.¹ Otic disorders are responsible for approximately 1.9% of yearly ambulatory care visits.² Specifically, cerumen impaction is one of the top three diagnoses managed by otolaryngologists.¹ Excessive or impacted cerumen is common, and incidence rates are reported as 10% in children, 5% in adults, and greater than 30% in the developmentally challenged and geriatric populations, especially nursing home residents.^{3,4} Approximately 12 million patients visit a primary care provider yearly for cerumen impaction, with more than 8 million requiring removal procedures.^{4,5} This common outpatient procedure cost over \$46 million in 2012 within the Medicare population alone.^{4,5} The primary impact of excessive cerumen is transient hearing loss, which affects patients of all ages.³⁻⁶

Self-treatment with nonprescription medications and complementary therapies should be restricted to minor external ear disorders, which include disorders of the auricle and the external auditory canal (EAC). Excessive cerumen and water-clogged ears are self-treatable EAC disorders for which the U.S. Food and Drug Administration (FDA) has approved nonprescription otic medications. Other self-treatable disorders of the auricle include atopic dermatitis, seborrhea and psoriasis, and allergic and contact dermatitis. [Chapters 33](#), [34](#), and [35](#), respectively, provide detailed discussions of the etiology and treatment for these disorders.

Head and neck diseases can cause referred pain, which patients often perceive as originating from the ear. The health care provider must attempt to determine the cause of pain before recommending self-treatment or medical referral. This chapter first briefly examines the anatomy of the ear and pathophysiology of ear disorders and then reviews associated nonprescription therapies for excessive or impacted cerumen and water-clogged ears. Next, an approach to the assessment of self-treatable otic disorders is described, with relevant case studies, followed by sections on patient counseling and

evaluation of patient outcomes.

Pathophysiology of Otic Disorders

The anatomy of the ear is conducive to certain types of otic disorders, especially in children; therefore, an overview of the anatomic features is included. The external ear consists of the auricle (pinna), the EAC ([Figure 30–1](#)), and the tympanic membrane (eardrum), which separates the external ear from the middle ear.⁶ The auricle is composed of cartilage with a closely apposed thin layer of highly vascular skin.^{7,8} The lobe has fewer blood vessels and is composed primarily of fatty tissue. The triangular piece of cartilage in front of the ear canal adjacent to the cheek is the tragus.

FIGURE 30–1 Anatomy of the auricle and external ear.

The EAC consists of an outer cartilaginous portion, which makes up one third to one half of its length, plus an inner body, or osseous portion.^{7,8} At the end of the canal is the tympanic membrane.⁹ The EAC in children is shorter, straighter, and flatter than that in adults, in whom the canal tends to lengthen

and form an S shape. The eustachian tube (within the inner ear) in a child also is shorter and flatter than that in an adult. By adulthood, the eustachian tube lengthens downward from the middle ear to the nasopharynx. This conformation helps promote drainage and inhibits aspiration of pharyngeal and nasal contents into the middle ear, which may help explain why children have more frequent middle ear infections than adults.¹⁰

The skin that covers the auricle is susceptible to bleeding when scratched, because of the lack of flexibility usually afforded by a subcutaneous layer of fat, not present in this location, and the generous blood supply to the area.^{7,8} The skin is highly innervated, resulting in a disproportionate degree of otalgia (ear pain) relative to any inflammation present. Skin farther along the course of the EAC is thicker and contains apocrine and exocrine glands as well as hair follicles. The skin in the canal is continuous with the outer layer of the tympanic membrane.

Cerumen, or earwax, present in the EAC consists of a mixture of sebum, an oily secretion from the exocrine glands, and a milky, fatty fluid from the apocrine glands. It lines the skin surface in the outer half of the EAC and may mix with desquamated cells.⁴ Cerumen lubricates the canal, traps dust and foreign materials, and provides a waxy, waterproof barrier to the entry of pathogens.⁷ Within the cerumen are various antimicrobial substances (lysozymes), and it has an acidic pH, which helps inhibit bacterial and fungal growth.¹¹

The canal skin sheds continuously and mixes with cerumen. The debris-laden cerumen slowly migrates outward with jaw movements (in chewing and talking). This migration serves as a process of self-cleaning.⁴ Cerumen may appear dry and flaky (gray color) or have an oily or paste-like consistency (honey color).¹²

Because the EAC forms a blind cul-de-sac, it is prone to collecting moisture. Its dark, warm, moist environment is ideal for fungal and bacterial growth. In the pre-inflammatory stage, moisture, local trauma, or both can remove the lipid layer covering the skin. Local trauma from fingernails, cotton-tipped swabs, or other items inserted into the canal can abrade the skin, allowing pathogens to enter. Because a normal, healthy ear canal is impervious to potentially pathogenic organisms, skin integrity generally must be interrupted before such microorganisms can produce an infection. Ear trauma from thermal injuries, sports injuries, ear piercing, and poorly fitting or improperly cleaned ear devices or hearing aids all can contribute to the breakdown of the EAC's

natural defenses.⁷ When involving the ear, dermatologic skin disorders, such as contact dermatitis, seborrhea, psoriasis, and malignancies, may also compromise these defenses.¹³

Patients engaging in self-care should be educated on the natural defenses of the ear canal. Considerations include the protective role of cerumen, the importance of maintaining the normal pH (<6.5) of the EAC, and the purpose of the hairs that line the outer half of the canal. The hairs within the ear canal prevent debris from reaching the ear drum, assist with hearing, and maintain a person's balance.

Viral or bacterial ear infections usually manifest as a sore throat, symptoms of the common cold, or an upper respiratory infection and arise in the middle ear behind the tympanic membrane. This presentation is due to the breakdown of natural defenses in the middle and inner ear, especially in younger children, whose immune system is not able to fight off infections as well as adults. These nasopharyngeal secretions can be aspirated and accumulate in the middle ear, leading to bacterial proliferation and an increased risk of infections.¹⁰ Holding back or stifling a sneeze can force secretions into the middle ear and therefore should be strongly discouraged, even in adults.

Excessive or Impacted Cerumen

Cerumen is a naturally occurring substance that assists in the defense of the external ear canal; it is recognized to clean, protect, and lubricate the EAC.⁴ A common myth that all earwax should be removed by cleaning may lead to excessive attempts at clearing the ear canal, with consequent damage to the EAC if done improperly.

Pathophysiology of Excessive or Impacted Cerumen

Impacted cerumen is defined as “lodged, wedged, or firmly packed” cerumen in the EAC.⁴ Various factors can disrupt the normal flow of cerumen toward the outer EAC. These causes include anatomic variability resulting in a narrow or irregularly shaped EAC, presence of excessive hair, irritation from foreign

objects used to assist in amplification or blocking of sound (hearing aids or ear plugs), use of cotton-tipped swabs, atrophy of the ceruminous glands with aging, or a genetic tendency.¹⁴⁻¹⁶ Recent research suggests that hearing aid use does not increase the likelihood of cerumen impaction, but more studies need to be performed.¹⁶ Inappropriate methods of removal of excessive or impacted cerumen including use of cotton swabs can push wax deeper into the ear or damage the EAC or tympanic membrane, potentially resulting in otitis media.¹⁵

Clinical Presentation of Excessive or Impacted Cerumen

The sensations of ear fullness, dull pain, or itching may be associated with excessive or impacted cerumen.^{3,4,6,15} Other common symptoms may include discomfort, tinnitus, dizziness, vertigo, cough, hearing loss, and hearing aid malfunction or feedback. Sometimes ear discharge and an odor may be present. Another potential negative effect is impaired cognition, especially in the elderly.

Treatment for Excessive or Impacted Cerumen

Treatment Goals

The goals of treating excessive or impacted cerumen are to remove the cerumen using safe and effective products while preventing potential adverse events. Appropriate use of cerumen removal treatments can be expected to eliminate signs and symptoms specific to the condition and other associated symptoms. The health care provider should assist the patient to choose a product that is cost-effective and readily administered at home.

General Treatment Approach

Therapeutic interventions include the use of cerumen-softening agents with or without irrigation.^{3,4,6} Manual removal of cerumen is an option for primary care providers with the proper skills and instrumentation, but caution is warranted with patient attempts, which are associated with greater risk of EAC damage (bleeding, pain, or perforation).¹¹ The updated clinical practice guidelines state that if the presence of excessive cerumen is asymptomatic, active management is not required.⁴ Manual removal of cerumen is stated as optional rather than recommended treatment.

The earwax-softening agent should be instilled into the ear for the appropriate amount of time, followed by rinsing with warm water, often done using a bulb syringe.¹⁷ Drying of the ear canal can be hastened by gently toweling off the outer ear structures or with use of a handheld blow dryer.¹⁸ Figure 30–2 includes a list of exclusions for self-treatment and presents an algorithm outlining the appropriate self-treatment approach for excessive or impacted cerumen.

Nonpharmacologic Therapy

Earwax should only be removed when it has migrated to the outermost portion of the EAC. The nonpharmacologic method to eliminate cerumen is with an ear-cleaning tool, or curette, for manual earwax removal. The curette can be reused and is only for adult use (e.g., Clinere Ear Cleaners, Ototek Loop Ear Wax Removal Tool). The Clinere Ear Cleaners are marketed only to clean the entrance area of the EAC.^{19,20} Even though the ear cleaners can be inserted into the EAC, caution is indicated because of the associated risk of trauma to the canal skin or tympanic membrane. Warm water irrigation with a bulb syringe is also an option, using sterile water; however, it has not been well studied.⁴ Use of a home oral jet irrigator in the ears is not recommended.⁴ The high-pressure water jet from the irrigator, as well as introduction of copious moisture into the EAC, may potentially cause otitis externa, a perforated tympanic membrane, localized painful injury, vertigo, otitis media, or tinnitus. With attempts to remove cerumen from the EAC, if patients experience pain or bleeding after repeated tries or if symptoms persist, an immediate medical referral is necessary. Medical referral also is warranted and nonprescription treatment is contraindicated in patients with previous ear surgery or a suspected tympanic membrane rupture.^{4,6} The use of cotton-tipped swabs for

ear cleaning or any other product intended for insertion into the EAC may cause increased cerumen impaction with occlusion of the canal and is not recommended in the practice guidelines.⁴ Accordingly, impacted cerumen should be removed only by a properly trained primary care provider.^{4,14}

Pharmacologic Therapy

Currently the only FDA-approved nonprescription earwax-softening agent is carbamide peroxide 6.5% in anhydrous glycerin.²¹ Other cerumen removal products studied include water-based agents that improve water miscibility (choline salicylate, docusate sodium, phenazone, potassium carbonate, urea peroxide, saline, distilled water) or oil-based agents that soften by dissolution (almond oil, benzocaine, chlorbutanol, or triethanolamine polypeptide). Results show that these agents are no more effective than carbamide peroxide and not recommended for use at this time.^{4,22,23}

Carbamide Peroxide

Carbamide peroxide 6.5% in anhydrous glycerin is FDA approved for use in the removal of hardened or impacted cerumen within the EAC. It is neither oil nor water based. It can be used alone or in conjunction with warm water irrigation to remove the loosened cerumen. This product can be used in children 12 years of age and older and adults. Use in patients younger than 12 years should be directed by the advice of a primary care provider.

For correct administration, 5 to 10 drops of the solution are instilled into the affected ear(s), with care to prevent the applicator tip from entering the EAC. Care also is warranted to prevent contact of the solution with the eyes during administration. The solution should remain in the EAC for several minutes for effective softening of excessive earwax. As carbamide peroxide is exposed to moisture, hydrogen peroxide and oxygen release slowly, resulting in a weak antibacterial effect and mechanical loosening of cerumen.

Anhydrous glycerin acts to soften and penetrate cerumen to help loosen excessive earwax. Anhydrous glycerin is widely used as a solvent and vehicle that has both emollient and humectant properties.²⁴ Any cerumen remaining after treatment may be removed with gentle, warm-water irrigation administered with a rubber otic bulb syringe.^{4,25} Earwax removal syringes are now widely marketed, with claims of increased safety and effectiveness

compared with bulb ear syringes. Caution is essential to ensure that the syringe tip is correctly placed and not over-inserted into the EAC.

Carbamide peroxide may be administered twice daily for up to 4 days. Patients should contact a primary care provider if symptoms persist after 4 days of use, if adverse effects develop, or if the presence of infection is suspected. Reported adverse effects include pain, rash, irritation, tenderness, redness, discharge, and dizziness.²⁶

Other Cerumenolytics

Other options to reduce the buildup of cerumen in the EAC include hydrogen peroxide and docusate.⁴ Hydrogen peroxide can be a source of nascent oxygen when exposed to moisture and function as a weak antibacterial agent.²⁷ Hydrogen peroxide 3% has been used to flush the ear canal during procedures for softening or removing earwax.³ Because hydrogen peroxide solutions contain water, overuse may predispose the ear to infection from tissue maceration caused by excessive water left in the EAC. This product is not FDA approved to treat excessive/impacted cerumen. Docusate is also a water-based cerumenolytic and used off-label.³ In comparison of docusate with other such products, no difference was found in rate of adverse effects (discomfort, irritation, pain) or clearance of ear wax.^{4,22} It may improve cerumen clearance relative to no treatment.⁶ Olive oil (sweet oil) drops or sprays are not recommended and are not FDA approved to treat excessive or impacted cerumen.⁴

Product Selection Guidelines

Table 30–1 lists examples of cerumen-softening and other otic products. No nonprescription cerumen-softening agents are approved for patients younger than 12 years. No special consideration for use is necessary in pregnant or lactating women or in older adults.

TABLE 30–1 Selected Nonprescription Products for Otic Disorders	
Trade Name	Primary Ingredient(s)
Cerumen-Softening Products	
Debrox Otic Drops	Carbamide peroxide 6.5%; glycerin; packaged with or without syringe

Trade Name	Primary Ingredient(s)
Earwax Removal	
Murine Ear Wax Removal	Carbamide peroxide 6.5%; glycerin; packaged with or without syringe
Ear-Drying Products	
Auro-Dri Drops	Isopropyl alcohol 95%; anhydrous glycerin 5%
Swim-Ear Drops	Isopropyl alcohol 95%; anhydrous glycerin 5%
Botanical & Homeopathic Products	
Similasan Ear Wax Relief	Causticum 12X; Graphites 15X; Lachesis 12X; Lycopodium 12X
Similasan Earache Relief	Chamomilla 10X; Mercurius solubilis 15X; Sulphur 12X
Hyland's Earache Drops	Belladonna 30C HPUS; Calcarea Carbonica 30C HPUS; Chamomilla 30C HPUS; Lycopodium 30C HPUS; Pulsatilla 30C HPUS; Sulphur 30C HPUS

Key: HPUS = *Homeopathic Pharmacopeia of the United States* (source for ingredients).

Complementary Therapies

An available homeopathic remedy to remove excessive cerumen is the use of ear candles. In accordance with the instructions for such products, a hollow ear candle is inserted into the EAC, and the candle's external protrusion is then lit on fire. It is hypothesized that the flame of the burning candle creates a negative pressure sufficient to draw cerumen from the EAC and into the hollow area of the candle. Currently, clinical practice guidelines advise against this treatment because of potential dangers and injuries associated with this practice. These risks include ear canal obstruction, hearing loss, tympanic membrane perforation, otitis externa, and burns to the patient's hair, face, or ear.⁴ FDA posted a consumer alert and video warning advising against the use of such products.²⁸ Also, the Center for Device and Radiological Health issued an alert notifying that the product labeling is "false and misleading," with no scientific evidence to support the practice.²⁹ For patients who inquire about ear candles, it is important to emphasize the associated risks, because these

candles may be available in pharmacies or on the Internet. (See [Chapters 51](#) and [52](#) for more information on natural products and complementary and alternative therapies.)

Water-Clogged Ears

Water-clogged ears constitutes a disorder defined as the retention of water within the EAC. The prevalence is unknown. This water retention can lead to hearing impairment, localized discomfort, or a sensation of fullness in the ear canal.²¹ Water-clogged ears should not be confused with otitis externa or swimmer's ear. Only isopropyl alcohol 95% in anhydrous glycerin 5% base as the active ingredient is recognized by FDA to be safe and effective when used as an ear-drying agent.²¹ Approved labeling for ear-drying products is limited to statements that may include "dries water in the ears and relieves water-clogged ears after swimming, showering, bathing, washing the hair." Any misleading statements would be considered misbranding.²¹ Of note, these products are approved only to aid in ear drying after such activities and not for prevention of moisture accumulation or treatment of an inflammatory process.

Pathophysiology of Water-Clogged Ears

A few specific host and environmental factors are recognized to contribute to the presence of excessive moisture within the EAC. Physical or anatomic changes within the EAC, such as excessive hair growth and canal narrowing, may lead to wax or debris buildup, which can lead to moisture retention. Excessive moisture may become trapped within the ear from sweating, high humidity, or swimming.¹⁸

Clinical Presentation of Water-Clogged Ears

The presence of water in the ear can cause transient hearing impairment or a sensation of localized discomfort or fullness. Heat and humidity can lead to swelling within the EAC, skin maceration, itching, and possible infection.³⁰ Patients with a history of ear surgery or those experiencing pain, dizziness, or ear drainage, or who display symptoms suggestive of otitis externa, infection,

or inflammation within the EAC, should receive a medical referral.³¹

Algorithm: Water-Clogged Ears

FIGURE 30–3 Self-care for water-clogged ears. Key: CAM = Complementary and alternative medicine.

Treatment of Water-Clogged Ears

Treatment Goals

The goals of treating a water-clogged ear are to dry the EAC using a safe and effective agent and prevent recurrences in persons who are prone to retaining moisture in the ears.

General Treatment Approach

Before recommending an agent to treat water-clogged ears, the health care provider should determine whether the patient has a ruptured tympanic membrane or a tympanostomy tube in place. Ear-drying agents are very painful if instilled in either of these situations. [Figure 30–3](#) includes a list of additional exclusions for self-treatment and presents an algorithm outlining the appropriate self-treatment approach for water-clogged ears.

Nonpharmacologic Therapy

Nonpharmacologic measures include tactics to prevent exposure and accumulation of moisture within the EAC. Earplugs or a bathing cap can be recommended when swimming.^{31–33} A variety of products, intended to protect the ears from exposure to water or absorb water when present, are available including AquaEars, BioEars, and ClearEars. The ClearEars water-absorbing earplugs are inserted into the ear canal to absorb trapped water; adult supervision is required for use in children younger than 11 years. The earplugs are left within the canal for 5 to 10 minutes to absorb any trapped water and then gently removed and discarded.³⁴ One maneuver to dispel excessive

moisture from the ear canal is to pull the ear lobe gently while tilting the head downward; this action straightens the EAC, which promotes gravity drainage.^{29,32,33} Another method is using a blow dryer on the lowest heat setting to help dry the EAC.³² For “waterproofing” the ears, the efficacy of earplugs versus cotton balls coated with petroleum jelly has been evaluated in a simulation study. Inserting petroleum jelly–coated cotton balls in the outer ear canal was found to be adequate initially. However, if expected duration of water exposure will be longer than 15 minutes, earplugs are more effective to prevent water from permeating the EAC.³⁵ One comparative study showed that molded earplugs provide better water leakage prevention than other earplugs or cotton balls covered with petroleum jelly.³⁶

Pharmacologic Therapy

Isopropyl alcohol 95% in anhydrous glycerin 5% is considered a safe and effective “ear-drying aid.”²¹ No minimum age is listed on the ear-drying products generally accepted for use when the ears are exposed to moisture. Patients are instructed to instill 4 or 5 drops in the affected ear. The active ingredient contains a warning to keep the product away from fire, because it is flammable. Instillation into the eyes should be avoided. If pain, burning, or irritation occurs with application or if symptoms persist after several days of use, a medical referral is indicated.³⁴ (See [Table 30–1](#) for examples of products containing these agents.)

Isopropyl Alcohol in Anhydrous Glycerin

Alcohol is highly miscible with water and acts as a drying agent. In concentrations greater than 70%, alcohol is also an effective skin disinfectant.³⁵ Glycerin has been used in pharmaceutical preparations for its solvent, emollient, or hygroscopic properties. It is safe but stings when applied to open wounds or abraded skin. Repeated use of alcohol alone can cause overdrying of tissue in the canal. The combination of alcohol and glycerin, however, provides a product that reduces moisture in the ear without overdrying.

Product Selection Guidelines

[Table 30–1](#) lists examples of ear-drying and other otic products. No special consideration is necessary for use of these preparations in pregnant, lactating, or geriatric patients.

Assessment of Otic Disorders: A Case-Based Approach

The most common complaints in ear disorders are otalgia, pruritus (itching), and hearing loss. Evaluating the characteristics of each particular symptom, such as pain and hearing loss, as well as the specific combination of symptoms, is key to assessing otic disorders. Cases 30–1 and 30–2 provide examples of the assessment of two different patients with otic disorders; common otic symptoms and possible causes are highlighted. **Table 30–2** compares the signs and symptoms and other features of common otic disorders.^{3,4,7,21,33,37–40} **Table 30–3** summarizes common causative disorders and appropriate management for primary presenting complaints related to the ear: otalgia, otic pruritus, hearing loss, dizziness, tinnitus, and foreign body.^{3,7,10,13,18,21,41–44} Screening for hearing is typically performed in newborns or children and adults who present with potential deficits. Routine screening for hearing loss in older adults is currently not recommended, but the U.S. Preventive Services Task Force is reevaluating this issue.⁴⁵ If hearing loss is a concern, it is recommended that the patient seek medical referral.

TABLE 30–2 Differentiation of Common Otic Disorders						
TABLE 30–2 Differentiation of Common Otic Disorders						
Disorder	Etiology	Pain	Itching	Hearing Loss or Hearing	Discharge	Other Features
Ruptured tympanic membrane	Otitis media or trauma to ear such as a sharp blow, diving into water, forceful irrigation of ear	Brief, severe	No	Abrupt	If associated with otitis media	May be associated with otitis media (see that entry)
		Acute				Swollen ear
External otitis (swimmer's ear)	Local trauma to EAC caused by excessive moisture or abrasions; subsequent fungal/bacterial infections	Acute, ranges from mild to severe, with movement of tragus or auricle	Yes	Occasional	Occasionally, clear discharge changing to seropurulent	Swollen ear canal, discharge, swollen lymph nodes, fever, usually occurs in summer or in warm, humid

Disorder	Etiology	Pain	Itching	Loss of Hearing	Discharge	Other Features
		of tragus				stimates or in
		of auricle Sharp,				warm, humid climates Perforated or
Otitis media Otitis media	Bacterial infection of middle ear, infection of both ears can usually help in early infection respiratory tract infection	steady, frequently steady; frequently unilateral; does not increase withagus or auricle	No No	Is sometimes decreased sometimes decreased	Possible exudate through perforated eardrum	bulging Perforated or bulging nodes sometimes lymphadenofever, skin rashes usually no fever, dizziness; usually occurs
	Insects,	of tragus Dull auricle				in winter If obstruction
Foreign object in ear Foreign object in ear	insertion of objects, by insertion of objects by children, attempting to, sound	severe, with sense of fullness with sense of pressure during chewing	Yes Yes	Yes Yes	Possible exudate Possible secondary bacterial infection	not removed from ear acute otitis media and tinnitus may develop.
	attenuators Burns from curling iron,					
Trauma to ear Trauma to ear	Blow to the ear from blunt objects/ injury to the ear from blunt objects, sports injuries, piercing, improper techniques, abrasions of EAC, rashes, abrasions of EAC, rapid changes in air pressure	Ranges from sharp Steady sharp brief and severe to brief and severe	Rare Rare	Varies, can be abrupt Varies, can be abrupt to seldom	Seldom Seldom	Untreated hematomas may cause swelling, may cause tearing, may cause pain, may cause bleeding, may cause infection, may cause metal poisoning, may cause shock syndrome, hepatitis B.
	changes in air pressure disorders,					Continuous or intermittent
Tinnitus Tinnitus	blockage of EAC, exposure to loud noise levels, acoustic	Possible Possible	No No	Sometimes Sometimes	None None	continuous or intermittent ringing, roaring, or

Disorder	Etiology	Pain	Itching	Loss of Hearing	Discharge	Other Features
	EAC exposure to high noise levels, acoustic trauma, (from sulfate, disease, drug toxicity, foci, otitis media, aminoglycosides, and other antibiotics)					hearing as ringing, roaring, or humming
Excessive/impacted cerumen	Overactive sebaceous glands, obstructed migration of cerumen	Rare, dull pain if present	No	Often	None	Sense of fullness or pressure in ears
Excessive/impacted cerumen	Obstructed glands	Rare, dull pain if present	No	Often	None	Sense of fullness or pressure in ears
Water-clogged ears	migration of excessive cerumen moisture in EAC	None	No	Often	None	Sense of fullness or wetness
Water-clogged ears	Excessive moisture in EAC	None	No	Often	None	Sense of fullness or wetness

Key: EAC = External auditory canal.

TABLE 30–3 Etiology and Treatment of Common Otic Complaints

Complaint	Etiology	Treatment
Otalgia	<i>Intrinsic:</i> infection, trauma, foreign objects, perichondritis <i>Extrinsic:</i> dental or jaw problems, nasopharyngeal infections, tumors, cysts, migraine headaches, neuralgias, cervical arthritis	Medical referral unless cause is clearly obvious, self-limiting, and self-treatable; always refer patients with suspected infection; self-care may delay seeking proper treatment.
Otic pruritus	Seborrhea, psoriasis, contact dermatitis; infection (external otitis); excessive dryness related to decreased sebum production	See Chapters 34 and 35 ; medical referral is indicated for suspected infection; excessive dryness: administer 1–2 drops of mineral oil.

Complaint	Etiology	Treatment
Hearing loss	Foreign objects or water trapped in EAC; infection, congestion, neoplasms, tympanic membrane perforation, medication effects; excessive pressure or cerumen in EAC, or exposure to high noise levels	Medical referral is indicated unless hearing loss is related to excessive water or impacted cerumen in EAC.
Dizziness	Inner ear lesions, otitis media, rapid change in pressure on the tympanic membrane, migraine headache, ototoxic drugs, postural hypotension, cardiac disease, neoplasms, irrigation of ear canal with very hot or cold water, motion sickness	Medical referral is indicated unless complaint is related to motion sickness.
Tinnitus	See Table 30-2	Check for impacted cerumen; otherwise, medical referral is indicated.
Foreign body	Insects, beads, seeds, small batteries, or other objects in ear canal	Medical referral; mineral oil can be used to quickly suffocate an insect, with relief of distressing symptoms, until it can be removed by a PCP; moisture causes seeds to swell, making removal more difficult.

Key: EAC = External auditory canal; PCP = primary care provider.

Case 30-1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s)	For the last 2 days, the patient has noticed ear itching and

Relevant Evaluation Criteria	Scenario/Model Outcome
(i.e., nature, onset, duration, severity, associated symptoms)	hearing changes in that sounds are muffled.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	He started a new workout routine and has been wearing ear buds longer than normal during his workouts. He denies any pain, dizziness, or tinnitus.
c. Description of the patient's efforts to relieve the symptoms	He wipes his ears with a dry towel after showering.
d. Patient's identity	Patrick Walker
e. Patient's age, gender, height, and weight	32 years, male, 5 ft 10 in., 180 lb (82 kg)
f. Patient's occupation	Mr. Walker is a financial advisor.
g. Patient's dietary habits	He eats out most meals, primarily fast food. He wants to start making healthier choices.
h. Patient's sleep habits	He averages 6 hours at night owing to his busy work schedule.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Loratidine 10-mg tablet, oral, daily Multivitamin 1 tablet, oral, daily Acetaminophen 1 or 2 500-mg tablets, oral, as needed for pain
j. Allergies	Seasonal allergies in the spring
k. History of other adverse reactions to medications	Amoxicillin and peanuts
l. Other (describe) _____	Mr. Walker currently wants to work out more and lose weight. He started a routine 5 days ago with a plan to run 4 days a week and do strength training twice per week. He wears ear buds when he works out.
Assess	

Relevant Evaluation Criteria	Scenario/Model Outcome
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 30-2).	Mr. Walker is experiencing cerumen impaction, likely the result of wearing ear buds more frequently when working out.
3. Identify exclusions for self-treatment (Figure 30-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to an appropriate PCP. (2) Recommend a nonprescription cerumen-softening agent with proper ear hygiene (Table 30-1). (3) Recommend use of a nonprescription ear-drying agent (Table 30-1). (4) Recommend self-care until the patient can see an appropriate PCP. (5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Walker can use a nonprescription cerumen-softening agent with proper ear hygiene and nonpharmacologic therapy.
6. Describe the recommended therapeutic approach to the patient or caregiver.	The patient can use carbamide peroxide 6.5% in anhydrous glycerin 5 to 10 drops up to twice daily as needed for a maximum of 4 days. He also can use a curette as needed to help remove cerumen that is located in the outer part of the ear canal.
7. Explain to the patient or caregiver the rationale for selecting the recommended	"The carbamide peroxide will help loosen the excess cerumen in the outer part of the ear canal and help the cerumen move down the ear canal on its own. A curette can help remove the

Relevant Evaluation Criteria	Scenario/Model Outcome
therapeutic approach from the considered therapeutic alternatives.	excess cerumen once it leaves the ear canal to prevent cerumen impaction.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	“You can use a wet washcloth on the outside of the ear canal to help remove excessive earwax or use a curette as needed.” See the box “Patient Education for Self-Treatable Otic Disorders.”
a. Appropriate dose and frequency of administration	“Administer 5 to 10 drops of the carbamide peroxide in anhydrous glycerin into both ears, up to twice daily.”
b. Maximum number of days the therapy should be employed	“It can be used for up to 4 days as needed.”
c. Product administration procedures	“Tilt your head sideways. Instill ear drops using the applicator tips. Make sure that the applicator tip does not enter the ear canal. Keep drops in the ear for several minutes (up to 5 minutes) by keeping your head tilted or placing a piece of cotton at the end of the outer ear canal. After instillation of carbamide peroxide drops, the outer part of the ear canal can be gently flushed with warm water using a soft rubber bulb syringe.”
d. Expected time to onset of relief	“Relief may occur shortly after the first administration; however, this depends on the amount of earwax that is located in the ear canal and the dryness of the earwax.”
e. Degree of relief that can be reasonably expected	“Complete relief can be expected in a few days.”
f. Most common adverse effects	“Side effects usually do not occur with use of this product. Instilling the drops into the ears may cause local irritation.”
g. Adverse effects that warrant medical intervention should they occur	“If you experience pain, rash, irritation, tenderness, redness, discharge, or dizziness when using this product, it is recommended that you contact your PCP.”

Relevant Evaluation Criteria	Scenario/Model Outcome
h. Patient options in the event that condition worsens or persists	"Stop using the product immediately and see your PCP."
i. Product storage requirements	Keep cap on bottle when not using it. Store drops in original carton at room temperature, and do not store above 77°F (25°C).
j. Specific nondrug measures	See the box "Patient Education for Self-Treatable Otic Disorders."
Solicit follow-up questions from the patient or caregiver.	"Should I stop using ear buds?"
Answer the patient's or caregiver's questions.	"You can continue to wear the ear buds, but be aware of the effect of increased earwax. Make sure that you clean off the ear buds after each use and follow the package insert for directions. Always use safe ear hygiene techniques to minimize the risk of earwax impaction."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Walker in 4 days to evaluate his response to treatment and resolution of symptoms. If he is still complaining of symptoms, he will require a referral to a PCP.

Key: PCP = Primary care provider.

Case 30–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	

Relevant Evaluation Criteria	Scenario/Model Outcome
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient returned from a trip to a beach resort yesterday. Symptoms started on the flight home and include ear discomfort, a sense of fullness, and impaired hearing. Patient also describes a "water-logged" feeling of excess moisture in both ears and reports intermittent ear pain with discharge.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient spent a lot of time swimming at the beach and being outside in hot and humid weather.
c. Description of the patient's efforts to relieve the symptoms	Patient has used cotton-tipped swabs in the ear canal to dry them, but this has been unsuccessful at relieving the "water-logged" feeling.
d. Patient's identity	Angela Baker
e. Patient's age, gender, height, and weight	46 years, female, 5 ft 6 in., 145 lb (66 kg)
f. Patient's occupation	Office manager
g. Patient's dietary habits	Ms. Baker brings her lunch from home daily and prepares most of her meals at home. She states she tries to make healthy food choices. She eats out with friends on the weekends for dinner, usually on Friday and Saturday nights. She drinks 1 cup of coffee daily.
h. Patient's sleep habits	She sleeps 7 hours a night on weekdays but is able to sleep 8 hours a night on the weekends.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Omeprazole 20-mg capsule orally daily as needed. Melatonin 1-mg tablet orally at night for sleep. Occasional heartburn and insomnia.
j. Allergies	None
k. History of other adverse	Codeine

Relevant Evaluation Criteria	Scenario/Model Outcome
reactions to medications	
I. Other (describe) _____	Patient currently wants to be able to hear better and eliminate the moist feeling from her ears. It has made it very hard to hear at work and to speak on the phone.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 30-2).	Ms. Baker is experiencing a sensation of water-clogged ears with pain and discharge from both ears.
3. Identify exclusions for self-treatment (Figure 30-3).	Ear pain and ear discharge from both ears
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to an appropriate PCP. (2) Recommend a nonprescription cerumen-softening agent with proper ear hygiene (Table 30-1). (3) Recommend use of a nonprescription ear-drying agent (Table 30-1). (4) Recommend self-care until the patient can see an appropriate PCP. (5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. Baker should be referred to a PCP because of symptoms of ear pain and ear discharge. It should also be recommended that patient avoid using cotton-tipped swabs in the ears.
6. Describe the recommended therapeutic approach to the patient or caregiver.	Refer Ms. Baker to a PCP for an appointment today.

Relevant Evaluation Criteria	Scenario/Model Outcome
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Your symptoms suggest you have excess moisture in your ears. Of greater concern are your ear pain and ear discharge, which is not normal. It is highly recommended that you be seen by a PCP to make sure your ears are looked at and treated appropriately."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"You can use earplugs in the future when you swim to prevent water from getting into your ears." See the box "Patient Education for Self-Treatable Otic Disorders."
Solicit follow-up questions from the patient or caregiver.	"What can I do to prevent this from happening in the future?"
Answer the patient's or caregiver's questions.	"When you go on vacation and know that you will be in a hot and humid environment or swimming more than normal, you can wear molded earplugs to prevent water from entering into your ear canal. After you swim, you can tilt your head to the side and help the excess water drip out of your ears. You can also dry your ear canal by using a blow drier on the lowest heat setting."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Ms. Baker in 1 day to confirm she followed up with her PCP and to determine the current status of her symptoms.

Key: PCP = Primary care provider.

Patient Counseling for Otic Disorders

For patients attempting to self-treat otic disorders, it is important to ensure that they know which medication to use and that the product is appropriate for otic administration, as well as how to administer the agent. They also should demonstrate knowledge of appropriate technique for any otic devices (bulb syringe or curette). Patients should also be aware of the associated risk for injury to the EAC. The health care provider should discourage common harmful practices of relieving itching of the ear using cotton swabs, fingernails, or other devices, and provide instruction on the proper methods of removing excessive cerumen and moisture from the ears. Patients who are susceptible to these disorders should be advised to incorporate proper removal methods in their “aural hygiene” regimen. The health care provider should explain possible adverse effects of all recommended medications and when a medical referral is appropriate. The box “Patient Education for Self-Treatable Otic Disorders” lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Otic Disorders

The recommended self-treatment measures for impacted or excessive cerumen and water-clogged ears have been proved effective in most uncomplicated cases. If symptoms related to these conditions persist or worsen after 4 days of appropriate self-treatment, the patient should seek medical referral. Another important indication for medical referral to a primary care provider is the development of ear pain or ear discharge or drainage during treatment.

The health care provider can follow up with the patient by telephone in 4 days to determine whether the therapy is successful, or direct the patient to seek further medical evaluation as appropriate.

Patient Education for Self-Treatable Otic Disorders

Excessive or Impacted Cerumen

Cerumen is necessary to lubricate the ear canal, trap dust and foreign materials, and provide a waxy, waterproof barrier to the entry to prevent infections. The objective of self-treatment is to soften and remove any waxy buildup or to prevent the disorder from recurring in susceptible persons. For most patients, carefully following product instructions and self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Use a wet washcloth draped over a finger to remove earwax from the outer canal or an approved ear-cleaning tool following the product instructions.
- Do not insert objects including cotton swabs into the ear to remove earwax. This may injure the ear canal or push the wax farther into the canal.
- Never use an ear candle to remove earwax. This practice can cause serious ear injury or burns to other areas of the body.

Nonprescription Medications

- A combination of carbamide peroxide and anhydrous glycerin is recommended to soften and mechanically break down excessive or impacted cerumen.
- Carbamide peroxide is given by instilling 5–10 drops into the ear that has excessive or impacted earwax twice daily. The patient's head should be tilted and drops placed into the ear canal. The patient should remain in position for 5 minutes.
- Do not let the medication come into contact with the eyes.
- Do not use this medication if you have a fever, ear drainage, pain more severe than a dull pain, dizziness, or a ruptured eardrum, or have had ear surgery within the past 6 weeks.
- Do not use this medication to treat inflamed ear tissue, swimmer's ear, or itching of the ear canal.
- Prolonged contact between carbamide peroxide solution and the

skin of the ear canal can cause dermatitis. Discontinue treatment if irritation or a rash appears.

- Store product in a cool, dry area, and check expiration date before using.

When to Seek Medical Attention

- Monitor for changes in your hearing and symptoms of infection such as pain and itching.
- If severe pain occurs or your hearing worsens, see a primary care provider immediately. Severe pain may indicate a ruptured eardrum.
- If you used carbamide peroxide for 4 days and are still experiencing symptoms, see a primary care provider.
- Patients younger than 12 years of age with ear symptoms also should see a primary care provider.

Water-Clogged Ears

Water can become trapped in the ear, causing a sense of fullness or wetness. The goal of self-treatment is to remove excess moisture from the ear canal or to prevent water from remaining in the ear canal in persons who are prone to this condition. For most patients, carefully following product instructions and the self-care measures will help prevent or treat this condition and ensure optimal therapeutic outcomes.

Nondrug Measures

- Tilt the head with the affected ear down, and gently manipulate the outer ear to help drain water from the ear. Gently towel dry the outer ear area.
- Immediately after swimming or bathing, use a blow dryer on low-heat and low-speed settings to help dry the ear canal. Do not blow air directly into the ear.
- Wear earplugs, preferably molded earplugs, or a bathing cap when ears will be exposed to water for an extended period of time for either bathing, showering, or swimming.

Nonprescription Medications

- Use an isopropyl alcohol 95% in anhydrous glycerin 5% product that is an FDA-approved formulation.
- Do not use this medication if you have a ruptured eardrum or a tympanostomy tube in place.
- Instill 4 or 5 drops in each affected ear. Allow the solution to remain for 1–2 minutes.
- Do not let the medication come into contact with the eyes.
- Keep medication away from fire and flames.
- Store product in a cool, dry area, and check expiration date before using.
- This product is safe for use in children.

When to Seek Medical Attention

- See a primary care provider if you develop pain, burning, or irritation of the ear with medication use.
- See a primary care provider if you have ear drainage or discharge, dizziness, or recent ear surgery,

Key Points for Otic Disorders

- Limit self-treatment of otic disorders to relief of minor symptoms such as a sense of fullness, pressure, or wetness in the ears.
- Seek a medical referral for further evaluation in patients younger than 12 years of age with impacted cerumen, as well as those with signs and symptoms of ear infection, bleeding or signs of trauma, tympanostomy tubes, or ruptured tympanic membrane and patients who had ear surgery within the past 6 weeks.
- Instruct patients on how to use specific otic products that are proved safe and effective.
- Advise patients with self-treatable symptoms to contact a primary

care provider if symptoms worsen or no improvement occurs after 4 days.

- Educate patients about proper ear hygiene, along with the role of cerumen in the healthy ear canal, to prevent further problems.

Chapter 31: Prevention of Hygiene-Related Oral Disorders

Authors: Karlene Melody

Dental diseases and disorders are recognized to affect the health and well-being of Americans throughout their lifespan. Professional dental care is essential to maintain oral health. The most commonly recommended interval of examination is every 6 months; however, this frequency should be individualized according to historical, clinical, and radiographic findings. Patients at high risk for periodontal disease need more frequent visits, and low-risk patients are recommended to return for follow-up assessments at a minimum of once a year. Children should have their first visit to a dental care provider at the time of the first tooth eruption, at no later than 12 months of age. Despite these recommendations for optimal oral health, more than 30% of adults have not visited a dentist in the past year.¹ By comparison, approximately 85% of children 2–17 years of age have been seen by a dentist within the year.¹ In the United States, 46% of children 2–19 years of age have dental caries, and 13% of these cases go untreated.² The overall frequency of dental caries increases as children get older, from 21% for those 2–5 years of age to greater than 50% for school-age children.² Furthermore, rates of dental caries in Hispanic children and non-Hispanic black children, at 57% and 48%, respectively, are significantly higher than those in non-Hispanic white youth.² Significant disparities in caries frequency also are correlated with socioeconomic status. Poor oral health is particularly detrimental for children in that it affects nutrition, growth, and development.

Improper oral hygiene is a direct cause of dental caries, periodontal disease (gingivitis and periodontitis), halitosis, and some cases of denture-related discomfort. Nonprescription products for prevention of oral disease are widely available in pharmacies, food stores, and other retail venues; educating the public about proper use of these products is key to preventing dental diseases.

The teeth and supporting structures are necessary for effective mastication and articulation, as well as for normal appearance. The primary (deciduous or baby) dentition first appears at the age of approximately 6 months, when the mandibular (lower jaw) central incisors erupt; the process usually is complete with eruption of the upper second molars at approximately 24 months of age.

Each of the upper and lower arches holds 10 deciduous teeth, for a total of 20. Generally, emergence of the permanent dentition (adult teeth) begins when the mandibular first molar erupts behind the deciduous second molar at the age of approximately 6 years, and the process continues in a regular pattern, usually with replacement of deciduous teeth as they are shed. Of the 32 total permanent teeth, 28 usually are present by the age of 14 years; third molars (wisdom teeth) may appear between the ages of 17 and 21 years.

Anatomically, the teeth are viewed grossly as having two parts, the roots and the crown ([Figure 31-1](#)). The roots, which extend below the gingival (gum) line or margin and thus are normally concealed from view, are essential in supporting and attaching the tooth to the surrounding tissues. The crown is the part of the tooth visible above the gingival margin and provides appropriate surfaces for effective mastication. Each tooth has four major structural components: enamel, dentin, pulp, and cementum.

FIGURE 31-1 Anatomy of the tooth.

Enamel is composed of very hard, crystalline calcium phosphate salts (hydroxyapatite). It is 1.5–2 mm thick at its thickest part and protects the underlying tooth structure. It covers the crown of the tooth, ending around the gum line at the cemento-enamel junction. Enamel's hardness enables the crown to withstand the wear of mastication. *Dentin*, which is softer, lies just beneath the enamel and makes up the largest part of the tooth structure. It contains a network of microscopic tubules that transport nutrients from the dental pulp. Dentin protects the dental pulp from mechanical, thermal, and chemical irritation. The bone-like *cementum* is softer than dentin and covers the root of the tooth, extending apically from the cemento-enamel junction.

The *pulp* occupies the pulp chamber and canal. It is continuous with the tissues surrounding the tooth by an opening at the apex of the root (apical foramen). The pulp consists primarily of vascular and neural tissues. The only nerve endings in the pulp are free nerve endings; therefore, any type of stimulus to the pulp is interpreted as pain.

The *periodontium* comprises the hard and soft tissues that surround the teeth, including the periodontal ligament, the encompassing alveolar bone, and the gingiva. The tooth is suspended hammock-like in bone by the *periodontal ligament*. The cementum's major function is as a surface for attachment of the tooth to the periodontal ligament by periodontal fibers. The periodontal ligament is connective tissue that attaches the tooth to the surrounding alveolar bone and gingival tissue. The periodontal ligament performs supportive, formative, sensory, and nutritive functions. The *alveolar bone* forms the sockets of the teeth. The *gingiva* is the soft tissue surrounding the teeth. Gingiva is categorized as either attached gingiva or unattached gingiva. Attached gingiva normally is pink and stippled (like an orange peel) and is attached to the cementum by periodontal ligament fibers. Unattached gingiva appears light pink or coral in color, is not bound to the underlying tissue of the tooth, and is the first tissue to respond to inflammation.

The major salivary glands—parotid, submandibular, and sublingual—are responsible for secreting *saliva*, an alkaline, slightly viscous, clear secretion that contains enzymes (lysozymes and ptyalin), albumin, epithelial mucin (a mucopolysaccharide), immunoglobulin, leukocytes, and minerals. Normal salivary gland function promotes good oral health in several ways. First, saliva lubricates and facilitates the removal of carbohydrates and microorganisms from the oral cavity. Second, saliva also buffers the decline in pH caused by the

acid formed by carbohydrate fermentation. Third, the mineral components of saliva have a protective role in the demineralization and remineralization of tooth enamel.

Caries

Although the period spanning 2011–2012 through 2015–2016 saw a decrease in dental caries among children in the United States, this improvement was statistically nonsignificant, and caries remains a major public health concern.² Strategies that have been successful in reducing caries include fluoridation of the municipal water supply, topical fluoride treatments, education on proper tooth brushing with a fluoride dentifrice, mouth rinses, daily flossing, a proper diet, and regular dental office visits.⁴

Patients with poor oral hygiene are at greatest risk for developing caries. Other risk factors for the development of caries include presence of orthodontic appliances, xerostomia (dry mouth), use of tobacco products, frequent alcohol use, diabetes, and gum tissue recession that exposes root surfaces. Certain medications may cause xerostomia (see [Chapter 32](#)); this condition also is more likely to develop in patients who have undergone head and neck radiation therapy.

Access to dental care has improved over the last few years, with approximately 77% of the U.S. population covered for such care in 2016, compared with only 55% in 2011.⁵ This increase is likely attributable to the recent expansion of access for adults on Medicaid insurance. Nevertheless, disparities remain, particularly with respect to racial and ethnic minorities and people older than 65 years. In 2015 only about 34% of patients with Medicare insurance had dental benefits, either purchased through individual dental care coverage or available as a supplemental benefit on a Medicare Advantage plan.⁶ For all Americans, access often is limited owing to financial barriers, with prioritization of health crises and basic living needs. Access also may be influenced by government legislation pertaining to health insurance coverage. The Affordable Care Act specified that dental care for children is an Essential Health Benefit; however, purchasing a dental plan was not mandatory under federal law, and ultimately the decision was left up to the family.⁷ The American Health Care Act (AHCA) would allow states to choose which Essential Health Benefits to cover; this coverage would begin in 2020. The impact of the

AHCA, if ultimately passed, on dental care is unknown: Although uninsured rates could potentially increase if Medicaid is converted to a block grant program, the use of health savings accounts to cover dental care may become more widespread.⁸ Delayed access to dental care for children adversely affects not only their oral health but also their general health, well-being, and readiness to start school.

Pathophysiology of Caries

Dental caries is considered an infectious disease that affects the calcified tissues of the teeth. Certain plaque bacteria generate acid from dietary carbohydrates, which demineralizes tooth enamel and dentin, leading to the formation of soft carious lesions (areas of altered calcification or decay evident as pits that, if left untreated, will eventually destroy the tooth). Formation of dental caries requires growth and attachment of cariogenic microorganisms of various species (e.g., *Streptococcus mutans*, *Lactobacillus casei*, *Actinomyces viscosus*) to exposed tooth surfaces. If oral hygiene is neglected, dental plaque (the biofilm containing these organisms) remains on the tooth surfaces and over time attracts more bacteria, thereby promoting decay.

The carious process is characterized by an imbalance between the usual cycle of destruction (demineralization) and repair (remineralization).

Demineralization is caused by organic acids (e.g., lactic and formic acids), which are produced (usually anaerobically) by microbial metabolism of low-molecular-weight carbohydrates (sugars) that readily diffuse into plaque. The resulting reduction in pH on the tooth surface leads to demineralization of dental enamel. Saliva, which is rich in calcium and phosphate ions, is crucial in remineralizing enamel in early changes involved in developing carious lesions. The presence of fluoride ions in the mouth also promotes remineralization and slows demineralization, thereby retarding enamel dissolution.

A carious lesion starts slowly on the enamel surface and initially produces no clinical symptoms. Once demineralization progresses through the enamel to the softer dentin, the destruction proceeds much more rapidly, becoming clinically or radiographically evident as a carious lesion. At this point, the patient can become aware of the lesion either by observing it or by experiencing symptoms of sensitivity to stimuli (e.g., heat, cold, sweet foods) or chewing. If untreated, the carious lesion can progress to involve the dental

pulp (with continuous pain as a common symptom), with eventual necrosis of vital pulp tissue. In addition to pain and difficulty chewing, untreated caries can lead to abscess formation, tooth loss, and serious infections.

Clinical Presentation of Caries

Plaque is commonly recognized as the source of microbes that cause caries and periodontal disease. After meals, food residue may be incorporated into plaque by bacterial degradation. Left undisturbed, plaque thickens, and bacteria proliferate. Plaque growth begins in protected cracks and fissures and along the gingival margin. If not removed within 24 hours, dental plaque (especially in areas opposite the salivary glands) begins to calcify by calcium salt precipitation from the saliva, forming calculus, or tartar. This hardened, adherent deposit is removable only by professional dental cleaning.

Calculus is generally considered to be a substrate on which additional plaque can develop and is not considered the primary causative factor in periodontal disease. However, most periodontists agree that supragingival and subgingival calculus (located above and below the gingival margins, respectively) can promote the progression of periodontal disease by accumulating new bacterial plaque in contact with sensitive tissue sites and by interfering locally with dental self-hygiene efforts to remove plaque.

Prevention of Caries

General Approach

The key to preventing caries is controlling dental plaque. Because a combination of diet high in carbohydrates, oral bacteria, and host resistance is involved in developing caries, prevention should be aimed at modifying these factors. The amount and frequency of refined carbohydrate intake should be reduced; plaque should be regularly removed, usually by mechanical means (e.g., brushing, flossing); and host resistance should be increased through appropriate exposure to fluoride ion.

The declining prevalence of dental caries in permanent teeth among youths,

adolescents, and most adults in the United States may be attributed to a combination of interventions such as increased exposure to fluoride in drinking water, dentifrices, and mouth rinses; changed patterns of diet; and overall improved oral hygiene.

Mechanical removal (brushing with a dentifrice and flossing) and chemical management (e.g., using specific products to prevent plaque accumulation or aid its removal) are two methods used to manage plaque. Plaque on interproximal (between the teeth) surfaces can be removed efficiently only with dental floss and other interdental cleaning aids (e.g., interproximal brush, dental tape, tapered picks).

Nonpharmacologic Therapy

Dietary Measures

Cariogenic foods and beverages, which predispose the tooth enamel to deleterious effects (i.e., erosion), should be avoided in favor of those that are less cariogenic. A food is considered highly cariogenic if it contains more than 15% sugar, clings to the teeth, and tends to remain in the mouth after it is chewed. Conversely, foods are less cariogenic if they have a high water content (e.g., fresh fruit), stimulate the flow of saliva (e.g., carrots, other fibrous foods that require a lot of chewing), or are high in protein (e.g., dairy products). Both the water content of fresh fruit and the resulting flow of saliva tend to wash away the fruit's sugar and neutralize the acid it creates. Milk protein also raises pH and tends to inhibit binding of bacteria. Chewing sugarless gum for 20 minutes after meals can also help reduce tooth decay as an adjunct to brushing and flossing in adults and children older than 5 years of age.⁹ The associated increase in salivary flow helps wash out food debris, and saliva neutralizes acid produced by plaque bacteria.

Plaque Removal Devices

Toothbrushes, dental floss, oral irrigating devices, and specialty aids (e.g., interproximal dental brushes) are the primary devices used in facilitating plaque removal. To ensure the health of teeth and gingival tissues, the American Dental Association (ADA) recommends brushing at least twice daily and flossing at least once daily.

Toothbrushes

The toothbrush is the most universally accepted device available for removing dental plaque and maintaining good oral hygiene. Toothbrushing removes plaque from the lingual (tongue side), buccal (cheek side), and occlusal (biting) surfaces of the teeth. Thoroughness of plaque removal without gingival trauma is more important than the method used. [Table 31-1](#) describes the proper method of brushing teeth.

TABLE 31-1 Guidelines for Brushing Teeth
• Brush teeth after each meal or at least twice a day. • If using toothpaste, apply a small amount of paste to the toothbrush. • Use a gentle scrubbing motion, with the bristle tips held at a 45-degree angle against the gum line so that the tips of the brush do the cleaning. • Do not use excessive force because it may result in bristle damage, cervical abrasion, irritation of delicate gingival tissue, or gingival recession with associated hypersensitivity. • Brush for at least 2 minutes, cleaning all tooth surfaces systematically. • Gently brush the upper surface of the tongue to help remove debris, plaque, and bacteria that can cause oral hygiene problems. • Rinse the mouth, and spit out all of the water (do not swallow).

Manual toothbrushes vary in size, shape, texture, and design, with new product designs proliferating rapidly. These toothbrushes have either nylon or natural bristles that usually are rated as soft, medium, or firm.

Powered toothbrushes, which are widely available on the market, either are battery-operated or have a rechargeable battery system. Battery-operated devices (e.g., Arm & Hammer Spinbrush, quip Electric Toothbrush) use a rotary and/or vibratory motion and are less expensive, but their effectiveness deteriorates over time as the disposable battery loses power. Rechargeable battery toothbrushes may also use a rotary and/or vibrating motion (e.g., Oral B) or ultrasonic vibration (e.g., Sonicare, Oral B) to remove plaque. These powered brushes tend to be more expensive, but they maintain constant effectiveness because of their rechargeability. Powered toothbrushes may be of benefit for certain patients, such as those who are disabled or who have dexterity issues.

Although no definite guideline specifies how often to buy a new toothbrush, ADA recommends that the patient replace the toothbrush every 3–4 months. Two compelling reasons are recognized for replacing toothbrushes frequently: bristle wear and bacterial accumulation. Because different brushing methods cause bristles to wear differently and worn, bent, or matted bristles do not remove plaque effectively, toothbrushes should be replaced at the first sign of bristle wear. Some brands of toothbrushes have color-impregnated bristles that indicate the need for replacement when the color disappears halfway down the bristles.

Product Selection Guidelines. Health care providers should recommend toothbrushes that are ADA approved, as described in the box “American Dental Association (ADA) Seal of Acceptance.”¹⁰ ADA criteria for acceptance are based on safety and efficacy concerns. Available evidence indicates that powered toothbrushes can provide a statistically significant reduction in the occurrence of plaque and gingivitis compared to manual brushing.^{11–13} However, both manual and powered toothbrushes have the ADA Seal of Acceptance, so selection should be based on patient preference.

Dental professionals recommend toothbrushes according to the individual patient’s manual dexterity, oral anatomy, and periodontal health. The toothbrush should be of a size and shape to allow the user to reach every tooth in the mouth. Innovations in head shapes and bristle configurations continue to be introduced in an attempt to improve cleaning contact with tooth and gum line surfaces. Toothbrush firmness is not standardized; toothbrushes designated as soft, medium, or hard may not be comparable across manufacturers. Use of medium- or hard-bristle toothbrushes may result in damage to the tooth enamel and gingival tissue. Softer bristles are more effective at working themselves into crevices and spaces between the teeth, and they are less abrasive on teeth with exposed areas of recession, as well as gentler on soft tissue. Many dental providers and dental hygienists prefer soft, rounded, multitufted, nylon bristle brushes, both because nylon bristles are more durable and easier to clean than natural bristles and because soft, rounded bristle tips are more effective in removing plaque below the gingival margin and on proximal tooth surfaces.

Children’s toothbrushes are smaller than adult toothbrushes and typically are sized by age. Toothbrush size and shape should be individualized according to the size of the child’s mouth. Soft bristles are recommended for children’s

toothbrushes. Children usually can remove plaque more easily with a brush that has short and narrow bristles.

Dental Floss

Plaque accumulation in the interdental spaces contributes to proximal caries and periodontal pocketing. Interdental plaque removal has been reported to reduce gingival inflammation and prevent periodontal disease and dental caries. Dental flossing is the most widely recommended method of removing dental plaque from proximal tooth surfaces that are not adequately cleaned by toothbrushing alone. By removing plaque and debris interproximally, proper flossing also polishes the tooth surfaces and reduces gingival inflammation. Proper flossing technique requires some finger dexterity and practice. If performed improperly, flossing can injure gingival tissue and cause cervical wear on proximal root surfaces. [Table 31–2](#) describes the proper use of dental floss.

TABLE 31–2 Guidelines for Using Dental Floss

- Pull out approximately 18 inches of floss from the dispenser, and wrap most of it around the middle finger.
- Wrap the remaining floss around the same finger of the opposite hand. Approximately an inch of floss should be held between the thumbs and forefingers.
- Do not “snap” the floss down between the teeth; instead, use a gentle, sawing motion to guide the floss up or down to the gum line.
- When the gum line is reached, curve the floss into a C shape against one tooth, and gently slide the floss into the space between the gum and the tooth until you feel resistance.
- Hold the floss tightly against the tooth, and gently scrape the side of the tooth with an up-and-down motion.
- Curve the floss around the adjoining tooth, and repeat the procedure.
- Advance the length of floss to use a new segment for each tooth surface, to avoid the transfer of plaque and bacteria to other teeth.

Floss is a multifilament nylon yarn that is available in waxed or unwaxed form and in various widths, ranging from thin thread to thick tape. Many brands feature product lines of flosses that are coated with additives, such as flavoring, baking soda, or fluoride. In addition, several manufacturers are marketing floss made of materials with superior antishredding properties (e.g., Glide, Oral B Essential).

Product Selection Guidelines. The health care provider should recommend a dental floss product with the ADA Seal of Acceptance.¹⁰ Because there are no differences among various floss types in terms of removing plaque and preventing gingivitis, patient factors (e.g., tightness of tooth contacts, presence of tooth roughness, manual dexterity, personal preference) should be considered in product selection.

Waxed or antishredding floss may be passed between tight-fitting teeth with less shredding and resistance than unwaxed floss. If contacts at the crowns of teeth are too tight to permit interdental flossing, floss threaders can be used to pass floss between the teeth and under the replacement teeth (pontics) of fixed bridges. Floss threaders, available in reusable and disposable forms, usually are thin plastic loops or soft plastic, sewing needle–like appliances. Floss holders have one or two forks that are rigid enough to keep floss taut and a mounting mechanism that allows quick rethreading of floss. Floss picks are small plastic tools with a curved end that holds a piece of dental floss that make flossing with one hand simple. Additionally, the other end of the floss pick can be used to remove large food particles. Products such as these are recommended for patients who lack manual dexterity and for caregivers who assist disabled or hospitalized patients.

American Dental Association (ADA) Seal of Acceptance

ADA evaluates the safety and efficacy of dental products used by dental professionals and the public through its Council on Scientific Affairs' Seal of Acceptance evaluation program. Manufacturers of dentifrices or mouth rinses with therapeutic potential for gingivitis and supragingival dental plaque control may voluntarily submit data to ADA for evaluation. Product labels and promotional material must also comply with ADA standards. The ADA Council on Scientific Affairs allows only products that demonstrate safety and efficacy to support its product category.²⁴

Once a product has earned the ADA seal, it may display that seal for 5 years, provided that it continues to meet all of the requirements.²⁴ The ADA online home page (www.ada.org) provides searchable access to a current listing of dental consumer products that have been awarded the ADA Seal of Acceptance.

Specialty Aids

Cleaning devices that adapt to irregular tooth surfaces better than dental floss are recommended for interproximal cleaning in patients with large interdental spaces. Increased interdental spacing often is characteristic of periodontal disease. The most commonly used aids are tapered triangular wooden toothpicks (Stim-U-Dent) and interdental brushes (Proxabrush). Literature suggests that in addition to regular tooth brushing, interdental brushes may be more effective than flossing; both interdental brushes and flossing reduce plaque better than tooth brushing alone.¹⁴

Oral Irrigating Devices

Oral irrigators, also known as water flossers, work by directing a high-pressure stream of water through a nozzle to the tooth surface. Such devices, however, remove only a minimal amount of plaque from tooth surfaces. Therefore, an irrigating device cannot be viewed as a substitute for a toothbrush, dental floss, or other plaque removal devices, but their use should be considered as an adjunct in maintaining good oral hygiene. These devices are useful for removing loose debris from those areas that cannot be cleaned with a toothbrush (e.g., around orthodontic bands or fixed bridges). Several brands on the market carry the ADA Seal of Acceptance.¹⁰

Oral irrigators also are valuable as vehicles for administering chemotherapeutic agents that inhibit microbial growth in inaccessible regions of the mouth. Patients with advanced periodontal disease should use these devices only under professional supervision, because transient bacteremia may occur after manipulative procedures with the oral irrigator. Oral irrigation devices also are contraindicated in patients who are at risk for the development of bacterial endocarditis.

Pharmacologic Therapy

Chemical Management of Plaque

Chemical management of plaque and calculus can enhance mechanical removal either by acting directly on the plaque bacteria or by disrupting components of plaque to aid in its removal during routine oral hygiene. The use of chemical agents in plaque control may be particularly appropriate for

selected patients who may be unable to brush and floss effectively. Physically or mentally disabled persons (who may not be able to master the manual techniques necessary to brush and floss effectively) and patients with orthodontic appliances (i.e., fixed prostheses) may benefit from adding antiplaque agents to their oral hygiene regimen.

Desirable characteristics for antiplaque agents include the following:

- Selective antibacterial activity; interference with the rate of accumulation or metabolism of supragingival plaque
- Substantivity (sustained retention of the agent in the mouth)
- Compatibility with dentifrice ingredients
- Lack of undesirable adverse effects for the user
- Noninterference with the natural ecology of the normal oral microflora

Use of Fluoride

Fluoride is believed to help prevent dental caries through a combination of effects. When it is incorporated into developing teeth, fluoride acts systemically to reduce the solubility of dental enamel by enhancing the development of a fluoridated hydroxyapatite, which is more resistant to demineralizing acids, at the enamel surface. When applied topically, fluoride facilitates remineralization within early carious lesions during repeated cycles of demineralization and remineralization. Some evidence suggests that fluoride interferes with the bacterial cariogenic process: Fluoride that is chemically bound to organic constituents of plaque may interfere with plaque adherence and may inhibit glycolysis (the process by which sugar is metabolized to produce acid).¹⁵

Fluoridation of the public water supply is an effective and economically sound public health measure that has played a major role in decreasing the incidence of caries.¹⁵ According to the Centers for Disease Control and Prevention, approximately 75% of the U.S. population resides in communities in which the public water supply contains either naturally occurring or added fluoride at optimal levels for decay prevention (1 ppm or 1 mg/L).¹⁶ In addition to reducing dental caries in children, fluoridation has benefits that extend through adulthood, resulting in (1) fewer decayed, missing, or filled teeth; (2) better tooth retention; and (3) a lower incidence of root caries. Current concepts of the action of fluoride relative to its presence in saliva and plaque provide a

rationale for its topical application to prevent caries in all age groups. Most bottled water does not contain fluoride. If manufacturers choose to add fluoride, the U.S. Public Health Service (PHS) recommends limiting the concentration to no more than 0.7 mg/L.¹⁷ This recommendation replaces the previously recommended level of 0.7–1.2 mg/L and aims to promote balance between protection from dental caries, which lead to tooth decay, and the risk of dental fluorosis. The U.S. Food and Drug Administration (FDA), which previously advised manufacturers of bottled water to follow the earlier recommendation, is now proposing a rule to enforce the PHS recommendation.

Mouth rinses and gels that contain sodium fluoride are therapeutic topical applications of fluoride for prevention of dental caries. Use of fluoride mouth rinses enables patients to apply fluoride interproximally. Patients who may benefit from these products include those with fixed orthodontic appliances, those with decreased salivary flow, those at risk for developing root caries, and anyone with difficulty maintaining good oral hygiene. Package directions for fluoride rinses and gels should be followed closely to maximize the safe and effective use of these products. [Table 31–3](#) describes the proper method of applying fluoride treatments.

TABLE 31–3 Guidelines for Using Topical Fluoride Treatments

- Use topical fluoride treatments no more than once a day.
- Brush teeth with a fluoride dentifrice before using a fluoride treatment.
- If using a fluoride rinse, measure the recommended dose (most commonly, 10 mL), and vigorously swish it around the oral cavity, forcing it between the teeth, for 1 minute.
- If using a fluoride gel, brush the gel on the teeth. Allow the gel to remain for 1 minute.
- After 1 minute, spit out the fluoride product. Do not swallow it.
- Do not eat or drink for 30 minutes after the treatment.
- Supervise children receiving fluoride treatments as necessary until they can use the product without supervision.
- Instruct children younger than 12 years in good rinsing habits, to minimize swallowing of the product.

When recommending a nonprescription fluoride mouth rinse, the health care provider should emphasize the need for parents and caregivers to supervise children younger than 12 years as necessary until they are capable of using the

product correctly. Furthermore, children younger than 6 years should avoid these products owing to the increased risk of dental fluorosis, a mottled appearance of the surface enamel of the tooth, if the rinse is repeatedly swallowed.¹⁸ Dental fluorosis can occur when children ingest an excess amount of any fluoride product, particularly for an sufficient period during the time of tooth formation. Although a mild degree of fluorosis is an aesthetic concern, more severe cases can result in pitting and surface defects (see [Color Plates](#), photograph 9). FDA determined that unlike dental caries, mild dental fluorosis does not compromise oral health or tooth function; therefore, the risk of dental caries from inadequate fluoride protection is a greater health hazard than the cosmetic detriment of fluorosis.

Dentifrices

Using dentifrices (e.g., toothpastes) with a toothbrush has been associated with a greater reduction of plaque than that obtained with mechanical brushing alone.¹⁹ Products are marketed as having properties such as caries prevention, plaque reduction, antitartar activity, gingivitis reduction, remineralization induction, cosmetic effect (whitening and stain removal), antisensitivity, or other specialty (e.g., holistic and all natural). Many products may offer multiple such benefits. Dentifrices are available as pastes or gels ([Table 31–4](#)) and commonly contain an abrasive, a surfactant, a humectant (moistening agent), a binder or thickener, a sweetener, flavoring agents, and one or more therapeutic agents (e.g., fluoride) for anticaries activity.

TABLE 31–4 Selected Nonprescription Dentifrices With ADA Seal of Approval

Dentifrice abrasives are pharmacologically inactive and insoluble compounds. Common abrasives include silicates, dicalcium phosphate, alumina trihydrate, calcium pyrophosphate, calcium carbonate, and sodium metaphosphate. Dentifrices vary in their degree of abrasiveness; factors such as the size and shape of the abrasive particle, individual brushing technique, and individual salivary characteristics affect the abrasive's potential effectiveness. The ideal abrasive would provide maximal cleaning while causing minimal damage to tooth surfaces. Unfortunately, because of the variability in patients' brushing techniques and oral health status, the ideal dentifrice abrasive does not exist. Low-abrasive dentifrices (including most dentifrice formulations currently marketed in the United States) usually have a low concentration of silica abrasives (10%–25%), whereas high-abrasive dentifrices typically have higher concentrations of the inorganic calcium or aluminum salts previously mentioned (40%–50%). Baking soda, a mild abrasive found in many dentifrices, can prevent caries, reduce plaque, and remove stains and has anti-tartar activity. Studies have demonstrated that toothpastes with baking soda are more effective at removing plaque and stains than toothpastes without it.^{20–22} Sodium lauryl sulfate, present in nearly all toothpastes, does not reduce plaque or gingivitis. It is a chemical used to create a foaming action, which has been implicated as a cause of irritative lesions of the oral mucosa such as aphthous ulcers (i.e., canker sores; see [Chapter 32](#)).²³ Some dentifrices that do not contain sodium lauryl sulfate are listed in [Table 31–4](#).

Fluoride Dentifrices

Fluoride dentifrices are indicated for both preventing and treating carious lesions. In all countries that show a reduction in caries, use of fluoride-containing dentifrices for caries prevention is the norm. All toothpastes with the ADA seal contain fluoride. The most commonly used fluoride sources are sodium fluoride, sodium monofluorophosphate, and stannous fluoride. The first two forms remineralize and strengthen weakened enamel, in addition to reducing gingivitis and sensitivity. In addition to these beneficial effects,

stannous fluoride also creates a protective mineral layer over the teeth to prevent plaque. Patients may experience slight (but noticeable) tooth discoloration after using stannous fluoride dentifrices continuously for 2–3 months. The staining is not permanent and is readily removed at the next professional dental cleaning.

Tartar Control Dentifrices

A number of fluoride dentifrices contain anticalculus compounds for tartar control. Although plaque—not supragingival calculus—is the primary etiologic contributor in marginal periodontal disease, reducing calculus formation remains a goal of good oral hygiene. The ingredients of tartar control dentifrices that prevent or retard new calculus formation are zinc chloride, zinc citrate, and soluble pyrophosphates, which act to inhibit crystal growth. ADA regards the inhibition of supragingival calculus as a nontherapeutic use and therefore does not evaluate anticalculus claims. However, all advertising claims made for accepted products are reviewed for accuracy as described in the box “American Dental Association (ADA) Seal of Acceptance.”²⁴

The use of tartar control toothpastes has been associated with a type of contact dermatitis in the perioral region. The addition of pyrophosphate compounds to these products to increase alkalinity requires increased concentrations of other components for solubilizing (e.g., flavorings, surfactants); presence of such ingredients at high levels is hypothesized to be the cause of irritant contact dermatitis. Patients experiencing such a reaction should be advised to discontinue the tartar control dentifrice and to switch to a non-tartar control fluoride product.

Antiplaque and Antigingivitis Dentifrices

Two toothpastes that are currently accepted by ADA for both antiplaque and antigingivitis indications are Colgate Total, containing triclosan, and Crest Pro-Health, containing stannous fluoride. These dentifrices are not intended for use in children younger than 6 years and 12 years, respectively.¹⁰

Whitening Dentifrices

Although some whitening dentifrices are marketed as strictly cosmetic and do not make any therapeutic claims, numerous products also provide anticaries and gingivitis reduction in addition to effectively removing stains.²⁵ Many

whitening dentifrices, however, contain higher concentrations of abrasives, which are not advised for long-term use or for use by patients with exposed root surfaces. As mentioned previously, toothpastes containing baking soda (e.g., Arm & Hammer Dental Care) have been shown to be effective at stain removal.^{21,25} Other products may contain a pigment (e.g., titanium dioxide, blue covarine) that produces a temporary brightening effect.²⁵ Whitening dentifrices that incorporate oxygenating agents or enzymes rely on a debriding action to remove stained pellicle. Numerous products offer a combination of baking soda and peroxide with fluoride. Whitening dentifrices should not be confused with tooth-bleaching products, as described in the box “A Word About Tooth-Bleaching Products.”

Botanical-Based Dentifrices

Some evidence indicates that nonbotanical-based and botanical-based dentifrices are equally effective at reducing plaque. Reported studies, however, have small sample sizes and were conducted outside of the United States.^{27,28}

Administration Guidelines

Table 31–1 describes the proper method for brushing teeth using a fluoride dentifrice. Children usually are unable to brush by themselves until they are 4 or 5 years of age; to clean their teeth effectively, children may require supervision until 8 or 9 years of age. FDA recommends that caregivers instruct children 6–12 years of age about good brushing and rinsing habits to minimize swallowing of fluoride. All fluoride dentifrice products must contain the following warning on the labeling: “Warning: Keep out of the reach of children under 6 years of age. If you accidentally swallow more than used for brushing, seek professional assistance or contact a poison control center immediately.”

A Word about Tooth-Bleaching Products

The popularity of tooth bleaching has increased in the United States in recent years. Three methods are currently in use: (1) in-office dental bleaching, (2) dental office–supported home bleaching, and (3) nonprescription home bleaching. All three methods use basically the same chemical agents: carbamide peroxide or hydrogen peroxide in

various strengths. The in-office method has the advantage of a one-time treatment, but the stronger bleach and the accelerator light are not necessary to obtain the same result with the dental office-supported home-bleaching process. The latter method involves the use of custom trays. With this process, patients can fine-tune the extent of lightening to personal preference.

The following two nonprescription products (from among many) may aid in lightening teeth:

- Rembrandt Intense Stain Dissolving Strips contain hydrogen peroxide. The kit contains 56 whitening strips that are applied to both upper and lower teeth. Strips dissolve in 5 to 10 minutes, with nothing to remove. The kit is designed for use over a 2-week period.
- Crest 3D WhiteStrips Vivid are translucent film strips impregnated with hydrogen peroxide and other ingredients. The strips are peeled away from a protective backing and then applied by folding them over the 6 upper or lower front teeth (different strips are provided for upper and lower teeth). The teeth will look as though they are covered with small pieces of transparent food wrap. The strips are applied once a day and left in place for 30 minutes. A kit contains enough strips for 10 days.

Product Selection Guidelines

Unless otherwise advised by their dental providers, patients (especially those with periodontal disease, significant gum recession, and/or exposed root surfaces) should choose the least abrasive dentifrice that effectively removes stained pellicle. Although dentifrice abrasives do not pose a risk to dental enamel, toothbrushing action and excessive abrasiveness (which may lead to tooth hypersensitivity) can damage the cementum (the softer material of exposed root surfaces) and dentin.

Extra-strength fluoride dentifrices may be beneficial to patients who have a greater tendency to develop cavities or who reside in an area with non-fluoridated water. Health care providers should recommend a dentifrice that is sodium lauryl sulfate-free for patients with a history of canker sores.

Flavored gel dentifrices disperse rapidly in the mouth and are popular with children. Manufacturers of gel dentifrices have advertised that children brush longer and more thoroughly because of the preferable consistency, translucence, dispersibility, and flavor of these products. This claim has not been substantiated, but many dentifrices marketed for children are of the gel type. Children's products usually have fruit flavors rather than "breath-freshening" minty or cinnamon flavors, which adults prefer.

Mouth Rinses

Regular use of a mouth rinse with plaque or calculus control properties is indicated as an adjunct to proper flossing and toothbrushing with fluoride toothpaste. Antiseptic mouth rinses have demonstrated effectiveness to reduce plaque and gingivitis; however, evidence for the prevention of periodontitis is insufficient.²⁹ Mouth rinse and dentifrice formulations are very similar. As with dentifrices, mouth rinses may be classified as cosmetic or therapeutic ([Table 31-5](#)). Both may contain surfactants, humectants, flavor, coloring, water, and therapeutic ingredients.

TABLE 31-5 Selected Nonprescription Mouth Rinses With ADA Seal of Approval

Trade Name	Primary Ingredient(s)
Fluoride Mouth Rinses	
ACT Anticavity Fluoride Rinse	Sodium fluoride 0.05%
Crest Anticavity Fluoride Rinse	Sodium fluoride 0.022%
Colgate Phos-Flur Ortho Defense	Sodium fluoride 0.044%
Listerine Total Care Anticavity Mouthwash	Sodium fluoride 0.2%
Plaque/Gingivitis Control Mouth Rinses	
Listerine Antiseptic	Thymol 0.064%; eucalyptol 0.92%; methyl salicylate 0.06%; menthol 0.042%
Equate Antiseptic Mouth Rinse	Eucalyptol 0.0.92%; menthol 0.042%; methyl salicylate 0.06%; thymol 0.064%
Cosmetic Mouth Rinses	

Trade Name	Primary Ingredient(s)
CloSYS Alcohol-Free Oral Health Rinse	n/a
TheraBreath Fresh Breath Oral Rinse	n/a

Key: ADA = American Dental Association; n/a = not applicable.

A mouth rinse approximates a diluted liquid dentifrice that does not contain an abrasive. Mouth rinses often contain alcohol, which adds “bite” and freshness, enhances flavor, solubilizes other ingredients, and contributes to the mouth rinse’s cleansing action and antibacterial activity. Flavor contributes pleasant taste and breath-freshening action. Surfactants are foaming agents that aid in the removal of debris. Other active ingredients may include astringents (alum or zinc chloride) that neutralize odoriferous sulfur compounds produced in the oral cavity, demulcents (sorbitol or glycerin) that provide a protective film soothing to oral mucosa, antibacterial agents (cetylpyridinium chloride or thymol), and fluoride.

Cosmetic mouth rinses freshen the breath and clean some debris from the mouth. Mouth rinses can be classified by appearance, flavor, alcohol content, and active ingredients. The most popular cosmetic mouth rinses are medicinal and mint-flavored. Healthy persons normally have some degree of oral malodor, typically on awakening (i.e., “morning breath”). This malodor results from reduced salivary flow, contributing to enhanced bacterial activity and production of odoriferous sulfur compounds, as noted earlier.³⁰ (Other causes of oral malodor in healthy persons are noted later in the “Halitosis” section.) The FDA Advisory Review Panel on Over-the-Counter Oral Health Care Products considers products that are intended to eliminate or suppress mouth odor of local origin in healthy people with healthy mouths to be cosmetics unless they contain antimicrobial or other therapeutic agents.

One important consideration is the potential for breath-freshening mouth rinses to disguise or delay treatment of pathologic conditions that may contribute to lingering oral malodor (e.g., periodontal disease, purulent oral

infections, respiratory infections). If marked breath odor persists after proper toothbrushing, investigation for an underlying cause is warranted; masking the odor with mouth rinse will not address the issue.

Plaque control ingredients include (1) aromatic oils (thymol, eucalyptol, menthol, and methyl salicylate), which are antibacterial and have some local anesthetic activity, and (2) agents with antimicrobial activity (e.g., quaternary ammonium compounds). Listerine, containing the active ingredients thymol, eucalyptol, methyl salicylate, and menthol, was the first mouth rinse to be accepted by ADA as a nonprescription antiplaque/antigingivitis mouth rinse.

Many dental care providers have found anecdotally that use of rinses containing phenol oils, methyl salicylate, and alcohol may bring about a sloughing of the oral epithelium, which subsides when the rinse is discontinued. A similar effect has been observed with the use of lozenges or candies containing cinnamon or other common flavoring substances.

Mouth rinses and gels are generally safe when used as directed, but occasional adverse reactions (e.g., burning sensation, irritation) have been reported. Overuse should be discouraged. Consultation with a health professional is indicated if irritation persists after the patient discontinues use of the product.

Unsupervised use of mouth rinses is contraindicated in patients with mouth irritation or ulceration. These products should be kept out of children's reach. In case of accidental ingestion, the caregiver should seek professional assistance or contact a poison control center.

The alcohol content in mouth rinses ranges from 0% to 27%. Ingestion of alcohol-containing rinses poses a danger for children, who may be attracted by the bright colors and pleasant flavors of these products. Toxicity data concerning children's ingestion of alcohol-containing mouth rinses demonstrate that the amount of alcohol in available mouth rinse preparations is sufficient to cause serious illness and injury. In 2017, more than 1700 cases were reported to poison control centers in which children younger than 12 years of age consumed alcohol-containing mouth washes. Approximately 13% of these cases were categorized as having an outcome of moderate to major health significance.³¹ Responding to concern over the potential danger to children, the Consumer Products Safety Commission issued a final rule that required child-resistant packaging for mouth rinses containing 3 g or more of absolute alcohol per package—the amount that is present in a small quantity

(approximately 2.6 ounces) of a mouth rinse with alcohol 5%. For the purposes of this final rule, the term *mouthwash* includes liquid products that are variously called mouthwashes, mouth rinses, oral antiseptics, gargles, fluoride rinses, antiplaque rinses, and breath fresheners. The rule does not include throat sprays or aerosol breath fresheners. These products should be kept out of children's reach and should not be administered to children younger than 6 years. Labeling includes a warning not to swallow the product but to seek professional assistance or contact a poison control center immediately in case of accidental ingestion.

Complementary and Alternative Therapies

Activated Charcoal

Recently the market has seen a surge of topical oral hygiene products with activated charcoal, particularly those advertising whitening properties. This effect presumably derives from the notable ability of charcoal, with its high surface area, to absorb pigments and stains. Although 96% of commercially marketed products make claims to whiten teeth, data demonstrating this efficacy are very limited, and such claims may rest partly on their novelty.^{32,33}

Probiotics

Because the accumulation of an oral biofilm containing microorganisms results in tooth decay, oral probiotics have been hypothesized to be able to prevent or treat oral diseases like caries, gingivitis, or periodontitis. They exert this action by altering the bacterial biofilm composition and balancing the microflora antimicrobial activity against the effects of pathogenic bacteria. Probiotics may be beneficial in managing periodontal disease such as gingivitis or periodontitis; at present, however, insufficient evidence is available to recommend probiotics for managing dental caries, until more research is conducted.^{34,35}

Vitamin D

Studies have demonstrated that a deficiency in vitamin D can result in low bone mineral density and increased infectious and inflammatory diseases, which has been linked to caries, gingivitis and periodontitis.^{36,37} Vitamin D is vital in the mineralization of bones and teeth, so attaining an optimal vitamin

D level is essential for maintaining oral health. Because this mineralization begins during the fetal period, evidence supports the use of vitamin D supplementation in pregnancy to reduce caries in children.³⁸

Special Population Considerations for Caries Prevention and Plaque Removal

Efforts to reduce childhood caries can begin in infancy, since at birth, the 20 primary teeth that will erupt are present but not visible. Parents should avoid putting the child to bed with a bottle to avoid “baby bottle caries,” which results when the infant is allowed to nurse continuously from a bottle of juice, milk, or sugar water, and should take care to remove plaque and milk residue from the baby’s mouth after each feeding and before bed by wiping the gums with a wet gauze pad. For toddlers, filling training cups with water instead of milk or juice between meals can reduce exposure to cavity-causing bacteria.³⁹

The deciduous teeth usually start to erupt at the age of approximately 6 months and without proper oral care can begin to decay at any time. When the teeth have erupted, a soft, child-size toothbrush can be used for cleaning. ADA recommends that caregivers use a smear (approximately the size of a grain of rice) of fluoride toothpaste for children younger than 3 years and no more than a pea-sized amount of toothpaste for children 3–6 years of age.^{40,41}

In patients with fixed orthodontic appliances, very careful attention to oral hygiene to prevent gingivitis and caries is required because of the ease with which plaque accumulates along the orthodontic brackets. Patients with such appliances need to use a combination of toothbrush types to clean all surfaces effectively. Use of power toothbrushes, oral irrigating devices, floss threaders, and interdental brushes may help remove plaque and debris around orthodontic bands. Orthodontic patients also may want to use a nonprescription fluoride mouth rinse while undergoing treatment.

Patients with removable orthodontic appliances should consult their orthodontist about using a denture cleanser. In addition to manual brushing of orthodontic appliances, some dental care providers recommend a denture cleanser to remove plaque, tartar, odor-causing bacteria, and stain that accumulate on orthodontic appliances.

In patients of advanced age who have natural dentition, topical fluoride

application in the form of a dentifrice, rinse, or gel is indicated to prevent coronal and root caries. Health care providers should continue to recommend fluoride anticaries products to older adult patients. For counseling on oral health care in this age group, review and update of the medication history are essential. Because senior patients are more likely to be taking multiple medications, the incidence of drug-induced or disease-related changes in oral physiology is increased.

No special considerations related to plaque removal have been identified for pregnant or lactating women or for males and females of reproductive age.

Assessment of Caries

When asked to recommend plaque control products, the health care provider should determine what dental care measures the patient is taking, whether these measures meet recommended oral hygiene standards, and how often the patient sees a dental care provider. It also is important to ascertain whether the patient has a history of caries or if the patient suspects that a new carious lesion has developed. Presence of dental caries symptoms—toothache, tooth sensitivity with chewing, or tooth pain with exposure to hot, cold, or sweet foods or beverages—warrants referral to a dental care provider for evaluation and treatment.

Patient Counseling for Caries Prevention

In patient counseling for caries prevention, all explanations of the purposes of various oral hygiene products and the methods for using them should be tailored to the patient's level of understanding. Patients with a history of caries should be encouraged to brush after meals and to consult with a dental provider about the use of topical fluoride products. If caries recurs or is widespread, the patient should be encouraged to visit a dental care provider for treatment. The health care provider should explain the precautions for these products, as well as the possible adverse effects of certain therapeutic ingredients in other products. The box "Patient Education for Prevention of Caries, Gingivitis, and Halitosis" lists specific information for patient counseling on plaque-induced oral disorders.

Beyond these considerations in patient counseling, the health care provider can use the initial clinical encounter to educate the patient about signs and symptoms of oral pathology for which self-care is not adequate or appropriate, as summarized in the box “Exclusions for Self-Treatment for Hygiene-Related Oral Disorders.” The presence of any such exclusion warrants referral of the patient for further evaluation by a primary care provider.

Patient Education for Prevention of Caries, Gingivitis, and Halitosis

The primary objective of self-care for oral hygiene is the removal of plaque to prevent caries, gingivitis, and halitosis. For most patients, carefully following product instructions and the self-care measures listed here will help ensure good oral hygiene.

Nondrug Measures and Other Considerations

- Avoid cariogenic foods, such as foods that contain more than 15% sugar, cling to the teeth, and tend to remain in the mouth after swallowing.
- Eat low-cariogenic-index foods, such as foods that have a high water content (e.g., fresh fruit), stimulate the flow of saliva (e.g., fibrous foods that take longer to chew), or are high in protein (e.g., dairy products).
- To help prevent mouth odor, maintain proper oral hygiene and limit or avoid consumption of foods and products that may cause oral malodor. Also, if you wear dentures, do not wear them while sleeping.
- Note that use of alcohol and tobacco is associated with caries, gingivitis, and halitosis.
- Note that hormonal changes during pregnancy increase the risk of gingivitis.
- Chewing sugarless gum for 20 minutes after meals helps reduce tooth decay as an adjunct to brushing and flossing.

Plaque Removal

Brushing Teeth

- Mechanically remove plaque buildup by brushing teeth at least twice daily with a fluoride dentifrice. (See [Table 31–1](#) for proper brushing technique.)
- Use a brush with soft nylon bristles.
- Replace the brush when the bristles show signs of wear.
- For children younger than 3 years, use a smear (the size of a grain of rice) of fluoride gel once teeth erupt.
- For children 3–6 years of age, apply a pea-sized amount of toothpaste to a child-sized toothbrush, and brush the child's teeth until the child can brush properly.
- Teach children how to rinse the mouth and spit out the toothpaste, to avoid swallowing fluoride.
- Note that tartar control toothpastes have been related to a type of contact dermatitis in the perioral region. If you experience itching or irritation of the mouth after brushing, discontinue the tartar control toothpaste, and switch to a non-tartar control fluoride toothpaste.
- If you are prone to developing caries or gingivitis, consider using a toothpaste with antiplaque or antigingivitis activity. Such toothpastes contain stannous fluoride.
- If you are prone to developing aphthous ulcers, consider using a toothpaste that does not contain sodium lauryl sulfate.

Flossing Teeth

- Floss your teeth at least once a day. (See [Table 31–2](#) for proper flossing technique.)
- Use waxed or Teflon-coated floss for teeth with tight contacts.

Using Mouth Rinses and Gels

- To freshen breath, use a mouth rinse that contains zinc chloride and zinc citrate to eliminate odoriferous volatile sulfur compounds.
- If you are prone to developing caries or gingivitis, consider using a

mouth rinse classified as having antiplaque/antigingivitis activity.

- Note that overuse of mouth rinses containing cetylpyridinium can stain teeth.

Using Topical Fluoride Treatments

- If your drinking water (including bottled water) is not fluoridated, or if you are prone to developing caries, consider using fluoride mouth rinses. (See [Table 31–5](#) for proper use of these products.)
- Supervise children younger than 12 years of age until they are capable of using the product correctly.

Exclusions for Self-Treatment for Hygiene-Related Oral Disorders

- Symptoms of toothache (e.g., pain with or without chewing, localized swelling, hot or cold sensitivity, fever or headache)
- Development of a mottled appearance to the teeth
- Bleeding, swelling, or reddened gums
- Persistent mouth odor despite regular use of fluoride toothpaste, or for which a cause cannot be identified

Gingivitis

Periodontal disease (which may result in tooth loss) affects an estimated 46% of U.S. adults 30 years of age and older.⁴² Similar to statistics for dental caries, the prevalence of periodontal disease is disproportionately higher in Hispanics (63.5%), non-Hispanic blacks (59.1%), and non-Hispanic Asian Americans (50.0%), compared with non-Hispanic whites (40.8%).⁴² Curtailing buildup of plaque can prevent or control this common and significant public health

problem. All forms of periodontal disease are associated with oral hygiene status, not with age. However, as life spans increase and people retain more teeth later in life, both the number of teeth at risk and the susceptible period for development of periodontal disease increase.

Gingivitis, the mildest form of periodontal disease, is a common and reversible inflammation of the gingiva without loss or migration of epithelial attachment to the tooth. Periodontitis occurs when the periodontal ligament attachment and alveolar bone support of the tooth have been compromised or lost (see [Color Plates](#), photographs 10 and 11). Gingivitis may progress to more severe periodontal diseases such as acute necrotizing ulcerative gingivitis and periodontitis, particularly if left untreated.

Pathophysiology of Gingivitis

Gingivitis results from the accumulation of supragingival bacterial plaque. If this accumulation is not controlled, the plaque proliferates and invades subgingival spaces. Although not all gingivitis progresses to periodontitis, the progression from supragingival plaque to gingivitis to periodontitis is well documented, so controlling gingivitis is a reasonable approach to limiting periodontitis.

Other possible etiologic factors include effects of medications such as calcium channel blockers, cyclosporine, and phenytoin. Anticholinergics and antidepressants may cause gingivitis by reducing the flow of saliva. The use of tobacco (both smokeless and smoked) also has been linked to periodontal disease.

Pregnant patients are more susceptible to the development of dental caries and gingivitis. In addition to local factors, varying hormone levels in pregnancy may make gingival tissue more sensitive to bacterial dental plaque. These changes in the connective tissues that make up the periodontium appear to be the primary pathogenic mechanism. Pregnancy gingivitis can be prevented or resolved thorough plaque control. The severity of the inflammatory response and the resulting gingivitis decrease post partum, with a return to pre-pregnancy levels after approximately 1 year.⁴³

Clinical Presentation of Gingivitis

The marginal gingiva (the border of the gingiva surrounding the neck of the tooth) is held firmly to the tooth by a network of collagen fibers.

Microorganisms present in the plaque in the gingival sulcus (the space between the gingiva and the tooth) are capable of producing harmful products (e.g., acids, toxins, enzymes) that damage cellular and intercellular tissue. Early-stage gingivitis signs and symptoms include dilation and proliferation of gingival capillaries, increased flow of gingival fluid, and increased blood flow with resulting erythema of the gingiva. The gingivae themselves also may enlarge, change contour, and appear puffy or swollen as a result of the inflammation (see [Color Plates](#), photograph 10). The inflammatory process of early-stage gingivitis is reversible with effective oral hygiene.

Some common indications that early-stage gingivitis has become chronic gingivitis include changes in gingival color, size, and shape, as well as changes in the ease with which gingival bleeding occurs. Additionally, the flat, knife-edge appearance of the margin of healthy gingiva is replaced by a ragged or rounded edge. Progression usually is slow and insidious—and often painless.

Left untreated, chronic gingivitis may advance to the inflammatory condition of chronic destructive periodontal disease, or periodontitis (see [Color Plates](#), photograph 11). Progression of gingivitis may parallel an increase in the proportion of bacterial species implicated in the genesis of periodontitis.

Prevention of Gingivitis

Because prevention of gingivitis depends on calculus prevention and plaque control, the same measures described for prevention of caries pertain to gingivitis. Active ingredients that prevent gingivitis and are commonly found in dentifrices, mouth rinses, and other antiplaque products include triclosan, cetylpyridinium chloride, and stabilized stannous fluoride. Brushing and flossing can cure early gingivitis that arises from irritating food debris and plaque. The most important factors in reversing gingivitis and in preventing and controlling periodontal disease are adequate removal and control of supragingival plaque. Patients who notice signs of early gingivitis such as

bleeding gums during tooth brushing should be referred to a dental care provider.

Special Population Considerations for Gingivitis

In general, self-care for prevention of gingivitis requires no specific considerations for the following patient populations: children, pregnant or lactating women, males and females of reproductive age, and older adults.

Assessment of Gingivitis

Before recommending oral hygiene products, the health care provider should evaluate the patient's oral hygiene regimen. An important issue is whether the patient has a history of gingivitis or current signs and symptoms of gingivitis, as well as what preventive measures the patient has tried or is using. Checking the medical and medication histories will identify asymptomatic patients who are at risk for gingivitis. Any signs or symptoms of gingivitis—swollen gums, gums that bleed with brushing or flossing, receding gums, or gums that appear darker red than usual—warrant referral to a dental care provider for evaluation and treatment.

The health care provider should be cognizant of the association between pregnancy and gingivitis and should address this potential issue during counseling on prescription prenatal vitamins. Besides monitoring the pregnant patient's medications for safety, the provider has an opportunity to encourage the patient to have a dental checkup and to stress the importance of careful attention to brushing and flossing to avoid oral health problems.

Patient Counseling for Gingivitis

Because gingivitis is not usually associated with pain, patients are unlikely to seek dental care for this problem alone. A more likely scenario is patient-initiated contact with a health care provider to request oral hygiene information and product recommendations. In such encounters, it may be appropriate to suggest specific oral hygiene methods and emphasize possible adverse effects of certain products. Case 31-1 provides an example of

assessment of a patient with gingivitis. The box “Patient Education for Prevention of Caries, Gingivitis, and Halitosis” lists specific information for patient counseling.

The health care provider should also use such clinical encounters as an opportunity to warn patients with suspected gingivitis that the disease is a serious problem warranting professional attention. Counseling should emphasize that adherence to an oral hygiene program is vital to preventing gingivitis.

Considerations in pregnant patients are reviewed under “Assessment of Gingivitis.”

Case 31–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has had red, slightly swollen gums for the past 3 weeks.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She experienced a “little bit of bleeding” at her dental cleaning visit 2 days ago.
c. Description of the patient's efforts to relieve the symptoms	Patient brushes her teeth twice daily.
d. Patient's identity	Katherine Stonesifer
e. Patient's age, gender, height, and weight	42 years, female, 5 ft 3 in., 155 lb
f. Patient's occupation	School teacher

Relevant Evaluation Criteria	Scenario/Model Outcome
g. Patient's dietary habits	Normal, healthy diet
h. Patient's sleep habits	6–8 hours of sleep each night
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Patient has hypothyroidism and takes levothyroxine 125 mcg PO daily.
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Ms. Stonesifer's dentist referred her to your pharmacy for dental hygiene products.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	The patient appears to have gingivitis.
3. Identify exclusions for self-treatment.	Although Ms. Stonesifer had red, swollen gums and bleeding at her dental cleaning, which are exclusions for self-care (see the box "Patient Education for Prevention of Caries, Gingivitis, and Halitosis"), she was recently seen by a dental care provider (i.e., she was not avoiding treatment), who referred her to you. You can recommend self-care.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Stonesifer to a dental care provider. (2) Recommend self-care with a mouth rinse and floss with education about proper oral care. (3) Recommend self-care until Ms. Stonesifer can see a dental care provider.

Relevant Evaluation Criteria	Scenario/Model Outcome
	(4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend self-care with a mouth rinse and flossing, with education about proper oral care.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Regular use of a plaque/gingivitis mouth rinse and flossing, in addition to brushing your teeth, will improve your oral health with a decrease in your symptoms."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"A plaque/gingivitis mouth rinse has ingredients that some other mouth rinses do not have to treat your symptoms. It is important to select one that has the American Dental Association Seal of Acceptance. Regular flossing helps prevent plaque from depositing in hard-to-reach places between your teeth, which can lead to inflamed gums."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	"Use a plaque/gingivitis mouth rinse such as Listerine Antiseptic once daily and waxed floss once daily."
b. Maximum number of days the therapy should be employed	n/a
c. Product administration procedures	See Tables 31-2 and 31-3 .
e. Most common adverse effects	"You may experience a little burning from the mouth wash. Your gums may bleed with flossing for the first few days."
f. Adverse effects that warrant	"If your gums bleed with flossing for more than a few

Relevant Evaluation Criteria	Scenario/Model Outcome
medical intervention should they occur	days or you have bleeding that won't stop, see your dental care provider."
g. Patient options in the event that condition worsens or persists	"See your dental care provider for further evaluation."
h. Product storage requirements	Store at room temperature.
i. Specific nondrug measures	"Continue to brush your teeth twice daily."
Solicit follow-up questions from the patient or caregiver.	"Should I change my manual toothbrush to a powered one?"
Answer the patient's or caregiver's questions.	"There is some evidence that powered toothbrushes reduce plaque and gingivitis better than manual brushing, so you could switch to a powered toothbrush."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Call Ms. Stonesifer in 1 week to evaluate her response to your recommendations.

Key: n/a = Not applicable.

Halitosis

A recent meta-analysis estimated that halitosis, or oral malodor (usually known as bad breath), affects greater than 31.8% of the population worldwide.⁴⁴

Pathophysiology of Halitosis

Causes of halitosis may be related to both systemic and oral conditions; in a majority of cases, however, the etiology involves oral pathology (e.g. dental caries, periodontal disease, oral infections, mucosal ulcerations, tongue

coating, impacted food or debris).⁴⁵

Medications that have anticholinergic properties often cause xerostomia, which also can lead to mouth odor. Many foods and products such as garlic, tobacco, onions, alcohol, and other substances may contribute to mouth odor as well.

Most foul breath odors arise from volatile sulfur compounds (VSCs), which can be produced by breakdown of food debris left in the mouth or in systemic conditions in which VSCs are eliminated in exhaled air.

Prevention of Halitosis

Prevention of halitosis relies on the removal of plaque and the prevention of calculus formation as described for prevention of caries. One of the primary sites for the formation of VSCs is the back of the tongue. Plaque and VSCs in this area of the mouth can seed the tonsillar crypts with malodorous debris. Brushing both the teeth and tongue is helpful, but some dental care providers have found that the use of a tongue-cleaning device (e.g., a tongue blade) may be the best way to clean the circumvallate papillae area of the tongue. Cleaning this posterior dorsal area not only will remove the VSCs but also will prevent them from spreading to the tonsils.

Zinc salts and chlorine dioxide are most effective in the chemical prevention of oral malodor. Zinc salts reduce the receptor binding necessary for VSC production and kill gram-negative bacteria. Chlorine dioxide breaks disulfide bonds and oxidizes the precursors of VSCs.

Any patient who complains of severe or lingering halitosis without a readily identifiable cause (e.g., smoking) should be advised to see a dental care provider for a thorough evaluation. Masking foul taste and odor with cosmetic mouth rinses may delay necessary dental or medical assessment and any needed treatment.

Special Population Considerations for Halitosis

No self-care considerations related to prevention of halitosis have been identified for the following patient populations: children, pregnant or lactating

women, males and females of reproductive age, and older adults.

Assessment of Halitosis

When assessing a patient for halitosis, the health care provider should evaluate the patient's dental hygiene. Ideally, both medication and medical histories are obtained to help identify the cause of the halitosis, as discussed in the "Pathophysiology of Halitosis" section (see also "Xerostomia" in [Chapter 32](#)). Patients with medical conditions associated with halitosis and those with halitosis that persists despite proper dental hygiene should be referred to their dental care provider for evaluation and treatment.

Patient Counseling for Halitosis

For patients with mouth odor related to poor dental hygiene, the health care provider should reinforce proper techniques for maintaining dental hygiene to prevent tooth and gum problems, including brushing and flossing, and should recommend appropriate products, with explanations of their use. The box "Patient Education for Prevention of Caries, Gingivitis, and Halitosis" lists specific information for patient counseling on prevention of halitosis.

Hygiene-Related Denture Problems

Pain along the gingival ridge under a denture prosthesis suggests the presence of *denture stomatitis* or a related condition. Denture stomatitis, an inflammation of the oral tissue in contact with a removable denture, results from poor cleaning of dentures and can lead to chronic candidiasis.⁴⁶

Pathophysiology of Hygiene-Related Denture Problems

Dentures accumulate plaque, stain, and calculus by a process very similar to that occurring on natural teeth. Contact of the denture plaque mass with oral

tissues leads to predictable toxic results. Poor denture hygiene contributes to fungal and bacterial growth that not only affects the patient aesthetically (with unpleasant odors and staining) but also seriously compromises the patient's oral health (from inflammation and mucosal disease) and ability to wear the dentures successfully.

Chronic atrophic candidiasis is common in patients with full or partial dentures. This condition may be attributed to infection with *Candida* organisms, which is more prevalent among denture wearers.⁴⁶ On inspection, the inflamed denture-bearing area may appear granular or erythematous and edematous, associated with soreness or a burning sensation (see [Color Plates](#), photograph 12). Inflammation secondary to *Candida* infection is generalized, involving the entire denture-bearing tissue area, whereas inflammation secondary to the trauma of ill-fitting dentures usually is localized to the specific area of the trauma. Failure to remove the denture at bedtime and to clean it regularly will worsen this condition.

Angular cheilitis (soreness and cracking at the corners of the mouth) is commonly associated with chronic atrophic candidiasis, other forms of oral candidiasis, and poor denture fit. The cheilitis lesions often can be treated effectively with terbinafine cream. If a staphylococcal organism also is involved, a prescription from the patient's primary care provider will be needed.

Prevention of Hygiene-Related Denture Problems

Removing plaque from dentures helps prevent gum infections, staining of dentures, and mouth odor. Specialty brushes and aids are available to remove plaque from hard-to-clean areas on fixed orthodontic appliances (e.g., spaces around a bridge, implant, or orthodontic band) and dentures. Dentures should be cleaned thoroughly at least once daily to remove unsightly stains, debris, and plaque. Abrasive and chemical cleansers formulated specifically for dentures are available ([Table 31–6](#)). A combination regimen of brushing dentures with an abrasive cleaner and soaking them in a commercial cleaning solution is recommended.

TABLE 31-6 Selected Nonprescription Denture Products

Denture Adhesive
Adhesadent Denture Adhesive Cream
Denture Cleaners
Cleanadent Cleansing Paste
Efferdent Denture Cleanser Tabs
Fresh 'N Brite Denture Cleaning Paste

Denture cleansers for brushing, in either a paste or powder formulation, contain mild abrasives (e.g., calcium carbonate) and must be applied properly with specialty brushes adapted to the denture's contour to remove stains, plaque, and calculus. Overly vigorous scrubbing can abrade the denture's acrylic materials and deform the metal clasps. To prevent irritation of oral tissues, the patient should thoroughly rinse the abrasive cleaner from the denture. After initial brushing, the denture should be soaked in a cleansing solution (alkaline peroxide, hypochlorite, or dilute acids) to help remove remaining plaque and bacteria. Brushing the denture after it has soaked further enhances plaque removal.

Alkaline peroxide products are the most commonly used chemical denture-soaking cleansers. These powders or tablets are dissolved in water to become alkaline solutions of hydrogen peroxide, causing oxygen to be released for a mechanical cleaning effect. These products are most effective on new plaque and stains when the denture is soaked for 4 to 8 hours. The alkaline peroxides have few serious disadvantages and do not damage the surface of acrylic resins.

Sodium hypochlorite (bleach) removes stains, dissolves mucin, and is both bactericidal and fungicidal. *Denture plaque* consists of cells embedded in a matrix that serves as a surface on which calculus may develop. Hypochlorite cleansers act directly on the organic plaque matrix to dissolve its structure, but they cannot dissolve calculus once it has formed. The most serious drawback with any hypochlorite product is that the bleach corrodes metal denture

components (e.g., the framework and clasps of removable partial dentures, solder joints, and possibly the pins holding the teeth). The addition of anticorrosive phosphate compounds has greatly reduced this problem, but these products should be used for only 10-minute soaks (to limit exposure) and not more often than once a week.

Acid-containing soaking solutions also can be corrosive to metals, so short soaking times are recommended with use of these solutions. A sonic or ultrasonic cleaning device, when used with a commercially prepared solution, is easy to operate and cleans more effectively than soaking alone. However, some hand brushing may still be required.

All denture-cleansing products should be rinsed off the denture completely before it is inserted into the mouth, to reduce tissue irritation. All denture cleansers should be kept out of children's reach because of the potential for eye or skin irritation, and because they are toxic if accidentally ingested. Stains that are resistant to proper denture brushing and soaking in available solutions should be evaluated by a dental care provider.

Only products that are specifically formulated for denture cleansing should be used. Household cleansers (sometimes used by patients for soaking dentures) are not appropriate and may be ineffective or may damage the denture material. The use of whitening toothpastes (which are formulated for use with natural dentition) should be discouraged as well, because they are too abrasive to be used safely on denture material.

Patients should not soak or clean dentures in hot water or hot soaking solutions, because distortion or warping may occur.

Patients of advanced age or disabled persons may prefer an alkaline peroxide soak solution for daily, overnight cleaning. Unlike alkaline hypochlorite and acid cleansers, alkaline peroxide cleansers do not corrode metal components of dentures.

Assessment of Hygiene-Related Denture Problems

Before recommending any type of oral hygiene product, the health care

provider should identify what denture care measures the patient is taking and assess whether those measures are adequate for oral health and successful wear of dentures or other appliance. Another important aspect of the initial assessment is to determine whether the patient suffers from denture stomatitis or inflammation secondary to ill-fitting dentures, necessitating referral to a dental care provider for evaluation and treatment. Case 31–2 illustrates assessment of a patient with a hygiene-related denture problem.

Case 31–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient is complaining of gum inflammation and soreness in the back upper right area of his mouth. He also noticed some white patches on his tongue.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms are worse when he wears his dentures overnight. They decrease somewhat when he soaks them in a cleaner overnight.
c. Description of the patient's efforts to relieve the symptoms	He removes the dentures when the sore area gets really uncomfortable, but he can't always do this, especially in public.
d. Patient's identity	George Clancy
e. Patient's age, gender, height, and weight	64 years, male, 6 ft 1 in., 210 lb
f. Patient's occupation	Retired mailman
g. Patient's dietary habits	Normal healthy diet
h. Patient's sleep habits	Averages 6 hours per night and takes a 1-hour nap every afternoon.
i. Concurrent medical conditions,	<i>High blood pressure:</i> amlodipine 10 mg, 1 tablet

Relevant Evaluation Criteria	Scenario/Model Outcome
prescription and nonprescription medications, and dietary supplements	daily; hydrochlorothiazide 25 mg, 1 tablet daily
	<i>High cholesterol:</i> simvastatin 40 mg, 1 tablet daily
j. Allergies	Sulfa
k. History of other adverse reactions to medications	Oxycodone/APAP: upset stomach
l. Other (describe) _____	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Mr. Clancy has denture stomatitis and possible <i>Candida</i> infection.
3. Identify exclusions for self-treatment.	Symptoms of denture stomatitis and signs of infection (white patches on tongue)
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mr. Clancy to a dental care provider. (2) Recommend appropriate self-care with a denture dentifrice. (3) Recommend self-care until Mr. Clancy can see a dental care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer Mr. Clancy to a dental care provider. Educate him about denture care: His dentures should be thoroughly cleaned with a denture brush and denture paste daily. Then they should be soaked in a dental cleanser solution. He also should remove his dentures every evening.

Relevant Evaluation Criteria	Scenario/Model Outcome
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You will need to see a dental health care provider for your symptoms."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best because you may have an infection that requires an antifungal medication to be prescribed."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Proper denture hygiene is important to prevent this condition in the future. Brush your dentures using a denture brush and denture paste daily. Then soak the dentures in a dental cleanser. Be sure to remove your dentures every evening."
Solicit follow-up questions from the patient or caregiver.	"Can I use whitening toothpaste to remove stains on my dentures?"
Answer the patient's or caregiver's questions.	"No. Only products that are specifically formulated for denture cleansing should be used. Whitening toothpastes are too abrasive to use on dentures."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Clancy within 1 or 2 days to make sure he made an appointment and sought dental care.

Key: APAP = Acetaminophen; n/a = not applicable.

Patient Education for Hygiene-Related Denture Problems

The objective of self-care is to prevent bacterial or fungal infections of the mouth by removing plaque from the dentures. For most patients, carefully following product instructions and the self-care measures listed here will help ensure good denture hygiene.

- Thoroughly clean dentures at least once daily to remove unsightly stain, debris, and potentially harmful plaque.
- Preferably, brush dentures with an abrasive cleaner using a brush designed to adapt to the dentures contour, and then soak them in a chemical cleanser. This combination regimen is more effective in removing plaque and bacteria.
- Do not scrub the denture surface vigorously; this action can abrade the acrylic materials and deform the metal clasps.
- If using sodium hypochlorite or acid-containing cleansers, limit soaking to 10 minutes to avoid corrosion of metal denture components.
- To prevent irritation of oral tissues, thoroughly rinse the dentures after using an abrasive cleaner or chemical cleanser.
- Keep all denture cleansers out of children's reach. These agents can cause eye or skin irritation or toxicity if accidentally ingested.
- Do not use household cleansers or whitening toothpastes to clean dentures. These agents may damage denture material.
- Do not soak or clean dentures in hot water or hot soaking solutions. Distortion or warping of the denture may occur.
- Do not sleep while wearing your dentures. Decreased levels of saliva during sleep may contribute to plaque buildup on the denture.

Patient Counseling for Hygiene-Related Denture Problems

Denture wearers may tend to blame their appliances for any oral discomfort, rather than their hygiene regimen. The health care provider should emphasize that diligent plaque removal from dentures is the key to preventing denture stomatitis. The methods of cleaning dentures, including their advantages and

disadvantages, should be explained. The health care provider should recommend a denture cleanser that accommodates the patient's preferences and should reinforce the methods of use. The box "Patient Education for Hygiene-Related Denture Problems" lists specific information for patient counseling.

Key Points for Prevention of Hygiene-Related Oral Disorders

- Removing plaque and modifying the diet are the main goals of self-care to prevent caries, gingivitis, and halitosis.
- Mechanical removal of plaque by brushing and flossing is essential for good oral health.
- Mouth rinses may augment the benefits of brushing and flossing procedures and may be used to freshen breath or as antiplaque or antigingivitis adjuncts.
- Topical fluorides may be used in patients with high caries activity.
- Parents must supervise oral hygiene measures in children younger than 12 years as necessary until they can use the products without supervision.
- Denture cleaners may be used to remove debris physically and to prevent bacterial and/or fungal infections.
- If a patient has specific problems related to the purpose or use of these products, consultation with a dental care provider should be recommended.

Chapter 32: Orofacial Pain and Discomfort

Authors: Nicole Paolini Albanese, Mark Donaldson

Tooth Hypersensitivity

Tooth hypersensitivity, or dentin hypersensitivity, is one of the orofacial pain and discomfort ailments that can occur throughout the human life span.¹ This disorder is characterized by a short, sharp pain arising from exposed dentin (i.e., mineralized tissue of teeth internal to crown enamel and root cementum) in response to a stimulus—thermal, chemical, or physical—that cannot be ascribed to any other form of dental defect or disease.^{2–5} Tooth hypersensitivity affects 10%–30% of the adult population, with increased incidence between the ages of 20 and 50 years.^{3,5} Some investigators suggest that the first premolars and canines are the teeth most commonly affected, in keeping with their prominent position in the maxillary and mandibular arches.³

Pathophysiology of Tooth Hypersensitivity

Two processes are required for the development of dentin hypersensitivity: (1) Dentin must become exposed through loss of enamel or gingival recession (lesion localization, facial piercings), and (2) the dentin tubules must be open to both the oral cavity and the pulp (lesion initiation).^{2–4} The roots of teeth are usually covered by gum tissue (gingiva), but infection (e.g., periodontal disease) or injury² (e.g., aggressive or improper brushing) can cause the gums to recede. The cementum covering affected root surfaces may be reduced by further injury (attrition, abrasion, or erosion), eventually exposing the underlying porous dentin. When stimuli such as heat, cold, pressure, or acid touch exposed dentin or reach an open tubule, fluid flow in the dentin tubule is increased, and the underlying nerves are stimulated, resulting in pain.^{2–4,6}

Enamel, which covers the anatomic crowns of the teeth and is the most densely mineralized body tissue, is resistant to abrasion by normal toothbrushing. Consistent clinical data correlating brushing habits and dentin hypersensitivity are lacking, with an array of conflicting opinions, although overly aggressive brushing may be a contributing factor.^{2,6,7} Clark and Levin

define aggressive brushing as the use of excessive force with a hard-bristled toothbrush.³ However, a clear association between diet and resulting hypersensitivity is recognized. The intake of acidic foods and beverages is correlated with effect on the basis of duration of exposure, rather than frequency of use. In other words, taking a long time to eat or drink an acidic food causes more damage than the frequency of eating or drinking the acidic food.⁶ Tooth hypersensitivity is more common in persons with periodontitis or after procedures such as deep scaling, root planing, orthodontic tooth movement, or periodontal (gum) surgery.^{2,3,6} Tooth whitening procedures, whether done at home or by a trained clinician, also can cause dentin sensitivity.

Clinical Presentation of Tooth Hypersensitivity

The patient with tooth hypersensitivity experiences pain from hot, cold, sweet, or sour solutions, as well as when hot or cold air touches the teeth. As individual pain thresholds vary, so does the pain experienced from tooth hypersensitivity. Pain varies in intensity, ranging from mild discomfort to sharp, excruciating pain. Although tooth hypersensitivity is self-treatable, toothache is not; therefore, it is critical to differentiate between these two conditions (Table 32–1). Resolution of pain associated with toothache, fractured dentition, ill-fitting dentures, or suspected infection (abscess) requires professional dental care. Only a dentist can adequately evaluate and treat these conditions; therefore, the affected patient should see a dentist without delay.

TABLE 32–1 Differentiation of Tooth Hypersensitivity and Toothache

Feature	Tooth Hypersensitivity	Toothache
Etiologic mechanism	Exposed and open dentin tubules	Bacterial invasion extending to the pulp
Pathophysiology	Stimuli (heat, cold, pressure, acid) cause fluid in the dentinal tubules to expand and shrink, stimulating pulp nerve fibers and resulting in pain.	Inflammatory response to invading bacteria stimulates free nerve endings in the pulp.

Feature	Tooth Hypersensitivity	Toothache
Causes	Attrition, abrasion, erosion, tooth/restoration fracture, faulty restoration, or gingival recession	Cavitation/decay present in tooth/teeth under existing restoration, tooth/restoration fracture, or trauma to the dentition
Symptoms	A quick, fleeting, sharp, or stabbing pain on exposure to thermal, chemical, or physical stimuli, which stops after stimuli are no longer present	Pain that remains even in the absence of stimulus; intermittent, short, and sharp pain on stimulation may indicate reversible damage; continuous, dull, and throbbing pain without stimulation usually indicates irreversible damage.
Assessment	Hypersensitivity due to attrition, abrasion, or erosion is not serious and is self-treatable; sensitivity due to fracture, faulty restoration, or gingival recession warrants referral to a dentist.	Requires dental care for resolution

FIGURE 32-1 Self-care for tooth hypersensitivity. (Source: References 2-9.)

Treatment of Tooth Hypersensitivity

Treatment Goals

The goals of self-treating tooth hypersensitivity are (1) to repair the damaged tooth surface using an appropriate toothpaste and (2) to replace aggressive or improper toothbrushing practices with optimal technique. When these goals have been achieved, tooth hypersensitivity may be eliminated.

General Treatment Approach

Pain related to tooth hypersensitivity can be challenging. Acute pain may

cause anxiety, and the patient may not seek care from a dentist but rather will try to self-treat with the aid of a pharmacist.² Before recommending self-treatment for tooth pain, the health care provider should determine if the patient is a candidate for self-care. [Figure 32–1](#) outlines self-treatment for tooth hypersensitivity and lists exclusions for self-care.^{2–8}

Nonpharmacologic Therapy

Treatment plans for tooth hypersensitivity should include identification and elimination of predisposing factors, such as acid exposure and potentially improper or aggressive toothbrushing technique. Brushing teeth within 30–60 minutes of consuming acidic foods or drinks should be avoided, to reduce the effects of acids and abrasions. If correct brushing techniques with a fluoride toothpaste do not result in improvement, a desensitizing dentifrice containing either stannous fluoride, sodium fluoride, or sodium monofluorophosphate or a low-abrasion toothpaste should be used ([Table 32–2](#)). For this purpose, a 1-inch strip of a desensitizing toothpaste with fluoride is applied to a soft-bristle toothbrush, followed by brushing as usual. Dentin permeability can be increased after ingestion of acidic foods or beverages.^{2,6} Fluoride is discussed in further detail in [Chapter 31](#).

TABLE 32–2 Selected Nonprescription Desensitizing Toothpastes	
Trade Name	Primary Ingredient(s)
Colgate Sensitive Multiprotection	Potassium nitrate 5%; sodium fluoride 0.24%
Colgate Sensitive Pro-Relief	Arginine 8%
Colgate Sensitive Pro-Relief Original	Potassium nitrate 5%; sodium fluoride 0.24%
Colgate Sensitive Pro-Relief Enamel Repair	Potassium nitrate 5%; sodium monofluorophosphate 1.14%
Colgate Sensitive Pro-Relief Whitening	Potassium nitrate 5%; sodium fluoride 0.24%
Colgate Total Zx Pro-Shield Plus Sensitivity	Potassium nitrate 0.24%; sodium monofluoride 0.055%; zinc citrate trihydrate 0.096%
Colgate Total Whole Mouth	Stannous fluoride 0.454%

Trade Name	Primary Ingredient(s)
Health	
Crest Pro-Health ^a	Stannous fluoride 0.454%
Crest Pro-Health Whitening ^a	Stannous fluoride 0.454%
Crest Gum and Sensitivity, Gentle Whitening	Stannous fluoride 0.454%
Crest 3D White	Potassium nitrate 5%; sodium fluoride 0.243%
Sensodyne Fresh Impact ^a	Potassium nitrate 5%; sodium fluoride 0.15%
Sensodyne Maximum Strength with Fluoride	Potassium nitrate 5%; sodium fluoride 0.15%
Sensodyne ProNamel	Potassium nitrate 5%; sodium fluoride 0.15%
Tom's of Maine Sensitive	Potassium nitrate 5%; sodium fluoride 0.24%
Tom's of Maine Whole Care	Sodium monofluorophosphate 0.76%

^a Carries the American Dental Association (ADA) Seal of Acceptance.

Pharmacologic Therapy

In general, two pharmacologic mechanisms have been recruited for the treatment of tooth hypersensitivity. The first mechanism involves depolarizing the excited nerves in the tubules and pulp to disrupt the pain stimulus neuronal response.^{2,3,6} A potassium salt, usually potassium nitrate, diffuses along the dentin tubules to decrease the excitability of intradental nerves and alter its membrane potential. The potassium nitrate acts on the dentin to block the perception of stimuli that patients with healthy teeth usually do not experience. The second mechanism involves minimizing the flow of fluid by sealing the exposed dentin.^{2,3,6} A fairly recent technology using 8% arginine, an amino acid naturally found in saliva, combined with calcium carbonate, works by occluding the exposed dentinal tubules.^{2,3,6} This treatment prevents the fluid from moving into the tubules, which is the cause of hypersensitivity. Both of these mechanisms have been implemented in the design and manufacture of desensitizing dentifrices. **Table 32–2** lists selected desensitizing toothpastes

and their active ingredients.

Potassium nitrate 5% is the most widely used and generally accepted ingredient in products for decreasing tooth sensitivity. Most commercially available desensitizing dentifrices are combination products containing potassium nitrate and sodium fluoride, in various concentrations. Some studies have demonstrated that patients with tooth sensitivity experience a reduction in their symptoms after using a potassium nitrate-containing dentifrice for just 2 weeks.^{3,7}

Additionally, products containing arginine and calcium carbonate or calcium sodium phosphosilicate also have been found to be efficacious for the treatment of tooth sensitivity.^{2-4,6} Clinically important drug interactions for desensitizing toothpastes are listed in [Table 32-3](#). Patients consuming calcium-containing products need to be aware that the excess calcium can affect the bioavailability of fluoride. This potential adverse interaction should be emphasized by the oral healthcare practitioner (OHCP) and pharmacist during counseling before initiation of fluoride-containing products.

TABLE 32-3 Clinically Important Drug-Drug Interactions With Nonprescription Orofacial Pain and Discomfort Agents

Active Ingredient	Interacting Drug	Potential Interaction	Management/ Preventive Measures
Desensitizing Toothpastes			
Potassium nitrate	ACEIs, ARBs, potassium- sparing diuretics	These agents increase the risk for development of hyperkalemia.	Be cautious with this combination.
Sodium fluoride	Calcium-rich foods	Foods rich in calcium can decrease the bioavailability of fluoride by up to 25%.	Avoid concurrent use if possible.
Stannous fluoride	Calcium	Calcium can form insoluble compounds with fluoride and reduce absorption by 10%-25%.	Avoid concurrent use if possible.
Oral Debriding and Wound-Cleansing Agents			

Active Ingredient	Interacting Drug	Potential Interaction	Management/ Preventive Measures
Carbamide peroxide	No drug interactions with topical carbamide peroxide have been reported.		
Hydrogen peroxide	No drug interactions with topical hydrogen peroxide have been reported.		
Topical Oral Anesthetics			
Benzocaine	Concurrent use of other drugs that can cause methemoglobin formation, such as prilocaine, nitrates, or sulfonamides	Rare and sometimes fatal cases of methemoglobinemia have been reported with the use of topical or oromucosal benzocaine products.	Avoid concurrent use.
Camphor	Hepatotoxic herbs and supplements	Theoretically, concomitant use of camphor with other potentially hepatotoxic herbs and supplements may increase the risk of developing liver damage.	Avoid concurrent use with androstenedione, chaparral, comfrey, DHEA, germander, kava, niacin, pennyroyal oil, red yeast, and others if possible.
Herpicin-L Lip Balm	No drug or herbal interactions with any of the individual ingredients comprising topical Herpicin-L Lip Balm have been reported.		
Topical Oral Protectants			
Menthol	No drug interactions with topical menthol have been reported.		
Glycyrrhiza (licorice) extract	Antihypertensive medications	Theoretically, licorice may reduce the effect of antihypertensive drug therapy because it is recognized to increase blood pressure in a dose-dependent manner.	Avoid concurrent use if possible.
	Warfarin	Licorice seems to increase metabolism	Avoid concurrent use.

Active Ingredient	Interacting Drug	Potential Interaction	Management/ Preventive Measures
		and decrease levels of warfarin, probably by induction of CYP2C9 metabolism.	
	CYP3A4 substrates (lovastatin, clarithromycin, cyclosporine, diltiazem, estrogens, indinavir, triazolam, numerous others)	Licorice appears to induce CYP3A4 metabolism.	Avoid concurrent use if possible.
Oral Rinses			
Eucalyptol	Antidiabetic medications	Preliminary research suggests eucalyptus may have hypoglycemic activity and may have additive effects when used with antidiabetes medications.	Avoid concurrent use if possible and monitor blood glucose levels closely.
Bee Propolis	Anticoagulant and antiplatelet medications	In vitro evidence suggests that the propolis constituent caffeic acid phenethyl ester can inhibit platelet aggregation.	Avoid concurrent use if possible.
Topical Treatments			
Docosanol	No drug or herbal interactions with topical docosanol have been reported.		
Saliva Substitutes and Other Xerostomia Products			
Isomalt	No drug or herbal interactions with isomalt have been reported.		
Xylitol	No drug or herbal interactions with xylitol have been reported.		

Active Ingredient	Interacting Drug	Potential Interaction	Management/ Preventive Measures
Glucose oxidase	No drug or herbal interactions with glucose oxidase have been reported.		
Sodium carboxymethylcellulose	No drug or herbal interactions with sodium carboxymethylcellulose have been reported.		
Sorbitol	Sodium polystyrene sulfonate	Concomitant use has been implicated in cases of colonic necrosis.	Avoid concurrent use.
	Dichlorphenamide	Metabolic acidosis is associated with the use of dichlorphenamide and large volumes of sorbitol.	Avoid concurrent use.
Sodium monofluorophosphate	Calcium	Calcium can form insoluble compounds with fluoride, with consequent reduction in its absorption by 10%–25%.	Avoid concurrent use if possible.

Key: ACEIs = Angiotensin-converting enzyme inhibitors; ARBs = angiotensin receptor blockers; CYP = cytochrome P450; DHEA = dehydroepiandrosterone.

Source: References [13](#), [23–25](#), [29–31](#), and [33](#).

Guidelines for brushing teeth can be found in the previous chapter ([Table 31–1](#)) and can be applied to brushing with desensitizing dentifrices.⁹ A single application typically has no effect; for some patients, long-term use (over 4–6 weeks) may be necessary to relieve the symptoms. The desensitizing dentifrice should be used until the sensitivity subsides or for as long as the dentist recommends. If the hypersensitivity is not relieved within 4–6 weeks of using a desensitizing dentifrice, the patient should see a dentist for an in-office method of treatment or an appropriate OHCP for further evaluation.⁸

Product Selection Guidelines

Patients with hypersensitive teeth should be cautioned against using high-abrasion toothpastes such as cosmetic pastes that whiten teeth or remove stains.

Special Populations

Dentifrices containing potassium nitrate 5% are not recommended for children younger than 12 years. Some toothpastes containing potassium nitrate have earned the American Dental Association (ADA) Seal of Acceptance, which means they have been shown to be not only efficacious but also safe. Therefore, no special considerations are necessary in choosing products for pregnant or lactating women or for geriatric patients.

Assessment of Toothache and Tooth Hypersensitivity: A Case-Based Approach

The primary objectives of the assessment are to determine whether the patient has a history of dental problems, whether the patient's oral self-care regimen is adequate, and whether the patient receives regular professional dental care. This information will help determine the patient's level of care and risk for a toothache versus tooth hypersensitivity ([Table 32-1](#)).

Patient Counseling for Tooth Hypersensitivity

Subsequent to a definite diagnosis of tooth hypersensitivity, patients should be counseled on the proper use of desensitizing toothpastes and safe methods of toothbrushing, as outlined in the box "Patient Education for Tooth Hypersensitivity." Use of the desensitizing toothpaste should continue for as long as the dentist recommends, and then switching to a low-abrasion (non-whitening) fluoride dentifrice is appropriate.

Evaluation of Patient Outcomes for Tooth

Hypersensitivity

The patient with tooth hypersensitivity should use a desensitizing dentifrice for at least 4 weeks. If the pain is resolved, the patient should continue treatment as recommended by an OHCP. The patient should be advised to continue the recommended dental hygiene measures (i.e., regular flossing, brushing teeth at least twice daily, and visiting the dentist twice a year). If the pain persists or worsens, or if new symptoms develop after 4–6 weeks, the patient should see the dentist for further evaluation.⁸

Teething Discomfort

Not all babies suffer discomfort during teething. For those who do, nonprescription products can provide symptomatic relief.

Pathophysiology of Teething Discomfort

Teething is the eruption of the deciduous (primary or baby) teeth through the gingival tissues. Usually, this normal physiologic process is essentially uneventful. In some children, however, it can cause pain, sleep disturbances, or irritability.

Clinical Presentation of Teething Discomfort

Mild pain, irritation, reddening, excessive drooling, mouth biting, gum rubbing, low-grade fever, or slight swelling of the gums while teething may precede or accompany sleep disturbances or irritability.¹⁰ Teething is not associated with vomiting, diarrhea, nasal congestion, malaise, fever, or rashes; these signs and symptoms may indicate presence of an ear or gastrointestinal infection. Bluish soft, round swellings (called eruption cysts) sometimes form over emerging incisors and molars. Eruption cysts are not the result of infection and will disappear if left alone. In addition, three bumps, called mamelons, may be present on the biting surfaces (*incisal edges*) of emerging incisors. The mamelons will wear away as the teeth begin to occlude against the opposing

dentition. If the underside of the tongue becomes irritated, a dentist may try to smooth the edges of the mamelons to prevent further irritation. Teeth eruption can begin as early as the age of 3 months, and for each tooth that erupts, the teething period usually extends over an 8-day window.^{10–12}

Patient Education for Tooth Hypersensitivity

The objectives of self-treatment of tooth hypersensitivity are (1) to repair the damaged tooth surface using an appropriate toothpaste and (2) to replace abrasive toothbrushing practices with preferred technique. For most patients, carefully following product instructions, the dentist's recommendations, and the self-care measures listed here will help ensure optimal therapeutic outcomes.

- If adherence to correct brushing techniques with a fluoride toothpaste fails to effect improvement, a desensitizing toothpaste should be used.
- If a desensitizing toothpaste is needed, apply a 1-inch strip of an appropriate dentifrice to a soft-bristle toothbrush and brush at least twice daily.
- Note that relief of the sensitivity may take several days to several weeks. The better the patient is at removing bacterial plaque, the more quickly the sensitivity will resolve.
- Use the dentifrice for as long as the dentist recommends, and then switch to a low-abrasion (non-whitening) fluoride dentifrice.
- Note that some cases of tooth hypersensitivity require long-term treatment or several repeated treatments.
- Do not use desensitizing toothpastes in children younger than 12 years.
- Do not use high-abrasion toothpastes, such as cosmetic pastes that whiten or remove stains.

When to Seek Medical Attention

- see a dentist if the pain worsens during treatment or if new symptoms develop.

Source: [References 2–9](#).

Treatment of Teething Discomfort

Treatment Goals

The goal of self-care for teething discomfort is to relieve gum pain and irritation, thereby reducing the child's distress and sleep disturbances.^{10,12}

General Treatment Approach

Parents and caregivers should be cautioned to exercise restraint in treating a child's teething discomfort. Eruption cysts are a feature of the normal physiologic process and should be left alone to resolve spontaneously. If cut or punctured, the cysts will form scars that may delay the tooth's eruption. Parents should try all nonpharmacologic measures to determine which ones are helpful. If additional treatment is needed, pediatric doses of certain systemic analgesics can be used. Furthermore, the use of teething necklaces should be discouraged, in view of the potential risk of choking and strangulation, versus accessorizing the child with a product that has never been proved to be effective.^{10,11} FDA has additional information and warnings on the agency's website about not using these products.¹⁵

Nonpharmacologic Therapy

If the baby cooperates, massaging the gum around the erupting tooth may provide relief. Babies may be made more comfortable by providing them with a cold teething ring. Teething products made of plastic and filled with fluid should not be subjected to extreme temperatures, as with boiling to sanitize or freezing; such exposure can weaken the plastic, with subsequent leakage of the fluid.^{10,11} The cold temperature causes beneficial local vasoconstriction, in addition to the pressure on the gums that the child feels on biting down on the object. The [HealthyChildren.org](https://www.healthychildren.org) website for parents and caregivers also emphasizes washing the hands first and consideration of light, gentle

massage and providing damp washcloths that have been twisted and frozen. Additional strategies are discussed on the website. If the child is at an age to tolerate food such as dry toast or teething biscuits, such foods may be offered to chew on. Foods high in sucrose should be avoided.^{10,11} The American Dental Association recommends regular dental checkups, which includes a dental visit within 6 months of eruption of the child's first tooth but no later than the child's first birthday.

Pharmacologic Therapy

Pharmacologic management of infant teething discomfort is limited to pediatric doses of certain systemic analgesics. Topical oral anesthetics carry strict warnings from the U.S. Food and Drug Administration (FDA) against their use. Clinically important drug interactions for topical oral anesthetics are listed in [Table 32–3](#).

Topical Oral Anesthetics

Benzocaine is available in concentrations ranging from 5%–20% and is generally not accepted as a safe topical anesthetic for teething pain. In addition, the safety of benzocaine use during pregnancy has not been established.^{11,13} [Table 32–4](#) provides additional information regarding use of benzocaine in pregnancy.¹³ (See the Preface for a detailed explanation of the pregnancy data.)

TABLE 32–4 Selected Nonprescription Medications for Recurrent Aphthous Stomatitis and Herpes Simplex Labialis

Trade Name	Primary Ingredient(s)	Pregnancy Data ^a
Oral Debriding and Wound-Cleansing Agents ^b		
Cankaid Liquid Oral Antiseptic	Carbamide peroxide 10%	Information is not available about the use of carbamide peroxide in pregnancy, but it is unlikely that any significant concentration reaches the fetus. Pregnant patients should consult a dentist along with their primary care provider before considering use of these products. No adequate and well-controlled studies have been conducted in pregnant women.
Gly-Oxide Antiseptic	Carbamide peroxide 10%	

Trade Name	Primary Ingredient(s)	Pregnancy Data^a
Oral Cleanser		
Orajel Antiseptic Rinse for Mouth Sores	Hydrogen peroxide 1.5%	Pregnant patients should consult a dentist along with their primary care provider before considering use of these products. No adequate and well-controlled studies have been conducted in pregnant women.
Colgate Peroxyl Mouth Sore Rinse	Hydrogen peroxide 1.5%	
Topical Oral Anesthetics		
Anbesol Regular Strength Gel/Liquid	Benzocaine 10%	Pregnant patients should consult a dentist along with their primary care provider before considering use of these products. No adequate and well-controlled studies have been conducted in pregnant women.
Zilactin-B Gel	Benzocaine 10%	
Anbesol Maximum Strength Gel	Benzocaine 20%	
Kank-A Liquid	Benzocaine 20%	
Orabase Paste	Benzocaine 20%	
Benzodent	Benzocaine 20%	
Orajel Mouth Sore Gel	Benzocaine 20%; benzalkonium chloride 0.02%; zinc chloride 0.1%	
Campho-	Camphor	Pregnant patients should consult a dentist along with their

Trade Name	Primary Ingredient(s)	Pregnancy Data^a
Phenique Gel/Liquid	10.8%; phenol 4.7%	primary care provider before considering use of these products. No adequate and well-controlled studies have been conducted in pregnant women.
Blistex Lip Medex Ointment	Camphor 1%; menthol 1%; phenol 0.54%; petrolatum 59.14%	
Carmex Lip Balm Ointment	Menthol 0.7%; camphor 1.7%; phenol 0.4%	
Herpicin-L Lip Balm	Dimethicone 1%; meradimate 5%; octinoxate 7.5%; octisalate 5%; oxybenzone 5%	
Topical Oral Protectants^b		
Canker Cover	Menthol 2.5 mg	Pregnant patients should consult a dentist along with their primary care provider before considering use of these products. No adequate and well-controlled studies have been conducted in pregnant women.
Cankermelts	Glycyrrhiza extract (GX) 30 mg (includes 1.4 mg glycyrrhizin) per disc	
Oral Rinses		
Original Listerine Antiseptic	Eucalyptol 0.092%; menthol 0.042%;	Pregnant patients should consult a dentist along with their primary care provider before considering use of these products. No adequate and well-controlled studies have been conducted in pregnant women.

Trade Name	Primary Ingredient(s)	Pregnancy Data ^a
	methyl salicylate 0.060%; thymol 0.064%	
Canker-Rid	Bee propolis	
Topical Treatments^c		
Abreva cream	Docosanol 10%	Pregnant patients should consult a dentist along with their health care provider before considering use of these products. No adequate and well-controlled studies have been conducted in pregnant women.

^a See the Preface for a detailed explanation of the pregnancy data.

^b Use limited to recurrent aphthous stomatitis.

^c Use limited to herpes simplex labialis.

Key: FDA = U.S. Food and Drug Administration; ID = insufficient data to determine pregnancy category. Source: [References 13, 25, 30, and 31](#).

In the highest concentration approved for nonprescription use (20%), benzocaine is too potent for infants and can even cause death from drug overdose.^{11,13} In April 2011, FDA released a MedWatch safety alert that warned health care providers of the reports linking benzocaine use and methemoglobinemias.¹⁴ FDA and the American Academy of Pediatrics no longer recommend the use benzocaine containing products for teething.¹⁵ Patients with known hypersensitivity to common local anesthetics should not use products containing benzocaine. Benzocaine is a known sensitizer (allergen), and its use in these patients can cause a hypersensitivity reaction.

In June 2014, FDA released a Drug Safety Communication regarding the use of topical agents for infant and child teething discomfort.¹⁶ The communication warned that prescription oral viscous lidocaine 2% solution should not be used

to treat infants and children with teething pain. Furthermore, the agency requires the following boxed warning to appear on the product packaging: “Oral viscous lidocaine solution is not approved to treat teething pain, and use in infants and young children can cause serious harm, including death.” In addition, this safety communication recommends against use of nonprescription topical medications for teething pain, which would include benzocaine-containing products. These products are sold under different brand names, such as Anbesol, Hurricaine, Orajel, Baby Orajel, Orabase, and various store brands. FDA supports following the American Academy of Pediatrics’ recommendations to help lessen teething pain. These modalities are discussed in detail earlier in the “Nonpharmacologic Therapy” section.

A warning released by FDA in September 2016 warns of the risk that homeopathic teething tablets and gels can pose to children, including those distributed by CVS, Hyland’s, and possibly other companies, although other manufacturers were not named specifically.¹⁷ FDA recommends that consumers stop using these products immediately and seek medical attention if their child experiences symptoms consistent with belladonna toxicity after using any of these products.¹⁷ Teething should be managed using nonpharmacologic modalities, which are described in detail earlier.

Systemic Analgesics

Pediatric doses of certain systemic nonprescription analgesics (e.g., acetaminophen) may be used to relieve teething discomfort. (See [Chapter 5](#) for discussion of these agents, recommended dosages, clinically important drug interactions, and pregnancy safety data.)

Product Selection Guidelines

Topical teething products labeled for the temporary relief of sore gums due to teething in infants and children are no longer recommended by FDA as safe and effective.^{14–17} Nonpharmacologic measures and certain systemic analgesics, given at the appropriate pediatric doses, should be used for symptom management.

Special Populations

The pediatric population should avoid topical teething products.^{14–17}

Assessment of Teething Discomfort: A Case-Based Approach

In most cases, teething discomfort must be assessed on the basis of the parent's description of the child's symptoms. If the child cooperates, visual inspection of the gums may confirm that the child is teething. Nonetheless, the signs and symptoms of teething must be distinguished from those of an infection.

Patient Counseling for Teething Discomfort

Patient counseling for parents should include both nonpharmacologic and pharmacologic remedies for teething discomfort, as outlined in the box "Patient Education for Teething Discomfort." Parents should be urged to contact a primary care provider when uncharacteristic symptoms of teething discomfort are present.

Evaluation of Patient Outcomes for Teething Discomfort

The parent should be asked to call back after 2 days of treatment. If neither nonpharmacologic measures nor nonprescription medications are relieving the symptoms, the parent should be advised to take the baby to a pediatrician, pediatric dentist, or other primary care provider. Furthermore, if symptoms uncharacteristic of teething discomfort have developed, the baby should be evaluated by an appropriate primary care provider.

Patient Education for Teething Discomfort

The objective of parent or caregiver self-treatment for teething discomfort is to relieve gum pain and irritation, thereby reducing the affected child's

distress and sleep disturbances. For most patients, the parent's or caregiver's careful following of product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- If possible, massage the gum around the erupting tooth to provide relief.
- Give the baby a cold teething ring or cold wet cloth or an appropriate food (e.g., dry toast or teething cookies) to chew on.
- The American Dental Association recommends regular dental checkups, which includes a dental visit within 6 months of eruption of the child's first tooth but no later than the child's first birthday.

Nonprescription Medications

Topical Analgesics

- Do not use teething preparations containing benzocaine in infants and young children.
- Do not use prescription viscous lidocaine 2% solution in infants and young children.

Systemic Analgesics

- If desired, use pediatric formulations of certain oral nonprescription analgesics such as acetaminophen to relieve teething discomfort.
- Read the label carefully, and do not exceed recommended doses or frequency of use.

When to Seek Medical Attention

- If the baby is vomiting or has diarrhea, fever, nasal congestion, malaise, pain, or other symptoms not typical of teething discomfort, take the baby to a pediatrician or other primary care provider.

Source: [References 10–17](#).

Recurrent Aphthous Stomatitis

Recurrent aphthous stomatitis (RAS), in which the lesions are also known as canker sores or aphthous ulcers, and can affect up to 25% of the general population.¹⁸ Eighty percent of patients with RAS are considered to have a mild form of the disease.¹⁸ The lesions affect only nonkeratinized mucosa (e.g., labial, buccal) and will spontaneously heal in 10–14 days.^{18,19}

Pathophysiology of Recurrent Aphthous Stomatitis

The cause of RAS is unknown in most patients. Precipitating factors such as local, systemic, immunologic, genetic, allergic, and nutritional factors have been proposed. Local trauma (e.g., smoking, chemical irritation, biting the inside of cheeks or lips, injury caused by toothbrushing or braces) has been implicated as a leading cause of lesions.^{18,19} Streptococci and varicella-zoster virus have been implicated as infectious agents.^{18,19} Systemic conditions associated with RAS include Behçet disease, systemic lupus erythematosus, neutrophil dysfunction, inflammatory bowel disease, and human immunodeficiency virus infection/acquired immunodeficiency syndrome (HIV/AIDS). Nutritional conditions associated with RAS include gluten-sensitive enteropathy and deficiencies of iron, B vitamins (B₁, B₂, B₆, B₁₂), and folic acid.

Clinical Presentation of Recurrent Aphthous Stomatitis

RAS manifests as an epithelial ulceration on nonkeratinized mucosal surfaces of movable mouth parts, such as the tongue, floor of the mouth, soft palate, or inside lining of the lips and cheeks. Rarely, ulcerations affect keratinized tissue such as the gingiva or the external lips (vermilion). Individual ulcers are usually (1) round or oval, (2) flat or *crateriform* (having a depressed, crater-like center), and (3) gray to grayish yellow, with an erythematous halo of inflamed tissue surrounding the ulcer (see [Color Plates](#), photograph 13).

RAS occurs in three clinical forms: minor, major, and herpetiform. The RAS form can be distinguished primarily by the number of lesions, the size of the ulcer, and the number of days that the lesion persists. [Table 32–5](#) compares the features of the three forms of RAS and cold sores.^{18–21} Some patients may experience a pricking or burning sensation (prodrome) approximately 2–48 hours before the lesion actually appears.²⁰ The lesions can be very painful, with the pain increasing with eating and drinking, and normal functions including eating, drinking, swallowing, talking, and routine oral hygiene may be severely limited. Usually, fever or lymphadenopathy does not accompany RAS; however, such signs and symptoms may arise if a secondary bacterial infection is present.

TABLE 32–5 Differentiation of Recurrent Aphthous Stomatitis (RAS) and Herpes Simplex Labialis (HSL)

	RAS (“canker sores”)		HSL (“cold sores”)	
Feature	Minor	Major	Herpetiform	Recurrent
Clinical manifestation	Oval, flat ulcer; erythematous tissue around ulcer	Oval, ragged, gray/yellow ulcers; crateriform	Small, oval ulcers in crops, similar to minor RAS	Red, fluid-filled vesicles; lesions may coalesce; crusted when mature
Location	All areas except gingiva, hard palate, vermillion border (at junction of oral mucosa and external skin)	Any intraoral area, but predilection for lips, soft palate, and throat	Any intraoral area	Junction of oral mucosa and skin of lip and nose
Incidence	13%–26%	1.5%–3%	0.5%–1%	20%–30%
Incidence among RAS sufferers	80%	10%	5%–10%	n/a
Number of lesions	1–5	Several (1–10)	10–100 (in crops)	Several
Size of lesion	<0.5 cm	>0.5 cm	<0.5 cm	1–3 mm
Duration	10–14 days	≥6 weeks	7–10 days	10–14 days

	RAS (“canker sores”)		HSL (“cold sores”)	
Feature	Minor	Major	Herpetiform	Recurrent
Pain	None-moderate	None-moderate	Moderate-severe	None-moderate
Scarring	None	Common	None	Rare
Comments	Immunologic defect	Immunologic defect	Immunologic defect	Induced by HSV-1

Key: HSV-1 = Herpes simplex virus type 1; n/a = not applicable.

Source: [References 18, 20, 22, 32, 38](#), and [46](#).

Algorithm: Recurrent Aphthous Stomatitis

FIGURE 32–2 Self-care for recurrent aphthous stomatitis (RAS). Key: D/C = Discontinue; HSL = herpes simplex labialis; OTC = over-the-counter. (Source: [References 13 and 18–30](#).)

Treatment of Recurrent Aphthous Stomatitis

RAS cannot be cured; however, nonprescription medications can provide symptomatic relief.

Treatment Goals

The primary objective of self-treatment for RAS is to relieve pain and irritation so that the lesions can heal and the patient can eat, drink, and perform routine oral hygiene. The secondary objective is to prevent complications, such as secondary infection, and to deter recurrence.²²

General Treatment Approach

If possible, the lesions should be inspected to determine whether their

appearance and location are characteristic of RAS. If possible, factors that may have led to development of the ulcer should be identified, and precipitating or contributing factors should be removed. For example, if local trauma is suspected, perhaps a softer toothbrush and gentler brushing technique could be suggested. It also is helpful to determine whether the patient has a history of RAS. If the treatments used are appropriate and previously have been successful for the patient, they should be continued. [Figure 32–2](#) outlines the self-treatment for RAS and lists exclusions for self-care.^{13,18,19,22,23}

Nonpharmacologic Therapy

If a nutritional deficiency (e.g., iron, folate, vitamins) is diagnosed as a contributing factor, the patient should increase consumption of foods high in the deficient nutrients or take appropriate nutritional supplements. For patients in whom a food allergy is thought to be a contributing factor, elimination of the offending agent from the diet may help to control or resolve RAS. The box “Patient Education for Recurrent Aphthous Stomatitis” lists additional nonpharmacologic measures.

Pharmacologic Therapy

Several types of nonprescription medications (oral debriding and wound-cleansing agents, topical oral anesthetics, topical oral protectants, oral rinses, certain systemic analgesics) provide symptomatic relief of RAS, but they do not prevent its recurrence. [Table 32–4](#) lists a variety of the commercially available products for relief of orofacial pain and discomfort and their pregnancy category risk rating, if known.

Clinically important drug interactions with these agents—oral debriding and wound-cleansing agents, topical oral anesthetics, topical oral protectants, and oral rinses—are discussed in [Table 32–3](#).

Oral Debriding and Wound-Cleansing Agents

It is reasonable to begin treatment with topical medication and advance to systemic medication as necessary, with a goal of decreasing recurrence rate and severity of the outbreaks of RAS. Oral debriding agents and wound cleansers may be used (1) to aid in the removal of debris, phlegm, mucus, or other secretions associated with a sore mouth; (2) to cleanse minor wounds or

areas of minor gum inflammation; and (3) to cleanse recurrent aphthous ulcers. Products that release nascent oxygen can be used as debriding and cleansing agents to provide temporary relief of RAS discomfort.²⁵ Hydrogen peroxide and carbamide peroxide release oxygen immediately on contact with tissue enzymes (catalase and peroxidase), but tissue and bacterial exposure to the oxygen is very brief.^{23,24}

For direct application, a few drops of carbamide peroxide (10%–15%) or hydrogen peroxide (1.5%) are applied to the affected area and allowed to remain in place for 1 minute before expectorating. This can be done up to 4 times a day. As a rinse, carbamide peroxide drops are placed on the tongue, mixed with saliva, and swished in the mouth for 1 minute. An aqueous solution of hydrogen peroxide 3% should be mixed with an equal amount of water before rinsing the mouth. Prolonged rinsing with oxidizing products can lead to soft tissue irritation, transient tooth sensitivity from decalcification of enamel, cellular changes, and overgrowth of undesirable organisms that could possibly result in development of a black hairy tongue.²³

Self-medication with any of these products should not be continued for longer than 7 days, and patients should contact an OHCP if symptoms (i.e., irritation or inflammation of the mouth or throat) worsen or persist beyond that time. If at any time a rash develops during the self-treatment regimen, the patient should discontinue use of the product and contact an OHCP. These products should be used after meals (3–4 times a day), and the patient should avoid eating or drinking for at least 30 minutes after application. The patient is directed to swish the liquid around the mouth for 10–15 minutes (or as long as tolerated, but no longer than 15 minutes). It is important not to swallow these medications.

Topical Oral Anesthetics

Topical oral anesthetic/analgesic products, including benzocaine 5%–20%, benzyl alcohol 0.05%–0.1%, dyclonine 0.05%–0.1%, and hexylresorcinol 0.05%–0.1%, generally are recognized as effective for temporary relief of pain associated with RAS.^{25,26} These are the active ingredients in certain products including Anbesol, Blistex, Orajel, and Benylin. It is important to avoid the concurrent use of potentially inflammatory products containing substantial amounts of menthol, phenol, or camphor. These agents may cause tissue irritation and damage or systemic toxicity. To reduce the incidence of RAS,

patients should also avoid the use of dentifrices containing sodium lauryl sulfate.^{18–21}

Topical Oral Protectants

Oral mucosal protectants such as denture adhesives are pharmacologically inert substances that coat and protect the ulcerated area. Coating the ulcer with a topical oral protectant can be effective in protecting ulcerations, decreasing friction, and giving temporary symptomatic relief. These products create a barrier by using a paste, an adhering film, or a dissolvable patch to cover the lesion. Some products are available in combination with an oral anesthetic. Products available as a patch or dissolving disc must be placed against the sore for 10–20 seconds. Once the disc adheres to the lesion, the barrier is formed and the disc will stay in place until dissolved, approximately 8–12 hours.²⁷ A study from Istanbul found that a mucoadhesive biopatch containing citrus essential oil resulted in satisfying pain alleviation and restoration of oral functions, with a significant improvement in oral health-related quality of life.²⁸

Patient Education for Recurrent Aphthous Stomatitis

The primary objective of self-treatment of recurrent aphthous stomatitis is to relieve pain and irritation so that the lesions can heal and the patient can eat, drink, and perform routine oral hygiene. The secondary objective is to prevent complications, such as secondary infection. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- If a deficiency of iron, folate, or vitamin B₁₂ is diagnosed as a contributing factor, increase consumption of foods high in the deficient nutrient, or take appropriate nutritional supplements.
- Avoid spicy or acidic foods until the lesions heal.
- Avoid sharp-textured foods that may cause increased trauma to the lesion.
- If desired, apply ice directly to the lesions in 10-minute increments

but for no longer than 20 minutes in a given hour.

- Do not use heat. If an infection is present, heat may spread the infection.

Nonprescription Medications

- If longer-lasting relief is desired, nonprescription medications such as oral debriding and cleansing agents, topical oral anesthetics, topical oral protectants, oral rinses, and certain systemic analgesics can be used.

Oral Debriding and Wound-Cleansing Agents

- Use a product containing one of the following ingredients: carbamide peroxide 10%–15% or hydrogen peroxide 1.5%. Apply after meals up to 4 times daily.
- Do not use these medications longer than 7 days. Chronic use can cause tissue irritation, decalcification of enamel, and black hairy tongue.
- Do not swallow these medications.

Topical Oral Anesthetics

- Use products containing one of the following medications: benzocaine 5%–20%, benzyl alcohol 0.05%–0.1%, dyclonine 0.05%–0.1%, or hexylresorcinol 0.05%–0.1%.
- Do not use benzocaine if you have a history of hypersensitivity to other benzocaine-containing products.

Topical Oral Protectants

- Use topical oral protectants or denture adhesives to coat and protect the lesions. These agents also will provide temporary relief of discomfort.
- Apply these products as needed.

Oral Rinses

- Rinse the mouth with Original Listerine Antiseptic to hasten healing of the lesions.
- Rinse the mouth with a saline solution to soothe discomfort or to prepare the lesion for application of a topical medication. For saline solution, add 1–3 teaspoons of salt to 4–8 ounces of warm tap water.

Systemic Analgesics

- Certain oral analgesics (e.g., aspirin or other NSAID, acetaminophen) can be used for additional relief of mouth discomfort.
- Do not hold an aspirin tablet in the mouth or place it on oral lesions. The acetylsalicylic acid can cause a chemical burn and tissue damage.

When to Seek Medical Attention

- See a primary care provider for any of the following outcomes:
 - Symptoms do not abate after 7 days of treatment with oral debriding or wound-cleansing agents.
 - The lesions do not heal in 14 days.
 - Symptoms worsen during self-treatment.
 - Manifestations of systemic infection, such as fever, rash, or swelling, develop.

Key: NSAID = Nonsteroidal anti-inflammatory drug.

Source: [References 13](#) and [18–30](#).

Oral Rinses

Rinsing the mouth with an antiseptic rinse will hasten the healing of the lesions. Saline rinses (1–3 teaspoons of salt in 4–8 ounces of warm tap water) may soothe ulcers and can be used before topical application of a medication. This can be used up to 4 times a day. Similarly, a paste of baking soda applied to the lesions for a few minutes may soothe irritation.

Systemic Analgesics

Certain systemic nonprescription analgesics (e.g., aspirin, nonsteroidal anti-inflammatory drugs, acetaminophen) give additional relief of mouth discomfort. (See [Chapter 5](#) for discussion of these agents, recommended dosages, clinically important drug interactions, and pregnancy safety data.) Aspirin tablets should not be retained in the mouth before swallowing, nor placed in the area of the oral lesions. The acetylsalicylic acid can cause a chemical burn with subsequent tissue damage (see [Color Plates](#), photograph 14).

Product Selection Guidelines

Patients with known hypersensitivity to common local anesthetics should not use any product containing a local anesthetic. Benzocaine is a known sensitizer (allergen), and its use in these patients can cause a hypersensitivity reaction. Patients with known sensitivity to aspirin also should avoid salicylic acid. Various dosage forms are available (e.g., liquid, gel, rinse, dissolvable patch); drug delivery is a major concern, however, because topical applications can be easily washed away by saliva. Gels are the preferred drug delivery application because they are easy to apply and are not as easily washed away.^{18–22,27–29} A topical anesthetic will provide short-term relief of the pain and discomfort associated with RAS, and the oral debriding agents will help to keep the ulcer clean. Using both types of agents should help alleviate immediate discomfort and heal the ulcer quickly.

Special Populations

The safety of these agents (oral debriding and wound-cleansing agents, topical oral anesthetics, topical oral protectants, and oral rinses) with use during pregnancy is mostly unknown. [Table 32–4](#) provides additional information regarding use of these agents. (See the Preface for detailed explanation of the pregnancy data.) No special considerations are necessary in choosing products for older adults. It is unknown how these products affect lactating women. These products should not be used or are not approved for use in pediatric patients.^{13,23,24,30–32}

Assessment of Recurrent Aphthous Stomatitis: A Case-Based Approach

Controlling the pain and preventing infection are the primary concerns when RAS is suspected. If possible, factors that may have precipitated or contributed to the development of the ulcer should be identified and then removed. The patient should be asked about previous self-treatments and their effectiveness. If the treatments used are appropriate and have been successful for the patient, they should be continued. Case 32–1 provides an example of the assessment of a patient with RAS.

Patient Counseling for Recurrent Aphthous Stomatitis

All nonpharmacologic and pharmacologic measures for treating RAS, as outlined in the box “Patient Education for Recurrent Aphthous Stomatitis,” should be explained to the patient. The patient should also be cautioned about using ineffective or harmful therapies. Possible adverse effects, drug interactions, contraindications, and precautions should then be explained for all nonprescription agents. In addition, patients must be alerted to the conditions that warrant dental or medical evaluation.

Case 32–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity,	Patient noticed a burning/prickling sensation about a day ago. On looking in her mouth, she noticed a

Relevant Evaluation Criteria	Scenario/Model Outcome
associated symptoms)	grayish oval-shaped lesion with a bumpy-appearing surface.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient started a smoking cessation program at your pharmacy 2 weeks ago and has been smoke free for 1 week.
c. Description of the patient's efforts to relieve the symptoms	Patient has not tried anything yet.
d. Patient's identity	Rebecca Sithgib
e. Patient's age, gender, height, and weight	32 years, female, 5 ft 9 in., 155 lb
f. Patient's occupation	High school German teacher
g. Patient's dietary habits	Excellent eater, although she admits to having a "sweet tooth."
h. Patient's sleep habits	6–8 hours nightly
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Multivitamin once daily for 2 years; NuvaRing for 2 months
j. Allergies	NKDA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Given the location and appearance of the lesion, it is highly likely that the patient has recurrent aphthous stomatitis (see Table 32–5). She is at high risk for developing this condition because she just quit smoking and also recently started using NuvaRing, associated with fluctuation in hormone levels.

Relevant Evaluation Criteria	Scenario/Model Outcome
3. Identify exclusions for self-treatment.	None (see Figure 32-2)
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Sithgib to her OHCP or other primary care provider. (2) Recommend an OTC product to relieve her discomfort. (3) Recommend nondrug measures. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Use of an oral debriding/cleansing agent (e.g., Peroxyl) and a topical anesthetic (e.g. Anbesol) would be an appropriate initial option. (See Table 32-4 for a complete list of appropriate options.)
6. Describe the recommended therapeutic approach to the patient or caregiver.	"A topical anesthetic will provide short-term relief of the pain and discomfort. An oral debriding/cleansing agent will help to keep the ulcer clean to aid in healing."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Using both of these agents should help to ease your discomfort as well as heal the ulcer quickly. If you are not experiencing pain or discomfort, the topical anesthetic does not need to be used."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"The debriding/cleansing mouth rinse can be used up to 4 times a day (after meals)." See the box "Patient Education for Recurrent Aphthous Stomatitis."
Solicit follow-up questions from the patient or caregiver.	"Should I maintain my normal oral hygiene routine?"

Relevant Evaluation Criteria	Scenario/Model Outcome
Answer the patient's or caregiver's questions.	"Yes. Continue to brush and floss twice a day, and use a toothpaste that contains fluoride."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Ms. Sithgib to call to update you on her response to your recommendations, or you could call her in a week to evaluate her response.

Key: n/a = Not applicable; NKDA = no known drug allergy; OHCP = oral health care provider; OTC = over-the-counter.

Evaluation of Patient Outcomes for Recurrent Aphthous Stomatitis

Minor RAS lesions typically are self-limiting and resolve within 14 days. Oral debriding and wound-cleansing agents are labeled for use for up to 7 days. If the symptoms have abated, the patient should discontinue treatment but continue other dental hygienic measures (e.g., regular flossing and twice-daily toothbrushing). Symptoms that persist or worsen during treatment necessitate medical evaluation.

Minor Oral Mucosal Injury or Irritation

Pathophysiology of Minor Oral Mucosal Injury or Irritation

Minor wounds or inflammation resulting from minor dental procedures; accidental injury (e.g., biting of the tongue, cheek or abrasion from sharp, crisp foods); or other irritations of the mouth, gums, or palate may be treated with

various nonprescription medications.

Algorithm: Minor Oral Mucosal Injury or Irritation

FIGURE 32–3 Self-care for minor oral mucosal injury or irritation. Key: D/C = Discontinue. (Source: [References 23–26, 29, 30, 33, and 35.](#))

Treatment of Minor Oral Mucosal Injury or Irritation

Treatment of mouth injury (traumatic laceration or ulcer) and irritation is similar to that for RAS. Mouth injury and irritation differ from RAS with regard to etiology and certain treatment considerations.

Treatment Goals

The goals of treating minor mucosal injury and irritation are (1) to control discomfort and pain, (2) to aid healing with the appropriate use of nonpharmacologic and pharmacologic measures, and (3) to prevent secondary bacterial infection.

General Treatment Approach

Treatment should focus first on relieving discomfort, readily accomplished with application of ice. Local anesthetics, certain oral analgesics, and saline rinses also are safe and effective.^{18,19,22} Once the discomfort has resolved, the focus should be on healing the affected area. Homemade sodium bicarbonate rinses and oral debriding and wound-cleansing agents can help achieve this objective. Finally, concomitant use of oral protectants can relieve discomfort and aid healing by protecting the area from further irritation. [Figure 32–3](#) outlines this approach and lists exclusions for self-care.^{23–25,29,33}

Nonpharmacologic Therapy

When tissues of the lips, tongue, cheeks, or palate are bruised, topical application of ice wrapped in a cloth or other barrier may reduce the swelling. Ice should be applied in 10-minute increments but not longer than 20 minutes in a given hour. Longer application times may cause local tissue damage.

Sodium bicarbonate solutions (1/2–1 teaspoon of household baking soda in 4 ounces of water) can act as an oral debriding agent and wound cleanser.^{34,35} The solution is swished in the mouth over the affected area for at least 1 minute and then expectorated. Sodium bicarbonate's mucolytic action is related to its alkalinity. Saline rinses (1–3 teaspoons of salt in 4–8 ounces of warm tap water) can cleanse and soothe the affected area.^{26,34,36} Both sodium bicarbonate and saline rinses can be used up to 4 times a day.

Pharmacologic Therapy

As with RAS, topical analgesics/anesthetics, oral protectants, and oral debriding and wound-cleansing agents constitute the mainstay of pharmacologic therapy. The “Pharmacologic Therapy” section under “Treatment of Recurrent Aphthous Stomatitis” discusses these agents in further detail. In addition to these various agents, astringents may be used. Astringents cause tissues to contract or arrest secretions by causing proteins to coagulate on the cell surface.³⁷ Dentists may suggest use of oxidizing mouth rinses or topically applied steroids (which are available only by prescription) as an adjunctive treatment for specific conditions or as a postoperative aid in cleaning the affected area, relieving discomfort, and assisting the healing process.

Assessment of Minor Oral Mucosal Injury or Irritation: A Case-Based Approach

The cause and nature of the injury or irritation are the primary considerations in patient assessment. If the disorder is self-treatable, the OHCP should ascertain whether the injury or irritation has occurred previously, how it was treated, and whether the patient has known contraindications to the nonprescription medications used to treat the disorder.

Patient Counseling for Minor Oral Mucosal Injury or Irritation

Once the problem is determined to be a minor irritation or injury of the mouth, the patient should be counseled on (1) the steps in the treatment regimen; (2) the purpose of each agent; and (3) the length of time the products can be used safely. Signs and symptoms that indicate infection should be explained. See the box “Patient Education for Minor Oral Mucosal Injury or Irritation.”

Patient Education for Minor Oral Mucosal Injury or Irritation

The objectives of self-treatment of minor oral mucosal injury or irritation are (1) to control discomfort and pain, (2) to aid healing with the appropriate use of drug and nondrug measures, and (3) to prevent secondary bacterial infection. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Rinse with a sodium bicarbonate solution to remove injured tissue and cleanse the affected area. Add 1/2–1 teaspoon of sodium bicarbonate to 4 ounces of water. Swish the solution in the mouth over the affected area for at least 1 minute, and then spit out the solution. This can be done up to 4 times a day.
- Use saline rinses to cleanse and soothe the affected area. Add 1–3 teaspoons of salt to 4–8 ounces of warm tap water. This can be done up to 4 times a day.
- For bruised lips or cheeks, apply ice in 10-minute increments to reduce swelling. Do not apply ice for longer than 20 minutes in a given hour.

Nonprescription Medications

- If longer-lasting relief is desired, use the following types of nonprescription medications: oral debriding and wound-cleansing agents, astringents, topical oral anesthetics, topical oral protectants, and certain systemic analgesics.

Debriding and Cleansing Agents

- Use a product containing carbamide peroxide 10%–15% or hydrogen peroxide 1.5%.
- Do not use these medications for longer than 7 days. Chronic use can cause tissue irritation, decalcification of enamel, and black hairy tongue.
- Do not swallow these medications.
- These products should be used after meals (3–4 times a day), and the patient should avoid eating or drinking for at least 30 minutes after application. Swish the liquid around the mouth for 10–15 minutes (or as long as the patient can tolerate, but no longer than 15 minutes).

Topical Oral Anesthetics

- Use a product containing one of the following medications: benzocaine 5%–20%, benzyl alcohol 0.05%–0.1%, dyclonine 0.05%–0.1%, or hexylresorcinol 0.05%–0.1%.
- Do not use benzocaine if you have a history of hypersensitivity to other benzocaine-containing products.
- Avoid potentially inflammatory products containing substantial amounts of menthol, phenol, or camphor. These agents may cause tissue irritation and damage or systemic toxicity.
- These products should be used after meals (3–4 times a day), and the patient should avoid eating or drinking for at least 30 minutes after application.

Topical Oral Protectants

- Use topical oral protectants or denture adhesives to coat and protect the lesions.
- These products should be used after meals (3–4 times a day), and

the patient should avoid eating or drinking for at least 30 minutes after application.

Systemic Analgesics

- If desired, take an oral analgesic (e.g., aspirin or other NSAID, acetaminophen) for additional relief of mouth discomfort.
- Do not hold aspirin in the mouth or place it on oral lesions. The acetylsalicylic acid can cause a chemical burn and tissue damage.

When to Seek Medical Attention

- See a primary care provider if any of the following occur:
 - Symptoms persist after 7 days of treatment.
 - Symptoms worsen during self-treatment.
 - Manifestations of systemic infection such as fever, redness, or swelling develop.

Key: NSAID = Nonsteroidal anti-inflammatory drug.

Source: [References 23–25, 29, 30, 33, and 35](#).

Evaluation of Patient Outcomes for Minor Oral Mucosal Injury or Irritation

Minor injury or irritation should resolve within 7 days of treatment and within 10 days of the initial insult or injury.³⁷ If the symptoms resolve, no further treatment is necessary. If symptoms persist or worsen, or swelling, rash, or fever develops, the patient should be evaluated by a primary care provider.

Herpes Simplex Labialis

Herpes simplex labialis (HSL), manifesting as cold sores or fever blisters, is a disorder caused by a virus of the family Herpesviridae. Herpes simplex virus

type 1 (HSV-1) is primarily associated with oral and labial lesions, whereas herpes simplex virus 2 (HSV-2) usually produces genital sores. However, predilection of a specific HSV infection for an anatomic site is changing, in part because of variability in sexual practices.^{38,39} Any of the human herpesviruses (e.g., cytomegalovirus, Epstein–Barr virus), not just HSV-1 and HSV-2, can cause oral lesions. Anyone who comes in contact with the herpesvirus can potentially become infected. After the primary infection, HSV infection can be latent and reactivate at a later date as the more commonly known herpes labialis, or cold sores.^{38,39}

Pathophysiology of Herpes Simplex Labialis

HSV infection is contagious and believed to be transmitted by direct contact. Fluid from herpes vesicles contains live virus, which can be transmitted from patient to patient. Because the virus remains viable on surfaces for several hours, contaminated objects also may be a source of infection. Transmission commonly occurs through kissing or sharing utensils or drinking vessels.^{34,38} HSV enters the host through a break in the skin or intact mucous membranes. Once the virus has infected a host, it remains in a latent state in the trigeminal ganglia. The virus can be reactivated on exposure to a triggering stimulus, such as ultraviolet radiation, stress, fatigue, cold, or windburn. Other possible triggers include fever, injury, menstruation, dental work, infectious diseases, and factors that suppress the immune system (e.g., chemotherapy, radiation therapy).^{38,39} Although the virus can go through periods of dormancy and reactivation, the person is infected for life. On reactivation, the lesions often arise repeatedly in the same location.

Clinical Presentation of Herpes Simplex Labialis

HSL is so named because it commonly affects the lip or areas bordering the lips; the usual site is at the junction of mucous membrane and skin of the lips or nose. HSL lesions also may occur intraorally (primarily involving keratinized mucosa such as the hard palate). The lesions are recurrent, painful, and cosmetically objectionable. Onset of HSL often is preceded by a prodrome in which the patient notices burning, *pruritus* (itching), tingling, or numbness in

the area of the forthcoming lesion. Patients experience the prodromal stage approximately 2–48 hours before the lesion actually appears.²⁰ Other signs and symptoms may include pain, fever, localized bleeding, swollen lymph nodes, and malaise.

The initial lesion in an episode of HSL is a collection of small red papules of fluid-containing vesicles 1–3 mm in diameter. Often, many lesions coalesce to form a larger area of involvement. An erythematous, inflamed border around the fluid-filled vesicles may be present. In mature lesions, a crust often forms over the top of many coalesced, burst vesicles; its base is erythematous (see [Color Plates](#), photograph 15). Presence of pustules or pus under the crust of a herpesvirus lesion may indicate a secondary bacterial infection; prompt evaluation and treatment with a targeted antibiotic, if indicated, are appropriate. [Table 32–5](#) further describes the clinical presentation of HSL and compares its features with those of RAS.

A related disease, acute (primary) herpetic gingivostomatitis, is seen mainly in children but can occur in adults, especially those who are immunocompromised. Although the oral lesions of this disease can develop anywhere on the oral mucosal surface, they commonly occur on the lips, areas bordering the lips, or the gums. Herpetic gingivostomatitis is distinguished from RAS gingivostomatitis by infected gums, which are very red and covered by a pseudomembrane or studded with ulcerations. Other symptoms of herpetic gingivostomatitis may include submandibular lymphadenitis, swallowing difficulties, and halitosis. Referral to an appropriate health care provider is warranted if this disorder is suspected.

On the basis of clinical appearance, HSL and RAS should be easy to distinguish from oral candidiasis, which develops as part of yeast infections. In the mouth, candidiasis is often referred to as thrush and is characterized by white plaques with a milk curd appearance. These plaques, seen on the oral mucosa, usually can be detached easily, revealing erythematous, bleeding, sore areas beneath (see [Color Plates](#), photograph 12). Patients with signs of oral candidiasis should be referred for medical evaluation and should not self-treat.

Treatment of Herpes Simplex Labialis

Although HSL and RAS differ in etiology, overall treatment for these disorders

is similar. The patient should be instructed to avoid circumstances that induce more lesions (e.g., stress), to keep the lesions free of counterirritants, and to keep existing lesions as clean as possible, thereby avoiding secondary infections. [Table 32–4](#) lists common classes of nonprescription medications used to treat RAS and HSL. (Note: Of the products listed in [Table 32–4](#), oral debriding and wound-cleansing agents and oral mucosal protectants are *not* used to treat HSL.)

Treatment Goals

The objectives of self-treatment for HSL (cold sores) are (1) to relieve pain and irritation while the sores are healing, (2) to prevent secondary infection, and (3) to curtail spread of the lesions.

General Treatment Approach

The lesions should be inspected to determine whether their appearance and location are characteristic of HSL. If possible, agents or practices that may have led to development of lesions should be identified, so that precipitating or contributing factors can be removed. For example, if trauma is suspected, perhaps a softer toothbrush and gentler brushing technique could be suggested. It also is helpful to ascertain whether the patient has a history of HSL. The medical history should be reviewed to determine whether an underlying pathologic process predisposes the patient to recurrent HSL or could complicate treatment. The interviewing health care provider should inquire about previous self-treatments and their effectiveness. If the treatments used are appropriate and have been successful for the patient, they should be implemented and continued. Treatment should focus on cleansing the affected area, protecting the lesions from infection, and relieving the discomfort of burning, itching, and pain. [Figure 32–4](#) outlines self-treatment for HSL and lists exclusions for self-care.^{28–35,38,39}

Nonpharmacologic Therapy

Lesions should be kept clean by gently washing with mild soap solutions. Handwashing is important in preventing lesion contamination and minimizing autoinoculation of herpesvirus. The involved skin should be kept moist to prevent drying and *fissuring* (cracking). Cracking may render lesions more

susceptible to secondary bacterial infection, may delay healing, and usually increases discomfort. Factors that delay healing (e.g., stress, local trauma, excessive wind or sun exposure, fatigue) should be avoided. Patients who identify sun exposure as a precipitating event should be advised to routinely use an appropriate sunscreen product on the lips and face. (See [Chapter 39](#) for more detail about sunscreens and sun protection factor [SPF] requirements.)

Pharmacologic Therapy

Topical skin protectants help to protect the lesions from infection, relieve dryness, and keep the involved tissue soft, but they do not reduce the duration of symptoms. These products should be used after meals (3–4 times a day), and the patient should avoid eating or drinking for at least 30 minutes after application.²²

Externally applied analgesics or anesthetics, in bland, emollient vehicles, also relieve the discomfort of burning, itching, and pain, but they do not reduce the duration of symptoms. Ingredients that are generally used include benzocaine 5%–20%, dibucaine 0.25%–1%, dyclonine hydrochloride 0.5%–1%, benzyl alcohol 10%–33%, camphor, and menthol. Menthol in concentrations greater than 1% and camphor in concentrations greater than 3% can stimulate cutaneous sensory receptors and produce a counterirritant effect; such preparations are therefore contraindicated.³²

Docosanol 10% (Abreva Cream) is the only FDA-approved nonprescription product proven to reduce the duration and severity of symptoms. The agent inhibits direct fusion between the herpesvirus and the human cell plasma membrane, thereby preventing viral replication.^{31,37} Docosanol should be applied at the first sign of an outbreak (prodromal stage), 5 times a day, until the lesion is healed, but for no more than 10 days. Treatment with docosanol reduces the median healing time to healing by approximately 1 day (18 hours) compared with placebo.⁴⁰ Docosanol-treated patients also note a significant reduction in the duration of symptoms, including pain and/or burning, itching, or tingling, compared with placebo (20% reduction in the median time to complete cessation of these symptoms).³⁸ The safety of docosanol with use during pregnancy is unknown. [Table 32–4](#) provides additional information regarding use of docosanol. (See the Preface for detailed explanation of the pregnancy data.) Clinically important drug interactions with docosanol are discussed in [Table 32–3](#).

Abreva Cream, which contains docosanol 10%, should not be mistaken for Abreva Conceal, which is a nonmedicated patch.³¹

If evidence of secondary bacterial infection is seen (e.g., failure of crusting to occur, persistence of an erythematous border), topical application of a thin layer of triple-antibiotic ointment 3–4 times daily may be recommended as a nonprescription option.^{41,42} (See [Chapter 41](#) for more information about these agents.) Follow-up evaluation by a physician may be indicated if this occurs. Mupirocin ointment or calcium hydroxide/chlorhexidine paste may also be effective, but these are prescription products. Certain systemic nonprescription analgesics may provide additional pain relief.

HSL is not considered a steroid-responsive dermatosis, so the use of topical steroids is contraindicated. Products that are highly astringent also should be avoided. Zinc sulfate should be avoided as well, because oral mucosal absorption and toxicity could occur with frequent application of these agents to the lip and other tissue adjoining the oral cavity.³⁰

Complementary Therapies

The essential oil of *Melaleuca alternifolia*, or tea tree oil, has been shown to have activity against HSV in vitro.⁴³ Although some data are conflicting, lysine may have a preventive effect and may decrease the frequency of outbreaks when taken daily.^{39,44} Extract of the leaves of *Melissa officinalis*, or lemon balm, also has been used in patients with HSL. Studies comparing lemon balm with placebo have shown a reduction in symptoms, shortened healing time, prevention of infection spread, and patient preference for lemon balm.⁴⁵

Algorithm: Herpes Simplex Labialis

FIGURE 32–4 Self-care for herpes simplex labialis (HSL). Key: D/C = Discontinue; OTC = over-the-counter; RAS = recurrent aphthous stomatitis. (Source: [References 26, 29–34, and 36–41.](#))

Assessment of Herpes Simplex Labialis: A

Case-Based Approach

Although many of the same nonprescription medications are indicated for RAS and HSL, the disorders still need to be differentiated. Because herpes simplex lesions are contagious, additional measures are necessary to prevent transmission of the virus. The medical history will help determine the presence of an underlying pathologic process that predisposes the patient to recurrent HSL or could complicate treatment. Case 32–2 provides an example of the assessment of a patient with herpes simplex labialis.

Patient Counseling for Herpes Simplex Labialis

Patient counseling should emphasize that HSL lesions are contagious and should include appropriate measures to prevent transmission of the virus, as outlined in the box “Patient Education for Herpes Simplex Labialis.” Patients should be advised that the disorder is self-limiting, and that pharmacologic therapy with appropriate agents can keep the affected tissue moist and supple, decrease the itching and pain, protect involved skin from secondary bacterial infection, and help reduce the duration of active infection. The action of each recommended product, its proper use, and possible adverse effects also should be explained.

Evaluation of Patient Outcomes for Herpes Simplex Labialis

In immunocompetent patients, HSL typically is mild and self-limiting, with healing of lesions within 10–14 days.^{22,23,36,46} If the symptoms have resolved, no further treatment is necessary. However, if the condition worsens (e.g., if pain and itching persist, redness increases, or signs of secondary infection are apparent), referral to the patient’s primary care provider is warranted.

Case 32–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of a burning, itching, tingling feeling on the top of his lip, which he has had for almost 3 weeks. He reports that he has had about 6 cold sores over the past 4 months.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient reports that he is under a lot of stress, as he has been studying for his LSATs for the past 4 months.
c. Description of the patient's efforts to relieve the symptoms	He has tried an ice pack to relieve the burning and itching, which works until the ice melts. He has also used Carmex and Blistex, which did help with the pain and discomfort.
d. Patient's identity	William Thanyou
e. Patient's age, gender, height, and weight	22 years, male, 6 ft 1 in., 180 lb
f. Patient's occupation	Law student
g. Patient's dietary habits	Eats a lot of fast food, pasta, and pizza.
h. Patient's sleep habits	Roughly 6 hours nightly
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Seasonal allergies, for which he takes loratidine. Exercise-induced asthma, for which he uses albuterol before exertion.
j. Allergies	NKDA
k. History of other adverse reactions to medications	None

Relevant Evaluation Criteria	Scenario/Model Outcome
I. Other (describe) _____	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	This patient's signs and symptoms are consistent with recurrent HSL or "cold sore." He seems to be in the prodrome stage, in which a lesion has yet to appear (Table 32-4).
3. Identify exclusions for self-treatment (Figure 32-5).	Increased frequency of breakouts and lesions present for >14 days (Figure 32-4)
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to an appropriate OHCP. (2) Recommend self-care with a nonprescription product for xerostomia. (3) Recommend self-care until the patient can see an appropriate OHCP. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Thanyo is not a self-care candidate because he meets two of the exclusion criteria.
6. Describe the recommended therapeutic approach to the patient or caregiver.	Mr. Thanyo should consult an appropriate OHCP for treatment.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best because you have these symptoms for 3 weeks and you have had frequent episodes over the past 4 months."
Implement	

Relevant Evaluation Criteria	Scenario/Model Outcome
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Is there something I can use to help with the pain and discomfort until I can see my physician tomorrow?"
Answer the patient's or caregiver's questions.	"Any product containing benzocaine 20% should provide acute relief." (Refer to Table 32-4.)
Follow up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Thanyo in 1 or 2 days to ensure that he has called or made an appointment with an OHCP.

Key: HCTZ = Hydrochlorothiazide; n/a = not applicable; NKDA = no known drug allergy; OHCP = oral health care provider.

Algorithm: Xerostomia

FIGURE 32-5 Self-care for xerostomia. (Source: [References 46-51.](#))

Patient Education for Herpes Simplex Labialis

The objectives of self-treatment of herpes simplex labialis (cold sores) are (1) to relieve pain and irritation while the sores are healing, (2) to prevent secondary infection, and (3) to prevent spread of the lesions. For most

patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Keep labial or extraoral lesions clean by gently washing them with mild soap solutions.
- Wash hands frequently to prevent contaminating the lesions and to avoid spreading the virus.
- Avoid factors believed to delay healing such as stress, local injury, wind exposure, excessive sun exposure, and fatigue.
- If outbreaks are related to sun exposure, always use a lip and face sunscreen with appropriate SPF protection. (See [Chapter 39](#) for further discussion related to SPF.)

Nonprescription Medications

- Use topical anesthetics such as benzocaine or dibucaine to relieve burning, itching, and pain. Do not use benzocaine if you have a history of hypersensitivity to other benzocaine-containing products.
- If using products containing camphor and menthol, make sure that the concentration of camphor does not exceed 3% and that the concentration of menthol does not exceed 1%.
- Do not apply hydrocortisone to the lesions.
- If evidence of secondary bacterial infection is seen, apply a thin layer of triple-antibiotic ointment 3–4 times daily.
- Apply the topical agent docosanol 10% (Abreva Cream) to limit the burning, tingling, and itching sensations. Docosanol 10% also can speed up the healing process, thereby reducing the duration of the symptoms.
- If desired, take an oral nonprescription analgesic (e.g., aspirin or other NSAID, acetaminophen) for additional pain relief.
- Do not hold an aspirin tablet in the mouth or place it on oral lesions. The acetylsalicylic acid can cause a chemical burn and tissue damage.
- These products should be used after meals (3–4 times a day), and the patient should avoid eating or drinking for at least 30 minutes

after application.

When to Seek Medical Attention

- See a primary care provider for any of the following outcomes:
 - The lesions do not heal in 14 days.
 - The lesions recur despite appropriate self-care.
 - The self-treatment measures do not relieve discomfort.
 - Signs or symptoms of systemic illness such as fever, malaise, rash, or swollen lymph glands emerge.
 - Symptoms change or worsen.

Key: NSAID = Nonsteroidal anti-inflammatory drug; SPF = sun protection factor.

Source: [References 26, 29–34](#), and [36–41](#).

Xerostomia

Xerostomia, commonly referred to as *dry mouth*, is a syndrome in which salivary flow is limited or completely arrested. A person with normal salivary flow produces up to 1.5 L of saliva every 24 hours. Between 5.5% and 46% of the population is said to be afflicted with persistent dry mouth.⁴⁶

Pathophysiology of Xerostomia

Patients with certain disease states, including *Sjögren syndrome* (an autoimmune condition in which the salivary glands become partly or completely dysfunctional and the presenting manifestations typically include dry mouth and/or dry eyes), diabetes mellitus, depression, and Crohn's disease, are prone to xerostomia.^{46,47} In addition, radiation therapy of the head and neck can cause atrophy of the salivary glands; in the vast majority of treated patients, irreversible compromise of salivary gland function results. Medications that have anticholinergic activity or cause depletion of salivary

flow volume (e.g., antihistamines, decongestants, antihypertensives, diuretics, antidepressants, antipsychotics, sedatives) also can cause xerostomia.^{46,48}

Older patients, who are more likely to be taking multiple medications for chronic diseases, typically are more commonly affected. However, if the xerostomia is drug-induced and the causative medication can be discontinued, normal salivary flow may resume in some cases.⁴⁹⁻⁵¹

Nonpharmacologic causes of xerostomia include the use or consumption of alcohol, tobacco, caffeine, or hot spicy food; blockage of ducts by salivary gland stones (*sialolithiasis*); and mouth breathing.

Clinical Presentation of Xerostomia

Xerostomia can result in difficulty talking and swallowing, stomatitis, burning tongue, and halitosis. Unmoistened food cannot be tasted; therefore, xerostomia can cause loss of appetite with eventual decline in nutritional status.⁴⁶⁻⁴⁸ As a consequence of the decrease in salivary flow and the lack of buffering capacity that saliva provides, the teeth can become hypersensitive.⁴⁶⁻⁴⁸ Xerostomia also can result in an increased incidence of *cervical caries* (decay around the root surfaces of teeth) despite excellent oral hygiene. The inadequacy of salivary flow, which normally washes away food and debris from the teeth, is responsible for this increase in tooth decay.^{46,48} Depending on the status of the patient's dentition, xerostomia can increase the incidence of caries, gingivitis, and more severe periodontal disease or can reduce denture-wearing time. Furthermore, reduced flow of saliva can disturb the balance of microflora species in the oral cavity and predispose affected patients to the development of candidiasis.

Treatment of Xerostomia

Dry mouth should never be discounted as inconsequential. Failure to treat this condition can result in serious complications for some patients.

Treatment Goals

The objectives of self-treatment of xerostomia are (1) to relieve the discomfort of dry mouth, (2) to reduce the risk of dental decay, and (3) to prevent and treat

infections and periodontal disease.

General Treatment Approach

The patient should stop using substances that dry the mouth or erode tooth enamel. If possible, medications that are known to cause xerostomia should be discontinued. To reduce the risk of caries, the patient must maintain good oral hygiene. In mild cases, using sugarless sweets and chewing gums or sucking on ice chips may help to stimulate residual salivary flow.⁴⁸

Commercial artificial saliva products can be used as needed to relieve soft tissue discomfort. [Figure 32–5](#) outlines the self-treatment of xerostomia and lists exclusions for self-care.^{46–49}

Nonpharmacologic Therapy

The patient should avoid exposure to substances that reduce salivation, including tobacco (smoked and smokeless), caffeine, hot spicy foods, and alcohol (including mouth rinses). Medication schedules should be modified in consultation with the treating OHCP to coincide with periods of natural stimulation. For example, patients could take medications that cause dry mouth 1 hour before meals, because eating naturally stimulates an increase in salivary flow. Consequently, the duration of dry mouth would be reduced.

To prevent tooth decay, the xerostomic patient should limit intake of sugary (e.g., candy), starchy (e.g., cookies, potato chips), and acidic foods (e.g., orange juice) that may have been tolerated before but now pose significant danger to oral health.^{49–51} Sugar promotes the bacterial production of acid, which causes tooth decay. Acidic foods also may decrease the pH of saliva, resulting in caries and tooth erosion. Chewing gum sweetened with sugar alcohols (e.g., xylitol), however, may be beneficial. Chewing gum increases salivary flow, and xylitol has not been shown to be cariogenic.^{46–48,50,51} Increasing water intake, especially if it is fluoridated, also will be of benefit. Using a cool mist humidifier at home can help to add moisture in the air, which may provide some level of relief.⁴⁹ Finally, the use of very-soft-bristle toothbrushes will help prevent decay by minimizing tissue abrasion.

Pharmacologic Therapy

Artificial saliva products are the primary agents for relieving the discomfort of dry mouth. They are designed to mimic natural saliva both chemically and physically, and typically these products consist of carboxymethyl or hydroxyethylcellulose solutions with or without fluoride. However, they do not contain the many naturally occurring protective components that are present in innate saliva (digestive and bactericidal enzymes and other naturally occurring proteins). Because these products do not stimulate salivary glands to increase natural saliva production, they must be considered to provide replacement therapy, not a cure for xerostomia. However, such products can be used on an as-needed basis in patients with little or no salivary flow. [Table 32–6](#) lists selected nonprescription saliva substitutes and other xerostomia products. Clinically important drug interactions for xerostomia products are listed in [Table 32–3](#).

TABLE 32–6 Selected Nonprescription Saliva Substitutes and Other Xerostomia Products

Trade Name	Primary Ingredient(s)
ACT Dry Mouth Lozenges	Isomalt, xylitol, glycerin, natural and artificial flavors, sucralose, beta-carotene
Biotene Dry Mouth Oralbalance Gel Biotene Dry Mouth Moisturizing Spray	Glycerin, water, sorbitol, xylitol, carbomer, hydroxyethyl cellulose, sodium hydroxide purified water, glycerin, xylitol, PEG-60 hydrogenated castor oil, VP/VA copolymer, flavor, sodium benzoate, xantan gum, methylparaben, propylparaben, sodium saccharin, cetylpyridinium chloride
Entertainer's Secret Spray	Sodium carboxymethylcellulose; dibasic sodium phosphate; potassium chloride; parabens; aloe vera gel; glycerin
Biotene Dry Mouth Gum	Titanium dioxide, lecithin, xylitol, carnauba wax, sorbitol, resinous glaze, natural and artificial flavor, maltitol syrup, potassium acesulfame, glucose oxidase, lactoperoxidase, potassium thiocyanate, gum base

Key: w/v = Weight per volume.

Source: [Reference 25](#).

Product Selection Guidelines

A majority of artificial saliva products are available as sprays and gels; however, gums and toothpastes also are available. Proper use of a gel involves placing approximately a 1/2-inch length of extruded product onto the tongue and spreading it thoroughly in the mouth. These products can be used at any time; a minimum suggested regimen is after all meals and before going to bed. Products that contain preservatives, such as methyl- or propylparaben, may cause hypersensitivity reactions in certain patients. Patients on low-sodium diets should avoid artificial salivas that contain sodium.

Special Populations

No special considerations are required with use of these products in children (although some products such as Biotene suggest use be targeted to patients 12 years of age or older), pregnant or lactating women, or older adults.²⁷

Assessment of Xerostomia: A Case-Based Approach

The patient should be asked about any history of xerostomia, oral hygiene practices, and regularity of dental care visits. The patient's symptoms should be evaluated to determine whether the condition has progressed to the point that complications are likely. A review of the patient's medical and medication history can identify factors associated with reduced salivation. Furthermore, the interviewing health care provider should determine whether lifestyle or other practices could be contributing to the condition. Asking the patient about concurrent dry eyes or joint symptoms will assess the risk for Sjögren syndrome. Similarly, the assessment should establish whether any salivary gland pain or swelling occurs with eating or after meals, to determine the risk for salivary gland stones.

Patient Counseling for Xerostomia

In general, patients with xerostomia require professional dental management for the condition, in addition to the self-care methods discussed previously and outlined in the box “Patient Education for Xerostomia.” Patients should be encouraged to practice good oral hygiene measures and to see their dentist regularly. In addition, patient counseling should include appropriate information about nonpharmacologic and pharmacologic measures for keeping the oral cavity moist and treating dry mouth, to minimize the increased risk for tooth decay associated with xerostomia. Finally, patient education should highlight signs and symptoms that indicate complications from dry mouth.

Patient Education for Xerostomia

The objectives of self-treatment of xerostomia (dry mouth) are (1) to relieve the discomfort of dry mouth, (2) to reduce the risk of dental decay, and (3) to prevent and treat infections and periodontal disease. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- To help prevent reduction in salivary flow, avoid use of cigarettes and smokeless tobacco.
- Do not drink or use products that contain alcohol (including mouth rinses) or medications that cause depletion of salivary flow.
- Avoid food or drinks that contain caffeine.
- Avoid hot spicy foods.
- To prevent tooth decay, limit consumption of sugary (e.g., candy), starchy (e.g., cookies, potato chips), and acidic foods (e.g., orange juice). Do not suck on hard candy or lozenges sweetened with sugar.
- If desired, chew gum sweetened with sugar alcohols, such as xylitol, to help increase flow of saliva.

- If possible, take medications 1 hour before meals so that the natural saliva flow caused by food can counteract any mouth dryness.
- To help prevent tooth decay, use a very soft toothbrush to reduce abrasion of the teeth.
- Drink plenty of water especially if it is fluoridated.
- Use a cool mist humidifier at home to help moisten the air.

Nonprescription Medications

- Use artificial saliva products that contain fluoride to relieve the discomfort of dry mouth and to prevent tooth decay.
- If you are on a low-sodium diet, avoid artificial salivas that contain sodium.
- Brush and floss your teeth at least twice daily using a regular toothpaste with fluoride, and see your dentist regularly.

When to Seek Medical Attention

- If your symptoms do not decrease in severity or if they worsen, see a dentist.

Source: [References 46–51](#).

Evaluation of Patient Outcomes for Xerostomia

The patient with xerostomia should return for evaluation after 5–7 days of self-treatment. If the mouth dryness is lessened, the patient should continue using artificial saliva and fluoride products as recommended by an OHCP. The patient also should be advised to continue with nonpharmacologic measures. If the dryness becomes worse or additional symptoms or complications develop, the patient should return to an OHCP for further evaluation.

Key Points for Orofacial Pain and Discomfort

- Tooth hypersensitivity and teething discomfort are not serious and are considered self-treatable problems.
- Self-treatment for toothache should be limited to the temporary relief of pain, because professional dental care is required for complete resolution of the underlying condition.
- RAS is amenable to self-treatment for the relief of pain and irritation so that the lesions can heal, thereby allowing the patient to eat, drink, and perform routine oral hygiene while preventing further complications.
- Minor oral mucosal injury or irritation may be self-treated by controlling discomfort and pain, by using appropriate drug and nondrug measures to aid healing, and by preventing secondary bacterial infection.
- The goals of self-treatment for HSL (cold sores) are to relieve pain and irritation while the sores are healing, to prevent secondary infection, and to prevent spread of the lesions to other areas of the body and to other people.
- Self-treatment of xerostomia (dry mouth) can relieve discomfort from dry mouth, thereby reducing the risk of dental decay as well as preventing and, at times, treating infections.
- If the pain or discomfort worsens or persists after appropriate self-treatment and nondrug measures, medical referral for further treatment is imperative.

Chapter 33: Atopic Dermatitis and Dry Skin

Authors: Kim W. Benner

An estimated one in four persons will seek treatment for a skin disorder in a given year.¹ In the United States, 15%–20% of children and 1%–3% of adults are estimated to have the atopic variant of dermatitis.² Most patients with this chronic skin disorder are believed either to be undertreated or to be self-treating with primarily nonprescription medications.³ Such considerations highlight the need for health care providers to be able to recognize and differentiate among common skin disorders, suggest appropriate treatment, and know when referral to the patient's primary care provider or a dermatologist is warranted.

Dermatitis is a nonspecific term for numerous dermatologic disorders that generally are characterized by erythema and inflammation. The designation *eczema* encompasses a group of inflammatory skin disorders that often are of unknown etiology. *Atopic dermatitis* (AD) is a form of eczema in which the skin is chronically scaly, erythematous, edematous, papular, and crusty.⁴ This chapter focuses on AD and dry skin (xerosis), a common accompanying complaint in many dermatoses. Dry skin, which increases in incidence with age, may contribute to decreased quality of life even when of mild to moderate degree, as a consequence of the associated pruritus and, rarely, infection, pain, and inflammation.⁵

Role of Skin in Drug Absorption

An important function of skin and its appendages (hair and nails) is to protect the body from external harmful agents such as pathogenic organisms, ultraviolet solar radiation, and numerous chemicals.⁵ The skin's ability to maintain this protection depends on patient factors of age, immunologic status, and underlying disease states, as well as an intact stratum corneum. Skin also is important in hydroregulation in that it controls moisture loss from the body—specifically, transepidermal water loss (TEWL). If the stratum corneum becomes dehydrated, it loses elasticity and exhibits increased permeability. Despite near-constant exposure to a variety of chemical and environmental insults, the skin demonstrates remarkable resiliency and

recuperative ability.⁶

Human skin has three functionally distinct regions: epidermis, dermis, and hypodermis (Figure 33–1). The epidermis, the outermost, thin layer of the skin, with the *stratum corneum* at its surface, regulates the water content of the skin and controls drug transport into the lower layers and the systemic circulation. The middle layer, the dermis, is 40 times thicker than the epidermis and contains nerve endings, vasculature, and hair follicles. The hypodermis primarily provides nourishment and cushioning for the upper two layers. Skin thickness is variable but averages about 1–2 mm. The thickest skin is on the palms and soles, and the thinnest skin is on the genitalia. These areas with thinner skin areas are more permeable, allowing substances to be absorbed more easily than in areas with thicker skin. As people age, their skin becomes more fragile, requiring a longer recovery time after injury.⁵

FIGURE 33–1 Cross section of human skin.

A drug applied topically must be released from its vehicle if it is to exert an effect at the desired site of activity (skin surface, epidermis, or dermis). Release occurs at the area of contact between the skin surface and the applied layer of

product. The physical–chemical relationship between the drug and the vehicle determines the rate and amount of drug released. A drug’s solubility in the vehicle, its diffusion coefficient in the vehicle, and its partition coefficient into the sebum and stratum corneum are significant considerations for its efficacy.⁷ The major mechanism of drug absorption is passive diffusion through the stratum corneum, followed by transport through the deeper epidermal regions and then the dermis. The stratum corneum often is the rate-limiting barrier to percutaneous absorption, so its hydration status can affect drug diffusion. Occlusion (blocking or covering an area) increases hydration of the stratum corneum, which enhances the transfer of most drugs. Wounds, burns, and other lesions can alter the integrity of the stratum corneum, with consequent increase in absorption of substances to which it is exposed. Inflammation also can enhance percutaneous absorption of topically applied medications, which may result in higher systemic drug levels.⁷ Therefore, caution is warranted with use of topical medications on compromised skin, particularly if large surface areas are involved.

Atopic Dermatitis

AD is a common, pervasive inflammatory condition of the epidermis and dermis that is characterized by episodic flares and periods of remission. Fifty percent of patients are diagnosed within the first year of life, and as many as 85% present with symptoms before the age of 5 years.² Prevalence of AD worldwide is increasing, possibly because of environmental influences such as climate, urbanization, diet, and pollution/tobacco smoke, but microbial exposure also may be a contributing factor.²

Asthma and allergic rhinitis can occur in up to 80% of patients with AD, emerging either in childhood or with aging.⁸ These three disorders are linked together as the “atopic triad”; a related concept, the “atopic march,” refers to the process whereby infants with AD, via sensitization, are predisposed to the development of asthma and/or allergic rhinitis later in life.⁹ In 80% of cases, AD is classified as mild and can be safely treated with nonprescription products in patients older than 2 years of age.¹⁰ Of note, however, the disorder can place significant social, psychological, and economic burdens on both patients and their families.¹¹ In addition, many persons with AD do not seek medical care for the condition; ultimately, distress over the skin lesions or a flare of symptoms may bring the affected patient or a concerned family member to the local

pharmacy for advice regarding self-care.

Pathophysiology of Atopic Dermatitis

AD is primarily related to two major alterations in the epidermal barrier and the immune system, respectively.¹² Atopic skin is inflamed owing to overexpression of cytokines (the interleukins IL-4 and IL-13) and chemokines produced by T-helper 2 cells.^{12,13} An abundant protein in the epidermal differentiation complex, filaggrin, is related to the development of AD. Thirty-five mutations are known to exist in the filaggrin gene (*FLG*), and presence of even one such mutation increases the risk of AD. The *FLG* mutations can lead to the deficient skin barrier characteristic of AD, including an increased penetration of allergens, a decrease in skin barrier proteins, higher peptidase activity, and lack of protease inhibition. In addition, because of a decreased concentration of lipids, such as ceramides, cholesterol, and fatty acids, atopic skin has an increased TEWL (or a decreased ability to retain moisture).^{5,12,14} The genetic basis for AD is evidenced by definitive diagnosis of the disorder in a patient with a positive family history or in monozygous twins.^{2,15}

AD is diagnosed according to clinical criteria (**Table 33–1**).¹⁶ No established confirmatory laboratory tests are recognized, although elevated immunoglobulin E (IgE) usually is correlated with atopic disease. Patients can have normal total IgE; any elevations in IgE typically do not appear early on and may never occur in some children.^{17,18} Three currently validated disease severity assessments for AD are the SCORAD (SCORing Atopic Dermatitis), EASI (Eczema Area and Severity Index), and POEM (Patient-Oriented Eczema Measure).^{19,20}

TABLE 33–1 Diagnostic Criteria for Atopic Dermatitis

Essential Features

- Pruritus
- Eczema (chronic or relapsing history)

Important Features

- Early age at onset
- Atopy (immunoglobulin E reactivity)
- Xerosis

Note: There are other associated features and exclusionary conditions to consider in diagnosing atopic dermatitis.

Source: [Reference 16](#).

Clinical Presentation of Atopic Dermatitis

AD often manifests within the first year of life, typically by 2–3 months of age. Infantile or childhood AD initially appears as erythema and scaling of the cheeks, which may progress to involve the face, neck, forehead, and extremities (see [Color Plates](#), photographs 16A, B, and C). Crusts and pustules can form from the trauma of scratching and rubbing. Remission can occur by the end of the second year; however, AD and xerosis can continue into adulthood in up to 30% of patients.²¹ AD manifests quite differently in adults than in children and may be less severe in adults.^{14,21} Areas primarily affected in adults include the antecubital and popliteal fossae, neck, forehead, eyes, and hands.²¹ The trigger in adults often is environmental, attributed to chemicals, or skin trauma.²¹

Pruritus, the hallmark symptom of AD, is sometimes referred to as the “itch that rashes.” Patients with AD are more susceptible to pruritus-inducing stimuli. Scratching and repeated rubbing can lead to lichenification (thickened plaques of skin), and excoriations may be seen.²² In all patients, plaques appear erythematous, scaly, exudative, and/or crusty.^{4,23} Of note, atypical presentations are not uncommon, and any undiagnosed skin lesions that persist unchanged over time or that get worse with self-treatment should be evaluated by an appropriate health care provider.

AD has three clinical forms: acute, subacute, and chronic. *Acute AD*, which is characterized by intensely pruritic, erythematous *papules* (small, firm, elevated lesions) or *vesicles* (fluid or air-filled sacs) over erythematous skin, often is associated with excoriation and *serous exudates* (secretions). *Subacute AD* is characterized by erythematous, excoriated papules and *plaques* (large, slightly elevated lesions with a flat surface) that can be scaly. *Chronic AD* is characterized by lichenification and accentuated skin markings.²³

Secondary or associated cutaneous infections, especially bacterial, can be difficult to prevent and typically aggravate the underlying AD. Among patients

with AD-related skin lesions, >90% exhibit lesion colonization with *Staphylococcus aureus* (in contrast with a skin colonization rate of 5% in unaffected persons); streptococci also may be found alone or in association with *S. aureus*.^{9,17,23} Infections manifest as yellowish crusting of the eczematous lesions.⁹

Patients with AD also are susceptible to viral skin infections such as herpes simplex or molluscum contagiosum.^{9,23} True infection of the skin is more common in children with AD, whereas colonization is seen at higher rates in adult patients.²¹ Patients should be counseled to seek medical attention promptly when signs of bacterial or viral skin infection, such as *pustules* (circumscribed, elevated lesions, 1 cm in diameter, containing pus), vesicles (especially those filled with exudate or pus), or crusting, are noticed.²⁴

Treatment of Atopic Dermatitis

Treatment Goals

The goals of self-treatment for AD are (1) to stop the itch–scratch cycle, (2) to maintain skin hydration and barrier function, (3) to avoid or minimize factors that trigger symptoms or aggravate the disorder, and (4) to prevent secondary infections.

General Treatment Approach

At the initial assessment, health care providers should emphasize that AD cannot be cured but that most symptoms can be managed. As in treating any skin condition, nonpharmacologic measures should be attempted first, such as minimization of exposure to factors known to trigger skin irritation. Although only a few new prescription topical agents have been approved for use in AD in the past decade (refer to “Pharmacologic Therapy” section), much has been learned about the pathogenesis of skin barrier changes in AD.^{4,6,12} Enhancing hydration and maintaining the skin barrier in atopic skin can be achieved through nonpharmacologic measures, including the use of moisturizers that can contain emollients (e.g., silicone, oils, or petrolatum, which soften the skin). If pharmacologic therapy is needed, a topical agent should always be the first-line choice. Topical corticosteroids, including hydrocortisone, can relieve itching and inflammation. The algorithm in [Figure 33–2](#) summarizes the approach to self-care for this disorder; exclusions for self-

treatment also are listed.^{9,23}

Nonpharmacologic Therapy

Treatment should be tailored to a patient’s needs and preferences, consistent with the patient’s age, and social conditions, along with the site(s) and severity of the lesions. Education on trigger avoidance and hydration of the skin is of utmost importance in the prevention as well as treatment of AD. Common triggers that patients should avoid are listed in [Table 33–2](#).^{9,15,25} Compared with that of nonaffected persons, the skin of patients with AD may be more reactive to irritants. Accordingly, implementation of preventive measures, with appropriate lifestyle changes, can be expected to reduce symptoms. Such changes include using cotton sheets and clothing, as opposed to wool or other fabrics, which can irritate skin; laundering and thoroughly rinsing new sheets and clothing with unscented or chemical-free laundry detergent; and avoiding fabric softeners. (If fabric softeners are used, liquid products are preferred over dryer sheets.) Bathing can provide hydration and remove bacteria.²⁶ Recommendations for frequency or duration of bathing are lacking, but guidelines state that baths should be limited in duration and taken in lukewarm water without additives.^{27,28} Additionally, moisturizers should be applied immediately after bathing to rehydrate the skin.^{27,28} Because some soaps can be irritating and cause dry skin, mild nonsoap cleansers that are hypoallergenic and fragrance-free (e.g., Cetaphil) are preferred.²⁷

TABLE 33–2 Triggers Associated With Atopic Dermatitis
Food allergens (e.g., egg, milk, peanut, soy, wheat, nuts)
Aeroallergens (e.g., dust mites, cat dander, molds, grass, ragweed, pollen)
Psychological stress
Airborne irritants (tobacco smoke, air pollution, traffic exhaust)
Cosmetics, fragrances, and astringents
Exposure to temperature extremes (heat or cold)
Use of electric blankets
Excessive hand washing or bathing/showering

Use of irritating soaps, detergents, and scrubs
Tight-fitting or irritating clothes (wool or certain synthetics)
Dyes and preservatives

Source: [References 9, 15, and 25.](#)

Although allergens such as plant or animal proteins from food, pollens, or pets are known to aggravate AD, the role of food allergies in exacerbating AD is unclear. It has been previously reported that in about one third of children, food allergies may exacerbate moderate to severe AD.²⁹ These allergies often include sensitivities to egg, milk, peanut, soy, and wheat. Patients with food allergies often have more severe AD, with an earlier onset.²⁸ Children who present with food allergies and AD should be evaluated by an appropriate health care provider, particularly if they are younger than 5 years of age with severe AD.^{10,28} Dietary restriction, especially in children, is difficult to maintain, and although it may produce some symptomatic improvement in AD initially, complete resolution is unlikely. Experts have maintained that patients with moderate to severe AD should eliminate known food allergens.^{9,15,25} However, guidelines state that restriction of offending foods does not alter the risk of developing AD,¹⁶ and note that although food allergies are prevalent in patients with AD, they are not always the cause. Other measures recommended for prevention of AD in childhood, such as breastfeeding and delaying introduction of solid food, remain controversial. Limited studies have investigated these interventions and their role in the prevention of AD; guidelines state that no definite evidence indicates that breastfeeding and solid food introduction will significantly affect risk of development of AD.^{16,28}

Patients with AD often are intolerant of extreme temperatures, as well as sudden and drastic changes in temperature and humidity. High temperatures, by enhancing perspiration, and low humidity, with consequent drying of the skin, both can lead to increased itching. Use of humidifiers in dry environments can provide some benefit.

Pruritus often is bothersome for many patients, who find it difficult to refrain from scratching. Recommending that fingernails be kept short, smooth, and

clean is important to avoid introduction of bacteria through microfissures; in addition, wearing cotton gloves at night can be a helpful preventive measure.

The use of moisturizers is standard of care for AD because maintaining skin hydration and the skin barrier is key to successful management. Moisturizers, especially those containing emollients, should be used at least twice daily for preventive and maintenance therapy to keep skin soft and pliable. The use of natural moisturizing factors, ceramides or pseudoceramides in emollients, can aid in preventing epidermal water loss by means of “barrier repair therapy.”^{6,30} Patient preference should direct specific emollient choice; however, the higher water content in lotions can have a drying effect through evaporation, and their use should be avoided. Ointments may have more effective dermal penetration, but some patients find them unappealingly greasy.^{25,27} Little evidence exists to support one product over the other; therefore, choosing a product that the patient is satisfied with is paramount.^{9,31} Specific information on nonpharmacologic and pharmacologic therapy for AD is presented in the later section “Nonprescription Medications Used to Treat Atopic Dermatitis and Dry Skin.”

Pharmacologic Therapy

Topical corticosteroids are recommended for first-line therapy for AD when nonprescription anti-inflammatory therapy is warranted during acute disease flares.²⁷ Although their exact mechanism of action is unknown, corticosteroids are believed to suppress cytokines involved in the development of inflammation and itching—symptoms that are associated with various dermatoses.

Hydrocortisone, a low-potency corticosteroid, is the nonprescription active ingredient available for self-care. This corticosteroid is safe when used as directed for the short term on virtually any area of the body (including the face, neck, axillae, and groin) and is recognized as safe to use in patients older than 2 years of age.²⁷ Compared with high-potency topical corticosteroid products, hydrocortisone 0.5% and 1% products, when used properly, carry a very low risk of local and systemic adverse effects.^{23,26} Hydrocortisone cream often is the patient-preferred dosage form. Ointment formulations, while often greasy, are preferred for use on areas of thick skin or if the patient’s skin is dry, lichenified, or scaly.^{23,26,32} Hydrocortisone should be applied sparingly twice daily to affected lesions during AD flares, before application of any moisturizers.^{9,27,32}

Ointments should be avoided if the AD lesions are weeping, and all hydrocortisone products should be avoided if the skin is infected, open, or cracked.³³

Topical hydrocortisone rarely produces systemic complications because its systemic absorption in adults is relatively minimal (approximately 1%). Therefore, the risk of adrenal suppression, growth suppression, osteoporosis, and other metabolic complications is slight when low-potency hydrocortisone is used on a short-term basis or rotated with other treatments. Certain local adverse effects such as skin atrophy rarely occur with nonprescription concentrations; they are more common with the more-potent prescription corticosteroids. Intermittent courses of corticosteroids are advised when possible because response to topical hydrocortisone may decrease with continued use. These intermittent courses can include daily use of hydrocortisone only during flares; during remission, use once-or twice weekly dosing, or no hydrocortisone at all, accompanied by continued maintenance strategies such as emollient use.²⁶

Refractory cases of AD necessitate referral to a primary care provider for prescription therapy with a higher-potency topical corticosteroid; a topical calcineurin inhibitor (CNI) (e.g., tacrolimus, pimecrolimus); or a systemic immunomodulator (e.g., cyclosporine, azathioprine, methotrexate).³⁴ Two new prescription agents have recently been approved for AD and provide another promising treatment option for patients with refractory symptoms: Crisaborole is a topical phosphodiesterase inhibitor that was approved for mild to moderate AD in patients >2 years of age. It has a low molecular weight, yielding improved skin penetration, and has proved to be of clinical benefit and safety for up to 48 weeks of use.^{11,35} Dupilumab is an IL-4 receptor antagonist that is approved for adults and children down to 6 years of age with moderate to severe AD.³⁶ This agent is given by subcutaneous injection and has proven efficacy and safety for up to 52 weeks.^{12,13} Because these agents were approved after release of the AD guidelines, their specific place in treatment remains to be established; however, they both offer alternatives to the older agents that are associated with black box warnings (CNIs) or serious adverse events (systemic immunomodulators).

Preventing and managing infections are important in patients with AD because their altered skin barrier predisposes them to such disorders. Guidelines state that the use of topical antibiotics may reduce skin

colonization. However, this effect does not appear to improve patient outcomes, and these products are not routinely recommended.²⁷ Twice-daily diluted bleach baths and intranasal mupirocin have been associated with decreased disease severity and are recommended in moderate to severe AD.^{27,37} Patients should be instructed to prepare a diluted bleach bath by adding ½ cup of bleach per 40 gallons of water (a full bathtub).^{15,25,26}

Although time-consuming for patients and caregivers, the use of “wet wraps” can increase skin hydration and help decrease scratching. This modality entails applying a steroid or emollient to symptomatic lesions, wrapping the affected areas in a wet and then a dry layer, and retaining the wraps for an overnight period.⁹ A growing body of literature is available on the use and efficacy of wet wraps^{38,39}; guidelines recommend their use to decrease disease severity.²⁷

Antipruritics

The pruritus associated with dermatitis may be mediated through several mechanisms, which may explain why local anesthetics, antihistamines, and hydrocortisone all are useful as antipruritics. Older guidelines do not recommend routine use of these local anesthetics (e.g., lidocaine, benzocaine),¹⁵ and newer guidelines do not even mention their potential use.²⁷ Additionally, itching also may be mediated by various endogenous substances, including histamine. On this basis, topical antihistamines (e.g., diphenhydramine) were proposed as agents for alleviating pruritus, with the potential for a cooling effect due to the vehicle.¹⁵ Although topical antihistamines may provide some short-term relief from itching, their use is not recommended and, furthermore, may be associated with sensitization.^{15,27} Oral antihistamines also are not recommended for routine treatment for pruritus in AD because of the lack of demonstrated efficacy and the hypothesis that the pruritus in AD often is not histamine-related.^{15,27} However, an oral antihistamine may help with sleep in the patient who has complaints of insomnia due to excess scratching, and if concurrent depression is a problem, an antidepressant with anticholinergic properties may help further with management of pruritus. In either case, sedation may be a problem, as may the anticholinergic adverse effects in patients with disorders such as benign prostatic hypertrophy or closed-angle glaucoma.⁴⁰ Furthermore, although products marketed as containing “counterirritants” such as menthol, camphor, or capsaicin claim effectiveness, such products are not mentioned in available guidelines.^{15,27}

Complementary Therapies

Although widely used, few complementary therapies have proven benefit in AD. Early research indicated that the use of probiotics in infants, such as *Lactobacillus*, may delay the presentation of AD⁴¹; however, a systematic review revealed no significant difference in AD symptoms.⁴² Published guidelines recommend against the routine use of prebiotics or probiotics for treatment of established AD.⁴⁰ Furthermore, a recent randomized trial provided further evidence of the lack of effectiveness of probiotics for eczema prevention in high-risk infants.⁴³ (Refer to [Chapter 20](#) for more information on probiotics.) The use of phototherapy in patients with AD is of documented benefit and is recommended in the guidelines as second-line therapy for acute and chronic AD.³⁴ Although this agent is not specifically mentioned in the guidelines, some evidence supports the use of topical coconut oil in mild to moderate AD.⁴⁴ Anecdotally, many oils have been utilized by patients for AD; however, the American Academy of Dermatology (AAD) states that there is insufficient evidence to recommend fish, evening primrose, or borage oils; Chinese herbal therapy; and other vitamins/minerals for topical therapy of AD.³⁹ Other natural products used in skin disorders are discussed in [Chapter 51](#).

Algorithm: Self-Care of Dermatitis

FIGURE 33–2 Self-care for dermatitis. Key: ACD = Allergic contact dermatitis; ICD = irritant contact dermatitis; OTC = over-the-counter; PCP = primary care provider.

Dry Skin

Xerosis, or *dry skin*, is the result of decreased water-holding capacity of the skin with resultant alteration of the stratum corneum. Although dry skin can occur at any age, it affects more than 50% of adults older than 65 years. Environmental factors such as temperature extremes and frequent showering can lead to or aggravate dry skin.^{31,45} The prevention of dry skin as well as appropriate skin care for the condition may become a major focus for health care providers as the population of older adults continues to increase.

Pathophysiology of Dry Skin

Dry skin is related to a barrier dysfunction, leading to a decreased water-holding capacity. This barrier dysfunction is due to a decreased amount of lipid components such as ceramides, free fatty acids, and cholesterol, not to a lack of natural skin oils.^{30,46} The decreased water-holding capacity leads to epidermal water loss with consequent dry, cracked skin. Impairment of keratinocyte differentiation also can contribute to the dysfunctional skin barrier.³¹

With advancing age, skin changes occur that include a thinner epithelium, decreasing lipids in the stratum corneum and natural moisturizing factor, and increased susceptibility to drying and bruising. A degraded skin barrier, particularly after insult, is conducive to water loss (and thus xerosis) and a loss of elasticity.^{5,31} Systemic disorders associated with dry skin can include hypothyroidism, cholestasis, renal failure, and dehydration.⁴⁶

Clinical Presentation of Dry Skin

Dry skin is characterized by one or more of the following signs and symptoms: roughness, scaling, cracking, fissuring, and erythema. Affected patients commonly complain of pruritus.^{31,46}

Treatment of Dry Skin

Treatment Goals

The goals of self-treatment for dry skin (xerosis) are (1) to improve skin hydration and minimize water loss, (2) to restore the skin's barrier function, and (3) to educate the patient about prevention and treatment of this chronic disorder.

General Treatment Approach

Treatment involves recognizing the problem as well as modifying the environment and bathing habits to maintain skin hydration. Nonprescription products such as bath oils and moisturizers that contain emollients can aid in moisturizing, softening, and restoring and maintaining barrier function. If needed, topical hydrocortisone can be used to reduce pruritus and erythema.

Nonpharmacologic Therapy

The most important aspects of care are the proper use of moisturizers containing emollients that soften and smooth the skin and modifications to bathing practices. The patient should apply these oil-based emollients immediately after bathing while the skin is damp, with frequent reapplication during the day. Room humidity can be increased with a portable humidifier, or a humidification unit can be added to the home heating system. The patient should be encouraged to stay well hydrated by drinking ample water daily unless contraindicated by any medical disorders. [Table 33–3](#) reviews nonpharmacologic therapy for dry skin.

TABLE 33–3 Nonpharmacologic Therapy of Dry Skin

- Take tub baths with addition of bath oil 2–3 times per week for brief periods (3–5 minutes). Take sponge baths on other days.
- Bathe in tepid water, not more than 3°F above body temperature.
- Within 3 minutes of getting out of the tub, pat the body barely dry, leaving beads of moisture, and generously apply body moisturizer to trap the moisture.
- Apply the body moisturizer at least 3 additional times during the day to the whole body (preferably) or at least to the most affected areas.
- Additional measures include
 - Using corticosteroid ointments rather than creams if short-term use is indicated
 - Maintaining high room humidity

Pharmacologic Therapy

Dry skin is more prone to itching, inflammation, and development of secondary infections. Most moisturizers are mixtures of oils and water, but more severe cases of dry skin may require a product containing a humectant (e.g., glycerin, urea, lactic acid) to enhance hydration. To improve barrier function, agents such as phospholipids and ceramides can be added to these moisturizers. Dry skin responds minimally to topical corticosteroid therapy, although short-term (≤ 7 days) use of topical corticosteroids may reduce symptoms of erythema and pruritus. If resolution does not occur within 1 week, referral for further medical evaluation is warranted because other options may be required for relief of the dry skin.

Nonprescription Medications Used to Treat Atopic

Dermatitis and Dry Skin

Nonprescription medications for dermatitis and dry skin that restore skin hydration include bath products and emollients, which can contain hydrating and keratin-softening agents. Often these ingredients are combined in commonly available nonprescription products (Table 33–4). Many such preparations are available for use on AD lesions or dry skin. These products, reviewed next, can be recommended according to patient preference and therapeutic response.

TABLE 33–4 Selected Nonprescription Dry Skin Products

Primary Ingredient(s)	Trade Name
Petrolatum-Containing Products	
Absorbase Ointment ^a	Petrolatum; mineral oil; ceresin wax; wool wax alcohol; potassium sorbate
AmLactin Cream/Lotion	Ammonium lactate 12%
Aquaphor Ointment	Petrolatum 41%; water
Cetaphil Cream ^a	Petrolatum; glycerin
Cetaphil Gentle Cleansing Bar ^a	Sodium cocoyl isethionate; stearic acid; sodium tallousate; PEG-20; petrolatum
Eucerin Cream ^a	Petrolatum; mineral oil; mineral wax; wool wax alcohol
Jergens Ultra Healing Lotion	Petrolatum; mineral oil; dimethicone; cetearyl alcohol; cetyl alcohol; glycerin
Moisturel Cream/Lotion ^a	Petrolatum; dimethicone; cetyl alcohol; glycerin
Vaseline Intensive Care Advanced Lotion	White petrolatum; mineral oil; dimethicone; glyceryl stearate; cetyl alcohol; glycerin
Ceramide Containing Products	
CeraVe Moisturizing Lotion	Glycerin; ceramide 1, 3, 6, and 11; hyaluronic acid; dimethicone; petrolatum, potassium phosphate

Primary Ingredient(s)	Trade Name
Eucerin Professional Repair Concentrated Lotion	Ceramide 3; glycerin; urea
Counterirritants	
Sarna Anti-Itch Lotion	Camphor 0.5%; menthol 0.5%; carbomer 940; cetyl alcohol; DMDM hydantoin; glyceryl stearate; petrolatum
Miscellaneous Emollients	
Cetaphil Gentle Skin Cleanser Liquid ^a	Cetyl alcohol; stearyl alcohol; PEG
Gold Bond Ultimate Healing Lotion	Glycerin; petrolatum; cetyl alcohol; aloe; cetearyl alcohol; propylene glycol; glyceryl stearate
Keri Original Dry Skin Lotion	Mineral oil; lanolin oil; glyceryl stearate; propylene glycol
Lubriderm Advanced Therapy Lotion	Cetyl alcohol; glycerin; mineral oil; PEG-40; emulsifying wax; vitamin E
Lubriderm Daily Moisturizing Lotion	Mineral oil; petrolatum; sorbitol; lanolin; lanolin alcohol; triethanolamine
Neutrogena Body Oil	Isopropyl myristate; sesame oil
Neutrogena Soap	TEA-stearate; triethanolamine; glycerin
Nivea Body Lotion	Glycerin; mineral oil; isopropyl palmitate; vitamin E; lanolin alcohol
Purpose Gentle Cleansing Bar	Sodium tallowate; sodium cocoate; glycerin; BHT

^a Fragrance-free formulation.

Key: BHT = Butylhydroxytoluene; DMDM = dimethylol dimethyl; PEG = polyethylene glycol; TEA = triethanolamine.

Bath Products

Bath Oils

Bath oils generally consist of a mineral or vegetable oil plus a surfactant. Some commercially available bath oil products include colloidal (ground) oatmeal in

an attempt to provide better relief of itching. Bath oils are minimally effective in improving a dry skin disorder because they are greatly diluted in water. When applied as wet compresses, bath oils (1 teaspoon in $\frac{1}{4}$ cup of warm water) help lubricate dry skin and may allow a decrease in the frequency of full-body bathing. Of note, however, bath oils make the tub and other surfaces slippery, creating a safety hazard, especially for older adults or children.

Cleansers

Typical bath soaps generally contain salts of long-chain fatty acids (commonly oleic, palmitic, or stearic acid) and alkali metals (e.g., sodium, potassium). Combined with water, these products act as surfactants that remove many substances from the skin, including the lipids that normally keep the skin soft and pliable. Glycerin soaps, which are more water-soluble, have a higher oil content than standard soaps because of the addition of castor oil. They are closer to a neutral pH and are regarded as less drying than traditional soaps. Although little objective proof exists to prove their superiority, glycerin soaps are advertised for, and well accepted by, people with skin disorders. Mild cleansers such as Cetaphil or Phisoderm can be recommended if soap is to be avoided.

Moisturizers

Moisturizers are vital in the treatment of AD and dry skin owing to their ability to impart moisture to the skin, thereby increasing skin flexibility. Most moisturizers contain abundant water (60%–80%), which functions as a diluent and evaporates, leaving behind active agents. Emollients, ingredients commonly found in moisturizers, include silicone, dimethicone oils, and petrolatum. These additives function to soften and smooth the skin by filling the space between the desquamating skin scales with oil droplets through which moisture cannot readily escape. The lipid components make the scales on the skin translucent and flatten them against the underlying skin. This flattening eliminates air between the scales and the skin surface, which is partly responsible for a white, scaly appearance.⁶ Unfortunately, this effect is only temporary. However, prudent use of emollients can reduce the incidence of AD, and these agents may be as effective as low-potency topical corticosteroids.⁴

Moisturizers can contain several other components, some of which include

emulsifiers, such as polysorbates and potassium cetyl sulfate, which keep water and lipids in one continuous phase; humectants, such as glycerin, propylene glycol, alpha hydroxy acids, and urea, which help skin retain water; preservatives; fragrance (or none in fragrance-free products); and color (dyes). Specialty additives, such as vitamins (vitamins A, C, D, B complex), which have no known clinical effect, and natural moisturizing factors (e.g., lactate, urea, ammonia, uric acid, glucosamine) also can be added and are reported to regulate the moisture content of the stratum corneum. Owing to the increasing understanding of lipid deficiencies and their relation to barrier dysfunction, lipid ingredients such as ceramides or pseudoceramides are being added to some products to enhance skin barrier protection.^{26,30} Additionally, plant oils derived from avocado, coconut, almond, peanut, safflower, sunflower, olive and others may be included in dry skin products (or used alone), presumably because of their unsaturated fatty acid content, to aid in barrier protection.⁴⁷ Although use of these oils contributes to skin flexibility and lubricity, they are less occlusive than white petrolatum. The differences between moisturizer products often are due to the addition of fragrances, exotic oils, vitamins, protein or amino acid products, and other minor moisturizing aids. Use of such products should be avoided in persons with an allergy to any component.

Vehicle Selection

Moisturizers come in a variety of formulations including butters, gels, oils, ointment, lotions, and creams. In general, creams, ointments, and butters are more difficult to spread, especially in hairy areas (where lotions may be beneficial). *Butters* are stiffer moisturizing formulations sold in jars and often contain shea butter, which is extracted from the nut of the African shea tree. Patients with tree nut allergies appear to be able to use shea butter with minimal risk of an allergic reaction. *Gels* can feel good on the skin because the alcohol component exerts a “cooling” effect, as well as an unwanted drying effect. This component also can cause hypersensitivity in some patients.

Ointments typically are water-in-oil emulsions. Often containing petrolatum, they generally lack consumer appeal because of their greasy texture, difficulty of spreading and removing, and staining properties. The simplest and most economical hand ointment is petroleum jelly, applied at bedtime and covered with wraps or gloves (or socks). To avoid the greasy feeling, patients can gently warm the product in the hands, apply a very thin layer, and massage it into the

skin. Ointments are inappropriate for use with oozing AD lesions because their occlusive effect will not allow the lesions to dry and ultimately heal. Additionally, petrolatum should not be applied over puncture wounds, infected areas, or lacerations because its high-occlusive property may lead to maceration and further inflammation. Application of petrolatum to intertriginous areas (e.g., armpits, groin, perianal region), mucous membranes, and acne-prone areas should be minimized; only a preparation with a low concentration of petrolatum is tolerated in these areas. In addition, ointments may be too occlusive in very warm weather, making creams a better choice.²⁶

Lotions and *creams* typically are oil-in-water emulsions that are less greasy than ointments. These agents help alleviate the pruritus associated with dry skin by virtue of their cooling effect as water evaporates from the skin surface. Lotions may be preferred in milder cases of dryness or in warm weather when the occlusive properties of ointments are an issue.²⁶

Frequency of application depends on the severity of the dry skin disorder and the hydration efficiency of the occlusive agent. Generally, moisturizers should be applied liberally and frequently, or a minimum of 3 times daily, to achieve maximum benefit.²⁷ For dry hands, the patient may need to apply the moisturizing agent after each hand washing, as well as at numerous other times during the day.

Topical Hydrocortisone

Hydrocortisone (0.5% or 1%) is currently the only corticosteroid available without a prescription for the topical treatment of dermatitis in the United States. Although its exact mechanism is unknown, hydrocortisone most likely suppresses cytokines involved in the development of inflammation and itching, which are associated with various dermatoses. U.S. Food and Drug Administration (FDA) monograph indications for use of hydrocortisone in patients older than 2 years include temporary relief of itching associated with minor skin irritations, inflammation, and rashes caused by dermatitis, seborrheic dermatitis, insect bites, poison ivy/oak/sumac dermatitis, soaps, detergents, cosmetics, and jewelry.⁴⁸ Concentrations of 0.5% or 1% are considered appropriate for treating localized dermatitis. Many commercially available nonprescription hydrocortisone products now also contain aloe. (The “Pharmacologic Therapy” section under “Atopic Dermatitis” provides more information on hydrocortisone; also refer to [Chapter 35](#).)

For dry skin of mild degree, a hydrocortisone cream is acceptable; however, an ointment formulation generally provides the best results with chronic, non-oozing dermatoses. Maximizing the application of moisturizers (lotions, creams, ointments) in dry, itchy skin disorders may lessen the required frequency of use of medicated products, such as hydrocortisone.^{21,31}

Product Selection Guidelines

Special Populations

Topical medications are used to treat many common skin disorders in infants and children. Infants have a reduced capability for biotransformation of drugs absorbed by the cutaneous route, owing to an immature hepatic enzyme system. In addition, because the ratio of surface area to body weight in a neonate is approximately two to three times that in an adult, the proportion of drug absorbed per kilogram of body weight is greater in a newborn.⁴⁹ Therefore, patients younger than 1 year should be referred to a primary care provider for the care of skin disorders. Pregnant or lactating patients can be safely treated with topical products if used appropriately. In pregnant patients, any risk to the fetus appears to be low if topical steroids are used in limited quantities and over limited areas of the body.⁵⁰ Use of these agents in pregnancy should be limited to clinical situations in which the potential benefit justifies the potential risk to the fetus; refer to the Preface for a detailed explanation of the pregnancy data. Geriatric patients are more likely to have dry skin owing to age-related skin changes. Bath oils and greasy ointments should be used with caution in older patients because such products can create slippery surfaces, with associated increased risk of falls and/or hindrance of the ability to grasp items, potentially impairing postural stability. Additionally, elderly patients may be at greater risk for the adverse effects of some agents owing to increased absorption through their thinner skin.

Patient Factors and Preferences

When deciding which product to recommend for dermatitis or dry skin, the health care provider must evaluate the active ingredients and the vehicle. Primary active ingredients contained in nonprescription skin products are water and oil. However, a variety of secondary ingredients are added to enhance product “elegance” and stability. Many of these ingredients, such as

preservatives like parabens or benzyl alcohol, have the potential to produce contact dermatitis through either an irritant or a sensitizing effect.³²

The type of vehicle (e.g., ointment, cream, lotion, gel, solution, aerosol) may significantly affect treatment of dermatitis, so product selection should be based on patient preference and location of lesions. Refer to the earlier “Vehicle Selection” section for more information on choosing the appropriate vehicle for each patient. Of note, some novel formulations such as foams, mousses, and gels can be more expensive than traditional creams and ointments. Cases 33–1 and 33–2 are examples of the assessment of patients with dry skin and AD, respectively.

Case 33–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient is an older man who presents complaining of patches of red, scaly skin on his hands and legs. He claims he has had these lesions on and off for years. He states that they do occasionally itch but not enough to wake him up at night. He notes that the soles of his feet and palms of his hands are very rough, with some fissures but no open wounds.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	The patient states that the skin symptoms are more bothersome in the winter months and have worsened as he has aged.
c. Description of the patient’s efforts to relieve the symptoms	He has tried using a store-brand unknown “lotion” on the lesions occasionally (“maybe once a week”), with minimal improvement.
d. Patient’s identity	James Smith

e. Patient's age, gender, height, and weight	72 years, male, 5 ft 7 in., 230 lb
f. Patient's occupation	Retired landscaper
g. Patient's dietary habits	"Low carb" diet appropriate for patients with diabetes; drinks black coffee and "a little water."
h. Patient's sleep habits	6–7 hours of sleep per night
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Hypertension</i> : lisinopril 20 mg once daily; <i>type 2 diabetes</i> : metformin 500 mg twice daily
j. Allergies	No known drug allergies
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Mr. Smith states that he takes long hot tub baths 5–6 times per week. He lives in Madison, Wisconsin, and keeps the temperature in his home at 75 degrees year-round, although he uses a humidifier in his bedroom during the winter months.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Mr. Smith has dry skin that is most likely caused by environmental factors, in combination with his advancing age.
3. Identify exclusions for self-treatment (Figure 33–2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to his primary care provider or a dermatologist. (2) Recommend self-care with nonprescription moisturizers and nondrug measures. (3) Recommend appropriate self-care until the

	patient can see an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Smith should begin using a nonprescription moisturizer, in a regimen of at least twice-daily applications of white petrolatum or a moisturizing cream to affected areas. If intense itching is troublesome, nonprescription hydrocortisone 1% cream or ointment may be applied to symptomatic lesions 2 times daily, followed by a moisturizer. (Table 33-3 provides additional information on dry skin therapy.)
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Take brief (3- to 5-minute) full-body baths 2-3 times per week using lukewarm (tepid) water. (Bath oils should be avoided because they make surfaces slippery, increasing the risk of falling.) Pat the skin dry after bathing; apply moisturizer generously. Drink plenty of water daily to help improve skin hydration, and increase the humidity in your home to minimize water loss from the skin."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Dry skin can be managed with nonprescription topical therapy such as moisturizers plus changes in your bathing habits. I see that you have been occasionally using a lotion, but these products can be drying to the skin, so try a cream or ointment instead. If cost is an issue, I can help you pick out a cost-effective agent."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	See the box "Patient Education for Atopic Dermatitis and Dry Skin."
b. Maximum number of days	"It is likely the moisturizer will need to be used chronically,

the therapy should be employed	for as long as you have the dry skin lesions. Avoid daily prolonged use (>7 days) of topical hydrocortisone." See the box "Patient Education for Atopic Dermatitis and Dry Skin."
c. Product administration procedures	See the box "Patient Education for Atopic Dermatitis and Dry Skin."
d. Expected time to onset of relief	See the box "Patient Education for Atopic Dermatitis and Dry Skin."
e. Degree of relief that can be reasonably expected	See the box "Patient Education for Atopic Dermatitis and Dry Skin."
f. Most common adverse effects	See the box "Patient Education for Atopic Dermatitis and Dry Skin."
g. Adverse effects that warrant medical intervention should they occur	See the box "Patient Education for Atopic Dermatitis and Dry Skin."
h. Patient options in the event that condition worsens or persists	"If the symptoms get worse or if your lesions, particularly those on the feet, become open, seek assistance from a primary care provider."
i. Product storage requirements	Store in a cool, dry place out of children's reach.
j. Specific nondrug measures	See the box "Patient Education for Atopic Dermatitis and Dry Skin."
Solicit follow-up questions from the patient or caregiver.	"Can I just use my Jergen's Lotion rather than using the Vaseline on my feet and legs?"
Answer the patient's or caregiver's questions.	"Ointments such as Vaseline hold moisture in the skin better than creams or lotions do. Although you may be able to use only your lotion after your skin improves, you would have to apply it 4-5 times daily to achieve the same results that Vaseline will provide."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mr. Smith to call you to report how his dry skin responded to the recommended therapy, or call him in 1 week to evaluate his response.

Key: ASA = Acetylsalicylic acid; CVD = cardiovascular disease.

Case 33–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient is brought to the community pharmacy by her mother for advice regarding lesions on her face and the tops of her arms. The mother reports that these lesions, which appeared when the patient was about 6 months old, have gotten worse since then despite regular applications of a moisturizing cream. The child seems to scratch the lesions a good deal, but the pruritus does not appear to wake her up at night.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The mother states that the skin lesions seem to have worsened after introduction of some new solid foods, and she recently changed laundry detergents. The daughter seems to scratch the lesions more often during the winter months.
c. Description of the patient's efforts to relieve the symptoms	The mother has applied a topical moisturizing cream to the patient's lesions for months, but in the winter when the lesions worsened, she also would apply a thin layer of topical hydrocortisone 1% cream once a day, which resulted in some temporary relief.
d. Patient's identity	Julie Taylor
e. Patient's age, gender, height, and weight	23 months, female, 33 inches, 24 lb

f. Patient's occupation	Julie attends daycare 3 mornings per week.
g. Patient's dietary habits	Drinks soy milk; tolerates bland soft table foods.
h. Patient's sleep habits	Sleeps 6 hours per night with 2 naps a day. Mother thinks the itching minimally affects her sleep.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Infant multivitamin once daily
j. Allergies	No known allergies; intolerant to cow's milk
k. History of other adverse reactions to medications	None
l. Other (describe) _____	The family history includes allergies in both parents and asthma in a 5-year-old sibling. The mother reports no tobacco use in the home.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Patient has lesions consistent with atopic dermatitis (due to lesion description and family history of allergies). They are likely to worsen with continued irritation from scratching.
3. Identify exclusions for self-treatment (Figure 33-2).	Julie is not yet 2 years of age and has lesions on her face.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Julie and her mother to her primary care provider/pediatrician, or a dermatologist, for a definitive diagnosis. (2) Recommend an appropriate nonprescription product. (3) Recommend use of an appropriate nonprescription product until Julie can be seen by an appropriate health care provider.

	(4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient or caregiver preferences.	Mrs. Taylor should continue to apply a topical moisturizer cream or ointment to Julie's lesions 3–4 times daily with clean hands. She also should try to keep the lesions and surrounding skin as clean as possible. In addition, Julie should be seen as soon as possible by her primary care provider/pediatrician or a dermatologist. Hydrocortisone should be avoided owing to her age (2 years), unless under the direction of a primary care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Until you can see Julie's pediatrician or other primary care provider or a dermatologist, you should continue to apply a topical moisturizer cream 3–4 times daily to the lesions."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Because of Julie's age and the progression of the lesions despite use of topical therapy, the next step is medical consultation to determine the best treatment options."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Try to prevent or discourage Julie from scratching the lesions; putting her in cotton sleep gloves at night may help."
	See the box "Patient Education for Atopic Dermatitis and Dry Skin" for additional information that can be discussed with the primary care provider or dermatologist.
Solicit follow-up questions from the patient or caregiver.	"Are there other nonprescription medications that might help?"
Answer the patient's or caregiver's questions.	"Continual use of a nonprescription topical corticosteroid may assist in lesion clearance, if under the direction of an

	appropriate health care provider. Otherwise, prescription medications are available for treatment of Julie's skin condition as determined by her primary care provider or dermatologist."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mrs. Taylor in 1-2 days to ensure that she sought further medical care for Julie.

Patient Counseling for Atopic Dermatitis and Dry Skin

Patients with AD should be counseled about achieving control of their disease, the chronic nature of the condition, avoiding exacerbating factors, and appropriate treatment options. The health care provider also should explain factors that cause dry skin and the appropriate measures for restoring barrier function. Finally, the potential for duplications in drug therapy should be addressed; for example, a patient using a nonprescription hydrocortisone product should be advised to stop that medication if a stronger topical corticosteroid is prescribed but to continue using moisturizers. The box "Patient Education for Atopic Dermatitis and Dry Skin" lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Atopic Dermatitis and Dry Skin

For patients with AD and dry skin, management should include reevaluation 7 days after initiation of therapy. Visual assessment is the best method of determining treatment response, so a scheduled visit is preferable to a phone consultation. If the symptoms have not abated or have worsened (as evidenced by continued or additional itching, redness, scaling, lesions, or tissue breakdown), medical referral is appropriate.

Patient Education for Atopic Dermatitis and Dry Skin

The primary objectives of self-treatment for atopic dermatitis (AD) are (1) to promote adequate skin hydration, (2) to maintain the skin barrier, (3) to avoid or minimize factors that trigger or aggravate the disorder, and (4) to prevent secondary infections. The primary objective in self-treatment for dry skin—restoring skin moisture and the skin’s barrier function—also can help relieve the discomfort of AD. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes. Understanding that implementing a treatment plan for AD requires patience is key to a successful outcome, because some therapeutic measures can be time-consuming to implement, and often a delay occurs in the time to maximal benefit.

Atopic Dermatitis

Nondrug Measures

- Avoid factors that trigger allergic skin reactions such as clothing or environmental irritants and proven food allergens. Avoid temperature extremes and changes in humidity.
- Take short showers or baths, using lukewarm (tepid) water and a nonsoap cleanser.
- If possible, substitute sponge baths (with tepid water) for full-body bathing.
- Pat skin dry after bath or shower.
- To help prevent injury to the affected area caused by scratching, keep your fingernails short, smooth, and clean. At night, wear cotton gloves or socks on your hands to lessen scratching.

Nonprescription Medications

- Gently wash the affected areas with a nonsoap cleanser before applying topical moisturizers or medication. Apply a moisturizer within 3 minutes after washing while skin is still damp.

- Wash hands before applying any medication.
- Apply a thin layer of nonprescription hydrocortisone 1–2 times daily to dry lesions. Do not use this medication longer than 7 days.
- With proper use of medications and nondrug measures, noticeable improvement can be observed in 24–48 hours.
- Although completely eliminating the rash and itch is possible, the chronic nature of this condition increases the likelihood that lesions could worsen, especially during the winter and summer months.

When to Seek Medical Attention

- If the atopic dermatitis does not improve or worsens after 2–3 days of treatment, consult your primary care provider.

Dry Skin

Nondrug Measures

- Avoid excessive bathing; take brief full-body baths 2–3 times per week, using lukewarm (tepid) water.
- If possible, take sponge baths on other days using lukewarm water to maintain skin hydration.
- Pat dry after bathing or showering.
- Drink plenty of water daily.
- Avoid caffeine and alcohol because they can contribute to dehydration.
- Keep the room humidity higher than normal to minimize evaporation from the skin.
- Moisturizer should be generously applied 3–4 times daily; this regimen should be continued as long as dry skin persists.
- Moisturizers should be applied within 3 minutes after bathing, plus an additional 3 times per day.
- Although complete resolution may be difficult, initial improvement should be seen within 24–48 hours.

Nonprescription Medications

- Apply a moisturizer immediately after bathing while your skin is

damp. Reapply the moisturizer frequently.

- For more severe cases of dry skin, use a product that contains ceramides or pseudoceramides.
- If moisturizers alone do not improve skin lesions, you can apply a thin layer of nonprescription-strength hydrocortisone (before moisturizer) 1–2 times daily to dry lesions. Do not use this medication longer than 7 days.

When to Seek Medical Attention

- If skin dryness worsens after 7 days of treatment, consult a primary care provider.

Key Points for Atopic Dermatitis and Dry Skin

- Most patients with mild to moderate AD or dry skin are candidates for self-treatment with a combination of nonprescription agents and nonpharmacologic modalities.
- Patients with yellow, crusting, eczematous AD lesions and all children younger than 1 year of age with AD require referral to a primary care provider/dermatologist for evaluation and treatment.
- Assessment of patients presenting with dry or eczematous skin lesions should ascertain any recent changes in exposure to soaps, detergents, fragrances, chemicals, irritants, temperature extremes, allergens, and other triggers, followed by recommendations for avoidance of such triggers.
- Counsel patients with dry skin disorders to take brief baths, use lukewarm water, pat dry, and apply moisturizers within 3 minutes of completing the bath or shower.
- Advise patients to use mild skin cleansers and to apply moisturizers at least two times daily.

- Educate the patient with chronic dry skin disorders about the importance of stopping the itch–scratch cycle and maintaining adequate hydration.
- Advise patients to use ointment-based products, whenever possible, to maximize the hydrating benefit. Cream-based products can be recommended for patients who will not comply with use of ointments or for patients with weeping lesions.
- Instruct patients how to properly apply topical hydrocortisone products, using the smallest amount possible only on affected lesions and thoroughly rubbing in the product.
- Advise patients with self-treatable symptoms to contact their primary care provider if symptoms worsen or do not abate within 7 days.

Chapter 34: Scaly Dermatoses

Authors: Rupal Patel Mansukhani, Lucio Volino

Chronic scaly dermatoses include dandruff, seborrheic dermatitis, and psoriasis. These disorders involve the uppermost layer of skin, the epidermis. Their primary manifestation is scaling of the skin, with inflammation, erythema, and other changes in appearance of variable degree and severity. *Dandruff* is a less inflammatory form of scaly dermatoses, manifested as more of a subtle dermatitis with relatively fine scaling confined to the scalp and, occasionally, mild erythema or inflammation.¹⁻³ *Seborrheic dermatitis*, which affects the scalp, face, and chest (usually the sternum), typically features significant inflammation and erythema; their degree and extent are based on disease severity.² *Psoriasis* is a highly inflammatory skin disorder characterized by raised plaques and adherent thick, silvery white scales.^{1,4}

Use of nonprescription products constitutes appropriate treatment for most cases of dandruff and seborrheic dermatitis. Mild psoriasis may be responsive to nonprescription treatment, but the management of acute exacerbations (“flares”) may require the attention of a knowledgeable health care provider, often a dermatologist.

Dandruff

Dandruff is a mildly inflammatory scalp disorder that results in excessive scalp scaling.^{2,4} It can be a substantial cosmetic concern and is associated with social stigma and concomitant distress.^{3,4} Previously thought to be a separate entity, this disorder represents the milder end of the seborrheic dermatitis spectrum.^{2,5}

Dandruff generally appears around the onset of puberty with the associated increase in sebaceous gland and hormonal activity.^{6,7} Dandruff shows no gender preference, and bald spots typically are dandruff-free. Sebaceous secretions and individual factors such as skin permeability and fatty acid penetration also may play a role.^{7,8} Finally, intrinsic (e.g., psychological stress) and extrinsic (e.g., cold temperatures) factors may affect hormone levels and skin moisture, respectively, to exacerbate dandruff symptoms.⁶ These factors

play a role in damaging the stratum corneum and worsening dandruff.

Pathophysiology of Dandruff

Dandruff is a hyperproliferative epidermal disorder, characterized by an accelerated epidermal cell turnover and abnormal keratinization, resulting in mild inflammation, flaking, and pruritus.^{2,6} This process involves the presence of *Malassezia* yeast, disruption in skin proliferation, differentiation, and barrier function.² The accelerated cell turnover rate is thought to be caused by the irritant effects of fatty acids and cytokines produced by the *Malassezia* fungi.^{2,6,7} With dandruff, crevices occur deep in the stratum corneum, which cause superficial cracking and the development of large flakes.⁹ If the large scales are broken down to smaller units, dandruff becomes less visible.

Clinical Presentation of Dandruff

Scalp scaling, the sloughing of small white or gray loosely bound flakes, is the only visible manifestation of dandruff. The scaling may occur in small patches or may be distributed across the scalp surface. Patients may experience additional, less common symptoms such as scalp pruritus, dryness, tightness, and irritation. Unlike seborrheic dermatitis and psoriasis, dandruff involves minimal inflammation or erythema.^{2,10}

Treatment for Dandruff

Treatment Goals

The goals of self-treatment for dandruff are (1) to reduce the epidermal turnover rate of the scalp skin by reducing the number of *Malassezia* fungi on the scalp, (2) to minimize the cosmetic embarrassment of visible scaling, and (3) to minimize itch.

General Treatment Approach

Routine shampooing with a general-purpose nonmedicated shampoo daily or every other day often is sufficient to control mild to moderate dandruff. If this approach is not effective, the health care provider may recommend nonprescription medicated antidandruff products. Shampoos containing harsh surfactants such as sodium lauryl sulfate or sodium laureth sulfate

should be avoided because of their damaging effects on the stratum corneum.⁶

A cytostatic agent (e.g., pyrithione zinc, selenium sulfide) generally is recommended initially. Contact time is the key to effectiveness of cytostatic medicated shampoos that contain pyrithione zinc or selenium sulfide to suppress the replication of *Malassezia* fungi.^{11,12} The patient should massage the medicated shampoo into the scalp and leave on the hair for 3–5 minutes before rinsing. Repeated rinsing (2–3 times) after the desired contact time is suggested with medicated shampoos that contain selenium sulfide to ensure that a residue is not left on the hair, where it may cause discoloration. The patient should be instructed to use the medicated shampoo daily for 1 week, then 2–3 times weekly for 2–3 weeks, and thereafter once weekly or every other week to control the disorder.¹³ African American patients may benefit from shampooing once weekly and can consult with a dermatologist for product selection.¹⁴ Scalp scrubbers are useful in all patients, especially those with longer hair, to help ensure adequate contact of the medicated shampoo with the scalp.

Alternatively, nonprescription ketoconazole shampoo, an antifungal shampoo that also has anti-*Malassezia* activity, can be used. Shampoos containing coal tar are usually of limited use and reserved for second-line therapy because they may discolor light hair, clothing, and jewelry. These agents reduce scaling by decreasing the turnover rate of scalp cells.^{15,16} A keratolytic shampoo containing salicylic acid or sulfur also may also be used but is of limited efficacy.

The section “Nonprescription Medications Used to Treat Scaly Dermatoses” provides more information on these agents. If dandruff proves resistant to these agents, the patient should be referred to a knowledgeable health care provider or dermatologist for further evaluation.

Seborrheic Dermatitis

Seborrheic dermatitis is a chronic inflammatory disorder that occurs predominantly in the areas of greatest sebaceous gland activity (e.g., scalp, face, chest).^{3,11,17} It commonly manifests as a red, scaly, itchy rash affecting infants (up to 30 months old), adolescents/young adults, and 1%–3% of adults,

more commonly men.^{5,17,18} Typically more severe during the winter and in low-humidity environments, seborrheic dermatitis also may be aggravated by emotional stress.^{17,19} The risk for development of seborrheic dermatitis is increased in states of immunosuppression (e.g., human immunodeficiency virus [HIV] infection, acquired immunodeficiency syndrome [AIDS], antirejection regimen effects after organ transplantation) and in association with chronic neurologic disorders (e.g., Parkinson disease).²⁰⁻²²

Pathophysiology of Seborrheic Dermatitis

Similar to dandruff, seborrheic dermatitis involves *Malassezia* species and accelerated epidermal proliferation. Areas with dense distribution of sebaceous glands are predominantly affected and exhibit more inflammation compared with dandruff.^{5,7,20} The characteristic accelerated cell turnover and enhanced sebaceous gland activity give rise to skin changes consisting of prominent yellow, greasy scales with erythema.^{4,5}

Clinical Presentation of Seborrheic Dermatitis

Seborrheic dermatitis can manifest in a variety of forms based on its severity and body areas affected. It can involve the scalp, eyebrows, glabella, eyelid margins, cheeks, paranasal areas, nasolabial folds, beard area, presternal area, central back, and retroauricular creases, and typical changes may be evident in and about the external ear canal. The usual clinical presentation consists of fairly well-demarcated, dull, yellowish, oily, scaly areas on reddened skin. Pruritus is common.^{1,4}

The infantile form of seborrheic dermatitis, also known as *cradle cap*, is common in the first 3 months of life. The prevalence diminishes significantly by 1 year of age and then gradually over the next few years.²³ In affected infants, thick, white to yellow-brown greasy scales tend to concentrate on the scalp, but the scales can extend across the entire scalp and into the face, neck, trunk, and extremity regions with subsequent redness and inflammation.^{17,19} Children of color may not have the white to yellow scales and can present with hypopigmentation, flaking, and erythema.²⁴

The most common presentation of seborrheic dermatitis in adults is characterized by yellow, greasy scales on the scalp that often extend to the middle third of the face with subsequent eyebrow involvement (see [Color](#)

Plates, photograph 17). Typically, seborrheic dermatitis manifests as greasy, scaling patches or plaques, exudation, and thick crusting. On the face, flaky scales or yellowish scaling patches on red, itchy skin are seen within the eyebrows and on the glabella.^{3,19} Red scaling, fissures, and swelling may be present in the ear canals, around the auditory meatus, in the postauricular region, or under the earlobe. V-shaped areas of the chest and back intertriginous areas, such as the side of the neck, axillae, submammary region, umbilicus, groin, and gluteal crease, also may be involved.^{1,19} Darker-skinned adults may present with hypopigmentation, and erythema may be difficult to see. Arcuate and petaloid lesions are commonly seen along the hairline in this population.²⁴ In adults, the disease is chronic, lasting for years to decades, with periods of improvement in warmer seasons and periods of exacerbation in the colder months.¹⁹

Treatment for Seborrheic Dermatitis

Treatment Goals

The goals of self-treatment for seborrheic dermatitis are (1) to reduce inflammation and the epidermal turnover rate of the scalp skin by reducing the level of *Malassezia* fungi, (2) to minimize or eliminate visible erythema and scaling, and (3) to minimize itch.¹⁷

General Treatment Approach

Because of the inflammatory nature of seborrheic dermatitis, its treatment is similar to but more aggressive than that for dandruff. Patients should be educated that therapy works by controlling the disease rather than by curing it. Therapy is directed at loosening and removal of scales and crusts, inhibiting yeast colonization, controlling secondary infection, and reducing erythema and itching. The scales and crust loosen with the use of topical antifungal agents, which constitutes first-line treatment for seborrheic dermatitis. If the scales are difficult to remove, applying mineral or olive oil and washing with dishwashing liquid may be beneficial.¹³ Because seborrheic dermatitis is a chronic disorder, regular use of medicated shampoos such as pyrithione zinc and selenium sulfide is key. Patients should work the shampoo into the scalp and then leave the lather on the hair and affected areas for 3–5 minutes. Initially, the shampoo should be used daily for the first week or 2; this regimen is then reduced to 2–3 times per week for the next 4 weeks. African American

patients may benefit from foam shampooing once weekly and can consult with a dermatologist for product selection.²⁴

In infants, seborrheic dermatitis usually is self-limited and is treated primarily by gently massaging the scalp with baby oil, followed by the use of a nonmedicated shampoo (e.g., Johnson's Baby Shampoo, Mustela Foam Shampoo) to remove scales.¹ In cases that do not respond to this treatment, the patient should be referred to a pediatrician. Shampooing is the foundation of treatment in adults, regardless of skin lesion location. Once the disorder is controlled, shampoos containing pyrithione zinc, selenium sulfide, or ketoconazole should be used once a week to prevent relapse regardless of age.

If the odor of a medicated shampoo is objectionable, its use can be followed by a more cosmetically acceptable shampoo or conditioner. Topical corticosteroids are not helpful in controlling dandruff; however, these agents are needed more frequently to treat the more significant inflammation in seborrheic dermatitis.¹⁷ Corticosteroid products may be used to manage seborrheic dermatitis whenever erythema persists after therapy with medicated shampoos. Hydrocortisone ointment should be applied no more than twice daily because of the reservoir effect of the stratum corneum, which slowly releases the corticosteroid over time, and potential greasiness. Treatment should continue until symptoms subside but for no more than 7 consecutive days, since seborrheic dermatitis is rarely cured by nonprescription treatment. If the disorder worsens or symptoms persist longer than 7 days, a dermatologist or other knowledgeable health care provider should be consulted.¹²

Psoriasis

Psoriasis is a chronic inflammatory disease estimated to affect approximately 7.5 million Americans.²⁵ Lesions are often localized, but they may become generalized over much of the body surface. Remissions and exacerbations are unpredictable.^{1,26} Approximately 50% of people with psoriasis find that lesions may clear spontaneously and remain clear for varying periods of time.¹⁹ Unrelenting generalized psoriasis may cause enough psychological and physical distress to adversely affect a patient's quality of life.^{26,27}

The incidence of psoriasis is distributed almost equally between men and

women. Obese patients can have a higher incidence. Psoriasis is seen in all races and geographic regions, but the incidence is lower among people living in countries close to the equator and among people of African American, West African, Native American, and Asian descent.^{1,19}

Although the cause of psoriasis is unknown, exacerbations can be triggered by any of the following^{1,19,26,27}:

- Environmental factors such as physical, ultraviolet, and chemical injury
- Various infections (streptococcal infection, HIV infection)
- Prescription drug use (e.g., antimalarials, beta blockers, interferons, lithium, nonsteroidal anti-inflammatory drugs) and withdrawal of systemic corticosteroids
- Emotional and psychological stress
- Use of alcohol and tobacco

Pathophysiology of Psoriasis

Immunologic mechanisms such as T-cell induction, cytokine production, and keratinocyte and epidermal proliferation are believed to contribute to the development and exacerbation of psoriasis. A genetic predisposition is associated with early-onset disease and first-degree familial history.²⁷

Epidermal cell turnover rate is approximately 8 times shorter in psoriatic skin than in normal skin.²⁸ The duration of psoriasis is variable, with spontaneous exacerbations and remissions possible. Lesions may last a lifetime or disappear quickly.^{19,26}

Clinical Presentation of Psoriasis

Regardless of the clinical form, psoriasis typically is symmetrical.

Approximately 90% of patients experiencing psoriasis present with psoriasis plaque. Lesions start as small papules, which grow and unite to form plaques. Plaques typically are well demarcated and are covered with a silvery-white scale. Plaques also may be painful or itchy.^{19,26,27} (See [Color Plates](#), photographs 18A, B, C.) Common sites for psoriasis plaques are the extensor surfaces of the elbows and knees, lumbar region of the back, scalp, trunk, and genital area. When the scale is lifted from the base of the plaque, punctate bleeding points sometimes are seen within the plaque site (Auspitz sign).^{19,26}

Treatment for Psoriasis

Treatment Goals

The goals of self-treatment for psoriasis are (1) to control or eliminate the signs and symptoms (inflammation, scaling, itching) and (2) to prevent or minimize the likelihood of flares.

General Treatment Approach

Mild cases of psoriasis, characterized by presence of a few localized lesions no larger than a quarter, are amenable to self-treatment with topical agents such as hydrocortisone or emollients. With areas of involvement greater than 5%, facial lesions, or the presence of joint pain, treatment by the patient's primary care provider or a dermatologist with more effective prescription medications and phototherapy will be required.²⁹ In cases not responding to emollients and nonprescription strengths of hydrocortisone or in children younger than 2 years, referral to a knowledgeable health care provider or dermatologist also is warranted.

Numerous nondrug measures can be used by patients in the treatment of psoriasis for both mild and moderate to severe cases. Although these treatments can help relieve symptoms and enhance the local effectiveness of nonprescription and prescription products, such measures alone are unlikely to control the signs and symptoms of the disorder. Patients should avoid physical, chemical, or ultraviolet (UV) trauma to the skin because of the likelihood of development of lesions at the site of skin trauma. Scale removal is an important component of treatment, because scales facilitate the continuation of psoriatic plaques and interfere with the penetration of topical agents.³⁰ Patients with psoriasis should be encouraged to bathe with lubricating bath products (see [Chapter 33](#)) 2–3 times per week using tepid water.³¹

Daily lubrication of the skin after a bath or shower is an essential part of therapy. Emollients moisturize, lubricate, and soothe dry and flaky skin, as well as reduce fissure formation within plaques and help maintain flexibility of the surrounding skin. Pruritic dry skin is common in psoriasis, and emollients and lubricating bath products often provide some relief for this symptom.³² Emollients (e.g., Lubriderm Lotion, Nivea Cream) should be applied to the

lesions within minutes of bathing. To be effective, these products need to be applied liberally with gentle rubbing, up to 4 times daily. Loose scales can be removed by gently rubbing with a soft cloth. Hydrocortisone ointment 1% is the nonprescription medication of choice for treatment of bright red lesions. In some patients, nonprescription treatment may be ineffective and more aggressive treatments may be needed.²⁷

In most cases, psoriasis will not be controlled by nonprescription treatment, and referral to a knowledgeable health care provider or dermatologist will be necessary. In such cases, the selection of therapy must be individualized based on the site, severity, duration, and previous treatment of the disorder, as well as the patient's age. Treatment may be topical, systemic, or a combination of both.

Psoriasis can be controlled but not cured, and remissions do occur. Patients should be educated on controlling the disorder to increase compliance with burdensome and prolonged treatment regimens. In addition, education on understanding and acceptance of the disorder may help reduce the associated emotional stress and the frequency of psychogenic exacerbations. Prevention of flare-ups (flares) should be emphasized. During flares, however, signs and symptoms usually can be controlled adequately using self-care measures, detailed in appropriate patient education and treatment. Flares can be prevented by minimizing known precipitating factors such as emotional stress, skin irritation, and physical trauma.

Management of Scaly Dermatoses

Clinical management of scaly dermatoses (e.g. dandruff, seborrheic dermatitis, and psoriasis) consists of use of various nonprescription medications, for control or eradication of symptoms, with differing mechanisms of action, in combination with self-treatment measures specific to each type of disorder. Appropriate patient counseling and education, as detailed further on, also are essential to optimal clinical outcomes.

Nonprescription Medications Used to Treat Scaly Dermatoses

A variety of products are used to treat or reduce the severity of scaly dermatoses. Hydrocortisone is used to control the inflammation associated

with seborrheic dermatitis and psoriasis. [Table 34–1](#) summarizes the concentrations and indications for currently approved agents,^{19,33} and the algorithm in [Figure 34–1](#) outline self-treatment with these agents.

Table 34–1 Concentrations of Approved Nonprescription Ingredients for Products Used to Treat Scaly Dermatoses			
	Concentration (%)		
Ingredient	Dandruff	Seborrheic Dermatitis	Psoriasis
Coal tar	0.5–5	0.5–5	0.5–5
Hydrocortisone	–	0.5–1	0.5–1
Ketoconazole	1	1	1
Pyridione zinc (brief exposure)	0.3–2	0.95–2	2
Pyridione zinc (residual)	0.1–0.25	0.1–0.25	0.25
Salicylic acid	1.8–3	1.8–3	1.8–3
Selenium sulfide	1	1	1
Sulfur	2–5	2–5	–

Source: [References 19](#) and [33](#)

Patients should shampoo with a nonmedicated, nonresidue regular shampoo to remove dirt, oil, and scales from scalp and hair before using a medicated shampoo. Many shampoos leave a residue on the hair shaft and scalp that may cause local aggravation of the skin changes in scaly dermatoses. Nonresidue shampoos, by contrast, leave the scalp clean and receptive to optimal effects from medicated shampoos. After the nonresidue shampoo is rinsed away, a medicated shampoo is applied and left on the scalp for up to 5 minutes. This treatment regimen can be used daily, if needed, until symptoms are relieved and then 2–3 times weekly.¹²

Cytostatic Agents

Topical cytostatic agents include pyridione zinc, selenium sulfide, and coal tar.

These agents are known to decrease the rate of epidermal cell replication. This curtailment increases the time required for epidermal cell turnover, which in turn allows the possibility of normalizing epidermal differentiation, resulting in a slow decline in visible scales. However, these products have limited efficacy and multiple other detriments that make them poor alternatives.³

Pyrithione Zinc

Pyrithione zinc's mechanism of action is its anti-*Malassezia* activity, which reduces the yeast count in the scalp and skin. Pyrithione zinc binds strongly to both hair and the external skin layers of the scalp, and the extent of binding correlates with clinical performance. The U.S. Food and Drug Administration (FDA) recommends concentrations of 0.3%–2% for treating dandruff and 0.95%–2% for treating seborrheic dermatitis.³⁴ Nonprescription shampoos and soaps are currently available in 1% and 2% concentrations. Pyrithione zinc shampoo is well tolerated when used as directed and is not associated with any major adverse effects. Contact with the eyes should be avoided to prevent stinging.

Selenium Sulfide

Selenium sulfide and pyrithione zinc have a similar mechanism of action.²⁰ As with pyrithione zinc, selenium sulfide is more effective with longer contact time and therefore should be applied in a similar manner.^{11,12} Selenium sulfide must be rinsed from the hair thoroughly; otherwise, discoloration may result, especially with light or dyed hair. Frequent use may leave a residual odor and an oily scalp.

Selenium sulfide is approved in a 1% concentration in nonprescription products to treat dandruff and seborrheic dermatitis.³⁴ A 2.5% lotion formulation is available by prescription for use in resistant cases and other topical fungal infections. The risk of irritation of the mucous membranes and scalp from selenium sulfide is minimal, and no adverse effects are associated with routine use of the 1% shampoo. Contact with the eyelids should be avoided because of the potential for eye irritation.

Coal Tar

For many years, the therapeutic response to coal tar products was believed to be caused solely by its phototoxicity. Now it is believed that coal tar may work

by its ability to cross-link with DNA and arrest excessive skin cell proliferation. Coal tar products have long been popular for treating dandruff, seborrheic dermatitis, and psoriasis. Although many nonprescription products are available, their usefulness is constrained by their potentially unacceptable cosmetic properties and limited clinical efficacy.¹⁵

Coal tar is available in concentrations of 0.5%–5% as creams, ointments, pastes, lotions, bath oils, shampoos, soaps, and gels to self-treat dermatologic disorders.³⁴ This variety of dosage forms is partly the result of attempts to develop a cosmetically acceptable product—one that masks the odor, color, and staining properties of crude coal tar, which most patients find esthetically unappealing.

Adverse effects associated with the use of coal tar include folliculitis (particularly of the axilla and groin), stains to the skin and hair (particularly blond, gray, and dyed hair), photosensitization, and irritant contact dermatitis.³⁵ Rarely, the disorder may worsen on exposure to coal tar products. This possibility is of particular concern in the acute phase of psoriasis, when topical corticosteroids are recommended to reduce inflammation before coal tar preparations are used.³⁵

Coal tar products may be applied to the body, arms, and legs, preferably at bedtime. Because coal tar stains most materials, the patient should use bed linen and clothing for which staining would not present a problem. Overnight application is followed by a bath in the morning to remove residual coal tar and to loosen psoriatic scales. Patients using coal tar preparations should avoid sun exposure for 24 hours after application.

Antifungal Agent

Ketoconazole

Ketoconazole, a synthetic azole antifungal agent, is available as a nonprescription shampoo formulation. Ketoconazole 1% is active against most pathogenic fungi but is indicated specifically for *Malassezia* infections. Patients should use ketoconazole shampoo twice a week for 4 weeks, with at least 3 days between each treatment. Once the disorder is controlled, the shampoo can be applied once weekly to prevent relapse. Adverse effects associated with use of 1% ketoconazole shampoo typically are minimal, but hair loss, skin irritation, abnormal hair texture, and dry skin have been

reported. Patients should be advised to avoid contact of ketoconazole shampoo with the eyes, where it can cause significant irritation.

Keratolytic Agents

The keratolytic agents, salicylic acid and sulfur, can be used in dandruff and seborrheic dermatitis to loosen and lyse keratin aggregates, thereby facilitating their removal from the scalp in smaller particles. These agents act by dissolving the “cement” that holds epidermal cells together. Vehicle composition, contact time, and concentration are important factors in the success of a keratolytic agent. Keratolytic concentrations in nonprescription scalp products are not sufficient to impair the normal skin barrier, but they do affect the abnormal, incompletely keratinized stratum corneum.

Keratolytic agents have a primary, concentration-dependent irritant effect, particularly on mucous membranes and the conjunctiva of the eye. The directions and precautions for the use of keratolytic shampoos are similar to those for ketoconazole shampoo, with the exception that prolonged use (>4 weeks) usually is necessary to obtain a therapeutic response for keratolytics.³⁶

Salicylic Acid

Salicylic acid decreases skin pH, which causes increased hydration of keratin and therefore facilitates its loosening and removal. Topical salicylic acid is useful for psoriasis when thick scales are present. However, application over extensive areas should be avoided because of the potential for percutaneous absorption. Salicylic acid has been approved in concentrations of 1.8%–3% for self-treatment for dandruff, seborrheic dermatitis, and psoriasis.³⁴ One study showed that shampoos containing 1.5% ciclopirox olamine and 3% salicylic acid had efficacy similar to that of 2% ketoconazole shampoo for treatment of dandruff.³⁷ The combination product with ciclopirox is not available in the United States.

Sulfur

Sulfur is believed to cause increased sloughing of cells and to reduce corneocyte counts. Sulfur has been approved in concentrations of 2%–5% to self-treat dandruff only.³⁴ Despite its recognition as a single-entity active ingredient, sulfur often is combined with salicylic acid. Although not an FDA-approved indication, this combination has been commonly used to self-treat

seborrheic dermatitis.²⁶ The use of nonprescription topical preparations containing sulfur has not been associated with any significant adverse effects. **Table 34–2** lists nonprescription products used to treat scaly dermatoses.

Table 34–2 Selected Nonprescription Products to Treat Scaly Dermatoses	
Trade Name	Primary Ingredient(s)
Cytostatic Products^a	
DHS Tar Shampoo; DHS Tar Gel Shampoo; Pentrax Shampoo	Coal tar 0.5%
Head & Shoulders Dandruff Shampoo, Zincon Shampoo	Pyrrithione zinc 1%
DHS Zinc Shampoo, Sebulon Shampoo, ZNP Cleansing Bar	Pyrrithione zinc 2%
Head & Shoulders Clinical Strength Shampoo, Selsun Blue Medicated Treatment Shampoo	Selenium sulfide 1%
Neutrogena T/Gel Shampoo	Tar 2% (equivalent to coal tar 0.5%)
Neutrogena T/Gel Extra Strength Therapeutic Shampoo	Tar 4% (equivalent to coal tar 1%)
Neutrogena T/Derm Body Oil	Tar 5% (equivalent to coal tar 1.2%)
Keratolytic Products	
Sebucare Lotion	Salicylic acid 1.8%
Sebulex Conditioning Shampoo with Protein	Salicylic acid 2%; sulfur 2%
Denorex Extra Strength	Salicylic acid 3%
MG217 Medicated Tar-Free Shampoo	Salicylic acid 3%; sulfur 5%
X-Seb Shampoo	Salicylic acid 4%
Sulfoam Medicated Antidandruff Shampoo, Sul-Ray Dandruff Shampoo	Sulfur 2%
Sul-Ray Cleansing Bar	Sulfur 5%
Antifungal Product

X-Seb T Shampoo	Coal tar solution 10%; salicylic acid 4%
X-Seb T Plus Shampoo	Coal tar solution 10%; salicylic acid 3%; menthol 1%

^a Coal tar is not preferred.

Topical Hydrocortisone

Topical hydrocortisone 0.5% and 1% is available without a prescription and is FDA approved for inflammatory skin disorders like scaly dermatoses, which is accompanied by inflammation that is unresponsive to medicated shampoos.^{11,12,19,20} Nonprescription hydrocortisone products can play a role in managing mild psoriasis. Topical corticosteroids have several effects (e.g., anti-inflammatory, vasoconstrictive, immunosuppressive) on cellular activity, which can result in decreased redness and itching. Hydrocortisone ointment is the most potent and effective dosage form. It is preferred in the treatment of psoriasis. Patients should apply the ointment, wait 30 minutes, and then cover the area of the psoriatic plaque with another greasy emollient such as petrolatum to serve as an occlusive dressing.

Adverse effects associated with the use of topical corticosteroids include local atrophy after prolonged use and aggravation of certain cutaneous infections. The possibility of systemic sequelae is enhanced with use of the more potent compounds, use of occlusive dressings, or application to large areas of the

body.

Assessment of Scaly Dermatoses: A Case-Based Approach

Differentiation of the scaly dermatoses involves several factors. The appearance of the scales in the early stages of a disorder is not always definitive. In such cases, the presence and nature of other symptoms and the location of the dermatitis constitute additional important clues in its assessment. Recognition of factors that precipitate or exacerbate the disorder also is helpful in defining the disorder. [Table 34–3](#) describes the distinguishing features of these three dermatoses. Cases 34–1 and 34–2 illustrate the assessment of patients with different scaly dermatoses.

Table 34–3 Distinguishing Features of Scaly Dermatoses			
Feature	Dandruff	Seborrheic Dermatitis	Psoriasis
Location	Scalp	Scalp, face, trunk	Scalp, elbows, knees, trunk, lower extremities
Exacerbating factors	Generally, a stable condition but may be exacerbated by psychological stress, cold temperatures, dry climate	Immunosuppression, neurologic conditions, environmental factors, stress	Environmental factors, infection, medications, stress, alcohol, tobacco
Appearance	Thin, white, or grayish flakes; even distribution on scalp	Macules, patches, and thin plaques of discrete yellow, oily scales on red skin	Discrete symmetrical red plaques with sharp borders; silvery white scales; small bleeding points when scale is removed; difficult to distinguish from seborrhea in early stages or in intertriginous zones
Inflammation	Absent	Present	Present
Epidermal hyperplasia	Absent	Present	Present
Epidermal kinetics	Turnover rate 2 times faster than	Turnover rate about 3 times faster than	Turnover rate about 8 times faster than normal

Feature	Dandruff	Seborrheic Dermatitis	Psoriasis
	normal	normal

Patient Counseling for Scaly Dermatoses

An important point to convey in patient counseling is that scaly dermatoses are rarely cured by pharmacotherapy; rather, nonprescription agents help control the signs and symptoms of the disorders. Patients also should be advised that fluctuation in severity of seborrheic dermatitis and psoriasis may be related to emotional, physical, or environmental factors.

Explanations of the proper use of antifungal, cytostatic, and keratolytic agents should include information about the contact time of the agent on the affected area(s), possible adverse effects, and signs and symptoms that may indicate a need for medical attention. The box “Patient Education for Dandruff and Seborrheic Dermatitis” and the box “Patient Education for Psoriasis” list specific information to provide in patient counseling for these conditions.

Evaluation of Patient Outcomes for Scaly Dermatoses

Follow-up assessment of the patient’s progress should be done after 1 week of self-treatment. If the symptoms have worsened after this period, the patient should be referred for consultation with a knowledgeable health care provider, such as a dermatologist. If symptoms have not worsened, the patient should return for reassessment after a second week of treatment. If the symptoms persist or have worsened after this period, further medical evaluation is warranted.

Algorithm: Scaly Dermatoses

FIGURE 34–1 Self-care for scaly dermatoses. Key: BSA = Body surface area; OTC = over-the-counter.

Case 34–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of yellow, oily scales along his hairline and around his nose. Some minor erythema also is evident in these areas.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The condition has grown worse since the onset of cold weather.
c. Description of the patient's efforts to relieve the symptoms	Washing the face twice daily with hand soap has not been proven to be beneficial.
d. Patient's identity	Robert Platt
e. Patient's age, gender, height, and weight	57 years, male, 5 ft 9 in., 185 lb
f. Patient's occupation	Sales manager
g. Patient's dietary habits	Normal healthy diet
h. Patient's sleep habits	6–7 hours per night
i. Concurrent medical conditions, prescription and nonprescription	<i>Depression:</i> sertraline 50 mg daily; <i>hypertension:</i> lisinopril 10 mg daily

Relevant Evaluation Criteria	Scenario/Model Outcome
medications, and dietary supplements	
j. Allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 34-3).	Mr. Platt appears to have seborrheic dermatitis on his face. His scalp should be examined closely for involvement as well.
3. Identify exclusions for self-treatment (Figure 34-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend self-care with an appropriate nonprescription product and nondrug measures. (2) Recommend self-care with an appropriate nonprescription product and nondrug measures until Mr. Platt can consult his regular health care provider or a dermatologist. (3) Refer Mr. Platt for further medical evaluation. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into	Nonprescription treatment with pyrithione zinc shampoo can be used initially. Ketoconazole or selenium sulfide shampoo can be recommended if the patient prefers to use an alternative product. Hydrocortisone 1% ointment can be

Relevant Evaluation Criteria	Scenario/Model Outcome
account patient preferences.	applied to reddened areas if 1 week of treatment with medicated shampoo does not resolve redness.
6. Describe the recommended therapeutic approach to the patient or caregiver.	“For the first week, shampoo the hair with the medicated shampoo daily and also use it to wash affected areas of the face. Leave on for 5 minutes; then rinse off. For the next 4 weeks, repeat this procedure only 2–3 times per week. Regardless of the location of the lesions, the hair needs to be regularly shampooed to prevent relapse. Once the condition is controlled, the hair should be shampooed at least once a week to prevent relapse.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“You may use the pyrithione zinc, selenium sulfide, or ketoconazole shampoo according to personal preference and cost.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See the box “Patient Education for Dandruff and Seborrheic Dermatitis.”
Solicit follow-up questions from the patient or caregiver.	“What should I use on my hair on the days I do not use the medicated shampoo?”
Answer the patient’s or caregiver’s questions.	“Any type of nonmedicated shampoo is fine to use. One that does not leave a residue is preferred. Once your condition is controlled, daily use of a shampoo is not necessary unless your scalp is especially oily.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Platt in 1 week to assess his progress in resolving his seborrheic dermatitis.

Key: n/a = Not applicable; NKA = no known allergies.

Case 34-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient has had shiny scales bilaterally on her elbows for longer than 6 months. Some minor bleeding occurs when the scales are removed. She now complains of the development of lesions on both of her knees.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The lesions appeared to worsen after her recent divorce from her husband.
c. Description of the patient's efforts to relieve the symptoms	Use of hydrocortisone 1% cream once daily has been marginally effective. Application of lotion to the lesions is soothing.
d. Patient's identity	Elaine Abel
e. Patient's age, gender, height, and weight	43 years, female, 5 ft 6 in., 195 lb
f. Patient's occupation	Factory line worker
g. Patient's dietary habits	Reports normal diet
h. Patient's sleep habits	Averages 6-8 hours per night.
i. Concurrent medical conditions, prescription and nonprescription	<i>Diabetes</i> , diagnosed 2 years previously: fairly well controlled with metformin 500 mg twice daily;

medications, and dietary supplements	<i>hypothyroidism</i> present for 15 years: well controlled with levothyroxine 100 mcg once daily; <i>allergic rhinitis</i> , present for 20+ years: controlled with loratadine 10 mg once daily
j. Allergies	Penicillin (manifested as rash)
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Mrs. Abel showers once or twice daily.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 34-3).	Mrs. Abel possibly has a flare of psoriasis. The type of lesions and bilateral involvement support this assessment.
3. Identify exclusions for self-treatment (Figure 34-1).	The worsening symptoms and appearance of the lesions on the patient's knees indicate exacerbation of a medical condition that requires more than self-care.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mrs. Abel to her regular health care provider or a dermatologist for definitive diagnosis. (2) Recommend a nonprescription product (hydrocortisone ointment 1% and an appropriate emollient) to use until the appointment for medical evaluation. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer the patient to a dermatologist or other knowledgeable health care provider for definitive diagnosis and treatment.
6. Describe the recommended	"Contact your regular health care provider or a

therapeutic approach to the patient or caregiver.	dermatologist to accurately diagnose your condition. Until your appointment, you could switch to applying hydrocortisone ointment 1% to the affected areas 2 times daily. Wait 30 minutes and then liberally apply an emollient.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“You need to see your regular health care provider or dermatologist, because nonprescription therapy won’t be as effective as prescription medications for disease as extensive as yours.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See the box “Patient Education for Psoriasis” for nondrug measures to treat psoriasis.
Solicit follow-up questions from the patient or caregiver.	“I saw on the Internet that treatment with coal tar products is an option for psoriasis. Should I use one of these products?”
Answer the patient’s or caregiver’s questions.	“Although coal tar products have been used for a long time, use of a topical corticosteroid is now considered first-line topical therapy for most patients. The smell and mess associated with using coal tar products are major drawbacks, plus they have limited efficacy.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Call Mrs. Abel in 2 days to ensure that she made an appointment with her regular health care provider or a dermatologist.

Patient Education for Dandruff and Seborrheic Dermatitis

The primary objective of self-treatment for dandruff and seborrheic dermatitis is to reduce the turnover rate of skin cells, which is responsible for the scaly lesions. Controlling inflammation and itching of the affected areas is another treatment objective. Although these disorders are chronic and incurable, carefully following product instructions and the self-care measures can help ensure optimal therapeutic outcomes for many patients.

General Measures

- Nonpharmacologic approaches include avoiding environmental exacerbating factors such as physical trauma, ultraviolet light exposure, and chemical injuries; emotional or psychological stress; or use of alcohol and tobacco.
- Shampoo the hair with the medicated shampoo. Leave the shampoo on the hair for 5 minutes. Then rinse the scalp and face thoroughly.
- Use the shampoo for a minimum of 2 weeks to determine effectiveness; after 4 weeks of use, apply the shampoo once a week to control the condition.
- If you are experiencing persistent itching and inflammation, apply a thin layer of hydrocortisone cream no more than 2 times a day. Wash the affected area(s) before use.
- With use of medication and proper nondrug therapy, noticeable improvement could be observed within 7–14 days. Complete control of the disorder is possible with weekly use of the medicated shampoo. It is likely that exacerbations may occasionally appear, especially during the winter months.
- Stinging or burning may occur if a medicated shampoo enters the eyes.

Dandruff

- Use a medicated shampoo containing pyrithione zinc, selenium sulfide, or ketoconazole. If these agents are ineffective, consult your regular health care provider or a dermatologist. Massage the medicated shampoo into the scalp and leave on the hair for 3–5

minutes before rinsing. Repeated rinsing (2–3 times) after the desired contact time is suggested. Use the shampoo daily for 1 week; then use it 2–3 times weekly for 2–3 weeks, and thereafter once weekly or every other week to control the disorder.

- Coal tar products can be used; however, they have limited efficacy. Coal tar shampoos can stain light hair and cause *folliculitis* (inflammation of hair follicles), dermatitis, and *photosensitization* (sensitivity of the skin to sunlight).
- Keratolytic shampoos also can be used but require longer treatment periods.

Seborrheic Dermatitis

- More aggressive doses of the anti-*Malassezia* shampoos are used for seborrheic dermatitis than for dandruff. Regardless of the location of the lesions, the hair needs to be shampooed. The scalp always has the highest concentration of *Malassezia* yeasts and is the source of the fungus that causes skin lesions. Apply the shampoo to hair, scalp, and any lesions on face, hairline, or body; then massage these areas thoroughly. Use product once daily for 1–2 weeks; then reduce use to 2–3 times a week for the next 4 weeks. Use a medicated shampoo containing ketoconazole, pyrithione zinc, or selenium sulfide. Shampoo the hair and scalp, and apply shampoo directly to any lesions on the face and hairline. Washing the hair at least weekly with a cytostatic agent is absolutely essential to prevent relapses, even when lesions appear only on the face.
- If redness persists after therapy with medicated shampoos, apply hydrocortisone ointment 2 times a day until symptoms subside, and then apply the ointment intermittently to control acute exacerbations. Do not use this agent longer than 7 days. Prolonged use can cause rebound flares when the hydrocortisone is discontinued.

When to Seek Medical Attention

- Consult a knowledgeable health care provider or dermatologist if

clinical improvement does not occur or if the condition worsens after 2 weeks of treatment with nonprescription medications.

Patient Education for Psoriasis

The primary objective of self-treatment for psoriasis is to reduce the turnover rate of skin cells, which is responsible for the scaly lesions. Controlling inflammation and itching of the affected areas and hydrating the skin are other treatment objectives. Although psoriasis is chronic and incurable, carefully following product instructions and self-care measures can help ensure optimal therapeutic outcomes for many patients.

- For itchy, dry skin, use emollients and lubricating bath products (see [Chapter 33](#)). Remove scales by gently rubbing them with a soft cloth after the bath. Do not rub vigorously.
- Prevent flares by minimizing factors that you know are likely to exacerbate the disorder, such as emotional stress, skin irritation, and physical trauma.

When to Seek Medical Attention

- If you have psoriasis lesions plus joint pain, consult a knowledgeable health care provider or a dermatology or rheumatology specialist for treatment.
- Consult your primary care provider or a dermatologist for treatment with prescription products if hydrocortisone ointment and emollients are not effective, the affected area has more than a few lesions, or any lesion is larger than quarter size.
- Consult your primary care provider or a dermatologist if reduction in symptoms does not occur or if the condition worsens after 2 weeks of treatment with nonprescription medications.

Key Points for Scaly Dermatoses

- Mild to moderate scaly dermatoses often can be effectively managed with topical nonprescription products.
- Product selection should be based on the patient's history and previous response to treatment, as well as a careful evaluation of the risks and benefits associated with use of specific nonprescription products.
- A crucial component of management is patient education about the proper application of topical agents, which greatly affects the efficacy of therapy.

Chapter 35: Contact Dermatitis

Authors: Cortney M. Mospan

Contact dermatitis is a skin disorder characterized by inflammation, redness, and often vesicle and pustule formation, with symptoms of pruritus (itching), burning, and stinging, that develops subsequent to contact with an inciting exogenous substance.^{1,2} The two primary types of contact dermatitis, classified by etiology and presentation, are considered in this chapter. *Irritant contact dermatitis* (ICD) is an inflammatory skin reaction caused by exposure to an irritant substance. *Allergic contact dermatitis* (ACD) is an immunologic skin reaction elicited by an antigen formed in response to contact with an allergenic substance.¹

Contact dermatitis is a major cause of workplace disability.² More than 13 million U.S. workers are potentially exposed to chemicals absorbed through the skin each year.³ According to the U.S. Bureau of Labor Statistics, work-related skin disorders accounted for 18.5% of total workplace injuries in 2017, making occupational skin exposure the second most frequent cause of occupational disorders, with 2.3 cases per 10,000 workers.^{4,5} Overall, contact dermatitis causes 70%–90% of occupational skin diseases, with cosmetologists, cooks, florists, metalworkers, manufacturing workers, and those employed in cleaning, painting, agriculture, health care–related professions, and food service at greatest risk.⁶ Approximately 80% of the cases are ICD.^{2,6} The estimated cost of managing contact dermatitis, which includes treatment and workdays lost, is \$1 billion annually.⁷

Irritant Contact Dermatitis

Persons who frequently wash their hands, handle food, and/or have repeated contact with skin irritants, such as hairstylists and restaurant dishwashers, are at increased risk for development of ICD.^{1,8,9} Substances associated with ICD are listed in [Table 35–1](#). A majority of ICD cases are related to occupation, particularly jobs that involve work with water or exposure to irritant substances. ICD also occurs in the home; however, incidence statistics are available only for exposure associated with employment.

TABLE 35-1 Selected Substances Commonly Associated With Irritant Contact Dermatitis

- Acids, strong (e.g., hydrochloric, nitric, sulfuric, hydrofluoric)
- Alkalis, strong (e.g., sodium, potassium, calcium hydroxides)
- Detergents, soaps, and hand sanitizers
- Epoxy resins
- Ethylene oxide
- Fiberglass
- Flour
- Oils (e.g., cutting, lubricating)
- Oxidants, plasticizers, and activators in athletic shoe components
- Oxidizing agents
- Reducing agents
- Radiation
- Solvents
- Urine and feces
- Water
- Wood dust and products

Source: [References 11](#) and [14](#).

Pathophysiology of Irritant Contact Dermatitis

In most instances, ICD occurs on exposed skin surfaces, such as the face and dorsal surfaces of the hands and forearms. Clinical manifestations may follow a single exposure or develop only after multiple exposures of direct skin contact with a chemical or physical irritant.¹⁰

The three main steps in the pathogenesis of ICD are irritation of and disruption of the skin barrier, stimulation of epidermal cells, and release of proinflammatory cytokines that produce inflammation and skin changes.¹¹ The irritant may be absorbed through the cell membrane, thus destroying cell systems. Destruction to epidermal cells also may be a result of the release of cytokines from chemical exposure.^{1,7} ICD is a non-immune-modulated irritation of the skin by a substance.¹

Several factors may affect the magnitude of the skin response. The presence of existing skin conditions, such as atopic dermatitis, can result in a more profound dermatitis secondary to increased or enhanced permeability of the dermis. The quantity and concentration of substance exposure also affect the

severity of the response. Chemical irritants, acids, and alkalis are likely to produce immediate and severe inflammatory reactions. With mild irritants, such as detergents, soaps, and solvents, repeated exposures often are required before the dermatitis appears. Occlusive clothing and diapers can prolong skin contact with the irritant, promoting greater skin absorption of the irritant and leading to a more severe reaction. In addition, environmental factors such as warmer ambient temperature and higher humidity may contribute to more severe ICD.⁷

Clinical Presentation of Irritant Contact Dermatitis

After exposure to an irritant, the skin becomes inflamed, swells, and turns erythematous. Symptoms often are delayed in onset and generally do not occur immediately after exposure. ICD manifests primarily as dry or macerated, painful, cracked, and inflamed skin. Itching, stinging, and burning commonly accompany the rash. Lesions can develop into bullae, pustules, or coalescing vesicles that are well demarcated and confined to the contact area. The inflammatory reaction varies in severity, ranging from these initial symptoms to ulcer formation and localized necrosis.¹¹ Within days, the dermatitis may crust. If the patient avoids further contact with the irritant, the dermatitis generally resolves in several days.

In patients chronically exposed to an irritant, the affected areas of skin will remain inflamed, may develop fissures and scales, and may become hyper- or hypopigmented.¹ Some patients with chronic ICD recover completely despite continued exposure, whereas others improve but continue to have recurrences. In some cases, chronic exposure to an irritant may lead to necrosis, inflammation, and crusting comparable to or worse than the skin changes observed with the original insult. A finding specific to chronic forms of ICD is *lichenification*, or leathery thickening of the skin.¹

Treatment of Irritant Contact Dermatitis

Treatment Goals

The goals of self-treatment for ICD are (1) to remove the offending agent and to prevent future exposure to the irritant; (2) to provide prompt treatment to

prevent development of chronic dermatitis; (3) to relieve the inflammation, dermal tenderness, and irritation; and (4) to educate the patient on self-management to prevent or treat recurrences.¹²

General Treatment Approach

The primary treatment advice is use of preventive measures to avoid further irritant exposure and appropriate selection and use of therapy. Medical referral is indicated for children younger than 2 years; for patients with involvement of the eyes, eyelids, mouth, face, neck, and genitals; and for patients with dermatitis that involves >10% of the skin's surface. Medical referral also is appropriate when (1) the rash has not decreased in severity within 1 week and (2) chronic dermatitis symptoms are present.

Nonpharmacologic Therapy

Patients should wash the exposed area with copious amounts of lukewarm water and cleanse with a mild or hypoallergenic soap, such as Cetaphil or Dove, to reduce contact time with the irritant and to minimize local symptoms.^{2,13} Patients also can use a saline soak (in a solution of 1 teaspoon of salt dissolved in 1 pint of water) to remove the irritant.¹¹

Pharmacologic Therapy

Removal of the irritant can be achieved by soaking the affected area in Burow's solution (aluminum acetate 5% solution), which has anti-inflammatory, cooling, and antibacterial effects.¹¹ Liberal application of emollients, especially those with high lipid content, to the affected area can restore moisture to the stratum corneum, accelerate regeneration of the skin barrier, and protect the area from further exposure.⁹ Petrolatum is considered the gold standard for prevention of epidermal water loss. Barrier creams can accelerate the rate of healing in damaged skin by promoting increased hydration.¹¹ Colloidal oatmeal baths may help relieve itching.¹

Topical corticosteroids do not target the pathophysiologic process of ICD, and the available evidence is insufficient to support a recommendation for their use in treatment of this condition. Differentiation of ICD from ACD is difficult, however, and these agents may reduce inflammation and relieve itching.¹ Prolonged use has been shown to increase risk for development of ICD.¹¹

Topical caine-type anesthetics and agents commonly found in therapeutic products, including propylene glycol, lactic acid, and salicylic acid, should be avoided because of their ability to cause further skin irritation and potential ACD.¹⁴

Preventive Measures

Irritant exposure can be reduced by using protective clothing, gloves, or other equipment. Frequent changes in coverings can limit the time skin areas are occluded. Routine application of postexposure barrier creams can prevent dermatitis, but the benefit of preexposure application is more questionable.¹⁵ However, an expert panel of dermatologists recommends prophylactic barrier cream application before starting a work period, after washing hands, and after completing a work shift to prevent occupational contact dermatitis.¹⁶ Barrier creams inhibit or delay cutaneous absorption of irritants to reduce effects, but when used alone, they probably do not have a clinically important protective effect. Moisturizers, used alone or in combination with barrier creams, provide a clinically important protective effect for primary prevention of ICD.¹⁷

Water-in-oil emulsions are beneficial against aqueous solutions of irritations, whereas oil-in-water emulsions are beneficial for lipophilic materials. If the irritant is an acid, alkaline, detergent, or water-soluble irritant, a water-repellant barrier cream should be selected.⁹ Oil-repellant type barrier creams are protective against oil, varnishes, and organic solvents. Treatment selection also varies based on acuity of symptoms. With acute ICD, hydrophilic preparations (gel, lotion, or cream) generally are sufficient to provide moisture to the skin barrier, whereas with chronic ICD, water-in-oil-based preparations (i.e., ointments) are more likely to be effective.¹⁷

Despite limited evidence to determine clinical efficacy, emollients, moisturizers, and barrier creams can be recommended to assist in repairing the epidermis and to prevent future exposures.⁸ (See [Chapter 33](#) for more information on these products.) Available evidence supports use of barrier creams for protection against hydrophilic solvents and detergents, but benefit against lipophilic solvents is debatable.⁹ Lipid-rich moisturizers and moisturizers containing urea (in concentrations of 5% or greater) or glycerin in particular also have been shown to be of benefit in ICD.¹² Avoidance of hazardous agents is the best prevention strategy for ICD.¹³

Allergic Contact Dermatitis

Some 3000 chemicals have been cited as substances causing ACD.¹⁸ The most common causes of ACD in the United States are poison ivy, poison oak, and poison sumac, as well as nickel used in jewelry, clothing, and electronics. Nickel is found in some food items, but dermatitis related to nickel generally is localized to areas of contact.^{18,19} Approximately 19% of patients patch-tested for allergies are allergic to nickel, including 11 million children in the United States.^{19,20} Latex allergy is common in health care workers and other frequent wearers of latex gloves, and the latex found in waistbands and sock cuffs also can cause ACD. Fragrances, cosmetics, and skin care products are other common potential allergens.¹⁸ **Table 35–2** lists selected allergenic substances.

TABLE 35–2 Selected Substances Commonly Associated With Allergic Contact Dermatitis

Allergen	Sources
Balsam of Peru	Cough syrups, flavorings
Benzocaine	With sensitivity to caine-type anesthetics, crossover allergy observed with other caine-type local anesthetics, topical medications (for skin, eye, ear), other oral medications
Chromium salts	Potassium dichromate electroplating, cement, leather-tanning agents, detergents, dyes
Cobalt chloride	Cement, metal plating, pigments in paints
Colophony (rosin)	Rosin cake for string instrument bows, sport rosin bags, cosmetics, adhesives
Epoxy resins	Constituents before mixing and hardening
Formaldehyde	Germicides, plastics, clothing, glue, adhesives
Fragrances	Cosmetics, household products, eugenol, cinnamic acid, geraniol, oak moss absolute
Lanolin	Lotions, moisturizers, cosmetics, soaps
Latex	Gloves, syringes, vial closures, elastic waistbands, socks, condoms

Allergen	Sources
Nickel sulfate	In jewelry, blue jean studs, utensils, pigments, coins, tools, many metal alloys encountered daily
Neomycin sulfate	Medications, antibiotic ointments, other aminoglycosides
Plants	<i>Toxicodendron</i> species (poison ivy, oak, sumac), primrose (<i>Primula obconica</i>), tulips, others
Rubber (carba mix)	Added ingredients, accelerators, activators, other processing chemicals
Thimerosal	Preservative in many medications, injectables, cosmetics

Source: [References 1, 14, 18, and 25](#).

Pathophysiology of Allergic Contact Dermatitis

ACD is a delayed hypersensitivity reaction resulting from exposure to a foreign substance that acts as an allergen. Sensitized T cells are activated and migrate to the site of contact to release inflammatory mediators. The rash of ACD ordinarily does not appear on first contact but develops after the exposed person has been previously sensitized to that allergen.¹⁰ ICD often is a precursor to further contact sensitization and subsequent ACD.²¹ The pathophysiologic process leading up to clinical manifestation of the dermatitis consists of several steps: during the induction phase, initial exposure to the antigen sensitizes the immune system. Subsequent contact with the antigen induces a cell-mediated, type IV delayed hypersensitivity reaction, within 24 hours to 21 days. This reaction results in dermatitis and symptoms associated with ACD. In persons previously sensitized, the rash and related symptoms typically appear within 24–48 hours after exposure.^{1,14,18}

Urushiol-Induced Allergic Contact Dermatitis

In the United States, four species of *Toxicodendron* plants belonging to the family Anacardiaceae—Northern or Western poison ivy, Eastern and Western poison oak, and poison sumac—cause dermatoses on exposure ([Table 35–3](#)). As much as 80% of the U.S. population is estimated to be sensitive to urushiol, the

allergic oily sap in these plants. On exposure, urushiol enters the skin within 10 minutes, beginning the sensitization process. Poison ivy/oak/sumac dermatitis has been reported in toddlers, but sensitivity increases into adulthood; of interest, sensitivity appears to be reduced in older persons, but the rash tends to take longer to heal.²²

TABLE 35-3 Toxicodendron Plants Indigenous to North America

Plant	Other Common Names	Common Geographic Location(s)
Poison ivy (<i>Toxicodendron radicans</i>)	Poison vine, mark weed, three-leaved ivy, poor man's liquid amber	Present throughout North America, ranging throughout the United States (Central Plains, Midwest, south central, southeastern, lower Mississippi Valley regions); Canada (Ontario, Nova Scotia); and Mexico
Poison oak, Eastern (<i>Toxicodendron toxicarium</i>)	–	Grows widely in the southeastern United States
Poison oak, Western (<i>Toxicodendron diversilobum</i>)	–	Present throughout the Pacific Coast
Poison sumac (<i>Toxicodendron vernix</i>)	Poison elder, poison ash	Present from Quebec to Florida, primarily in the eastern third of the U.S. coast

Source: [References 24](#) and [25](#).

A person who exhibits sensitivity to one *Toxicodendron* species generally is allergic to all of them. These species are most easily identified as having three leaves emanating from a central stem, with the middle leaflet appearing at the terminal end of the stem. Although “Leaves of three, let it be!” is a helpful warning, some members of the genus differ in the number of leaflets attached to the central stalk.²³

Urushiol is contained and carried within resin canals of the plant. The release

of urushiol occurs only through damage to the plant, either directly by a human agent or from natural causes (e.g., wind, rain, insects, animals).²³ Unwashed, contaminated hands, feet, clothes, or shoes may transfer urushiol to other areas of the body and to other persons. Dermatitis can occur on any skin surface, including the eyes, lips, underarms, buttocks, anus, and genitalia, on contact with or transfer of urushiol.

Poison Ivy

The most common *Toxicodendron* plant found throughout central and northeastern United States and Canada is poison ivy (*Toxicodendron radicans* and *Toxicodendron rydbergii*). The leaves are reddish in the spring, green in the summer, and yellow, orange, or red in the fall. The plant may have greenish-white flowers and whitish-yellow berries. It commonly grows up poles, trees, and buildings, and along roads, hiking trails, streams, dry rocky canyons, and embankment slopes. (See [Color Plates](#), photograph 19A.) *Toxicodendron radicans* is composed of nine subspecies of small shrubs or climbing vines with aerial rootlets. Each leaf has three glossy leaflets with smooth or toothed edges. *Toxicodendron rydbergii* is a dwarf shrub with large, broad, spoon-shaped leaves that have a hairy underside; *T. rydbergii* is the principal variety of poison ivy growing in the northern United States and southern Canada.²³

Poison Oak

Two species of poison oak are indigenous to the United States: *Toxicodendron diversilobum*, which grows in tall clumps or as long vines along the West Coast, and *Toxicodendron toxicarium*, a low-growing shrub found in the eastern and southern areas of the United States. Both species possess leaves similar to those of oak trees, with three fuzzy leaflets per stem. Leaflets edges may be unlobed, lobed, or deeply toothed with rounded tips. The plant may have yellow-white berries. (See [Color Plates](#), photograph 19B.) It is found along streams, in thickets, on wooded slopes, and in dry woodlands. Western poison oak (*T. diversilobum*) may have 3–11 leaflets per stem, with leaves similar to those of California live oak.²⁴

Poison Sumac

Poison sumac (*Toxicodendron vernix*) grows in remote areas of the eastern third and Midwest areas of the United States in bogs and swampy areas. It appears as a tall shrub or small tree, attains a height of roughly 9.8 feet (3 m),

and may resemble an elder or ash tree. Hence, it is also known as “poison elder” and “poison ash.” Its leaves are odd-numbered and pinnate and may be 16 inches (40 cm) long, with 7–13 smooth-edged leaflets that come to a tip. The leaves are orange in the spring, green in the summer, and yellow, orange, or red in the fall. The plant may have greenish-yellow flowers and whitish-green fruits that hang in clusters.^{24,25} (See [Color Plates](#), photograph 19C.)

Clinical Presentation of Allergic Contact Dermatitis

General Presentation

Although ACD and ICD can have similar clinical presentations, ACD is initially distinguished from ICD by the distribution and presentation of the rash, with differentiation more difficult in chronic cases.¹⁵ Furthermore, ACD and ICD often coexist.¹¹ Both ICD and ACD can occur anywhere on the body that is exposed to an irritant, but ICD often is limited to the hands and forearms as a result of occupational exposure. The rash in ACD typically is limited to the area of antigen contact and the immediate surrounding area. Unlike those in ICD, ACD lesions are not well circumscribed and frequently disseminate. For example, reactions to latex gloves involve only the areas covered by the glove and immediately surrounding areas.¹¹ Sensitivity to latex in undergarments occurs in areas of direct contact, such as the waist (in waistbands) or calves (in sock cuffs). The lesions of urushiol-induced ACD, however, often are linear in distribution and/or occur over a broad area, as urushiol may be transferred to other parts of the body from the hands or inanimate objects. ACD generally manifests with papules, small vesicles, and/or bullae over inflamed, swollen skin. Erythema at the site of contact is common. Stronger reactions can include rupture of vesicles, with oozing and weeping and subsequent crust formation.²⁶ Significant itching is a prominent feature of ACD. Chronic forms of ACD may feature lichenification.^{1,14,18}

Presentation of Urushiol-Induced Dermatitis

Symptoms occur only where contact was made with urushiol and begin within a few hours, generally 24–48 hours after contact. The rash does not spread but may appear to do so, as urushiol is absorbed at different rates at different anatomic sites. The affected person also may incur inadvertent repeated

exposure from contaminated objects, clothing, or bed linens or from transfer of urushiol under the fingernails during scratching. Intense itching of exposed skin surfaces is followed by erythema and formation of vesicles or bullae. Presentation depends on patient sensitivity and extent of exposure. The vesicles or bullae may break open, releasing their fluid contents. This fluid does not contain antigenic material and is not a vector for transfer of irritant to other areas of the body or to other people. Patients should be educated that the development of the rash over time in different areas is caused by the response time, skin thickness, and severity of exposure. Oozing and weeping of vesicular fluid generally occur for several days. Papules and plaques may develop in addition to or instead of vesicles and bullae (see [Color Plates](#), photograph 20A). Streaks of vesicles that correspond to the points of urushiol contact from the damaged plant suggest *Toxicodendron* exposure (see [Color Plates](#), photograph 20B). In the last stage of the dermatitis, the affected areas undergo crusting and begin to dry (see [Color Plates](#), photograph 20C).

Severity of Poison Ivy/Oak/Sumac Dermatitis

Mild dermatitis is localized to the unprotected areas of the body that were exposed to the urushiol oil. Linear streaks may be seen, and itching may be minimal. Signs of moderate dermatitis include the appearance of erythema, bullae, papules, and vesicles and inflammation of the exposed skin, in addition to pruritus. Severe dermatitis is distinguished by extensive involvement and edema of the extremities and/or face. Involvement of the eyelids, caused by rubbing them with urushiol-contaminated hands, may occur, with the lids swollen shut in severe cases. Extreme itching, marked irritation and formation of numerous vesicles and bullae may limit daily activities.²⁷ Medical referral for systemic therapy is warranted with dermatitis or edema affecting the eyes, genitalia, face, neck, or large surface areas, as well as secondary infections from scratching.²⁸

Treatment of Allergic Contact Dermatitis

Treatment Goals

The goals of self-treatment for ACD are (1) to remove and avoid further contact with the offending agent; (2) to treat the inflammation; (3) to relieve itching and prevent excessive scratching; (4) to relieve the accumulation of debris from oozing, crusting, and scaling of the vesicle fluids; and (5) to prevent

secondary skin infections.

General Treatment Approach

Because of intense itching and discomfort, the widespread nature of the dermatitis, and/or the magnitude of other symptoms, patients will seek advice on treatment for ACD. Treated or untreated dermatitis will naturally resolve in approximately 10–21 days as a result of defense mechanisms of the patient's own immune system. Topical nonprescription products may be used for symptomatic relief.^{1,29,30} Removing the antigen from the skin as soon as possible may reduce the risk of a full-blown immune reaction and the severity of the immune response (e.g., avoiding jewelry or leather watch bands; switching to latex-free underwear and socks; washing urushiol-contaminated clothes; washing affected areas of the body with mild soap and lukewarm water).

In general, the first several days after the initial appearance of ACD are the most uncomfortable. Treatment depends on the severity of the symptoms from the antigenic reaction ([Figure 35–1](#)). Hydrocortisone 1% cream may be applied to localized areas to reduce inflammation and relieve itching. The cream allows weeping lesions to dry and is preferred over the occlusive ointment for weeping areas. Topical corticosteroids may contain contact sensitizers and can contribute to ACD. This possibility does not rule out use, but ACD secondary to topical corticosteroid ingredients should be considered when the patient does not respond to topical treatment or experiences a flare-up after medication application.³¹ The patient also may use astringent compresses and lukewarm baths to dry oozing vesicles.

Other symptomatic treatment options include use of products containing calamine to assist in drying and colloidal oatmeal baths to relieve itching. Patients should be advised that calamine leaves a visible pink film on the skin, and that colloidal oatmeal makes the bathtub slippery and can clog the drain if residual oatmeal clumps are not removed.

Medical referral is indicated for children younger than 2 years; for patients with involvement of the eyes, eyelids, mouth, and genitals; and for patients with dermatitis that involves more than 20% of the skin's surface when urushiol-induced ACD is suspected.³² For other suspected causes of ACD, dermatitis cases that involve more than 10% of the skin's surface should be referred for

medical evaluation and treatment.³³ Medical referral also is appropriate when (1) signs and symptoms of infection occur (temperature >100.0°F [>37.8°C] or presence of pus or tenderness on the rash); (2) numerous large bullae are present; or (3) the rash has not begun to abate within 1 week.

Nonpharmacologic Therapy

Prevention of Urushiol-Induced Allergic Contact Dermatitis

Patients presenting with ACD should be provided with descriptions and/or photographs of *Toxicodendron* plants. Persons involved in outdoor work or activities should survey the surrounding vegetation to determine the potential risk of exposure and, if needed, take preventive measures. Table 35–4 provides preventive and protective measures, including how to clean contaminated clothing and items. Urushiol may linger on almost any surface for years until it is washed off with soap and water or rubbing alcohol.²⁷

TABLE 35–4 Preventive and Protective Measures for Poison Ivy/Oak/Sumac Dermatitis

Preventive Measures

- Learn the physical characteristics and usual habitat of *Toxicodendron* plants. When outdoors, survey the area to assess potential risk for *Toxicodendron* exposure.
- Cover nose and mouth with a mask and wear protective clothing when eradicating *Toxicodendron* plants near your residence. Mechanically remove the plant and its roots, or apply an herbicide recommended by the state farm bureau or the U.S. Department of Agriculture (USDA) extension services. Do not burn the leaves or roots of *Toxicodendron* plants.

Protective Measures

- Wear protective clothing to cover exposed areas.
- Immediately after exposure, remove and wash clothes with ordinary laundry detergent.
- Wash contaminated clothing separately from noncontaminated clothing.
- Wash bed linens to prevent the transfer of urushiol to other parts of the body.
- Take a shower or wash suspected areas of exposure with soap as soon as possible. Avoid tub baths after initial exposure, because oleoresin may remain in the tub and contaminate body areas that were not originally exposed.
- Clip and meticulously clean fingernails to avoid transferring entrapped urushiol to other skin surfaces.
- If dry cleaning clothes, put contaminated clothing in a plastic bag for transport, and warn facility personnel of possible contamination.
- As soon as possible, thoroughly wash shoes, gloves, jackets or other protective garments,

- sports equipment, garden and work tools, and equipment suspected of carrying urushiol.
- Wear vinyl gloves when washing contaminated objects.
 - Bathe pets after known or suspected exposures to *Toxicodendron* plants.

Source: [References 24](#) and [25](#).

Eradication of Toxicodendron Plants

The eradication of *Toxicodendron* plants may be required when extremely sensitive persons live in close proximity to the plant and its oleoresin. It is essential to cover the nose and mouth with a mask for the eradication process, which should *never* include burning. Patients presenting with *Toxicodendron* ACD in midwinter or during off-season periods may have come in contact with urushiol-contaminated objects. Urushiol remains active within dead and dried parts of plants and on inanimate objects for prolonged periods, sometimes years. It is not unusual for an object to become contaminated with urushiol during the growing season and retain its antigenicity over the winter, causing rashes with each use of the object in succeeding seasons. Apparel including shoes and outerwear, upholstery and carpets, garden and work tools, and recreational and camping equipment such as golf clubs, baseball bats, fishing rods, and tents all have been implicated in such recurrent reactions. Urushiol often is carried into the home or transferred to the person's skin on the fur of pets.^{24,34}

Removal of Antigen at Time of Exposure

Urushiol quickly binds to skin, but it is readily degraded in the presence of water. Washing exposed areas with mild soap and water reduces the risk of transfer and the severity of the rash. Immediate washing is preferred, although washing within 30 minutes of contact may remove urushiol that has not yet entered the dermal layers. Once urushiol has entered the skin and attached to tissue proteins, the antigenic process and reaction begins.^{2,35} Good handwashing technique, including meticulous cleansing under or clipping of the fingernails, is necessary to avoid contaminating additional skin surfaces. Antigen removal methods such as vigorous scrubbing of contaminated skin with a harsh soap or household bleach and use of isopropyl alcohol, hand sanitizers, or other cleansers and organic solvents are not recommended

because they may cause further damage to the skin.

Several products are marketed to wash or cleanse the skin after urushiol exposure. Product prices range widely, and cost should be a consideration in selecting a product. One such product, Zanafel, a poison ivy, oak, and sumac wash (a mixture of alcohol solubles and anionic surfactants), is a topical soap scrub that can be used at any time subsequent to urushiol exposure, even after rash develops, to provide relief from pain and itching. It is intended to prevent or relieve the rash by bonding with urushiol within the dermal layer of the skin to create an aggregate that can be washed away with water.³⁶ Small-cohort studies suggest that Zanafel ameliorates or prevents *Toxicodendron*-induced ACD and reduces the redness and blistering after urushiol exposure, but larger-scale studies are needed to confirm Zanafel's efficacy.^{37,38} Tecnu Original Outdoor Skin Cleanser is another agent formulated for removal of urushiol from the skin to prevent rash and itching. The product contains deodorized mineral spirits, water, propylene glycol, octylphenoxypolyethoxyethanol, mixed fatty acid soap, and fragrance. TEC Labs also markets Tecnu Extreme Medicated Poison Ivy Scrub, which contains the anti-itch ingredient Grindelia robusta 3X.³⁹Table 35–5 provides usage guidelines for these three products.

TABLE 35–5 Usage Guidelines for Products That Remove Urushiol
Zanafel 1. Wet the affected area. 2. Measure 1½ inches of the extruded product into one palm. 3. Wet both hands and rub the product into a paste. 4. Rub both hands on the affected area until complete relief of itching is obtained (for up to 3 minutes). 5. Rinse the affected area thoroughly. 6. If itching returns after several hours, the product may be used again.
Tecnu Original Outdoor Skin Cleanser 1. Apply product to dry, contaminated areas as soon after exposure as possible. 2. Cleanse the treated skin areas by rubbing vigorously for 2 minutes. 3. Wipe away product using a cloth, or rinse off with cool water. 4. Product can be used up to 8 hours after exposure to remove any free oil from the skin. 5. Product also may be used to remove urushiol from objects and pet fur.
Tecnu Extreme Medicated Poison Ivy Scrub

1. Squeeze product into the palm of one hand.
2. Add an equal amount of water to the product and mix.
3. Apply the product to affected skin, and gently rub the area for 15 seconds.
4. Rinse with cool water and gently towel dry.
5. Repeat as needed.

Source: [References 36](#) and [39](#).

A study evaluated the efficacy of three different agents for post-contact rash prevention versus no treatment: a chemical inactivator (Tecnu), a surfactant (Dial Ultra dishwashing soap), and an oil-removing compound (Goop). All three products provided good protection against development of poison ivy rash when used to cleanse skin exposed to urushiol. The difference in protective ability among the products was not significant, but Tecnu had a substantially higher cost.⁴⁰

Relief of Itching

Cold or lukewarm soapless showers temporarily relieve the itching associated with ACD. Hot showers typically intensify itching and may cause scalding or thermal skin injuries to affected areas. Patients may use hypoallergenic soap to maintain cleanliness. Patients should trim fingernails to reduce the risk of secondary bacterial skin infections from scratching.

Pharmacologic Therapy

Pruritus (Itching)

Topical ointments and creams containing anesthetics (e.g., benzocaine), antihistamines (e.g., diphenhydramine), or antibiotics (e.g., neomycin) should not be used for pruritus related to ACD. These agents are known sensitizers and can cause a drug-induced ACD superimposed on the existing ACD.⁴¹ If the patient requires nighttime sedation because of itching, then first-generation oral antihistamines can be used.⁴¹ If itching is not alleviated, referral to a primary care provider for further care may be indicated.

Weeping

Astringents applied to unhealthy serous skin or mucous membranes will decrease weeping, oozing, discharge, or bleeding from dermatitis. They decrease edema, exudation, and inflammation by reducing cell membrane permeability and by hardening the intercellular cement of the capillary epithelium. When applied as a wet dressing or compress, astringents cool and dry the skin through evaporation. They induce vasoconstriction, thereby reducing blood flow in inflamed tissue. In wet dressing form, they also allow cleansing the skin of exudates, crust, and debris. Because astringents generally have low cell penetrability, their activity is limited to the cell surface and interstitial spaces. The protein precipitate that forms may serve as a protective coat, allowing new tissues to grow underneath.

Aluminum acetate solution USP (i.e., Burow's solution) contains approximately 5% aluminum acetate. Its drying ability likely involves complexing of the astringent agent with proteins, thereby altering their ability to swell and hold water. [Table 35–6](#) provides guidelines for preparing and applying Burow's solution to affected areas. In addition to softening and removing crusting, Burow's solution has a mild antipruritic effect.^{[18,42](#)}

TABLE 35–6 Usage Guidelines for Burow's Solution

- Prepare a 1:40 aluminum acetate solution (i.e., Burow's solution) using prepackaged tablets or powder, or add 1–3 tablets or powder packets to 1 pint of cool tap water.
- Stir or shake until fully dissolved.
- Soak affected area 15–30 minutes 3–4 times daily.
- Alternatively, loosely apply a compress to the affected area:
 - Prepare compress by soaking a washcloth, cheesecloth, or small towel in the prepared solution.
 - Gently wring the compress and apply it to the affected area.
 - Rewet and reapply the compress for 20–30 minutes, 4–6 times daily.
- Prepare a fresh container of solution for each soak or application of a compress.

Source: [References 18](#) and [42](#).

Inflammation

Hydrocortisone (0.5% and 1%) is the most effective nonprescription topical agent for treating symptoms of mild to moderate ACD that does not involve edema or extensive areas of the skin. Hydrocortisone is a low-potency corticosteroid capable of vasoconstriction, thereby reducing inflammation and pruritus. It is approved for use in minor skin irritations, itching, and rashes caused by eczema, insect bites, poison ivy, poison oak, poison sumac, soaps, detergents, cosmetics, and jewelry.^{43,44} Urushiol ACD may require a prescription corticosteroid, as the nonprescription strength may be too weak to allow effective treatment of the rash.³² Hydrocortisone is recognized as safe to apply to all parts of the body except the eyes and eyelids. Although systemic absorption is minimal with intact skin, use of topical hydrocortisone over large surface areas, prolonged use, use with an occlusive dressing, or use when skin integrity is compromised can lead to significant systemic absorption. Hydrocortisone cream can be applied as frequently as 3–4 times per day.^{32,43,44}

Generally, topical hydrocortisone is well tolerated, with limited adverse reactions such as a subjective sensation of burning and irritation. Pharmacists should be aware that topical hydrocortisone may rarely cause contact dermatitis.^{44,45} No dressing or bandages should be applied when hydrocortisone is used in self-care treatment. Topical hydrocortisone should not be used in children younger than 2 years of age, except as advised by the family's primary care provider or pediatrician. Other contraindications include persistence of the dermatitis beyond 7 days and reemergence of symptoms a few days after initial clearing, unless the patient is under medical management. When greater than 20% of the body is affected, systemic therapy is recommended, for which referral to an appropriate health care provider is indicated.³²

Product Selection Guidelines

Special Populations

Treatment of contact dermatitis in pediatric patients is similar to the approach used in adults. Emollients, barrier creams, and topical corticosteroids can be used in pediatric patients as described for adults (in accordance with product label instructions). Of note, however, children younger than 8 years of age are more susceptible to systemic absorption of topical pharmacologic agents.¹¹ Use of pharmacologic products in pediatric patients younger than 2 years

without the advice of a pediatrician is discouraged.²⁷

Topical preparations generally are considered safe for use during pregnancy, so long as they are not used for long periods or over extensive areas of the body.⁴⁶ The risk of adverse effects in pregnancy is considered limited with low-potency, topical nonprescription formulations.^{47,48} Other topical preparations (e.g., calamine, colloidal oatmeal, aluminum acetate) are in the “undetermined” pregnancy category. The same precautions described for self-treatment in adults apply in pregnant women. For other treatments, pregnant patients should be referred for medical evaluation. (See the Preface for a detailed explanation of the pregnancy data.)

Older adults should avoid first-generation antihistamines (e.g., diphenhydramine) because of associated sedation and anticholinergic effects. Relief of pruritus should be a primary concern in patients in this age group because of the increased risk for skin damage and infections secondary to scratching. Oatmeal baths and creams and topical hydrocortisone, if used on a small area, can be used to manage itching in these patients.

Patient Preferences

Nonprescription medications for ACD are available in numerous dosage forms. *Creams* are quickly absorbed into the skin, so they allow vesicle fluid to flow freely from blisters and do not trap bacteria. Because a cream is an oil-in-water emulsion, it tends to be drying and is best for use with open weeping lesions. In addition, creams are more cosmetically appealing to patients.⁴⁸ *Gels* offer ease of application and rapid absorption of active ingredients into the skin. Some gels may contain alcohol or similar organic solvents that may cause irritation or burning when applied to open lesions. The use of *ointments* is not recommended when weeping lesions are present. Ointments also should not be applied to open lesions because they may trap bacteria beneath the oleaginous film, potentially leading to secondary infections. *Spray* products are convenient and easily applied to large areas of skin. The use of a spray does not require touching the dermatitis, which could trigger itching. However, aerosol sprays may contain propellants that can cause inflammation and/or alcohol, which causes drying and irritation. [Table 35–7](#) lists specific products to treat poison ivy/oak/sumac dermatitis.

TABLE 35–7 Selected Nonprescription Topical Products for Treatment of Poison Ivy/Oak/Sumac Dermatitis

Trade Name	Primary Ingredient(s)
Aveeno Soothing Bath Treatment	Colloidal oatmeal 100%
Burow's solution	Aluminum acetate 5%
Caladryal Lotion	Calamine 8%; pramoxine hydrochloride 1%
Cortaid Cream	Hydrocortisone cream 1% or 0.5%
Domeboro Astringent Solution Powder Packets	Aluminum sulfate 1347 mg; calcium acetate 952 mg
Ivarest Poison Ivy Itch Spray	Pramoxine HCl 1%, zinc acetate 0.12%

Assessment of Contact Dermatitis: A Case-Based Approach

Circumstances surrounding the emergence of the symptoms and skin changes can help determine the type of dermatitis ([Table 35–8](#)). The main factors that help to distinguish ICD from ACD are (1) history of irritant or allergen exposure, (2) history of known sensitivity on previous exposure, (3) time from exposure (at home, at work, during recreation) to appearance of rash, (4) distribution and appearance of the lesions, (5) severity of symptoms, and (6) improvement of the dermatitis with avoidance of irritants.^{1,2,14,18} Much of the information that distinguishes between ICD and ACD is obtained by taking the patient's history; the distribution and appearance of lesions will be the only factor directly observable at the time of the patient interview. Determining the type and success of previous treatments of similar rashes will aid in selecting appropriate nonprescription medications.

TABLE 35–8 Differentiation of Irritant and Allergic Contact Dermatitis

Symptom or Characteristic	Irritant Contact Dermatitis	Allergic Contact Dermatitis
Itching	Yes, later	Yes, early
Stinging, burning	Early	Late or not at all

Symptom or Characteristic	Irritant Contact Dermatitis	Allergic Contact Dermatitis
Erythema	Yes	Yes
Vesicles, bullae	Rarely or no	Yes
Papules	Rarely or no	Yes
Dermal edema	Yes	Yes
Time to reaction (rash) after exposure	Dependent on irritant	Dependent on antigen
Appearance of symptoms in relation to exposures	Initial or repetitive exposures	Delayed for first exposure; in subsequent exposures, varies according to antigen and sensitivity
Causative substances	Water, urine, flour, detergents, hand sanitizers, soap, alkalis, acids, solvents, salts, surfactants, oxidizers	<i>Toxicodendron</i> plants, fragrances, nickel, latex, benzocaine, neomycin, leather
Substance concentration at exposure	Important	Less important
Mechanism of reaction	Direct tissue damage	Immunologic reaction
Common location	Hands, wrist, forearms, diaper area	Anywhere on body that comes in contact with antigen
Rash/lesions	Demarcated, confined to contact area	Uncircumscribed, frequently disseminate

Source: [References 1, 14, 18, and 19](#).

Cases 35–1 and 35–2 illustrate the assessment of two patients with different presentations of contact dermatitis.

Patient Counseling for Contact Dermatitis

For a patient who presents with possible ICD or ACD but cannot identify contact with irritant chemicals, allergens, or *Toxicodendron* plants, counseling should begin with a review of chemicals or allergens likely to cause dermatitis. Then preventive and protective measures, as well as nonprescription pharmacologic treatment options, should be explained. Information about specific nonprescription agents should include clinical purpose and appropriate use, possible adverse effects, expected time to obtain relief, and signs and symptoms that warrant medical referral for further evaluation. An important self-care consideration is that even though skin may appear normal on initial resolution of the ICD rash, it will take weeks to months for the skin barrier to return to normal, so extra care to protect the skin is necessary.⁴⁹

The box “Patient Education for Contact Dermatitis” lists specific information to provide in patient counseling.

Algorithm: Allergic Contact Dermatitis

FIGURE 35–1 Self-care for contact dermatitis. Key: ACD = Allergic contact dermatitis; ICD = irritant contact dermatitis.

Case 35–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature,	The patient is seeking treatment for a rash on both hands and wrists. She has been working as a cosmetologist for 3 years but

Relevant Evaluation Criteria	Scenario/Model Outcome
onset, duration, severity, associated symptoms)	recently changed the brand of products she uses in her salon. She also washes her hands frequently and is exposed to water and chemicals throughout the day. The rash is inflamed, and her skin also is dry and cracked. Upon examination, no vesicles, bullae, open lesions, or signs of infection are evident. Skin changes are limited to the lower arms.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The problem worsened as she started working longer shifts and stayed booked with more clients. Dryness and itching progressively increased over the past month.
c. Description of the patient's efforts to relieve the symptoms	She tried a "generic lotion" she had on hand, and although it felt soothing upon application, no improvement occurred and the rash persisted.
d. Patient's identity	Stacey Martinez
e. Patient's age, gender, height, and weight	28 years, female, 5 ft 8 in., 150 lb
f. Patient's occupation	Cosmetologist
g. Patient's dietary habits	Normal diet with weekend use of alcohol
h. Patient's sleep habits	Averages 6–7 hours of sleep per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	The patient has taken the same oral contraceptive (ethinyl estradiol/levonorgestrel) for the past 6 years. She occasionally uses ibuprofen 400 mg by mouth every 6 hours as needed for headache.
j. Allergies	Amoxicillin (hives)
k. History of other adverse reactions to medications	None
l. Other (describe) -----	n/a
Assess	

Relevant Evaluation Criteria	Scenario/Model Outcome
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Ms. Martinez is suffering from irritant contact dermatitis. The likely source is the chemicals used in hair products and dyes, with excessive hand washing on the job as a background factor.
3. Identify exclusions for self-treatment (Figure 35-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Martinez to her primary care provider or a dermatologist. (2) Recommend self-care with a nonprescription product and/or nondrug measures. (3) Recommend self-care until the patient can be seen by an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. Martinez should take protective measures when at work to minimize irritant exposure from hair products and dyes. She should use only mild cleansers, such as Cetaphil, when necessary. She should prophylactically apply a barrier cream every 3-4 hours. She should wear gloves when working with products such as dyes if the glove material is not an additional source of irritation. Emollients such as Aquaphor can be used as well, to increase moisture in the skin.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Completely dry your hands after washing with a mild cleanser such as Cetaphil; then use a hypoallergenic hand cream to provide a barrier against irritants before work and every 3-4 hours. Also, apply an emollient to your hands at bedtime, and cover them with cotton gloves overnight."
7. Explain to the patient or caregiver the rationale for	"Washing and drying your hands will cleanse them of irritants. The hypoallergenic hand cream will relieve dryness. The addition

Relevant Evaluation Criteria	Scenario/Model Outcome
selecting the recommended therapeutic approach from the considered therapeutic alternatives.	of cotton gloves will increase the amount of moisture retained in your skin.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	See the box “Patient Education for Contact Dermatitis.”
b. Maximum number of days the therapy should be employed	See the box “Patient Education for Contact Dermatitis.”
c. Product administration procedures	See the box “Patient Education for Contact Dermatitis.”
d. Expected time to onset of relief	See the box “Patient Education for Contact Dermatitis.”
e. Degree of relief that can be reasonably expected	“Partial symptomatic relief is likely, because continued exposure cannot be avoided.”
f. Most common adverse effects	See the box “Patient Education for Contact Dermatitis.”
g. Adverse effects that warrant medical intervention should they occur	See the box “Patient Education for Contact Dermatitis.”
h. Patient options in the event that condition	“You should consult a primary care provider if the condition does not improve or if irritation is intolerable.”

Relevant Evaluation Criteria	Scenario/Model Outcome
worsens or persists	
i. Product storage requirements	See the box “Patient Education for Contact Dermatitis.”
j. Specific nondrug measures	See the box “Patient Education for Contact Dermatitis.”
Solicit follow-up questions from the patient or caregiver.	“When should the irritation start to decrease?”
Answer the patient’s or caregiver’s questions.	“You should see a difference in 1 week. If you do not see improvement, contact your primary care provider.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Ms. Martinez to contact you in 1 week and report how the problem responded to the recommended therapy, or call her in 1 week to evaluate her treatment outcome.

Key: n/a = Not applicable.

Case 35–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e.,	The patient presents to the pharmacy with intense

Relevant Evaluation Criteria	Scenario/Model Outcome
nature, onset, duration, severity, associated symptoms)	pruritus (itching) on his hands, arms, and lower legs. Vesicles and bullae are present, and some of the vesicles on his arms have extensive oozing. It appears that 20%–25% of his body surface area is affected.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The itching and skin involvement have gotten worse over the past 48 hours and seem to increase the more the patient scratches to relieve the itching. He has not tried anything other than scratching the affected area when he finds the itching "unbearable." Symptoms began after he pulled some weeds and shrubs on the job.
c. Description of the patient's efforts to relieve the symptoms	Patient reports that no treatment has been used.
d. Patient's identity	James Sullivan
e. Patient's age, gender, height, and weight	25 years, male, 6 ft 1 in., 205 lb
f. Patient's occupation	Landscaper
g. Patient's dietary habits	Normal diet with occasional junk food
h. Patient's sleep habits	The patient sleeps 5–6 hours a night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Allergies	Nickel
k. History of other adverse reactions to medications	Upset stomach with codeine
l. Other (describe) _____	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Mr. Sullivan is suffering from an allergic contact dermatitis as a result of urushiol exposure from poison ivy. His symptomatology (e.g., redness, swelling, itching,

Relevant Evaluation Criteria	Scenario/Model Outcome
	vesicle and bulla formation) has worsened over time as a result of delayed response to urushiol on different anatomic sites and spread of the irritant through scratching.
3. Identify exclusions for self-treatment (Figure 35-1).	Significant proportion of body surface affected (>20%)
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mr. Sullivan to his primary care provider or a dermatologist. (2) Recommend self-care with a nonprescription product and/or nondrug measures. (3) Recommend self-care until Mr. Sullivan can obtain medical attention. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend self-care until Mr. Sullivan can see an appropriate health care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Owing to the extent of skin involvement, your poison ivy dermatitis is likely best treated with an oral corticosteroid prescription from your health care provider. While waiting to get an appointment, you can use topical hydrocortisone 1% cream to reduce itching, an astringent like Burow's solution, and cool or lukewarm showers."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Allergic contact dermatitis from urushiol involving greater than 20% of the body should not be treated with self-care products."

Relevant Evaluation Criteria	Scenario/Model Outcome
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Expect some relief within a few hours of application. Complete relief of your symptoms is unlikely with nonprescription products, but they will resolve within 10–21 days regardless of treatment."
Solicit follow-up questions from the patient or caregiver.	"I've heard about Zanfel. I work outside for a living. Should I use that in the future?"
Answer the patient's or caregiver's questions.	"The best approach is to learn how to identify <i>Toxicodendron</i> plants and to wear long layers and gloves when you must work near or with these plants. If you suspect you have been exposed to urushiol, you can use Zanfel or Tecnu irritant cleansers to reduce exposure."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Sullivan within 2–3 days to ensure that he made an appointment and received medical care.

Key: n/a = Not applicable.

Patient Education for Contact Dermatitis

Irritant Contact Dermatitis

The goals of self-treatment for irritant contact dermatitis (ICD) are (1) to remove the offending agent and to prevent future exposure to the irritant; (2) to provide prompt treatment to prevent development of chronic dermatitis; (3) to relieve the inflammation, dermal tenderness, and irritation; and (4) to educate the patient on self-management to prevent or treat recurrences. For most patients, carefully following product

instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Avoid or limit contact with common skin irritants, such as detergents, soaps, and solvents.
- Change clothing and gloves used for cleaning more frequently.
- Wash the affected area gently to remove the skin irritant.

Nonprescription Medications

- Use emollients liberally to restore moisture to skin.
- Use barrier creams if persistent exposure to irritant is anticipated.⁹
 - Apply adequate amounts (e.g., 1g/hand) to entire skin surface that will be exposed. Pay special attention to cutaneous skin folds, cuticles, and skin under nails.
 - Wait 1–3 minutes before exposure.
 - Reapply every 3–4 hours.
- Use colloidal oatmeal baths or soaks to soothe and cleanse areas of the rash and to reduce itching:
 - Sprinkle a 30-g packet or a cupful of fine-ground oatmeal into fast-running bath water and then agitate the water to avoid lumping of the oatmeal.
 - Soak for 15–20 minutes in the oatmeal bath at least twice a day.
 - Pat skin dry rather than wiping it.
 - Oatmeal baths can leave the tub slippery and can clog the drain.
- Store nonprescription medications in a cool, dry place out of children's reach.
- Rash and itching should begin to subside within 5–7 days. If either the rash or the itching worsens, consult your primary care provider.
- Using nonprescription medications longer than 7 days for dermatitis without consulting an appropriate health care provider is not recommended.

Allergic Contact Dermatitis

The goals of self-treatment for allergic contact dermatitis (ACD) are (1) to remove and/or avoid further contact with the offending agent; (2) to treat the inflammation; (3) to relieve itching leading to excessive scratching; (4) to cleanse the skin of debris that accumulates from oozing, crusting, and scaling with release of vesicle contents; and (5) to prevent secondary skin infections. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Use the measures outlined in [Table 35–4](#) to prevent poison ivy/oak/sumac dermatitis.
- Take cold or lukewarm, soapless showers to relieve itching.
- When cleansing the affected areas, do not use harsh cleansers or scrub vigorously.
- Use clean white cloths for cool water compresses; apply for 20–30 minutes as often as needed or desired.
- To avoid potential allergic reactions, use hypoallergenic cosmetics and soapless cleansers.

Nonprescription Medications

- If desired, to reduce inflammation and the itching and redness, apply topical hydrocortisone cream *only* as follows:
 - Apply a small amount to affected areas up to 3–4 times a day.
 - Avoid applying the cream around the eyes or on eyelids.
- To avoid infection, do not apply ointments to open lesions.
- Apply aluminum acetate (Burow’s solution) compresses to areas with vesicles, bullae, and/or weeping lesions, as follows:
 - Mix a prepackaged tablet or packet of aluminum acetate with a pint of cool tap water, wet a cloth with the solution, and apply the compress to rash areas.
 - Apply compresses for 20–30 minutes at least 4–6 times a

day or as needed.

– Prepare fresh solution for each application.

- Use colloidal oatmeal baths or soaks to soothe and cleanse areas of the rash and to reduce itching:
 - Sprinkle a 30-g packet or a cup full of fine-ground oatmeal into fast-running bath water, and then agitate the water to avoid lumping of the oatmeal.
 - Soak for 15–20 minutes in the oatmeal bath at least twice a day.
 - Pat skin dry rather than wiping it.
 - Oatmeal baths can leave the tub slippery and can clog the drain.
- Use a sedating oral antihistamine, such as diphenhydramine or doxylamine, for nighttime sedation, and follow the label instructions. These medications can cause drowsiness that may potentially extend to the next morning.
- Store nonprescription medications in a cool, dry place out of children's reach.
- Using nonprescription medications for dermatitis longer than 7 days without consulting an appropriate health care provider is not recommended.

When to Seek Medical Attention

- Contact your primary care provider for the following situations:
 - The rash does not begin to improve in 7 days.
 - The symptoms from the rash worsen.
 - The rash continues to develop for several weeks after initial exposure.
 - Joint swelling or other evidence of systemic involvement emerges.
 - The rash covers large areas of the face or causes swelling of the eyelids.
 - The rash involves the genitals.

Evaluation of Patient Outcomes for Contact Dermatitis

The patient should be encouraged to contact the health care provider for additional advice if the itching has not subsided significantly within 5–7 days. If, at follow-up evaluation, the rash has significantly increased in size, exhibits signs of infection, affects the eyes or genitals, or covers extensive areas of the face, referral to the patient's primary care provider or a dermatologist is warranted. Complete remission of the dermatitis may take up to 3 weeks. However, slow but steady reduction in itching, weeping, and extent and severity of the rash should be evident after 5–7 days of therapy.

Key Points for Contact Dermatitis

- The leading cause of ICD is frequent, unprotected exposure to wet environments that may include irritants such as detergents and cleaning solutions.
- ACD is produced through sensitization to an antigenic substance.
- Many substances are antigenic. Common antigenic substances include fragrances, metals, medications, plants, and chemicals. Urushiol from poison ivy/oak/sumac is one of the most common allergens.
- Patients with recognized sensitivity to specific irritants or allergens including urushiol should take precautions to eliminate exposure by avoiding these agents, limiting exposure time, and wearing protective clothing and equipment.
- Once exposed to an irritant or antigen, the patient should shower with mild soap and water or apply large volumes of cool water to the area immediately after exposure to reduce the risk for development of dermatitis.
- ACD may begin as localized streaks or patches of highly pruritic rash that, with time, may become more numerous or coalesce

into larger plaques on exposed dermal areas. The rash may affect the eyelids or face or, more rarely, less accessible areas such as the axillae or anal region.

- Patients should be referred for further evaluation if there is involvement of the face, genitalia, or anus; signs of infection; considerable edema anywhere on the body (including eyelids); or extensive lesions covering a large portion of the body.
- Treatment of localized, pruritic ACD rash consists of a topical application of hydrocortisone cream or soothing compresses or baths. Zanafel also is recommended to treat localized rash because it may be used for relief any time a rash develops. Weeping vesicles or bullae may be treated with aluminum acetate compresses.
- Irritant and allergic contact dermatitis will resolve in approximately 10–21 days with or without topical therapy. Nonprescription medications primarily relieve symptoms, and improvement should be seen in 5–7 days.

Chapter 36: Diaper Dermatitis and Prickly Heat

Authors: Miranda Wilhelm

Irritant contact diaper dermatitis (commonly referred to as diaper rash) and prickly heat (also known as miliaria, miliaria rubra, or heat rash) are acute dermatologic conditions that primarily affect infants. In most cases, neither diaper dermatitis nor prickly heat causes serious illness. However, these conditions typically are associated with discomfort, irritation, and itching, which may engender considerable distress, with consequent agitation, irritability, and “fussiness” in infants.

Diaper Dermatitis

Diaper dermatitis is an acute inflammation of the skin occurring in the region of the perineum, buttocks, lower abdomen, and inner thighs. Despite the perception that this condition is limited to infancy, it can and does occur in association with incontinence in any age group.¹ This chapter focuses on infant diaper dermatitis, but the information presented may be generalized to the adult population. (See [Chapter 49](#) for specific information regarding treatment of adult incontinence.) Both irritant contact and allergic contact diaper dermatitis can be the cause of a diaper-area rash.² The primary focus of this chapter is irritant contact diaper dermatitis. Irritant contact diaper dermatitis is referred to simply as *diaper dermatitis* or *diaper rash* throughout. Allergic contact dermatitis is discussed briefly in appropriate contexts.

Diaper dermatitis is the most common dermatologic disorder of infancy, resulting in more than 1 million primary care provider office visits per year.³ In a majority of cases, diaper dermatitis affects infants 2 years of age and younger. Diaper dermatitis can manifest as early as 7 days after birth.⁴ In view of the almost universal practice of diapering, the actual incidence of the condition is likely underreported. Literature has suggested prevalence rates of 7%–50%, with a peak between the ages of 9 and 12 months.^{3,5} However, a majority of children experience diaper dermatitis at least once before they are out of diapers. The steady decline in the number of cases of diaper dermatitis in infants since the 1970s is attributable to the increased use of disposable

diapers. The decline was accelerated in the 1980s and 1990s with improvements in diaper technology and the rise of superabsorbent core materials and breathable diaper coverings.^{6–8}

Pathophysiology of Diaper Dermatitis

Multiple factors have been implicated in the pathogenesis of diaper dermatitis. Occlusion, moisture, microbes, exposure to gastrointestinal tract proteolytic enzymes and bile salts, a shift from the normal acidic skin pH (i.e., 4.0–5.5) to a more alkaline pH, mechanical chafing, and friction all can cause skin compromise, exerting adverse effects in additive or synergistic ways, with diaper dermatitis as the end result.^{3,9–16}

The skin of the infant perineal region is about $\frac{1}{2}$ – $\frac{1}{3}$ the thickness of adult skin. Because the perineal region typically is occluded by a diaper, this area is subjected to prolonged conditions of moisture and wetness, predisposing it to irritation and infection.¹⁷ Frequent urination and defecation, combined with infrequent changing of the diaper, contribute to increased skin moisture. The development of diaper dermatitis is closely related to the exposure to urine and feces along with the occlusion associated with wearing a diaper. The younger the infant, the greater the frequency of elimination. Newborns typically will require a diaper change every 2 hours because of a high wetting frequency, but diaper changes in older infants can be decreased to every 3–4 hours.¹⁸ Skin that remains wet for long periods becomes waterlogged or hyperhydrated, which plugs sweat glands, increases susceptibility to abrasion and frictional harm, and diminishes the barrier function of the stratum corneum in the diaper area. Diminished barrier capabilities, in turn, make the skin more susceptible to irritation, absorption of chemicals, and injury or frank infection by opportunistic microbes.

Urine and fecal bacteria can contribute to skin breakdown. Urea-splitting bacteria from the colon are believed to convert urine components into ammonia. Ammonia raises the pH of the skin, making it more susceptible to damage or infection. The role of this etiologic factor, however, has been lessened by the use of absorbent disposable diapers, which minimize mixing of urine and feces in the diaper area.^{5,19} Mechanical irritation also can lead to epidermal breakdown, allowing other irritants (e.g., fecal bacteria) to harm the skin. Tight-fitting, stiff, or rough diapers and the use of plastic or rubberized covers or pants over cloth diapers can contribute to damage from mechanical

friction and occlusion-induced skin breakdown, respectively.

Medications and foods that affect the motility or microbial flora (e.g., antibiotics) of the gastrointestinal tract, or that hinder autonomic control of urination and defecation, may contribute to diaper dermatitis. Foods high in hexitols, sorbitol, sucrose, and fructose may induce diarrhea and predispose the affected patient to diaper dermatitis. Dairy products can induce diarrhea, especially if the child is lactose-intolerant. (See [Chapter 16](#) for a discussion of diarrhea.) Compared with formula-fed infants, breastfed infants have a decreased incidence of diaper dermatitis.²⁰ The feces of breastfed infants are less copious, less alkaline, and less caustic to the skin. Transitions in the type of food consumed (e.g., from breast milk to solid foods) also can contribute to diaper dermatitis.

Some products (e.g., detergent or soap residues, household cleaning products, lotions, sunscreens, insect repellents), plant materials (e.g., ragweed, thistle), and diaper product ingredients can produce an allergic contact dermatitis that resembles diaper dermatitis.²¹ Many of these agents may not be intended for use in the diaper region, and if present, they may have an unexpected effect on skin under a diaper. Chemicals used to launder and sanitize reusable cloth diapers, if not adequately rinsed, may leave residues that exacerbate diaper dermatitis and skin irritation. Allergic contact dermatitis in the diaper region routinely manifests only in areas of contact with the allergen, often sparing the inguinal skin folds. Allergic contact dermatitis should be considered as a diagnosis when standard care measures do not lead to healing in the diaper area.¹ (See [Chapter 35](#) for discussion of allergic contact dermatitis.)

Clinical Presentation of Diaper Dermatitis

Diaper dermatitis usually manifests as red to bright red (erythematous), sometimes shiny, wet-looking patches and lesions on the skin (see [Color Plates](#), photograph 21). Lesions may appear dusky maroon or purplish on darker skin. Generally, diaper dermatitis involves the skin covered by the diaper, but in severe cases the rash can spread outside the diaper area. If an infant, for example, lies primarily on the abdomen, the rash may appear more anterior to the perineum. In the same manner, if the infant lies primarily on the back, the rash may appear more posterior to the perineum.

A disconcerting feature of diaper dermatitis is that a full-blown rash can

appear in a matter of hours, yet it often can take days to completely resolve. Most likely, the process of skin breakdown is not pronounced or visible initially, but the skin changes quickly undergo transition from unobservable to observable. The entire process from normal to noticeably erythematous skin takes longer than the time between normal diaper changes, so early stages can easily escape detection.

Less commonly, severe diaper dermatitis can progress to maceration, papule formation, the presence of vesicles or bullae, oozing, erosion of the skin, or ulceration. Diaper dermatitis also can predispose affected infants to secondary infections and genital damage. As skin pH changes, it can foster the growth of opportunistic infections that can be bacterial (e.g., streptococci or staphylococci), fungal (e.g., yeasts), or viral (e.g., herpes simplex virus) in etiology. If infection is a concern, visual inspection of the diaper area is beneficial for proper diagnosis. With secondary *Candida* infections, for example, the clinical presentation is distinct from that of uncomplicated diaper dermatitis. The typical *Candida* superinfection manifests as papular or pustular lesions around the margins of the affected area, often with involvement of adjoining skin folds or creases. Untreated or infected diaper dermatitis can progress to skin ulceration, infections of the penis or vulva, and urinary tract infections, all necessitating medical referral.

Diaper dermatitis also can be a manifestation of other diseases and conditions, such as Kawasaki syndrome, granuloma gluteale infantum, cytomegalovirus infection, and nutritional deficiencies. Infants born to immunocompromised mothers (e.g., those with human immunodeficiency virus [HIV] infection or genital herpes) should be considered at increased risk for unusual manifestations of diaper dermatitis or diaper dermatitis-like presentations. Primary infections of the skin can resemble diaper dermatitis and be misdiagnosed. Inguinal swelling, fever, chills, tachycardia, blisters, vesicles, and irregular borders bounded by bumps are indicators of infections that warrant medical referral.^{3,22} Diaper dermatitis can exist concurrently with other skin conditions such as psoriasis and seborrhea¹¹; therefore, these skin conditions may be misdiagnosed as diaper dermatitis.

Treatment of Diaper Dermatitis

Treatment Goals

The goals of diaper dermatitis treatment are (1) to relieve symptoms, (2) to rid the patient of the dermatitis, (3) to prevent secondary infection, and (4) to prevent recurrences.

General Treatment Approach

The general treatment approach for diaper dermatitis is the use of nonpharmacologic measures or a combination of pharmacologic and nonpharmacologic modalities as outlined in [Figure 36–1](#). The components of treatment are identified in the mnemonic ABCDE: *air*, *barrier*, *cleansing*, *diaper*, and *education* ([Table 36–1](#)).¹ The ideal, yet often impractical, preventive practice would be to change the diaper immediately after the infant defecates or urinates. The self-treatment approach often will involve increased caregiver vigilance in keeping the infant dry and use of skin protectants in the diaper area. Management based on the use of self-treatment measures should be limited to diaper dermatitis that is uncomplicated (e.g., absence of comorbid conditions or constitutional symptoms) and mild to moderate (e.g., absence of oozing or blood at lesion sites, or lesions present less than 7 days) in presentation. [Figure 36–1](#) presents a thorough list of characteristics of complicated and severe diaper dermatitis. Medical referral is warranted when one or more of the listed exclusions for self-treatment is present.

TABLE 36–1 ABCDE Mnemonic for Diaper Dermatitis Treatment

A = Air	Allow diaper area skin to air dry frequently; allow diaper-free time.
B = Barrier	Apply barrier skin protectant liberally to diaper area with each diaper change to prevent and treat diaper dermatitis.
C = Cleansing	Gently cleanse the diaper area with a soft cloth and warm water or with a baby wipe when stool is present.
D = Diaper	Change the diaper frequently (every 2 hours) and as soon as it is soiled, if possible. Use absorbent disposable diapers if affordable for the parent/caregiver.
E = Education	Educate parents/caregivers about nonpharmacologic diaper hygiene practices and pharmacotherapy, verifying understanding to ensure adherence.

Source: [Reference 1](#).

Nonpharmacologic Therapy

Nonpharmacologic therapy plays an integral role in the treatment of diaper dermatitis. The goals of nonpharmacologic therapy are (1) to reduce occlusion, (2) to reduce contact time of urine and feces with skin, (3) to reduce mechanical irritation and trauma, (4) to protect the skin from further irritation, (5) to encourage healing, and (6) to prevent secondary infection. Discussing nonpharmacologic measures with parents and other caregivers and ensuring comprehension are critical for adherence and quick resolution.¹

Treatment of uncomplicated diaper dermatitis should be initiated with nonpharmacologic therapy. Increasing the frequency of diaper changes to a minimum of 6 per day is advisable. Although challenging to implement, an effective strategy to prevent diaper dermatitis, known as a *diaper holiday*, is to expose the buttocks to air as long as possible, to limit the duration of contact between skin and wet fabric, in an attempt to reduce friction-induced skin changes.¹⁸

When the perianal area requires cleansing, gentle patting with a chemical-free soft cloth or low-abrasive baby wipe is appropriate. Sensitive-skin baby wipe products are readily available. Used with finesse and gentle technique, baby wipes are as mild on the skin as or milder than washcloths.²³ Few baby wipes still contain alcohol, perfumes, soap, or other ingredients that can cause contact dermatitis or actually burn or sting the infant's skin. Products that list such ingredients on the label should be avoided. Of importance, the unsoiled part of a diaper should never be used to clean or wipe the skin because it may harbor bacteria. An alternative to use of baby wipes is careful rinsing of the skin with warm water followed by gentle nonfriction drying. The infant's diaper area should be allowed to thoroughly air dry before rediapering. Cleansing should be limited to occasions when stool is present to minimize irritation from excessive rubbing.¹

With improving technology, the disposable diaper has become a critical component of nonpharmacologic therapy for diaper dermatitis.^{5,6} Some disposable diapers feature absorptive materials that pull moisture away from direct contact with the skin, to reduce skin hyperhydration and mixing of urine

with feces. Some of these products already contain a protectant (e.g., petrolatum). Disposable diapers with dyes should be avoided because they have been identified as a source of allergic contact dermatitis. Research that compared disposable and cloth diapers indicates that use of disposable diapers decreases the incidence of severe diaper dermatitis.^{5,24-26} When cloth diapers are used, they should be laundered with a mild detergent, with extra rinse cycles if sanitizing agents are used.

Pharmacologic Therapy

The goals of pharmacologic therapy are (1) to protect the skin from further contact with urine and feces, (2) to soothe any discomfort caused by the lesions, (3) to encourage healing, and (4) to prevent secondary infection.

Skin Protectants

Skin protectants serve as physical barriers between the skin and external irritants. Protectants also serve as lubricants in areas in which skin-to-skin or skin-to-diaper friction could aggravate diaper dermatitis or predispose the area to development of diaper dermatitis. Protectants absorb moisture or prevent moisture from coming into direct contact with skin. Protective effects of these products allow the body's normal healing processes to work. Because skin protectants are remarkably safe, their use for both treatment and prevention is acceptable. A skin protectant should be applied with each diaper change to aid in preventing diaper dermatitis.¹⁸

Protectants are the only products considered safe and effective for use in diaper dermatitis without medical referral. The U.S. Food and Drug Administration (FDA) has approved 17 ingredients, all skin protectants, for treatment of infant diaper dermatitis ([Table 36-2](#)).²⁷ Two or more of the approved ingredients are commonly combined in commercial products for treating diaper dermatitis. Of note, some products contain an approved ingredient in combination with other ingredients that are unsafe or of dubious value for treating diaper dermatitis. The other ingredients may be unsuitable or even toxic when applied to skin compromised by diaper dermatitis. Therefore, a general rule is to suggest the simplest possible products that contain FDA-approved ingredients. By law, products that contain antimicrobials, topical analgesics, and antifungals cannot present claims for treatment of diaper dermatitis. Ingredients routinely included in skin

protectant formulations but not approved for treatment of diaper dermatitis are listed in [Table 36–3](#).

TABLE 36–2 FDA-Approved Skin Protectants to Treat Diaper Dermatitis^a	
Agent	Concentration (%)
Allantoin	0.5–2
Aluminum hydroxide ^b	0.15–5
Calamine	1–25
Cocoa butter	50–100
Cod liver oil (in combination)	5.0–13.56
Colloidal oatmeal	≤0.007
Dimethicone	1–30
Glycerin ^b	20–45
Hard fat	50–100
Kaolin	4–20
Lanolin	12.5–50
Mineral oil	50–100
Petrolatum	30–100
Topical cornstarch	10–98
White petrolatum	30–100
Zinc carbonate	0.2–2
Zinc oxide	1–25

^a Owing to safety concerns, products containing sodium bicarbonate and zinc acetate are not appropriate for use in children <2 years of age and have been excluded from this list.

^b Consultation with a primary care provider is suggested before use in infants <6

months of age.

Key: FDA = U.S. Food and Drug Administration.

TABLE 36–3 Selected Nonmonograph Ingredients in Diaper Dermatitis Products

Aloe	Flower extract	Sweet clover
Beeswax	Honey	Tea tree oil
Calendula	Goldenseal	Vitamin A
Castor oil	Jojoba	Vitamin D
Chamomile	Lavender	Vitamin E
Comfrey	Peruvian balsam	

Of the skin protectants listed in [Table 36–2](#), a select few are commonly incorporated into trade-name skin protectant products. Useful comparative studies of the skin protectants are lacking. Zinc oxide is one of the most commonly used semisolid skin protectants in products that treat diaper dermatitis. A major drawback of many zinc oxide ointment preparations and other hydrophobic diaper dermatitis preparations is the necessity for soap to remove the product from the skin. However, the hydrophobic nature of the preparations is beneficial in forming a protective barrier for the compromised skin. Some zinc oxide preparations are formulated to be more washable and creamlike and are therefore easier to apply and remove. Ease of use, however, must be weighed against ability to adequately protect the skin.

Petrolatum and white petrolatum are commonly used oleaginous ingredients that serve as excellent skin protectants. These products are ubiquitous ointment bases. Petrolatum may be listed as an active or inactive ingredient in skin protectant formulations. Lanolin is a bacteriostatic product obtained from a fatty substance found in wool and also is commonly used alone or in combination with other skin protectants. Although approved for use in diaper

dermatitis, lanolin also is a common contact sensitizer. The risk for sensitization should be considered if lanolin is applied in the diaper area where the skin is inflamed and more vulnerable to contact allergens.

Calamine is a mixture of zinc and ferrous oxides. It has absorptive, antiseptic, and antipruritic properties and is available in numerous dosage forms. Mineral oil coats the skin with a water-impenetrable film that must be washed off with each diaper change to avoid buildup in pores and subsequent folliculitis. Mineral oil often is used in small quantities in skin protectant products. It often is listed as an inactive ingredient in formulations despite FDA approval for use as an active ingredient. Dimethicone is a silicone-based oil that repels water and soothes and counteracts inflammation. It is used in combination with other skin protectants such as zinc oxide.

Topical cornstarch and talc are used as loose powders. They provide benefit by reducing moisture and friction.¹ Topical cornstarch is an absorbent material, whereas talc functions as a lubricant. Both products carry warnings against inhalation of the powder because of an associated risk of severe respiratory disease. The warning states: “Keep powder away from child’s face to avoid inhalation, which can cause breathing problems.”²⁷ Some health care providers suggest pouring the powder into the hands away from the infant and gently rubbing it onto the perineal area; however, because of the inhalation risk, these products should be avoided.¹ Talc specifically should not be applied to broken or oozing skin; it can cake on the edges of wounds, potentially precipitating infection or retarding healing. In addition, two recent meta-analyses found an association between perineal talc use and ovarian cancer.^{28,29} Although the results of these studies are for women and not infants, it may be advisable to avoid use of talc altogether.

Although it has not been studied for safety and efficacy, an aluminum hydroxide–magnesium hydroxide oral antacid suspension has become a popular topical agent for treatment of diaper dermatitis when mixed with Aquaphor.¹ Burow’s solution (aluminum acetate in water) has been compounded with petrolatum and zinc oxide to form 1-2-3 Paste, which also has been used for irritant contact dermatitis in the diaper area despite a lack of supporting clinical evidence.¹ **Table 36–4** lists selected widely available trade-name products and their active ingredients.

TABLE 36–4 Selected Nonprescription Products for Diaper Dermatitis

Trade Name	Primary Ingredient(s) (With Selected Additional Ingredients)
A + D Original Ointment	Petrolatum 53.4%; lanolin 15.5% (cod liver oil; mineral oil; beeswax ^a)
A + D Zinc Oxide Cream	Zinc oxide 10%; dimethicone 1% (aloe vera ^a ; coconut oil ^a ; cod liver oil; mineral oil; beeswax ^a)
Aquaphor Baby Healing Ointment	Petrolatum 41% (lanolin; mineral oil)
Baby Anti Monkey Butt Diaper Rash Powder	Calamine powder 8% (cornstarch)
Balmex Diaper Rash Cream	Zinc oxide 11.3% (beeswax ^a ; dimethicone; mineral oil; soybean oil ^a ; evening primrose ^a ; olive leaf extract ^a)
Boudreaux's Original Butt Paste	Zinc oxide 16% (castor oil ^a ; mineral oil; paraffin ^a ; balsam ^a ; petrolatum)
Burt's Bees Baby Bee Natural Diaper Rash Ointment	Zinc oxide 40% (sweet almond oil ^a ; beeswax ^a ; lanolin; castor oil ^a ; jojoba oil ^a ; shea butter ^a ; olive oil ^a ; chamomile ^a ; lavender oil ^a ; calendula ^a ; rosemary ^a ; soybean oil ^a ; canola oil ^a)
CeraVe Baby Healing Ointment	Petrolatum 46.5% (mineral oil, dimethicone)
Desitin Maximum Strength Original Paste	Zinc oxide 40% (cod liver oil; lanolin; petrolatum; talc ^a)
Desitin Multi-Purpose Healing Ointment	White petrolatum 71.3% (mineral oil; paraffin ^a ; cocoa butter)
Desitin Daily Defense Cream	Zinc oxide 13% (mineral oil; petrolatum; beeswax ^a ; dimethicone; aloe ^a ; glycerin)
Flanders Buttocks Ointment	White petrolatum 66.2%; zinc oxide 13.4% (beeswax ^a ; castor oil ^a ; mineral oil; Peruvian balsam ^a)
Triple Paste Medicated Ointment	Zinc oxide 12.8% (cornstarch; lanolin; white petrolatum; beeswax ^a)

^a Nonmonograph ingredients.

Skin protectant dosing and application are straightforward. The protectant is applied liberally to the skin in the diaper area. Any remaining protectant from the previous diaper change should not be removed, to minimize additional irritation that may result from the rubbing. Special attention is needed to ensure complete coverage of erythematous areas with the protectant if diaper dermatitis is already present. Overapplication (overdosage) of approved skin protectants is not a concern. Underapplication, however, can reduce the protective effect of the product. The protectant should be reapplied as needed and with every diaper change. Research suggests that applying a skin protectant regularly with each diaper change is an important element of prevention of diaper dermatitis.¹³ Skin protectants do not interact with other agents; however, the use of ointment preparations will preclude retention of other topically applied products. With diaper dermatitis that does not necessitate medical referral, dramatic improvement commonly is seen within 24 hours of initiation of pharmacologic and nonpharmacologic treatment.

Contraindicated Agents

Topical nonprescription antibiotic and antifungal agents are not appropriate for use in the self-treatment approach to diaper dermatitis. If an infection is suspected, medical referral is advised. Topical analgesics also are not recommended because they can alter sensory perception in a population in which the ability to communicate such changes often has yet to mature. These agents also may excoriate macerated skin, cause pain, and retard healing, thereby further complicating diaper dermatitis.

Hydrocortisone is indicated for minor skin irritation but should not be used in diaper dermatitis without supervision by an appropriate health care provider. Hydrocortisone can increase the risk of secondary infection via immune response suppression. Additionally, the diaper area constitutes a significant proportion of the infant's body surface area. Hydrocortisone absorption into the skin is enhanced under occlusive conditions. When this agent is applied to macerated skin or a large surface area, its absorption may lead to serum levels that interfere with the infant's pituitary–adrenal axis. Nonprescription

hydrocortisone is labeled to be avoided in patients younger than 2 years. (See [Chapter 35](#) for additional information on the use of hydrocortisone.)

Product Selection Guidelines

Although no particular product among those approved for diaper dermatitis possesses evidence-based advantages, personal preferences for certain product characteristics will likely determine which product caregivers use to treat diaper dermatitis. As previously mentioned, some commonly used products contain nonapproved (i.e., nonmonograph) ingredients. These products may be used for formulation purposes, or they may be unregulated nutraceuticals listed as inactive or active ingredients. Unapproved ingredients also could be included in preparations to support marketing claims. For example, camphor may be present to provide a “medicated” fragrance; aloe may be present to appeal to the public perception that aloe is a wound-healing agent; or vitamins may be present to convey “natural” characteristics. To make the claim to treat diaper dermatitis, the product, however, must meet FDA-published guidelines for active ingredients. Although diaper dermatitis is a condition primarily of infants and older adults, no additional concerns have emerged in relation to product selection in these age groups.

Complementary Therapies

Complementary therapies are not recommended for use in newborns and infants because of insufficient evidence regarding their safety and effectiveness in these populations. Rates of systemic absorption are unknown. Although some of these agents have been used without incident in adults, no credible data on their safety or efficacy in infants are available. Recently, honey has received attention as a treatment option for diaper dermatitis; it has been used for several years in wound care. Manuka honey in particular has been found to have hygroscopic, fungicidal, and antibacterial properties and helps to regulate the mildly acidic pH of the skin. Initial studies have shown honey, beeswax, and olive oil to be effective in management of diaper dermatitis.³⁰ Although these agents should not be recommended at this time, with more robust studies, they may become acceptable therapeutics in the future.

Assessment of Diaper Dermatitis: A Case-Based Approach

When a caregiver or patient seeks information about management for suspected diaper dermatitis, the health care provider should evaluate the presentation of the diaper-area rash itself and assess for the presence of any factors conducive to exacerbation of diaper dermatitis. Under appropriate conditions, visual inspection of the affected area is indicated. In settings that preclude such inspection, open-ended questioning techniques will yield an adequate description of the dermatitis. Case 36–1 illustrates assessment of a patient with diaper dermatitis. If the problem is deemed to be uncomplicated diaper dermatitis amenable to a self-care approach, appropriate nonpharmacologic and pharmacologic modalities should be recommended. Nonpharmacologic management should begin with establishing the type of diaper being used and the frequency of diaper changes. On this basis, the provider can consider whether increasing the frequency of diaper changes and other nonpharmacologic measures are likely to be sufficient to heal the diaper dermatitis or whether pharmacologic treatment is warranted. In view of the minimal risk associated with use of pharmacologic products approved for treatment, various options are available for recommendation to the patient or caregiver ([Table 36–2](#)).

Algorithm: Diaper Dermatitis

FIGURE 36–1 Self-care for diaper dermatitis. Key: HIV = Human immunodeficiency virus; OTC = over-the-counter.

Case 36–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	

Relevant Evaluation Criteria	Scenario/Model Outcome
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A parent seeks advice on treatment for his infant daughter's pronounced red rash on the diaper area. He reports that she woke up from a nap a little fussy, and he noticed the rash while changing her diaper. He is "in shock," he states, because the rash seemed to appear "out of nowhere." He describes the affected skin as bright red and shiny and sensitive to any touch. His daughter cried when he was cleaning her bottom with a baby wipe.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Similar rashes have occurred before, but the baby's father cannot remember which cream he used. Previous rashes have resolved without any need to see the pediatrician.
c. Description of the patient's/caregiver's efforts to relieve the symptoms	The father has not tried anything so far. In general, he uses disposable diapers and sensitive-skin baby wipes.
d. Patient's identity	Aurora William
e. Patient's age, gender, height, and weight	6 months, female, 25 in., 16 lb
f. Patient's occupation	n/a
g. Patient's dietary habits	Aurora is formula-fed 6 times daily; her father is beginning to introduce baby cereal and prepared baby food into her diet.
h. Patient's sleep habits	Normal for age
i. Concurrent medical conditions,	None

Relevant Evaluation Criteria	Scenario/Model Outcome
prescription and nonprescription medications, and dietary supplements	
j. Allergies	NKA
k. History of other adverse reactions to medications	None noted
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Findings are consistent with mild to moderate diaper dermatitis. The description of the rash, along with the quick onset and the child's irritability and sensitivity, supports this diagnosis.
3. Identify exclusions for self-treatment (Figure 36-1).	None noted
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend self-care with drug, nondrug, and/or complementary therapies. (2) Refer the patient to her pediatrician or other primary care provider for treatment. (3) Recommend a self-care approach until an appropriate health care provider can be consulted. (4) Take no action.
Plan	

Relevant Evaluation Criteria	Scenario/Model Outcome
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The best option would be to use both nonpharmacologic measures and nonprescription products to treat the rash. Specifically recommend increased diaper changes and allowing the area to air dry between diaper changes. Also recommend liberal application of skin protectant (see Table 36–4 for a listing of available products) with every diaper change as needed. Use of the product may be continued after the rash heals, to prevent future diaper rash.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"A skin protectant will help protect Aurora's skin from further irritation and will allow the diaper rash to heal. Changing her diaper more often and allowing the skin to air dry will quicken healing time and reduce the likelihood of the rash coming back. You also should use plain warm water or sensitive-skin baby wipes to clean the area before air drying."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Based on the appearance of Aurora's diaper rash, you should be able to use nonprescription products for treatment. She currently does not need to see her pediatrician, but be sure to contact an appropriate health care provider if no improvement is seen within 7 days, if the skin under her diaper looks worse, or if she shows any other symptoms or skin changes not limited to the diaper area."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	"Apply Desitin Daily Defense Cream liberally to the affected area with every diaper change and as needed."
b. Maximum number of days the therapy	"Skin protectants can be applied to both treat and prevent diaper rash. There is no maximum length of therapy for this medication."

Relevant Evaluation Criteria	Scenario/Model Outcome
should be employed	However, if the rash and sensitivity do not subside within 7 days, seek medical attention.”
c. Product administration procedures	“Wash your hands and clean the diaper region with a sensitive-skin baby wipe or plain warm water. Allow the area to thoroughly air dry. Then apply the cream to the diaper region liberally. Change diapers at least 6 times a day, every 3–4 hours at a minimum.”
d. Expected time to onset of relief	“You should see noticeable improvement in the affected skin within 24 hours.”
e. Degree of relief that can be reasonably expected	“The rashy area will become less tender with continued application. The skin should return to normal within 7 days—more quickly if diapering technique is adjusted.”
f. Most common adverse effects	“There are no common adverse effects reported with this product.”
g. Adverse effects that warrant medical intervention should they occur	n/a
h. Patient/caregiver options in the event that condition worsens or persists	See the box “Patient Education for Diaper Dermatitis” and Figure 36–1 .
i. Product storage requirements	“Store this product out of reach of children and away from heat and moisture.”
j. Specific nondrug measures	See the box “Patient Education for Diaper Dermatitis.”
Solicit follow-up questions from the patient or caregiver.	“What are the differences between the various diaper rash products?”
Answer the patient’s or caregiver’s questions.	“Ointments, pastes, and creams usually are preferred over powders, which can be dangerous if inhaled. Almost all of the agents provide similar benefit and lack any major adverse effects. Children may be sensitive to products containing lanolin, especially if they suffer from other allergies. Products containing mineral oil must be washed off

Relevant Evaluation Criteria	Scenario/Model Outcome
	with each diaper change, to avoid occurrence of folliculitis. Zinc oxide and other greasy products require soap for removal from the skin. It probably is best to avoid products containing any extra 'natural' ingredients, which usually lack evidence of benefit."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mr. William to call you in 2 days to discuss how Aurora's rash is resolving with the suggested treatment plan.

Key: n/a = Not applicable; NKA = no known allergies.

Patient Education for Diaper Dermatitis

The goals of diaper dermatitis treatment are (1) to relieve the symptoms, (2) to rid the patient of the dermatitis, (3) to prevent secondary infection, and (4) to prevent recurrences. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Use the mnemonic ABCDE (*air, barrier, cleansing, diaper, education*) in managing diaper dermatitis.
- Change diapers frequently, at least 6 times a day, to limit exposure of the infant's skin to moisture and feces.
- Do not use rubber or plastic pants over cloth diapers. Tightly covering the skin encourages skin breakdown.
- When stool is present, use plain water to clean the diaper area. Gently dry area or allow it to air dry.

- Do not wipe the infant with any part of the diaper. Even areas that appear clean may be contaminated with fecal bacteria.
- Avoid commercial baby wipes that contain alcohol, perfumes, and soap, which may burn or sting the skin.
- If feasible, allow the infant to go without a diaper, even for very short periods, to promote drying of the rash.

Nonprescription Medications

- To treat diaper dermatitis, use a product containing one or more of the skin protectants listed in [Table 36–2](#). The product can be used even after the rash clears to prevent recurrences.
- Do not use products that contain ingredients listed in [Table 36–2](#) if they are combined with benzocaine or an antibacterial such as benzethonium chloride. Benzocaine can cause an allergic reaction; antibacterials are not suitable for use with diaper dermatitis.
- Do not use hydrocortisone.
- Do not use topical (external) analgesics such as phenol, menthol, methyl salicylate, or capsaicin to treat diaper rash. These medications are inappropriate for use on infant skin and may cause harm.
- Powders for children or infants should ideally be avoided; if used, they should be gently poured into the caregiver’s hands away from the infant’s face and then rubbed onto the skin, using a sufficient amount to cover the affected area. Do not vigorously shake powders near the infant. Avoid infant or self-inhalation of powders.
- Apply cream or ointment liberally to cover the affected area.
- If mineral oil has been applied, wash it off at every diaper change to avoid clogging skin pores.
- Throw away products that are discolored or whose expiration dates have passed. (The health care provider should point out expiration dates on the products.)

When to Seek Medical Attention

- Consult a primary care provider if any of the exclusions in [Figure 36–1](#) apply.

Patient Counseling for Diaper Dermatitis

Patient and caregiver counseling should begin with education on proper cleaning of the diaper area. Recommendations for self-care management also should emphasize the need to avoid occlusion of the area, when feasible, and to avoid prolonged contact of urine or feces with the infant's skin. The health care provider should explain the proper methods of applying nonprescription skin protectants and should identify signs and symptoms indicating that the dermatitis has worsened and warrants medical attention. The box "Patient Education for Diaper Dermatitis" lists specific information to provide in patient and caregiver counseling.

Evaluation of Patient Outcomes for Diaper Dermatitis

Treatment for diaper dermatitis should be of relatively short duration. If 7 days of treatment have elapsed and the condition is not showing signs of healing, medical referral is warranted. At the conclusion of therapy, the skin should return to its pre-diaper dermatitis condition. If diaper dermatitis occurs routinely or is severe, prophylactic use of skin protectants is suggested; the safety of the various preparations presented in [Table 36–2](#) is well established.

Prickly Heat

Prickly heat, also known as heat rash, is a transient inflammation of the skin that appears as a very fine, pinpoint, and usually red raised rash. It can appear on any part of the body that has sweat glands (e.g., groin, chest, axillae). This condition may occur in patients of any age with active sweat glands.³¹ The highest incidence is during the first month of life and in up to 30% of adults living in hot and humid conditions.³¹ This condition is likely underreported because it is less troublesome than diaper dermatitis and generally clears up rapidly. Prickly heat often manifests in hot working conditions and with activities associated with sweating (e.g., manual labor, exercise, athletics).^{32,33}

Pathophysiology of Prickly Heat

Prickly heat results from partially clogged sweat glands. (See [Chapter 38](#) for a review of the anatomy of the sweat gland.) The trapped sweat causes dilation and rupture of epidermal sweat pores, resulting in acute inflammation of the dermis that may manifest as stinging, burning, or itching.

Prickly heat can arise from normal skin with little or no physiologic prodrome. The condition is most often associated with very hot, humid weather or during illnesses that cause significant or profuse sweating. It is commonly associated with the inability of the skin to “breathe” because of excessively tight, flame-resistant, or occlusive clothing such as leather, polyester, athletic clothing materials (e.g., neoprene), or athletic protective or safety garments and devices.³⁴ Chemicals added during the laundering process also can be a cause of prickly heat.³⁵

Clinical Presentation of Prickly Heat

The hallmark presentation of prickly heat is pinpoint-sized lesions that are raised and red or maroon, forming erythematous papules (see [Color Plates](#), photograph 22). The lesions may appear in small numbers clustered together or spread over the occluded area on a pink to red field (miliaria rubra). Common sites for prickly heat dermatitis include the axillae, chest, upper back, back of the neck, abdomen, and inguinal area. The lesions often trace the pattern of the occlusion and, in uncomplicated cases, do not extend beyond the occluded area. If resolution does not occur within a reasonable period (approximately 3–10 days) after correction of etiologic factors, the condition can evolve into the same kinds of complications seen in diaper dermatitis (e.g., infection, pustule formation, generalized dermatitis). Complications, however, are extremely rare.

Treatment of Prickly Heat

Treatment Goals

The primary goal of treatment in prickly heat is removal of the causative agent or agents. Lesions associated with prickly heat usually resolve without pharmacologic treatment if the cause is removed. A secondary goal in the

treatment of prickly heat is alleviation of symptoms associated with the condition.

General Treatment Approach

The nonpharmacologic treatment goals for prickly heat are (1) to eliminate occlusion of skin, (2) to protect skin from further irritation, (3) to promote healing of skin, and (4) to prevent secondary infection.

Pharmacologic therapy for prickly heat has the same goals, with approved products chosen to help keep skin dry, soothe any discomfort caused by lesion(s), promote healing, and prevent secondary infection.

The algorithm in [Figure 36–2](#) outlines self-treatment for prickly heat.

Nonpharmacologic Therapy

Nondrug therapy for prickly heat includes measures to decrease sweating and to increase air flow to the affected area. If the sweating is caused by a fever, use of systemic antipyretics may be appropriate, unless contraindicated. Wearing loose, light-colored, and lightweight clothing is palliative in prickly heat, allowing airflow to the skin. Cooling baths and use of air conditioning also will be helpful in symptom management. To that end, all excess clothing should be removed. Patients must be warned not to apply oleaginous substances to prickly heat lesions because these substances plug pores that need to be patent.

Pharmacologic Therapy

Pharmacologic therapy with nonprescription products for relief of prickly heat should be limited to mild to moderate, uncomplicated cases. Affected areas should not be occluded during therapy. Overall, this disorder can be ameliorated in less time and with less total drug exposure than are required for diaper dermatitis.

Emollients, Skin Protectants, and Antipruritics

A drug product that relieves burning and itching and does not block exposure of skin to air should be used to treat the symptoms of prickly heat. Options include water-washable antipruritic products, as well as bland emollients and

protectants that soothe the skin and maintain skin moisture and texture. Colloidal oatmeal bath products and lotions also are useful because of their antipruritic and soothing properties. Powders should be used only prophylactically to absorb moisture and keep skin dry. (See [Table 36–5](#) for selected trade-name products and [Chapter 33](#) for a discussion of skin emollients.)

TABLE 36–5 Selected Nonprescription Products for Prickly Heat

Trade Name	Primary Ingredient(s) (With Selected Additional Ingredients)
Aveeno Daily Moisturizing Lotion	Dimethicone 1.2% (glycerin; oat kernel flour)
Extra Strength Benadryl Itch Stopping Cream	Diphenhydramine HCl 2%; zinc acetate 0.1%
Cortizone-10 Maximum Strength Anti-Itch Cream	Hydrocortisone 1% (aloe; beeswax; glycerin; mineral oil; petrolatum)
Eucerin Calming Itch Relief Treatment	Menthol 0.1% (glycerin; colloidal oatmeal; dimethicone; evening primrose oil; castor oil)
Lubriderm Daily Moisture Lotion	Water; mineral oil; glycerin; dimethicone

Other Pharmacologic Agents

As with diaper dermatitis, hydrocortisone is contraindicated in infants. In adults, hydrocortisone may be useful if the body surface area involved is 10% or less. (See [Figure 41–3](#) for information on calculating body surface area.) Because prickly heat rapidly clears without drug therapy, hydrocortisone should be used only when relief of itching is required. Topical antihistamines and local anesthetics (see [Chapter 37](#)) carry the risk of sensitization, but they can be used as antipruritic agents. Patients who have a fever, in whom the associated sweating may be causing prickly heat, can use standard systemic analgesics to manage the fever (see [Chapter 6](#)).

Product Selection Guidelines

In treating prickly heat, the skin needs to dry and dissipate moisture. Therefore, only water-washable, cream-based products should be used. For moisture absorption and prevention of wetness, powders are reasonable;

however, prolonged use or overuse can lead to clogged pores, precipitating prickly heat. For use on the chest or neck, cornstarch or talc powder should be placed in the hand and applied manually to the skin with light friction to avoid inhalation, which can cause severe respiratory disease. Any product that has a potentially toxic ingredient (e.g., phenols, boric acid) if absorbed through thin, compromised skin should not be recommended for infants. Bathing children and infants who have prickly heat in colloidal oatmeal or lukewarm water may be recommended as a first option.

Assessment of Prickly Heat: A Case-Based Approach

Patient assessment for prickly heat involves identifying the site(s) of the lesions and potential causes. If the patient is an infant, the health care provider should gather information regarding potential environmental characteristics (e.g., sleeping conditions, presence/absence of air conditioning) that could be exacerbating the condition.

Case 36–2 provides an example of assessment of a patient with prickly heat.

Algorithm: Prickly Heat

FIGURE 36–2 Self-care for prickly heat. Key: OTC = over-the-counter; PCP = primary care provider.

Case 36–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	

Relevant Evaluation Criteria	Scenario/Model Outcome
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient seeks advice from the pharmacist regarding treatment for “red bumps that look like tiny dots” on his chest and back. He has had the rash for 2 days. He states that the rash is itchy but not painful.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	Patient seems to get this rash every summer. He is training for a marathon and notices the rash when he wears athletic workout apparel.
c. Description of the patient’s efforts to relieve the symptoms	Patient tries to prevent rash through good personal hygiene techniques (e.g., taking showers more frequently) and applying a thick cream to problem areas to keep them moist; however, these measures do not always prevent the rash.
d. Patient’s identity	Tho Nguyen
e. Patient’s age, gender, height, and weight	28 years, male, 5 ft 10 in., 170 lb
f. Patient’s occupation	Accountant and marathon runner
g. Patient’s dietary habits	Normal diet; social drinker
h. Patient’s sleep habits	Averages 7 hours of sleep nightly.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Allergies	Allergy to penicillin (hives)
k. History of other adverse reactions to medications	None
l. Other (describe) _____	n/a
Assess	
2. Differentiate patient’s signs/symptoms, and correctly identify the patient’s primary	Prickly heat secondary to sweating, exercise, heat, and occlusion from athletic wear and equipment

Relevant Evaluation Criteria	Scenario/Model Outcome
problem(s).	
3. Identify exclusions for self-treatment (Figure 36-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend self-care with drug, nondrug, and/or complementary therapies. (2) Refer the patient to an appropriate health care provider for treatment. (3) Recommend self-care until an appropriate health care provider can be consulted. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient education about the cause of prickly heat is important in prevention of future occurrences. Colloidal oatmeal lotions should provide relief from itching and also provide soothing benefits. Powders may be used prophylactically to absorb moisture. Cooling baths and air conditioning also are recommended.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Discontinue the thick cream because it can block pores, worsening your prickly heat. Topical hydrocortisone will help with the itching, but do not apply it more than 3-4 times a day and to more than 10% of your body."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Prickly heat often heals with time once the cause is removed and can be effectively managed with nonprescription products and improved hygiene practices. Keeping the area dry and minimizing clogged pores are key measures. If relief of itching is needed, hydrocortisone is preferred, because topical antihistamines and local anesthetics carry the risk of sensitization."
Implement	
8. When recommending self-	

Relevant Evaluation Criteria	Scenario/Model Outcome
care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	“Cortizone 10 Maximum Strength: apply to affected area(s) not more than 3–4 times daily as needed. Johnson’s Baby Powder: apply 1 time daily after showering. Be careful not to inhale powder.”
b. Maximum number of days the therapy should be employed	“Use of nonprescription protectants and self-treatment measures for prickly heat is limited to 7 days.”
c. Product administration procedures	See the box “Patient Education for Prickly Heat.”
d. Expected time to onset of relief	“The itching and rash should start to subside within 24 hours or less if nonpharmacologic measures are employed as directed.”
e. Degree of relief that can be reasonably expected	“Skin should return to normal within 7–10 days; protectants may not provide sufficient itch relief. Prickly heat is likely to return if nonpharmacologic strategies are not implemented.”
f. Most common adverse effects	Powders used in excess may clog pores, exacerbating the condition.
g. Adverse effects that warrant medical intervention should they occur	Respiratory inhalation of powders
h. Patient options in the event that condition worsens or persists	See “Exclusions for Self-Treatment” in Figure 36-1 .
i. Product storage requirements	“Store this product out of reach of children and away from heat and moisture.”
j. Specific nondrug measures	See “Nondrug Measures” in the box “Patient Education for Prickly Heat.”

Relevant Evaluation Criteria	Scenario/Model Outcome
Solicit follow-up questions from the patient or caregiver.	"Are there specific athletic clothing items that make this better or worse?"
Answer the patient's or caregiver's questions.	"Any type of tight or occlusive clothing will worsen or make prickly heat more likely. Neoprene materials in athletic clothing have been found to make prickly heat more likely. Wearing loose athletic clothing and removal of clothing immediately after working out and then showering will minimize your risk."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mr. Nguyen to call you in 3 days to update you on his response to your treatment plan.

Patient Counseling for Prickly Heat

The health care provider should emphasize that prickly heat usually is easily treated by removing factors that clog skin pores, while also explaining appropriate nonpharmacologic and pharmacologic measures for promoting healing or alleviating symptoms. An important point to include in patient education is that excessive use of skin protectants can exacerbate the disorder. The box "Patient Education for Prickly Heat" lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Prickly Heat

Treatment for prickly heat should be of relatively short duration. Considerable improvement is commonly noted in as little as 24 hours after initiation of nonpharmacologic and pharmacologic therapy. If the condition is not completely resolved or has worsened after 7 days of treatment, referral for further medical evaluation is indicated. Monitoring of treatment success

involves simple observation of lesions. At the end of therapy, the affected skin should have returned to its precondition state.

Patient Education for Prickly Heat

The goals of self-treatment are (1) to relieve the discomfort of prickly heat and (2) to eliminate its cause. For most patients, following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- To prevent clogging skin pores, avoid excessive sweating by resting, cooling off, or going to a cool environment.
- Wear loose, light-colored, breathable, and lightweight clothing to allow airflow to the skin.
- Shower, bathe, or change clothes immediately after heavy sweating, and wear loose-fitting clothes when such activity is anticipated. Remember to drink plenty of fluids, and allow the body to cool down after any strenuous activity.

Nonprescription Medications

- Unless a health care provider advises otherwise, use systemic analgesics, such as acetaminophen or ibuprofen, to reduce a fever and the sweating it can cause. (See [Chapter 6](#) for dosing information.)
- Do not apply oily substances to prickly heat lesions because they clog skin pores.
- Use powdered skin protectants to absorb moisture and help prevent wetness ([Table 36–4](#)). Place cornstarch or talc powder in the hand, and apply to the skin with light friction. Note that prolonged use or overuse of powders can lead to clogged pores, which can precipitate prickly heat.
- Do not use hydrocortisone in infants. However, it may be used to relieve itching in adult cases of prickly heat if no more than 10% of

the body surface area is involved.

- Water-washable emollients applied in a thin film twice a day can help the skin return to normal. (See [Chapter 33](#).)
- If redness, burning, itching, peeling, or swelling develops after a product is applied, rinse any remaining product off the skin and avoid further use.
- To soothe discomfort in adults or infants, wash the affected skin with bland soap or soak the area in a colloidal oatmeal solution.
- The condition should respond with observable improvement in 24 hours.

When to Seek Medical Attention

- If the condition persists after 7 days of treatment, consult a primary care provider.

Key Points for Diaper Dermatitis and Prickly Heat

Diaper Dermatitis

- Diaper dermatitis is exacerbated by moisture and occlusion.
- Increasing the frequency of diaper changes (i.e., decreasing contact time between skin and urine/feces) plays a major role in the nonpharmacologic management of diaper dermatitis.
- Pharmacologic therapy should be limited to use of products containing FDA-approved ingredients indicated for the treatment of diaper dermatitis ([Table 36–2](#)); exotic additives and complementary therapies should be avoided.
- Apply hydrophobic skin protectants liberally to diaper dermatitis areas; over application should not be a concern.

- Do not use hydrocortisone in the self-treatment approach to diaper dermatitis.
- A majority of diaper dermatitis cases will resolve when occlusion and wetness are adequately suppressed.
- With diaper dermatitis that persists after 7 days of treatment, the patient should be referred for further medical evaluation.

Prickly Heat

- Prickly heat is exacerbated by heat, humidity, and occlusion.
- Generally, prickly heat will resolve when occlusion and wetness are adequately suppressed.
- Pharmacologic treatment of prickly heat should be targeted at providing relief from itching or burning.
- Products containing emollients or anti-itch ingredients in water-washable dosage forms are favored in the treatment of prickly heat. Powders may be used to help dry the skin, albeit judiciously to avoid clogged pores, and careful application technique is essential to prevent inhalation.
- With prickly heat that persists after 7 days of treatment, the patient should be referred for further medical evaluation.

Chapter 37: Insect Stings and Bites and Pediculosis

Authors: Patricia H. Fabel, Elizabeth W. Blake

Insect bites and stings are common, and anyone who spends time outdoors is at risk. These injuries usually cause only a local reaction, but they can produce a mild allergic reaction or life-threatening anaphylaxis in patients who are sensitive to compounds in the insect's saliva or venom. Approximately 0.5%–3% of the population may show signs of systemic allergic reactions to insect stings, and simultaneous multiple insect stings of 500 or more may cause death from toxicity.¹ In the United States, more people die of insect stings than of bites from all poisonous animals combined.² The exact number of people who experience systemic allergic reactions to insect bites is unknown.

Despite the potentially fatal consequences, encounters with biting and stinging insects are typically brief. Pediculosis (lice infestation) and scabies, however, are parasitic infections, and the arachnids remain on the host until eradicated. Approximately 10–12 million people in the United States are affected by pediculosis each year, most of them children ages 3–12 years.³

This chapter covers the stings of insects only but discusses the bites of both insects and arachnids (e.g., ticks, mites, spiders, lice). The term *insect* is used to cover general statements about these invertebrates.

Insect Bites

Pathophysiology and Clinical Presentation of Insect Bites

Bites from insects (e.g., mosquitoes, fleas, bedbugs) and arachnids (e.g., ticks, mites, spiders, lice) are nonvenomous. Each insect has distinctive biting organs and salivary secretions that contribute to the characteristic signs and symptoms for each type of bite.

Mosquitoes

Mosquitoes are found in abundance worldwide, particularly in humid, warm climates. After landing on the skin, mosquitoes inject an anticoagulant saliva into the victim, which causes the characteristic welt and itching. These bites may expand into larger blisters or urticarial reactions with systemic symptoms of fever and joint swelling in some patients. Although rare, anaphylaxis may occur.⁴

Mosquitoes serve as vectors for spreading serious systemic infections including malaria and West Nile, Chikungunya, and Zika viruses, with West Nile virus being the most common.⁵ Although most patients infected with West Nile virus do not experience symptoms, about 20% of infected patients experience influenza-like symptoms with fever, fatigue, and possible joint pain. Few patients experience severe symptoms, and the illnesses are rarely fatal.⁶

Fleas

Fleas are tiny bloodsucking insects that can be found worldwide but breed best in a humid climate. Humans often are bitten after moving into a vacant flea-infested habitat or when living with infested pets. Flea bites usually are multiple and grouped and, in humans, primarily occur on the legs and ankles. Each lesion is characterized by an erythematous region around the puncture and intense itching. In addition to being annoying, fleas can transmit diseases such as bubonic plague and endemic typhus.⁷

Sarcoptes scabiei

Scabies is a contagious parasitic skin infection caused by *Sarcoptes scabiei*, a very small and rarely seen arachnid mite.⁸ The mites burrow up to 0.4 in. (1 cm) into the stratum corneum, and the females then deposit eggs in their “tunnels.” Common infestation sites are interdigital spaces of the fingers, flexor surfaces of the wrists, external male genitalia, buttocks, and anterior axillary folds (see [Color Plates](#), photograph 23). Scabies infection is characterized by inflammation with a papular rash and intense itching, although symptoms may not appear for 4–6 weeks. Mites are transmitted from an infected individual to others through physical contact. A scabies infection requires treatment with prescription drugs.

Bedbugs

Bedbugs usually hide and deposit their eggs in crevices of walls, floors, picture frames, bedding, folds of linens, corners of suitcases, and furniture during the day; they bite their victims at night. The increased mobility of society worldwide has heightened concern for an increased incidence of bedbug infestations in the United States in places frequented by travelers, such as hotels.⁹ In addition, bedbugs have developed resistance to commonly used pesticides. Bedbug bites typically appear along exposed areas of skin, such as the head, neck, and arms.¹⁰ Bites occur in clusters and may appear in a straight line. It may take several days for a bite mark to appear. The reaction to a bedbug bite can range from irritation at the site to a small dermal hemorrhage, depending on the sensitivity of the individual; however, most of these bites involve intense itching.

Ticks

Ticks feed on the blood of humans and animals. During feeding, the tick's mouthparts are introduced into the skin, enabling it to hold firmly (see [Color Plates](#), photograph 24). If the tick is removed, but the mouthparts are left behind, intense itching and nodules requiring surgical excision may develop. If left attached, the tick becomes fully engorged with blood and remains for up to 10 days before dropping off. Ticks should be removed intact using fine tweezers within 36 hours of attachment. Tick removal by heating methods, such as a match or hot nail, or by painting substances onto the tick, such as nail polish or petrolatum, is not recommended. These methods can irritate the tick, causing it to secrete more saliva or even regurgitate gut contents, thereby increasing the likelihood of transmission of a tick-borne illness. After removal of the tick, the affected area should be cleaned with rubbing alcohol or washed with soap and water.¹¹

The local reaction to tick bites consists of itching papules that disappear within 1 week. Certain species of ticks, however, can transmit systemic diseases such as Rocky Mountain spotted fever and Lyme disease. Rocky Mountain spotted fever, transmitted by dog ticks, is characterized by severe headache, rash, high fever, and extreme exhaustion. Lyme disease is caused by a spirochete found in deer ticks that is transmitted into the victim after the tick is attached for 36 hours. Of the 300,000 cases of Lyme disease diagnosed annually, the majority occur in the northeast and upper Midwest regions of the United States. Most

acute stages of Lyme disease are heralded by skin rash and influenza-like symptoms. The rash appears first as a papule at the bite site and may become an enlarged circle with a clear center called a “bull’s-eye rash” or *erythema migrans*. Tender urticarial lesions appear 3–30 days after the bite.¹² If left untreated, complications such as neurologic symptoms, cardiac disturbances, musculoskeletal symptoms, and arthritis may occur. Early diagnosis and prompt treatment by a health care provider are essential to prevent development of these serious manifestations.

Chiggers

Chiggers, or red bugs, live in shrubbery, trees, and grass. A common myth is that chiggers burrow into the skin and stay there. After attaching to the skin, usually around the edges of tight-fitting clothing, the larvae secrete a digestive fluid that causes cellular disintegration of the affected area, clusters of red papules, and intense itching. This fluid also causes the skin to harden and form a tiny tube in which the chigger remains to feed until engorged. It then drops off and changes into an adult.⁹

Spiders

Although all species of spiders are venomous, most are unable to penetrate the skin because their fangs are too short or too fragile. The black widow, brown recluse, and hobo spiders are three major exceptions. Deaths from spider bites are rare, but symptoms can be serious. Reactions to black widow bites includes erythema or a halo-shaped lesion, delayed intense pain, muscle spasms, abdominal disturbances, fever, chills, and dyspnea. Most brown recluse bites result in just a local reaction with itching and erythema. These bites, however, can progress into a necrotic ulceration, particularly in fatty areas of the body. Hobo spider bites typically present with a moderate to severe, slow-healing wound.¹³ If a spider bite is suspected but cannot be confirmed, the wound area should be monitored for these symptoms.

Complications of Insect Bites

Secondary bacterial infection of insect bites can occur if skin of the affected area is abraded from scratching. Skin infections, such as impetigo, may be a complication of insect bites. These infections may appear as yellow crusting, purulent drainage, and/or significant redness and swelling of the skin around

the bite.

Treatment of Insect Bites

Specific nonprescription external analgesics are labeled for use in treating minor insect bites.

Treatment Goals

The goals of self-treating insect bites are to relieve symptoms and prevent secondary bacterial infections.

General Treatment Approach

Application of an ice pack wrapped in a washcloth may provide sufficient relief of the pain and irritation of bites from mosquitoes, chiggers, bedbugs, or fleas. The ice pack is applied to the affected area for up to 10 minutes, with at least a 10-minute rest between applications. If this treatment does not work, applying an external analgesic to the site should relieve symptoms. Patients should be advised to avoid scratching the bite. Prevention of future insect bites also is important.

Self-treatment of insect bites with a nonprescription product is appropriate if the reaction is confined to the site of the bite and the patient is younger than 2 years. No effective nonprescription product is available to treat scabies. Patients with bites from ticks and spiders require medical referral because of possible systemic effects. [Figure 37–1](#) outlines treatment of insect bites and lists exclusions for self-treatment.

Nonpharmacologic Therapy

Nondrug measures include the two methods of preventing insect bites: avoiding insects and using repellents. Specific measures are listed in the box “Patient Education for Insect Bites” (see the section “Patient Counseling for Insect Bites.”)

Avoidance of Insects

Recommendations for avoiding insects are included in the box “Patient

Education for Insect Bites.”

Use of Insect Repellents

Insect repellents are useful in preventing bites from insects such as mosquitoes, fleas, and ticks, but these products are not effective in repelling stinging insects. Selection of an insect repellent should be based on product ingredients, concentration, preferred formulation, anticipated type and length of exposure, and patient-specific considerations. Most commercial products contain *N,N*-diethyl-*m*-toluamide, commonly called DEET, in concentrations ranging from 5% to 100%. DEET is considered to be the most efficacious repellent. Other insect repellent ingredients include synthetic chemicals such as 3-[*N*-butyl-*N*-acetyl]-aminopropionic acid, ethyl ester (IR3535), and picaridin, as well as plant-based components such as oil of lemon eucalyptus (OLE) (p-methane-3,8-diol [PMD]); catnip oil; and 2-undecanone. Examples of available insect repellents and their ingredients are included in [Table 37–1](#).

TABLE 37–1 Selected Nonprescription Insect Repellents

Trade Name	Primary Ingredient(s)
Cutter Skinsations Insect Repellent Pump Spray	DEET 7%; aloe vera; vitamin E
Cutter Sport Insect Repellent	DEET 15%
OFF! Deep Woods Sportsmen Insect Repellent I Pump Spray	DEET 98.25%
OFF! ACTIVE Insect Repellent I	DEET 15%
OFF! FamilyCare Insect Repellent II	Picaridin 5%
OFF! Deep Woods Insect Repellent Towelettes	DEET 25%
Skin So Soft Bug Guard Plus IR3535 Gentle Breeze SPF 30 Lotion	IR3535 7.5%; SPF 30 sunscreen
Skin So Soft Bug Guard Plus Picaridin Aerosol Spray	Picaridin 10%
Repel Plant-Based Lemon Eucalyptus Insect Repellent Pump Spray	Oil of lemon eucalyptus 30%
Repel Insect Repellent Sportsmen Max Formula Aerosol	DEET 40%
Repel Insect Repellent Mosquito Wipes	DEET 30%
Coleman Insect Treatment Gear & Clothing Aerosol Spray	Permethrin 0.5%

Trade Name	Primary Ingredient(s)
Sawyer Fisherman's Formula	Picaridin 20%

Key: DEET = *N,N*-Diethyl-*m*-toluamide.

***N,N*-Diethyl-*m*-Toluamide (DEET)**

The exact mechanism of action for DEET is not fully known. Similar to other repellents, DEET only repels insects from biting; it does not kill insects. When applied to skin or clothing, the volatile repellent releases vapors that tend to discourage the approach of insects.

Repellents, available in sprays, solutions, creams, wipes, and other forms, are applied as needed to skin or clothing according to package directions, usually no more frequently than every 4–8 hours. Concentrations less than 30% are preferable for children, and use of DEET insect repellents on children younger than 2 months should be discouraged.¹⁴ Products with DEET concentrations ranging from 10% to 35% provide adequate effect and sufficient protection for adults in routine situations, with concentrations of 20% or higher recommended to prevent tick bites. Concentrations greater than 50% do not offer any additional protection, but they may have a longer repellent effect. Unfortunately, products with such concentrations also may be associated with a higher incidence of skin reactions. Table 37–2 provides a summary from the Environmental Protection Agency, as well as other sources, regarding the application and safe use of DEET products.^{14–18}

TABLE 37–2 Guidelines for Safe Use of DEET
• Read and follow all directions and precautions on the product label. • Use just enough repellent to cover exposed skin and/or clothing. Do not use product under clothing. • Do not apply product over cuts, wounds, or irritated skin. • Do not apply product to hands or near eyes and mouth; apply in small amounts around ears. • To apply to face, spray product on hands first, and then rub on face. Do not spray product directly onto face. • Do not allow young children to apply this product. • Avoid overapplication of repellent. • Do not spray product in enclosed areas.

- Avoid inhalation of repellent.
- When sunscreen needs to be used in conjunction with a repellent, apply sunscreen first followed by the repellent.
- Product may damage synthetic fibers and plastics.
- Use of this product may cause skin reactions in rare cases.
- After returning indoors, wash treated skin with soap and water.
- Wash treated clothing before wearing it again.

Key: DEET = *N,N*-Diethyl-*m*-toluamide; EPA = Environmental Protection Agency.

Source: [References 11–14](#).

Although rare, skin irritation can occur after application of DEET-based insect repellents, with occlusion of the application area possibly contributing to skin rashes or eruptions. Central nervous system reactions, including seizures, ataxia, hypotension, encephalopathy, and angioedema, have been reported in association with improper use or ingestion.^{14,16,18} The Food and Drug Administration (FDA) advises against the use of products that combine insect repellents and sunscreen.¹⁹ Sunscreen products require more frequent applications compared with insect repellents; therefore, use of combination products can increase the risk of excessive DEET absorption.^{16,18} These products are considered safe if used appropriately, even in women who are pregnant or breastfeeding. [Table 37–2](#) lists warnings and precautions for use of DEET.

Other Insect Repellents

Alternative products include citronella, OLE, soybean oil, cedar oil, lavender oil, tea tree oil, garlic, and scented moisturizers in mineral oil (e.g., Skin-So-Soft). These products generally have been found to be less effective than DEET as repellents against mosquitoes, particularly with regard to length of action. Picaridin, an alternative to DEET, is being promoted as being less odorous and less irritating to skin.¹⁴ OLE should not be used in the “pure” form because its effects have not been studied. OLE and DEET provide similar protection against malaria, but OLE’s effect does not last as long. In addition, OLE should be avoided in children younger than 3 years.¹⁸ Limited information is available

regarding the safety and efficacy of catnip oil and 2-undecanone. Insect repellents containing permethrin 0.5% are designed for use only on clothing and camping equipment; they can effectively repel mosquitoes, ticks, and flies.¹⁴

Pharmacologic Therapy

External analgesics, such as local anesthetics, topical antihistamines, hydrocortisone, and some counterirritants, are approved for treating pain and itching associated with insect bites. These agents are not approved for use in children younger than 2 years.

Topical skin protectant agents may be used to reduce inflammation and promote healing. First-aid antiseptics and antibiotics can help prevent secondary infections (see [Chapter 41](#)).

Systemic antihistamines often are used in treating itching related to insect bites, but this use is not a label indication. [Chapter 11](#) discusses systemic antihistamines in detail.

Local Anesthetics

Local anesthetics such as benzocaine, pramoxine, benzyl alcohol, lidocaine, dibucaine, and phenol are approved in topical preparations for relief of itching, irritation, and pain caused by insect bites.

Local anesthetics cause a reversible blockade of conduction of nerve impulses at the site of application, thereby producing loss of sensation. Phenol exerts topical anesthetic action by depressing cutaneous sensory receptors.

Topical preparations containing local anesthetics are available as creams, ointments, aerosols, and lotions. These products generally are applied to the bite area up to 3–4 times daily for no longer than 7 days.

Local anesthetics are relatively nontoxic when applied topically as directed, and systemic absorption typically does not occur. However, allergic contact dermatitis may occur. Compared with other local anesthetics, pramoxine and benzyl alcohol do not commonly cause adverse effects and exhibit less cross-sensitivity. Dibucaine, a common allergen, may cause systemic toxicity if excessive absorption occurs. Convulsions, myocardial depression, and death

have been reported from systemic absorption.²⁰ Phenol solutions of concentrations less than 2% are irritating and may cause sloughing and necrosis of skin, but the concentration of phenol in nonprescription products ranges from 0.5% to 1.5%. Nonprescription products containing phenol should not be applied to extensive areas of the body, especially under compresses or bandages because of the risk of skin damage and systemic absorption.²¹ Products containing phenol should be avoided in pregnant patients and children.

Topical Antihistamines

Topical antihistamines exert an anesthetic effect by depressing cutaneous receptors and are approved for temporary relief of pain and itching related to minor insect bites.²² Products are available in several topical dosage forms; they are generally applied to the bite area up to 3–4 times daily for no longer than 7 days. Diphenhydramine hydrochloride in concentrations of 0.5%–2% is the agent used in most products that contain a topical antihistamine.²²

Although absorption occurs through skin, topical antihistamines generally are not absorbed in sufficient quantities to cause systemic adverse effects, even when applied to damaged skin. Systemic absorption is of more concern when these products are used over large body areas, especially in young children. Topical antihistamines can cause photosensitivity and hypersensitivity reactions; continued use of these agents for 3–4 weeks increases the possibility of contact dermatitis.

Counterirritants

Low concentrations of the counterirritants camphor and menthol are used in some topical analgesic products. [Chapter 7](#) discusses these agents in more detail. These products generally are applied to the bite area 3–4 times daily for up to 7 days.

Camphor

At concentrations of 0.1%–3%, camphor depresses cutaneous receptors, thereby relieving itching and irritation by exerting an anesthetic effect. However, camphor-containing products can be very dangerous if ingested. Patients should be warned to keep these products out of children's reach.

Menthol

In concentrations of <1%, menthol depresses cutaneous receptors and exerts an analgesic effect. Menthol is considered a safe and effective antipruritic when applied to the affected area in concentrations of 0.1%–1%.

Hydrocortisone

Hydrocortisone 1% topical preparations are indicated for temporary relief of minor insect bites. A wide variety of topical hydrocortisone dosage forms are available and should be applied as directed to the bite area 3 or 4 times daily for up to 7 days. [Chapter 35](#) provides additional information about topical hydrocortisone.

Skin Protectants

Medications such as zinc oxide, calamine, and titanium dioxide are applied to insect bites mainly in the form of lotions, ointments, and creams. These agents act as protectants and tend to reduce inflammation and irritation. Zinc oxide works as a mild astringent with weak antiseptic properties.²³ Zinc oxide and calamine also absorb fluids from weeping lesions. FDA considers nonprescription drugs containing zinc oxide and calamine to be safe and effective in concentrations of 1%–25%. These preparations should be applied to the affected area as needed. They have minimal adverse effects and are recommended for adults, children, and infants. Although its mechanism of action is similar to that of zinc oxide, titanium dioxide's safety and effectiveness have not been determined by FDA.

Product Selection Guidelines

Sensitization, specifically contact dermatitis, can occur with use and overuse of local anesthetics. Pramoxine and benzyl alcohol have a low incidence of adverse effects. Dibucaine and phenol have the most potential for adverse effects, especially if systemic absorption occurs from improper application.

Adverse effects and systemic absorption generally are not a concern with short-term use of the topical antihistamine diphenhydramine hydrochloride. Its prolonged use, however, can cause allergic or photoallergic contact dermatitis. Similarly, short-term use of hydrocortisone usually does not cause adverse effects or clinically significant systemic absorption. Patients with

scabies, bacterial infections, or fungal infections should not use hydrocortisone without medical supervision because it can worsen or mask these disorders. Camphor-containing products can be very dangerous if ingested, making them an inappropriate choice for use in children. Patients must understand that topical antipruritics and anesthetics should not be used for more than 7 days unless their health care provider specifically advises such use.

The patient's preference of dosage forms also should guide product recommendations. **Table 37–3** lists selected trade-name products in various dosage forms.

TABLE 37–3 Selected Nonprescription External Analgesic Products for Insect Bites and Stings	
Trade Name	Primary Ingredient(s)
Local Anesthetics	
Itch-X Gel/Pump Spray	Pramoxine HCl 1%; benzyl alcohol 10%
Lanacane First Aid Aerosol Spray 2-in-1 Fast Acting Pain Relief	Benzocaine 20%; benzethonium chloride 0.2%
Solarcaine Pain Relieving Aerosol Spray	Lidocaine 0.5%; aloe, vitamin E
Topical Antihistamines	
Benadryl Itch Stopping Cream	Diphenhydramine HCl 2%; zinc acetate 0.1%
Benadryl Itch Stopping Gel, Extra Strength	Diphenhydramine HCl 2%
Counterirritants	
Blue Star Ointment	Camphor 1.24%
Sarna Anti-itch Lotion Original	Camphor 0.5%; menthol 0.5%
Corticosteroids	
Aveeno Active Naturals Anti-Itch Maximum Strength Cream	Hydrocortisone 1%; aloe vera
Cortizone-10 Intensive Healing Anti-Itch Cream	Hydrocortisone 1%
Cortizone-10 Easy Relief Liquid	Hydrocortisone 1%; aloe vera

Trade Name	Primary Ingredient(s)
Combination Products	
Aveeno Anti-Itch Concentrated Lotion	Pramoxine HCl 1%; calamine 3%; dimethicone
Benadryl Extra Strength Anti-Itch Cooling Spray	Diphenhydramine HCl 2%, zinc acetate 0.1%
Caladryl Clear Lotion	Pramoxine HCl 1%; zinc acetate 0.1%; camphor
Campho-Phenique Gel	Camphor 10.8%; phenol 4.7%; eucalyptus oil
Chigarid External Analgesic	Camphor 2.6%; phenol 1.5%; menthol 0.1%; eucalyptus oil 0.5% in collodion
StingEze Insect Bite Relief	Benzocaine 5%; phenol 1.35%, camphor
Sting-Kill Swabs	Benzocaine 20%; menthol 1%

Assessment of Insect Bites: A Case-Based Approach

The type of insect that inflicted the patient's injury should be determined first. Patients with suspected spider or tick bites require a medical referral because of the risk of complications. For other insect bites, the seriousness of the reaction should be evaluated before a nonprescription product or nondrug measure is recommended. If a nonallergic reaction is present, the appropriate external analgesic for symptomatic relief should be recommended. Recommending a skin protectant to reduce irritation and inflammation or to prevent secondary bacterial infection is appropriate.

Patient Counseling for Insect Bites

Counseling for insect bites includes an explanation of how to treat the injury and how to prevent recurrences. Nondrug measures and proper use of recommended nonprescription products should be explained. The explanation should include potential adverse effects of these agents, plus signs and symptoms that indicate the injury needs medical attention. The time to improvement will vary depending on the type of insect bite and individual patient characteristics. Appropriate use of insect repellents to prevent further

bites also should be discussed. The box “Patient Education for Insect Bites” lists specific information to provide patients.

Evaluation of Patient Outcomes for Insect Bites

Follow-up should occur after 7 days of self-treatment. The patient should be advised to seek medical attention if symptoms such as redness, itching, and localized swelling worsen during treatment, or if the patient develops secondary infection, fever, joint pain, or lymph node enlargement. Medical attention also is necessary for symptoms that persist after 7 days of treatment.

FIGURE 37–1 Self-care for insect bites. Key: AH = Antihistamine; D/C = discontinue; OTC = over-the-counter. Source: [References 4, 11, and 13.](#)

Insect Stings

Pathophysiology and Clinical Presentation of Insect Stings

Venomous insects such as honeybees, wasps, hornets, yellow jackets, and fire ants belong to the order Hymenoptera. They attack their victims to defend themselves or to kill other insects. The injected venom contains allergenic proteins and pharmacologically active molecules. Because venom contents vary within the Hymenoptera order, venom is discussed here in general terms.¹³

Most people will complain of pain, itching, and irritation at the site following an insect sting, but they generally will have no systemic symptoms. Individuals who are allergic to insect stings may experience hives, itching, swelling, and burning sensations of the skin. Although anaphylaxis is rare, those with severe allergies may experience a fall in blood pressure, light-headedness, chest tightness, dyspnea, and even loss of consciousness. These reactions may appear as soon as 10–15 minutes but no later than 6 hours after the sting.

Patients who receive multiple stings, such as from Africanized bees, may experience a toxic reaction with responses similar to anaphylaxis. Insect stings also may lead to delayed local inflammation 1–2 weeks after the sting.²⁴

Wild Honeybees, Wasps, Hornets, and Yellow Jackets

Wild honeybees are found most commonly in the western and midwestern United States; they usually nest in hollow tree trunks. Because the honeybee stinger is barbed, it remains embedded in the skin, even after the bee pulls away or is brushed off, and continues to inject venom. The venom from honeybees may cause a greater release of histamine compared with venom of other stinging insects.²⁵ Paper wasps, hornets, and yellow jackets are found more commonly in the southern, central, and southwestern United States. Paper wasps tend to nest in high places, under eaves of houses, or on branches of high trees, whereas hornets prefer to nest in hollow spaces, especially hollow trees. Yellow jackets, considered the most common stinging culprits, usually nest in low places, such as burrows in the ground, cracks in sidewalks, or small shrubs.²⁵ The stinging mechanism of wasps, hornets, and yellow jackets resembles that of the honeybee, except their stingers are not barbed. Their stingers can be withdrawn easily after venom is injected, enabling them to sting repeatedly.⁷

Patient Education for Insect Bites

The objectives of self-treatment for insect bites are (1) to relieve swelling, pain, and itching; (2) to prevent scratching that may lead to secondary bacterial infection; (3) to monitor for infections transmitted by ticks; and (4) to prevent future insect bites. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Apply ice pack promptly to bite area to reduce swelling, itching, and pain.
- Avoid scratching the affected area; keep fingernails trimmed and clean.

- Remove ticks with tweezers by grasping the tick's head and gently pulling; the head should be removed. Keep the removed tick in a sealed container for future identification in case of systemic symptoms. After removal of the tick, clean the affected area with rubbing alcohol or soap and water to disinfect the skin.
- Do not wear rough, irritating clothing over bite area.

Preventive Measures

- To prevent exposure, cover as much skin as possible with clothing and socks, and cuff clothing around ankles, wrists, and neck. Clothing may be treated with permethrin to deter biting insects.
- Avoid swamps, dense woods, and dense brush that harbor mosquitoes, ticks, and chiggers.
- Keep pets free of pests.
- Remove standing water from around the home to reduce breeding areas for mosquitoes.
- Limit the amount of time spent outside at dawn and dusk.
- Use barriers such as window screens and netting.
- Apply insect repellent according to package recommendations to repel biting insects (see [Table 37–2](#)); these repellents do not deter stinging insects.
- To prevent transmission of scabies, avoid close, physical contact with infected individuals.

Nonprescription Medications

Topical Analgesics

- Use an external analgesic to relieve the pain and itching of insect bites. The choice of medications includes local anesthetics, topical antihistamines, counterirritants, and hydrocortisone.
- These products can be applied to the bite area 3–4 times daily. Do not use on children younger than 2 years. Do not use longer than 7 days.
- Note that local anesthetics can cause sensitization. If these agents are preferred, pramoxine and benzyl alcohol are less likely to cause

adverse effects.

- Do not use dibucaine in large quantities, particularly over raw surfaces or blistered areas. Such use could cause myocardial depression, convulsions, or death.
- Do not apply phenol to extensive areas of the body or under compresses and bandages. Such application increases the possibility of skin damage or systemic absorption.
- Do not use topical diphenhydramine longer than the recommended 7 days. Prolonged use can cause hypersensitivity reactions or systemic effects.
- Do not use hydrocortisone on scabies, bacterial infections, or fungal infections without a medical recommendation. Hydrocortisone can mask or worsen these disorders.
- Do not allow children to ingest camphor-containing products. Camphor is toxic when ingested.

Skin Protectants

- If a medication is needed to reduce irritation or inflammation, use a skin protectant such as zinc oxide or calamine.
- Apply protectant to affected area as needed up to 4 times daily.
- Some insect bite products contain external analgesics and skin protectants.

When to Seek Medical Attention

- Seek medical attention if the condition worsens during treatment or if symptoms persist after 7 days of topical treatment.
- Patients who were bitten by ticks or spiders or have scabies should seek medical attention promptly.

Fire Ants

Fire ants, imported from South America early in the 20th century and now found in the southeastern United States, live in underground colonies and form large raised mounds. Some ants only bite, whereas others bite and sting simultaneously; however, the bite is believed to cause the reactions. Fire ant

bites cause intense itching, burning, vesiculation, tissue necrosis, and anaphylactic reactions in hypersensitive individuals. The reaction to the bites initially leads to formation of pustules and may progress to ulcerated lesions.¹³

Treatment of Insect Stings

Although labeling of nonprescription products for insect-related injuries mentions only “insect bites” as an indication, it is generally accepted that FDA had intended the term to also cover insect stings.

Treatment Goals

The goal of self-treating insect stings is to relieve the itching and pain of cutaneous nonallergic reactions. Allergic or toxic reactions require immediate medical attention.

General Treatment Approach

Removal of the stinger followed by application of an ice pack in 10-minute intervals is the first step in treating insect stings. Application of topical hydrocortisone, local anesthetic, skin protectant, antiseptic, or counterirritant to the sting site is appropriate if the reaction is confined to the site and if no exclusions for self-treatment apply.¹³ Patients may benefit from oral diphenhydramine 25–50 mg per dose.²⁵ [Figure 37–2](#) lists exclusions for self-treatment and outlines the treatment of insect stings.

Algorithm: Insect Strings

FIGURE 37–2 Self-care for insect stings. Key: AH = Antihistamine; D/C = discontinue; OTC = over-the-counter. Source: [Reference 13](#).

Avoiding future insect stings can prevent an individual from developing allergic reactions to stings. If symptoms of an allergic reaction develop, emergency treatment should be administered, and the patient should seek medical attention. Patients with severe allergic reactions should be advised to wear a bracelet or carry a card identifying the nature of the allergy. They also should contact their primary care provider about carrying an injectable form of epinephrine.

Nonpharmacologic Therapy

Prompt application of cold packs to the sting site in 10-minute intervals helps to slow absorption of the venom and to reduce itching, swelling, and pain. Removal of the honeybee's stinger and venom sac, which are usually left in the skin, is important. The patient should remove the stinger before all venom is injected; approximately 2–3 minutes are needed to empty all contents from the honeybee's venom sac. The patient should not use tweezers or squeeze the sac because rubbing, scratching, or grasping it releases more venom. Scraping away the stinger with a fingernail or the edge of a credit card minimizes the venom flow. After the stinger is removed, an antiseptic, such as hydrogen peroxide or alcohol, should be applied.

Measures to avoid attracting stinging insects are included in the box "Patient Education for Insect Stings," which can be found in the section "Patient Counseling for Insect Stings."

Pharmacologic Therapy

The section "Treatment of Insect Bites" discusses the following topical products approved for treatment of insect bites and, by inference, insect stings: local anesthetics, topical antihistamines, counterirritants, hydrocortisone, and skin protectants.

Product labels for systemic antihistamines do not include treatment of itching associated with insect stings as an indication, even though these products are often used for this purpose.

Complementary Therapies

Meat tenderizer has been used on insect stings to "break down" proteins in venom. Ammonia and baking soda have been used to "neutralize" venom in insect bites. These products may affect itching. Most reports of their success are anecdotal, however, and to date their effectiveness has not been determined.

Assessment of Insect Stings

The critical determination in assessing a patient with an insect sting is

whether the patient is allergic to the venom. Patients experiencing allergic reactions should be referred immediately for emergency medical attention.

Case 37–1 illustrates assessment of a patient who has an insect sting.

Patient Counseling for Insect Stings

The health care provider should advise the patient that local reactions to insect stings usually are transient, but that severe reactions to insect stings can occur if sensitization to the insect venom develops with repeated exposure. The symptoms of allergic reactions should be explained. Patients who have a known hypersensitivity to insect stings should have epinephrine injection available at all times for emergency self-treatment.

For nonallergic reactions to stings, the provider should recommend one or more topical medications to manage immediate symptoms. The patient should be advised about adverse effects and any contraindications. The box “Patient Education for Insect Stings” lists specific information that should be provided.

Evaluation of Patient Outcomes for Insect Stings

Follow-up for nonallergic reactions to insect stings should occur within 7 days. The patient should be advised to seek medical attention if symptoms of pain, itching, and localized swelling worsen during the treatment period or persist after 7 days of treatment. Symptoms of secondary infection or fever also warrant medical attention. Follow-up for patients who have allergic reactions should occur the same day, if possible.

Case 37–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical	A 42-year-old man approaches the pharmacy counter to request assistance with a tick bite. He had been

Relevant Evaluation Criteria	Scenario/Model Outcome
history, including	walking in the park across the street when he noticed the tick attached to his right ankle.
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	He has been walking in the park for the last 2 hours, so he believes the tick crawled onto his skin during that time. He does not feel any symptoms at this time. He appears anxious regarding possible consequences of the tick bite. He does not appear to have any other local or systemic symptoms.
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	n/a. He denies applying insect repellent prior to his walk.
c. description of the patient's efforts to relieve the symptoms	He has not tried to remove the tick. He knows that it needs to be removed carefully, so he is requesting assistance.
d. patient's identity	Sam Newton
e. age, gender, height, and weight	42 years old, male, 72 in., 210 lb
f. patient's occupation	Artist
g. patient's dietary habits	Sam is well nourished. He does not follow any specific diet.
h. patient's sleep habits	He generally works late into the night and then sleeps until midday. Sleeps 6-7 hours a night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Hypertension:</i> amlodipine 5 mg daily and atorvastatin 10 mg daily
	<i>Dyslipidemia:</i> benazepril 20 mg daily
	<i>Pain:</i> occasional use of nonprescription acetaminophen
j. allergies	Sulfa antibiotics (rash)
k. history of other adverse reactions	Rash to sulfa antibiotics occurred when he was little.

Relevant Evaluation Criteria	Scenario/Model Outcome
to medications	No other reactions noted.
I. other (describe) _____	n/a
Assessment and Triage	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Sam appears to have been bitten by a tick on his right ankle while walking in the park.
3. Identify exclusions for self-treatment.	History of a tick bite
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Application of local anesthetic, topical antihistamine, counterirritant, antiseptic, or hydrocortisone, including the following: a. anesthetic: Lanacane First Aid 2-in-1 Aerosol Spray (benzocaine 20%; benzethonium chloride 0.2%) b. antihistamine: Maximum Strength Benadryl Cream/Spray (diphenhydramine 2%) c. counterirritant: Blue Star Ointment (camphor 1.24%) d. antiseptic: hydrogen peroxide or alcohol e. hydrocortisone: Cortizone-10 Cream (hydrocortisone 1%) (2) Refer Sam for immediate medical attention. (3) Recommend self-care until an HCP can be consulted. (4) Take no action.
Plan	

Relevant Evaluation Criteria	Scenario/Model Outcome
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer Sam for immediate referral to an HCP because the tick needs to be identified to ensure appropriate treatment is provided for possible infection.
6. Describe the recommended therapeutic approach to the patient or caregiver.	Refer Sam to his usual HCP or an urgent care center.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You need immediate treatment for this tick bite. Depending on the type of tick, you may need to start antibiotic therapy within 36 hours of the bite to prevent certain infections."
Patient Education	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"How do I remove the tick?"
Answer the patient's or caregiver's questions.	Ticks need to be removed as soon as possible and carefully to ensure all parts of the mouth are extracted: • Use a set of fine-tipped tweezers. • Attach the tweezer tips to the tick right at the edge of the skin to grab as much of the tick as possible. • Pull the tick straight away from the skin. • Do not squeeze the body of the tick. • Clean the area with rubbing alcohol or soap and water after removing the tick. • Do not apply nail polish or petrolatum to the tick, or use heating methods such as a hot nail or hot match to kill or remove the tick. • Take the tick in a container or plastic bag to an HCP for identification of the specific type

Relevant Evaluation Criteria	Scenario/Model Outcome
	of tick to determine the appropriate therapy. Applying an appropriate insect repellent prior to future outdoor activities is recommended.
Evaluation of Patient Outcome	
9. Assess patient outcome.	Call the patient within 1-2 days to ensure that he was able to see an HCP and, if indicated, to start appropriate prophylactic treatment. If he has not sought medical attention, advise him of the importance of prompt treatment to prevent complications from the tick bite.

Key: n/a = Not applicable; HCP = health care provider.

Patient Education for Insect Stings

The objectives of self-treatment for insect stings are (1) to relieve the swelling, pain, and itching of insect stings; (2) to monitor any reaction to the sting to determine whether an allergic reaction is developing; and (3) to prevent future insect stings. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- For honeybee stings, removing the honeybee stinger immediately is important. Scraping the stinger away with the edge of a credit card or fingernail is effective. Try not to squeeze or rub the stinger; these actions will actually release more venom.

- Apply an ice pack or a cold compress promptly to the sting site to help slow absorption of the venom. This action will reduce itching, swelling, and pain.
- Avoid scratching the affected area; keep fingernails trimmed and clean. Gloves or mittens may be used on small children during sleep to avoid unconscious scratching.
- To avoid attracting stinging insects, avoid wearing perfume, scented lotions, and brightly colored clothes; control odors in picnic and garbage areas; change children's clothing if it becomes contaminated with summer foods such as fruits; wear shoes when outdoors; and destroy nests of stinging insects near homes.
- If you are hypersensitive to stings, wear a bracelet or carry a card showing the nature of the allergy.

Nonprescription Medications

- For nonallergic stings, apply a topical nonprescription external analgesic such as a local anesthetic, topical antihistamine, counterirritant, or hydrocortisone to the affected site to relieve pain and itching. A skin protectant also can be recommended to prevent irritation and inflammation as well as to prevent secondary bacterial infection.
- These products can be applied 3–4 times daily for up to 7 days.

When to Seek Medical Attention

- If you have experienced previous severe reactions to insect stings, seek emergency medical care immediately. If a primary care provider has prescribed epinephrine or an oral antihistamine and you have it on your person, administer it according to the provider's instructions.
- Seek medical attention if you develop symptoms of an allergic reaction, such as hives, excessive swelling, dizziness, vomiting, or difficulty breathing.
- Seek medical attention if the pain and itching worsen during treatment or if they do not improve after 7 days of topical treatment.

Pediculosis

Pathophysiology and Clinical Presentation of Pediculosis

Lice are irritating pests, and lice infestations in the United States are common. Three types of lice that infest humans are head lice (*Pediculus humanus capitis*), body lice (*Pediculus humanus corporis*), and pubic lice (*Phthirus pubis*).

Head Lice

Head lice are the most common cause of lice infestation; outbreaks of lice infestation are common in places such as schools and daycare centers. Infestations most commonly are spread through direct head-to-head contact with an infected person. Sharing personal items such as caps, hairbrushes, and combs is unlikely to cause spreading.³ Outbreaks usually peak after the opening of schools each year, between August and November. All socioeconomic groups are affected. Head lice create problematic infestations, but they generally do not contribute to the spread of other diseases in the United States.²⁷

Head lice usually infest the head and live on the scalp (see [Color Plates](#), photographs 25A and B). A lice egg or nit is about 0.04 in. (1 mm) in diameter and is typically found within 0.16 in. (4 mm) of the scalp. Once hatched, the louse must begin feeding within 24 hours or it dies. The *nymph*, or newly hatched, immature louse, resembles an adult and matures within 8 to 9 days. Without treatment, this cycle may repeat every 3 weeks.²⁶ The bite of a louse causes an immediate wheal to develop around the bite, with a local papule appearing within 24 hours. Itching and subsequent scratching may result in secondary infection. Adult lice, which are about the size of a sesame seed, often are difficult to locate because they move when the hair is moved during inspection of the scalp. However, nits and nit casings generally can be spotted at the base of hair shafts when hair is parted for physical inspection. Hair inspections should focus on the crown of the head, near the ears, and at the base of the neck. The grayish nits blend in well with the hair, but nit casings (hatched nits) are a lighter color and are more easily located. Nits and nit

casings may be differentiated from dandruff, dirt, and so forth because of their firm attachment to the hair shaft. The presence of black powdery specks, lice feces, also is evidence of an infestation.

Body Lice

Body lice (or “cooties”) live, hide, and lay their eggs in clothing, particularly in the seams and folds of underclothes. They periodically attack body areas for blood feedings and can transmit infections such as typhus and trench fever. Body lice infestations generally occur in individuals who do not shower or change clothing frequently, such as the homeless.²⁷

Pubic Lice

Pubic lice or “crabs,” referring to their crab-like appearance, generally are transmitted through high-risk sexual contact, but they also may spread by way of toilet seats, shared undergarments, or bedding. The lice usually are found in the pubic area but may infest armpits, eyelashes, mustaches, beards, and eyebrows.²⁸

Treatment of Pediculosis

Nonprescription pediculicide agents, appropriate hair combing for nit removal, and home vacuuming and cleaning of personal items are primary treatments for lice infestation.²⁶

Treatment Goals

The goal of treating pediculosis is to rid the infested patient of lice by killing adult and nymph lice and by removing nits from the patient’s hair.

General Treatment Approach

A pediculicide is applied to the scalp for the designated amount of time to rid the patient of lice. The hair is then combed with a lice or nit comb to remove nits from the hair shaft; combing also will remove dead lice. Once rid of lice, patients should be instructed on how to avoid future infestations. [Figure 37–3](#) outlines treatment of lice infestations and lists exclusions for self-treatment.²⁶

Nonpharmacologic Therapy

Because none of the pediculicides kills 100% of lice eggs, the National Pediculosis Association recommends careful visual inspection of the hair for nits and combing with an FDA-approved nit comb, such as the LiceMeister comb; removal of nits is helpful in treating and controlling head lice.²⁹ The AirAllé (formerly called the LouseBuster) is a machine that applies heat to the hair and scalp to dehydrate and kill lice and nits. Preliminary evidence suggests this procedure kills more than 90% of nits.³⁰ Unfortunately, it is expensive and requires a certified technician to operate the machine.

Direct physical contact with an infested individual should be avoided, and articles such as combs, brushes, towels, caps, and hats should not be shared. However, use of borrowed protective head gear during sports or recreational activities should not be avoided because of fear of lice transmission. Clothing and bedding should be washed in hot water and dried in a clothes dryer to kill lice and their nits; an alternative to washing would be to seal contaminated items in a plastic bag for 2 weeks. Hairbrushes and combs should be washed in very hot water. Carpets, rugs, and furniture should be vacuumed thoroughly and regularly.²⁶ Use of insecticidal sprays on these items generally is not recommended because lice usually survive for less than 48 hours when not in contact with a host.²⁶ Given the increasing resistance to pediculicides, some patients are choosing to use nondrug therapy exclusively; these nondrug methods, specifically combing and vacuuming, can be effective, but they are labor intensive and tedious.³¹ Complete head shaving also has been used as a lice treatment, but the social stigma involved makes this a distasteful option. Body lice are controlled by appropriate body hygiene and frequent changing and appropriate laundering of clothing and bed linens.²⁸

Pharmacologic Therapy

Two nonprescription pediculicide agents are available for treating pediculosis: permethrins and synergized pyrethrins. Health care providers should be concerned about increasing resistance to the nonprescription pediculicides. Research published in 2016 reported that 42 states in the United States had lice with genetic mutations, indicating resistance to nonprescription pediculicides.³²

Synergized Pyrethrins

Synergized pyrethrins are approved for the treatment of head and pubic lice. Pyrethrins are synergized by addition of piperonyl butoxide. This agent limits the ability of lice to break down pyrethrins.

Pyrethrins block nerve impulse transmission, causing the insect's paralysis and death. As noted, piperonyl butoxide synergizes pyrethrins' insecticidal effect through inhibition of pyrethrin breakdown, increasing the insecticide levels within the louse to more toxic concentrations.^{26,33} Excessive contact time or occlusion of the scalp after product application may increase skin absorption of topical pyrethrins.

Pyrethrins, in concentrations ranging from 0.17% to 0.33%, generally are used in combination with 2%–4% piperonyl butoxide. This combination is considered an effective pediculicide when applied topically as shampoos, foams, solutions, or gels. The medication is applied to the affected area for 10 minutes; then the treated area is rinsed or shampooed as recommended. Combing with a lice comb should follow the treatment. This treatment is repeated in 7–10 days to kill any remaining nits that have since hatched. The drug should not be applied more than twice in 24 hours.²⁶

When applied according to directions, pyrethrins have a low order of toxicity. Most adverse reactions are cutaneous and include irritation, erythema, itching, and swelling.^{26,33} Contact with eyes and mucous membranes should be avoided.

Individuals allergic to pyrethrins or chrysanthemums should not use this agent; ragweed-sensitive individuals risk cross-sensitivity. Pyrethrins should not be used in children younger than 2 years.

Permethrin

Permethrin, a synthetic pyrethroid, is available as a nonprescription cream rinse for treating head lice only. Permethrin acts on the nerve cell membrane of lice. It disrupts the sodium channel, delaying repolarization and causing paralysis and death of the parasite.

When permethrin is applied, an estimated less than 2% is absorbed, after which the agent is metabolized.

The 1% cream rinse is applied in sufficient quantities to cover or saturate washed hair and scalp. It is left on the hair for 10 minutes before rinsing; the hair is then combed with a lice comb. The rinse has residual effects for up to 10 days; therefore, retreatment in 7–10 days is not required unless active lice are detected.

Primary adverse effects, which can occur in up to 10% of the patient population, include transient pruritus, burning, stinging, and irritation of the scalp. Contact with eyes and mucous membranes should be avoided.

Permethrin is contraindicated in patients who are sensitive to pyrethrins or chrysanthemums. Permethrin should not be used on infants younger than 2 months.

Pharmacotherapeutic Comparison

When treatment involves a single application of a pediculicide, permethrin is more effective than the pyrethrin and piperonyl butoxide combination. However, to date, no significant difference exists in effectiveness of these agents when treatment consists of two applications. A comprehensive meta-analysis is ongoing.²⁶

Product Selection Guidelines

Preparations that contain synergized pyrethrins may be used on children ages 2 years and older, but they should be used in pregnancy and lactation only if prescribed by a health care provider. Synergized pyrethrins may be recommended for treating pubic lice. For treatment of head lice, synergized pyrethrins or permethrin may be selected on the basis of preferred dosage form, desire for single application, or patient allergies and sensitivities. [Table 37–4](#) lists selected trade-name products containing available nonprescription pediculicide agents.

TABLE 37–4 Selected Nonprescription Pediculicides and Alternative Therapies

Trade Name	Primary Ingredient(s)
A-200 Lice Killing Shampoo	Pyrethrins 0.33%; piperonyl butoxide 3%

Trade Name	Primary Ingredient(s)
RID Lice Killing Shampoo	Pyrethrins 0.33%; piperonyl butoxide 4%
Nix Lice Killing Cream Rinse	Permethrin 1%
Pronto Lice Killing Shampoo	Pyrethrins 0.33%; piperonyl butoxide 4%
LiceMD	Dimethicone 100%
Vamousse Lice Treatment	Natrum muriaticum 2X (HPUS)
Licefreee Spray	Natrum muriaticum 2X (HPUS)
Clearlice Shampoo	Proprietary blend: enzyme proteins; neem oils; <i>Wrightia tinctoria</i> ; tea tree oil; <i>Acorus calamus</i> ; peppermint oil; <i>Cocos nucifera</i> ; Natrum muriaticum

Alternative Therapies

A variety of alternative therapies have been used to eliminate lice infestations; however, none are approved by FDA. Lice enzyme shampoos, which claim to break down the lice exoskeleton, are being promoted as an alternative to traditional pediculicides. A product containing 10% tea tree oil and 1% lavender oil applied weekly for 3 weeks was more effective at eradicating lice than a pyrethrin/piperonyl butoxide product applied twice (1 week apart).³⁴ Tea tree oil must be used with caution because of potential significant allergic reactions and possible liver toxicity.³⁵ Other oil-based products such as petroleum jelly and mayonnaise also are being used on the basis of the theory that they impair lice respiration; however, these products are not very effective and most likely only slow the movement of lice.^{26,35} Dangerous alternative treatments such as gasoline and kerosene always should be avoided because of their flammability and potential for toxicity.²⁶

A homeopathic remedy containing *Natrum muriaticum*, also known as sodium chloride, works by drying out lice and their eggs. In a randomized trail

including 42 pediatric patients with head lice, the sodium chloride spray demonstrated efficacy superior to that of permethrin.³⁶ These products are applied to sections of dry hair for 15 minutes followed by combing with a nit comb. **Table 37–4** lists specific sodium chloride products available in the United States.

Battery-operated louse combs with oscillating teeth (MagiComb and RobiComb) also are available; although they claim to kill lice, no published studies that evaluate their effectiveness are available. Use of the electronic combs should be avoided in patients with pacemakers or histories of seizures.²⁶

Emerging Therapies

A new potential treatment under study uses dry-on, suffocation-based pediculicide (DSP) lotions. The Nuvo method, the first DSP product to be tested, contains Cetaphil Gentle Skin Cleanser and is a nontoxic lotion that “shrink-wraps” lice.³⁷ It is applied to hair and dried with a hairdryer to form a shrink-wrap film over hair and lice. The lotion covers breathing holes, suffocating the louse. One study suggests that suffocation products may be more effective than pyrethrins/piperonyl butoxide; however, additional research is needed.³⁴

Dimethicone 100% gel also has been shown to cure pediculosis while causing less irritation than traditional therapy. Furthermore, dimethicone works by coating the lice and irreversibly immobilizing them within 5 minutes of application.³⁸

Assessment of Pediculosis: A Case-Based Approach

In many cases of pediculosis, visual inspection of the scalp will verify the presence or absence of head lice or nits. Similarly, presence of body lice can be determined by identifying adult lice and nits in seams of clothing. If a patient does not want such an inspection or if lice/nits have not been confirmed by another health care provider, a pediculicide should not be recommended. When the disorder is confirmed, the appropriate pediculicide should be recommended. If resistance to pyrethrins or permethrin has been reported in the region, patients should be referred to a health care provider for a

prescription pediculicide. However, because of the cost of prescription products for head lice, an alternative therapy can be recommended.²⁶

Case 37–2 illustrates assessment of a patient who has a head lice infestation.

Patient Counseling for Pediculosis

Control of pediculosis requires both pharmacologic and nonpharmacologic intervention. The health care provider should reassure parents of children with head lice that the condition is not the result of poor hygiene. Patients with confirmed head or pubic lice infestations should be counseled on which product is best for the situation and how to use the product properly; preventive measures also should be discussed. Additional information regarding patient counseling for pediculosis can be found in the box “Patient Education for Pediculosis.”

Case 37–2

Relevant Evaluation Criteria	
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of	A frantic woman comes into the pharmacy asking about OTC options

Relevant Evaluation Criteria	
symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	for head lice. She says that her 7-year-old daughter has just returned from summer camp complaining of an “itchy” scalp that started a day or so ago. Her daughter admits to sharing another girl’s cap the day before leaving camp and denies any itching prior to that event. Upon further inspection, the woman noticed clusters of small red bumps that cover the child’s scalp and appear on the base of the neck. She also noticed tiny, light-colored “dandruff looking things” attached firmly to the hair shaft. She reports her daughter’s complaints are itching and mild scalp pain.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	The woman explains that she had just picked up her daughter from camp when she noticed her daughter scratching her head. She inspected her daughter’s scalp once they returned home. She was not able to comment on any precipitating or exacerbating symptoms because the daughter was at camp.
c. Description of the patient’s efforts to relieve the symptoms	The woman has taken all of her daughter’s clothes out of her suitcase and placed them in a large plastic bag to be washed when she goes home.
d. Patient’s identity	Caroline Davis
e. Patient’s age, gender, height, and weight	7 years, female, 45 inches, 52 lb
f. Patient’s occupation	Second-grade student
g. Patient’s dietary habits	Mother says that Caroline usually eats a well-balanced diet.
h. Patient’s sleep habits	Caroline usually sleeps about 9 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None

Relevant Evaluation Criteria	
j. Allergies	Chrysanthemums (rash), amoxicillin (rash)
k. History of other adverse reactions to medications	None
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient has observable nit casings and small red papules throughout the scalp and base of the neck. Patient has recently returned from summer camp and reports sharing head ware with another child, a common occurrence associated with head lice infestation.
3. Identify exclusions for self-treatment (Figure 37-3).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Purchase nit comb for nit observation and removal. (2) Use pyrethrins 0.33% with piperonyl butoxide 4% shampoo products. (OTC permethrin product should be avoided due to chrysanthemum allergy.) (3) Refer patient to an HCP. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem,	Pyrethrins 0.33% with piperonyl butoxide 4% shampoo products

Relevant Evaluation Criteria	
taking into account patient preferences.	
6. Describe the recommended therapeutic approach to the patient or caregiver.	• “Your daughter appears to have head lice and is eligible for self-treatment. I recommend a nonprescription product to kill the head lice.” • “Use a pyrethrin shampoo first: – Apply enough to wet the dry hair and scalp. – Allow the treatment to stay for 10 minutes. – Lather the shampoo throughout the hair and then rinse. – Use a nit comb to remove dead lice and eggs. – Repeat this in 7–10 days if lice or nits are detected.” “When using the nit comb, part the hair into segments, and comb each segment to ensure thorough removal of the nits.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“This product should kill the head lice.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	“To prevent the lice from spreading, make sure to follow all directions on the product labeling, and wash or seal items that your daughter may have come in contact with.”
Solicit follow-up	“What else should I do to help prevent the spread of lice?”

Relevant Evaluation Criteria	
questions from the patient or caregiver.	
Answer the patient's or caregiver's questions.	• "Wash hairbrushes, combs, and toys that have come in contact with your daughter in water that is 130°F (39.4°C) or higher for 10 minutes." • "Clothes, bedding, and towels used by your daughter also should be washed in water that is 130°F (39.4°C) or higher. They should be dried on the hottest dryer setting possible." • "Items that cannot be washed should be sealed in plastic bags for 2 weeks" • "Vacuum living areas regularly." • "Visually inspect hair and scalp before, during, and after treatment for lice or nits."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	• "If head lice are still present after two rounds of treatment, you will need to contact your primary care provider to see if you can obtain a prescription product." • Advise the parent that significant skin irritation or exposure of eyes to pediculicides require medical attention.

Key: HCP = Health care provider; OTC = over the counter.

Patient Education for Pediculosis

The objectives for self-treatment of pediculosis are (1) to rid the body of lice and nits and (2) to implement measures to prevent future infestations. For most patients, carefully following product instructions and the self-

care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Wash hairbrushes, combs, and toys of infested patients in water at a temperature of 130°F (39.4°C) or higher for 10 minutes.²⁰
- Use water at a temperature of 130°F (39.4°C) or higher to wash the clothes, bedding, and towels of infested patients. Dry the items on the hottest dryer setting that the fabric permits.²⁰
- Objects or clothing that cannot be washed should be sealed in plastic bags for the length of the louse's life cycle (2 weeks) so that it is unable to feed on a host.
- Avoid close physical contact with an infested patient; do not share articles such as combs, brushes, towels, caps, and hats.
- Vacuum living areas thoroughly and regularly during treatment period.
- Visually inspect the hair and scalp before, during, and after treatment for evidence of lice or nits.
 - Use a nit comb diligently to remove nits.
 - Part hair into segments and comb the hair in each segment. (Individual hairs can be trimmed if nit removal proves difficult.)

Nonprescription Medications

- Treatment of other family members should be determined on the basis of the presence of lice or nits and the family members' level of contact with the infested individual; unnecessary treatment should be avoided.
- Application steps for a pyrethrin shampoo include the following:
 - Apply sufficient quantity to wet the dry hair and scalp. (Foams should also be applied to dry hair.)
 - Allow the treatment to remain for 10 minutes.
 - Work the shampoo into a lather and then rinse thoroughly. (Remove foams with shampoo or soap and water.)
 - Use a nit comb to remove dead lice and eggs as described previously.

- Application steps for a permethrin cream rinse include the following:
 - Shampoo with regular shampoo, rinse, and towel dry hair.
 - Apply sufficient cream rinse to wet hair and scalp.
 - Allow the treatment to remain for 10 minutes; then rinse and towel dry.
 - Use a nit comb as described previously.
- Avoid contact of the pediculicide with eyes and mucous membranes.
- The pediculicide can cause temporary irritation, erythema, itching, swelling, and numbness of the scalp; itching should be relieved in a few days.
- For pyrethrin products, repeat entire process in 7–10 days; permethrin products can be used again in 7–10 days if lice or nits are detected. Because of treatment resistance, proper use of these products is required and overuse must be avoided.
- If desired, contact the National Pediculosis Association at www.headlice.org or 1-617-905-0176 for information about treatment of lice infestations.
- If pediculicides are ruled out as a treatment option, alternative products such as citronella, lemon eucalyptus oil, soybean oil, cedar oil, lavender oil, tea tree oil, garlic, and scented moisturizers in mineral oil (e.g., Skin-So-Soft) may be tried.

When to Seek Medical Attention

- Significant skin irritation or excessive exposure of eyes or mucous membranes to pediculicides.
- If symptoms of lice infestation persist after the second treatment.
- If resistance to pyrethrins or permethrin has been reported in the region.

Evaluation of Patient Outcomes for

Pediculosis

Follow-up of lice infestations should occur within 10 days. If signs of lice infestation persist after a second application of a pediculicide, the patient should be advised to seek medical attention. Overuse of these products should be discouraged, and use of nonpharmacologic control measures should be emphasized.³¹

Key Points for Insect Bites and Stings and Pediculosis

- Insect stings and bites cause local irritation, inflammation, swelling, and itching; a cold pack may be applied to reduce local symptoms.
- For relief of the itching and pain resulting from insect bites, topical nonprescription preparations that contain local anesthetics, antihistamines, hydrocortisone, or counterirritants can be used in patients ages 2 years and older.
- In hypersensitive people, anaphylactic reactions may pose serious emergency problems; these patients require immediate medical attention.
- Suspected spider bites should be referred; nonprescription treatments are not appropriate. If possible, the spider should be sealed in a container for identification.
- A tick should be removed by grasping it near the head with tweezers and gently pulling to cause the tick to release from the skin. The patient should be monitored for systemic effects such as Lyme disease and Rocky Mountain spotted fever.
- Appropriate use of insect repellents containing DEET will help prevent bites from mosquitoes, ticks, and fleas.
- Exposure to mosquito bites warrants monitoring the patient for

symptoms of mosquito-borne viruses.

- Nondrug measures are an important component in treatment of lice infestation.
- Available nonprescription pediculicides contain either synergized pyrethrins or permethrin.
- Pediculicides are designed for initial treatment and retreatment in 7–10 days; hair should be combed with a nit comb after treatment.
- If resistance to pyrethrins and permethrin has been reported in the region, patients should be referred to a medical provider for a prescription pediculicide, or an alternative therapy should be recommended.

Chapter 38: Acne

Authors: Jamie L. Woodyard, Chelsea M. Baker

Acne, also known as *acne vulgaris*, is an inflammatory skin disease affecting 40–50 million people in the United States.¹ The Latin word *vulgaris* means “common” or “affecting the masses.” The 2010 Global Burden of Disease study ranks acne as the eighth most prevalent disease worldwide.² Acne is a disorder of the pilosebaceous glands, resulting in lesions most commonly found on the face. Locations for extrafacial lesions include the back (52%), chest (30%), lower back (22%), shoulders and arms (16%), and neck (8%).³

Acne is most common during adolescence. Cordain et al. have described acne as a universal disease that affects 79%–95% of adolescents in Westernized societies.⁴ The age for peak prevalence of acne is 14–17 years in girls and 16–19 years in boys. Although clinical improvement typically is seen starting at 20–25 years of age, the condition may persist in 7%–17% of affected persons, with an even higher rate of nearly 24% for women. Late-onset acne, defined as emergence of acne signs and symptoms in persons older than 25 years, accounts for 8% of the cases.⁵ Acne persists in 1% of men and 5% of women after the age of 40.⁵

Acne was once considered a disease of teenagers.⁶ The onset of acne correlates with the onset of puberty; however, acne may occur in adolescents younger than 12 years.⁶ Recently, the prevalence of acne in children has increased, with rates of 28%–61% reported for those 10–12 years of age. According to Eichenfield et al., acne also is common in preadolescents (ages 7–12 years).⁶ Additionally, acne has been observed in children 4–7 years of age.⁴

The effect of acne on certain health indicators should not be overlooked. Associations have been shown between acne and lower self-esteem.⁷ Acne may have a negative impact on quality of life similar to that experienced by patients with asthma or epilepsy.⁷ Additional associated morbidity may include scarring, depression, and anxiety. In 2019, the manufacturing industry for nonprescription acne treatments reported revenue of \$425.3 million.⁸ In 2017, sales of nonprescription acne products totaled \$607 million.⁹ In the United States, direct and indirect costs related to acne treatment were reported at \$3 billion.¹⁰

Pathophysiology of Acne

Acne is the result of several pathologic processes that occur within the pilosebaceous unit located in the *dermis*, or middle layer of the skin (Figure 38–1A). Each unit consists of a hair follicle and associated sebaceous glands and is connected to the skin surface by a duct (*infundibulum*) lined with epithelial cells through which the hair shaft passes. The sebaceous glands produce sebum, which normally functions to protect the skin from light and to retain moisture. Sebum possesses an antibacterial property that is both pro- and anti-inflammatory and is involved in the wound healing process.¹¹ The sebaceous gland acts as an endocrine organ and responds to changes in androgens and hormones similar to the action of the hypothalamic–pituitary–adrenal axis; hence, the sebaceous gland has been called the “brain of the skin.” Corticotropin-releasing hormone (CRH) influences the sebaceous glands’ endocrine function.¹² CRH is the primary hormone involved in neuroendocrine and behavioral responses to stress. In acne-prone skin, CRH is found throughout the sebaceous glands and has been associated with the immune and inflammatory processes that lead to stress-induced acne.¹¹

FIGURE 38–1 Pathogenesis of acne. (Source: Adapted with permission from Fulton JE, Bradley S. The choice of vitamin A acid, erythromycin, or benzoyl peroxide for the topical treatment of acne. *Cutis*. 1976;17(3):560.)

The etiology of acne is multifactorial. In addition to the intricate pathophysiology of this condition, genetics, diet, and gender play important contributory roles. In a study of 200 patients with postadolescent acne by Ebede et al., 50% of the subjects reported at least one first-degree family relative with acne.¹³ More research is needed to explore the role of genetics in acne.³ Recent literature has increasingly focused on the role of environmental factors, such as diet, in the etiology of acne. Cordain et al. studied acne prevalence in young people, including adolescents, in non-Westernized populations.⁴ One study cohort comprised 1200 Kitava Islanders (Papua New Guinea), including 300 subjects 15–25 years of age, who were examined every 6 months over a period of 843 days: no case of acne was observed in this cohort. The investigators also observed 115 Aché (indigenous Paraguay) subjects, 15 of

whom were 15–25 years of age, for more than 2 years and again found no cases of active acne.⁴ These authors concluded that the absence of contributing environmental factors, especially diets characterized by high glycemic loads with corresponding insulin spiking, typical for Western populations, may be key in this virtual immunity to acne and suggested that clinicians should look toward these differences to treat the condition.⁴

Additional epidemiologic studies have correlated acne with the Western diet.¹⁴ The non-Western diets, with low glycemic loads, also featured lower consumption of dairy products, alcohol, cereals, oil, sugar, and salt.¹⁴ Foods with a high glycemic index elevate plasma concentrations of insulin, which regulates insulin-like growth factor-1 (IGF-1) and IGF-binding protein, promotes unregulated tissue growth, and enhances androgen synthesis.¹⁵ Hormones such as androgens and IGF-1 act on sebaceous glands and keratinocytes.¹⁵ Dietary milk also causes a rise in the serum level of IGF-1 through substantial elevation of blood glucose and serum insulin levels.¹⁴ Melnik examined the role of mTORC1 (mammalian target of rapamycin complex 1) as a nutrient-derived signal involved in the exacerbation of acne through diet.¹⁶ The mTORC1 signal is activated with consumption of foods with a high glycemic index and high intakes of fat, dairy, and meat. These foods are characteristic of those found in the Western diet.¹⁶ The mTORC1 kinase integrates signals of cellular energy, growth factors (insulin, IGF-1), and protein-derived signals, predominantly leucine, which is provided in large amounts by milk proteins and meat, with resultant increases in androgen and sebum production, respectively, which further perpetuates the pathogenesis of acne.¹⁶ As noted by Melnik, the role of diet in acne pathogenesis is still controversial, but the discovery of nutrient signaling pathways, such as mTORC1, helps explain the link between diet and acne exacerbation.¹⁶ Currently, no specific dietary changes are recommended in the management of acne, although emerging data show evidence that diets consisting of high-glycemic-index foods may be associated with acne.¹⁷

Pathologic factors involved in the development of acne are (1) sebum production by the sebaceous gland, (2) follicular colonization by *Cutibacterium acnes* (previously known as *Propionibacterium acnes*), (3) alteration in the keratinization process, and (4) release of inflammatory mediators in the skin.¹²

The rise in androgenic hormones coincides with the start of puberty and the appearance of acne. Conversion of testosterone to dihydrotestosterone stimulates an increase in the size and metabolic activity of sebaceous glands.

The excess sebum serves as a breeding ground for *C. acnes* as the comedo (whitehead or blackhead) develops. Increases in androgen levels also are responsible for abnormal follicular desquamation within the infundibulum. Sebum includes several matrix metalloproteinases.¹² This group of enzymes have a prominent role in inflammatory matrix remodeling and proliferative skin disorders.¹³ Medications targeting these enzymes are being developed for acne treatment. Examples of these medications are adapalene and prescription antibiotics such as tetracyclines and macrolides.¹⁸ Evidence also indicates that follicular keratinocytes release interleukin-1, which may stimulate comedo formation. Specifically, the skin of people without acne has been shown to exhibit inflammatory responses that occur before the hyperproliferation of keratinocytes in acne.¹² The understanding of the pathophysiology of acne is still evolving. A landmark study from 2003 demonstrated that the pathogenesis of acne begins with an inflammatory process, rather than with hyperkeratinization and comedogenesis.¹⁹ This study also found that inflammatory responses are a key component in the early stages of acne lesion formation.¹⁹

Figures 38–1 and 38–2 illustrate the complex interplay of the pathophysiologic processes in acne. Hyperproliferation of keratinocytes results in cell cohesion and formation of a plug that blocks the follicular orifice. This plug distends the follicle to form a *microcomedo*, the initial pathologic lesion of acne (Figure 38–1B).²⁰ As more cells and sebum accumulate, the microcomedo enlarges and becomes visible as a *closed comedo*, or *whitehead*, a small, pale nodule beneath the skin surface (Figure 38–1C). If the contents of the plug cause distention of the pore's orifice, the plug will protrude, creating an *open comedo*, or *blackhead*. The lesion is named for the presence of melanin and oxidation of lipids upon exposure to air.

FIGURE 38–2 Pathophysiology of acne. (Source: [References 5 and 20.](#))

Currently, no exact and clear explanation has emerged for the pathogenesis of acne.²¹ Newly recognized potential pathophysiologic factors include T-helper cells, acne subtype, and nutritional status.²¹ Acne is no longer believed to be caused by a proliferation of *C. acnes*, as studies have demonstrated similar amounts of *C. acnes* in the follicles of both unaffected persons and those with acne.^{22–24} More recent research has focused on the effects of a subset of *C. acnes* strains with enhanced pathogenicity and the interplay of *C. acnes* with other bacterial species, particularly *Staphylococcus epidermidis*, on the skin microbiota equilibrium.^{22,25–30} Greater understanding of *C. acnes* strains and the role of other bacteria in the etiopathogenesis of acne may assist in the development of alternative treatment options.

Clinical Presentation of Acne

Information continues to evolve around the presentation of acne. Through production of lipases, *C. acnes* breaks down sebum into highly irritating free

fatty acids. As a result of the irritation and inflammation, localized tissue destruction occurs. Toll-like receptors (TLRs) are mammalian proteins that act as a vital regulator of host responses to infection.¹² Research shows cytokine induction by *C. acnes* occurs through TLR-2, which stimulates inflammatory lesions. In acne, TLR-2 invokes a significant inflammatory response as well as cellular apoptosis and tissue injury.³¹ Redness and inflammation in and around the follicular canal are the hallmarks of a *papule* (Figure 38–1E). A *pustule* (Figure 38–1F) possesses those same qualities but has visible purulence in the center of the lesion. *Nodules* result from disruption of the follicular wall and release of its contents into the surrounding dermis.²⁰

Several factors contribute to the exacerbation of existing acne and cause periodic flare-ups (“flares”) of acne in some patients (Table 38–1).^{32–34}

TABLE 38–1 Etiologic Subtypes of Acne With Exacerbating Factors	
Etiologic Subtype	Description
Acne cosmetica	Development of noninflammatory comedones on the face, chin, and cheek caused by occlusion of the pilosebaceous unit by oil-based cosmetics, moisturizers, pomades, or other health and beauty products
Acne excoriee (excoriated)	A form of acne caused by constant picking, squeezing, or scratching at real or perceived lesions, which worsens the appearance of the skin
Acne mechanica	Local irritation or friction from occlusive clothing, headbands, helmets, or other friction-producing devices
	Excessive contact between face and hands, such as resting the chin or cheek on the hand
Chloracne	An acneiform eruption caused by exposure to chlorine compounds
Drug-induced acne	<i>More common:</i> anabolic steroids, bromides, corticosteroids, corticotropin, isoniazid, lithium, phenytoin
	<i>Less common:</i> azathioprine; cyclosporine; disulfiram; phenobarbital; quinidine; tetracycline; vitamins B ₁ , B ₆ , B ₁₂ , and D ₂
Hormone-induced acne	Hormonal alterations, specifically increased androgen levels induced by medical conditions, pregnancy, or medications
Hydration-induced acne	Hydration-induced decrease in size of pilosebaceous duct orifice and prevention of loosening of comedones caused by high-humidity environments

Etiologic Subtype	Description
	and prolonged sweating
Occupational acne	Exposure to dirt, vaporized cooking oils, or certain industrial chemicals, such as coal tar and petroleum derivatives
Stress- and extreme emotion-induced acne	May induce expression of neuroendocrine modulators and release of CRH, which play a role in centrally and topically induced stress of the sebaceous glands and possibly progression of acne

Key: CRH = Corticotropin-releasing hormone.

Source: [References 32–34](#).

Until recently, acne was categorized as noninflammatory or inflammatory (see [Color Plates](#), photographs 26 and 27). Noninflammatory lesions included open or closed comedones. Inflammatory lesions included papules, pustules, and nodules. Subsequently, however, Do et al. discovered that although 54% of inflammatory lesions were preceded by comedones, 28% developed in normal skin. Furthermore, it was demonstrated that cellular inflammatory lesions could occur at every stage of acne. According to these authors, noninflammatory lesions should be considered comedones, and probable new evidence supports occurrence of the inflammatory process at every stage of acne.³⁵ Acne lesions typically are found on the face, chest, upper back, and upper arms.²⁰ Affected women in their 30s and 40s not uncommonly have lesions concentrated on the chin and along the jaw line.³⁶ At clinical presentation, the patient may exhibit one or more types of lesions. Acne severity is defined by the number and type of acne lesions³⁷; however, no consensus has emerged on an optimal grading system.^{17,38} [Table 38–2](#) describes a commonly used acne grading system to assess acne severity.³⁷

TABLE 38–2 Grading and Classification of Acne

Mild	Moderate	Severe
Few erythematous papules	Many erythematous	Extensive pustules, erythematous

Mild	Moderate	Severe
and occasional pustules mixed with comedones	papules and pustules and prominent scarring	papules, and multiple nodules on an inflamed background

Source: [Reference 38](#).

If acne lesions persist beyond the affected person's mid-20s or first appear in the mid-20s or later, the clinical manifestations may signal rosacea, rather than acne. Differentiation between the two conditions is necessary because the treatment of rosacea, although similar to that for acne, has unique elements. In rosacea, erythema and telangiectasias or facial flushing on the cheeks are characteristic, but no comedones are present.³⁸

In addition to the negative psychosocial impact of acne, physical scarring can be a complication of the condition.³⁹ Scarring manifests as (1) hypertrophic areas and keloids caused by increased tissue formation and (2) a loss of skin resulting in so-called ice pick, boxcar, or rolling scars.³⁹ In an observational study of patients with and without scarring, Kircik concluded that the subjects with scarring exhibited an initial cellular response to acne that was weaker and less effective throughout the resolution of lesions. These patients also experienced a later influx of macrophages and increased inflammatory responses that resulted in persistent inflammatory hyperpigmentation.¹⁹

Treatment of Acne

In most cases, acne is self-limiting and can be controlled to a variable degree. Adherence to therapeutic regimens will reduce the frequency and severity of clinical manifestations and minimize or prevent scarring. Because acne persists for long periods, treatment must be long-term, continuous, and consistent.

Treatment Goals

Although lesion elimination is ideal, a realistic primary treatment goal is a

decrease in the number and severity of lesions. Additional goals include prevention of future lesions, scar formation, and hyperpigmentation, along with improvement in quality of life.

General Treatment Approach

Patients and health care providers should identify any exacerbating factors for the acne ([Table 38–1](#)). It also is imperative for providers to classify the type of acne ([Table 38–2](#)), to allow selection of the most appropriate therapeutic option(s).³⁸ Once the subtype of acne has been established, treatment should be initiated and adherence to medication therapy encouraged.¹² A major global problem with acne treatment is lack of adherence.⁴⁰

Gollnick has described a general three-pronged treatment approach for acne: (1) eliminating visible lesions that occur during the acute phase of acne, (2) maintaining treatments that prevent relapse, and (3) implementing adjunctive procedures to treat scarring or other complications.⁴⁰

Nonpharmacologic Therapy

An important first step in self-care management of acne is to eliminate or avoid exacerbating factors ([Table 38–1](#)). Patients should be advised to cleanse the skin with a mild soap or nonsoap cleanser no more than twice daily, as use of abrasive products and excessive cleansing may worsen acne.

Another essential self-care measure is staying well hydrated. Dehydration may lead to an increase in inflammatory chemicals in the cell and cause dysfunction in the natural desquamation process of the stratum corneum. According to Decker and Graber, normal skin has a pH of 5.3–5.9. Washing the face with harsh soaps that increase the pH by 2 or more units can cause skin dryness and create an environment supporting growth of *C. acnes*.⁴¹ Facial toners may decrease a tendency to oily skin and will help remove makeup and traces of dirt. However, patients should not overuse such products because they can cause increased skin irritation.⁶ Patients also could consider dietary changes by eliminating or cutting back on foods with a high glycemic index to determine whether the acne improves or remains the same.⁴²

Physical Treatments

Physical treatments include light therapies and mechanical therapies such as use of scrubs, cleansing cloths, brushes, and heating devices (Table 38–3).⁴¹ Comedo extraction also is an example of a physical treatment.¹⁷ A wide range of self-applied, acrylate glue–based material strips can aid in the extraction of impacted comedones.⁴¹ The American Academy of Dermatology working group for the guidelines on care and management of acne notes that professional comedo extraction is a useful adjunct to the overall acne regimen and often results in immediate improvement; however, evidence for effectiveness of physical therapies is limited.¹⁷

TABLE 38–3 Description of Physical Treatments	
Implement	Treatment
Brushes	The oscillating motion of the brush is used to deeply cleanse the skin while removing makeup. The impact of this treatment has not been clinically evaluated.
Cleansing cloths	Cloths are less abrasive than scrubs while providing conditioning and exfoliation of the skin.
Cosmetic adhesive pads	Pads were developed to remove adherent corneocytes, dirt, oil, or to loosen open comedones from the skin.
Heating devices	Heating devices are marketed to treat acne vulgaris by directly contacting the lesion. A beneficial effect deriving from exposure to heat and phototherapy has been described.
Light therapy	Examples are visible light, pulsed dye laser, and photodynamic therapies. The most abundant evidence exists for photodynamic therapy in treating acne. A photosensitizer is applied to the affected skin for 15 minutes to 3 hours.
Scrubs	Abrasion opens closed comedones and prevents their progression; however, the abrasive effects of such products can damage the integrity of the skin.

Source: [Reference 41](#).

The U.S. Food and Drug Administration (FDA) has approved several light-based

therapies for the treatment of acne. These treatments target reduction of *C. acnes* and disruption of sebaceous gland function. *C. acnes* bacteria produce porphyrin compounds during normal metabolism. Porphyrins absorb visible light at a variety of wavelengths, which excites the porphyrin compound, causing the formation of oxygen and free radicals.⁴³ The oxygen radicals are thought to destroy *C. acnes* organisms by damaging lipids in their cell walls.¹² Light therapy currently is considered a modality to be used in conjunction with traditional pharmacologic therapy for acne. Additional research on regimens that include light therapy as a standard of treatment is needed.¹⁷

Pharmacologic Therapy

Recent evidence indicates that nonprescription topical therapy offers benefits and should have a role in the treatment of acne.⁴¹ Topical therapy is the standard of care in acne treatment.⁴⁴ Health care providers should be familiar with the nonprescription products available for treatment of acne.

Adapalene

On July 8, 2016, FDA approved adapalene gel 0.1% (Differin Gel) for nonprescription treatment of acne. It is the first new ingredient approved for acne treatment since the 1980s and the first full prescription-strength retinoid to become available without a prescription.⁴⁵ Adapalene is a first-line topical drug for acne treatment.^{20,45} Its mechanism of action differs from that of other available nonprescription acne agents. Adapalene appears to modulate epithelial cell differentiation, keratinization, and inflammation and is preferred for treatment of comedonal acne because of its mechanism of action.^{17,46} Patients should follow all label directions for this product. A thin layer of the product should be applied to affected, intact skin areas once daily at bedtime. The affected areas should be protected from sun exposure, as adapalene increases susceptibility to sunburn.⁴⁶

Redness, scaling, dryness, itching, and burning are the most common adverse effects of adapalene, but they often diminish after the first month of therapy. Acne may worsen during the first weeks of therapy because this medication affects lesions that are not yet visible on the skin. The full therapeutic effect of adapalene will become apparent after 8–12 weeks of treatment.⁴⁶ If acne-related signs and symptoms worsen or fail to abate in 3 months with proper use of the agent, patients should consult their primary care provider. In

addition, product users who experience allergic reactions, become pregnant, or are planning to become pregnant should discontinue use of adapalene and consult their primary care provider for other treatment options.⁴⁶

Benzoyl Peroxide

Benzoyl peroxide (BP) is the most common topical acne product available both with and without a prescription. BP has keratolytic and antibacterial properties against skin *C. acnes*.¹⁷ BP kills bacteria by introducing oxygen into the environment, thereby killing *C. acnes*, which can thrive only in an oxygen-free environment.²⁰

BP has been the mainstay of treatment for acne since the 1930s.⁴¹ In March 2010, FDA issued a final rule for topical acne drug products that included BP as a generally recognized as safe and effective (GRASE) active ingredient in nonprescription topical acne products.⁴⁷ BP had been classified as a non-GRASE ingredient since 1995 because of concern about benzoyl's weak mutagenic effect in vitro and BP's tumor promotion potential.⁴⁷ FDA later concluded that BP in concentrations of 2.5%–10% is a GRASE ingredient for acne on the basis of animal studies suggesting that BP is not carcinogenic or photocarcinogenic.⁴⁷

One of the main benefits of BP is its ability to prevent or eliminate the development of treatment resistance by *C. acnes*, which has increased with the use of conventional antibiotics (e.g., macrolides, tetracyclines) over the past 3 decades.¹² Resistant strains have been found in 50% of acne patients who had close contact with a resistant organism.¹² *Close contact* is defined as exposure to those persons living in the same household with family members with acne. The use of BP in combination with antibiotics is recommended to minimize *C. acnes* resistance.¹² BP often is used in combination with other oral or topical antibiotics. In a 2009 literature review, BP was more effective than topical antibiotics such as clindamycin and erythromycin. In addition, BP in combination with either of these antibiotics was more effective and better tolerated than either of the antibiotics alone.¹²

Nonprescription formulations of BP are available in concentrations of 2.5%–10% as a gel, wash, or cream. Higher strengths of BP have the same antibacterial effects as for the lower strengths⁴¹ but may cause more skin irritation.⁴⁸ All new users of nonprescription acne products should test the product by

applying it sparingly to 1–2 small affected areas over the first 3 days. If discomfort does not occur, the product should be used according to label directions.⁴⁷

Avoidance of contact with clothes or hair is advised, as this product may cause bleaching. In addition, BP can cause photosensitivity, so avoidance of excessive sun exposure and use of a broad-spectrum sunscreen product with a sun protection factor (SPF) of 15 or higher are recommended. Minor improvement may occur with once-daily application of BP. The number of applications can be increased gradually to 2 or 3 times daily if needed. If excessive peeling or drying occurs, the frequency of application or the BP concentration should be reduced. Results have been seen in as few as 5 days or by week 3 of treatment. Maximum lesion reduction may occur after 8–12 weeks of use. Some patients may experience only mild erythema and scaling during the first few days, which usually subside within 1–2 weeks.

BP is recommended for mild acne in adults and pediatric populations (preadolescents and adolescents).⁶ Allergic contact dermatitis reactions, characterized by a sudden onset of erythema and vesiculation, are considered rare, with an occurrence rate of 1 in 500. A 2014 FDA Drug Safety Communication reported rare but serious allergic reactions to BP and salicylic acid that ranged from symptoms of local irritation to local and systemic hypersensitivity, including anaphylaxis.⁴⁸ FDA has not determined if the products' active ingredients, inactive ingredients, or both are responsible for these reactions. Use of BP products should be discontinued when an allergic reaction such as itching or development of hives occurs. Medical attention should be sought for manifestations of hypersensitivity reactions such as throat tightness, difficulty in breathing, a feeling of faintness, or swelling of the eyes, face, lips, or tongue.⁴¹ The box "Patient Education for Acne" presented later in the chapter lists other precautions for use of BP.

Other Nonprescription Acne Agents

Other FDA-approved nonprescription topical anti-acne ingredients include hydroxy acids in various strengths, sulfur 3%–10% (in single-ingredient products), and combinations of sulfur 3%–8% with either resorcinol 2% or resorcinol monoacetate 3%.⁴⁹

Hydroxy Acids

Keratolytic agents such as alpha hydroxy acids (AHAs) and beta hydroxy acids (BHAs) also are common nonprescription acne products. Hydroxy acids are considered less potent and often are used when patients cannot tolerate other topical acne products.⁴⁹ Some hydroxy acids have comedolytic properties and are moderately effective in the treatment of acne.⁴⁹

AHAs are natural exfoliating acids that occur in sugar cane, milk products, and fruits; the most common AHAs are glycolic, lactic, and citric acids, respectively.⁴⁰ AHAs are not able to penetrate the pilosebaceous unit to exert a comedolytic effect. AHAs are available in several nonprescription formulations in concentrations of 4%–10% or as prescription-only products in higher concentrations. In a study comparing BP with AHAs, BP demonstrated a superior effect at 8 weeks. Once acne is controlled, a light chemical peel with AHAs may be useful to help correct scarring and hyperpigmentation.¹² However, several treatments are needed, and the results are not long-lasting. The duration of dosing is once every 15 days for 4–6 months.¹⁷ **Table 38–4** lists contraindications to glycolic acid peels of which the health care provider should be aware.

TABLE 38–4 Glycolic Acid Peel Contraindications

Active infection or open wounds (herpes simplex, excoriations, open acne cysts)
History of abnormal scar formation or delayed wound healing
History of rosacea, seborrheic dermatitis, atopic dermatitis, psoriasis, vitiligo, active retinoid dermatitis
History of therapeutic radiation exposure
Isotretinoin therapy within the past 6 months
Lack of psychological stability and mental preparedness
Poor general health and nutritional status
Unrealistic expectations
<i>For medium and deep peels only:</i>
Medium-depth or deep resurfacing procedure within the past 3–12 months

Source: [Reference 17](#).

Polyhydroxy acids constitute a category of AHAs that have fewer adverse effects, such as irritation and stinging. They are marketed for patients with more clinical sensitivity and have moisturizing and humectant properties.³⁹ Lactobionic acid, a type of polyhydroxy acid, inhibits the breakdown of matrix metalloproteinase enzymes with sun exposure. This effect reduces “photoaging” of the skin.³⁹

Salicylic acid, often described as a BHA, is a comedolytic agent available as various nonprescription acne products in concentrations of 0.5%–2%.^{39,49} The comedolytic effect is concentration-dependent. Higher concentrations are used in prescription products and chemical peels.³⁹ Salicylic acid is a milder, less effective alternative to prescription agents such as topical retinoids.¹⁵ In cleansing preparations containing salicylic acid, this ingredient is considered an adjunctive agent. As a comedolytic, salicylic acid should be applied 1–3 times daily as needed. If dryness or peeling occurs, the frequency of application should be reduced to once daily or every other day.⁴² Salicylic acid is a phytohormone chemically similar to the active component of aspirin. It is important for health care providers to be aware of potential drug–drug interactions ([Table 38–5](#)) with the use of this agent. Salicylic acid is lipid-soluble and able to penetrate the pilosebaceous unit to produce a comedolytic effect.⁴⁹ Of note, with topical application of 2% salicylic acid, up to 20% of the preparation’s drug content can be absorbed in the skin. The degree of absorption depends on several factors, including the vehicle used, the pH of the drug, skin structure, the frequency of application, and whether or not an occlusive covering is used. A risk of salicylism or salicylic acid toxicity associated with topical application to extensive areas of the skin has been recognized, especially in children, who metabolize drugs differently. Accordingly, some patients will require additional monitoring, as well as possible dose adjustments of any maintenance medications, if the treatment regimen includes chronic use of salicylic acid or frequent widespread applications.¹⁷

TABLE 38–5 Drug–Drug Interactions With Salicylic Acid

Interacting Drug/Drug Class	Potential Interaction	Management
Anticoagulants	Increased anticoagulation	Use with caution and monitor closely.
Antidiabetic agents	Increased activity of glyburide; hypoglycemia	Monitor closely; use alternative acne agent, if possible.
Aspirin	Increased anticoagulation; increased serum level of potassium	Monitor closely; consider alternative agent.
Corticosteroids	Prednisone may increase renal clearance; increased risk of gastrointestinal tract ulceration	Monitor closely.
Diuretics	Increased serum level or effect of salicylates	Monitor closely.
Methotrexate	Increased serum level of methotrexate	Monitor closely.
Heparin	Decreased platelet adhesiveness and interference with hemostasis in heparin-treated patients	Monitor closely.
Uricosuric agents	Effect of probenemide, sulfinpyrazone, and phenylbutazone inhibited	Monitor closely.
Pyrazinamide	Pyrazinamide-induced hyperuricemia inhibited	Monitor closely; may consider alternative acne agent.

Source: [Reference 17](#).

Salicylic acid products also offer protection from the sun by inhibiting ultraviolet B (UVB) radiation–induced formation of “sunburn cells” occurring after exposure to UVB rays, which cause irreversible damage to cellular DNA, and by increasing the removal of UVB-induced *dimers* (premutagenic lesions) in skin.⁴⁹ However, patients using these products should continue to wear a broad-spectrum sunscreen with an SPF of 15 or higher to protect their skin from further sun damage. Use of BHA products is contraindicated in diabetic

patients or persons with poor blood circulation. Application of these products should be limited to the affected area, as use over extensive surfaces for prolonged periods may result in toxicity. Signs and symptoms of salicylate toxicity include nausea, vomiting, dizziness, hearing loss, tinnitus, lethargy, hyperpnea, diarrhea, psychological disturbances, inner ear damage, hypoglycemia, and hypersensitivity.⁴⁹ In 2014, FDA warned of potentially life-threatening hypersensitivity reactions for nonprescription anti-acne products containing salicylic acid or BP (see the section “Benzoyl Peroxide”).

Sulfur

Sulfur, precipitated or colloidal, is included in anti-acne products as a keratolytic and antibacterial in concentrations of 3%–10%.⁴⁹ Sulfur generally is accepted as effective in promoting the resolution of existing comedones, but with continued use it may have a comedogenic effect. Alternative forms of sulfur such as sodium thiosulfate, zinc sulfate, and zinc sulfide are not recognized as safe and effective.

Adverse effects with these products are rare but include noticeable odor and dry skin, depending on the formulation used.⁴¹ Sulfur often is combined with sodium sulfacetamide to mask the odor of sulfur in prescription drugs, and sulfur is combined with resorcinol in nonprescription medications for treatment of acne.⁴⁹

Sulfur/Resorcinol

Combinations of sulfur 3%–8% with resorcinol 2% or resorcinol monoacetate 3%, both of which enhance the effect of sulfur, are available in nonprescription acne products.^{41,49} These products function primarily as keratolytics, fostering cell turnover and desquamation. Resorcinol is not effective when used for monotherapy. However, it is believed to have antibacterial, antifungal, and keratolytic effects when used with other anti-acne products such as sulfur.⁴¹

Pharmacotherapeutic Comparison

Table 38–6 provides a comparison of the therapeutic properties of the major anti-acne products.

TABLE 38–6 Comparison of Properties for Nonprescription Topical Anti-Acne Agents

Agent	Property			
	Antibacterial	Comedolytic	Anti-inflammatory	Keratolytic
Adapalene 0.1%	No	Yes	Yes	Yes
Benzoyl peroxide 2.5%–10%	Yes	Yes	No	Yes
Salicylic acid 0.5%–2%	No	Yes	Yes	No
Sulfur 3%–10%	Yes	No	No	Yes
Resorcinol 2% with sulfur 3%–8%	Yes	No	No	Yes
Resorcinol monoacetate 3% with sulfur 3%–8%	Yes	No	No	Yes

Source: [References 6, 17, 40, 41, and 48](#).

Product Selection Guidelines

Product selection should be based on individual patient needs, skin type, and severity of acne. Nonprescription acne medications are indicated for mild acne. Skin cleansers and topical acne products are available in a variety of vehicles and strengths. Medicated cleansing products (bars and liquids) are less effective, as they leave little active ingredient residue on the skin. Generally, gels are the most effective formulations because they are astringents and remain on the skin the longest. Gels and solutions have a drying effect and may cause contact dermatitis. However, these dosage forms are not greasy and may be more beneficial in patients with oily skin. Creams and lotions generally are less irritating to the skin than gels and solutions.⁵⁰ They are acceptable alternatives to more effective gels and are recommended for dry or sensitive skin and for use during dry winter weather. Ointment vehicles are not used, because they are occlusive and tend to worsen acne. Patients should start with the lowest strength available and gradually increase the concentration to minimize irritating effects of the product. The product should be applied only once daily; if the applications are well tolerated with no

redness or skin irritation, the frequency of application may be increased to twice daily. **Table 38–7** lists selected nonprescription trade-name anti-acne products in these and other formulations.

TABLE 38–7 Selected Nonprescription Anti-Acne Products	
Trade Name	Primary Ingredient(s)/Component(s)
Retinoid Product	
Differin Gel, 15 g	Adapalene 0.1%
Benzoyl Peroxide Products	
Proactiv Repairing Treatment, 2 oz	Benzoyl peroxide 2.5%
Neutrogena Rapid Clear Stubborn Acne Cleanser, 5 oz	Benzoyl peroxide 10%
Clearasil Ultra Rapid Action Vanishing Treatment Cream, 1 oz	Benzoyl peroxide 10%
Salicylic Acid Products	
Neutrogena Oil-Free Acne Stress Control Power Cream Wash, 6 oz	Salicylic acid 2%
Clean & Clear Advantage Acne Spot Treatment, 0.75 oz	Salicylic acid 2%
Alpha Hydroxy Acid Products	
Alpha Hydrox AHA Soufflé 12% Glycolic AHA, 1.6 oz	Glycolic acid 12%
Gly Derm Face Lotion Lite Plus 10, 4 oz	Glycolic acid 10%
Alpha/Beta Hydroxy Acid Product	
M.D. Forté Skin Rejuvenation Hydra-Masque, 4 oz	Glycolic acid; salicylic acid
Polyhydroxy Acid Product	
NeoStrata Bionic Face Cream, 1.4 oz	Gluconolactone 8%; lactobionic acid 4%
Sulfur Product	
De La Cruz Sulfur Ointment 10% Acne Medication, 2.6 oz	Sulfur 10%
Sulfur/Resorcinol Product	

Trade Name	Primary Ingredient(s)/Component(s)
Adult Acnomel Tinted Cream, 1.3 oz	Resorcinol 2%; sulfur 8%
Physical Treatment Products	
Bioré Deep Cleansing Pore Strips	Comedo extraction strip
BlueMD Blue Light Therapy	Infrared LED lights
Garnier SkinActive Clean+ Refreshing Remover Cleansing Towelettes	Cleansing cloth
Olay Pro-X Advanced Cleansing System	Acne brush
Tanda Zap Acne Spot Treatment Device	Heat therapy

Key: LED = Light-emitting diode.

Many patients will use nonprescription medications in combination with prescription products to manage acne. Patients should be aware of current medications that may cause acne as well as potential drug interactions that may occur with nonprescription products. Product selection and adherence are important for the successful treatment and management of acne. Consultation with an appropriate health care provider is important for proper diagnosis and grading of acne. For example, women who experience acne related to hormonal imbalance may benefit more from correction of the imbalance with hormone therapy, such as oral contraceptives, whereas a peripubertal teenager or young adult may benefit more from recommendations for avoidance of comedogenic products and adherence to regimens based on nonprescription products such as BP.⁵⁰

Special Populations

In pregnant patients, acne may develop because of hormonal imbalances. In most cases, if pregnancy occurs during treatment with any acne medication, the medication should be discontinued and the obstetrician advised of current or previous product use because of the potential for teratogenic effects. Very

limited human data are available to describe the use of topical BP, sulfur, hydroxyl acids, and photodynamic therapy during pregnancy.⁵¹ (See the Preface for a detailed explanation of the pregnancy data.) Glycolic acid peels have not been rated for use in pregnancy. Use in pregnancy of any treatment options should be limited to clinical situations in which the potential benefit justifies potential risk to the fetus.

Acne occurs in all age groups, including the pediatric population. This population comprises neonates, infants, and young children. Most cases of infantile and neonatal acne are self-limiting; however, a differential diagnosis by appropriate health care providers, which may include a pediatric endocrinologist, is needed for treatment recommendations.⁶ Use of aspirin and aspirin-containing products, such as salicylic acid, in children or teenagers who have or are recovering from chickenpox or flulike symptoms should be avoided because of the risk of Reye syndrome. (See [Chapter 5](#) for further discussion of Reye syndrome.)

Complementary Medicine, Vitamins, and Vitamin Analogs

Tea tree oil is widely known for its antibacterial and antifungal properties. *Staphylococcus aureus*, a common pathogen found on the skin, is sensitive to tea tree oil. Tea tree oil also has anti-inflammatory properties.⁵² Terpinen-4-ol, the active ingredient in tea tree oil, has been suggested to suppress production of inflammatory mediators and inflammation.⁴¹ Topical tea tree oil has been shown to be effective at reducing lesion counts, but no robust conclusive studies have assessed its efficacy in acne.⁴¹

Oral zinc may be considered as an alternative to tetracyclines.^{12,41} Zinc is bacteriostatic against *C. acnes*, inhibits chemotaxis, and has shown effectiveness against severe acne. One study found that although zinc was 17% less effective than minocycline, it could be used as an alternative to tetracycline therapy, especially in the summer, because it does not cause phototoxicity. However, zinc's adverse effects of nausea, vomiting, and diarrhea have made it less desirable for acne therapy, with poor patient compliance due to these adverse effects limiting its use.^{41,49}

Vitamin A is a naturally occurring retinol that is transformed into several metabolites.⁴⁹ The metabolite retinoic acid is used in cosmetics to help

eliminate wrinkles and fine lines. Theoretically, retinol also should work against acne. However, few studies have emerged to validate this claim. Oral vitamin A or retinol may be beneficial in acne in doses up to 300,000 international units (IU) daily for women and 500,000 IU daily for men.⁴⁹ Common adverse effects include xerosis and cheilitis.

Nicotinamide, a water-soluble derivative of vitamin B₃, also is used for acne.⁴¹ Nicotinamide is an active form of niacin and has been postulated to be of benefit for the treatment of acne by several mechanisms of action: It is an anti-inflammatory that improves the texture of sun-damaged skin and also decreases sebum production.^{21,53} Data on nicotinamide's role in acne are limited, however, and more research needs to be conducted to assess its benefit for this condition.

Limited data are available on the safety and efficacy of other complementary and alternative therapies for their use in acne.¹⁷

Algorithm: Acne

FIGURE 38–3 Self-care for acne. Key: OTC = Over-the-counter.

Assessment of Acne: A Case-Based Approach

Assessment begins with the initial patient interview to define the condition. Physical assessment, which involves observing the affected area and further questioning of the patient as directed by the clinical findings, is the next step in evaluation. This process will determine whether the disorder is acne or another dermatologic condition with similar signs and symptoms. Physical assessment also will determine whether the severity of the condition precludes self-treatment ([Figure 38–3](#)). Before self-care is recommended, a review of current medication use, prescription and nonprescription, is necessary to reveal prescribed treatments for the disorder or use of medications known to cause acne ([Table 38–1](#)).

Cases 38–1 and 38–2 are examples of assessment of two different patients presenting with acne.

Patient Counseling for Acne

The success of the treatment regimen depends largely on the patient’s adherence. It is crucial for the health care provider to communicate the causes of acne, correct any misconceptions, and clearly explain the rationale for treatment. Patient buy-in will facilitate adherence and increase the likelihood of a successful outcome. Key patient factors are maturity and willingness to adhere to a skin care program that involves a continued daily regimen of washing affected areas and applying medication. Reassurance and emotional support often are necessary to reduce patient concern, as acne may only be controlled—not cured. The box “Patient Education for Acne” lists specific information to provide in patient counseling.

The internet is a source of supplemental information about acne in nontechnical language, including nonprescription drugs used to treat the condition, and treatment expectations. Selected sites are listed in [Table 38–8](#). If not copyrighted, online materials can be printed and given to the patient during consultation. If the material is copyrighted, the health care provider should instead provide the website address.

U.S. Food and Drug Administration	www.fda.gov

Evaluation of Patient Outcomes for Acne

Although the patient may expect complete resolution of acne, a more realistic expectation for self-treatment is clinical improvement, defined by a decrease in both the number and severity of lesions. The health care provider should medically refer patients whose acne shows no improvement after 6 weeks of adherence to self-treatment or after 6 months of diet changes, or if a patient has moderate to severe acne. If some improvement is observed, the provider

may suggest monthly follow-up to monitor progress and adjust the self-treatment regimen as needed.

Case 38–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A young woman comes to the pharmacy counter requesting a treatment option for acne. She expresses distress over her visible facial lesions: "I hate going to my dance classes because I feel people are staring at the pimples on my face." She has noticed a few yellowish pimples but states that most of the spots are red raised bumps. She reports that she has had occasional mild "breakouts" since her early teens but notes the condition has been worsening over the past 3 weeks.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She states that her acne gets worse whenever she has a dance performance, which is nearly once a week.
c. Description of the patient's efforts to relieve the symptoms	None. She states that she has been wearing some concealer to "hide" the spots.
d. Patient's identity	Bailey Marshall
e. Patient's age, gender, height, and weight	18 years, female, 5 ft 5 in., 135 lb
f. Patient's occupation	College student who studies dance.
g. Patient's dietary habits	Eats a healthy breakfast and lunch; has a homecooked dinner most nights. On dance recital nights she usually eats fast food

Relevant Evaluation Criteria	Scenario/Model Outcome
	while traveling.
h. Patient's sleep habits	She gets about 8 hours of sleep most evenings.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Asthma</i> : albuterol inhaler 90 mcg; inhale 1–2 puffs every 4–6 hours as needed
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) -----	History of mild acne that responded to self-treatment with salicylic acid face wash
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 38–2).	The current presentation of papule formation accompanied by few pustules is consistent with mild acne, likely stress-induced from her dance performances.
3. Identify exclusions for self-treatment (Figure 38–3).	If her acne worsens or begins to cause scarring
	If she is pregnant or plans to become pregnant soon
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Marshall to an appropriate health care provider. (2) Recommend self-care with available nonprescription products and nondrug lifestyle modifications. (3) Recommend self-care until the patient can see her

Relevant Evaluation Criteria	Scenario/Model Outcome
	regular health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend that Ms. Marshall use an over-the-counter acne treatment product and implement nondrug measures to minimize/control her acne.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Using an over-the-counter formulation of a benzoyl peroxide gel and following some simple steps to modify your lifestyle would be a great option for you." See the box "Patient Education for Acne" for additional information.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Benzoyl peroxide is an effective over-the-counter acne treatment. You likely have a mild form of acne, and this medication should help alleviate any breakouts and help prevent them from occurring. Although this medication should help, it is important that you consider that the acne may be linked to your stress. Engaging in stress management techniques also may be beneficial."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	"Start by applying a thin layer of the gel once daily to a few affected areas for 2–3 days. If you do not experience significant skin irritation, the product can be applied in a thin layer once daily to affected areas for 1–2 weeks. If this regimen does not result in significant skin irritation, you can slowly increase the

Relevant Evaluation Criteria	Scenario/Model Outcome
	applications to 2–3 times daily thereafter as tolerated.” See the box “Patient Education for Acne” for additional information.
b. Maximum number of days the therapy should be employed	“If skin irritation develops with use of the product, it should be discontinued immediately. Otherwise, there is no maximum number of days for use of this medication. Continued and consistent use is required for full effectiveness.” See the box “Patient Education for Acne” for additional information.
c. Product administration procedures	“Apply a thin layer of the gel topically. Avoid touching hair or clothing as this product may cause bleaching. Wash and dry hands before and after applying. Avoid all mucous membranes while applying (eyes, nose, mouth). Wear a protective sunscreen if you will be spending a significant time in the sun because the medication increases your risk for sunburn.” See the box “Patient Education for Acne” for additional information.
d. Expected time to onset of relief	“You may see improvement in your skin within a few days of using the gel; however, it can take many weeks (ranging anywhere from 3 to 6) to see the full effect.”
e. Degree of relief that can be reasonably expected	“You should notice fewer breakouts with diminished redness and yellow pimples. Even with lifestyle changes, it could take some time before improvement is seen.”
f. Most common adverse effects	“Common adverse effects that can occur with use of this gel are related to general skin irritation and include redness, burning, peeling, and itching.” See the box “Patient Education for Acne” for additional information.
g. Adverse effects that warrant medical intervention should they occur	Intolerable skin irritation. See the box “Patient Education for Acne” for additional information.
h. Patient options in the event that condition worsens or persists	“If you do not experience improvement in 6 weeks or if the acne worsens, you should consult your regular health care provider and consider other treatment alternatives.” See the box “Patient Education for Acne” for additional information.
i. Product storage requirements	“Store at room temperature, out of reach of children and pets.”

Relevant Evaluation Criteria	Scenario/Model Outcome
j. Specific nondrug measures	“Consider using an oil-free concealer to prevent oil buildup on the skin, which can worsen acne. Stress management techniques also may be beneficial to reduce your body’s acne response.” See the box “Patient Education for Acne” for additional information.
Solicit follow-up questions from the patient or caregiver.	“Would a salicylic acid wash work better? When I had acne problems before, I just used it and it helped.”
Answer the patient’s or caregiver’s questions.	“Topical washes and cleansers do not leave a lot of the active acne-fighting ingredient behind, oftentimes making them less effective treatment options. Using a wash instead of the benzoyl peroxide would not be as effective in clearing and preventing future breakouts. Using the products together could lead to extreme skin drying and peeling.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Ms. Marshall in 2 weeks to see if she has experienced any decrease in her acne and to check for toleration of the product recommended. Recommend that she contact her regular health care provider if her acne worsens or if she does not see improvement after 6 weeks of consistent treatment.

Case 38–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history,	

Relevant Evaluation Criteria	Scenario/Model Outcome
including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient, a young man with severe acne on cheeks and chin, presents to the pharmacy for self-care recommendations. The acne lesions are large and cystlike in form and appear inflamed. He complains of intense burning when he tries to “pop the zit,” as well as periodic itching. His symptoms began 2 weeks ago when the weather started to get very humid. The patient states that he has had acne since he was a teenager, but it recently has gotten worse. He reports running regularly during the summer in nature parks. He also spends a lot of time outside for his botany internship.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient states that his acne started worsening when he began to run outside every day. Patient claims some relief of pain and itching when he takes cool showers and stays out of the sun. Claritin D also has helped with the itching.
c. Description of the patient's efforts to relieve the symptoms	Patient has consistently used nonprescription benzoyl peroxide 10% gel and an acne facial wash containing salicylic acid for 6 weeks, with no significant improvement.
d. Patient's identity	Adam Adenola
e. Patient's age, gender, height, and weight	24 years, male, 5 ft 8 in., 150 lb
f. Patient's occupation	University graduate student
g. Patient's dietary habits	Patient follows a vegetarian diet.
h. Patient's sleep habits	Patient sleeps 4–10 hours a night, depending on his course work and internship schedule.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Seasonal allergies:</i> Claritin D (loratadine/pseudoephedrine) in the spring and fall. This medication has helped with the itching associated with the acne.

Relevant Evaluation Criteria	Scenario/Model Outcome
j. Allergies	Spring allergies, no known drug allergies
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Patient has a history of mild acne, for which nonprescription products generally have been of benefit.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 38-2).	Patient is suffering from acne inflammation due to bacteria buildup with resulting formation of cystlike lesions.
3. Identify exclusions for self-treatment (Figure 38-3).	Severe skin symptoms, cyst formation; resistance to treatment with nonprescription products
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to an appropriate health care provider. (2) Recommend self-care with a nonprescription acne and nondrug measures. (3) Recommend self-care until Mr. Adenola can see an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem,	Patient should be referred to an appropriate health care provider for further evaluation.

Relevant Evaluation Criteria	Scenario/Model Outcome
taking into account patient preferences.	
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a knowledgeable health care provider for treatment of your acne lesions."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"General recommendations say that you should talk to an appropriate health care provider if you have seen no improvement of your skin after 6 weeks of self-treatment. Your acne is most likely caused from bacteria buildup in your skin, so you will need a prescription to obtain improvement."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See the box "Patient Education for Acne."
Solicit follow-up questions from the patient or caregiver.	"Will popping the cysts myself help clear out the bacteria from my skin?"
Answer the patient's or caregiver's questions.	"Popping acne cysts is not advised because it can lead to scarring and formation of additional lesions, and it can make your skin susceptible to other infections."
Follow-up: Monitor and Evaluate	
9. Assess patient	Contact Mr. Adenola in 1-2 days to ensure that he has made an

Relevant Evaluation Criteria	Scenario/Model Outcome
outcome.	appointment for further medical care.

Patient Education for Acne

The goal of self-treatment is to control mild acne, thereby preventing more serious forms from developing. The condition usually can be managed with diligent and long-term treatment. The best approaches to controlling acne are use of cleansers and medications to keep the pores open and avoidance of factors and situations that worsen acne. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Disease Information

- Acne is the result of several pathophysiologic changes that occur within the pilosebaceous unit located in the dermis, or middle layer of the skin.
- Acne may be controlled by using certain medications, but it is not curable, although resolution occasionally may occur over time.

Nondrug and Preventive Measures

- Cleanse skin thoroughly but gently twice daily to produce a mild drying effect, which loosens comedones for removal. Use a mild, oil-free cleanser and warm water.
- To prevent or minimize acne flares, consider using a skin toner to remove excess dirt and oil. Avoid or reduce exposure to environmental factors such as dirt, dust, petroleum products, cooking oils, or chemical irritants.
- To prevent friction or irritation that may cause acne flares, do not wear tight-fitting clothes, headbands, or helmets; avoid resting the

chin on the hand.

- To minimize acne related to cosmetic use, use noncomedogenic, oil-free makeup and frequently clean cosmetic brushes, if used.
- To prevent excessive hydration of the skin, which can cause acne flares, avoid environments with high humidity.
- Avoid stressful situations when possible and practice stress management techniques. Stress can worsen existing acne.
- Do not pick or squeeze pimples, which can further irritate skin and possibly lead to infection, worsening of acne, and scarring.
- Note that sexual activity plays no role in the occurrence or worsening of acne, although the onset of sexual activity and occurrence of acne may take place within the same time span.

Nonprescription Medications

- Most commonly available nonprescription products contain adapalene, benzoyl peroxide, salicylic acid, or sulfur, and these products come in a variety of formulations (e.g., cleansers, creams, gels, astringents).
- Benzoyl peroxide and adapalene are the most effective nonprescription medications for treating mild acne.

Adapalene

- Adapalene is believed to normalize the development of skin cells, resulting in decreased acne symptoms.
- Do not use adapalene if you have very sensitive skin or are sensitive to benzoyl peroxide.
- Because adapalene increases susceptibility to sunburn, avoid unnecessary sun exposure and use a broad-spectrum sunscreen with an SPF of 15 or higher when using this product.
- To avoid possible excessive irritation, avoid contact of adapalene with eyes, lips, mouth, and nose, as well as cuts, scrapes, and other abrasions.
- Use of other acne medications with adapalene may cause excessive dryness and peeling. Such combination therapy should be directed by a knowledgeable health care provider.

- Redness, itching, dryness, scaling, and burning are common adverse effects that tend to diminish after the first month of treatment.
- Acne may worsen temporarily after beginning treatment with adapalene.
- It will take 8–12 weeks of treatment with adapalene before noticeable clinical improvement is obtained.
- If acne lesions or symptoms worsen or improvement does not occur in 3 months with proper use of the agent, consult your primary care provider.
- If you experience allergic reactions, become pregnant, or are planning to become pregnant, discontinue use of adapalene and consult your primary care provider for other treatment options.

Benzoyl Peroxide

- Benzoyl peroxide inhibits the growth of *Cutibacterium acnes*, the bacterium involved in acne development; it also helps unclog pores by causing a mild peeling effect.
- Do not use benzoyl peroxide if you have very sensitive skin or have a recognized sensitivity to this agent.
- Because benzoyl peroxide increases susceptibility to sunburn, avoid unnecessary sun exposure and use a broad-spectrum sunscreen with an SPF of 15 or higher when using this product.
- To prevent possible excessive irritation, avoid contact of benzoyl peroxide with eyes, lips, mouth, and nose, as well as cuts, scrapes, and other abrasions. Avoid contact of benzoyl peroxide with hair and dyed fabrics, which may be bleached by this product.
- Skin irritation, characterized by redness, burning, itching, peeling, or possibly swelling, may occur with the recommended treatment regimen. Irritation may be reduced by using the product less frequently or in a lower concentration.
- Note that use of other acne medications with this product may cause excessive dryness and peeling. Do this only as directed by a knowledgeable health care provider.
- After the initial 1–2 weeks of treatment, applications can be increased up to 2–3 times per day over a period of 2–3 days, as

tolerated.

- Slight improvement may be noticed in as little as a few days, but maximum effectiveness may take up to 3–6 weeks of continued use.
- If treatment is tolerated but the problem persists, the benzoyl peroxide strength may be increased to 5% after 1 week and to 10% after 2 weeks, if necessary.
- Continue the treatment regimen even after lesions have cleared to prevent the formation of new ones.

Salicylic Acid

- Salicylic acid helps unclog pores by causing slight peeling.
- This agent is less effective than benzoyl peroxide and adapalene.
- Salicylic acid can be used 1–3 times daily as a cleanser or as a topical gel.
- Gel formulations should be applied only to the affected area.
- If excessive peeling occurs, limit use to once daily or every other day.
- Salicylic acid may cause sun sensitivity, so limit sun exposure and use a broad-spectrum sunscreen with an SPF of 15 or higher.
- Lack of response after 6 weeks is an indication of need for medical referral.

Sulfur

- Sulfur is believed to work by inhibiting the growth of *C. acnes*.
- This medication can be applied 1–3 times daily, but its use is limited by its chalky yellow color and characteristic unpleasant odor.
- Sulfur is not as effective as benzoyl peroxide or adapalene.
- Patients who are allergic to sulfa drugs should not use sulfur-containing acne products.

When to Seek Medical Attention

- If severe skin irritation or sensitivity develops, stop use of irritant and see an appropriate health care provider.
- If improvement has not occurred after 6 weeks of treatment with benzoyl peroxide or salicylic acid or 8–12 weeks of adapalene, seek

further medical evaluation.

- If you experience tightness in the throat, breathing problems, feeling faint, or swelling of the eyes, face, tongue, or lips with use of an acne product, seek emergency medical attention.

Key Points for Acne

- Acne is not a curable condition but may be controlled to improve cosmetic appearance and prevent progression to severe disease with resultant scarring.
- Adherence to treatment regimens is crucial in achieving a successful outcome.
- Minimizing environmental and physical factors that exacerbate acne can help limit the extent of the condition.
- Pharmacologic and nonpharmacologic therapies should be tailored to the individual patient.
- Medical referral should be considered for moderate to severe acne, presence of certain exacerbating factors (e.g., comedogenic drugs), possible rosacea, and acne resistant to self-treatment regimens.
- Proper counseling, including empathy and reassurance, will promote the patient's understanding that consistent treatment is needed for clinical improvement.

Chapter 39: Prevention of Sun-Induced Skin Disorders

Authors: Kimberly M. Crosby

Exposure to ultraviolet radiation (UVR) is cumulative and can produce serious, long-term problems. Sunburn is the most common skin problem caused by excessive UVR exposure. However, other conditions that are either directly caused or exacerbated by UVR exposure include a group of photoaggravated skin disorders: premature aging, skin cancers, cataracts, and photodermatoses ([Table 39–1](#)).^{1,2}

Skin cancer is the most serious UVR-induced skin disorder. Cumulative sun exposure from childhood to adulthood may predispose a person to develop precancerous and cancerous skin conditions. Epidemiologic studies conducted since the 1950s demonstrate a strong relationship between chronic, excessive, and unprotected sun exposure and human skin cancer. Skin cancers such as basal cell, squamous cell, and melanoma are the most commonly diagnosed cancer malignancy in the United States. According to the most recent estimates, 3.5 million basal and squamous cell carcinomas were diagnosed in 2012. The American Cancer Society estimates approximately 96,500 cases of malignant melanoma were diagnosed in 2019.^{3–5} Avoiding excessive UVR exposure through the use of sunscreens and other measures will reduce the incidence of sun-induced skin disorders: sunburn, premature aging of the skin, photodermatoses, skin cancer, and other long-term dermatologic effects. Education about the safe and effective use of sunscreen and suntan products is a public health need. To perform this function, health care providers should be aware of the hazards of UVR and the criteria for selection and proper use of sunscreen products. Providers are encouraged to participate in efforts to educate the public about the morbidity and mortality associated with excessive UVR exposure.^{3–5}

Pathophysiology of Sun-Induced Skin Disorders

Ultraviolet Radiation

The UV spectrum is divided into 3 major bands: ultraviolet C (UVC), ultraviolet B (UVB), and ultraviolet A (UVA), all of which may cause or exacerbate sun-induced skin disorders. However, UVA and UVB primarily are responsible for photodamage because all UVC radiation is removed by the ozone layer.²

UVB is the most active UVR for producing erythema. UVB radiation that reaches the Earth is at its highest intensity from 10:00 AM to 4:00 PM. UVB once was considered the primary inducer of skin cancer; however, UVA is now known to also play a role in causing skin cancer. Both UVA and UVB primarily are responsible for photoaging effects.^{2,6} The only true therapeutic effect of UVB exposure is synthesis of vitamin D₃ in the skin. However, the availability of vitamin D-rich foods and supplements have eliminated the need for UVB exposure to increase vitamin D production. The American Academy of Dermatology position statement on vitamin D states that UVR exposure should not be used as a source of vitamin D because of the associated risks.⁷

Cloud cover, white or light-colored surfaces (e.g., snow, sand), and altitude all contribute to the amount of UVR exposure received. Severe sunburn may result even when an individual is sitting in the shade or cloud cover is present. Water reflects no more than 5% of UVR, allowing the remaining 95% to penetrate and burn the swimmer. Therefore, even if the swimmer is completely submerged, time in the water should be considered part of the total time spent in the sun. Dry clothes reflect almost all UVR. If light passes through dry clothing when held up to the sun, however, UVR also will penetrate the clothing. Tightly woven material offers the greatest protection. Wet clothes allow transmission of approximately 50% of UVR.^{2,8,9}

UVB is blocked by glass in automobiles. The laminated glass in automobile windshields filters most UVA. However, side windows are not made from laminated glass; therefore, a significant amount of UVA may pass through them to riders in the vehicle. Therefore, patients sensitive to UVA (e.g., those with photodermatoses, those taking photosensitizing drugs) should use an appropriate sunscreen even when driving with the windows closed.¹⁰

The Environmental Protection Agency has developed a UV index that uses a scale to rate the amount of skin-damaging UVR that reaches the earth's surface at any given time ([Table 39-2](#)). As the rating increases, the risk of

exposure increases. The noon UV index value typically is used; however, the UV index changes throughout the day. Factors that influence the UV index are time of day (UVR exposure is greater at midday than in the early morning or late afternoon); ozone (limited amounts of ozone increase the amount of UVR exposure); altitude; season (UVR exposure is greater in spring and summer); surface reflectivity; latitude (UVR exposure is increased in areas closer to the equator); and land cover (less tree cover increases UVR exposure).^{11,12}

TABLE 39–2 Global Solar UV Index

Rating Number	Interpretation of UVR Exposure Risk
1–2	Low
3–5	Moderate
6–7	High
8–10	Very high
11+	Extreme

Key: UV = Ultraviolet; UVR = ultraviolet radiation.

Source: [Reference 10](#).

Sunburn and Suntan

Sunburn and suntan present as reactions to UVR exposure. The degree to which a person will develop a sunburn or a tan depends on several factors, including type and amount of radiation received, thickness of the epidermis and stratum corneum, skin pigmentation, skin hydration, and distribution and concentration of peripheral blood vessels. Most UVR that strikes the skin is absorbed by the epidermis.

A sunburn is an acute reaction to excessive UVR exposure, resulting in inflammation of the exposed skin. Exposure to both UVA and UVB can result in sunburn. The cellular mechanism for this response is complex, involving skin cells and numerous inflammatory mediators. Erythema, swelling, and pain occur after UVR exposure, reaching a maximum response at 6–24 hours. A

sunburn usually resolves in 72 hours. However, the sunburn may occur sooner and last longer depending on the duration of exposure to UVR.^{6,13}

A suntan is produced when UVR stimulates the melanocytes in the skin layers to generate and redistribute melanin in the skin. UVA and UVB both contribute to the development of a suntan. Tanning may be described as immediate or delayed. *Immediate tanning*, caused by a redistribution of melanosomes, begins to be visible rapidly after exposure and may last for 3–4 days after UVR exposure. The darkening of pigment may not be visible on lighter skin types. *Delayed tanning* occurs because of the increase in number and activity of melanocytes after UVR exposure. Delayed tanning of the skin becomes visible 3–4 days after exposure to UVR and will last from 10 to 30 days depending on skin type and amount of UVR exposure. Delayed tanning serves as a protective mechanism for the skin to diffuse and absorb additional UVR. However, tanning does not protect an individual from developing skin cancer, photodermatoses, premature photoaging, or other UVR-related negative health risks. Tanning also does not protect against future sunburns.^{6,13}

Photodermatoses

The exact pathologic mechanism for the development of photodermatoses is unknown. UVB most often is responsible for these reactions; however, UVA and some visible light also may cause photodermatoses.

Photosensitivity encompasses two types of conditions: photoallergy and phototoxicity. *Drug photoallergy* involves an increased, chemically induced reactivity of the skin to UVR and/or visible light. UVR (primarily UVA) triggers an antigenic reaction in the skin. This reaction, which is not dose related, is usually seen after at least one prior exposure to the involved chemical agent or drug.

Similar to photoallergy, *phototoxicity* is an increased, chemically induced reactivity of the skin to UVR and/or visible light. However, phototoxicity is not immunologic. It often is seen on first exposure to a chemical agent or drug, is dose related, and usually exhibits no drug cross-sensitivity. Some drugs associated with phototoxicity are listed in [Table 39–3](#). This type of reaction is not limited to drugs: it also is associated with plants, cosmetics, and soaps.^{1,13}

TABLE 39–3 Selected Medications (by Drug Category) Associated With Photosensitivity Reactions

Anticancer Drugs

Dacarbazine

Daunorubicin

Fluorouracil

Methotrexate

Vinblastine

Anticonvulsants

Skin Cancer

Melanoma causes the majority of deaths due to skin cancers. However, the majority of skin cancers are nonmelanoma skin cancers (NMSCs). These cancers commonly occur on sun-exposed areas of the body (face, head, neck, and backs of the hands). The two most common types of NMSC are basal cell carcinoma (BCC) and squamous cell carcinoma (SCC). BCC often is an aggressive, invasive disorder of the epidermis and dermis that can cause serious damage to the skin and underlying tissue; however, it rarely metastasizes. SCC found in epithelial keratinocytes grows very slowly and has only an approximately 4% annual incidence of metastasis.

The pathophysiology of melanoma differs from that of the NMSCs. Although most melanomas arise from normal skin, about 30% involve existing nevi

(moles).

Some of the risk factors for skin cancer include a family or personal history of melanoma; sun sensitivity (e.g., difficulty tanning, burning easily); large numbers of atypical nevi; a previous history of SCC or BCC; tanning bed use; and a history of excessive sun exposure and sunburns. Regardless of risk factors, skin cancer may develop in all individuals with increased exposure to UVR. A growing amount of evidence supports the supposition that sun exposure plays a role in the development of all types of skin cancers.^{5,6,13-17}

Clinical Presentation of Sun-Induced Skin Disorders

Sunburn

Sunburn usually is seen as a superficial burn with a reaction that ranges from mild erythema to tenderness, pain, and edema (see [Color Plates](#), photograph 28). Severe reactions to excessive UVR exposure can sometimes produce burns that range in severity from superficial partial thickness to full thickness, with the development of *vesicles* (blisters) or *bullae* (many large blisters) as well as fever, chills, weakness, and shock. Shock caused by heat prostration or hyperpyrexia can lead to death.^{6,13} (See [Chapter 41](#) for treatment of sunburn.)

Drug Photosensitivity

Drug photoallergy presents similar to allergic contact dermatitis (e.g., poison ivy) and is characterized by pruritus with erythematous papules, vesicles, bullae, and/or urticaria (see [Color Plates](#), photograph 29). *Phototoxicity* is most likely to appear as an exaggerated sunburn with pruritis,^{1,13} but urticaria also may occur (see [Color Plates](#), photograph 30).

Photodermatoses

Each photodermatosis has a unique morphology. *Polymorphous light eruption* alone can have multiple morphologic presentations of pruritus as papules, vesicles, plaques, and/or urticaria.¹

Premature Aging

Premature aging is characterized by wrinkling and yellowing of the skin. Conclusive evidence reveals that prolonged exposure to UVR results in *elastosis* (degeneration of the skin caused by a breakdown of the skin's elastic fibers). Pronounced drying, thickening, and wrinkling of the skin also may result. Other physical changes include cracking, *telangiectasia* (spider vessels), *solar keratoses* (growths), and *ecchymoses* (subcutaneous hemorrhagic lesions).^{5,6,13–16} (See [Chapter 40](#) for measures to reverse photoaging.)

Skin Cancer

BCC is a translucent nodule with a smooth surface. It usually is firm to the touch and may be ulcerated or crusted. *BCC* generally is found as an isolated lesion on the nose or other parts of the face, although multiple lesions are sometimes found. Conversely, *SCC*, is a slow-growing, isolated papule or plaque on sun-exposed areas of the body.^{6,13}

Self-examination for melanoma uses four factors (A-B-C-D-E) for evaluation: Asymmetric shape; Border irregularity or poorly defined border; Color variation within the same mole or a change in color; Diameter larger than 6 mm; and an Evolving or a changing mole. A mole with these characteristics and any new growth or change in appearance of the skin (including the lips) should be evaluated by a dermatologist.^{17,18}

Prevention of Sun-Induced Skin Disorders

The short-term goals in preventing sun-induced skin disorders are relatively simple: avoid or minimize sunburn, photosensitivity reactions, and photodermatoses induced or exacerbated by UVR. The expected long-term outcomes are prevention of skin cancer and avoidance of premature aging of the skin.

UVR-induced skin disorders can be prevented by minimizing exposure to UVR and by using sunscreen agents. The sunscreen product selected and the degree of protection will vary, depending on the patient's intended use for the product and the conditions under which the product will be used ([Figure 39–1](#)).

FIGURE 39–1 Self-care for sun protection. Key: CAM = Complementary and alternative medicine; HCP = health care provider; SPF = sun protection factor. Source: References 1, 2, 5, 14, 15, 20, 21, and 24.

As the risk a patient has of developing a UVR-induced skin disorder increases, the need to avoid sun exposure increases accordingly. Providers can assist the patient in striking a balance between completely avoiding sun exposure, wearing protective clothing, and using sunscreen products. With regard to preventing sunburn, the patient's natural skin type will be the primary factor in determining the appropriate sun protection factor (SPF) of the sunscreen product. The lightness of a patient's natural skin and the speed at which the patient develops a burn determine the SPF required for the sunscreen product to prevent sunburn. However, all skin colors, including darker skin, can suffer UVR damage, so patients of all skin types should be counseled about protection from UVR.⁵

Avoidance of Sun Exposure

Complete avoidance of UVR often is the best approach for patients who have the physical characteristics or history listed in [Table 39–4](#) or who suffer from a UVR-induced skin disorder. People who refuse to stay indoors or who must be outdoors for extended periods should wear protective clothing. (e.g., a hat with a 4-inch brim, long pants, a long-sleeved shirt or special sun protective clothing embedded with agents that absorb UVR). Many clothing items now list an *ultraviolet protection factor* (UPF) rating on their label, which identifies how much UVR the clothing can filter out. Clothing items that are darker in color, have a tighter weave, or contain a UVR-absorbing agent tend to block out more UVR. When the patient is unwilling or unable to avoid the sun or to wear protective clothing, the next best choice is to use a sunscreen product.⁵

TABLE 39–4 Patient Risk Factors for the Development of UVR-Induced Problems

- Fair skin that always burns and never tans
- A history of one or more serious or blistering sunburns
- Blonde or red hair
- Blue, green, or gray eyes
- A history of freckling
- A previous growth on the skin or lips caused by UV exposure

- The existence of a UV-induced disorder
- A family history of melanoma
- Current use of an immunosuppressive drug
- Current use of a photosensitizing drug
- Excessive lifetime exposure to UVR, including tanning beds and booths
- History of an autoimmune disease

Key: UV = Ultraviolet; UVR = ultraviolet radiation.

Source: [References 6](#) and [13](#).

UVR Protection

SPF

Purchasers of sunscreens usually are familiar with SPF, which is one parameter for determining a sunscreen's effectiveness for UV protection. Another parameter, minimal erythema dose (MED), is used to calculate a sunscreen's SPF. The *MED* is defined as the "minimum UVR dose that produces clearly margined erythema in the irradiated site, given as a single exposure."¹⁴ It is a dose of radiation, not a grade of erythema.

The SPF is derived by dividing the MED on protected skin by the MED on unprotected skin. For example, if a person requires 25 mJ/cm² of UVB radiation to experience 1 MED on unprotected skin and requires 250 mJ/cm² of radiation to produce 1 MED after applying a given sunscreen, the product would be given an SPF rating of 10. As the SPF increases, the agent's effectiveness in preventing sunburn increases. If 60 minutes of sun exposure usually is required for someone to experience a sunburn, a sunscreen with an SPF of 6 (reapplied in sufficient amounts at the recommended intervals) will allow that person to stay in the sun 6 times longer (or 6 hours) before experiencing the same degree of sunburn. The SPF is product specific because it is calculated on the basis of the final formulation of the product and cannot be determined on the basis of the active ingredient alone. A product with an SPF of 15 blocks 93% of UVB. Raising the SPF to 30 increases UVB protection to only 96.7%, and an SPF of 40 blocks 97.5%.¹⁴

New regulations for the testing and labeling of nonprescription sunscreen

products have been proposed to update the testing requirements for the safety and efficacy of sunscreen products. The SPF value for sunscreen products is determined by a standardized testing protocol. All products with an SPF of 15+ will be required to meet a minimum standard of UVA and UVB protection; these products will be considered “broad spectrum.” The proposed regulation also will require any approved sunscreen products to follow an updated defined labeling format. Only sunscreens with an SPF value of 15+ that are used as directed, along with other skin protection measures, will be able to claim a reduction in the risk of skin cancer and early skin aging. Sunscreens with an SPF value between 2 and 14, regardless of their UVA and/or UVB coverage, can claim only to help prevent sunburn and will not be labeled as “broad spectrum.” These products must also carry the following label warning: “Skin Cancer/Skin Aging Alert: Spending time in the sun increases your risk of skin cancer and early skin aging. This product has been shown only to help prevent sunburn, not skin cancer or early skin aging.”^{19,20}

A sunscreen’s efficacy also is related to its *substantivity*—that is, its ability to remain effective during prolonged exercising, sweating, and swimming. This property can be a function of the active sunscreen, the vehicle, or both. Generally speaking, products with cream-based (water-in-oil) vehicles appear more resistant to removal by water than those with alcohol bases. FDA regulations propose prohibiting “waterproof,” “sweatproof,” and “sunblock” claims on sunscreen products because these terms overstate effectiveness. Further, water-resistance claims on the front label must indicate whether the sunscreen remains effective for either 40 or 80 minutes during swimming or sweating. These times are based on the standard testing procedure. Products that are not water resistant must bear instructions for users to wear a water-resistant product while swimming or sweating.²⁰

FDA also is proposing to limit the maximum SPF value on sunscreen labels to 60+. Products with a tested SPF of 60–80 will be labeled as “60+.” Sunscreens that claim higher SPF values will have to go through a new drug application process.

The dosage forms proposed as safe and effective for use in sunscreen products are sprays, oils, lotions, creams, gels, butters, pastes, ointments, and sticks. Other application dosage forms (e.g., towelettes, wipes) have not been approved as safe and effective.²⁰

Types of Sunscreens

According to the therapeutic definitions, topical sunscreens can be divided into two major subgroups: chemical sunscreens and physical sunscreens. *Chemical sunscreens* absorb and thus block the transmission of UVR to the epidermis. An active ingredient absorbs at least 85% of the radiation in the UV at wavelengths from 290 to 320 nm, but the agent may or may not allow transmission of radiation to the skin at wavelengths longer than 320 nm. *Physical sunscreens* are generally opaque; instead of absorbing UVR, they reflect and scatter it. An active ingredient in opaque sunscreens reflects or scatters all light in the UV and visible spectrums at wavelengths from 290 to 777 nm. The sunscreen thereby minimizes suntan and sunburn.

The proposed rule updated data for marketed sunscreens. Twelve sunscreen agents currently found in nonprescription products have not been formally evaluated for efficacy and safety: cinoxate, dioxybenzone, ensulizole, homosalate, meradimate, octinoxate, octisalate, octocrylene, padimate O, sulisobenzene, oxybenzone, and avobenzone. Two sunscreens—zinc oxide and titanium dioxide in concentrations up to 25%—are considered Category I (generally recognized as safe and effective, or GRASE). Two sunscreen agents—aminobenzoic acid, or PABA, and trolamine salicylate—are considered to be Category II (not GRASE) due to safety concerns. The ruling states that the risks associated with aminobenzoic acid (skin reactions) and trolamine salicylate (bleeding risks and salicylate toxicity) outweigh the agents' benefits.^{19,20}

Chemical Sunscreens

Aminobenzoic Acid and Derivatives

Padimate O is a derivative of aminobenzoic acid used in sunscreens for UVB protection.^{15,21}

Anthranilates

The anthranilates are ortho-aminobenzoic acid derivatives. Meradimate is a weak UV sunscreen with maximal absorbance in the UVA range. It usually is found in combination with other sunscreen agents to provide broader UV coverage.^{15,21}

Benzophenones

The benzophenone group comprises three agents: dioxybenzone, oxybenzone (benzophenone-3), and sulisobenzene (benzophenone-4). As a group, these agents primarily absorb UVB radiation, but they can offer some protection against UVA. Many sunscreen formulations now contain benzophenones because of their broad spectrum of action and less likelihood of causing allergic reactions seen in some of the other sunscreen classes. Oxybenzone, also found in some cosmetic formulations, is a significant sensitizing agent among sunscreens.^{15, 21,22}

Cinnamates

Cinnamates include cinoxate, octinoxate, and octocrylene. Inclusion of octocrylene in commercial sunscreen preparations has increased, possibly

because of its broader spectrum of absorbance and its effectiveness as a photostabilizer. *Photostabilizers* are compounds often used in sunscreens to prevent the sunscreen agent from losing effectiveness upon exposure to sunlight. Octocrylene can decrease the rate at which other sunscreens degrade upon sun exposure. It often is combined with other sunscreens to improve their stability.

Unfortunately, cinnamates do not adhere well to the skin and must rely on the vehicle in a given formulation for their substantivity.^{15,21,22}

Dibenzoylmethane Derivatives

Avobenzone (butyl methoxydibenzoylmethane, originally known as Parsol 1789) is a new sunscreen agent that is effective throughout the UVA spectrum. However, this agent does not provide total protection throughout the entire UVA spectrum, so reactions from photosensitive drugs and chemicals still could occur. Its role in sunscreen products is to increase UVA coverage. Avobenzone is easily degraded by exposure to sunlight; it is found in newer sunscreen products combined with octocrylene, salicylates, 4-methylbenzylidene camphor, and micronized zinc oxide and/or titanium dioxide to enhance stability of the product and to extend the product's spectrum of coverage through the UVA and UVB spectrum.^{15,21,22}

Salicylates

Salicylic acid derivatives are weak sunscreens and must be used in high concentrations. They do not adhere well to the skin and are removed easily by perspiration or swimming.^{15,21}

Other Chemical Sunscreens

Ensulizole does not fit into any of the preceding classes. It is a pure UVB, water-resistant, broad-spectrum sunscreen. Ecamsule often is combined with octocrylene to increase the latter's stability to light.^{15,21}

Physical Sunscreens

Physical sunscreens (zinc oxide and titanium dioxide) are considered broad-spectrum UV protectants. They are used most often on small and prominently exposed areas by patients who cannot limit or control their exposure to the

sun (e.g., lifeguards). Earlier formulations of these agents were opaque and had an undesirable sticky or gritty sensation. Current formulations contain micro- or nano-sized particles of the agent. These formulations are transparent, which improves their cosmetic appeal. Because titanium dioxide increases the effective SPF of a product and extends the spectrum of protection well into the UVA range, the number of commercial products containing this agent has increased.^{15,21}

Combination Products

FDA has not recommended limits on the number of sunscreen agents that may be used together. However, each sunscreen agent must contribute to the efficacy of a product and must not be included merely for marketing promotional purposes.²⁰

The proposed regulation does limit the use of combination sunscreen and insect repellent products. Safety concerns for these products include their appropriate use and enhanced systemic absorption. Thus, FDA does not consider these combination products to be safe and effective.²⁰

Dosage and Administration Guidelines

The two major causes of poor sun protection from sunscreen use are application of inadequate amounts and infrequent reapplication.

For maximum effectiveness, sunscreens must be applied liberally to all sun-exposed areas of the body and reapplied at least as often as the label recommends. FDA-recommended labeling states that sunscreens should be applied 15–30 minutes before UV exposure and at least every 2 hours thereafter. Reapplication after every episode of swimming, towel drying, or excessive sweating also is recommended.^{20,21}

The standard for application of sunscreens is 2 mg/cm² of body surface area.²⁰ This standard means that, for sufficient protection, the average adult in a bathing suit should apply 9 portions of sunscreen of approximately ½ teaspoon each, or approximately 4 and ½ teaspoons (22.5 mL) total. The sunscreen should be distributed as follows:

- Face and neck (including ears): ½ teaspoon
- Arms and shoulders: ½ teaspoon to each side of body

- Torso: ½ teaspoon each to front and back
- Legs and tops of feet: 1 teaspoon to each side of body

Because of the cost of sunscreen products and the need to apply them often and in sufficient amounts, users may apply substantially less sunscreen than is required to provide adequate protection. Exposure to UVR should be within the limits of the SPF value of the sunscreen for the individual using the sunscreen. A higher SPF may be needed for longer or more intense exposure to UVR. The final rule requires that the sunscreen label recommend the following with regard to sunscreen application: Regardless of the water resistance of the product, it should be applied 15 minutes before sun exposure. Non-water-resistant products should be reapplied at least every 2 hours. Water-resistant products should be reapplied every 2 hours, after 40 or 80 minutes of swimming or sweating (as designated on the label), and immediately after towel drying.^{20,21}

Safety Considerations

The development of a rash, vesicles, hives, or exaggerated sunburn after use of the sunscreen product most likely is a sign of either a photosensitivity or an allergic reaction.^{1,22} The patient should be referred for medical evaluation of the situation. The degree of the reaction will determine what type of medical intervention (if any) is necessary.

A study published in the *Journal of the American Medical Association* on May 6, 2019, found that significant systemic absorption in excess of the FDA-established safety threshold of a plasma concentration of 0.5 ng/mL occurred after application of four commercially available sunscreens: avobenzone, oxybenzone, octocrylene, and ecamsule. The sunscreens were applied in a variety of common dosage forms, including sprays, creams, and lotions.²³ A follow-up study published in 2020 reported similar results. This study measured systemic absorption of six sunscreens (avobenzone, oxybenzone, octocrylene, homosalate, octisalate, octinoxate) used 1–4 times daily and applied to 75% of the body at a concentration of 2 mg/cm² for 4 consecutive days. The sunscreen formulations included aerosol spray, nonaerosol spray, pump spray, and lotion. The authors found that, after a single application, the mean plasma concentration of all six products exceeded 0.5 ng/mL by day 1.²⁴ Data from these studies support the need for additional safety monitoring for sunscreen products.

Product Selection Guidelines

Two primary factors will determine the best product for a given patient: the intended use of the product and specific patient characteristics. The decision of which sunscreen product to use must be based on the information obtained from both categories.

Articles have highlighted the environmental effects of chemical sunscreens on coral reefs and other aquatic life. The state of Hawaii and the city of Key West, Florida, have enacted bans on sunscreen products containing oxybenzone and octinoxate. The U.S. Virgin Island also has banned these products and the product octocrylene. The non-nanotized forms of approved physical sunscreen products—zinc oxide and titanium dioxide—appear to be safer for aquatic life. Patients should avoid products with a particle size of less than 100 nanometers if they are concerned about effects on the environment.^{25,26}

Intended Use

Some patients may want to use sunscreens to prevent sunburn or the photoaging effects of UVR, or to protect themselves from skin cancer. Others may need protection from sun exposure because they are taking photosensitive drugs or they suffer from a photodermatosis.

The higher the SPF of the sunscreen product, the greater the protection it provides against sunburn and tanning. Studies have shown that sunscreens can protect against the long-term hazards of skin cancer.^{5,15} Considerable research currently is being conducted on all aspects of UVR and its effects. However, experts are debating whether low-SPF products protect individuals from UV skin damage or allow them to receive dangerously high levels of UVR over extended periods of time. Because of the known health hazards associated with UVR, sunscreen products of at least SPF 15 should be recommended to patients.²⁰ Generally, if a product is to be used to prevent skin cancer, to reduce the chance of a photosensitivity reaction, or to reduce the risk of triggering a skin disorder induced or aggravated by UVR, a broad-spectrum SPF value of 15+ is needed.^{1,5}

Patient Factors

For patients not concerned with photosensitivity or photodermatoses, product selection is much simpler. The following factors can serve as a guide in

selecting products with the appropriate properties for a patient's particular situation.

The most important factors in product selection are the individual's natural skin type and tanning history. An SPF product of 30+ should be used by people who burn easily and, at best, tan minimally. If the individual plans to swim, participate in vigorous activity (e.g., sand volleyball), or work outdoors, the sunscreen product must be able to adhere to the skin more substantially than if the individual just lies on the beach. The expected duration of the physical activity also can help determine which sunscreen to use. Water-resistant products usually are effective for at least 40 or 80 minutes when used during the previously described activities.²⁰

At least one-third of the current commercial products are labeled "noncomedogenic," "fragrance-free," and "hypoallergenic." Noncomedogenic products do not plug the pores and, therefore, do not exacerbate acne. This property is especially important for teenagers, who usually spend more time outdoors than other age groups and generally would prefer not to use comedogenic sunscreens. Many patients are sensitive to various ingredients (e.g., fragrances, emulsifiers, preservatives). These patients should try to choose fragrance-free formulations or those that are hypoallergenic. The prevalence of a true allergy to sunscreen products has been reported as low as 1% in North Americans. However, adverse reactions to sunscreens are more common. Patients may develop phototoxic or photoallergic reactions to any sunscreen or inactive ingredient in the product. Although it may not be possible to determine which specific ingredient a patient is sensitive to, patients who have a history of sensitivity to sunscreens would do well to use a fragrance-free, hypoallergenic product, and to try to avoid using a product containing a sunscreen with which they had a previous reaction.^{21,22}

Some patients have normally dry skin; sunbathing can further exacerbate this problem. These patients should avoid ethyl and isopropyl alcohols, which are included in a number of commercial sunscreen products and can further dry the skin.

Use in Special Populations

FDA requires that sunscreen products be labeled with the statement "children under 6 months of age: ask a doctor." Caregivers should be extremely wary regarding sun exposure in children, especially infants. The American Academy

of Pediatrics recommends that infants younger than 6 months be kept out of direct sunlight and that parents/caregivers can apply a small amount of sunscreen with an SPF of 15+ to small areas such as the face or back of the hands.^{27,28} Although the evidence is not yet conclusive, researchers and providers agree that use of an SPF-15 product starting after 6 months of age and continuing throughout an individual's lifetime can reduce the incidence of long-term skin damage related to UVR. A product with an SPF of 30+ may further reduce sunburn, premature skin aging, skin cancer, and other skin problems.^{2,5}

Given the new data on systemic absorption of some chemical sunscreens, pregnant or lactating women may want to discuss the use of sunscreens with their health care provider to determine the safest choice for them and their fetus or nursing child.^{23,24} They also may choose a physical sunscreen containing zinc oxide or titanium dioxide, both of which have been classified as safe and effective.²⁰

Assessment of Sun-Induced Skin Disorders

The approach to UVR-induced skin disorders differs from that used in most self-care situations. These disorders are addressed from a preventive, rather than a treatment, standpoint.

Consequently, assessment of the patient should focus on *the individual patient characteristics* and *intended use* of the product. Clinical providers' interventions with patients occur in two primary situations. The first situation occurs when a patient requests a recommendation for a sunscreen product to prevent a burn and/or to allow development of a tan. The second situation is initiated by the provider when a patient is placed on a drug that can produce a photosensitivity reaction. In this second scenario, no real patient assessment is needed because prevention of exposure to UVR is the standard approach. Cases 39–1 and 39–2 are examples of assessment of patients with sun-induced skin disorders.

Patient Counseling for Sun-Induced Skin Disorders

Health care providers can provide a great service by counseling patients about the suntanning process and about proper selection and use of sunscreens.

One simple way to find out whether a patient is using a sunscreen properly is to ask how long the product currently being used has lasted. When applied properly, according to the suggested dosing guidelines and in accordance with the appropriate substantivity of the product, a sunbather could easily use about 1 ounce every 80–90 minutes. This use would amount to several ounces a day and several product containers per week. Incredibly, many frequent sunbathers use only one container in an entire season. This diminished usage demonstrates the importance of individuals’ receiving adequate counseling to get the protection they desire. The box “Patient Education for Protection from Sun Exposure” lists specific information to provide patients.

Patients should also be advised to wear sunglasses to protect their eyes from sun-induced damage. The box “A Word About Sun-Induced Ocular Damage” describes the categories of available sunglasses and their UVR filtration properties.²⁹

Case 39–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient describes a history of sunburns, especially since she began taking gabapentin for neuropathic pain.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	Staying completely out of the sun has been the only thing she has found that keeps her from getting burned, but she enjoys being outside and is trying to increase her exercise by walking 1–2 miles each day.
c. Description of the patient’s efforts to relieve the symptoms	She rarely uses sunscreens. She typically forgets to apply it before she leaves the house for her walk.

Relevant Evaluation Criteria	Scenario/Model Outcome
d. Patient's identity	Danessa Sam
e. Patient's age, gender, height, and weight	60 years old, female, 5 ft 5 in., 165 lb
f. Patient's occupation	Elementary school teacher
g. Patient's dietary habits	n/a
h. Patient's sleep habits	n/a
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Metformin 1000 mg 1 tablet twice a day; lisinopril 10 mg 1 tablet daily; gabapentin 300 mg 1 capsule 3 times a day
j. Allergies	None
k. History of other adverse reactions to medications	She cannot recall any.
l. Other (describe) _____	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	The patient is in need of sun protection to prevent sunburns and skin damage.
3. Identify exclusions for sun exposure (Figure 39-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Use a nonprescription sunscreen product daily 15-30 minutes prior to the outdoor walk. (2) Avoid sun exposure by staying in the shade or indoors. (3) Take no action.
Plan	

Relevant Evaluation Criteria	Scenario/Model Outcome
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Regularly using a sunscreen product while outdoors will allow the patient to enjoy the desired outdoor activities while minimizing the risk of sun-induced skin disorders.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Use a sunscreen product with an SPF of 15 or higher that provides protection against UVA and UVB. A water-resistant product will be a better choice if you tend to sweat during the walks. Apply the product liberally to all sun-exposed areas of the body."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Correct use of a sunscreen product will allow you to enjoy time outdoors without getting a sunburn. A broad-spectrum sunscreen that provides both UVA and UVB coverage is preferred. Additionally, using a sunscreen such as ecamsule, which is water-resistant, may be preferred during periods of physical activity.
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Apply the sunscreen product every day 15 or 30 minutes prior to going out into the sun. If you are sweating, reapply the sunscreen at least every 2 hours as directed on the product label. If you are in the water, reapply every 40 or 80 minutes. You will need to apply the sunscreen as follows: • Face and neck (including ears): ½ teaspoon. • Arms and shoulders: ½ teaspoon to each side of body. • Torso: ½ teaspoon each to front and back. • Legs and tops of feet: 1 teaspoon to each side of body."
Solicit follow-up questions from the patient or caregiver.	"What should I do if I have a reaction to the sunscreen?"
Answer the patient's or caregiver's questions.	"If you develop a rash or other skin reaction to the sunscreen, stop using it and see your health care provider."
Follow-up: Monitor and Evaluate	

Relevant Evaluation Criteria	Scenario/Model Outcome
9. Assess patient outcome.	n/a

Key: n/a = Not applicable; SPF = sun protection factor; UVA = ultraviolet A; UVB = ultraviolet B.

Case 39–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The mother of a 3-month-old infant would like to know what sunscreen is safe. She takes her children to the park each day and is worried her child will get a sunburn
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Children under 6 months of age are not included on the labeling for sunscreen products.
c. Description of the patient's efforts to relieve the symptoms	n/a
d. Patient's identity	Cassidy Jones
e. Patient's age, gender, height, and weight	3 months old, female, 13 lb

Relevant Evaluation Criteria	Scenario/Model Outcome
f. Patient's occupation	n/a
g. Patient's dietary habits	Child is consuming formula per normal expectations with no issues.
h. Patient's sleep habits	Child is sleeping and napping per normal expectations with no issues.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No current medications
j. Allergies	Mother is not aware that child has any allergies.
k. History of other adverse reactions to medications	Mother is not aware that child has had any adverse reactions to any medications
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Patient in need of sun protection
3. Identify exclusions for sun exposure (Figure 39-1).	Child younger than 6 months of age
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend avoidance of additional sun exposure. (2) Recommend use of a sunscreen product. (3) Refer child to her pediatrician for recommended measures.
Plan	
5. Select an optimal	Mother of a young child needing advice on sun protection for

Relevant Evaluation Criteria	Scenario/Model Outcome
therapeutic alternative to address the patient's problem, taking into account patient preferences.	her 3-month-old infant. However there is no recommended product for children younger than 6 months.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should contact your child's pediatrician for advice on what sunscreens may be safe to use on her. You can practice other sun-safety habits such as keeping her out of the sun by moving to a shaded area, or using an umbrella or a stroller with a shade cover. The American Academy of Pediatrics also recommends dressing young children in lightweight clothing that covers their arms and legs, and putting a brimmed hat on them to provide protection from the sun."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"There aren't good safety data for use of sunscreen products in very young children, so avoidance of sun exposure is the best choice."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See criterion 6.
Solicit follow-up questions from the patient or caregiver.	"Would it be okay to use just a small amount of sunscreen on her arms and legs?"
Answer the patient's or caregiver's questions.	"The safest recommendation is to eliminate sun exposure as much as possible and to talk with your child's health care provider."
Follow-up: Monitor and Evaluate	

Relevant Evaluation Criteria	Scenario/Model Outcome
9. Assess patient outcome.	n/a

Key: n/a = Not applicable.

Patient Education for Protection From Sun Exposure

The objectives of self-treatment depend on a patient's specific goal and health status. Protection from sun exposure can prevent sunburn or tanning, photosensitivity reactions in susceptible persons, or exacerbation of sun-induced photodermatoses. The primary long-term benefits are to prevent skin cancer and premature aging of the skin. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal outcomes.

Avoiding/Minimizing Sun Exposure

- Avoid exposure to the sun and other sources of UVR, such as tanning beds/booths and sunlamps.
- The sun's rays are the most direct and damaging between 10:00 AM and 4:00 PM. Avoid sun exposure as much as possible during this time of day.
- Sunburn can occur on a cloudy or overcast day; 70%–90% of UVR penetrates clouds.
- Wear protective clothing (e.g., long pants, a long-sleeved shirt, and a hat with a brim). Tightly woven fabrics that do not allow light to pass through will provide the most protection.
- Use a beach umbrella or other protection to reduce UVR.
- Water and wet clothing allow significant transmission of UVR. Even

if the body is completely submerged, consider time in the water as part of the total time spent in the sun.

Use of Sunscreens

- An SPF of 15 or greater provides the greatest protection against sunburn and other UVB-induced skin problems.
- A broad-spectrum sunscreen product (e.g., avobenzone used in combination with padimate O and/or octocrylene, meradimate, titanium dioxide, one of the benzophenones) provides optimal protection against UVA and UVB sun exposure. This type of sunscreen is especially recommended if you have a sun-induced disorder, if you are taking photosensitizing drugs, or if you just want to reduce sun exposure as much as possible to prevent long-term effects.
- Apply first dose 15 minutes before exposure.
- Apply approximately 1 ounce of sunscreen over the exposed areas of the body, avoiding contact with the eyes. The sunscreen should be distributed as follows: $\frac{1}{2}$ teaspoon to the face and neck (including ears) area, $\frac{1}{2}$ teaspoon to each arm and shoulder, $\frac{1}{2}$ teaspoon to the front and back torso each, and 1 teaspoon to each side on the leg and top of the foot.
- Use the most substantive sunscreen available; water-resistant sunscreens are recommended if you will be in water or perspiring excessively.
- Reapply the sunscreen according to the label instructions, usually every 40 or 80 minutes for water-resistant sunscreens while swimming or sweating or after towel drying. Apply every 2 hours for non-water-resistant products or for water-resistant products if you are not swimming or sweating.
- Always check the expiration date on the sunscreen product. Sunscreens can lose their effectiveness.
- Higher altitudes and lower latitudes increase the amount of UVR to which an individual is exposed. Take proper precautions (e.g., use a sunscreen with a high SPF) to protect skin from UVR.
- Snow and sand reflect UVR. Take proper precautions to protect exposed skin (e.g., wear sunglasses, use high-SPF sunscreens).

- Keep sunscreen out of direct sun, which can reduce its potency.
- Continue to use a sunscreen as long you are taking a photosensitizing drug or exhibiting signs and symptoms of photodermatitis.
- Avoid sunscreens containing aminobenzoic acid derivatives, benzophenones, cinnamates, or meradimate if you have had a prior allergic reaction to a sunscreen product.
- Stop using the sunscreen if redness, itching, rash, or exaggerated sunburn occurs.

Key: SPF = Sun protection factor; UVA = ultraviolet A; UVB = ultraviolet B; UVR = ultraviolet radiation.

Evaluation of Patient Outcomes for Sun-Induced Skin Disorders

The short-term outcomes for sunscreen use are readily apparent. Twenty-four hours after use, no obvious sunburn, photosensitivity reaction, or eruption of photodermatosis will be present. This success indicates that the appropriate sunscreen agents and/or SPF were used. However, the long-term effects of UVR (e.g., skin cancer, premature aging of the skin) may take up to 20–30 years to become evident.

A Word about Sun-Induced Ocular Damage

Recent studies have demonstrated a relationship between both UVA and UVB in cataract formation. UVR has been shown to cause temporary injuries such as photokeratitis (a painful type of snow blindness associated with highly reflective surfaces). Another concern involves an increase in the incidence of uveal (iris plus ciliary body) melanoma. These concerns

are even more serious because of the erroneous belief that all sunglasses screen out UVR. In response, the Sunglass Association of America, working with FDA, has developed a voluntary labeling program. Abbreviated information concerning sunglasses' UVR-screening properties is directly attached to each pair, and brochures describing the appropriate use of each type of lens are available at outlets selling the sunglasses.²⁹

According to its UVR filtration properties, each pair of sunglasses is placed in one of the following three categories:

1. Cosmetic sunglasses block at least 70% UVB and 20% UVA. They are recommended for activities in nonharsh sunlight (e.g., shopping).
2. General-purpose sunglasses block at least 95% UVB and 60% UVA. With shades that range from medium to dark, they are recommended for most activities in sunny environments (e.g., boating, driving, flying, hiking).
3. Special-purpose sunglasses block at least 99% UVB and 60% UVA. They are recommended for activities in very bright environments (e.g., ski slopes, tropical beaches).

Key: FDA = Food and Drug Administration; UVA = ultraviolet A; UVB = ultraviolet B; UVR = ultraviolet radiation.

Key Points for Sun-Induced Skin Disorders

- UVR (UVA and UVB) triggers a variety of photodermatoses and causes sunburn, photosensitivity, skin cancer, premature aging of the skin, cataracts, and a variety of other medical problems.
- No form of UVR exposure is safe. Tanning and use of tanning beds can result in negative health effects.
- The effects of UVR are cumulative over an individual's lifetime.
- The best protection against UVR is avoidance. The next best approach is to wear a hat, long sleeves, pants, and UV-protective

sunglasses.

- Maximum protection is provided by using a broad-spectrum sunscreen of SPF 15+.
- Because broad-spectrum sunscreens provide added UVA protection, they are the best choice for preventing long-term effects of sun exposure, regardless of the patient's history.

Providers need to appreciate sunscreen products as therapeutic agents rather than cosmetics. Unfortunately, most patients have the latter view. This perception makes good patient counseling even more important. Reinforcing the need for proper selection of the appropriate sunscreen product and correct use of these products are key to educating the public and reducing the risks of UVR exposure.

Chapter 40: Skin Hyperpigmentation and Photoaging

Authors: Katherine S. O'Neal

Skin Hyperpigmentation

Hyperpigmentation, manifested as an area of skin darker than the surrounding skin, usually is a benign phenomenon that nevertheless is challenging to treat. The altered pigmentation may be perceived by the patient as a disfigurement, especially when it involves the face and neck and is in noticeable contrast to the surrounding normal skin color. Although products used to treat hyperpigmentation serve a cosmetic function, it is important to recognize that they are drugs, with characteristic potential for toxicity and adverse effects.¹

Pathophysiology of Skin Hyperpigmentation

Systemic illnesses as well as localized skin diseases may cause pigment cells to become overactive (resulting in skin darkening) or underactive (resulting in skin lightening).² Endocrine imbalances caused by Addison disease, Cushing disease, or hyperthyroidism and conditions such as pregnancy are capable of altering skin pigmentation. Metabolic disturbances affecting the liver, as well as certain nutritional deficiencies, can be associated with diffuse melanosis. Inflammatory dermatoses (e.g., contact dermatitis from poison ivy or acne lesions) or physical trauma to the skin (e.g., thermal burn) may cause prolonged postinflammatory hyperpigmentation. In addition, certain drugs ([Table 40–1](#)) have an affinity for melanin, forming complexes with the protein or inducing its accumulation to cause hyperpigmentation. Thus, skin hyperpigmentation resulting from these conditions may occur as a result of increased melanin and melanocyte production accompanied by increased activity of melanocytes or deposits of other darkening chemicals in the skin.^{3–5} *Melanocytes* (pigment cells) produce *melanosomes*, pigment granules that contain the protein melanin, a brown-black pigment. These cells can be viewed as tiny single-celled glands with long projections used to pass pigment particles into the keratinocytes, from which the particles migrate upward to the skin surface. The melanocyte is believed to provide protection from

ultraviolet radiation (UVR). Compared with “fair” skin, dark skin usually has a greater number of melanocytes, which explains why UVR-induced skin cancers of all types are less common in darker skinned persons.^{5,6} A higher melanocyte count also may be why people with dark hair or darker complexions (Fitzpatrick skin types IV–VI; [Table 40–2](#)) and persons of Hispanic, African American, African, or Asian ancestry have been found to be more susceptible to development of hyperpigmentation.⁷

TABLE 40–1 Medications That May Cause Hyperpigmentation

Amiodarone
Anticonvulsants (e.g., carbamazepine, phenobarbital, phenytoin)
Antimalarial agents (e.g., chloroquine, hydroxychloroquine)
Antineoplastic agents (e.g., busulfan, cyclophosphamide, daunorubicin, doxorubicin, fluorouracil)
Clofazimine
Heavy metals (e.g., arsenic, bismuth, gold compounds, mercury, silver)
Hormone replacement therapy
Minocycline
Oral contraceptives
Phenothiazines (e.g., chlorpromazine, clomipramine, imipramine, thioridazine)
Tricyclic antidepressants (e.g., amitriptyline, desipramine, imipramine)
Zidovudine

Source: Adapted from reference 2; and Law RM, Law DT. Dermatologic drug reactions and common skin conditions. In: DiPiro JT, Talbert RL, Yee GC, et al. eds. *Pharmacotherapy: A Pathophysiologic Approach*. 10th ed. New York, NY: McGraw-Hill Professional; 2017:e99.

TABLE 40–2 Fitzpatrick Skin Type Classification

Fitzpatrick Skin Type	Characteristics	Response to UV Light
I	Unexposed skin is bright white	Always burns
	Blue/green eyes typical	Peels
	Freckling frequent	Never tans
II	Unexposed skin is white	Burns easily
	Blue, hazel, or brown eyes	Peels
	Red, blonde, or brown hair	Tans minimally
	European/Scandinavian ancestry	
III	Unexposed skin is fair	Burns moderately
	Brown eyes	Average tanning ability
	Southern or Central European ancestry	
IV	Unexposed skin is light brown	Burns minimally
	Dark eyes	Tans easily
	Dark hair	
	Mediterranean, Asian, or Latino ancestry	
V	Unexposed skin is brown	Rarely burns
	Dark eyes	Tans easily
	Dark hair	
	East Indian, Native American, Latino, or African ancestry	
VI	Unexposed skin is black	Almost never burns
	Dark eyes	Tans readily
	Dark hair	

Fitzpatrick Skin Type	Characteristics	Response to UV Light
	African or Aboriginal ancestry	

Key: UV = Ultraviolet.

Source: Adapted from D’Orazio J, Jarrett S, Amaro-Ortiz A, Scott T. UV radiation and the skin. *Int J Mol Sci.* 2013;14(6): 12222–48. doi: 10.3390/ijms140612222.

The three types of hyperpigmentation that are amenable to self-treatment with topical nonprescription agents are ephelides, solar lentigines, and melasma.⁸ *Ephelides*, or *freckles*, are spots of uneven skin pigmentation that first appear in childhood, are exacerbated by the sun, and tend to fade with reduced sun exposure. *Solar* or “*senile*” *lentigines* (age spots or liver spots) appear on exposed skin surfaces, particularly in fair-skinned people, and are induced by UVR. *Melasma* (also called *chloasma*), a condition characterized by macular hyperpigmentation, usually on the face or neck, often is associated with pregnancy (the “mask of pregnancy”), the use of oral contraceptives, and sun exposure.

Clinical Presentation of Skin Hyperpigmentation

Melasma is a common form of hyperpigmentation that occurs more often in women than in men.² Depending on the underlying cause of hyperpigmentation, the clinical presentation can vary.^{1,4,9} Most notably, affected patients complain of persistent macular discoloration on the face or other sun-exposed areas. A centrofacial distribution (involving the forehead, cheeks, upper lip area, nose, and chin) is the most common pattern.^{1,2} The abnormal pigmentation typically consists of a more intense brown coloration than that of surrounding normal skin and may range in intensity from dark to faint. Clinical evidence of hyperpigmentation and photoaging (considered later in the chapter) and their response to treatment are not easily quantifiable using standard-light photography or by routine clinical evaluation. Fluorescence photography will detect subtle but significant decreases in diffuse and mottled hyperpigmentation after topical treatment, which helps to

clinically evaluate the skin changes and accurately assess the efficacy of topical products.¹⁰

Treatment of Skin Hyperpigmentation

Treatment Goals

The goal of treatment for skin hyperpigmentation is to diminish the degree of pigmentation of affected areas so that the skin tone of these areas is consistent with surrounding normal skin.

General Treatment Approach

The general approach to clinical management of hyperpigmentation focuses on the melanin production pathway and consists of two broad categories of interventions: (1) stopping the skin cells from overproducing melanin and inhibiting melanosome formation and melanin synthesis and (2) chemically or mechanically removing the top few layers of the skin's surface.^{1-3,5} Although good outcomes can be achieved by using either strategy, the best results are accomplished through a combination of the two.

Exfoliation used to treat hyperpigmentation involves physically buffing away surface-layer skin, or *microdermabrasion*, and applying chemical agents (e.g., alpha hydroxy acids [AHAs]). Chemical peels, used as adjunct therapy, may enhance the efficacy of topical products.^{1,4} Because of the risk of subsequent scarring with hyperpigmentation and other adverse events, microdermabrasion is not considered standard therapy. Abrading skin also may cause irritation and burning.

To prevent negation of the effects of treatment with either bleaching agents or pharmacologic therapy, it is essential to avoid even minimal exposure to UVR, as a lifelong commitment. On an ongoing basis, patients also must use broad-spectrum sunscreen agents with a sun protection factor (SPF) of at least 30 in combination with a physical blocker such as titanium dioxide or oxybenzone, and wear protective clothing and broad-brimmed hats, even after discontinuing the bleaching agent.^{9,-11} The algorithm in [Figure 40-1](#) outlines self-treatment for skin hyperpigmentation.^{1-9,11-13}

Pharmacologic Therapy

Management of hyperpigmentation as directed by the patient's primary care provider may begin with use of topical prescription agents composed of ingredients known to cause lightening of the skin primarily through inhibition of tyrosinase, the rate-limiting step in melanin biosynthesis. Such products include tretinoin (retinoic acid), azelaic acid, hydroquinone, and corticosteroids. The disorder also may be treated with laser therapy alone. Combination products or laser therapy sometimes may be effective for postinflammatory hyperpigmentation that is resistant to treatment with a single-agent nonprescription product.^{1,4,12}

A number of nonprescription agents have been used in skin-bleaching preparations. The standard agents have included hydroquinone 2%, ascorbic acid, arbutin, glycolic acid, niacinamide, and kojic acid. Newer products are being formulated with rucinol, tranexamic acid, and aloesin.^{4,12-16} Thus far, however, only preparations containing hydroquinone have been submitted to the U.S. Food and Drug Administration (FDA) Advisory Review Panel on Over-the-Counter Miscellaneous External Drug Products, and products containing this agent remain the most effective nonprescription skin-bleaching preparations available. AHAs, promoted as nonprescription agents for skin repair in management of photoaging, are used to treat both disorders. [Table 40-3](#) lists selected trade-name products.

TABLE 40-3 Selected Nonprescription Skin-Bleaching/Fading Products

Trade Name	Primary Ingredient(s)
Alpha Skincare Dual Action Skin Lightener	Hydroquinone 2%; glycolic acid 10%
MD Complete Dark Spot Corrector	Hydroquinone 2%
Clinicians Complex 6% Skin Bleaching Cream	Hydroquinone 2%; kojic acid 2%
DDF Fade Gel 4	Hydroquinone 2%; kojic acid; azelaic acid; salicylic acid
Bianco Rose	Hydroquinone 2%
La Roche-Posay Mela-D Pigment Control Concentrated Serum	Glycolic acid; lipo-hydroxy acid

Trade Name	Primary Ingredient(s)
QRx Labs Whitening Serum	Alpha arbutin 2%; kojic acid; licorice root
Murad Rapid Age Spot and Pigment Lightening Serum	Hydroquinone 2%; glycolic acid
Noreva IKLEN Depigmenting Serum	Rucinol
Philosophy Miracle Worker Dark Spot Corrector	Niacinamide
Shiseido White Lucent Intensive Spot Targeting Serum	Tranexamic acid
SkinCeuticals Pigment Regulator	Kojic acid 2%; emblica extract 2%; glycolic acid
Verso Skincare Dark Spot Fix	Retinol 8 with retinyl retinoate; niacinamide

Key: PHA = Polyhydroxy acid.

Hydroquinone

Skin-bleaching agents diminish hyperpigmentation by inhibiting melanin production within the skin.⁴ Hydroquinone (*p*-dihydroxybenzene), a skin-bleaching agent currently is available for self-treatment for skin hyperpigmentation.^{13,14,17} Hydroquinone is considered the mainstay as well as the gold standard of hyperpigmentation therapy.^{1,12,13,16} However, the safety of bleaching creams that contain hydroquinone continues to be reviewed in the literature.¹⁴ In 2006, FDA proposed withdrawing the tentative final monograph that approved skin-bleaching creams and suggested replacing to replace it with a final rule stating that all drug products (including hydroquinone) used in nonprescription products to lighten skin are no longer generally recognized as safe and effective owing to the potential increased risk for cancer and *ochronosis*, a bluish-black discoloration of skin that occurs where hydroquinone has been applied. Subsequently, However, in December 2009, FDA nominated hydroquinone to undergo additional studies to determine whether its use poses a risk to humans.^{1,18} The National Toxicology Program's review was unable to show carcinogenicity for hydroquinone in humans exposed to this agent.^{1,18,19} Additionally, a review of cases from the period 1966–2007 found *ochronosis* to be a rare event.¹

Hydroquinone and its derivatives act by reducing conversion of tyrosine to dopa and, subsequently, to melanin by inhibiting the enzyme tyrosinase.²⁰ Other possible mechanisms of action include destruction of the melanocyte or melanosomes.¹² Hydroquinone is available in a concentration of 2%.¹⁴ Combining hydroquinone with an exfoliant, such as topical glycolic acid (an AHA), topical tretinoin, or a corticosteroid has shown increased efficacy compared with hydroquinone monotherapy.^{12,17}

Hydroquinone 2% should be rubbed gently but thoroughly into affected areas twice daily. The agent should be applied to clean skin before application of moisturizers or other skin care products. It should not be applied to damaged skin or near the eyes. If no improvement is seen within 2 months, its use should be discontinued and a dermatologist or other primary care provider should be consulted.¹ Once the desired benefit is achieved, hydroquinone can be applied as often as needed in a once- or twice-daily regimen to maintain the lightened skin color. Because of the lack of safety data, hydroquinone is not recommended for children younger than 12 years. Contraindications to the use of hydroquinone include hypersensitivity to the product and appearance of ochronosis.¹ Although not directly contraindicated, hydroquinone should be used during pregnancy only if absolutely needed (i.e., in the original FDA pregnancy risk schedule, it was labeled a category C drug). It is not known if topical hydroquinone can cause fetal harm.^{16,18,19} Studies in rats have found inconclusive evidence, and the FDA ruling was that reproductive and teratogenic effects were not prominent.¹⁸ (See the Preface for a detailed explanation of the pregnancy data.)

Alternative Agents

Kojic Acid

Kojic acid, derived from certain species of fungus (e.g., *Acetobacter*, *Aspergillus*, *Penicillium*), can be found in cosmetic products promoted to treat hyperpigmentation in concentrations ranging from 1% to 4%.^{12,13} This ingredient usually is combined with AHAs, with or without hydroquinone. It is dosed and applied according to the product type (e.g., cream, soap, lotion, drops). Kojic acid works primarily by inhibiting the production of tyrosinase through chelation of its copper, which reduces melanin synthesis. It also, however, can help reduce melanin proliferation.^{12,13} Adverse effects associated with this product include contact dermatitis, stinging, and erythema.²¹ One

study comparing kojic acid 1% alone and in various combinations with hydroquinone 2% and betamethasone valerate 0.1% demonstrated better results with the combination regimen.¹³

Tranexamic Acid

Tranexamic acid (trans-4-aminomethylcyclohexanecarboxylic acid) is an agent that has been available for many years and used for melasma.^{1,4,12,16,22} It works by decreasing the generation of arachidonic acid, which decreases melanocyte-stimulating hormone and pigment production. Studies have evaluated topical, intravenous, and oral dosage forms.¹⁶ Topical use has been shown to provide improvement within 3 months.^{22,23} With oral use, improvement occurs within 8 weeks.^{4,12,16,22} The oral dose most commonly being studied is 250 mg twice daily or 750 mg/day, and the currently available topical preparation is applied twice daily.²⁴ The most common adverse effect of the topical form was irritation to the applied area.¹⁶ The adverse effects associated with the oral form have included mild gastrointestinal discomfort, hypomenorrhea, allergic skin rashes, and slight elevations in alanine transaminase.¹⁶ Currently, tranexamic acid can be found as an adjunct ingredient in some nonprescription serums.

Niacinamide

Niacinamide is a form of vitamin B₃ and acts as an anti-inflammatory agent. Although most pharmacologic treatments for hyperpigmentation disrupt tyrosinase activity, niacinamide instead works by preventing the transfer of melanin to keratinocytes, improving appearance of the skin not only in hyperpigmentation but also in photoaging (with decrease in associated redness and wrinkles).²⁵⁻²⁷ Topical niacinamide 2% has been shown to reduce hyperpigmentation after 4 weeks of treatment.²⁵ The most common adverse effects are redness, burning, and itching.²⁶ Niacinamide also has demonstrated efficacy when used topically in combination with other agents, such as desonide 0.05%, 2% tranexamic acid, or 2% *N*-acetyl glucosamine.²⁵⁻²⁷

Arbutin

Arbutin, a beta-d-glucopyranoside derivative of hydroquinone, is obtained from the extract of the bearberry plant.¹² It works by inhibiting tyrosinase and melanosome maturation.¹² A study using 3% arbutin with 4% nicotinamide, 1% bisabolol, and 0.05% retinaldehyde applied once daily to the affected areas

showed a beneficial effect in 30 days. Although the effect is dose dependent, higher concentrations have been found to induce hyperpigmentation.¹²

Product Selection Guidelines

Product selection should be based on a suitable dosage form (e.g., cream, lotion, gel) for the patient's skin type (dry, normal, oily) and anatomic site (face, neck). For example, an emollient cream-based product may be more suitable for dry skin, whereas a gel-based preparation may be preferable for an oily skin type.

Assessment of Skin Hyperpigmentation: A Case-Based Approach

Assessment should involve evaluating the affected areas to determine whether the skin changes are characteristic of freckles, melasma, or lentigines. The patient's medication history and health status are important factors in pinpointing possible causes of the hyperpigmentation.

Case 40–1 is an example of the assessment of a patient with skin hyperpigmentation.

Patient Counseling for Skin Hyperpigmentation

The types of hyperpigmentation that are amenable to self-treatment should be explained to the patient, and the importance of avoiding sun exposure during and after treatment should be emphasized. The product instructions should be reviewed with the patient to ensure a successful therapeutic outcome. The box "Patient Education for Skin Hyperpigmentation" lists specific information to provide in patient counseling. Of note, the Melasma Quality of Life Scale has shown that presence of melasma, of any degree, negatively affects quality of life, especially in terms of social life, recreation, and emotional well-being.²⁸ As the health care provider of first resort for many patients with such skin changes, the informed pharmacist can therefore play a significant role in optimizing the clinical outcome.

Evaluation of Patient Outcomes for Skin Hyperpigmentation

Follow-up evaluation of the patient’s progress should be performed after 2 months of therapy. If the pigmented area shows no improvement, referral to the patient’s primary care provider or a dermatologist is indicated. If the desired outcome has been achieved, the patient should continue applying the agent once or twice daily as needed, along with use of a sunscreen, to maintain lightening of the skin.

Algorithm: Skin Hyperpigmentation

FIGURE 40–1 Self-care for skin hyperpigmentation. Key: AHA = Alpha hydroxy acid; BSA = body surface area.

Case 40-1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient seeks the pharmacist's advice regarding darkening of areas of skin on her cheeks, which first appeared a year ago last summer and went away over the winter.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient states that after spending 1 day in the sun, she "can already tell it's coming back."
c. Description of the patient's efforts to relieve the symptoms	The patient tried topical moisturizing lotions and exfoliation creams.

Relevant Evaluation Criteria	Scenario/Model Outcome
d. Patient's identity	Jill Colter
e. Patient's age, gender, height, and weight	31 years, female, 5 ft 6 in., 160 lb
f. Patient's occupation	Full-time outpatient nurse
g. Patient's dietary habits	Patient eats a well-balanced diet. She drinks wine and beer occasionally.
h. Patient's sleep habits	She averages 5 hours of sleep per night during the week and 10 hours per night on the weekend.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) _____	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	The patient has hyperpigmentation of the centropacial region, which first appeared last summer.
3. Identify exclusions for self-treatment (Figure 40-1).	The patient has tried nonprescription moisturizing and exfoliation products.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Colter to her regular health care provider or dermatologist for further evaluation. (2) Try a skin-lightening agent. (3) Take no action.

Relevant Evaluation Criteria	Scenario/Model Outcome
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient should try nonprescription products focused on skin-lightening or correcting dark spots.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Try a product containing hydroquinone 2% with or without added ingredients to increase the effects."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Moisturizers and exfoliation products that do not contain skin-lightening ingredients will not add much benefit."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Apply daily sunscreen or moisturizer with an SPF of 30.
Solicit follow-up questions from the patient or caregiver.	"A friend told me about laser treatment. Do you think I should try this first?"
Answer the patient's or caregiver's questions.	"Hydroquinone is currently the nonprescription product with the most evidence supporting its effectiveness. You should try this for 2 months first."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Ms. Colter in 2-3 days to check for any adverse skin reactions. Then ask her to call you in 1 month to report her response to your recommendations.

Key: n/a = Not applicable; SPF = sun protection factor.

Patient Education for Skin Hyperpigmentation

The objective of self-treatment with skin-bleaching products is to diminish the degree of pigmentation in affected areas. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Hydroquinone

- Use hydroquinone to lighten only limited areas of hyperpigmented skin that show brownish discoloration.
- Do not use these products on nevi (moles) or reddish or bluish areas, such as port wine discoloration.
- Time to initial response averages 6–8 weeks, but up to 3 months may be required before noticeable results are achieved.
- Test for possible irritant reactions to the product by applying it to a small test area and checking the area for redness, itching, or swelling after 24 hours.
- Do not apply the product near the eyes or to damaged skin.
- Apply a thin layer of the product to clean, dry skin in the affected area only. Rub product into the skin gently but thoroughly.
- If moisturizers or other topical agents are being used at the same time, apply the hydroquinone first.
- Before spending time outdoors, even briefly, apply an opaque sunblock or broad-spectrum sunscreen (see [Chapter 39](#)) to the affected area after applying the hydroquinone, unless the product already contains a sunscreen in the formulation.
- Once the desired lightening of skin is reached, apply the hydroquinone once or twice daily to prevent hyperpigmentation from recurring. Continue to protect the treated area from sun exposure.

When to Seek Medical Attention

Consult a primary care provider if

- No improvement is seen after 2 months of using hydroquinone.
- Skin pigmentation becomes darker during treatment with hydroquinone.

Photoaging

Photoaging, also referred to as premature skin aging or dermatoheliosis, is the pattern of characteristic skin changes associated with sun exposure. Persons with Fitzpatrick skin types I–III ([Table 40–2](#)) are more susceptible to photoaging. Most fair-skinned Americans will have some signs of photodamage by the age of 50 years. A variety of therapies to address photoaging are available, ranging from use of topical pharmacotherapeutic products, including certain cosmetics, to more invasive procedures such as botulinum toxin A injections, laser resurfacing, and skin-specific plastic surgery. Although some products are available by prescription only, many others are nonprescription, with AHAs being widely used to combat mild to moderate photodamage.²⁹

Pathophysiology of Photoaging

Aging skin results from a combination of intrinsic and extrinsic factors. Clinical and histologic changes that occur as intrinsic processes include genetically controlled skin and muscle changes, expression lines and sleep lines, and hormonal changes. Extrinsic factors are those associated with environmental influences such as UVR, smoking, wind, and chemical exposure.^{29–31} Medications known to induce photosensitivity can contribute to photoaging by making the skin sensitive to UVR (see [Chapter 39](#)).

Prematurely aged facial skin, with creases and wrinkles, dry texture, and blotchy hyperpigmentation, is largely attributed to cumulative UVR, or photoaging. Exposure to ultraviolet B (UVB) light (290–320 nm) is primarily responsible for photoaging, although the longer ultraviolet A (UVA) light

wavelengths (320–400 nm) contribute to damage as well.²⁹ The amount of UVA present in sunlight is 10 times that of UVB, which culminates in higher levels of exposure. UVA also can penetrate further to reach the dermal layer and can work synergistically with UVB to cause photodamage and skin cancers.

Microscopically, sun-damaged skin shows *dysplasia* (abnormal tissue development), atypical keratinocytes, and occasional cell necrosis. Irregularity of epidermal cell alignment also is common. Loss of collagen and elastin is seen deeper in the dermal layer.^{29–31}

Clinical Presentation of Photoaging

Clinical signs of photoaging include changes in color, surface texture, and functional capacity of the skin (Table 40–4). Photodamaged skin may have a sallow yellow color with discoloration and may show telangiectasias (visible distended capillaries). Textural changes include lack of characteristic smoothness, loss of subcutaneous tissue around the mouth, and epidermal thinning around the lips. As sebaceous glands hypertrophy, the skin begins to show coarse texture, with increased pore size. In addition, fine vellus hairs can develop into unwanted terminal hairs. Other manifestations of photoaging of the skin may include development of precancerous (actinic keratosis) and cancerous (basal cell, squamous cell, melanoma) tumors.^{29–31} Cosmetically, patients may notice freckling, discolorations, or *crow’s feet* (small parallel lines around the eyes). Postmenopausal skin is susceptible to reduced estrogen receptor stimulation of dermal metabolism and may undergo significant changes in collagen and moisture content. These changes lead to signs of skin aging, as evidenced by diminished elasticity and wrinkles.³¹

TABLE 40–4 Glogau Classification of Photoaging

Category	Characteristics
Type I: mild	No wrinkles, early photoaging, mild pigment changes
	20–30 years of age
Type II: moderate	Wrinkles in motion, early-moderate photoaging, keratoses palpable
	30–40 years of age

Category	Characteristics
Type III: advanced	Wrinkles at rest, advanced photoaging, obvious dyschromia and keratoses
	≥50 years of age
Type IV: severe	Only wrinkles, severe photoaging, yellow-gray skin
	≥60 years of age

Source: Glogau RG. Aesthetic and anatomic analysis of the aging skin. *Semin Cutan Med Surg.* 1996;15(3):134–138.

Treatment of Photoaging

Treatment Goals

The primary consideration in management is to prevent or minimize photodamage by using appropriate sun protection.³⁰ The goals of specific treatment for photoaging are (1) to reverse cumulative skin damage with efficacious prescription and nonprescription products and (2) to maintain the integrity of the skin and protect it from further extrinsic damage by making lifestyle changes and, most important, protecting the skin from further and prolonged sun exposure.

General Treatment Approach

The first step in preventing and treating photoaging of the skin is for the patient to commit to minimizing sun exposure by wearing sun-protective clothing, using large-brimmed hats, avoiding the sun during peak UVR times, and wearing sunscreen daily. Broad-spectrum sunscreens (UVA and UVB coverage) with an SPF of 30 can minimize further photodamage during any UVR exposure^{9,11,30} (see [Chapter 39](#)).

Proper cleansing of the skin removes bacteria, dirt, desquamated keratinocytes, cosmetics, sebum, and perspiration. However, excessive use of soap can lead to xerosis, eczematous dermatitis, and other pathologic skin conditions.³²

Pharmacologic Therapy

Various topical products are being used to treat aging skin. These products include vitamins, AHAs, and beta hydroxy acids (BHAs). Many pharmacotherapeutic ingredients in cosmetics, such as AHAs, function as active pharmaceuticals that are known to have a sustained effect on the skin.^{33,34} Of the vitamins, A, C, B₃, and E have the most evidence supporting their use in treatment and/or prevention of photoaging.^{14,33,34}

Hydroxy Acids

Current labeling on hydroxy acid (HA) cosmetic products includes recommendations for melasma, acne, collagen density, and fine wrinkling of photoaging.¹² The AHAs are used in various concentrations and in a wide array of available products. Most HA preparations are sold as cosmetics, and others are sold as pharmaceuticals through a health care clinic or other prescribing source.^{35–38} Nonpeeling AHA products range in concentration from 2% to 20%. As peeling agents (as used by estheticians or dermatologists), they are available in concentrations greater than 20%.³⁷

Many types of AHAs are available, with the most common being lactic and glycolic acids (Table 40–5). The Cosmetic Ingredient Review Expert Panel, the cosmetic industry’s self-regulatory body, concluded that use of AHAs in cosmetic products is safe if (1) concentrations are 10% or less, (2) the final pH is 3.5 or higher, and (3) the product is formulated with a sunscreen or includes directions to use a sunscreen.³⁹

TABLE 40–5 Selected Nonprescription Products for Photoaged Skin

Trade Name	Active Ingredient(s)
Glycolic Acid–Containing Products	
Aqua Glycolic Hand and Body Lotion	Glycolic acid 14%
Alpha Hydrox AHA Enhanced Anti-Wrinkle Crème	Glycolic acid 10%
Alpha Hydrox AHA Souffle	Glycolic acid 12%
DDF Glycolic Exfoliating Oil Control Gel	Glycolic acid 10%
DermaQuest Skin Therapy	Glycolic acid 5%; azelaic acid 2.5%; salicylic

Trade Name	Active Ingredient(s)
	acid 2%
Dr. Michelle Copeland AHA Face Cream	Glycolic acid 10%
M.D. Forte Facial Cleanser III	Glycolic acid 30%
Peter Thomas Roth Glycolic Acid Hydrating Gel	Glycolic acid 10%
Peter Thomas Roth AHA/BHA Cleaning Gel	Glycolic acid 10%; salicylic acid 2%
Reviva Labs Glycolic Acid Cream Exfoliation and Cell Renewal	Glycolic acid 10%
Retinol-Containing Products	
GlyMed Plus Retinol Restart Rejuvenation Serum	Retinol 5%
Paula's Choice Clinical 1% Retinol Treatment	Retinol 1%; vitamin C
Proactiv+ Skin Revitalizing Pads	Retinol
Exuviance Super Retinol Concentrate	Retinol
Salicylic Acid-Containing Products	
Paula's Choice Skin Perfecting 2% BHA Lotion Exfoliant	Salicylic acid 2%
Peter Thomas Roth Beta Hydroxy 2% Acne Wash	Salicylic acid 2%

Of the BHAs, salicylic acid is used widely, even as a chemical peel.³³⁻³⁸ Compared with AHA products, BHAs are more lipophilic and demonstrate keratolytic effects. Products containing BHAs as the active ingredients may be beneficial to acne-prone skin.

Polyhydroxy acids are the new generation of AHAs that appear to deliver results similar to those achievable with the alpha and beta hydroxy products, but with less irritation.³³

Used appropriately, HA products act as exfoliants by causing detachment of keratinocytes, resulting in a smoother, nonscaly skin surface with eventual

normalization of keratinization. The effect of the AHA product depends on its concentration and pH.^{17,33,36,37} The lower the pH, the more effective the product will be, and the higher the AHA concentration, the more deeply it will penetrate the stratum corneum. By improving skin elasticity, HAs have been shown to make skin more flexible and less vulnerable to cracking and flaking. Regular use has led to an increase in skin collagen and elastin and smoother skin texture, lessening of fine lines, and normalization of pigmentation.^{36–38}

Guidelines for treatment with HAs include identification of patient factors such as current and past medications, previous dermatologic and other procedures, and medical history, all of which may affect treatment outcome and influence patient expectations, which initially may be unrealistic.^{12,35} Care should be taken to apply HAs to dry skin, with an estimated wait time of 10–15 minutes after cleansing the face. It also is prudent to begin application gradually, starting every other night for approximately 1 week and then increasing the frequency, as tolerated, to a maximum of twice-daily application. HA products may make the skin more sensitive to sun exposure. Patients should be advised to use daily sunscreen or sunblock with an SPF of 30 or greater during use of AHAs and after discontinuation of the AHA regimen.^{33,35–38}

Common adverse effects of AHA and BHA products include mild transient stinging, burning, pruritus, skin lightening, and dryness. BHA products may be less irritating. Many of these effects can be ameliorated if products are used with caution and proper counseling. Patients also should be advised that other topically applied products, both medications and cosmetics, may contain active ingredients capable of exacerbating irritation (e.g., AHA, BHA, hydroquinone). Information regarding use during pregnancy and lactation is lacking; therefore, such use is not recommended.⁴⁰

Retinol and Retinaldehyde (Vitamin A Derivative)

Topical retinoids—tretinoin, isotretinoin, tazarotene, adapalene, retinol, and alitretinoin—constitute the mainstay of treatment for photoaging.³³ Retinol and its derivatives have been incorporated into many skin care formulations and are available in both prescription and nonprescription products. Retinoids increase collagen production and induce epidermal hyperplasia, which helps reduce the appearance of fine lines, improves skin texture, and corrects tone and skin elasticity. Retinol is very unstable and, with light exposure, easily degrades to biologically inactive forms.^{12,35} Thus, higher concentrations may be

needed for efficacy. Retinol is transformed into retinaldehyde and then into retinoic acid with a two-step enzymatic process that involves dehydrogenase in human keratinocytes. Topical retinaldehyde not only is well tolerated by human skin but also has been shown to have several effects identical to that of tretinoin. Common adverse effects of topical retinoids include scaling, redness, burning, and dermatitis. Retinoids may have to be used for at least 4 months before benefit can be seen. The use of vitamin A in women of childbearing age is controversial and should not be recommended in women who are pregnant or may become pregnant.³⁵

Ascorbic Acid (Vitamin C)

Ascorbic acid, or vitamin C, has antioxidant, anti-inflammatory, skin-lightening, and antihyaluronidase activity.^{14,33} Several studies have demonstrated reduced skin roughness and wrinkles with application of topical ascorbic acid 3%–5% for 12 weeks.^{14,33,35} Topical ascorbic acid also has been reported to have at least some photoprotective properties.³⁹ Of note, in the original FDA pregnancy risk schedule, this vitamin is labeled a category C drug.⁴¹ (See the Preface for a detailed explanation of the pregnancy data.)

Product Selection Guidelines

Skin type should determine the selection of product type. Creams are appropriate for drier skin types, lotions are best for combination or normal skin, and gels or solutions are useful for oilier skin. Use of products with higher concentrations and a lower pH may produce faster results. However, the patient should be forewarned that such products also may cause greater skin irritation.

Assessment of Photoaging: A Case-Based Approach

If careful inspection of the skin reveals signs of photoaging, the initial assessment should focus on the patient's history of UVR exposure, whether from sunlight or artificial sources (e.g., tanning beds). Knowledge of whether the patient's current occupational or recreational habits entail excessive UVR exposure is useful not only in determining the cause of the skin disorder but also in developing a treatment plan. It is important to assess for any diseases or current or past medication regimens that may predispose the skin to

premature photodamage or photosensitivity. The patient's health status, lifestyle practices, and daily skin maintenance regimen are other pertinent assessment criteria.

Case 40–2 is an example of assessment of a patient with photoaging.

Patient Counseling for Photoaging

Patient counseling should emphasize that premature wrinkling, creases, dry texture, and blotchy hyperpigmentation are not inevitable, and that proper protection from UVR can limit the effects of photoaging.¹¹ The health care provider should be proactive in identifying and recommending appropriate products for the patient's skin care needs. The box "Patient Education for Photoaging" lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Photoaging

Patients using nonprescription skin care products to combat photoaging should be assisted to set reasonable aesthetic goals. Obviously, such preparations cannot "erase wrinkles." The health care provider should monitor the progress of the treatment and be aware of potential issues that warrant medical referral (e.g., reactive hyperpigmentation, bacterial or fungal infections, epidermal cysts, acneiform eruption, scarring).⁴²

Case 40-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is an older man seeking advice regarding the recent onset of wrinkles, dry skin, crow's feet around his eyes, and areas of darkened skin.

Relevant Evaluation Criteria	Scenario/Model Outcome
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	He had not noticed any specific skin changes until now. He recently retired and is working outdoors a lot more.
c. Description of the patient's efforts to relieve the symptoms	He uses daily moisturizer but wants to "have less-wrinkled skin," as well as to prevent more wrinkles and avoid any additional darkening of the skin.
d. Patient's identity	Greg Smith
e. Patient's age, gender, height, and weight	68 years, male, 5 ft 9 in., 195 lb
f. Patient's occupation	Retired
g. Patient's dietary habits	Patient eats fast food often. He drinks alcohol socially and quit smoking 3 years ago.
h. Patient's sleep habits	Normal sleep schedule; he averages 6 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>High blood pressure:</i> lisinopril 10 mg daily; hydrochlorothiazide 12.5 mg daily
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) _____	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	The patient has noticeable wrinkles, crow's feet, dry skin, and hyperpigmented areas on his face caused by photoaging.
3. Identify exclusions for self-treatment.	The patient has no exclusions for self-treatment.
4. Formulate a comprehensive list of therapeutic alternatives for	Options include

Relevant Evaluation Criteria	Scenario/Model Outcome
the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	(1) Refer Mr. Smith to his regular health care provider or a dermatologist for further evaluation. (2) Recommend a 2-month trial of a topical retinoid product with dark spot correction and use of daily sunscreen. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient would like to try a nonprescription product.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Apply the chosen product, such as Alpha SkinCare Dual Action Skin Lightener, to clean, dry skin once or twice a day in the morning and/or evening. Smooth the product over your face and neck, allowing the product to absorb completely. Then in the morning, also apply a broad-spectrum sunscreen with an SPF of at least 30. Use this sunscreen daily."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Seeing a dermatologist may not be necessary with proper use of this product. Wrinkles will not be completely removed because they are part of the natural aging process. The dark spots may lighten up a bit."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and	"Apply once or twice a day in the morning and/or

Relevant Evaluation Criteria	Scenario/Model Outcome
frequency of administration	evening. Smooth the product over your face and neck, allowing it to absorb completely. Apply a broad-spectrum sunscreen with an SPF of at least 30 after applying the product in the morning. Use this sunscreen daily."
b. Maximum number of days the therapy should be employed	"Improvement can be seen in as little as 4 weeks but may take as long as 6 months."
c. Product administration procedures	"The product should be applied after cleansing the face."
d. Expected time to onset of relief	"Improvement may be seen in as little as 4 weeks."
e. Degree of relief that can be reasonably expected	"Fine lines may be reduced, pore size may decrease, dark spots may lighten, and dryness should be less noticeable. The wrinkling, however, may not disappear completely."
f. Most common adverse effects	"Mild irritation may occur. In addition, the areas being treated may appear to be lighter than surrounding skin."
g. Adverse effects that warrant medical intervention should they occur	"If the treated areas of the skin become severely irritated or darken significantly, you should see your primary care provider or a dermatologist."
h. Patient options in the event that condition worsens or persists	"If no improvement is seen within 2 months, you should see your primary care provider or a dermatologist."
i. Product storage requirements	"When not in use, the product should be stored at normal room temperature and tightly closed, and out of the reach of children."
j. Specific nondrug measures	"This product may make the skin more sensitive to sun exposure. A sunscreen with an SPF of at least 30 should be applied daily while using this product and for up to a week afterward."
Solicit follow-up questions from the patient or caregiver.	(1) "May I use this product more than twice a day?" (2) "Should I always wear sunscreen or only when I am using this product?"
Answer the patient's or caregiver's questions.	(1) "No, this product should be used a maximum of twice daily."

Relevant Evaluation Criteria	Scenario/Model Outcome
	(2) "This product will increase the overall sensitivity of your skin to the sun. In addition, because you often are outside, you should use a moisturizer or sunblocker with an SPF of at least 30 every day and also wear a broad-brimmed hat for protection."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mr. Smith to call you in about 3–4 weeks to update you on his response to your recommendations. Or you could call him in 1 month to evaluate his response.

Key: n/a = Not applicable; SPF = sun protection factor.

Patient Education for Photoaging

The objectives of self-treatment are (1) to reverse skin damage by using available nonprescription products and (2) to prevent further damage by making lifestyle changes and protecting the skin from sun exposure. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Alpha Hydroxy Acids

- Protect the skin from sun exposure by covering it with clothing. The U.S. Food and Drug Administration (FDA) recommends advising patients to wear long-sleeved clothing and hats with brim width of at least 4 inches. Patients also should commit to regular use of a sunblock or sunscreen product with an SPF of at least 30 for the duration of the alpha hydroxy acid (AHA) regimen and beyond, to prevent further damage.

- To prevent dry skin, cleanse the skin with a mild soap or a soap-free liquid cleanser. Do not cleanse skin more often than twice daily. Apply a pea-sized amount of an AHA product to clean, dry skin.
- To minimize transient mild tingling and stinging, wait 10–15 minutes after cleansing the face to apply an AHA product.
- Excessive skin dryness or irritation warrants decreased frequency of application.
- Note that AHA products contain an active ingredient and that the use of other products, including cosmetics, could result in skin irritation, including mild stinging, burning, or erythema.
- Do not apply the product too close to the eyes or mucous membranes.
- Begin applying this product once at bedtime every other day for approximately 1 week. Gradually increase application to twice a day.
- Use a daily moisturizer with sunscreen after applying the AHA product, to minimize dry skin and maintain the antiphotaging effect.
- Store this product in a cool dry place out of children's reach.
- Discontinue the AHA product if signs of severe irritation, such as redness or excessive dryness, appear or if a rash occurs.

Key Points for Skin Hyperpigmentation and Photoaging

- Photoaging and hyperpigmentation are cosmetically unacceptable skin conditions. Patients should be assisted to identify reasonable expectations with the use of nonprescription products, which should help to achieve even skin tone and to minimize appearance and occurrence of fine wrinkling.
- Hydroquinone is the only FDA-approved nonprescription skin-bleaching product. Patients should apply a 2% concentration to affected skin up to twice daily, as tolerated.

- Patients younger than 12 years, those with large areas of hyperpigmentation or disease- or drug-induced hyperpigmentation, and those with lesions showing changes in size, shape, or color should consult a dermatologist or their primary care provider.^{1,20}
- Patients should be referred to a dermatologist or their primary care provider if no improvement occurs within 2 months or if skin darkens during treatment for hyperpigmentation.¹
- Patients should avoid applying hydroquinone-containing products near the eye area or on damaged skin.
- Patients using HAs to reduce photoaging should be advised to apply the product to dry skin up to twice daily. Patients should be counseled that it may take up to 6 months to see the effect.
- Patients who use products to prevent photoaging or recurrence of hyperpigmentation should be instructed to protect the skin from daily sun exposure by using a sunscreen with an SPF of 30 to maintain results.

Chapter 41: Minor Burns, Wounds, and Sunburn

Authors: Nora Stelter

Thousands of people seek medical treatment for skin injuries each year. Annually, approximately 489,000 people with burn injuries and more than 1.2 million people with superficial skin injuries seek medical treatment at U.S. hospital emergency departments.¹ Sunburn at any age increases skin cancer risk, and every year, approximately one third of American adults experience sunburn. Sunburn is most prevalent in non-Hispanic white adults, although all ethnic groups experience preventable overexposure to ultraviolet radiation (UVR).² The most recent data for high school-aged children show that about five of every 10 high school boys and more than six of every 10 high school girls reported getting a sunburn in the previous year.³

Health care providers often provide guidance to patients seeking self-care recommendations for minor burns, sunburn, and wounds. Knowledge of common skin injuries, proper assessment of those injuries, and self-care recommendations are essential for health care providers who are likely to be consulted regarding treatment. Although healthy skin is well equipped for effective and efficient repair of minor acute skin injuries, providing patient education on appropriate self-care measures will help facilitate optimal healing, decrease the risk of complications, and minimize scar formation.

Pathophysiology of Minor Burns, Sunburn, and Wounds

Burns are wounds caused by exposure to UVR, or contact with thermal, electrical, or chemical sources. *Sunburn* is caused by overexposure to ultraviolet A (UVA) and ultraviolet B (UVB) rays from natural sunlight and from use of commercial tanning beds and tanning lamps (see [Color Plates](#), photograph 28). (See [Chapter 39](#) for a discussion of UVR bands.) *Thermal burns* result from skin contact with flames, scalding liquids, or hot objects (e.g., irons, hot pans, curling irons). *Electrical burns* occur when electricity flows through the body from an entry point to an exit point, and the heat of the electric

current damages the skin. *Chemical burns* occur secondary to exposure to corrosive or reactive chemicals that cause tissue damage. Some thermal burns and sunburns may be appropriate for self-treatment; however, all patients with electrical or chemical burns must be referred to a hospital emergency department for evaluation.

Wounds are injuries that cause a break in the skin. Minor wounds addressed in this chapter include abrasions and lacerations. *Abrasions* result from rubbing or friction applied to the epidermal layer of the skin, extending to the uppermost portion of the dermis. *Lacerations* (cuts and punctures) result from a sharp-edged object cutting through the various skin layers.⁴

Providers must understand the physiology of wound healing before they can recommend an appropriate course of action and provide patient counseling. Skin integrity depends on a delicate balance between structure and function. When a burn or wound disturbs this balance, prompt restoration is required to ensure that the body maintains homeostasis and that wounds heal properly.

The process of wound healing begins immediately after injury and consists of three overlapping phases: inflammatory, proliferative, and maturation (remodeling).⁵

The *inflammatory phase* is the body's immediate response to injury. This phase, which lasts approximately 3–4 days, is responsible for preparing the wound for subsequent tissue development and consists of two primary processes: hemostasis and inflammation. Hemostasis is initiated by the release of thromboplastin from the injured cells to form a clot. Clot formation is the main physiological process that stops bleeding so that tissue repair may begin. Later in the inflammatory phase, debris and bacteria are removed from the wound area, and collagen is formed to stimulate wound healing. Epithelial cells migrate to cover the wound bed and provide the initial layer (just one cell thick) of new skin that will cover the wound.⁵

In the next phase of healing, the *proliferative phase*, the wound is filled with new connective tissue and covered with new epithelium. This phase starts on day 3 or 4 and continues for approximately 3 weeks. The proliferative phase involves the formation of granulation tissue, which is a collection of new connective tissue (fibroblasts and newly synthesized collagen), new capillaries, and inflammatory cells.⁵

The final phase of healing, the *maturation* or *remodeling phase*, is the longest phase. It begins at approximately week 3, when the wound is completely closed by connective tissue and resurfaced by epithelial cells. This phase involves a continual process of collagen synthesis and breakdown, with replacement of earlier-constituted, weak collagen by high-tensile-strength collagen. This process peaks approximately 60 days after occurrence of the injury.⁵

Several local and systemic factors can affect how efficiently and to what extent a wound will heal. Providers who can recognize problems associated with these local and systemic factors can provide more effective wound care management instructions to aid in faster healing.

Local *factors* associated with delayed or otherwise poor healing include inadequate tissue perfusion and oxygenation; inadequate moisture; and the presence of foreign bodies (e.g., glass, dirt), necrotic tissue, or infection.⁶ Localized infection in the wound delays collagen synthesis and epithelialization, prolongs the inflammatory phase, and causes additional tissue destruction. Most minor wound infections are caused by bacteria, especially *Staphylococcus* and *Streptococcus*.⁷

Systemic factors that can impair the healing process are advanced age (>60 years); stress; inadequate nutrition; medical conditions such as diabetes and obesity; immunocompromised conditions such as cancer; alcoholism; smoking; and certain medications.⁶ Adequate nutrition provides the building blocks for wound repair, especially in chronic wounds. Protein, carbohydrates, vitamins, and trace elements are needed for collagen production and cellular energy. Medications that may impact wound healing include those that interfere with clot formation, platelet function, inflammatory responses, and cell proliferation.⁸ (See the section “Special Populations” for additional information.)

Clinical Presentation of Minor Burns, Sunburn, and Wounds

Minor burns, sunburn, and wounds are classified according to the cause of the injury; timing (whether the injury is acute or chronic); the depth of the injury

into the skin and underlying tissues; and the size of the injury.⁹ These factors determine whether the wound will heal with self-treatment or will require referral to a health care provider.

Skin injuries may be categorized as *acute* or *chronic* according to the rate of healing. *Acute wounds*, with proper care, tend to heal within 1 month in healthy adults. In contrast, any wound that does not heal properly through the normal stages of tissue repair and shows no progress toward healing in 30 days is considered a *chronic wound* and requires referral for more intensive medical care. Pressure ulcers (bed sores) and diabetic foot ulcers are examples of chronic wounds. This chapter discusses treatment of only minor burns, sunburn, and minor acute wounds.

Depth classification is divided into categories based on the increasing depth of the damage: superficial, superficial partial thickness, deep partial thickness, full thickness, and subdermal. [Figure 41-1](#) shows a cross-section of the anatomy of the skin and the depth of injury for burns or wounds of increasing severity. (See [Chapter 33](#) for further discussion of skin anatomy and physiology.) [Figure 41-2](#) illustrates the depth of burns and wounds whose depth exceeds that of a superficial skin injury.

FIGURE 41-2 Depth of burns and wounds beyond a superficial skin injury. A: Superficial partial-thickness injury involves all of the epidermis and superficial dermis. **B:** Deep partial-thickness injury extends deeper into the dermis. **C:** Full-thickness skin injury extends beyond the dermis with damage to subcutaneous tissue. **D:** Subdermal skin injury extends beyond the subcutaneous layer and may damage muscle, bone, and interstitial tissue.

Superficial skin injuries involve only the epidermis, with no loss of any skin layers, and are characterized by reddened; nonblanching (does not become pale or white when pressure is applied to the skin); unbroken; and nonblistering skin that is painful to the touch. Minor sunburn is a superficial skin injury with erythema (superficial reddening of the skin) and slight dermal edema that results from increased blood flow to the affected skin. The erythema begins to develop approximately 3–5 hours after exposure, peaking between 12 and 24 hours.¹⁰ A majority of superficial injuries can be managed with self-care or through ambulatory care centers and will heal without

scarring within 3–7 days.^{11,12}

Superficial partial-thickness skin injuries involve all of the epidermis and the superficial dermis. Because the injury involves a break in the skin, drainage from the wound area may occur, in addition to pain, edema, and erythema. If pressure is applied to the skin, the area will blanch but have a rapid capillary refill upon release of pressure. Blistering may occur in some cases, such as in severe sunburn. Healing usually occurs with minimal scarring in 10–14 days.^{11,12} Minor superficial and superficial partial-thickness skin wounds may be managed with self-care if they meet criteria listed in [Figure 41-3](#).

Deep partial-thickness skin injuries extend deeper into the dermis and present with edema, less blanching, and typically no blisters. Pain sensation may be altered. Healing typically occurs in 2–4 weeks with scarring present. Patients with deep partial-thickness burns should be evaluated in a hospital emergency department.^{11,12}

Full-thickness skin injuries extend through the epidermis and dermis and into the subcutaneous tissue layer. *Subdermal skin injuries* extend beyond the damage to the subcutaneous tissue layer of muscle, bone, and interstitial tissue. Full-thickness and subdermal burns normally require hospitalization for treatment. Deep lacerations bleed profusely, and underlying tissue layers may be visible in the wound bed.^{11,12} Patients suffering from deep lacerations or punctures should seek immediate emergency care.

Determining the size of a skin injury also is critical to determining severity of an injury and whether self-care or referral is warranted. The rule-of-nines method is used to estimate body surface area (BSA) by dividing the body into multiples of 9%.¹² [Figure 41-4](#) illustrates the rule-of-nines method for estimating the percentage of affected BSA. Another method of BSA estimation involves using the patient's hand, including the palm of the hand and fingers, as the measuring tool to estimate 1% BSA.¹³

Treatment of Minor Burns, Sunburn, and Wounds

Treatment Goals

The goals in treating acute, minor skin injuries are (1) to relieve symptoms, (2) to promote healing by protecting the burn or wound from infection and further trauma, and (3) to minimize scarring.

General Treatment Approach

In addition to the typical assessment of the patient, the cause, timing, depth, and size of minor superficial and superficial partial-thickness burns and wounds should be assessed for self-treatment. When breaks in the skin are present, assessment of the patient's tetanus status should be performed.⁴ If the patient has none of the exclusions for self-treatment for burns or wounds (Figure 41-3), the provider should recommend appropriate measures using the treatment approach outlined in the algorithm.

Treatment of acute minor skin injuries classified as superficial and superficial partial thickness (e.g., abrasions, lacerations, burns) requires basic supportive measures, including cleansing the wound, applying moist wound care, and relieving any pain or discomfort. Wound cleansing by irrigation with cool, clean tap water is recommended.¹⁴ Wound dressings are not indicated for use in some superficial-thickness burns, such as minor sunburn; however, providing moisture to the affected skin through the use of agents such as non-perfumed, hypoallergenic skin protectants should be recommended first. The use of a wound dressing for superficial partial-thickness injuries is recommended to keep the area moist, and it may provide some pain relief and prevent entry of bacteria into the affected area.¹⁴⁻¹⁶ In addition, proper wound healing is the most significant way to minimize scarring. Pain management may be achieved with oral pain medications and soothing skin protectants. In sunburned patients, topical anesthetics may provide temporary pain relief.

Patient education, monitoring, and follow-up are crucial to self-care of skin injuries. The initial appearance of a burn injury often leads to an underestimate of its severity. The inflammatory response to a burn injury evolves over the first 24–48 hours; thus, a burn injury should be reassessed after 24–48 hours. The patient should be educated on signs and symptoms of infection, so it can be identified and treated immediately. In addition, patient education may be provided on methods to minimize scarring after the skin injury has healed.

Nonpharmacologic Therapy

Nonpharmacologic therapy for superficial and superficial partial-thickness skin injuries involves a variety of first-aid measures to prevent contamination, relieve pain, and promote healing.

Wound Cooling and Cleansing

Reducing further trauma to the site of a burn-induced skin injury is achieved by immediately removing the source of heat and actively cooling the burn wound with cool tap water. Running water is the treatment of choice because it is inexpensive and readily available in first-aid situations. Continuous cooling of the wound within the first 20 minutes of the injury slows the burning process, reduces pain, and diminishes the inflammatory response.¹⁷ Although this treatment is most beneficial immediately after a burn occurs, benefit may be found up to 3 hours after its occurrence.¹⁸ The application of ice or ice-cold water should be avoided because this measure may cause numbness and intense vasoconstriction, resulting in further tissue damage.

Wound cleansing is important to prevent infection and promote safe healing. Irrigation with clean tap water is the preferred method.^{14,17} Saline irrigation products (e.g., Simply Saline Wound Wash) provide no advantage over tap water when clean tap water is available. For uncontaminated wounds, cleansing through irrigation should be performed as gently as possible to avoid further injury. In contaminated injuries, more aggressive irrigation is warranted. If the patient is unable to remove foreign bodies or debris from the injury, referral to a primary care provider is warranted.¹⁴ Tetanus prophylaxis should be updated if needed.

Patients should be advised not to pull at loose skin or peel off burned skin because viable skin may be removed in the process, thereby delaying healing. If small blisters (<6 mm) are present, evidence shows they should be left intact to prevent infection and speed healing. Larger blisters and those located over mobile areas may rupture on their own. In this case, the area should be washed with soap and water and a moist wound dressing applied.^{4,19}

Wound Dressing

Historically, wound management involved leaving a wound open to air or covering it with a nonocclusive textile dressing (gauze). However, this type of management leads to scab formation, which impedes reepithelialization of wounds and may create unwanted scar tissue (Figure 41-5A). Wound dehydration may delay healing and increase risk of bacterial entry into the wound. Current treatment recommendations are based on creating a moist wound environment (Figure 41-5B). A moist healing environment stimulates

cell proliferation and encourages epithelial cells to migrate to heal the wound. Moisture-retentive dressings also act as a barrier to prevent infection and absorb excess wound fluid to prevent maceration of the skin from too much moisture. These dressings also can help decrease pain, reduce the need for frequent dressing changes, and provide autolytic debridement.^{19,20}

FIGURE 41–5 Mechanisms by which semipermeable wound dressings create a moist environment for wound healing. A, Regenerating epidermal cells are forced to “tunnel” below the dry wound scab to attain wound closure. This tunneling delays wound closure. B, Semipermeable wound dressings prevent formation of scab by maintaining optimal moisture level at the wound bed. Unhindered by the presence of a dry scab, migrating epithelial cells are able to migrate and close the wound. (Source: Adapted with permission from Syzcher M, Lee SJ. Modern wound dressings: a systemic approach to wounds. *J Biomater Appl.* 1992;7:142–213.)

Recommendations for a wound dressing depend on proper assessment of the skin injury. Some minor superficial-thickness skin injuries (e.g., sunburn, minor abrasion) may be treated successfully with a topical agent to promote healing, provide pain control, and prevent infection.¹⁴ In contrast, superficial partial-thickness injuries should be covered with a wound dressing. A nonadherent, hypoallergenic dressing may be applied to the wound to protect the damaged area and speed wound healing.

Types of Wound Dressings

Wound dressings continue to evolve with new product advancements. An understanding of the potential use and function of specific wound dressings will guide the provider in proper product selection. The focus of this chapter is treatment of minor acute wounds and burns; thus, wound dressings for use on chronic wounds such as alginates, foams, hydrogels, and collagens will not be addressed. [Table 41–1](#) provides examples of common types of acute wound care dressings.

TABLE 41-1 Selected Acute Minor Burn and Wound Dressings

Trade Names^a	Product Type	Advantages	Disadvantages
Sterilux Bulky Gauze Bandage Conform Kerlix Rolls and Sponges	Gauze dressings (nonocclusive fiber dressing with loose, open weave)	Readily available in many sizes Cost effective Highly absorbent for wounds with exudate Nonocclusive Conformable	Moist healing environment is not provided unless used with another product (e.g., skin protectant). Debridement is nonselective. Removal may cause bleeding/ pain. Secondary dressing (e.g., surgical tape, self-adherent wrap) is required to adhere to skin. Frequent dressing changes are required.
Adaptic Curad Non-stick Pads Nexcare Non-Stick Pads Vaseline Gauze	Nonadherent (gauze-type) dressings (nonadherent, lightly coated porous dressings)	Readily available Less adherent than plain gauze	Many do not provide moist healing environment. Secondary dressing (e.g., surgical tape or self-adherent wrap) is needed to adhere to skin. Removal may cause bleeding/ pain. Frequent dressing changes may be required.

Trade Names^a	Product Type	Advantages	Disadvantages
Band-Aid Flexible Fabric Adhesive Bandages Curad Flex- Fabric Adhesive Bandages	Adhesive Bandages (adhesive bandage with nonadherent pad in the center)	Readily available in a variety of shapes and sizes Cost effective Less adherent than plain gauze Special characteristics with some products, including clear bandages for discreet wound healing, waterproof adhesion, antibacterial fabric, cushioned fabric and highly durable adhesion	Many do not provide moist healing environment. Removal may cause bleeding/pain. Frequent dressing changes may be required.
Band-Aid Advanced Healing Strips DuoDERM CGF Dressing Medline Exuderm Wound Dressing Nu-Derm	Hydrocolloids (wafer dressings composed of hydrophilic particles in an adhesive form covered by a water-resistant film or foam)	Provide moist healing environment Manage exudate by particle swelling Long wear time Self-adherent Occlusive Impermeable to fluids/bacteria Protective Conformable Thermal insulation Reduce pain	Dressing is used for uninfected wounds only. Peri wound trauma may occur on removal. Dressings make assessment of wound difficult. Dressings are impermeable to gases. Some may leave residue on skin or in wound. Dressings are less cost effective.
Bioclusive Opsite Tegaderm	Transparent adhesive films (semioclusive, translucent dressings with partial or continuous adhesive composed of polyurethane or copolyester thin film)	Provide moist healing environment Self-adherent Semioclusive Gas-permeable Easy inspection of wound under dressing Impermeable to fluids/bacteria Protective Comfortable Reduce pain	Dressings are used for uninfected wounds only. Dressings are not absorptive. Peri wound trauma may occur on removal. With continuous adhesives, removal of

Trade Names ^a	Product Type	Advantages	Disadvantages
			bandage may reinjure wound. With large amounts of exudate, maceration may occur. Dressings are less cost effective.

^a Each trade-name product is an example of available products for each type of wound dressing. These products do not constitute an all-inclusive list of wound dressings.

Patients should be advised to keep the dressing clean and change the bandage according to the product directions. Ideally, wound dressing changes should be limited because it may damage the healing skin burn or wound. Dressing changes should occur if the dressing is dirty, foul smelling, or not adhering to the area.

Gauze is cost effective and readily available in a variety of forms including pads and rolls. Examples of gauze products are Curad Gauze Roll or Band Aid Gauze Pads. Gauze generally is used in the care of burns and wounds that are bleeding or draining or those requiring debridement. Traditional gauze products do not provide a moist environment; however, it can be impregnated with nonadherent products such as petrolatum, as well as with antiseptics and antimicrobials. Disadvantages of traditional gauze are that it must be held in place by a second agent, such as surgical tape or a self-adherent wrap. Some newer adhesive gauze products have the benefit of avoiding the use of a secondary agent (e.g., Band-Aid Cushion Care Adhesive Gauze Pads). Gauze must be changed often to prevent the wound from drying out. Removal of a traditional gauze dressing often tears away not only the scab but also the new tissue under the scab, potentially causing pain.²⁰ However, some improved gauze products are nonadherent to the wound (e.g., Band-Aid Hurt Free Non-Stick Pads), thereby limiting pain and tissue damage.

Adhesive bandages are cost-effective wound dressings that are used widely for minor acute skin injuries. However, many traditional adhesive bandages do not provide a moist healing environment; thus, a topical skin protectant should be recommended in conjunction with the adhesive bandage.¹⁵ Adhesive bandages are available in a variety of shapes and sizes. Product lines include characteristics to meet patients' needs, including clear bandages for discreet wound healing, waterproof adhesion, antibacterial fabric, cushioned fabric, and highly durable adhesion (e.g., Nexcare Waterproof Bandages, Band-Aid Infection Defense with Neosporin Bandages).

Hydrocolloid dressings consist of an inner colloidal layer composed of a combination of gel-forming agents and an outer water-impermeable layer. They provide a moist healing environment and are useful for partial-thickness wounds with minimal to moderate exudate. When hydrocolloids come in contact with moisture from the injury, they form gels and help protect the wound by absorbing excess exudate and by maintaining moisture.²¹ Hydrocolloid dressings also are indicated for the protection of intact skin, such as minor burns or blisters. Although hydrocolloid dressings are used most commonly in the management of chronic wounds, recognition of the importance of a moist wound healing environment has led to the development of hydrocolloid bandages for self-treatment of acute minor wound healing (e.g., Band-Aid Brand Hydro Seal bandages). However, hydrocolloid dressings often cost more than traditional adhesive bandages.

Transparent adhesive films (e.g., Nexcare Tegaderm Waterproof Transparent Wound Dressing Bandage) are thin, elastic, waterproof polyurethane films that are permeable to gas but impermeable to bacteria. Because these dressings are not highly absorbent, they are indicated for superficial-thickness and superficial partial-thickness wounds with minimal exudate. The flexibility of these dressings makes them suitable for difficult-to-cover areas such as joints like the elbow or knee. The transparency of some films allows inspection of wounds without removing the wound dressing.²²

Liquid adhesive bandages (e.g., New Skin Liquid Bandage, Nexcare Liquid Bandage Spray) are an alternative to conventional bandages for simple cuts and lacerations. They are applied by either spraying or brushing on the liquid, which then forms a clear, flexible coating over the injury. However, little evidence exists to document their effectiveness over other types of wound dressings for self-treatment of minor acute skin injuries.²³ Liquid adhesive

bandages may be preferred either for cosmetic considerations (e.g., a wound located on the face) or when a more flexible dressing product is needed (e.g., a wound located on the finger or elbow). They may have antibacterial or antiseptic properties. A slight burning sensation may occur upon their application. The adhesives are waterproof and have a high bonding strength; they may stay on for 5–10 days. Liquid adhesive bandages should not be used on large areas of the body, over sutures, near the eyes, or on mucous membranes.²⁴

Minimizing Scarring

Scarring that occurs secondary to a minor burn or wound can lead to negative physical, aesthetic, psychological, and social consequences for patients.²⁵ Patients should be advised that the most significant way to minimize scarring is to promote proper moist wound healing.²⁵ Strategies for proper wound healing are explained in the section “General Treatment Approach.” Research also has shown that UVR increases scar pigmentation and worsens the clinical appearance of scars.²⁶ Patients should be advised to avoid extensive UVR exposure and to take proper precautionary measures, including generous application of a sunscreen before going outdoors. (See [Chapter 39](#) for more information on prevention of sun-induced skin disorders.)

The latest guidelines for scar management advocate silicone therapy as the gold standard. Silicone therapy is the only noninvasive preventive and therapeutic measure for which there is adequate supporting data to make evidence-based recommendations. Silicone is believed to prevent and treat scars through occlusion and subsequent hydration of scar tissue.²⁷ Silicone products also may help relieve itching and discomfort that often accompanies scar formation. In minor burns and wounds, these products may be used to minimize the appearance of scarring only after the skin injury has fully healed. Silicone products also may be used on existing scars to help minimize their appearance. Nonprescription silicone products are available in sheet and gel formulations.

Silicone sheets consist of a soft, semi-occlusive gel sheet composed of medical-grade silicone and reinforced with a silicone membrane backing.²⁵ Examples of these products include ScarAway Silicone Scar Sheets and Embrace Active Scar Defense. Silicone sheets present benefits such as durability and ease of handling. However, their use may be limited because

they can be difficult to use on large areas or near joints, and many patients may be reluctant to use them on exposed areas of the body.

Silicone gel formulations (e.g., ScarAway 100% Silicone Scar Gel) have the same long-chain silicone polymer that is used in silicone sheets. The gel is applied in a thin layer to the skin where it dries and forms a transparent, flexible, gas-permeable, water-impermeable silicone coating.²⁵ Silicone gels present few barriers to use because they can be applied over areas of any size or near a joint.

Limited evidence is available for the use of topical products that are marketed specifically for minimizing the appearance of scars. One such product, Mederma, contains allantoin, a skin protectant, and onion extract. One trial that compared the efficacy of silicone gel, silicone sheets, and a topical product containing onion extract and allantoin found a statistically significant greater improvement in scar appearance after 6 months of treatment in both silicone treatment groups versus the onion extract/allantoin group.²⁸ Similarly, other products such as mitomycin C, green tea, aloe vera, and vitamins D and E have been proposed as options for scar treatment; however, literature supporting their use is lacking.²⁹ Therefore, silicone products should be recognized as the mainstay of therapy.

Finally, more invasive scar treatment options such as injections and laser therapy are available but are outside the scope of this text. Patients who are dissatisfied with the results of nonprescription treatment or who express interest in more extensive treatment should be referred to their primary care provider.

Pharmacologic Therapy

Various products are useful in treating minor acute burns, sunburn, and wounds. Agents may be used to protect the area from further damage or infection, relieve pain, cleanse the area, and/or aid in the healing process.

Systemic Analgesics

An initial step in treating pain from a minor skin injury is to recommend short-term administration of a systemic analgesic such as a nonsteroidal anti-inflammatory drug (NSAID) (e.g., aspirin, naproxen, ibuprofen) or

acetaminophen.¹⁰ Researchers hypothesized that NSAIDs, as prostaglandin inhibitors, could decrease the erythema and speed the healing time of sunburn; however, little evidence to support their use beyond symptomatic pain relief is available.^{10,17,18} (See [Chapter 5](#) for discussion of dosages and safety considerations for systemic analgesics.)

Skin Protectants

Skin protectants (e.g., Aquaphor Healing Ointment) are emollients and moisturizers that protect the injured area from irritation caused by friction and rubbing, and they prevent drying of the stratum corneum, thus promoting moist healing ([Table 41–2](#)). Skin protectants also make the injured area less painful. Application of skin protectants may differ depending on the type and extent of the skin injury. In two studies, application of Aquaphor (petrolatum) 2 and 3 times daily demonstrated superior effectiveness in wound healing compared with nonprescription antibiotic ointments.^{30,31} Skin protectants also are recommended for the prevention of scarring following wound re-epithelialization.¹⁴ Ingredients vary based on the manufacturer’s formulation, but some common skin protectant ingredients are petrolatum, white petrolatum, dimethicone, zinc oxide, glycerin, lanolin, cocoa butter, and colloidal oatmeal. These products should be free of fragrance and potential allergens. (See [Chapter 33](#) for more information on emollients and moisturizers.)

TABLE 41–2 Skin Protectant Products Commonly Used in Treatment of Minor Burns, Wounds, and Sunburn	
Trade Name ^a	Primary Ingredient
Aquaphor Healing Ointment	Petrolatum
CeraVe Healing Ointment	
Desitin Multi-Purpose Healing Ointment	White petrolatum
Vaseline Original 100% Pure Petroleum Jelly	
Neutrogena Norwegian Formula Hand Cream	Glycerin
Palmer’s Cocoa Butter Formula	Cocoa butter
Vaseline Intensive Care Cocoa Radiant	

Trade Name ^a	Primary Ingredient
Aveeno Itch Relief Balm with Colloidal Oatmeal	Colloidal oatmeal
Aveeno Soothing Bath Treatment with Colloidal Oatmeal	
Cetaphil Soothing Wash with Colloidal Oatmeal	

^a Each trade-name product is an example of available products for each type of skin protectant. This list of products does not constitute an all-inclusive list of products that contain these agents.

First Aid Antibiotics

Nonprescription first aid antibiotics consist of one or more of these active ingredients: bacitracin, neomycin, and polymyxin B sulfate. Examples of these products include Neosporin (bacitracin, neomycin, and polymyxin B sulfate) and Polysporin (bacitracin and polymyxin B sulfate). These topical agents are indicated for the prevention of infection in minor acute skin injuries. They are not indicated for the treatment of infected wounds. Many topical antibiotic products are formulated as an ointment, which helps in maintaining a moist healing environment.

Each of the three nonprescription antimicrobial agents has a unique mechanism of action, which gives a first aid triple antibiotic ointment a wide spectrum of activity. Bacitracin inhibits cell wall synthesis in several gram-positive organisms. Neomycin is an aminoglycoside antibiotic that inhibits protein synthesis in gram-negative bacteria and some *Staphylococcus* species. Polymyxin B sulfate causes leakage of intracellular constituents in gram-negative bacteria.

Available published research on the effectiveness of nonprescription topical antibiotics in wound healing and the prevention of infection is limited and conflicting. A systematic review of four randomized, controlled clinical trials found that topical antibiotics reduced the infection rate of acute, minor, uncomplicated soft tissue wounds.³⁰ In contrast, other studies that compared Aquaphor (a topical emollient) with nonprescription topical antibiotics showed that Aquaphor had superior or equivalent effectiveness in wound healing and prevention of infection.^{31–33} Potential drug resistance related to overuse of

antibiotics also must be considered.³¹ More data on the efficacy of topical antibiotics are needed to effectively determine their place in therapy.

Use of topical antibiotic products is primarily well tolerated and carries a risk of minimal hypersensitivity. Published data demonstrate a higher incidence of allergic contact dermatitis with the use of bacitracin and neomycin versus polymyxin B sulfate.³¹ When used, topical antibiotic preparations should be applied to the skin injury after cleansing and before applying a sterile dressing. This process should be performed 1–3 times a day. Application of these preparations on large areas of denuded skin requires special caution because the potential for systemic toxicity can increase.³⁴

Topical Anesthetics

Benzocaine and lidocaine are the topical anesthetics used most often in nonprescription products for temporary relief of pain from minor wounds, burns, and sunburns. Examples of these products include Dermoplast First Aid Spray (benzocaine 20%) and Alocane Severe Sunburn Gel (lidocaine 4%). Pramoxine is another topical anesthetic often added to nonprescription topical antibiotic ointments or moisturizers for its pain- and itch-relieving properties (e.g., CeraVe Moisturizing Cream for Itch Relief, Neosporin + Pain Relief Dual Action Cream). These products are available as gels, solutions, creams, ointments, and skin patches.³⁵ Because of the differences in drug delivery systems, the Drug Facts Label should be used to guide application of a product. More information on topical anesthetic products is available in [Chapter 37](#).

Topical anesthetics interrupt the transmission of electrical impulses along nerves by inactivating sodium channels in sensory neurons, thereby relieving pain and itch.³⁵ They have a rapid onset of action; their duration of action depends on the dose, route, and area of administration. However, in general, their physiological effects are fairly short-lived.³⁶ These products have the benefit of producing clinically effective drug concentrations at the site of the injury, without resulting in high systemic concentrations that can lead to adverse effects.³⁷

Few studies that examine the efficacy of topical anesthetic use in the outpatient setting are available. More research is needed to confirm the place of this drug class in therapy. Topical anesthetics appear to be effective options

for patients seeking pain relief from minor wounds, burns, and sunburns, but they may not be effective in relieving histamine-induced pruritus.^{38,39} The safety of these products also must be evaluated and considered before they are recommended to patients. Systemic absorption of benzocaine is associated with methemoglobinemia and, secondarily, with cyanosis, dyspnea, syncope, seizures, and coma.⁴⁰ Before patients use these drugs, they must be made aware of the appropriate clinical indications, safe concentrations and doses, and application instructions.

First Aid Antiseptics

Antiseptics destroy or inhibit the growth of microorganisms in tissue. Conversely, they can be cytotoxic to the cells essential for wound healing and reduce the healing rate in open skin injuries. Compared with topical antibiotics, antiseptics have a broader spectrum of antimicrobial activity and are more cytotoxic; however, antibiotics show a higher probability of occurrence of bacterial resistance.⁴¹ The presence of exudate, serum, and blood may diminish the effectiveness of antiseptics. Chlorhexidine (e.g., Hibiclens Skin Cleanser), hydrogen peroxide, and povidone–iodine solution (e.g., Betadine Antiseptic Solution) are examples of commonly available nonprescription antiseptics.

Antiseptics have been used in practice for many years; however, the management of acute and chronic wounds has changed significantly in the past decade. Evidence to support the use of antiseptics to prevent infections and promote healing in open wounds and burns is unclear. Strong evidence is available to support the use of clean tap water for wound irrigation to clean minor acute skin injuries as safe and effective.^{14,41–44}

Product Selection Guidelines

Ointments are oleaginous-based preparations. They provide a protective film to impede the evaporation of water from the wound area, which helps keep the skin from drying. If the skin is broken, an ointment may not be appropriate because of its impermeability. The presence of excessive moisture trapped beneath the ointment may promote bacterial growth or maceration of the skin, thereby delaying healing. Ointments are more appropriate for minor burns and wounds in which the skin is intact.

Creams are water-based emulsions that allow some fluid to pass through the film and are preferred for application to broken skin. Generally, creams are easier to apply and remove than ointments. To prevent contamination of the preparation, the patient should not apply ointments and creams directly from the container onto the burn or wound. A preferred technique is to apply the topical product to a clean or gloved hand or gauze and then apply it directly to the injury site.

Lotions spread easily and are easier to apply to a large burn or wound area. However, lotions that produce a powdery cover should not be used on a wound bed because they tend to dry out the area, are difficult (and possibly painful) to remove, and provide a medium for bacterial growth under the caked particles.

Generally, aerosol and pump sprays are more costly than other topical dosage forms. Sprays offer the advantage of precluding the need to physically touch the injured area, so the application process is associated with less pain. Proper application requires holding the container approximately 6 inches from the skin and spraying the wound area for 1–3 seconds. This method decreases the chances of chilling the area (from the aerosol). Sprays usually are not protective because the aerosol is typically water- or alcohol-based and will evaporate. In addition, alcohol-based sprays can irritate or dehydrate the wound bed.

Special Populations

Older adults are at increased risk of experiencing a minor wound, burn, or sunburn due to physiological changes associated with aging. Older adults have decreased surface contact between the dermis and epidermis, which predisposes the skin to separation of the dermal–epidermal junction. They also experience a significant reduction in cutaneous blood flow and dermal lymphatic drainage, which reduces the ability of the wound to clear itself of pathogens.⁴⁵ Therefore, it is important to educate older adults presenting with open wounds about the signs and symptoms of infection and the proper measures to take if these symptoms appear.

Professional attention is warranted for wounds in patients with diabetes. Poorly controlled diabetes is associated with reduced healing of acute wounds and a higher incidence of chronic non-healing diabetic foot ulcers.⁶ *Hyperglycemia*, or high blood glucose levels, alter white blood cell

function and increase the risk for infection.

Obesity is associated with various skin manifestations such as impaired wound healing and increased risk of skin infection.⁴⁶ When an obese patient presents with a wound in the outpatient setting, the cause of the wound should be determined. If the wound was caused by a potential complication of obesity (e.g., pressure wound, open wound within a skin fold), immediate referral to the primary care provider is warranted.

Although many pharmacologic agents can augment wound healing, some drugs can impair wound healing or even directly damage skin integrity. Medications reported to delay wound healing include anticoagulants, antimicrobials, antineoplastics, anti-rheumatoid medications, NSAIDs, colchicine, nicotine, steroids, and vasoconstrictors.⁸ Patients taking one or more of these medications who present with a minor wound or burn should be monitored closely and, if appropriate, referred to their primary care provider. Direct skin damage secondary to the use of a pharmacologic agent usually is a result of a hypersensitivity reaction.⁸ If a patient presents with dermatitis or open wounds and an allergic reaction is suspected, the patient should be referred to his or her primary care provider immediately.

Additional factors such as poor nutritional status, dehydration, and smoking can hinder healing of skin injuries.⁴⁵ Patients presenting with minor wounds, burns, and sunburn should be counseled on the importance of healthy eating, drinking adequate amount of water, and avoiding use of tobacco products to promote proper healing.

Complementary Therapies

Natural products commonly used for their healing properties include honey, aloe vera, and *Calendula officinalis*. (See [Chapter 51](#) for a more in-depth review of natural products for skin care.)

The use of honey in wound management dates back many centuries. Honey has reemerged as a treatment option for burn and wound management, and nonprescription delivery forms are commercially available (e.g., Derma Sciences Medihoney Paste Wound and Burn Dressing, Derma Sciences Products Medihoney Calcium Alginate Dressing). Honey is highly viscous and delivers a moist wound-healing environment. Because honey has high

osmolarity, it can absorb exudates from the wound, inhibit bacterial proliferation, and promote moist wound healing.⁴² Evidence suggests that honey can promote healing in partial-thickness burns.¹⁶ More research is needed to compare different kinds of honey and to develop recommendations for its routine use in clinical practice.

Aloe vera gel is obtained from the mucilaginous center of the leaf of the aloe vera plant. It has been used for many centuries and is the major ingredient in various commercial skin and wound care products. Although topical aloe vera is widely used as a nonprescription agent and is likely safe, available evidence does not support its use for healing of wounds and burns.⁴²

Calendula (as *C. officinalis*), also known as “pot marigold” is used widely for the treatment of many diseases, including burns, wounds, and dermatitis. It is thought to promote wound healing by its reported anti-inflammatory and antibacterial properties.⁴⁷ A recent review identified some evidence for the beneficial effects of calendula extract in wound healing; however, larger, well-designed randomized control trials are needed.⁴⁸

Assessment of Minor Burns, Sunburn, and Wounds: A Case-Based Approach

In addition to the review of the patient’s medication and medical history, the cause, timing (acute vs. chronic), depth, and size of minor superficial and superficial partial-thickness burns and wounds should be assessed for self-treatment.⁹ The injury also should be inspected for signs of contamination or infection. Visual inspection of the affected area usually provides an accurate evaluation of these factors and helps to determine whether self-treatment of the injury is appropriate. Acute skin injuries that fall into the depth classification ([Figures 41-1](#) and [41-2](#)) of superficial and superficial partial thickness may be appropriate for self-treatment if exclusions for self-treatment are absent.

Cases 41-1 and 41-2 provide examples of patient assessment for minor burns and wounds.

Case 41-1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient complains of a burn on his forearm that occurred when he took a pizza out of the oven about an hour ago. His burn is about an inch long and ¼ inch wide, not blistered but red and painful.
b. Description of any factors that seem to precipitate, exacerbate and/or relieve the patient's symptom(s)	The patient reports that the pain is constant, but running cool water over the burn provides temporary relief.
c. Description of the patient's efforts to relieve the symptoms	The patient held the burned area under cool running water, which helped decrease the pain slightly. He wants to know what he can do to help it heal quickly.
d. Patient's identity	John Pool
e. Age, gender, height, and weight	22 years old, male, 5ft 10 in., 165 lb
f. Patient's occupation	College student
g. Patient's dietary habits	Eats a regular diet.
h. Patient's sleep habits	7 hours nightly
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Omeprazole 20 mg daily for gastroesophageal reflux disease
j. Allergies	None
k. History of other adverse reactions to medications	None

Relevant Evaluation Criteria	Scenario/Model Outcome
I. Other (describe)	None
Assess	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	John is suffering from a minor burn due to thermal exposure from the pizza pan in the oven.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to an appropriate health care provider. (2) Recommend self-care with a nonprescription analgesic and nondrug measures. (3) Recommend self-care until the patient can see an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient can use self-care measures to treat his acute burn. He can use a nonprescription systemic analgesic, skin protectant, and nonadherent wound dressing.
6. Describe the recommended therapeutic approach to the patient or caregiver.	Rinse the burn with cool water for pain relief. Then gently pat the area dry, and apply a thin layer of a skin protectant to hold in moisture and protect the injury. Gently cover the area with a nonadherent wound dressing to further protect the area and to promote moist wound healing. If you are still experiencing pain, take a nonprescription systemic analgesic for pain relief.
7. Explain to the patient or caregiver the rationale for selecting the recommended	"Minor burns can be properly managed with nonprescription systemic analgesics and nonprescription skin protectants as long as there are no exclusions for self-

Relevant Evaluation Criteria	Scenario/Model Outcome
therapeutic approach from the considered therapeutic alternatives.	treatment, as in your case.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See the box “Patient Education for Minor Burns and Sunburn.”
Solicit follow-up questions from the patient or caregiver.	“Should I apply triple antibiotic ointment to the burn?”
Answer the patient’s or caregiver’s questions.	“No. You do not need to apply triple antibiotic ointment because your risk of infection is very low.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome	“If you provide me with your phone number, I will give you a call in 7 days to see how you are healing.”

Case 41–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s)	The patient complains of a wound secondary to a dog bite on

Relevant Evaluation Criteria	Scenario/Model Outcome
(i.e., nature, onset, duration, severity, associated symptoms)	the back of her right calf. She was bitten by the neighbor's dog on her walk an hour ago. The area is red and swollen. One large puncture wound from the dog's teeth is visible, but the bleeding has stopped. The patient reports her pain as a 4 (on a scale of 1-10, with 10 being the worst).
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient reports that she experiences slight pain when walking, and that the area is slightly tender to the touch.
c. Description of the patient's efforts to relieve the symptoms	She washed the wound with soap and water when she got home.
d. Patient's identity	Keisha Ford
e. Age, gender, height, and weight	47 years old, female, 5 ft 5 in, 140 lb
f. Patient's occupation	Teacher
g. Patient's dietary habits	Gluten-free diet
h. Patient's sleep habits	8 hours a night
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) -----	None
Assess	
2. Differentiate patient's signs/symptoms and	Keisha is suffering from a wound secondary to a dog bite.

Relevant Evaluation Criteria	Scenario/Model Outcome
correctly identify the patient's primary problem(s).	
3. Identify exclusions for self-treatment.	Wound secondary to animal bite
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to an appropriate health care provider. (2) Recommend self-care with a nonprescription analgesic and nondrug measures. (3) Recommend self-care until the patient can see an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient should consult her primary care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult your primary care provider for treatment because self-treatment is not recommended for animal bites."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Wounds secondary to an animal bite require immediate medical attention to assess the need for systemic or topical antibiotics and potentially a tetanus booster to prevent infection. Seek medical help immediately."
Implement	
8. When recommending self-	Criterion does not apply in this case.

Relevant Evaluation Criteria	Scenario/Model Outcome
care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
Solicit follow-up questions from the patient or caregiver.	"Should I flush the wound with hydrogen peroxide to sterilize the area?"
Answer the patient's or caregiver's questions.	"No. Agents such as hydrogen peroxide cause damage to the injured skin and should be avoided. Cleanse the wound by irrigating it with running cool tap water. Gently pat it dry with a clean gauze pad. Apply a nonprescription first aid antibiotic or skin protectant, and cover the wound with a nonadherent wound dressing. See your primary care provider immediately to assess the need for further treatment.
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact the patient in 1-2 days to ensure that she sought proper medical care.

Patient Counseling for Minor Burns, Sunburn, and Wounds

Once a minor burn or wound is assessed as self-treatable, a discussion of cooling a burn and proper cleansing of a wound is appropriate. Ideally, cooling of a burn should occur immediately via irrigation with tepid tap water and last 20 minutes. However, this procedure is beneficial if it occurs within 3 hours after the burn occurred. Patients should be instructed to cleanse a wound through irrigation with tap water. Pain should be addressed and any necessary treatment recommendations provided. The patient should be advised how to promote moist wound healing, prevent infection, and, if needed, protect the injury with a skin protectant and wound dressing. Selection of a wound dressing should be based on wound characteristics. Patients should be

instructed to change a dressing only when it is soiled or not intact. Information on prevention of scarring with the use of skin protectants, prevention of UVR exposure, and application of silicone after the wound has healed also should be shared with the patient.

Because the inflammatory response to burns may evolve over the first 24–48 hours, follow-up for a burn injury should occur 24–48 hours after the injury to determine whether continuation of self-treatment or referral for further evaluation should be recommended. Patients should be educated on the signs and symptoms that indicate worsening of the injury. Minor acute superficial and superficial partial-thickness skin injuries should be healing satisfactorily by 7 days and fully healed by 14 days. Scar prevention and/or management may continue after the wound is healed. Medical referral for further evaluation is warranted if the skin injury does not show signs of healing after 7 days of self-treatment.

The box “Patient Education for Minor Burns, Sunburn, and Wounds” lists specific measures to provide patients to promote successful self-treatment for these injuries.

Patient Education for Minor Burns, Sunburn and Wounds

The objectives of self-treatment are (1) to relieve symptoms, (2) to promote healing by protecting the burn or wound from infection and further trauma, and (3) to minimize scarring. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Treat superficial burns with no blistering as follows:
 - Irrigate the affected area with cool (not cold) tap water for 20 minutes.
 - If the patient did not cool the area in the first 20 minutes after the burn, benefit is still observed by cooling a burn up to 3 hours after it occurred.

- Cleanse the area with cool (not cold) tap water.
 - Apply a skin protectant and wound dressing to promote moist wound healing.
- For small burns with minor blistering, follow the first two steps above; then apply a dressing. A hydrocolloid dressing may best protect the blistered burn. If possible, avoid rupture of the blisters.
- For sunburns, avoid further sun exposure, and follow the previous procedures according to whether blistering is present.
- If a wound is dirty, irrigate it with tepid tap water or normal saline solution, which is not toxic to cells. If it still contains debris after irrigation, the patient should seek care from their primary care provider.
- Apply a skin protectant and cover the wound with a dressing that will keep the wound site moist. Make sure the dressing is the appropriate size and contour for the affected body part.
- Continue using a moist wound dressing until the wound bed has firmly closed and signs of inflammation in surrounding tissue have subsided. This process usually takes 1–2 weeks. Failure to keep the wound covered may delay healing.
- Avoid disrupting the dressing unnecessarily; change the dressing only if it becomes soiled or is not intact. More frequent changes may remove resurfacing layers of epithelium and slow the healing process.

Nonprescription Medications

- For minor acute burns, sunburn, and wounds, treat the affected area with a thin application of a skin protectant.
- Topical skin protectants, such as Aquaphor, may be as effective as topical antibiotics to promote moist wound healing and prevent infection.
- For temporary relief of pain, take acetaminophen, ibuprofen, or naproxen. (See [Chapter 5](#) for dosage guidelines and safety considerations.)
- If a topical anesthetic is used for pain relief, avoid use on large areas of the body to prevent systemic absorption.

Evaluation of Patient Outcomes for Minor Burns, Sunburn, and Wounds

Burns should be reassessed after 24–48 hours because the full extent of skin damage may not be apparent at the first counseling session. If the extent or severity of the burn has progressed or worsened, the patient should be referred to an appropriate health care provider for further evaluation.

Minor burns and wounds should exhibit decreased redness and inflammation during healing. Signs that indicate the need for further evaluation by a health care provider include evidence of cellulitis or tissue infection, such as increasing redness, pain, and swelling that extend beyond the boundaries of the original wound.

Follow up with the patient should occur after 7 days to assess the healing progress. If the burn or wound shows no signs of healing or has worsened in nature or degree (as indicated by a foul odor or increased inflammation), the patient should be referred to a health care provider.

Key Points for Minor Burns, Sunburn, and Wounds

- Minor acute superficial and superficial partial-thickness burns, sunburn, and wounds often can be treated with self-care measures.
- Moist wound healing is considered the standard of care.
- Burn injuries should be treated with cool (not cold) tap water for the first 20 minutes after the burn occurred, but benefit is seen with cooling the injury up to 3 hours after the burn.
- Burn injuries may increase in severity over the first 24–48 hours, so reassessment is necessary.
- Patient complaints usually focus on pain. Skin protectants and

moist wound dressings should be recommended, and NSAIDs or acetaminophen may be helpful.

- Proper selection of first aid products, including appropriate wound dressing, is essential.
- Blisters should not be ruptured. If large blisters are present, the patient should be referred for medical treatment.
- Skin protectants, such as Aquaphor, are as effective as first aid antibiotics in promoting moist wound healing and preventing infection.
- Moist wound healing is critical for scar prevention. Use of skin protectants or silicon and prevention of sun exposure are useful for preventing and treating scars.

Chapter 42: Fungal Skin Infections

Authors: Megan G. Smith

Approximately 20%–25% of the world’s population suffers from fungal skin infections, including dermatophyte, non-dermatophyte, and candidal infections, with dermatophyte fungi being responsible for a majority of the cases.^{1,2} Most fungal infections are a result of a barrier breakdown in either the skin or nail or an associated comorbid condition affecting host defense mechanisms, including diabetes, obesity, and/or an immunocompromised state.^{1,3}

Fungal infections usually are superficial and can involve the hair, nails, and skin. The term *tinea* refers exclusively to dermatophyte infections. Most often, tinea infections are named according to the area of the body that is affected (e.g., scalp [tinea capitis]; groin [tinea cruris]; body [tinea corporis]; feet [tinea pedis]; nails [tinea unguium]).

Although many pathogenic fungi are recognized, the overall prevalence of actual superficial fungal infections is remarkably low. An estimated 10%–20% of the U.S. population will suffer from a tinea infection at any one time.^{4,5} Differing degrees of susceptibility, ranging from instantaneous “takes” by a single spore to severe trauma with massive exposure, can lead to clinical infection. Trauma to the skin, especially producing blisters (e.g., from wearing ill-fitting footwear), appears to be significantly more important than simple exposure to the offending pathogens.^{5,6}

In addition to specific fungi, other environmental factors, such as climate and social customs, contribute to dermatophytosis development. Footwear is a key variable, as illustrated by the notable incidence of tinea pedis in wearers of occlusive footwear, especially in the summer and in tropical or subtropical climates. Nonporous shoe material increases temperature and hydration of the skin, which interferes with the barrier function of the stratum corneum. Similarly, sweating and wearing wet clothing for long periods of time are predisposing factors for the development of tinea corporis and tinea cruris.

Other factors associated with the development of tinea infections include diabetes and other autoimmune diseases, use of immunosuppressive drugs, impaired circulation, and poor nutrition and hygiene.^{5,6} For example, patients

with diabetes or human immunodeficiency virus infection and older persons taking medications such as glucocorticoids should be instructed to self-monitor for signs and symptoms of tinea infections. The importance of proper hygiene and diet for prevention of tinea infections and other health problems also should be emphasized.

The most prevalent cutaneous fungal infection in humans is *tinea pedis*—dermatophytosis of the foot, or athlete's foot. Tinea pedis afflicts approximately 26.5 million people in the United States every year; 7 of every 10 persons affected are male. Approximately 45% will suffer with tinea pedis episodically for longer than 10 years. When exposure to infectious environments is equal, the incidence of tinea pedis infections in women approaches that in men.^{4–8} Tinea pedis is rare among blacks but common in whites, particularly those who live in urban tropical areas.⁹ An estimated 70% of people will be afflicted with tinea pedis in their lifetime. Although tinea pedis may occur at all ages, it is more common in adults, presumably because of the increased opportunities for exposure to pathogens in this age group.⁵

The risk for development of tinea pedis is greater in persons who use public pools or bathing facilities than in the general population. However, tinea pedis may be acquired in the home if one or more members of the household are already infected. High-impact sports that cause chronic trauma to the feet (e.g., long-distance running) also predispose athletes to the development of tinea pedis.^{4,5,10} The trauma affords pathogenic fungi the opportunity to invade the outer layers of the skin. In addition, wearing socks and shoes exacerbates the problem by impeding the dispersion of heat and the evaporation of moisture, both of which facilitate fungal growth. By contrast, people who most often use footwear that allows the feet to remain cool and dry (e.g., sandals) are less likely to develop tinea pedis.⁴

Tinea unguium—ringworm of the nails, or onychomycosis—causes about one half of all nail disorders and is sometimes associated with tinea pedis. The prevalence of tinea unguium is approximately 14%, and the incidence among children also has increased to approximately 20% of diagnosed dermatophyte infections.^{5,11} The U.S. Food and Drug Administration (FDA) has not approved topical self-treatment for onychomycosis. Rather, the condition must be treated with systemic prescription drug therapy (e.g., terbinafine, itraconazole), prescription combination topical (e.g., ciclopirox olamine 8% or efinaconazole 10% nail solutions) and systemic oral therapy, or surgical removal of the

affected nail.¹²

The next two most common fungal infections are tinea corporis and tinea cruris. *Tinea corporis*, also called ringworm of the body, is most common in the prepubescent age group. It is frequently transmitted among children in daycare centers and among teenage and younger athletes who participate in contact sports, such as wrestling. Additionally, this form of ringworm is more prevalent overall in adults and children who live in hot, humid climates. Persons who are under stress, overweight, or immunosuppressed also are at increased risk for development of tinea corporis.^{1,5,13}

Tinea cruris, or jock itch, often manifests as a pruritic, red rash and is most common during warm weather; however, it can occur at any time of the year if the skin in the groin area stays warm and moist for long periods. For example, sweating or prolonged contact with wet clothing provides ideal conditions for the growth of fungi. Tinea cruris occurs up to three times more often in men than in women and rarely affects children.⁵ Close indirect or direct physical contact between infected males and noninfected females does not mitigate the higher prevalence of tinea cruris in males. For example, females who live in the same household with infected males do not develop infections at the same rate as for noninfected males in the same household.⁵

Although its true incidence is unknown, *tinea capitis*, or ringworm of the scalp, occurs most often in children, both because their likelihood of having contact with infected persons is higher and because they are less attentive than adults to personal hygiene. Tinea capitis is the most common dermatophyte infection in children 3–14 years of age.^{5,10} Compared with black males and white children, black female children are infected more often, possibly because of the hair care products and practices (e.g., occlusive hair dressings, tight braiding) that are unique to this population.^{5,13} Tinea capitis can be spread by direct contact with an infected person, but spread often occurs by contact with infected fomites (e.g., using infected combs, toys, or telephones; wearing infected clothing or hats; using contaminated towels; sleeping on infected linens). In some instances, tinea capitis is spread through contact with other infected persons or with infected cats or dogs.¹⁴ As with onychomycosis, tinea capitis cannot be managed with nonprescription antifungals.

Pathophysiology of Fungal Skin Infections

Tinea infections are caused by three genera of pathogenic fungi: *Trichophyton*, *Microsporum*, and *Epidermophyton*.^{3,12,15} Tinea pedis and tinea cruris are caused by species of *Epidermophyton* and *Trichophyton*. Species of *Trichophyton* and *Microsporum* cause ringworm of the scalp. *Trichophyton* species also cause onychomycosis. Fungi of all three genera can cause tinea corporis, although *Trichophyton* is most common.⁵

Dermatomycoses often are referred to as ringworm because their characteristic lesions are ring-shaped, with clear centers and red, scaly borders. However, morphologic features can vary, and clinical findings may include single or multiple lesions that range from mild scaling to deep *granulomas* (inflamed, nodular lesions). The most common causative agents of dermatomycoses are *Trichophyton rubrum*, *Trichophyton tonsurans*, and *Trichophyton mentagrophytes*. *T. rubrum* is the most commonly isolated dermatophyte in the United States.^{1,10} Non-dermatophytes and species of *Candida* and other yeasts also may be involved in fungal skin infections; however, no nonprescription antifungals are currently available for self-management of cutaneous infections due to yeasts.¹⁶

Fungal transmission can occur through contact with infected people, animals, soil, or fomites. Dermatophytes are classified according to their natural habitat: anthropophilic (humans), zoophilic (animals), and geophilic (soil). Most tinea infections are caused by person-to-person contact with patients infected with anthropophilic dermatophytes.¹³

After a dermatophyte is inoculated into the skin under suitable conditions, a tinea infestation progresses through several stages: After an initial period of incubation, the infection progresses through stages of adherence and penetration, followed by a refractory period and a stage of involution. During the incubation period, the dermatophyte grows in the stratum corneum, sometimes with minimal signs of infection. After the incubation period and once the infection is established, two factors appear to play a role in determining the size and duration of the lesions: the growth rate of the organism and the epidermal turnover rate.¹⁷ The fungal growth rate must equal or exceed the epidermal turnover rate; otherwise the organism will be quickly shed.

Clinical Presentation of Fungal Skin

Infections

The clinical spectrum of tinea infections ranges from mild itching and scaling to a severe, exudative inflammatory process characterized by denudation, fissuring, crusting, and/or discoloration of the affected skin. Persons experiencing their first tinea infection and patients with infections secondary to zoophilic fungi tend to present with a greater degree of inflammation.¹³ **Table 42–1** summarizes key differences among fungal skin infections, contact dermatitis, and bacterial skin infections, to distinguish the underlying cause of a patient’s symptoms from other conditions that may have a similar clinical presentation.

TABLE 42–1 Differentiation of Fungal Skin Infections and Skin Disorders With Similar Presentations

Criterion	Fungal Skin Infection	Contact Dermatitis	Bacterial Skin Infection
Location	On or in areas of the body where excess moisture accumulates, such as the feet, groin, scalp, and underarms	Any area of the body exposed to the allergen/irritant; hands, face, legs, ears, eyes, and anogenital area most often involved	Anywhere on the body
Signs	Manifests either as soggy malodorous, thickened skin; acute vesicular rash; or fine scaling of affected area with a variable degree of inflammation; cracks and fissures in more severe cases	Manifests as a variety of lesions: raised wheals, fluid-filled vesicles, or both	Manifests as a variety of lesions, from macules to pustules to ulcers with surrounding redness; lesions often warmer than surrounding, unaffected skin
Symptoms	Itching and pain	Itching and pain	Irritation and pain
Distribution	Usually localized to a single region of the body but can spread	Affects all areas of exposed skin but does not spread	Usually localized to a single region of the body but can spread
Timing	Variable onset after exposure	Variable onset from immediately after exposure to 3	Variable onset after exposure

Criterion	Fungal Skin Infection	Contact Dermatitis	Bacterial Skin Infection
		weeks after contact	
Cause	Superficial fungal infection	Exposure to skin irritants or allergens	Superficial bacterial infection
Modifying factors	Treated with nonprescription astringents, antifungals, and nondrug measures to keep the area clean and dry	Treated with topical antipruritics, skin protectants, astringents, and nondrug measures to avoid reexposure	Treated with prescription antibiotics

Tinea Pedis

Clinically, tinea pedis has four accepted variants; two or more of these types may overlap. The most common is the *chronic interdigital* type,⁵ characterized by fissuring, scaling, or maceration in the interdigital spaces; malodor; pruritus; and/or a stinging sensation on the feet (see [Color Plates](#), photograph 31).

Typically, the infection involves the lateral toe webs, usually between either the fourth and fifth or the third and fourth toes. From these sites, the infection may spread to the sole or instep of the foot but rarely to the dorsum. Warmth and humidity aggravate this condition; if present, *hyperhidrosis* (excessive sweating) then becomes a major contributing factor and must be addressed along with the dermatophyte infestation.⁵

After initial invasion of the stratum corneum by dermatophytes, enough moisture may accumulate to trigger bacterial overgrowth. Increased moisture and temperature then lead to the release of metabolic products that readily diffuse through the underlying horny layer already damaged by fungal invasion. In more severe cases, gram-negative organisms intrude and may exacerbate the condition, causing skin maceration, white hyperkeratosis, or erosions with worsening symptomatology.⁵

The second variant of tinea pedis is the *chronic hyperkeratotic* type.⁹ It usually involves both feet and is characterized by mild inflammation and diffuse scaling in a moccasin-like distribution on the soles and lateral and medial aspects of the feet. Tinea unguium of one or more toenails also may be present and may continue to fuel the infection.

The third variant of tinea pedis is the *vesicular* type, usually caused by *T. mentagrophytes* var. *interdigitale*.¹⁵ Small vesicles or vesicopustules are observed near the instep and on the mid-anterior plantar surface. Skin scaling is seen in these areas as well as on the toe webs. This variant is symptomatic in the summer and is clinically quiescent during the cooler months.

The *acute ulcerative* type is the fourth and least common variant of tinea pedis. It often is associated with macerated, denuded, weeping ulcerations on the sole of the foot. Typically, white hyperkeratosis and a pungent odor are present. The term *dermatophytosis complex* has been used to describe this type of infection, which is complicated by an overgrowth of opportunistic, gram-negative bacteria such as *Proteus* and *Pseudomonas*. Such infections may feature one or more extremely painful, erosive, purulent interdigital spaces that can impede the patient's ability to walk.⁵

Tinea Unguium

Nails affected by tinea unguium gradually lose their normal shiny luster and become opaque. If left untreated, the nails become thick, rough, yellow, opaque, and friable. The nail may separate from the nail bed if the infection progresses secondarily to subungual hyperkeratosis. Ultimately, the nail may be lost altogether. Subungual debris also provides an excellent medium for the growth of opportunistic bacteria and other microorganisms, which can lead to further infectious complications.⁵

Tinea Corporis

Tinea corporis may have diverse clinical manifestations. Most often, the lesions, which involve *glabrous* (smooth and bare) skin, begin as small, circular, erythematous, scaly areas. The lesions spread peripherally, and the borders may contain vesicles or pustules. Infected persons also may complain of pruritus.¹⁸

Tinea corporis can occur on any part of the body. However, the location of the infection can provide clues to the type of infecting dermatophyte. For example, zoophilic dermatophytes often infect areas of exposed skin such as the neck, face, and arms. By contrast, infections secondary to anthropophilic dermatophytes often occur in occluded areas or in areas of trauma.⁵

Tinea Cruris

Tinea cruris is more common in males and occurs on the medial and upper parts of the thighs and the pubic area. The lesions have well-demarcated margins that are slightly elevated and are more erythematous than the central area; small vesicles may be seen, especially at the margins. Acute lesions are bright red, and in chronic cases the skin tends to have a more hyperpigmented appearance; fine scaling usually is present. This condition generally is bilateral, with significant pruritus; of note, however, the lesions usually spare the penis and scrotum. The characteristic lack of involvement of these areas can help to distinguish tinea cruris from candidiasis, which more typically affects the entire region.¹⁹ Pain also may be present during periods of sweating or when the skin becomes macerated or infected by a secondary microorganism.^{4,5}

Tinea Capitis

Clinically, tinea capitis may manifest as one of four variant patterns, depending on the causative dermatophyte. In *noninflammatory* tinea capitis, lesions begin as small papules surrounding individual hair shafts. Subsequently, the lesions spread centrifugally to involve all hairs in their path. Although there is some scaling of the scalp, little inflammation is present (see [Color Plates](#), photograph 32). Hairs in the lesions are a dull gray color and usually break off above the scalp level.⁵

The *inflammatory* type of tinea capitis produces a spectrum of inflammatory changes ranging from pustules to kerion formation. *Kerions* are weeping lesions whose exudate forms thick crusts on the scalp.⁸ In addition to fever and pain, patients with this type of tinea capitis may experience more intense pruritus. Regional lymph nodes also may be enlarged.⁵

The *black dot* variety of tinea capitis was named for the appearance of infected areas of the scalp. The location of arthrospores at the base of the hair shaft causes hairs to break off at the level of the scalp, leaving black dots on the scalp surface. Hair loss, inflammation, and scaling with this type of tinea capitis range from minimal to extensive. Therefore, this variant is especially challenging to diagnose.^{5,20,21}

The *favus* variant of tinea capitis typically manifests as patchy areas of hair loss and *scutula* (yellowish crusts and scales). Ultimately, these lesions can coalesce

to involve a major portion of the scalp. If left untreated, this condition can lead to secondary bacterial infections, scalp atrophy, scarring, and permanent hair loss.⁵

Treatment of Fungal Skin Infections

Overall, fungal skin infections do not have a significant impact on mortality; however, they can be difficult to treat, leading to chronic lesions and a decrease in quality of life.¹⁵

Treatment Goals

The goals of self-treatment for fungal skin infections are (1) to provide symptomatic relief, (2) to eradicate existing infection, and (3) to prevent future infections.

General Treatment Approach

In many instances, effective self-treatment for tinea pedis, tinea corporis, and tinea cruris can be achieved with nonprescription topical antifungals and nonpharmacologic measures. However, persons with tinea unguium or tinea capitis should be referred to their primary care provider or a dermatologist for treatment.

Before recommending therapy, the health care provider must be reasonably sure that the lesions are consistent with a tinea infection. Their appearance should conform to the descriptions provided in the section “Clinical Presentation of Fungal Skin Infections,” and the [Color Plates](#) photographs 31 and 32 of tinea lesions should be consulted for comparison. Furthermore, the lesions should not resemble any other skin conditions. When the true cause of a condition is in doubt, the patient should be advised to consult a dermatologist or other knowledgeable health care provider. [Figure 42–1](#) outlines appropriate self-treatment options for fungal skin infections.

A number of topical antifungals are available in a variety of dosage forms for self-treatment for fungal skin infections. The selection of a particular product depends on the type of infection and on individual patient characteristics and preferences. For example, in acute inflammatory tinea pedis, characterized by

reddened, oozing, and vesicular eruptions, the inflammation must be counteracted with solutions of astringent aluminum salts before antifungal therapy can be instituted.

A critical determinant of the outcome of therapy is the patient's ability to adhere to the recommended treatment regimen for the appropriate length of time. Adherence may be difficult, because these conditions may take between 2 to 6 weeks to resolve ([Table 42-2](#)). Patients may be tempted to terminate therapy when their symptoms subside but before the infection has been eradicated.

TABLE 42-2 Selected Nonprescription Topical Antifungal Products

Trade Name	Active Ingredient	Indications for Use	Directions for Use
Desenex Antifungal Powder	Miconazole 2%	For adults and children older than 2 years of age	For jock itch and ringworm, apply twice daily for 2 weeks.
			For athlete's foot, apply twice daily for 4 weeks.
Lotrimin AF Jock Itch Antifungal Powder Spray	Miconazole 2%	For adults and children older than 2 years of age	For athlete's foot and ringworm, apply twice daily for 4 weeks.
			For jock itch, apply twice daily for 2 weeks.
Micatin Antifungal Cream	Miconazole 2%	For adults and children 2 years of age and older	For athlete's foot and ringworm, apply twice daily for 4 weeks.
			For jock itch, apply twice daily for 2 weeks.
Lotrimin AF Clotrimazole Jock Itch Cream	Clotrimazole 1%	For adults and children 2 years of age and older	For athlete's foot and ringworm, apply twice daily for 4 weeks.
			For jock itch, apply daily for 2 weeks.
Lotrimin	Butenafine	For adults	For athlete's foot between the toes, apply twice

Trade Name	Active Ingredient	Indications for Use	Directions for Use
Ultra Jock Itch Cream	1%	and children 12 years and older	daily for 1 week, or once daily for 4 weeks.
			For jock itch and ringworm, apply once daily for 2 weeks.
Lamisil AT (cream, spray)	Terbinafine 1%	For adults and children 12 years and older	For athlete's foot between the toes, apply twice daily for 1 week.
			For jock itch and ringworm, apply once daily for 1 week.
Tinactin Athlete's Foot Cream	Tolnaftate 1%	For adults and children 2 years of age and older	For athlete's foot and ringworm, apply daily for 4 weeks.
			For jock itch, apply daily for 2 weeks.
Tinactin Powder Spray	Tolnaftate 1%	For adults and children 2 years of age and older	For athlete's foot and ringworm, spray twice daily for 4 weeks.
			For prevention, spray 1-2 times daily.
Fungicure (solution, cream)	Undecylenic acid 10%, 22%, 25%	For adults 18 years of age and older	For ringworm and athlete's foot, apply twice daily for 4 weeks.
Hypercare	Aluminum chloride	For adults with hyperhidrosis	Apply daily at bedtime; once excessive sweating has stopped, decrease to once or twice weekly or as needed.
Domeboro	Aluminum acetate	Temporary relief of minor skin irritation	<i>Soak:</i> Soak affected area in solution for 15-30 minutes as needed. May repeat 3 times daily.
			<i>Wet dressing:</i> Soak a clean, soft, white cloth in solution and apply loosely to affected area for 15-30 minutes; may repeat as needed for 4 to 8 hours.

Nonpharmacologic Therapy

Another determinant of therapeutic outcome is the patient's adherence to recommended nonpharmacologic measures recognized as important components of management of fungal infections, for both treatment and prophylaxis. These measures include keeping the skin clean and dry, avoiding the sharing of personal articles, and avoiding contact with infected fomites or persons who have a fungal infection.

The box "Patient Education for Fungal Skin Infections" describes nonpharmacologic measures intended to complement the effects of nonprescription antifungals and to prevent future infections. The patient should follow these measures during and after treatment of the infection.

Pharmacologic Therapy

An antifungal agent or ingredient must have at least one well-designed clinical trial that demonstrates its effectiveness in treating tinea infections before FDA will classify it as an approved agent for inclusion in the antifungal monograph.²² Clotrimazole, miconazole nitrate, terbinafine hydrochlorate, butenafine hydrochloride, tolnaftate, and undecylenic acid are considered safe and effective nonprescription topical agents for the treatment of fungal skin infections.¹⁶ Rare cases of mild skin irritation, burning, and stinging have occurred with use of nonprescription topical antifungals. These agents are labeled for treatment of athlete's foot, jock itch, and body ringworm. Nystatin (prescription only) is effective only for yeasts, not dermatophytes, and therefore should not be used for tinea infections.²³

Clotrimazole and Miconazole Nitrate

Topical clotrimazole and miconazole nitrate are imidazole derivatives that demonstrate fungistatic/fungicidal activity (depending on concentration) against *T. mentagrophytes*, *T. rubrum*, *Epidermophyton floccosum*, and *Candida albicans*.

These agents act by inhibiting the biosynthesis of ergosterol and other sterols and by damaging the fungal cell wall membrane, thereby altering its permeability and resulting in the loss of essential intracellular elements. These drugs also have been shown to inhibit the oxidative and peroxidative enzyme

activity that results in intracellular buildup of toxic concentrations of hydrogen peroxide; this toxicity may then contribute to the degradation of subcellular organelles and to cellular necrosis. In *C. albicans* infections, these drugs have been shown to inhibit the transformation of blastospores into the invasive mycelial form that causes infection.

FDA classifies clotrimazole 1% and miconazole nitrate 2% as safe and effective for topical nonprescription use in treating tinea pedis, tinea cruris, and tinea corporis. Clotrimazole and miconazole nitrate are applied twice daily. For athlete's foot and ringworm, these drugs should be applied twice daily for 4 weeks; for jock itch, they should be applied twice daily for 2 weeks.

A drug–drug interaction between warfarin and topical miconazole cream is possible: Coadministration of the drugs may increase the effects of warfarin.²⁴ No other drug–drug interactions have been reported with topical use of clotrimazole and miconazole nitrate for up to 4 weeks.¹⁶

Terbinafine Hydrochloride

Topical terbinafine hydrochloride 1% is an allylamine antifungal agent that inhibits squalene epoxidase, a key enzyme in fungal sterol biosynthesis. This inhibiting effect results in a deficiency in ergosterol and a corresponding accumulation of squalene within the fungal cell, causing fungal cell death. Terbinafine hydrochloride is indicated for interdigital tinea pedis, tinea cruris, and tinea corporis caused by *E. floccosum*, *T. mentagrophytes*, and *T. rubrum*. Similar to miconazole and clotrimazole, terbinafine hydrochloride should be applied sparingly to the affected area twice daily.

In clinical trials, this drug was demonstrated to provide mycologic cure of tinea pedis with 1 week of treatment. However, complete resolution of symptoms may require up to 4 weeks of treatment. For athlete's foot between the toes, terbinafine should be applied twice a day for 1 week. For athlete's foot on the bottom or sides of the foot, it should be applied twice a day for 2 weeks. For jock itch and ringworm, patients should apply terbinafine once a day for 1 week or as directed by the patient's primary care provider.

Clinical trials to date have demonstrated a low incidence of adverse effects for terbinafine hydrochloride. Such effects include irritation (1%), burning (0.8%), and itching/dryness (0.2%).^{25,26} No drug–drug interactions have been reported with topical use of this agent.

Butenafine Hydrochloride

Topical butenafine hydrochloride 1% also is an antifungal squalene epoxidase inhibitor. This mechanism of action results in a deficiency in ergosterol, a corresponding accumulation of squalene within the fungal cell, and eventually cell death.

Butenafine hydrochloride is indicated as a clinical and mycologic cure for tinea pedis between the toes, tinea cruris, and tinea corporis caused by *E. floccosum*, *T. mentagrophytes*, and *T. rubrum*. Similar to other nonprescription topical antifungals, butenafine hydrochloride also relieves the itching, burning, cracking, and scaling that can accompany these conditions. This agent's effectiveness for eradicating infection of the bottom or sides of the foot is unknown.

Patients suffering from tinea pedis should be advised to apply a thin film to affected skin between and around toes twice daily for 1 week or once a day for 4 weeks, based on patient preference, or as directed by the patient's primary care provider. Patients with tinea cruris or tinea corporis should apply a thin film to the affected area once daily for 2 weeks or as directed by the primary care provider.

Effective treatment rates of butenafine for interdigital tinea pedis with 1-week and 4-week application durations are reported to be approximately 38% and 74%, respectively. In clinical trials, butenafine kept users free of tinea pedis for up to 3 months.²⁷ To date, clinical trials demonstrate a low incidence of adverse effects, limited to burning and itching, for this agent.^{27,28} Furthermore, no drug–drug interactions have been reported with its topical use.

Tolnaftate

Topical tolnaftate has demonstrated clinical efficacy since its commercial introduction in the United States in 1965. In addition, for many years, it was the standard against which the efficacy of other topical antifungals was compared. Tolnaftate is approved for treatment of tinea pedis, tinea cruris, and tinea corporis.

Although tolnaftate's exact mechanism of action has not been reported, tolnaftate is thought to distort the hyphae and stunt the mycelial growth of the fungi species. Tolnaftate is the only nonprescription drug approved for

both preventing and treating tinea infections.¹⁶ It acts on fungi that are typically responsible for tinea infections, including *T. mentagrophytes*, *T. rubrum*, and *E. floccosum*.

Tolnaftate is valuable primarily in treating the dry, scaly lesions. Relapse of superficial fungal infections has occurred after discontinuation of tolnaftate therapy. Relapse may be caused by inadequate duration of treatment, patient nonadherence with the medication, or use of tolnaftate when an oral antifungal should have been used.

As a cream, tolnaftate is formulated in a polyethylene glycol 400/propylene glycol vehicle. The 1% solution is formulated in polyethylene glycol 400 and may be more effective than the cream. The solution solidifies when exposed to cold but liquefies with no loss in potency if allowed to warm. These vehicles are particularly advantageous in superficial antifungal therapy, because they are nonocclusive, nontoxic, nonsensitizing, water-miscible, anhydrous, easy to apply, and efficient in delivering the drug to the affected area.

The topical powder formulation of tolnaftate uses cornstarch/talc as the vehicle. The two agents combined absorb excess moisture in the affected area that allows fungus to thrive. The topical aerosol formulation of tolnaftate includes talc, alcohol, and the propellant vehicle.

Tolnaftate (1% solution, cream, gel, powder, spray powder, or spray liquid) is applied sparingly twice daily. Effective therapy usually takes 2–4 weeks, depending on the type of infection. For example, a patient should experience improvement of symptoms with tinea cruris within 2 weeks, but treatment for tinea pedis and tinea corporis may take 4–6 weeks. Tolnaftate is well tolerated when applied to intact or broken skin, although it usually stings slightly when applied. Delayed hypersensitivity reactions to tolnaftate are extremely rare. No drug–drug interactions have been reported with topical use of tolnaftate.

Undecylenic Acid

Undecylenic acid is an antifungal fatty acid providing astringent action that reduces rawness and irritation. It is commercially available as a solution that contains undecylenic acid 25%. For tinea pedis and corporis, it is applied twice daily for 4 weeks. For tinea cruris, it is applied twice daily for 2 weeks. Common adverse effects include local skin irritation and burning sensations. There are no known significant drug–drug interactions.

Salts of Aluminum

Because aluminum salts do not have any direct antifungal activity, these drugs are not included in the FDA final monograph for topical antifungal drug products. Rather, they are approved for the relief of inflammatory conditions of the skin, such as tinea pedis. However, their effectiveness as astringents and their possible use in treating tinea pedis merit their inclusion in this chapter. Historically, aluminum acetate has been the foremost astringent used for both the acute, inflammatory type and the wet, soggy type of tinea pedis. Aluminum chloride is also used to treat the wet, soggy type of infection.

Aluminum salts do not provide a definitive cure for athlete's foot but are useful when combined with other topical antifungal drugs. Application of solutions of aluminum salts merely shifts the disease process back to the simple dry type of athlete's foot, which can then be controlled with other agents such as tolnaftate or an imidazole.

Aluminum acetate for use in tinea pedis generally is diluted with about 10–40 parts of water. Depending on the clinical situation, the whole foot may be immersed in the solution for 20 minutes up to 3 times a day (every 6–8 hours), or the solution may be applied to the affected area in the form of a wet dressing.

For patient convenience, aluminum acetate solution (Burow's solution) or modified Burow's solution (which includes dextrin, polyethylene glycol, and sodium bicarbonate as inactive ingredients) is available for immediate use or as products formulated to be dissolved in water (powder packets, powder, effervescent tablets) (see [Chapter 35](#)). For preparation of packet-ready products, 1–3 packets are dissolved in 16 ounces of water.

Aqueous solutions of 20%–30% aluminum chloride have been the most beneficial for management of the wet, soggy type of athlete's foot.⁷ Twice-daily applications generally are used until the signs and symptoms (odor, wetness, whiteness) abate. After that, once-daily applications may be sufficient for control of symptoms. In hot, humid weather, the original condition may return within 7–10 days after the applications are stopped.

Pharmacotherapeutic Comparison

All of the topical antifungals approved for treating cutaneous fungal infections

have demonstrated effectiveness.^{28,29} A systematic Cochrane review of the data on tinea cruris and tinea corporis treatment found no superiority of one class over another; most evidence was of low quality, however, and clinical outcomes could be pooled only for terbinafine.²⁹ The allure of butenafine hydrochloride and terbinafine hydrochloride is their ability to cure athlete's foot in some patients after 1 week. A randomized trial of butenafine and clotrimazole for tinea cruris and tinea corporis showed butenafine to produce higher rates of clinical and mycologic cure at the end of week 1, yet no significance difference at 4 and 8 weeks of treatment.³⁰

A systematic review and meta-analysis for the treatment of any dermatomycosis also supports the effectiveness of azoles, allylamines, and other antifungals compared with placebo.³¹ There was no significant difference in efficacy rate between azoles and allylamines, but cure outcomes appeared to be sustained with allylamines (e.g., terbinafine) compared with azoles. No differences were found in safety or tolerability for any of the antifungal classes.³¹

Product Selection Guidelines

Before recommending a nonprescription product, the health care provider should review the patient's medical history for comorbid conditions affecting management. With coexisting diabetes, for example, good control of blood glucose levels is necessary because increased glucose in perspiration may promote fungal growth. Patients with allergic dermatitis often have a history of asthma, hay fever, or atopic dermatitis, so they may be extremely sensitive to many oral and topical agents. Acquiring a thorough medical history may aid in distinguishing a tinea infection from atopic dermatitis and may avoid the recommendation of a product that might cause further skin irritation.

Cutaneous antifungals are available as ointments, creams, powders, and aerosols ([Table 42-2](#)). Creams or solutions are the most efficient and effective dosage forms for delivery of the active ingredient to the epidermis and are preferable for dry and scaly tinea pedis. However, gels and sprays are preferred for macerated, erosive interdigital tinea pedis.²³

Patient adherence is influenced by product selection. Accordingly, the provider should recommend a drug and dosage form that are likely to cause the least interference with daily habits and activities, without sacrificing efficacy. For

example, older patients may require a preparation that is easy to use. Obese patients, in whom excessive sweating may contribute to the disease, should sprinkle talcum powder on the feet and in the shoes as adjunctive therapy to keep the feet dry.

In addition, product line extensions that carry the same brand name do not necessarily have the same active ingredient(s). For example, the cream and solution formulations of Lotrimin AF contain clotrimazole 1%, whereas the topical spray and powder formulations contain miconazole nitrate 2%. Lotrimin Ultra, the most recent line extension, contains butenafine hydrochloride. Similarly, Desenex spray liquid, spray powder, and spray powder formulations contain miconazole nitrate 2%, whereas these products formerly contained undecylenic acid.

Special Populations

Although topical medications are considered safer in pregnancy owing to limited systemic absorption, their safety profile must still be appropriately assessed. In a review of the relevant data for available nonprescription products used as topical antifungals in human and animal studies, clotrimazole and miconazole were preferred over butenafine and terbinafine.³² Please refer to the Preface for a detailed explanation of the pregnancy data.

Complementary Therapies

Bitter orange, tea tree oil, and garlic have been used with some success in the management of fungal skin infections, with few or no adverse effects. None of the studies that examined these ingredients included more than 60 patients, but the results suggest that further investigation of each complementary therapy is warranted.^{33–39}

Bitter orange has the least evidence of safety and efficacy. However, in one controlled trial, topical application of 25% oil of bitter orange 3 times daily demonstrated benefit in 1–4 weeks in most patients with tinea corporis, tinea cruris, or tinea pedis. The only reported side effect was mild, local irritation.³³

Investigations into the efficacy of tea tree oil for tinea pedis have yielded mixed results. In one study that compared tolnaftate 1% cream with tea tree oil 10% cream, both agents were equally effective in relieving the associated scaling, inflammation, itching, and burning, but neither agent was more effective than

placebo in achieving mycologic cure.³⁴ Results of two other studies suggest that tea tree oil 25% and 50% appear to result in both symptomatic and mycologic cure of tinea pedis. However, the mycologic cure rates were inferior to those for butenafine and clotrimazole.^{35,36}

Research relative to the efficacy of topical garlic for the management of tinea infections has yielded positive results. For example, application of a garlic gel containing 0.6% ajoene (a constituent of garlic believed to have antifungal activity) was demonstrated to be as effective as terbinafine 1% cream in a study of subjects with either tinea corporis or tinea cruris.³⁷ In another study comprising 34 patients, the use of ajoene 0.4% as a cream resulted in clinical and mycologic cure in all subjects after 2 weeks of use.³⁸ In a subsequent study, ajoene 1% cream was shown to produce a higher mycologic cure rate compared with ajoene 0.6% and terbinafine 1% creams.³⁹

Algorithm: Fungal Skin Infections

FIGURE 42–1 Self-care for fungal skin infections.

Assessment of Fungal Skin Infections: A Case-Based Approach

Fungal skin infections must be differentiated from bacterial skin infections and noninfectious dermatitis. If possible, the health care provider should examine the affected area to determine whether the clinical presentation is typical of a fungal infection ([Table 42–1](#)).⁴⁰ The only true diagnostic confirmation of a fungal infection is obtained by clinical laboratory evaluation of tissue scrapings from the affected area.

At the initial patient interview, assessment should be directed at identifying specific characteristics of the skin condition to determine symptoms, extent of disease, previous adherence to medication regimens, and any compounding disorders (e.g., diabetes, obesity) that may contribute to difficulties in management. Patients with diabetes, for example, may present with a mixed dermatophytid and candidal infection. In general, inspection of the affected

area is appropriate if privacy and sanitary conditions allow. Inspection is especially important for assessment in patients with diabetes.

Cases 42-1 and 42-2 are examples of the assessment of two different patients with a fungal skin infection.

The most common symptom associated with cutaneous fungal infections is pruritus. However, if fissures are present, particularly between the toes, the patient also may experience painful burning and stinging. If the affected area is abraded, denuded, or inflamed, weeping or oozing may occur, in addition to pain. Some patients may merely remark on the bothersome scaling of dry skin, particularly if the infection involves the soles of the feet. In other instances, small vesicular lesions may combine to form a larger bullous eruption marked by pain and irritation, or the only manifestations may be brittleness and discoloration of a hypertrophied nail.⁵

It is important to distinguish a tinea infection from diseases with similar symptomatology, such as bacterial infection, irritant contact dermatitis, allergic contact dermatitis, and atopic dermatitis. Accordingly, the typical clinical manifestations in these disorders are briefly reviewed here. In children, peridigital dermatitis or atopic dermatitis is more common than tinea pedis. Shoe dermatitis is perhaps the most common form of allergic contact dermatitis from clothing, so the assessment should ascertain the type of footwear worn by the patient, including recent footwear changes. The increased use of rubber and adhesives in footwear has paralleled the increase in reports of shoe dermatitis in the dermatologic and podiatric literature. Contact allergy to accelerators (the chemical compounds used to speed the processing of rubber used in sponge-rubber insoles for tennis shoes) also has been reported.⁴¹ In addition to accelerators, antioxidants have been implicated as major chemical allergens, and various phenolic resins used in adhesives also are troublesome. The patient usually is unaware that the footwear may be the cause of the problem.

Hyperhidrosis of interdigital spaces and of the sole of the foot is common, as is infection of the toe interspaces by gram-negative bacteria. In hyperhidrosis, tender vesicles cover the sole of the foot and toes, and these areas may be quite painful. The skin generally turns white, erodes, and becomes macerated. This condition is accompanied by a foul foot odor. A soggy wetness of the toe webs and the immediately adjacent skin characterizes infection by gram-negative bacteria; the affected tissue feels damp and softened to touch. The

last toe web (adjacent to the little toe) is the most common area of primary or initial involvement because it is deeper and extends more proximally than the web between the other toes. Other factors such as an abundance of exocrine sweat glands, a semiocclusive anatomic site, and the added occlusion provided by footwear contribute to development of the disease at this site. The provider must be careful not to confuse this condition with soft corns, which also appear between the fourth and fifth toes.

Case 42-1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient presents to the pharmacy with redness in the shape of eyeglasses on her nose and around both eyes. Scaling and weeping vesicles on both eyelids extend upward to both eyebrows. The patient has an open sore on the bridge of her nose that she admits she caused by scratching the area. She also complains of intense itching. Her symptoms began about a month ago, right after she started to swim competitively at school. She denies changes in swimming equipment, including goggles.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She says that the itching is worse after she removes her swim goggles.
c. Description of the patient's efforts to relieve the symptoms	She has tried hydrocortisone ointment with no relief.
d. Patient's identity	Sara Lansbury

Relevant Evaluation Criteria	Scenario/Model Outcome
e. Patient's age, gender, height, and weight	21 years, female, 5 ft 6 in., 128 lb
f. Patient's occupation	College student who participates in competitive swimming
g. Patient's dietary habits	Patient is a vegetarian.
h. Patient's sleep habits	Number of hours that patient sleeps each night varies.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Seasonal allergies:</i> Claritin D (loratadine/pseudoephedrine) in the spring and fall
j. Allergies	Ragweed and maple trees
k. History of other adverse reactions to medications	None
l. Other (describe) -----	Patient has a history of ringworm during swim season.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 42-1).	Patient is suffering from inflammation, weeping, denudation, and intense itching on her face, secondary to ringworm.
3. Identify exclusions for self-treatment (Figure 42-1).	Severe symptoms, eye involvement, eyebrow involvement
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and	Options include (1) Refer the patient to a dermatologist or other appropriate health care provider. (2) Recommend self-care with a nonprescription antifungal and nondrug measures.

Relevant Evaluation Criteria	Scenario/Model Outcome
share this information with the patient or caregiver.	(3) Recommend self-care until patient can see an appropriate PCP. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult a dermatologist or other knowledgeable health care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult an appropriate health care provider for treatment."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best because your skin problem is severe and is affecting areas near your eyes. You will need an oral medication that is available only by prescription to treat your condition."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Make sure you dry off well after swimming, and allow your face to air dry completely. Do not share towels or other sports equipment."
Solicit follow-up questions from the patient or caregiver.	"One of my teammates said that I should suffocate the ringworms by applying clear nail polish on the itchy spots. Does this really work?"
Answer the patient's or	"Ringworm is not actually caused by worms. It is caused by a

Relevant Evaluation Criteria	Scenario/Model Outcome
caregiver's questions.	fungus that lives in the superficial skin layers. Nail polish will have no effect on your symptoms. It can, however, cause severe irritation if you get it in your eyes."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Ms. Lansbury in 1-2 days to ensure that she made an appointment and sought medical care.

Case 42-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient is seeking a pharmacist's recommendation for intense pruritus (itching) and a red, scaly rash on and between the third, fourth, and fifth toes of each foot. He states that the problem began a week ago, soon after he began his summer job at a lawn maintenance service.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient states that the itching is worse after he gets home from work in the evening.
c. Description of the patient's efforts to relieve the symptoms	The patient has not tried anything other than scratching the affected area when the itching becomes "unbearable."
d. Patient's identity	Robert Grees
e. Patient's age, gender, height,	17 years, male, 5 ft 11 in., 175 lb

Relevant Evaluation Criteria	Scenario/Model Outcome
and weight	
f. Patient's occupation	High school senior with full-time summer job as lawn maintenance worker
g. Patient's dietary habits	Eats fast food for breakfast and lunch and a frozen prepared meal for dinner.
h. Patient's sleep habits	He sleeps 6–7 hours nightly.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) _____	N/A
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 42–1).	The scaly red rash and itching are manifestations of athlete's foot. The patient likely contracted the condition while working outside in the summer heat and humidity.
3. Identify exclusions for self-treatment (Figure 42–1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mr. Grees to an appropriate health care provider. (2) Recommend self-care with a nonprescription antifungal and nondrug measures. (3) Recommend self-care until Mr. Grees can see an appropriate health care provider.

Relevant Evaluation Criteria	Scenario/Model Outcome
	(4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Grees should use a nonprescription antifungal medication and nondrug measures to treat this condition.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Regular use of any of the commercially available nonprescription antifungals in any dosage form should alleviate the problem. However, for the medication to be optimally effective, you will have to keep the affected areas clean and dry."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Athlete's foot can be effectively managed with nonprescription antifungals and nondrug measures (if the area is kept clean and dry) as long as there is no evidence of secondary infection or preexisting medical conditions that would preclude self-treatment, as in your case. Sprays and powders are less effective because they often are not rubbed into the skin."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	See the box "Patient Education for Fungal Skin Infections."
b. Maximum number of days the therapy should be employed	See the box "Patient Education for Fungal Skin Infections."
c. Product administration procedures	See the box "Patient Education for Fungal Skin Infections."
d. Expected time to onset of relief	"Itching may be relieved somewhat within a few days, but eradication of the causative microorganism may take up

Relevant Evaluation Criteria	Scenario/Model Outcome
	to 4–6 weeks, depending on the agent used.”
e. Degree of relief that can be reasonably expected	“Athlete’s foot can be cured if you use the antifungal and nondrug measures properly.”
f. Most common adverse effects	See the box “Patient Education for Fungal Skin Infections.”
g. Adverse effects that warrant medical intervention should they occur	See the box “Patient Education for Fungal Skin Infections.”
h. Patient options in the event that condition worsens or persists	See the box “Patient Education for Fungal Skin Infections.”
i. Product storage requirements	“Store in a cool, dry place out of children’s reach.”
j. Specific nondrug measures	See the box “Patient Education for Fungal Skin Infections.”
Solicit follow-up questions from the patient or caregiver.	“Why do I have this? I am not an athlete.”
Answer the patient’s or caregiver’s questions.	“Your feet are sweating more than usual now because you are working in summer temperatures for prolonged periods during the day. As a result, the skin of your feet remains damp until you remove your shoes and socks after work. Moisture helps the fungus that causes athlete’s foot to thrive.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mr. Grees to call to update you on his response to your recommendations 1 week after initiating treatment. Or you could call him in a week to evaluate the outcome.

Key: N/A = Not applicable.

Patient Counseling for Fungal Skin Infections

The proper application technique for topical antifungals and the required duration of therapy should be emphasized in patient counseling, to prevent over- or undermedicating. The patient should be directed to apply the medication regularly throughout a complete course of therapy. The approved indications for the products also should be discussed, because some fungal infections are not amenable to management with nonprescription products, and marketing ploys (e.g., pictures) may be misleading. Information on measures that will help to control or eradicate the infection and that will minimize the likelihood of recurrent infections also may be provided. Such measures may include proper care of the infected skin site, use of appropriate laundry techniques and products, limiting wear of occlusive clothing, and avoidance of habits or behavior that may lead to recurring infections. A critical component of patient counseling is identification of conditions that warrant consultation with an appropriate health care provider for further evaluation and treatment (e.g., the development of a secondary bacterial infection). The box “Patient Education for Fungal Skin Infections” summarizes information to provide in patient counseling.

Evaluation of Patient Outcomes for Fungal Skin Infections

In general, the patient should begin to experience some relief of the itching, scaling, and/or inflammation within 1 week. If clinical improvement is seen within this time frame, continuing treatment for 1–4 weeks (depending on the type of tinea infection and medication being used) should be recommended. If the affected skin has not improved or the disorder has worsened, referral to a dermatologist or other knowledgeable health care provider for more aggressive therapy is appropriate. Recurrent skin infections may be a sign of undiagnosed diabetes, immunodeficiency, or another organic problem that requires medical evaluation.

Patient Education for Fungal Skin Infections

The objectives of self-treatment are (1) to relieve itching, burning, and

other discomfort; (2) to inhibit the growth of fungi and cure the disorder; and (3) to prevent recurrences of the infection. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- To prevent spreading the infection to other parts of the body, either use a separate towel to dry the affected area or dry the affected area last.
- Do not share towels, clothing, or other personal articles with household members, especially when an infection is present.
- Launder contaminated towels and clothing in hot water and then dry them on a hot dryer setting to prevent spreading the infection.
- Cleanse skin daily with soap and water, and thoroughly pat dry to remove oils and other substances that promote growth of fungi.
- If possible, do not wear clothing or shoes that cause the skin to stay wet. Wool and certain synthetic fabrics prevent optimal air circulation.
- If needed, allow shoes to dry thoroughly before wearing them again. Dust shoes with medicated or nonmedicated foot powder to help keep them dry.
- If needed, place odor-controlling insoles in casual or athletic shoes. These insoles also provide some additional support and cushioning for the feet. Change insoles routinely every 3–4 months or more often if their condition warrants. Take care that the shoe fit is not compromised by presence of the insoles.
- As with all topical medications, discontinue the use of an antifungal if irritation, sensitization, or worsening of the skin condition occurs.
- Avoid contact with people who have fungal infections. Wear protective footwear (e.g., rubber or wooden sandals) in areas of family or public use, such as home bathrooms or community showers.

Nonprescription Medications

- Ask a health care provider for assistance in picking the appropriate

antifungal agent and dosage form for your infection.

- Available agents include undecylenic acid, butenafine, clotrimazole, miconazole nitrate, terbinafine, and tolnaftate.
- It usually takes 2–4 weeks to cure tinea infections. Some cases may require 4–6 weeks of treatment.
- Apply the antifungal to the clean, dry affected area as directed (in the morning or evening if once daily, or both times if twice daily). Massage the medication into the area. Note that creams and solutions are easier to work into the skin.
- Avoid getting the product in your eyes.
- Wash hands thoroughly with soap and water before and after applying the product.
- Topical antifungals themselves may cause itching, redness, and irritation.
- Tolnaftate may sting slightly upon application.
- When the medication is to be applied to pressure areas of the foot, where the horny skin layer is thicker, apply a keratolytic agent (e.g., salicylic acid) to the affected area first to help the antifungal penetrate the skin.
- If oozing lesions are present, apply aluminum acetate solution to the area before applying the antifungal:
 - Soak the area in an aluminum acetate solution for 15–30 minutes up to 3 times a day (every 6–8 hours), or apply the solution to the affected area in the form of a wet dressing.
 - Note that aluminum acetate solution (Burow's solution) or modified Burow's solution is available for immediate use or can be prepared from various products formulated to be dissolved in water (powder packets, powder, and effervescent tablets).
 - Avoid getting the product in your eyes.
 - To avoid skin damage, use the solution for no more than 1 week. Discontinue use of the solution if inflammatory lesions appear or worsen.
- For the wet, soggy type of athlete's foot, apply aluminum acetate solution as a topical agent or as foot soaks before applying the antifungal:

- Soak feet with aluminum acetate solution twice daily until the odor, wetness, and whiteness are gone. After that, soak once daily to control the symptoms.
 - If deep fissures are present, use a more dilute solution of aluminum acetate for initial treatment.
 - A solution of 30% aluminum chloride twice daily can be applied for treating athlete's foot.
- Antifungal medication can be applied immediately after soaking once the area has dried.

When to Seek Medical Attention

- Discontinue use of the product and contact an appropriate health care provider if itching or swelling occurs, or if the infection worsens.
- Consult a primary care provider if the infection worsens or persists beyond the recommended length of therapy.
- Seek medical attention if the infection worsens, fails to respond to treatment within 1 week, or persists beyond the recommended duration of therapy.

Key Points for Fungal Skin Infections

- Tinea corporis, tinea cruris, and tinea pedis can be treated with nonprescription drugs. Clotrimazole, miconazole nitrate, terbinafine hydrochloride, butenafine hydrochloride, tolnaftate, and undecylenic acid are efficacious for this purpose.
- The effectiveness of topical antifungals will be limited unless the patient eliminates other predisposing factors to tinea infections.
- These drugs are effective in all available delivery vehicles, but the powder forms should be reserved only for extremely mild conditions or as adjunctive therapy.

- Because solutions and creams can spread beyond the affected area, they should be used sparingly.
- When recommended for suspected or actual dermatophytosis, these topical antifungals should be used once or twice daily (morning and night), depending on the indication. Treatment should be continued for 1–4 weeks, depending on the symptoms and the type of fungal infection. After that time, the patient and/or the provider should evaluate the effectiveness of the therapy.
- To minimize nonadherence, the provider should advise patients that alleviation of symptoms will not occur overnight. Patients also should be cautioned that frequent recurrence of any of these problems is an indication for seeking consultation with their primary care provider or a dermatologist.
- Dermatophytoses in immunocompromised patients and those with diabetes or circulatory problems require medical management.
- The only antifungal currently approved for prevention of athlete's foot is tolnaftate.

Chapter 43: Warts

Authors: Donna M. Adkins

Warts, or verrucae, are a common skin disorder caused by the human papillomavirus (HPV), of which various pathogenic subtypes are recognized.¹⁻¹² Approximately 7%–10% of the general population has warts, with common warts accounting for approximately 70% of the cases.¹⁻⁴ Warts occur more frequently in children and adolescents than in infants and adults, with the peak incidence among 12- to 16-year-olds.^{1,2,5} Warts are considered a benign condition, which often resolves without treatment. Approximately 23% of warts regress within 2 months and 65%–78% within 2 years.^{1,6,11} This chapter discusses self-treatment for nongenital warts—specifically, common and plantar warts, found typically on the hands and feet, respectively.

Pathophysiology of Warts

HPVs are double-stranded DNA viruses.^{1-6,8} More than 150 related viruses and 200 subgroups have been identified.² HPV infection occurs via person-to-person contact, autoinoculation, or transmission on fomites (contaminated objects or surfaces).^{1,3,7} Warts may affect skin and mucous membranes anywhere on the body. HPV infection is limited to the epidermal tissues and does not spread systemically. When minor skin abrasions are present, HPV may enter the epidermal layer and infect the basal keratinocytes.¹ The incubation period may be long (e.g., months).^{2,11} The manifestation of warts may depend on the immune response of the infected person. How quickly warts are cleared is influenced by factors such as viral type, patient immune status, and the extent of involvement and length of time the warts have been present.¹ Several risk factors for the development of warts are recognized, including existing or previous warts; immunocompromised status; presence of a chronic skin condition; going barefoot, especially on wet surfaces; use of swimming pools and public showers; employment in a meat-handling facility; and biting the nails.^{1-3,5,9}

Clinical Presentation of Warts

The appearance, size, shape, and response to treatment of individual warts vary by HPV subtype and the specific location of the lesion on the body.^{1,3,9} Although different types of HPV are not found exclusively in specific areas of the body, HPV-2, HPV-4, HPV-27, and HPV-57 constitute the most common cause of warts on the hands, and HPV-1 is the most common cause of warts on the feet.^{1,7,12}

Table 43–1 describes the categories of warts.

TABLE 43–1 Types of Nongenital Warts				
Wart Type	Common Location	Population(s) Commonly Affected	Characteristics	Self-Treatable
Common (verruca vulgaris)	Hands	Children and adolescents	Skin-colored or brown, dome-shaped, hyperkeratotic papules with a rough surface	Yes
Flat (verruca plana)	Face	Children	Smooth, flat-topped, yellow-brown papules; zcommon in children but rare in adults	No
Plantar (verruca plantaris)	Feet	Adolescents and young adults	Skin-colored, flat, callus-like, hyperkeratotic lesions with disruption of normal skin markings; located on the feet	Yes
Mosaic	Feet	Adolescents and young adults	Multiple, closely grouped plantar warts	No
Periungual	Nails	Persons who bite their nails	Thickened, fissured, cauliflower-textured skin around the nail plate	No
Filiform	Face		Flesh-colored, rapidly growing, with threadlike projections	No

Source: [References 1, 2, 5, and 9.](#)

Common warts are skin-colored or brown, hyperkeratotic, dome-shaped

papules with a rough-looking, often cauliflower-textured surface; they frequently occur on the hands (see [Color Plates](#), photograph 33).^{1,2} Common warts often are painless.² Plantar warts are skin-colored callus-like lesions that occur on the feet (see [Color Plates](#), photograph 34).² Because the underside of these lesions extends deeply into the epidermis, with an external conformation of sloping sides and a central depression, plantar warts may be painful, especially if they occur in a weight-bearing location.¹ When tightly clustered, multiple plantar warts may appear as one large wart. In this presentation, the lesion is called a mosaic wart.^{1,2}

Plantar warts can be confused with corns or calluses.¹ If there is any question about whether the lesion is a wart, the patient should be referred to an appropriate health care provider for evaluation and treatment. To distinguish plantar warts from calluses, the provider may remove the outer keratinous layer of the lesion. When the surface layer is removed, the wart exhibits pinpoint bleeding, which looks like small dark red or black dots. The bleeding is from thrombosed capillaries within the wart.¹

Plantar warts also can be confused with malignant growths.⁶ The latter usually are very painful and discolored, and they bleed and grow quickly.⁷ Patients with lesions displaying these characteristics should be referred for medical evaluation and treatment.

Treatment of Warts

No single treatment regimen is universally effective in the treatment of warts.^{1,4,9} Although several treatment options are available for relief of symptoms associated with warts and for their removal, none cure the HPV infection.^{1,4,9} High-quality evidence for the efficacy of most wart treatments is limited, and a placebo effect cannot be ruled out.^{1,4,7}

Because many warts will resolve without treatment, one management option is a wait-and-see approach. However, many patients seek treatment because of the pain, cosmetic appearance, and social stigma associated with warts or because of concern about transmitting warts to others. The decision to treat a wart is based on the patient's desire for treatment; the presence of pain or bleeding, disabling, and/or disfiguring lesions, or large or multiple lesions; the desire to prevent transmission of the warts; and the absence of any exclusions

for self-care such as immuno compromised status.^{4,8} Warts often recur after treatment. With recurrent or persistent warts, a combination of treatments may be required.¹

Treatment Goals

The goals for treatment of warts are (1) to eliminate associated signs and symptoms, (2) to remove the lesion without scarring, (3) to prevent recurrence of the warts, and (4) to prevent spread of HPV through autoinoculation or transmission to others.⁸

General Treatment Approach

Determining the optimal treatment for a patient with warts depends on a number of factors, including the patient's age; the type, number, size, location, and duration of the lesions; the patient's immune status; the cost of therapy; access to therapies; adverse effects; and treatment preference.^{1,4}

Although approximately 70% of warts will resolve after 2 years, even without treatment, only 46% of affected persons will remain wart-free.⁶ Warts are less likely to resolve spontaneously in adults, immunocompromised patients, and patients with other warts that persist despite treatment.¹ A wait-and-see approach allows the continued spread of warts through autoinoculation and transmission to others.^{4,6,7} Accordingly, prompt patient education regarding the cause of warts and ways to prevent their transmission to others is a key part of the treatment plan.

Figure 43–1 outlines the treatment of warts and lists exclusions for self-treatment. With multiple warts, warts in any area other than the hands and feet, warts on the fingernails, large warts, and/or painful warts, further medical evaluation is warranted to determine whether the lesions may be caused by a more serious condition. In patients with poor circulation or decreased skin sensitivity (e.g., patients with diabetes or peripheral vascular disease), self-treatment for warts is contraindicated because of the potential for injury.

Nonpharmacologic Therapy

Nonpharmacologic therapies focus mainly on preventing the spread of HPV. To prevent further development of warts from autoinoculation, patients should

be instructed to avoid cutting, shaving, or picking at warts; to wash hands before and after treating or touching warts; and to use a designated towel to dry wart-affected areas, with care taken to avoid its contact with the skin elsewhere. To prevent transmission of the virus to others, patients also should be instructed to avoid sharing towels, razors, socks, shoes, and so forth; to keep the wart covered; and to not walk barefoot, especially in bathrooms or in public places. For patients experiencing discomfort from plantar warts, padding such as lamb’s wool or moleskin may be used over the pressure points to help relieve the discomfort.

Pharmacologic Therapy

Salicylic Acid

Salicylic acid is a keratolytic agent available in several formulations for use in self-treatment for common and plantar warts: salicylic acid 17% liquid and gel and salicylic acid 40% plaster, pads, strips, and sticks.^{2,13} **Table 43–2** lists selected products that contain salicylic acid. Salicylic acid concentrations of 17% generally are used for common warts, and higher concentrations (i.e., 40%) are used for plantar warts.⁹

TABLE 43–2 Selected Self-Care Products for Warts	
Trade Name	Primary Ingredient(s)
Compound W One Step Pads	Salicylic acid 40%
Curad Medioplast Pads	Salicylic acid 40%
Dr. Scholl’s Clear Away One Step Clear Strips	Salicylic acid 40%
DuoFilm Wart Remover Patch	Salicylic acid 40%
WartStick	Salicylic acid 40%
Compound W Fast Acting Wart Removal Gel	Salicylic acid 17%
Compound W Fast Acting Wart Removal Liquid	Salicylic acid 17%
Dr. Scholl’s Clear Away Fast-Acting Liquid	Salicylic acid 17%
DuoFilm Liquid Wart Remover	Salicylic acid 17%

Trade Name	Primary Ingredient(s)

Source: References 19 and 20; and U.S. News & World Report and Pharmacy Times. Health: wart removers. Available at: <http://health.usnews.com/health-products/top-rec-wart-removers-146>. Accessed May 8, 2019.

Salicylic acid slowly destroys the virus-infected cells. It also may induce an immune response secondary to mild irritation.^{1,3-5,9} The U.S. Food and Drug Administration (FDA) recommends that use of salicylic acid for self-treatment for warts be restricted to common and plantar warts.¹³ Self-treatment is not recommended for other types of warts because of the difficulty in accurately recognizing and treating warts without the oversight of a dermatologist or other experienced clinician. Patients with painful plantar warts and lesions that are not easily recognizable as common or plantar warts require further medical evaluation.

The advantages of topical nonprescription products that contain salicylic acid include low cost, ready availability, few adverse effects if used as directed, and reasonable effectiveness.^{1,3,5} Compared with placebo, salicylic acid is more effective in treating warts on both the hands and feet, but it may be more effective for warts on the hands than those on the feet.⁵ Disadvantages include the need for consistent, frequent application of the product 1–2 times daily; the potential for damage to healthy skin surrounding the wart; and the duration of treatment needed to achieve a therapeutic response.^{1,3,5,9} Adverse effects include skin irritation and the potential for systemic toxicity.^{1,3,9}

In most instances, warts will begin to decrease in size within a couple of weeks of treatment with salicylic acid. Self-treatment for common and plantar warts

should not continue past 12 weeks. Patients with warts that do not completely resolve after 12 weeks should be referred for further medical evaluation.

Table 43–3 provides guidelines for using salicylic acid products.^{14–16}

TABLE 43–3 Guidelines for Treating Warts With Selected Salicylic Acid Products	
General Guidelines	• Wash hands before and after use. • Before treatment, soak the affected area in warm water for 5 minutes. • Wash and dry the affected area thoroughly.
Salicylic Acid 40% Plasters/Pads/Strips/Sticks¹⁴	• Trim a plaster to fit the wart, apply plaster, and cover with an occlusive tape; apply disc of appropriate size to wart and cover with pad; apply strip to wart, making sure the disc in the strip does not touch healthy tissue; or apply stick to wart, making sure the stick is not on healthy tissue, and bandage or cover. • Remove plaster/pad/strip/stick after 48 hours. • Repeat procedure every 48 hours as needed until the wart resolves. These products may be used for up to 12 weeks.
Salicylic Acid 17% Liquid/Gel^{15,16}	• Apply 1 drop at a time to cover the wart. Protect adjacent healthy skin from coming into contact with the gel. • Let solution dry completely. • Cover wart with self-adhesive discs or an occlusive tape. • Repeat procedure 1–2 times a day until the wart resolves. This product may be used for up to 12 weeks.

Cryotherapy

Cryotherapy with liquid nitrogen and other agents has been used for many years for treatment of warts in the office setting.⁶ With this modality, destruction of the lesion is accomplished by freezing the wart tissue.^{6,9} Liquid nitrogen can reach temperatures of approximately -196°C (-385°F).^{3,7} As temperatures decrease to -5°C to -15°C (-41°F to -59°F), extracellular ice crystals form.⁶ At -40°C (-104°F) and below, intracellular ice crystals form.⁶ Freezing of tissue creates localized microthrombi, with consequent ischemic necrosis and destruction of the HPV-infected keratinocytes.⁶ The freezing also

causes local inflammation that may clear the wart through a cell-mediated response.^{1,4}

FDA has approved nonprescription products that contain either nitrous oxide (NO) or a mixture of dimethyl ether and propane (DMEP) for self-treatment for common and plantar warts. Although neither NO nor DMEP can reach temperatures as low as the liquid nitrogen used in the office setting, both NO and DMEP can reach temperatures cold enough for destruction of warts by freezing.^{1,3,17} Nonprescription cryotherapy products have similar, but product-specific, directions for preparing the applicator. **Table 43–4** provides guidelines for using cryotherapy products.^{18–20} The cryotherapy preparation is applied directly to the wart. Patients must follow the directions carefully to avoid damaging the healthy skin surrounding the wart. A blister will form under the wart, and if the treatment is effective, after about 10 days the wart will fall off. Applicators must not be used more than once, to avoid reinfecting the tissue or spreading the virus to others.

TABLE 43–4 Guidelines for Treating Warts With Cryotherapy Products^{19,20}

General Guidelines

- Wash hands before and after use.
- Before treatment, soak the affected area in warm water for 5 minutes.
- Wash and dry the affected area thoroughly.
- May use a file or pumice stone to lightly abrade the surface of plantar warts.
- Do not hold the cryotherapy product canister close to the face, body, or clothing.
- These products are flammable. Do not use near heat sources.
- Application:
 - Prepare the device (refer to product-specific instructions).
 - Activate the device (refer to product-specific instructions).
 - Apply to the wart until a “halo” appears around the wart (refer to instructions).
 - Approximately 20 seconds for common warts
 - Approximately 40 seconds for plantar warts
- Discard single-use applicators after one use.
- Repeat after 2 weeks if needed. This product may be used for up to 3 treatments.

With regard to success in treatment of both common and plantar warts, cryotherapy is no more effective than salicylic acid or placebo.^{3,5,9} One study found that cryotherapy may be more effective than salicylic acid for warts on

the hands but not on the feet.²¹ The use of two freeze–thaw cycles, instead of one, during a cryotherapy treatment may improve the clearance of plantar warts, but this approach has not been shown to improve clearance of common warts on the hands.^{1,3,11} However, nonprescription cryotherapy products are not approved to be used with two freeze-thaw cycles during a treatment. Aggressive cryotherapy treatments are more effective (52%) than gentle treatments (31%) but are associated with an increased incidence of adverse effects.^{1,3,5,9} Treating the wart every 2–3 weeks with cryotherapy yields the best results.^{5,11}

The advantages of nonprescription cryotherapy products include their ready availability and lower cost, compared with the liquid nitrogen used in the clinician’s office; in some cases, even a single treatment may be sufficient to clear the wart. Disadvantages of cryotherapy relative to salicylic acid treatments include associated pain and the potential for damage to healthy skin surrounding the wart; also, self-treatments may not be as effective as the liquid nitrogen used in the office setting. Potential adverse effects include blistering, scarring, hypo- or hyperpigmentation, and tendon or nerve damage with aggressive therapy.^{1,3,9}

In some cases, warts will resolve after a single treatment with self-cryotherapy. Self-treatment for common and plantar warts may be repeated every 2 weeks if the wart does not resolve after the first treatment. However, treatments should not continue beyond a maximum of 3 sessions or for more than 12 weeks’ duration. If this regimen does not completely resolve the wart, the patient should be referred to an appropriate health care provider for evaluation and treatment.

Other Pharmacologic Therapies

Numerous prescription products, laser treatments, immunotherapies, and combinations of treatments are used to treat warts. Discussion of prescription products and procedures is outside the scope of this chapter. Only limited or inconsistent data are available for the effectiveness of products other than salicylic acid and cryotherapy for self-treatment for common and plantar warts.

Product Selection Guidelines in Special Populations

Several factors should be considered in selecting a wart removal product, including the patient's age and pregnancy or lactation status, as well as the presence of certain medical conditions. The specific product chosen also must be compatible with the patient's lifestyle and personal preferences.

Pregnancy

The potential effects of topical salicylic acid or cryotherapy products on an unborn child when used by an expectant mother for treatment of warts are unknown. Accordingly, products of either type should not be used for self-treatment during pregnancy. In such cases, the patient should be referred for medical evaluation and treatment.

Lactation

It is not known if topical salicylic acid passes into breast milk in sufficient amounts to harm the infant. How cryotherapy products will affect either mother or child in this setting has not been established. Products containing salicylic acid or cryotherapy-specific ingredients should therefore not be used for self-treatment for warts in nursing mothers. These patients should be referred to an appropriate health care provider for evaluation and treatment.

Children

Topical salicylic acid products should not be used for self-treatment for warts in children younger than 3 years because of the potential for systemic absorption and for epithelial damage in this patient population. Furthermore, salicylic acid-containing products should not be used in children or teenagers who have or are recovering from chickenpox or influenza-like symptoms because of the risk of Reye syndrome (see [Chapter 5](#) for further information). In addition, cryotherapy products should not be used for self-treatment for warts in children younger than 4 years. The specific effects of such products on the skin of young children have not been determined, but in this vulnerable age group, the potential to cause significant skin damage should not be overlooked.

Patients of Advanced Age

Both cryotherapy products and salicylic acid–based preparations may be used in persons of advanced age in a manner similar to that for younger adults. With application of such products, however, care should be taken to avoid the normal skin tissue around the wart, because older patients often have thinner, more friable skin at increased risk for injury.

Comorbid Conditions

Patients with diabetes or poor circulation should not use cryotherapy or salicylic acid–containing products because of the associated risk for delayed healing.

Dosage Form Considerations

The salicylic acid–containing products come in a variety of dosage forms that may appeal to specific patient preferences, such as colored pads for children to cover the wart or strips or pads that may be easier for some patients to apply than the liquid. Cryotherapy products may appeal more to patients who are looking for a product that requires minimal applications.

Complementary Therapies

Folklore

Numerous folk remedies for warts have been recommended. Most of these are based on anecdotal success, highlighting the probability that many warts resolve spontaneously without treatment.¹

Vitamin A

Retinoids such as vitamin A regulate epithelial cell differentiation and keratin expression. Vitamin A may interfere with HPV replication. One case report of use of topical vitamin A for recalcitrant hand warts in a 30-year-old woman found this agent to be effective in clearing the lesions.¹² The report noted that untreated warts on the opposite hand cleared without application of vitamin A, which may illustrate either a placebo effect or an unknown mechanism of action.¹²

Dietary Zinc

Deficiencies of zinc lead to decreased immunity.^{1,10} Dietary zinc is postulated to improve immune response and inhibit HPV replication.¹⁰ One placebo-controlled trial evaluated 10 mg/kg/day of zinc to treat recalcitrant warts. Complete clearance was reported in 35 of the 40 patients, or 87%, in the treatment group, versus no clearance in the placebo group.^{1,10}

Garlic (*Allium sativum*)

Garlic is thought to inhibit cellular proliferation of virus-infected cells.^{1,22} In a placebo-controlled trial, application of chloroform extracts of garlic resulted in complete resolution of warts in all 23 patients after 1–2 weeks, with no recurrence after 3–4 months.^{1,22}

Occlusion With Duct Tape

Occlusion with duct tape is an inexpensive, potentially less painful self-treatment for warts. The mechanism by which this approach clears warts is still unclear, but local irritation may cause stimulation of the patient's immune response.⁵

One randomized controlled study²³ compared duct tape occlusion with cryotherapy for the treatment of common warts. In the cryotherapy group, liquid nitrogen was applied to warts every 2–3 weeks, for a maximum of 6 treatments or until regression of the warts was achieved. In the occlusion therapy group, duct tape was applied to the wart, left in place for 6 days, removed on the evening of the sixth day, and replaced with a new piece of duct tape the next morning; this multistep procedure was repeated for up to 2 months or until the wart resolved. The treated warts regressed completely in 84.6% of the patients in the duct tape occlusion group and in 60% of the patients in the cryotherapy group.²³

Another randomized controlled trial yielded conflicting results. This trial compared use of moleskin overlaid with duct tape versus moleskin alone in occlusion therapy for warts. In both treatment groups, the wart was shaved; next, either a taped or untaped moleskin pad was applied for 6 of 7 days each week. The wart was then debrided with an emery board, and the taped or untaped pad was reapplied for an additional week. This procedure was

repeated for up to 2 months or until the wart resolved. At 6-month follow-up evaluation, patients were asked if the wart had recurred. The treatment groups demonstrated no difference in resolution or recurrence of the warts.^{5,24}

More evidence on the effectiveness of occlusion therapy with duct tape is needed. Duct tape occlusion may have a place in therapy for young children with warts or in combination with other treatments.¹

Algorithm: Warts

FIGURE 43–1 Self-care for warts. Key: DMEP = Dimethyl ether and propane; PVD = peripheral vascular disease; SA = salicylic acid.

Assessment of Warts: A Case-Based Approach

When a patient presents with a wartlike lesion, the health care provider should gather information from multiple sources to determine whether the lesion is suitable for self-treatment and whether available therapies are appropriate for that patient. Before a treatment plan is recommended, the provider should inspect the wart to accurately identify the lesion as a wart and to determine whether self-treatment is appropriate. The patient interview should include a current medication history to identify all prescription and nonprescription drugs with potential for adverse interactions and a health status review to disclose any concomitant medical conditions that constitute exclusions to self-care. The patient also should be asked about previous attempts to treat the lesion and whether any improvement was obtained with those attempts. Patient preferences for type of treatment may be used to help guide product selection.

Table 43–5 compares characteristics of warts, corns, calluses, and malignant growths. Cases 43–1 and 43–2 illustrate the assessment of two different patients with warts.

TABLE 43–5 Differentiation of Warts and Skin Disorders With Similar Presentation

Criterion	Warts	Corns	Calluses	Malignant Growth
Location	Any area of skin susceptible to the causative virus	Over bony prominences in the feet	Weight-bearing areas of the feet	Any area of the skin
Conformation/ clinical signs	Rough cauliflower-like appearance; plantar warts disrupt normal skin ridges	Raised, sharply demarcated, hyperkeratotic lesions with a central core	Raised, yellowish thickening of the skin; broad-based with diffuse borders; normal pattern of skin ridges	Bleeding; swelling; red, discolored, or multicolored and swollen
Pain symptoms	Usually not painful, but pain may occur if the wart is located in areas under constant pressure (e.g., soles of the feet)	Painful	Usually not painful, but pain may occur if the callus is located in an area where significant pressure may occur (e.g., soles of the feet)	Painful
Size/severity	Varies; may grow to approximately 1 inch in diameter	Varies; a few millimeters to 1 cm	Varies; a few millimeters to several centimeters	Varies; grows rapidly
Timing	Incubation period may be several months in duration; may progressively enlarge	Variable onset; may progressively enlarge	Variable onset; may progressively enlarge	Variable onset; grows rapidly
Cause	HPV infection of the epidermal layer	Friction	Friction, walking barefoot, structural foot problems	Mutations related to damaged DNA causing skin cells to grow unchecked
Modifying factors	Prevention of spread; treatment with salicylic acid or cryotherapy	Alleviation of causative factors; treatment	Alleviation of causative factors; treatment with salicylic acid	Surgical removal; prescription medications

Criterion	Warts	Corns	Calluses	Malignant Growth
		with salicylic acid		

Key: HPV = Human papillomavirus.

Patient Counseling for Warts

The health care provider has a crucial role in educating patients that warts are caused by HPV and are contagious. Consistent implementation of measures to prevent the spread of warts (see “Nonpharmacologic Therapy”) to other parts of the body or to other persons is a critical component of successful management. The differences between available products for wart removal, including their indications, contraindications, warnings, and precautions, also should be highlighted in discussions with the patient. The box “Patient Education for Warts” lists specific information to provide in patient counseling for use of either salicylic acid or cryotherapy products. If warts persist despite self-treatment for a maximum of 12 weeks of therapy, patients should be referred for medical evaluation and treatment.

Evaluation of Patient Outcomes for Warts

Salicylic acid may require up to 12 weeks of treatment to completely clear the wart. Patients should see some improvement in 1–2 weeks. Follow-up evaluation with the health care provider should occur after 4–6 weeks to assess progress in clearing the wart. If the wart does not appear to be resolved, the patient should be encouraged to continue treatment. If the wart has not cleared after 12 weeks, prescription therapies may be warranted, so the patient should be referred for further medical evaluation.

Cryotherapy may be repeated after 2 weeks for up to 12 weeks or 3 treatments. If the wart has not cleared after 12 weeks or 3 treatments, referral for medical evaluation and treatment is warranted.

Case 43–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient states that she has a rough spot on the bottom of her left big toe. She noticed it about 2 weeks ago. It is not painful. Even though it is small, she is self-conscious about it and embarrassed to go barefoot because of how she thinks it looks. The normal skin ridges are disrupted. No inflammation, bleeding, significant discoloration, or discharge from the lesion is evident.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None that patient has identified
c. Description of the patient's efforts to relieve the symptoms	Patient has not yet tried anything to get rid of the lesion.
d. Patient's identity	Sage Justus
e. Patient's age, gender, height, and weight	18 years, female, 5 ft 4 in., 130 lb
f. Patient's occupation	College student who works weekends as a lifeguard at the local public pool
g. Patient's dietary	Ms. Justus follows a generally healthy diet.

Relevant Evaluation Criteria	Scenario/Model Outcome
habits	
h. Patient's sleep habits	6–8 hours of sleep a night
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No medical conditions Medication(s): triphasic oral contraceptive daily; adult multivitamin daily
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Ms. Justus lives on campus in a dorm with a communal bathroom on each floor. She has one roommate.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Ms. Justus appears to have a plantar wart. She most likely contracted it by walking barefoot at the pool or in the dorm showers.
3. Identify exclusions for self-treatment (Figure 43-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health	Options include (1) Recommend self-care with a nonprescription wart removal product and nondrug measures. (2) Recommend self-care until the patient can consult a knowledgeable health care provider for evaluation and

Relevant Evaluation Criteria	Scenario/Model Outcome
care provider is required, and share this information with the patient or caregiver.	treatment. (3) Refer the patient for medical evaluation and treatment. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because Ms. Justus is concerned about the appearance of the wart and because there is significant possibility of transmitting the causative virus to others, pharmacologic treatment of the wart should be considered. Because the wart is a single, small, painless lesion confined to a single area, and the patient has no identifiable exclusions for self-treatment, she can be treated with a nonprescription wart removal product. She can prevent transmitting the wart to others by wearing shoes or covering the wart, especially when working at the local public pool or utilizing the communal showers in the dorm. She should avoid sharing towels or shoes with others.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Salicylic acid in a 40% pad or strip would be a good treatment choice in this situation." See Figure 43-1 and the box "Patient Education for Warts."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Salicylic acid in a 40% strip or pad form is effective for this type of wart, easy to use, and less painful than some other treatment options. Cryotherapy using nonprescription products is another self-care option for the treatment of warts. However, cryotherapy is more painful than salicylic acid, and small warts typically may be adequately treated with salicylic acid."
	"Warts may be effectively treated with nonprescription wart removal products and preventive measures so long as no exclusions to this approach are present and the lesion to be treated is small, with no complicated skin involvement. Self-treatment with salicylic acid is cost-effective and may provide acceptable results in resolving your

Relevant Evaluation Criteria	Scenario/Model Outcome
	wart.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	“Be sure to read and follow the directions that come with the wart removal product.” Table 43–3 and the box “Patient Education for Warts” provide information on removing warts safely.
a. Appropriate dose and frequency	Salicylic acid 40% pads/strip products should be applied every 48 hours.
b. Maximum number of days the therapy should be employed.	With salicylic acid therapy, up to 12 weeks may be required for the wart to resolve.
c. Product administration procedures	See Table 43–3 and the box “Patient Education for Warts.”
d. Expected time to onset of relief	See the box “Patient Education for Warts.”
e. Degree of relief that can be reasonably expected	See the box “Patient Education for Warts.”
f. Most common adverse effects	See the box “Patient Education for Warts.”
g. Adverse effects that warrant medical intervention should they occur	See the box “Patient Education for Warts.”

Relevant Evaluation Criteria	Scenario/Model Outcome
h. Patient options in the event that the condition worsens or persists	"If the wart does not resolve after 12 weeks of treatment, see an appropriate health care provider."
i. Product storage requirements	"Store the pads/strips at room temperature and avoid excessive temperatures."
j. Specific non-drug measures	See the box "Patient Education for Warts."
Solicit follow-up questions from patient or caregiver.	"Will the wart spread to other places on my body?"
Answer patient's or caregiver's questions.	"Warts are caused by a virus that is spread from person to person or by touching surfaces that have come in contact with the wart. Warts also may be spread from one area of the body to another by picking at, touching, or rubbing the wart and then touching other susceptible areas of the body. Various nondrug measures are helpful in preventing the spread of warts." See the box "Patient Education for Warts."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Ms. Justus in 4–6 weeks to assess her progress in clearing the wart with the recommended therapy.

Case 43–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the	

Relevant Evaluation Criteria	Scenario/Model Outcome
patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient, an older man who presents with 3 lesions on his left cheek, seeks his pharmacist's self-care recommendations for their removal. The lesions are small and have a rough, cauliflower-textured surface. He has noticed similar lesions during the past 6 months on his hands. He periodically scrapes off the ones on his hands with a knife, but they grow back. No inflammation, bleeding, significant discoloration, or discharge from the lesions on his face is evident.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None
c. Description of the patient's efforts to relieve the symptoms	The patient has tried using a nonprescription-strength salicylic acid liquid product on the warts on his hands. He states that the lesions "would go away for a while but then come back," so he quit using it and started scraping them off.
d. Patient's identity	George Williams
e. Patient's age, gender, height, and weight	60 years, male, 5 ft 11 in., 180 lb
f. Patient's occupation	Welder
g. Patient's dietary habits	Mr. Williams generally follows a healthy diet.
h. Patient's sleep habits	Averages 6–7 hours of sleep a night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Hypertension</i> : lisinopril daily; <i>hypothyroidism</i> : levothyroxine daily
j. Allergies	None
k. History of other adverse	None

Relevant Evaluation Criteria	Scenario/Model Outcome
reactions to medications	
I. Other (describe) -----	None
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Mr. Williams most likely has multiple common warts on his face from autoinoculation with the virus causing the warts on his hands.
3. Identify exclusions for self-treatment (Figure 43-1).	Multiple common warts and warts located on the face
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend self-care with a nonprescription wart removal product and nondrug measures. (2) Recommend self-care until the patient can consult an appropriate health care provider for evaluation and treatment. (3) Refer the patient for medical evaluation and treatment. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Williams should be referred to an appropriate health care provider for evaluation and treatment.
6. Describe the recommended therapeutic	"You should consult an appropriate health care provider to evaluate and treat the warts."

Relevant Evaluation Criteria	Scenario/Model Outcome
approach to the patient or caregiver.	
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Self-treatment is not recommended because the warts are on your face and because you have already used a nonprescription wart removal product without success.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from patient or caregiver.	“Is there anything I can do to keep this wart from coming back again after it is treated?”
Answer patient's or caregiver's questions.	“It is common for warts to recur even after treatment, but various self-care measures have been shown to reduce the risk of reinfection.” See the box “Patient Education for Warts.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Williams in 1 week to ensure that he has scheduled an appointment with an appropriate health care provider as directed.

Patient Education for Warts

In treating warts, the goals are (1) to eliminate signs and symptoms associated with the warts, (2) to remove the wart without causing scars, (3) to prevent the wart from recurring, and (4) to prevent spreading of warts to other areas of the body or to other persons. To ensure the best possible treatment outcomes, patients must follow product instructions carefully and must consistently use measures to prevent the spread of warts.

Nondrug Measures

- To decrease the chance of getting warts, avoid nail-biting; do not go barefoot; and keep feet clean and dry.
- To avoid spreading warts from one part of your body to another, do not cut, shave, or pick at warts; wash hands before and after treating or touching warts; and use a single specific towel to dry wart-affected areas, taking care to avoid touching skin on other areas of the body with the same towel.
- To avoid spreading warts to others, do not share towels, razors, socks, shoes, and so forth; keep the wart covered; and do not walk barefoot, especially in bathrooms or in public places.

Nonprescription Medications

- Select only nonprescription salicylic acid or cryotherapy products approved for self-treatment for warts. Follow the instructions on the label closely.
- Use these products only on common or plantar warts. Do not use on moles, birthmarks, warts with hairs growing from them, irritated or inflamed skin, or infected skin.
- If you are not certain that the condition is a wart, consult a health care provider before using these products.
- Do not use these products to treat warts on the face, mucous membranes, breasts, or genitals; in the armpits; or around fingernails.
- Do not use these products in women who are pregnant or breastfeeding, or patients who have diabetes or poor circulation, or are immunocompromised.
- Some of these products are flammable or contain collodions that

are poisonous if ingested. Keep away from heat and out of children's reach.

- Warts may recur after treatment.

Salicylic Acid Products

- Do not use salicylic acid products in children who are younger than 3 years of age.
- Keep these products away from the eyes. In the event of contact with the eyes, seek medical help immediately.
- Do not apply these products to healthy skin. In the event of such contact, wash the area with soap and water immediately.
- Improvement should be seen within 1–2 weeks of beginning treatment. The wart should completely clear within 6–12 weeks. Self-treatment should not continue for longer than 12 weeks.

Cryotherapy Products

- Do not use cryotherapy products on children younger than 4 years of age.
- You will feel an aching, stinging sensation when the product is applied.
- A blister will form and the wart should fall off after about 10 days.
- If the wart does not completely clear after the first treatment, the procedure may be repeated in 2 weeks. Cryotherapy products should not be used for more than 12 weeks overall, and the treatment should not be repeated more than 3 times.

When to Seek Medical Attention

- Stop using the products and consult a dermatologist or other appropriate health care provider if severe irritation or pain occurs immediately after application.
- If the wart has not cleared after 12 weeks of treatment, consult a knowledgeable health care provider for evaluation and treatment.

<http://health.usnews.com/health-products/top-rec-wart-removers-146>. Accessed May 8, 2019; and Compound W [product information]. Lynchburg, VA/Tarrytown, NY: Prestige Brands. Available at: <https://www.compoundw.com/wart-removal-products/salicylic-acid-wart-removal/compoundw-one-step-strip-kids>. Accessed August 8, 2019.

Key Points for Warts

- Because many warts will resolve without treatment, a wait-and-see approach may be an appropriate management option in some patients. However, this approach allows continued transmission of the highly contagious HPV.
- Patients with multiple warts, warts in any area other than the hands and feet, warts on the fingernails, or large warts should be evaluated by an appropriate health care provider.
- Plantar warts should be treated with higher concentrations of salicylic acid (40%). Warts on the hands or areas with thinner epidermis can be treated with lower concentrations of salicylic acid (17%).
- NO and DMEP products are available for home cryotherapy treatments.
- The directions for use of nonprescription salicylic acid and cryotherapy products should be followed carefully to prevent injury to healthy tissue surrounding the wart.
- Patients with diabetes, poor circulation, or immunodeficiency should not self-treat with salicylic acid or cryotherapy without first consulting their regular health care provider.
- Patients who experience adverse effects from nonprescription wart removal products or have warts that recur frequently should be evaluated by an appropriate health care provider.

Chapter 44: Minor Foot Disorders

Authors: Sneha Baxi Srivastava

The 52 bones of the feet account for one quarter of the bones in the body, reflecting the outsize role of the foot as the literal basis for locomotion. Both the bones and soft tissues of the feet are subject to the attendant stresses of weight-bearing as well as the unique functional maneuvers required for walking as simple forward navigation. The goal for a day's worth of walking to maintain general health is 8000–10,000 steps, adding up to several miles. By the age of 70, the average person may have walked an equivalent of circling the earth nearly four times.

Although it is not “normal” for feet to hurt (under typical usage), up to 75% of Americans will experience foot health problems at some point in their lives.^{1,2} Women are four times more likely to experience foot problems. In the United States, the most common disorders are corns or calluses (5%), ingrown toenails or other nail afflictions (5%), foot infections including athlete's foot and warts (5%), and foot injuries and structural problems—bunions, flat feet, and fallen arches (6%).¹ Many minor foot disorders and injuries occur as a consequence of neglect, lack of awareness of proper foot care, and years, even decades of wear and tear. Accordingly, health care providers likely to encounter patients with foot health problems should maintain clinical awareness of this category of disorders, as well as familiarity with their management, including recognition of specific signs and symptoms, recommendations for effective measures for prevention and treatment, and referrals, when indicated, to a podiatrist or other foot care specialist for further evaluation and management.

The pharmacist may be the first health care provider consulted by a person with a foot-related complaint. At the initial assessment, a thorough history is necessary to ensure that self-care is appropriate for both the patient and the foot problem. In some instances, self-care for foot disorders is inappropriate. For instance, children with congenital malformations, deformities, or specific diseases that affect the foot (e.g., juvenile arthritis) require medical management by an orthopedic surgeon or a podiatrist. Rapid growth in adolescents can result in foot irritation from changes in growth plates, which is a condition excluded from use of self-care measures. Older patients may present with foot problems related to aging (e.g., arthritis) or disease (e.g., peripheral vascular disease). Common foot disorders may potentially have

severe consequences in patients with comorbid diseases (e.g., diabetes) and also may indicate other serious underlying conditions.³ In some instances, inappropriate foot care practices may be life-threatening in patients with diabetes, severe arthritis, or impaired circulation^{3–6} (see the box “A Word About Chronic Diseases and Foot Disorders”). For some patients, however, foot problems causing mild to moderate discomfort and impaired mobility can be treated with self-care measures. Examples of such conditions are corns, calluses, ingrown toenails, tired/aching feet, and exercise-induced injuries.

Pathophysiology of the Foot

At birth, the infant’s foot has 33 joints, 19 muscles, 107 ligaments, and cartilage that will develop into 26 bones. The feet continue to develop and mature until the ages of 14–16 years for females and 15–21 years for males. There may be increased foot pain and soft tissue stiffness with a decreased range of motion and strength with advancing age. Such changes lead, in turn, to altered gait, with an increased risk of falls.⁷ After years of bearing the body’s weight, feet tend to broaden and flatten, thereby stretching ligaments and causing bones to shift position. This altered anatomy subjects the feet to stress even in the absence of overuse, which is then compounded by prolonged standing. Additionally, feet often are the first area of the body to exhibit clinical manifestations of conditions such as arthritis, diabetes, and neurologic or circulatory disorders.¹

Corns and Calluses

Corns and calluses are common foot disorders that often are overlooked by the affected patients themselves. However, these lesions may indicate a biomechanical problem, with potentially serious complications if the underlying condition is left untreated. When the clinical presentation includes a foot-related concern, even if the patient minimizes the issue, the initial assessment often will reveal the presence of such lesions. The health care provider should then attempt to identify any contributing factors in their pathogenesis, as well as recommend appropriate treatment.

Pathophysiology of Corns and Calluses

Under normal conditions, the cells in the skin's basal cell layer (*stratum basale*) undergo mitotic division at a rate that balances the continual surface cellular desquamation, eventuating in complete replacement of the epidermis in approximately 1 month. During corn or callus development, however, friction and pressure increase mitotic activity of the basal cell layer, leading to the migration of maturing cells through the prickly cell (*stratum spinosum*) and granular (*stratum granulosum*) skin layers (see [Chapter 33](#), Figure 33–1). As more cells reach the outer skin surface, they produce a thicker, horny layer (*stratum corneum*). This process is a natural protective mechanism of the skin surface and may signal biomechanical problems that result in abnormal weight distribution on the foot. When friction or pressure is relieved, mitotic activity returns to normal, with consequent remission and disappearance of the lesion.^{8,9}

A Word about Chronic Diseases and Foot Disorders

Some chronic diseases can predispose affected patients to foot complications. Patients with diabetes often have poor circulation and diminished limb sensitivity, making them especially vulnerable to infectious foot problems. Other susceptible patients include those with peripheral vascular disease or arthritis. Whether or not the clinical presentation includes foot-related complaints, questioning about daily medication use or a review of the patient's drug profile can alert the health care provider to the presence of such chronic diseases. Typical drug use patterns for high-risk patients include regimens of insulin, oral or injectable antidiabetic drugs, drugs for circulation disorders (e.g., clopidogrel, pentoxifylline); drugs for neuropathic pain (e.g., gabapentin, pregabalin, duloxetine); and drugs for arthritic disorders (e.g., acetaminophen, NSAIDs).

If not properly supervised in patients with impaired circulation, self-treatment with nonprescription products may induce more inflammation, ulceration, or even gangrene, particularly in cases of vascular insufficiency in the foot. Affected tissues in patients with diabetes and those with

peripheral circulatory impairments are particularly susceptible to development of gangrene. In addition, simple lesions may mask more serious abscesses or ulcerations. Without proper care, these underlying problems may lead to conditions such as osteomyelitis, which may necessitate hospitalization and aggressive intravenous antibiotic therapy.

Diabetes Mellitus

Poorly controlled diabetes is associated with increased health care costs, decreased quality of life, and increased morbidity and mortality. Additionally, affected patients are at a greater risk for lower extremity complications. Peripheral neuropathy, which results in loss of injury perception, and excessive plantar pressure are the two major causes of foot ulcerations. Plantar pressure contributes to decreased mobility and development of foot deformities. Poor foot hygiene, such as extremely hot water soaks, wearing inappropriate footwear, and lack of daily foot self-examinations, contributes to foot complications in patients with diabetes. Patients with this disorder need to be educated on proper foot care, such as trimming toenails appropriately, not applying creams/lotions between the toes, keeping socks clean and dry, and performing foot examinations at home. The following self-care and preventive measures can help reduce the risk of diabetic complications.

Foot Care

- All patients should have a yearly comprehensive foot evaluation. Evaluation should include assessing for any changes in foot appearance or tactile sensation.
- The 2019 American Diabetes Association (ADA) Standards of Care state that only patients with evidence of sensory loss or history of ulceration/amputation should have their feet inspected at every primary care provider visit.
- Advise patients at high risk for development of skin ulcers (e.g., those with neuropathy) to see a podiatrist regularly.
- Teach patient to clean and inspect feet daily for any changes (e.g., corn, callus, open wound, evidence of fungal infection).
- Instruct patient to trim nails carefully (straight across) and file them

with an emery board to the contour of the toe.

- Instruct patient to avoid walking barefoot.
- Recommend use of soft cotton, synthetic blend, or wool socks to absorb moisture.
- Recommend that patient wear proper-fitting, comfortable shoes and use caution when “breaking in” new shoes. Consider the use of specialized therapeutic footwear, especially in patients with severe neuropathy, foot deformity, or previous amputation.
- Recommend that patient inspect shoes for foreign objects before inserting feet.
- Recommend that patient (1) use moisturizing lotion sparingly on the tops and bottoms of dry feet, (2) allow feet to completely dry before donning shoes, to prevent excess moisture buildup, and (3) avoid use of moisturizers between the toes.

Peripheral Vascular Disease

Patients with peripheral vascular disease often have poor circulation in the feet and legs. Because of decreased blood flow and low oxygen perfusion, skin ulcerations and decreased wound healing may be problematic in these patients. They may complain of persistent and unusual feelings of cold, numbness, tingling, burning, or fatigue. Other manifestations of this disease may include discolored skin, dry skin, absence of hair on the feet or legs, or a cramping or tightness in the leg muscles. The health care provider should palpate for pedal pulses. The clinical interview also should include the following two important questions: (1) “Do you experience aching in your calves when you walk?” (2) “Do you have to hang your feet over the edge of the bed during sleep to relieve the soreness in your calves?” A yes response to either question warrants referral to a medical provider.

Localized redness or unilateral coldness may indicate a possible blockage (a clot) of circulation to the foot. The involved foot or lower leg may be physically larger than the other, may have a reddened or waxy appearance to the skin, may feature absence of hair growth on the toes, and will exhibit thickened nails. With suspected circulatory problems, if the patient’s medication history does not list preparations and products

intended to relieve such symptoms, immediate referral for further evaluation is warranted.

A daily footbath is a simple measure for managing peripheral vascular disease. After the foot is patted dry, an emollient foot cream can be applied to aid the skin in retaining moisture and pliability. The footbath also will soften brittle toenails for clipping and filing. The feet should be kept warm and moderately exercised every day.

Arthritis

Osteoarthritis is a noninflammatory, degenerative joint disease that occurs primarily in older people. Degeneration of the articular cartilage and changes in the bone result in a loss of resilience and a decrease in the skeleton's shock absorption capability. This condition, however, also is experienced by young persons in their late teens and early 20s as a secondary complication of a previous athletic injury. In this scenario, osteoarthritis can be evidenced by the development of *hallux limitus* (i.e., pain on flexion or extension of the big toe related to stiffness and spur formation in the metatarsophalangeal joint) or *rigidus* of the big toe (a stiff toe, unable to move). Subsequently, affected patients experience considerable difficulty with their shoes not fitting properly. Development of an osteoarthritic condition in the ankle joint is another possible complication. Referral for further evaluation is appropriate.

Most patients with rheumatoid arthritis eventually have foot involvement. The major forefoot deformities in these patients are painful metatarsal heads, hallux valgus, and clawfoot. Corrective surgical procedures often are indicated to reduce pain and improve function and mobility. Evidence for the efficacy of conventional nonsurgical therapy (e.g., orthopedic shoes, metatarsal inserts, conventional arch supports, metatarsal bars) is limited.

Proper palliative foot care is especially important for patients with arthritis that affects the feet. They should wear properly fitted shoes, pad their shoes with insoles to protect the feet from the shock of hard surfaces, and undergo regular podiatric or medical examinations.

Key: NSAID = Nonsteroidal anti-inflammatory drug.

Clinical Presentation of Corns and Calluses

Corns and calluses are similar in that both produce a marked hyperkeratosis of the stratum corneum, but they have marked clinical differences.

Corns

A *corn (clavus)* is a small, raised, sharply demarcated, hyperkeratotic lesion with a central core; the lesion is caused by pressure from underlying bony prominences or joints. The central core of the corn differentiates it from a wart (see [Chapter 43](#), [Table 43–5](#)). Misidentification of warts as corns is common. A corn has a hard center, whereas a wart will bleed because of the multiple capillary loops in its center.⁸ Corns generally are well circumscribed, with a diameter of 1 cm or less, and presentation may range from flesh-colored to white to yellowish gray. The base of the corn is on the skin surface; its apex points inward and presses on the nerve endings in the dermis, causing pain.^{8–11}

Polished, shiny, dry *hard corns (heloma durum)* are the most prevalent and usually occur on the bulb of the great toe, the dorsum of the fourth or fifth toe, or tips of the middle toes. *Soft corns (heloma molle)* are whitish thickenings of the skin and may be extremely painful. Accumulated perspiration macerates the epidermis, giving this corn a soft appearance. Soft corns may occur between any adjacent toes but most frequently are found between the fourth

and fifth toes⁹ (Figure 44–1).

FIGURE 44–1 Disorders affecting top and sole of foot: corns, callus, and plantar warts.

Pressure from inappropriate, tight-fitting shoes is the most frequent cause of pain from corns. As narrow-toed or high-heeled shoes crowd toes into a narrow toe box, the most lateral toe, the fifth, sustains the most pressure and friction and is the usual site of a corn. The resulting pain may be severe and sharp (on application of downward pressure) or dull and discomforting. Consumer research suggests that approximately 82% of women 35–54 years of age suffer moderate to severe pain from corns, with 35% consequently limited or restricted in their activities.^{7,10,11}

Calluses

A *callus* has a broad base, with relatively even thickening of skin, and generally is found on the bottom of the foot in areas such as the heel, ball of the foot, and toes, and on the sides of the foot (Figure 44–1). A callus has indefinite borders and ranges in diameter from a few millimeters to several centimeters. The lack of defined borders helps in differentiating calluses from corns, which have well-circumscribed margins. A callus usually is raised and yellow, with a normal pattern of skin ridges on its surface. Calluses form over joints and on weight-bearing areas of the hands and feet^{7,9–12} (see Color Plates, photograph 35).

Friction (caused by loose-fitting shoes or tight-fitting hosiery), walking barefoot, and structural biomechanical problems contribute to the development of calluses. Calluses can be both symptomatic and protective.

Two of the most common calluses found on the feet are discrete-nucleated and diffuse-shearing calluses. The *discrete-nucleated callus* is smaller and has a localized translucent center; this type of callus is painful with applied pressure because of its central keratin plug. The *diffuse-shearing callus* covers a larger surface area and does not have a central core, so it is not associated with pain.¹³

Treatment of Corns and Calluses

Treatment Goals

The goals of self-treatment are (1) to provide symptomatic relief, (2) to remove corns and calluses, and (3) to prevent their recurrence by correcting underlying causes.

General Treatment Approach

Although effective nonprescription products are available for removing corns and calluses, ultimate success depends on eliminating the causes. The algorithm in [Figure 44–2](#) outlines self-treatment for corns and calluses and lists potential exclusions for self-care.

Nonpharmacologic Therapy

Daily soaking of the affected skin area (for at least 5 minutes in warm, not hot, water) throughout the treatment period aids in softening dead tissue for removal. After normal washing of the foot, dead tissue should be removed gently, rather than forcibly, to avoid further damage. A callus file or pumice stone effectively accomplishes this purpose. Power-operated foot files may be too aggressive. Sharp knives or razor blades should not be used because these instruments may lacerate the skin, which could allow bacteria to enter the wound, potentially resulting in localized infection.⁸

Circular foam cushioning pads may aid in relieving painful pressure from inflamed tissue. Polymer gel pads provide a protective cushion without leaving a sticky residue. The gel pads also have a smooth outer surface that does not snag on socks and other hosiery.⁸ A silicone toe sleeve impregnated with mineral oil, such as the Pedifix Visco-Gel Toe Protector, is an option for toes affected by corns. The mineral oil is slowly released to soften the skin. The sleeve protects and cushions the corn area. A foam spacer or lamb's wool may be used to provide relief in areas with soft corns. Placement of a metatarsal pad or lamb's wool may help relieve pain and pressure from a callus.¹³

Eliminating the pressure and friction that induce corns and calluses entails using well-fitting, nonbinding footwear that evenly distributes body weight¹³ ([Table 44–1](#)). The stratum corneum will normalize after topical keratolytics are applied and total desquamation of the hyperkeratotic tissue occurs. For anatomic foot deformities, orthopedic corrections must be made. Orthotics

(i.e., arch supports) may be needed to help compensate for deformities by redistributing the mechanical forces incurred by the foot. These measures relieve pressure and friction, which allows normal mitosis of the basal cell layer to resume. Ultimately, surgical correction of toe deformities with resection of the underlying bone may be necessary.

TABLE 44-1 Selection of Proper-Fitting Footwear

- Buy shoes in the proper size (width and length). To obtain an accurate measurement, ask a trained salesperson to measure your feet. Recheck shoe size every 2 years.
- Base shoe length on the longest toe of your longest foot. The optimum distance between the tip of the shoe and the longest toe is approximately $\frac{1}{2}$ inch. In an athletic shoe, 1 inch is needed.
- For proper arch length, choose a shoe in which the first metatarsal head of the foot fits the metatarsal “break” of the shoe.
- For proper shoe width, choose a shoe that feels comfortable at the first metatarsal joint (so that toes do not feel cramped in the toe box).
- Once the shoe size is determined, choose a shoe shaped to match the shape of your foot.
- If you have abnormalities of the toes (e.g., hammer toes) or use orthotics or padding in your shoes, select a shoe with a toe box of adequate depth (vertical height) to prevent friction on the tops of the toes. A wide toe box will help relieve pressure between toes.
- Make sure the heel area fits snugly and helps hold the foot straight.
- If you are physically active, make sure the shoe’s midsole provides adequate cushioning and support.
- Try on both shoes at the time of purchase, preferably wearing a pair of socks or stockings of the type that will usually be worn with the new shoes.
- If your feet tend to swell, shop for shoes at the end of the day.

Pharmacologic Therapy

Salicylic Acid

Salicylic acid, a keratolytic agent, is formulated in various strengths (0.5%–40%). For the treatment of corns and calluses, the approved concentration ranges are 6%–17% in a topical gel, 12%–40% in a plaster vehicle, and 12%–27.5% in a collodion-like vehicle.^{14,15}

Salicylic acid is believed to act on hyperplastic keratin, without affecting viable

epidermis. On application of salicylic acid, the treated area will swell, soften, macerate, and then desquamate the affected epithelium. The U.S. Food and Drug Administration (FDA) has stated that presoaking the affected area before application of salicylic acid produced no significant positive effects. In its final rule, FDA proposed allowing manufacturers of these products to use the following statement as an optional direction to the consumer: “May soak corn/callus (or wart) in warm water for 5 minutes” to assist in removal.^{14,15}

The FDA advisory review panel evaluated more than 20 agents for the treatment of corns and calluses. Of these agents, only salicylic acid in a plaster, pad, disk, gel, or collodion-like vehicle dosage form is approved as safe and effective as a nonprescription preparation marketed for the removal of corns and calluses (Table 44–2). FDA recognizes that the term *plaster* includes disks and pads, because these dosage forms are similar.¹⁵

TABLE 44–2 Selected Corn and Callus Removal Products	
Trade Name	Primary Ingredient
Pedinol Hydrisalic Gel	Salicylic acid 17%
Dr. Scholl’s Corn/Callus Remover Liquid	Salicylic acid 17%
Dr. Scholl’s Duragel Callus Remover	Salicylic acid 40%
Dr. Scholl’s Duragel Corn Remover	Salicylic acid 40%
Curad Mediplast Corn, Callus & Wart Remover Pad	Salicylic acid 40%

Source: Reference 14.

Salicylic acid usually is applied to a corn, callus, or common wart in a collodion-like vehicle. These vehicles contain pyroxylin and various combinations of volatile solvents (e.g., ether, acetone, alcohol) or a plasticizer, which usually is castor oil. Pyroxylin is a nitrocellulose derivative that remains on the skin as a water-repellent film after the volatile solvents have evaporated.^{14,15}

The advantages of collodions and liquid dosage forms are that they form an adherent flexible or rigid film and prevent moisture evaporation. These

properties aid penetration of the active ingredient into the affected tissue, resulting in sustained local action of the drug. The delivery systems are largely water-insoluble, as are most of their active ingredients, including salicylic acid. They also are less prone than other liquid solutions to run onto surrounding skin.^{14,15}

A disadvantage of collodions is that they are extremely flammable and volatile. Some patients may inhale and abuse these vehicles. Another disadvantage is their occlusion of normal water transport through the skin, which allows systemic absorption of some drugs (e.g., salicylic acid). Percutaneous absorption may be problematic with prolonged use on large surface areas in children and patients with renal or hepatic impairment, because salicylic acid is largely metabolized in the liver and excreted in the urine. Although occlusive vehicles can enhance the percutaneous absorption of salicylic acid, it is highly unlikely that salicylate toxicity will result during corn, callus, or wart therapy at recommended dosages. However, if signs and symptoms of possible salicylic toxicity (nausea, vomiting, dizziness, hearing loss, tinnitus, lethargy, hyperpnea, diarrhea, or psychiatric disturbances) emerge, use of these products should be discontinued immediately.^{14,15}

Salicylic acid also may be delivered to the skin through the use of a plaster, disk, or pad. Such delivery systems provide direct and prolonged contact of the drug with the affected area, resulting in quicker resolution of the condition. Salicylic acid plaster is a uniform solid or semisolid adhesive mixture of salicylic acid in a suitable base that is spread on appropriate backing material (e.g., felt, moleskin, cotton, plastic). The usual concentration of salicylic acid in the base is 40%; with these dosage forms, the preparation may be applied directly to the corn or callus.^{8,14,15} **Table 44–3** provides instructions for applying salicylic acid products.

TABLE 44–3 Guidelines for Treating Corns and Calluses With Salicylic Acid Products

- Wash and dry the affected area thoroughly before applying any product.
- Soak the affected foot in warm water for 5 minutes. Then remove the macerated, soft white skin of the corn or callus by scrubbing gently with a rough towel, pumice stone, or callus file. Do not debride the healthy skin.

Salicylic Acid 17% in Collodion-Like Vehicle

- Apply product no more than twice daily for up to 14 days. Morning and evening usually are the most convenient times.
- Do not let adjacent areas of normal healthy skin come in contact with product. If this happens, immediately wash off the solution with soap and water.
 - A coating of petroleum jelly on healthy surrounding skin will serve as protection if delivery of the medication accidentally extends beyond the intended treatment area.
- Apply 1 drop at a time directly to the corn or callus until the affected area is well covered. Do not overuse the product.
- Allow the drops to dry and harden so that the solution does not run.
- After use, cap the container tightly to prevent evaporation, which would result in a higher, potentially harmful concentration of the active ingredients.
- Store the product in an amber or otherwise light-resistant container away from direct sunlight or heat.

Salicylic Acid 40% Plasters/Pads

- If using a plaster, trim it to follow the contours of the corn or callus. Apply the plaster to the affected skin, and cover it with adhesive occlusive tape.
- If using medicated disks with pads, apply the appropriate-sized disk directly on the affected area, and then cover the disk with the pad.
- Remove the plaster/pad and occlusive tape within 48 hours.
- After rubbing off the softened skin, reapply the plaster every 48 hours as needed to remove the corn/callus, but do not treat for longer than 14 days—that is, use no more than 7 applications.
 - Seek medical attention if redness or irritation of the skin occurs or if corn or callus is not removed after 14 days of treatment.

Source: [Reference 14](#).

Caution is essential in applying topical salicylic acid because of the risk of inflammation or ulcer formation with suboptimal technique (see the box “A Word About Chronic Diseases and Foot Disorders”). Use of these products may be hazardous in pregnancy, and they should not be used in patients who are breastfeeding because of adverse effects from systemic absorption and the potential for Reye syndrome. Salicylic acid may be used in pediatric patients older than 2 years at concentrations of 1.8%–6%. FDA requires the following warning on salicylic acid product labels:

Do not use this product on irritated skin, any area that is infected or reddened, moles, birthmarks, warts with hair growing from them, genital warts, warts on the face, or warts on the mucous membranes, such as inside the mouth, nose, anus, genitals, or lips. Do not use if you are diabetic, or if you have poor blood circulation.^{14,15}

Assessment of Corns and Calluses: A Case-Based Approach

The assessment should be in a private area where the patient can be comfortable removing the shoe(s) to allow direct inspection of the feet. The patient should be asked about any self-care attempts and their outcome. The patient's health status and current medication regimen also should be assessed. Additionally, lifestyle factors (e.g., occupation, daily exercise, footwear), underlying pathology (e.g., circulatory or neurologic disorders), the possibility of an aggravating event, and the walking/working surface must be evaluated. This information should be recorded and regularly updated in the patient's medical chart. [Figure 44–2](#) illustrates the assessment of a patient with corns or calluses.

Patient Counseling for Corns and Calluses

Remission of corns and calluses can take several days to several months. Patients with such lesions should recognize that effective treatment and maintenance depend on eliminating predisposing factors that contributed to the foot problem. It is important to emphasize the need for wearing footwear of adequate width and length. Pads and cushions also help to reduce the pressure and shearing associated with corn and callus development.

The patient or caregiver should be counseled on how to use nonprescription medications that remove corns and calluses. Because many such products contain corrosive materials, they must be applied only to the corn or callus. Patients should be alerted that products containing collodions are poisonous when ingested and that these products, as well as all other medications, should be stored out of children's reach. Case 44–1 illustrates the assessment of a patient with calluses. The box "Patient Education for Corns and Calluses" lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Corns and Calluses

The progress of the patient’s self-treatment regimen for corns or calluses should be checked after 14 days. The affected area should be visually inspected to determine whether the corns or calluses have decreased in size or resolved. The methods used to eliminate the corns or calluses also should be evaluated. If these conditions are still present, the patient should seek further medical evaluation.

Algorithm: Corns and Calluses

FIGURE 44–2 Self-care for corns and calluses.

Case 44–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient describes a large flesh-colored, thick dry area of “dead skin” on the ball of her foot that has been present for approximately 6 weeks. She has recently started wearing a new pair of shoes with heels to work.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient’s symptom(s)	The patient states that the thickened area bothers her when she walks and runs.
c. Description of the	She has tried wearing thicker socks and using a pumice stone

Relevant Evaluation Criteria	Scenario/Model Outcome
patient's efforts to relieve the symptoms	to remove excess skin on the affected area, but the excess tissue comes back.
d. Patient's identity	Janice Jones
e. Patient's age, gender, height, and weight	35 years, female, 5 ft 2 in., 126 lb
f. Patient's occupation	Banker
g. Patient's dietary habits	Smoothie for breakfast, salad or sandwich for lunch; dinner typically consists of a protein and carbohydrate (e.g., chicken and rice, falafel sandwich, spaghetti with meatballs).
h. Patient's sleep habits	She sleeps 7 hours nightly.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No pertinent medical conditions
j. Allergies	Penicillin–rash
k. History of other adverse reactions to medications	None
l. Other (describe) _____	None
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Ms. Jones has developed diffuse shearing calluses (Figure 44-1).
3. Identify exclusions for self-treatment.	None (Figure 44-2)
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to	Options include (1) Refer Ms. Jones to an appropriate health care provider.

Relevant Evaluation Criteria	Scenario/Model Outcome
determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	(2) Recommend self-care with a nonprescription callus remover and nondrug measures. (3) Recommend self-care until Ms. Jones can see an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. Jones should use a nonprescription callus remover, callus cushioning pads, and nondrug measures to treat this condition.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Daily foot soaks and a pumice stone or foot file may be used to reduce roughness of your calluses. Completely dry the feet before applying the callus remover. Use of cushioning pads will help protect pressure point areas on your feet, allowing the affected skin to improve. The shoes you recently started wearing may be causing the calluses—you also should consider getting fitted for appropriate shoes." See Table 44-1 .
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Calluses can be removed by nonprescription products and the use of foot files. However, it is important to assess the cause of the callus formation and to correct the cause with appropriate measures including selection of proper-fitting footwear."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	See Table 44-3 for instructions for applying salicylic acid products. Also see the box "Patient Education for Corns and Calluses." Ms. Jones should experience a response to treatment recommendations within 14 days.
Solicit follow-up questions	(1) "How long do I really need to use this product?"

Relevant Evaluation Criteria	Scenario/Model Outcome
from the patient or caregiver.	(2) Can I speed up the process by cutting down the callus with a razor blade before applying the nonprescription medication?" (3) "I really like wearing my new shoes—do I have to stop?"
Answer the patient's or caregiver's questions.	(1) "You should follow the appropriate treatment duration to receive the maximum benefit. You should experience resolution of symptoms within 14 days." (2) "It is best to soak the feet and use foot files to pare down the callus. Do not cut on your feet because of the risk of injury with subsequent infection." (3) "Unfortunately, your new shoes may be the underlying cause for this condition. It does seem like shoes that are good for the feet may not look as fashion-forward as wanted. Talk to a foot care specialist to see if certain types of shoes or padding would be your best options to maintain foot health."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Ms. Jones to call in 14 days to update you on the response to your treatment recommendations, or you could call her into the pharmacy to evaluate the response.

Patient Education for Corns and Calluses

The objectives of self-treatment are (1) to provide symptomatic relief, (2) to remove corns or calluses, and (3) to prevent their recurrence by correcting underlying causes. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- After use, carefully clean instruments used to remove dead skin, to

avoid bacterial contamination with potential infection on subsequent use.

- Do not use sharp knives or razor blades to remove dead skin from corns and calluses. Accidental cuts into the dermis with such instruments may lead to bacterial infections.
- If you have trouble applying the product only to the affected area, use petroleum jelly to coat healthy skin surrounding the treatment area before applying the corn and callus remover.
- For temporary relief of painful pressure in the area under a corn or callus, cover the affected area with a pad.
- Consult an appropriate health care provider if the symptoms described recur.

Preventive Measures

- To eliminate the pressure and friction that cause corns and calluses, wear well-fitted shoes that evenly distribute body weight (Table 44-1).
- Consult a podiatrist about foot deformity corrections.

Nonprescription Medications

- To remove corns and calluses, use a salicylic acid product labeled for use on these types of lesions (Tables 44-2 and 44-3).
- Do not use this product on irritated, infected, or reddened skin.
- Do not use this product if you are diabetic or have poor blood circulation.
- Salicylic acid is poisonous. Do not allow it to come in contact with the mouth, and keep it out of children's reach.
- Note that the medication sloughs off skin, which may leave an unsightly pinkish tinge to the affected area.

When to Seek Medical Attention

- Stop treatment and consult an appropriate health care provider if swelling, reddening, or irritation of the skin develops, or if pain occurs immediately with product application.

Tired, Aching Feet and Exercise-Induced Foot Injuries

With every step taken, gravity-induced pressure of up to twice the body's weight bears down on each foot, releasing powerful shocks of energy that the foot's natural padding must struggle to absorb.¹ In an unpadded shoe, the shock as the foot strikes the ground is transmitted through the foot to the ankle, leg, and back. This shock can fatigue muscles, resulting in tired, aching feet and/or back pain.^{16,17}

An estimated two thirds of Americans complain of tired, aching feet (the most common foot problem). In addition, 2 million adults are estimated to suffer from heel pain.¹⁸ In addition to recognizing the foot disorders due to daily impact, health care providers should be familiar with possible exercise-induced foot injuries, particularly those caused by running, jogging, or other high-impact physical activities (Figure 44–3). People seeking to increase their daily activity level may oftentimes plunge head first into a strenuous exercise program without understanding important precautions to avoid injury. To minimize the risk of injury, persons who are typically sedentary, are older than 35 years of age, suffer from hypertension, or have a history of heart disease or diabetes should seek medical evaluation before beginning a high-level exercise regimen.¹⁹ Patients with potential orthopedic problems may benefit from walking instead of engaging in more demanding activities.²⁰

FIGURE 44–3 Anatomic locations for selected foot and leg injuries associated with excessive impact shock.

Pathophysiology of Tired, Aching Feet and Exercise-Induced Foot Injuries

Aching feet can be caused by increased frequency of standing and/or walking (especially on hard surfaces), age-related erosion of the fat padding on the bottom of the foot, circulatory or neurologic disorders, and poor-fitting or inappropriate footwear.

Because the cause of heel pain is difficult to determine, treatment often can

be prolonged and expensive. The three most common types of heel pain are heel spurs, plantar fasciitis, and Sever's disease. Exercise-induced injuries include shin splints, stress fractures, Achilles tendonitis, blisters, ankle sprains, intermetatarsal neuritis, and toenail loss. The common causes, pathophysiologic mechanisms, clinical presentation, and therapeutic recommendations are summarized in [Table 44–4](#) for each of these conditions.

TABLE 44–4 Differentiation and Management of Exercise-Induced Foot Injuries

Type of Injury	Common Cause(s)	Pathophysiologic Mechanism(s)	Clinical Presentation	Recommendation(s)
Shin splints	Overzealous workout; inappropriate stretching; running/walking on sloped or hard surfaces; wearing ill-fitting footwear; overstriding	Excessive pronation weakening/straining posterior tibialis; anterior tibia muscle stretching away from periosteum that lines shin bone	Pain in medial lower third of shin, or below knee and above ankle; worsening pain with exercise; cramping, burning, and tightness on anterior lateral section of shin	PRICE or RICE therapy; acetaminophen or ibuprofen; shoe orthotic; medical referral
Stress fracture	Running on hard, rigid surfaces; rapid increase in physical activity; jumping; estrogen deficiency; nutritional deficiencies; obesity; ill-fitting footwear	Outer cortex of long bones of leg or foot cracking from tensile forces transmitted by ligaments, tendons, and muscles	Deep pain in lower leg; tenderness to touch; swelling; worsening pain with exercise	Medical referral; complete rest; NSAID therapy
Achilles tendonitis	Running on hills or in sand; ill-fitting footwear;	Inflammation of Achilles tendon; rupture of tendon	Posterior heel pain; tenderness; swelling	Medical referral

Type of Injury	Common Cause(s)	Pathophysiologic Mechanism(s)	Clinical Presentation	Recommendation(s)
	excessive pronation; arthritis			
Blisters	Repetitive movement; ill-fitting footwear; tight hosiery	Continual friction on small surface of foot separates stratum corneum and stratum lucidum skin layers, causing space between layers to fill with fluid	Accumulation of fluid beneath stratum corneum; may be painful	Do not remove blister; protect with topical bandage; medical referral for drainage may be indicated.
Ankle sprains	Ankle rotation outside acceptable range	Lateral ligament damage	Pain; bruising; tenderness; difficulty walking	PRICE or RICE therapy; compression bandage
Intermetatarsal neuritis	Small toe box space	Inflammation of nerves from compression of or entanglement between metatarsal heads and digital bases	Pain and numbness between toes	Proper footwear
Toenail loss	Long, thick toenails in small toe box space; friction and pressure from running in “stop and go” sports such as tennis	Fluid beneath nail plate elevating toenail from nail bed	Dark discoloration from blood underneath nail plate; pain at toe; nail loss	Referral to podiatrist or qualified primary care provider
Plantar fasciitis	High arches, flat feet, repetitive stress during athletic activity, pronated feet,	Strain on the connective tissue that attaches the arch to the front of the heel	Manifests with pain on arising in the morning or on standing up after sitting; the pain	

Type of Injury	Common Cause(s)	Pathophysiologic Mechanism(s)	Clinical Presentation	Recommendation(s)
	prolonged standing		results from tissue contraction. The sensation on the bottom of the heel is quite painful, and the patient may complain of a burning sensation.	
Heel spurs	Incorrect walking or running technique, excessive running, poor-fitting shoes, obesity, aging	Bony growth on the underside of the heel bone Possible formation of calcium deposits on the calcaneous bone (detected via x-ray imaging), causing pain of increasing intensity after prolonged periods of rest	Strained foot muscles, deterioration of fat tissue surrounding heel bone	
Sever's disease	Seen in children (predominantly occurs in boys 8-15 years of age), manifested as heel pain precipitated by running, jumping, or excessive walking; usually resolves on completion of bone growth	Calcaneal apophysitis	Manifests with no swelling, skin changes, erythema, or other visible abnormalities. The <i>squeeze test</i> aids in the diagnosis of Sever's disease: Pressure is applied at point of attachment of the	

Type of Injury	Common Cause(s)	Pathophysiologic Mechanism(s)	Clinical Presentation	Recommendation(s)
	or with curtailment of activity		calcaneal apophysis to main body of the os calcis to determine if the patient experiences pain.	

Key: NSAID = Nonsteroidal anti-inflammatory drug; PRICE = protection, rest, ice, compression, elevation; RICE = rest, ice, compression, elevation.

Source: [References 8, 11, 17, 19](#), and [21–32](#).

Assessment of Tired, Aching Feet and Exercise-Induced Foot Injuries

Treatment of tired, aching feet requires evaluation of lifestyle factors (e.g., occupation, daily exercise, footwear); the possibility of underlying disease (e.g., circulatory or neurologic disorders) or an aggravating event; and the walking/working surface. If an underlying pathologic condition is suspected, the patient should be referred to a primary care provider or podiatrist for further evaluation. Case 44–2 illustrates the assessment of a patient with tired, aching feet.

Case 44–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	

Relevant Evaluation Criteria	Scenario/Model Outcome
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient presents complaining of "tired, achy feet" that started approximately 2 weeks ago. Her right foot hurts more than the left, but both are affected.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Walking makes the symptoms worse, and the patient is upset about this because she likes to be active. She recently went for a strenuous hike, and since then, her feet have been hurting more than usual. Resting brings some relief.
c. Description of the patient's efforts to relieve the symptoms	The patient visited a local health spa for a foot massage, but that helped only temporarily.
d. Patient's identity	Agnes Martin
e. Patient's age, gender, height, and weight	61 years, female, 5 ft 7 in., 150 lb
f. Patient's occupation	Retired sports equipment sales associate
g. Patient's dietary habits	Eats a relatively healthy diet, 2-3 meals a day.
h. Patient's sleep habits	Typically sleeps 8 hours per night.
i. Concurrent medical conditions,	Diabetes type 1: takes insulin glargine 40 units daily and insulin aspart 10 units AC meals

Relevant Evaluation Criteria	Scenario/Model Outcome
prescription and nonprescription medications, and dietary supplements	
j. Allergies	NKDA
k. History of other adverse reactions to medications	None
l. Other (describe) -----	
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	The patient has tired, aching feet, which may be due to strenuous activity, possibly inappropriate footwear, and changes in anatomy due to aging.
3. Identify exclusions for self-treatment (Figure 44-5).	Diabetes
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mrs. Martin to an appropriate health care provider for further evaluation. (2) Recommend self-care with nonprescription products for treating tired, aching feet. (3) Recommend self-care until Mrs. Martin can see an appropriate provider. (4) Take no action.

Relevant Evaluation Criteria	Scenario/Model Outcome
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mrs. Martin should consult a podiatrist because she has diabetes. She may benefit from a podiatrist's evaluation to ensure that she has appropriate footwear, especially for her strenuous activities. She also should rest her feet until the pain is alleviated. She can take a nonprescription pain medication such as acetaminophen to help relieve discomfort until her specialist appointment.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult an appropriate health care provider about your tired, aching feet. Especially because you have diabetes, it's important that someone monitor the condition of your feet and check that you are wearing the most appropriate footwear. You may take acetaminophen for at least partial relief of the pain, and continuing to rest until you restart your strenuous activities may help too."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best for you since you typically are so active and you have a health condition that may put you at risk for worsening foot problems."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Definitely rest your feet as much as possible. If the pain continues, take acetaminophen 500 mg, 1 or 2 tablets by mouth, every 4–6 hours as needed for pain. Do not take more than 6 tablets in a 24-hour period."
Solicit follow-up questions from the patient or caregiver.	"I really don't like to sit still—can I just keep moving and get through the pain?"

Relevant Evaluation Criteria	Scenario/Model Outcome
	"I buy expensive shoes—are you sure that I am not using the right ones?"
Answer the patient's or caregiver's questions.	"Your active lifestyle is so healthy, especially for someone in your age group, and normally I would encourage you to continue your physical activity. But you are having pain right now, so it probably is best to rest until the symptoms subside. In the meantime, see a podiatrist or other foot care specialist to check your shoes for proper fit or needed cushioning or support. Everyone's feet are different and may exhibit anatomic changes over time. Because of your diabetes, it is especially important to have a podiatrist, who specializes in foot manifestations of chronic diseases, examine your feet and make the most appropriate suggestions for your care."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mrs. Martin to contact you if she has any further questions or concerns.

Key: NDKA = No known drug allergies.

Treatment of Tired, Aching Feet and Exercise-Induced Foot Injuries

Treatment Goals

The primary goal in self-treatment for tired, aching feet is to provide additional support and shock absorbance for the feet in order to reduce foot pain and fatigue. Stretching muscles to prevent limitations on daily activities also is important. The goals in self-treatment for exercise-induced foot problems are (1) to relieve any pain, (2) to prevent secondary bacterial infection if the skin is broken, and (3) to institute measures to prevent further injury.

General Treatment Approach

The first measure to avoid tired, aching feet and exercise-induced foot injuries is to choose well-fitted footwear that has sufficient padding and cushioning (Table 44–1). The second is to identify appropriate measures personalized to individual patient needs. For athletes, wearing sport-specific shoes with good arch support (e.g., running shoes) is an excellent measure for preventing heel pain. Persons who are physically active or stand for prolonged periods during the day may need to take additional measures, such as replacing worn shoes or heel pads, using a night splint, strapping or taping the arch, decreasing the amount of weight-bearing activity, and, if necessary, embarking on a weight reduction program.²¹ Oral and topical nonprescription anti-inflammatory agents as well as nonpharmacologic options such as ice applications (Table 44–5) also are appropriate. Magnesium sulfate (Epsom salts) baths have historically been used for soothing tired aching muscles, sprains, and bruising, but no scientific evidence supports these claims. When self-treatment fails, patients should be referred to an appropriate health care provider for evaluation for any bone malalignments and possible orthotic therapy. Figure 44–4 outlines self-treatment for tired, aching feet.

TABLE 44–5 Guidelines for Applying Cold Compresses

Ice Bag Method

- Fill the ice bag with crushed or shaved ice to one half to two thirds of its capacity, if possible. These forms of ice will promote greater contact with the injured body part.
- If necessary, break ice into walnut-sized pieces with no jagged edges. An overfilled bag will be difficult to apply because it will not rest on the contour of the body area.
- After filling the bag, squeeze out trapped air. Then dry the outside of the bag and check for leaks.
- Bind the injured body part with a wet elastic wrap. The wet wrap aids transfer of cold to the injured area.
- If the ankle is being treated, keep it in a dorsiflexed position (foot tipped toward the nose) when it is wrapped in the elastic bandage.
- Apply the ice bag to the specific body part.
- To avoid tissue damage, apply the ice bag for 10 minutes and then remove it for 10 minutes. If the bag is not cloth-covered, wrap the injured area or the ice bag in a thin towel to prevent tissue damage.
- Follow this application regimen 3–4 times a day.
- For most injuries, continue the cryotherapy until swelling decreases or for a maximum of 12–24 hours. Application of ice may be necessary for up to 48–72 hours, depending on the severity of the injury. (For example, the maximum swelling of ankle injuries may occur up to

48 hours after the injury.)

- Before storing the ice bag, drain it and allow it to air dry. If possible, turn it inside out for more efficient drying. Cap the bag and store it in a cool, dry place.

Cold Wraps

- To activate a single-use cold pack, squeeze the middle of the pack to burst the internal bubble. This action initiates an endothermic reaction of ammonium nitrate, water, and special additives.
- For a reusable cold wrap (cold pack or gel pack), store it in the freezer for 2 hours. Do not put the cloth cover in the freezer.
- Remove the cold wrap from the freezer, insert it in the cloth cover, and apply it to the injured body part.
- If the cold wrap is uncomfortable, remove it for 1–2 minutes and then reapply it.
- Alternate application of the cold wrap (10 minutes on, 10 minutes off) 3–4 times a day for 24–48 hours.
- After use, store the cold wrap in the freezer.
- Although some gel packs are nontoxic, keep all cold wraps out of children's reach.

Source: [References 20](#) and [26](#).

Additional measures to prevent exercise-induced injuries entail using suitable footwear that fits properly ([Table 44–1](#)); walking or running on nontraumatizing surfaces; using correct posture (i.e., running erect); and stretching muscles before exercising. Most running injuries can be successfully managed with measures such as shoe modifications and use of shoe inserts or in-shoe supports.

If an injury to the leg or foot occurs, activity usually must be interrupted to allow the injured leg or foot to rest and heal. The health care provider may be called on to play an important role in initial management of an exercise-induced injury to the foot ([Figure 44–5](#)). Identifying the location of the pain will help determine the type and extent of the injury. Establishing the nature and duration of the pain will help ascertain whether self-treatment for the injury is appropriate.

Relative rest (i.e., avoiding activities that produce the symptoms) often is indicated. Alternative exercise such as swimming, rowing, and/or bicycling (stationary or outdoor) should be encouraged. If the injury warrants, the

patient can be instructed on selecting and using nonprescription accessories (e.g., compression bandages, arch supports, heel cushions) and related modalities (e.g., cryotherapy, PRICE [protection, rest, ice, compression, elevation]) that will alleviate injuries or other underlying problems. Systemic analgesics also can relieve the pain and inflammation associated with minor foot injuries (see [Chapter 5](#)).

Nonpharmacologic Therapy

Shoe Inserts, Partial Insoles, and Heel Cups/Cushions

Full-shoe inserts, which can provide cushioning and absorb shock, are available in various sizes and thicknesses to accommodate the needs of most patients with exercise-related foot problems. Such inserts help decrease the incidence of lower back pain associated with the impact from walking. The selected insert should conform to the type of shoe worn.^{7,8}

Partial insoles are preferred when the patient needs cushioning or support in a certain portion of the shoe. For example, metatarsal arch supports, which fit into the ball-of-foot region of the shoe, help lift the arch behind the toes to alleviate pain associated with the spreading of the foot, a condition that occurs with increasing age in women. Inserts specifically designed to fit in high-heeled shoes (e.g., Dr. Scholl's for Her High Heel Insoles) also are available. Finally, the arch support insert is intended to cushion and support painful arches.^{9,13}

Use of a heel cup or heel cushion may be indicated, depending on the location and extent of the pain. For example, a heel cushion might be appropriate when the pain is confined to the bottom of the heel. A heel cushion supports the entire heel as it elevates the sensitive area to prevent further irritation. Alternatively, when the pain is widespread and diffuse, a heel cup might be more appropriate. Heel cups help relieve the pain caused by physiologically mediated breakdown of the heel's natural padding or by intense athletic activity.

Caution is warranted in the selection of shoe inserts. If an insole added for needed cushioning affects the gait, the patient should be referred to a podiatrist or pedorthist; the latter specializes in the designing, manufacturing, modifying, and fitting of footwear and orthotics. Insoles should be used only to

cushion the foot, not to correct malformation, which requires a specialist's attention.

Athletic Footwear

Appropriate footwear can be a powerful tool for manipulating human movement and can greatly influence the healing of injured tissues, both positively and negatively. A study focusing on the stresses incurred by runners' feet demonstrated that the type of footwear chosen by recreational runners is important in preventing injury, specifically highlighting the benefit of stride-neutral shoes or motion-controlled footwear.²⁰ It follows that inappropriate or worn-out shoes can result in foot injuries and pain. Athletic shoes should be replaced after 200–400 miles of use.²¹

Compression Stockings

Compression stockings also are an option to enhance support for people who spend many hours on their feet. Compression stockings may be purchased with or without a prescription in compressions ranging from 8 to 30 mm Hg. These stockings decrease inflammation by improving circulation, thereby reducing fatigue of the feet, legs, and back.^{22,23}

Compression Bandages

Typically, a compression bandage (e.g., Ace Bandage) is used to support a sprained ankle or knee. If a compression bandage is to be used, the width of the bandage depends on the injury site. For example, a foot or an ankle requires a 2- to 3-inch bandage.²⁴ **Table 44–6** describes the proper method of applying this type of bandage.

TABLE 44–6 Application Guidelines for Compression Bandages

- Choose the appropriate size of bandage for the injured body part. If you are unsure about the size, purchase a product designed for the appropriate body part.
- Recommended elastic bandage width for coverage area:
 - 2 inches: foot, wrist, ankle
 - 3 inches: elbow, knee, ankle
 - 4 inches: knee, lower leg, shoulder
 - 6 inches: shoulder, upper leg, chest

- Unwind approximately 12–18 inches of bandage at a time and allow the bandage to relax.
- If ice also is being applied to the injured area, soak the bandage in water to aid the transfer of cold.
- Wrap the injured area by overlapping the previous layer of bandage by approximately one third to one half of its width.
- Snugly wrap the point most distal from the injury. For example, if the ankle is injured, begin wrapping just above the toes.
- Decrease the tightness of the bandage as you continue to wrap. (Follow package directions on how far to extend the bandage past the injury.) If the bandage feels tight or uncomfortable or if circulation is impaired, remove the compression bandage and rewrap it. Cold or swollen toes and fingers indicate that the bandage is too tight.
- After using the bandage, wash it in lukewarm, soapy water; do not scrub it. Rinse the bandage thoroughly, and allow it to air-dry on a flat surface. Roll up the bandage to prevent wrinkles, and store it in a cool, dry place. Do not iron the bandage to remove wrinkles.

Source: [Reference 27](#).

Cryotherapy

Applying cold compresses to an injury, such as a muscle sprain, provides a local anesthetic effect and decreases pain and inflammation. Ice bags or cold wraps are useful for cold application in 10-minute increments. [Table 44–5](#) describes the proper method of cold application to injuries.

Contrast Bath Soaks

For acute injury, cold application is beneficial during the first 48 hours to decrease ensuing inflammation. Specifically, the cold therapy is intended to decrease inflammation. Subsequent warm therapy attempts to bring increased blood flow to the affected area and to facilitate smooth muscle relaxation.

Algorithm: Tired, Aching Feet

FIGURE 44–4 Self-care for tired, aching feet.

Algorithm: Exercise-Induced Injuries

FIGURE 44–5 Self-care for exercise-induced injuries. Key: PRICE = Protection, rest, ice, compression, elevation; RICE = rest, ice, compression, elevation.

Patient Counseling and Evaluation of Patient Outcomes for Tired, Aching Feet and Exercise-Induced Injuries

Recommendations to resolve pain in the soles or heels of the feet depend on whether the patient has exclusions for self-treatment and how long the foot problem has persisted. Follow-up evaluation is indicated after 1 week to determine whether the treatment recommendations, such as the use of new shoes and/or in-shoe supports, compression bandages, or cryotherapy or other anti-inflammatory therapy, have reduced or eliminated the discomfort. If the initial swelling and/or pain persist, medical referral is warranted. Depending on the acuity of the symptoms, patients should consult their primary care provider (for exercise-induced injuries) or podiatrist for an appropriate evaluation. The boxes “Patient Education for Tired, Aching Feet” and “Patient Education for Exercise-Induced Injuries” detail the patient counseling that should be provided along with indications for seeking medical attention.

Ingrown Toenails

The most frequent cause of ingrown toenail, or *onychocryptosis*, is incorrect trimming of the nails. The correct method is to cut the nail straight across without tapering the corners. Wearing pointed-toe or tight shoes or too-tight hosiery also has been implicated. Other causes and contributing factors are hyperhidrosis, trauma, obesity, and excessive pressure on the toes. Direct pressure on a toe can force the lateral or medial edge of the nail into the soft tissue. The embedded nail may then continue to grow, resulting in swelling and inflammation of the nail fold.^{21,25,26}

Bedridden patients are at increased risk for development of ingrown toenails from the pressure of tightly “tucked” or heavy bedcovers on the soft skin tissue against the nails. Other potential causes of ingrown toenails include nail curling, which can be hereditary or secondary to incorrect nail trimming; onychomycosis; or a systemic metabolic disease.

Pathophysiology of Ingrown Toenails

An ingrown toenail occurs when the nail curves and becomes embedded into the flesh at the corner(s) of a toe, causing pain (Figure 44–6). Puncture of the skin that is accompanied by soft tissue hypertrophy and subsequent invasion by opportunistic resident foot bacteria can lead to superficial infection. Swelling, inflammation, and ulceration are secondary complications that can accompany an ingrown toenail.²¹

FIGURE 44–6 Bunion and ingrown toenail.

Patient Education for Tired, Aching Feet

The objectives of self-treatment are (1) to reduce impact on the feet by providing additional support and shock absorbance and (2) to relieve foot discomfort. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

- To reduce friction of the feet and impact on weight-bearing parts of the feet, wear well-fitted footwear that has sufficient padding and cushioning (Table 44–1).
- Consider other measures to further reduce impact on the feet, such as decreasing the length of time spent standing or exercising, switching to exercises that have less impact on the feet, and, if necessary, losing weight.
- To relieve swelling or discomfort, apply an ice bag or cold wrap to the affected area (Table 44–5).
- For acute pain relief, NSAIDs such as ibuprofen or naproxen may be

used. [Chapter 5](#) discusses these agents in more detail.

- To improve circulation, select a compression stocking with mild to moderate compression (<20 mm Hg).
- Choose a full-shoe insert when the entire foot aches. Make sure the insert conforms to the shoe. For example, choose a thin insole for a woman's pump and a thicker insole for an athletic shoe.
- Use partial insoles to cushion or support a certain portion of the foot, such as the ball of the foot, the arch, or the toes.
- Use a heel cushion for pain confined to the bottom of the heel.
- Use a heel cup when the heel pain is widespread and diffuse.

When to Seek Medical Attention

- If discomfort or swelling continues after 1 week of implementing appropriate self-care measures, consult an appropriate health care provider.

Key: NSAID = Nonsteroidal anti-inflammatory drug.

Patient Education for Exercise-Induced Injuries

The objectives of self-treatment are (1) to rest the injured foot or limb to allow healing, (2) to relieve discomfort, and (3) to implement measures to prevent further injury. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

General Measures

- When a leg or foot injury occurs, rest the injured limb. If desired, perform other types of exercise that do not put a great deal of force on the feet, such as swimming or bicycling (stationary or outdoor).
- The following measures will help prevent exercise-induced injuries:
 - Stretch muscles before exercising.
 - Choose sport-specific shoes with good arch support for

athletic activities.

- Run or walk on a relatively smooth, level, and resilient surface.
- Keep the back straight when running.

Shin Splints

- Rest the feet and apply an ice bag or a cold wrap to the painful area (Table 44–5).
- If desired, take aspirin or another NSAID to relieve pain and reduce tissue inflammation.
- Do not use analgesics before a workout to suppress pain or to increase your endurance.

When to Seek Medical Attention

- Seek medical attention if the discomfort becomes a cramping, burning tightness that repeatedly occurs at the same distance or time during a run.

Blisters

- To prevent blisters during walking or running, wear moisture-wicking socks (e.g., wool or acrylic). If desired, wear two pairs of socks with ordinary talcum powder sprinkled between them. Using an acrylic sock next to the skin will assist in drawing moisture from the foot.
- Apply compound tincture of benzoin or a flexible collodion product (e.g., New Skin) to the blister before exercise to decrease pain and accelerate healing by promoting reepithelialization.
- Apply an antiperspirant that contains aluminum chloride 20% to the feet to decrease incidence of blisters.
- If blisters break, apply a first aid antibiotic to the broken skin to prevent secondary bacterial infection.
- Cover blistered area with moleskin to protect the surface.

Ankle Sprains

- Although maximum swelling will not occur for 48 hours, begin treatment as soon as possible.
- Stay off the injured foot, wrap a compression bandage around the ankle, apply ice, and elevate the affected foot. (Tables 44–5 and 44–6 provide guidelines on applying ice and compression bandages, respectively.)

When to Seek Medical Attention

- Seek medical attention if swelling persists more than 72 hours.

Toenail Blisters/Loss

- To prevent blisters under the toenail, keep toenails trimmed and wear only properly fitted shoes.
- Should a blister develop, do not disturb or puncture the blister roof.

When to Seek Medical Attention

- If the toenail separates from the skin or is lost, consult your primary care provider or a podiatrist for proper treatment.

Key: NSAID = Nonsteroidal anti-inflammatory drug

Treatment of Ingrown Toenails

Treatment Goals

The goals of self-treatment for ingrown toenails are (1) to relieve pressure on the affected nail, (2) to relieve pain, (3) to prevent recurrence of the disorder, and (4) to prevent infection.

General Treatment Approach

Patient education is the best means of preventing the development of ingrown toenails. In the early stages of development, therapy is directed at providing adequate room for the nail to resume its normal position adjacent to soft tissue. This therapy is accomplished by relieving the external source of

pressure. Warm water soaks for 10–20 minutes several times a day until resolution will help soften the area. Topical antiseptics prescribed by a primary care provider can be applied to prevent possible opportunistic infections. Insertion of small cotton wisps or dental floss under the impinged nail edge is associated with a 79% rate of symptomatic improvement. No evidence is linked to secondary infection from the cotton wisps or dental floss.²⁷ Medical referral is necessary if the condition is recurrent or gives rise to an oozing discharge, significant pain, or severe inflammation. Sometimes surgery is warranted; with subsequent systemic antibiotic therapy, the toe may take up to 3–4 weeks to heal. The most common surgical procedure is removal of the lateral edge of the nail followed by chemical matricectomy achieved by phenolization. This process destroys the exposed nail-forming matrix.^{21,26} Figure 44–7 outlines self-treatment options for ingrown toenails.²⁰

Pharmacologic Therapy

Sodium Sulfide Gel and Nonsteroidal Anti-inflammatory Drugs

Sodium sulfide 1% gel is applied topically, and a retainer ring is placed around the affected area to help maintain the product at the site of action. Sodium sulfide relieves pain by softening the nail or by hardening the nail bed. For relief of ingrown toenail discomfort, sodium sulfide may be applied twice daily for up to 7 days.^{28,29} Health care providers must be aware of misleading trade-name products marketed for ingrown toenails and educate patients accordingly. Products containing benzocaine 20% relieve pain associated with ingrown toenails, but this agent does not treat the underlying problem.^{27,29–31} Oral nonsteroidal anti-inflammatory drugs (NSAIDs), such as oral aspirin, ibuprofen, or naproxen, may be recommended in the absence of contraindications (Chapter 5).

Algorithm: Ingrown Toenail

FIGURE 44–7 Self-care for ingrown toenail. Key: NSAID = Nonsteroidal anti-inflammatory drug.

Assessment of Ingrown Toenail: A Case-Based

Approach

The pharmacist as health care provider can play a vital role in recommending measures for relieving acute pain from ingrown toenails and in preventing their recurrence. For clinical management of this condition, initial recommendations include warm bath soaks to soften the skin and oral anti-inflammatory therapy for temporary pain relief. If the toenail or nail bed is infected, immediate referral for medical care is warranted.

Patient Counseling for Ingrown Toenails

The box “Patient Education for Ingrown Toenails” lists specific information to include in patient counseling.

Evaluation of Patient Outcomes for Ingrown Toenails

Patient reevaluation after 3–4 weeks is indicated to determine whether pressure relief and preventive measures have been successful. Medical referral is appropriate if the condition shows no improvement or worsens or if a discharge from the site of irritation is noted.

Patient Education for Ingrown Toenails

The ultimate goals for self-treatment for ingrown toenails are (1) to relieve the pain and pressure associated with the condition and (2) to prevent recurrence.

- Ensure that shoes fit properly to eliminate pressure on the toenails (Table 44–1).
- Prevent recurrence of ingrown toenails by cutting nails straight

across, rather than at an angle or in a curve.

- Decrease pain and swelling of the ingrown toenail by taking an NSAID such as ibuprofen or naproxen.
- Relieve impingement of the nail by soaking the affected foot in warm water to soften the nail and the skin around it.
- Place cotton wisps or dental floss under the edge of the ingrown nail for almost immediate pain relief.

Key: NSAID = Nonsteroidal anti-inflammatory drug.

Key Points for Foot Disorders

- Foot pain is not normal and therefore should be evaluated by the health care provider as for any other health care complaint.
- Patients with diabetes, circulatory problems, and/or arthritis should be referred for further medical evaluation before implementing use of any nonprescription topical or oral medication.
- Nonprescription products may exacerbate certain conditions; the health care provider must monitor patient progress carefully and be attuned to patient comments that might indicate the occurrence of drug-related problems.
- The nonprescription drug of choice to treat corns and calluses is salicylic acid in a collodion-like vehicle or plaster form. Additionally, predisposing factors responsible for corns and calluses must be corrected.
- Patients also should be cautioned that frequent recurrence of any of these foot disorders is an indication to consult a podiatrist or primary care provider.
- Health care providers should be prepared to provide management recommendations for patients who present with

various exercise-induced injuries.

- Some exercise-induced injuries can be successfully managed with shoe modifications, use of in-shoe supports, modified training methods, ice applications, and stretching exercises. It is important for athletes to recognize and seek treatment for foot pain.
- Counseling on proper foot hygiene is an important aspect of whole-patient care.

Chapter 45: Hair Loss

Authors: Tricia M. Berry

A significant number of men and women experience hair loss. Up to 80% of white men and 40%–50% of white women are affected at some point in their lives, and white men are more likely to experience hair loss than men of other ethnicities.¹ Many potential contributing factors for hair loss are recognized (Table 45–1).^{2–10} Regardless of the cause, hair loss can have a significant psychological and social impact. People affected by hair loss often experience low self-esteem; personal, social, and work-related challenges; and psychiatric disorders, such as depression and anxiety.¹¹ The economic impact also is substantial, with patients spending approximately \$3.5 billion each year on products and procedures to combat hair loss.¹²

TABLE 45–1 Causes of Hair Loss	
Etiologic Category	Specific Examples
Hormonal changes	Hyperandrogenic conditions (e.g., polycystic ovary syndrome)
	Menopause
	Postpartum period
Physiologic stress	Fever, infections
	Hemorrhage
	Surgery
	Trauma
Chronic illnesses	Autoimmune diseases (e.g., rheumatoid arthritis, lupus)
	Eating disorders (e.g., anorexia, bulimia)
	Endocrine disorders (e.g., hypothyroidism/hyperthyroidism, hypopituitarism, diabetes mellitus, metabolic syndrome, hyperprolactinemia)
	Hepatic or renal failure

Etiologic Category	Specific Examples
	Infections (e.g., HIV infection, syphilis)
Medications	ACE inhibitors (e.g., enalapril, captopril)
	Allopurinol
	Androgenic action (e.g., oral contraceptives, danazol, testosterone, anabolic steroids)
	Anticonvulsants (e.g., phenytoin, carbamazepine, valproate)
	Anticoagulants (e.g., warfarin, heparin)
	Antidepressants (e.g., SSRIs, tricyclic antidepressants)
	Beta blockers (e.g., propranolol, metoprolol)
	Cholesterol-lowering drugs (e.g., clofibrate, gemfibrozil)
	Chemotherapeutic agents
Dietary changes or deficiencies	Protein restriction/deficiency
	Rapid weight loss including that associated with bariatric surgery
	Strict vegetarian diet
	Zinc, biotin, or iron deficiency
Local trauma	Hair care practices
	Tinea capitis
	Trichotillomania (compulsive hair plucking)
Genetics	Chromosomal loci 3q26 and 20p11 in AGA ⁹
	HLA alleles, such as HLA-DRB1*0401 and DQB1*0301, in alopecia areata ⁷
	Polymorphisms in the androgen receptor gene in AGA ^{8,9}

Key: ACE = Angiotensin-converting enzyme; AGA = androgenetic alopecia; HIV = human immunodeficiency virus; HLA = human leukocyte antigen; SSRIs = selective

serotonin reuptake inhibitors.

Source: [References 2–10](#).

Hair loss is broadly categorized as either nonscarring or scarring alopecia. Forms of nonscarring alopecia include *androgenetic alopecia* (AGA), or hereditary pattern hair loss; *alopecia areata* (rapid-onset, patchy hair loss); *anagen effluvium* (rapid shedding of growing hairs); *telogen effluvium* (rapid shedding of resting hairs); cosmetic hair damage; *trichotillomania* (a compulsive pulling out of one's hair); and tinea capitis (fungal infection/ringworm of the scalp). Types of hair loss secondary to medication use, acute or chronic illness, or dietary changes typically also are nonscarring. [Table 45–2](#) provides information on common types of nonscarring alopecia.^{1,3,5–8}

TABLE 45–2 Characteristics of Common Types of Nonscarring Alopecia

Type of Hair Loss	Etiology	Epidemiology	Clinical Presentation
Androgenetic alopecia/ hereditary pattern hair loss	Hormonal, hereditary	<i>Female:</i> 40%–50% affected by age 70 years ^{1,7}	Gradual onset with progression of gender-specific pattern hair loss
		<i>Male:</i> 80% affected by age 70 years ¹	<i>Female:</i> Central portion of scalp, sparing frontal hairline; wide midline part on the crown with progression to diffuse thinning over crown
		Affects white men more often than men of other ethnicities ¹	<i>Male:</i> Top rear of the head (vertex), frontal hairline, and occipital regions
Alopecia areata	Autoimmune	2% of U.S. population; affects men and women of all races equally; most cases (70%)	Abrupt onset (may wax and wane with relapses); usually patchy but can be generalized; can occur in any hair-bearing area; can progress to complete loss of scalp hair (alopecia totalis) or total loss of body hair

Type of Hair Loss	Etiology	Epidemiology	Clinical Presentation
		occur in children and young adults ⁸	(alopecia universalis)
Anagen effluvium	Chemotherapy, radiation therapy, heavy metal poisoning	Data not available	Abrupt, diffuse loss of hair within days of exposure
Telogen effluvium	Metabolic or hormonal disturbances, stress; severe illness or injury; medications	Exact prevalence unknown; can occur in either gender at any age	Diffuse, abrupt onset (often several months after trigger exposure); rapid hair thinning (e.g., clumps of hair loss)
Cosmetic hair damage ^a	Hair care practices (e.g., braiding, permanent waving, bleaching)	Any age; associated with specific social, cultural, and cosmetic practices	Gradual or abrupt loss on any area of the scalp depending on cause; broken hairs with blunt rather than tapered tips
Trichotillomania	Psychiatric compulsive disorder	More common in children but may persist into adulthood	Twisted and broken-off hairs visible in patchy areas across the scalp
Tinea capitis ^a	<i>Trichophyton tonsurans</i> infection	Any age; common in childhood	Any area of the scalp; usually round patch(es) of hair loss

^a In rare circumstances, chronic and/or severe cases can lead to scarring alopecia.

Source: [References 1, 3, and 5–8](#).

Scarring alopecia may be related to conditions such as discoid lupus erythematosus, syphilis, sarcoidosis, or lichen planus. Severe forms of tinea capitis and chronic hair care practices (e.g., braiding, permanent waving) that can significantly damage the hair and scalp also may lead to scarring alopecia.

AGA is the most common form of hair loss and the only type of alopecia for which U.S. Food and Drug Administration (FDA)– approved nonprescription medications are available. AGA is characterized by progressive, male or female pattern hair loss from the scalp.

Pathophysiology of Hair Loss

Hair follicle activity is cyclic ([Figure 45–1](#)). A variety of triggers can alter the hair follicle cycle, resulting in hair loss.

Copyright©American Pharmacists Association PharmacyLibrary.
All rights reserved. Any use is subject to the Terms of Use.

FIGURE 45–1 Normal hair follicle cycle.

In AGA, the hair follicle undergoes a stepwise literal miniaturization and change in growth dynamics. With each successive cycle, the anagen phase (active growth) becomes shorter and the telogen phase (resting phase)

becomes longer. Consequently, over time, the anagen–telogen ratio decreases from 12:1 to 5:1. Because telogen hairs are more loosely anchored to follicles, their presence in increased numbers eventually leads to increased shedding. In addition, the catagen phase lengthens, reducing the number of hairs. As telogen hairs are shed, they are gradually replaced by *vellus-like* (short and very fine) hairs or by anagen hairs that are too short to reach the surface.

Hair follicles and their sebaceous glands produce enzymes that convert weak androgens to estrogens, testosterone, and dihydrotestosterone (DHT) (Figure 45–2). These enzymes are believed to maintain androgen balance in the follicle, thereby regulating the hair cycle.

Copyright © American Pharmacists Association PharmacyLibrary.
All rights reserved. Any use is subject to the Terms of Use.

FIGURE 45–2 Androgen metabolism within the hair follicle. Key: DHEA = Dehydroepiandrosterone.

DHT is thought to be a primary repressor of hair growth. It binds 5 times more readily than testosterone to androgen receptors. Increased 5-alpha-reductase–mediated conversion of testosterone to DHT in the affected areas in women with AGA also supports the contention that DHT is important in this process. In contrast with men, women with AGA rarely lose all their hair, not only because they have less 5-alpha-reductase but also because they have more aromatase. The excess aromatase converts testosterone into estradiol, thereby reducing the level of androgen and increasing the estrogen level.¹³ In addition, hair follicles in women typically have fewer localized androgen receptors, so retention of actively growing hair is more likely.¹⁴

Although the pathomechanisms are not fully understood, alopecia areata is thought to have an autoimmune etiology and genetic influences.⁸

Chemotherapeutic agents (e.g., antimitotic drugs) are identified as a potential cause of anagen effluvium. Their physiologic effects include narrowing of the hair shaft, which may fracture the hair or stop hair growth. See [Table 45–1](#) for additional medications that may cause hair loss.

Certain triggers (e.g., severe illness, injury, stress, metabolic changes, thyroid disorders, autoimmune disorders) may precipitate telogen effluvium, which occurs when an increased number of hairs shift from the anagen phase to telogen phase. Nutritional deficiencies, particularly iron deficiency, also can cause hair loss.

Hair care products and hair-grooming methods potentially associated with microtrauma or burns to the scalp may result in scarring alopecia. *Traction alopecia* is seen primarily in persons who braid their hair tightly every day. Braiding traumatizes the hair follicles, causing hairs to loosen and break. Use of oily moisturizers to make hair more manageable and to stop the scalp from flaking may lead to development of folliculitis with consequent hair loss.

Psychological stress may potentiate several types of hair loss, although the literature on this subject is conflicting. Trichotillomania, a compulsive psychiatric disorder most common in children, involves repetitive pulling out or plucking of hairs, leading to patchy hair loss.

Untreated or improperly treated tinea capitis may lead to hair loss. Treatment for this condition requires a regimen of prescription systemic antifungals; hair regrowth occurs after eradication of the causative dermatophyte.

Scaly dermatoses (e.g., psoriasis, seborrheic dermatitis) also may lead to scarring alopecia. Nonprescription agents marketed for the treatment of psoriasis and seborrheic dermatitis are not effective in treating alopecia. [Chapter 34](#) provides additional information on self-care for scaly dermatoses.

Clinical Presentation of Hair Loss

The scalp of a patient with AGA shows no signs of inflammation or scarring. Hair loss is gradual; in contrast with the clinical picture in other types of alopecia, the number of hairs that come out during brushing or shampooing does not suddenly increase. Typically, male pattern hair loss (MPHL) starts at

some point after puberty and is insidious in onset. Progression fluctuates considerably, with 3–6 months of accelerated loss followed by 6–18 months of no loss, with subsequent resumption of this sequence. In most affected men, the hair loss occurs over a period of 15–25 years. MPHL begins with a recession of the frontal hairline and continues with thinning at the vertex until only a fringe of hair at the occipital and temporal margins remains. The pattern and extent of hair loss in this condition often are characterized using the Norwood Scale; images are viewable at the referenced website.¹⁵

In women with alopecia, hair loss typically is more diffuse. Female pattern hair loss (FPHL) manifests as gradual hair thinning over the crown and midfrontal portion of the scalp. Several scales (e.g., Ludwig, Sinclair, Savin) have been used to classify the extent of FPHL; the relevant images can be viewed at the referenced website.^{4,16} Such scales are helpful in visualizing the typical progression of hair loss in MPHL (Norwood) and FPHL (Ludwig, Sinclair, Savin), assessing the patient's pattern of hair loss as MPHL or FPHL, and evaluating appropriateness of a self-care approach.

FPHL, also classified as AGA, is attributed to genetic components along with hormonal factors.^{9,17} Women with AGA may present with signs and symptoms of *hyperandrogenism* (an excess of androgen), such as significant acne; *hirsutism* (hairiness in other parts of the body); menstrual irregularities; and infertility. It is conceivable that a patient with FPHL may be using a hair regrowth treatment agent on the scalp while also using an antihirsutism agent (e.g., topical eflornithine, oral spironolactone [off label]) to remove excess hair on the face. Androgen excess may indicate serious metabolic disturbances, such as cardiovascular disease, diabetes mellitus, polycystic ovary syndrome, and endometrial cancer.¹⁷ Women with multiple signs and symptoms should be referred for medical evaluation and treatment.^{9,17}

Alopecia areata occurs in three stages: sudden loss of hair in patches, enlargement of the patches, and regrowth. This cycle may take months or sometimes years, and any hair-bearing area may be affected. Up to 5% of patients lose all of the scalp hair (*alopecia totalis*), and 1% of patients lose all body and scalp hair, including eyebrows and eyelashes (*alopecia universalis*).³ Hair loss may accompany or be preceded by nail pitting or other nail abnormalities. Itching, tingling, burning, or other painful sensations also may be experienced in the patch of hair loss.

Telogen effluvium (also known as diffuse alopecia) can be acute (lasting <6

months) or chronic (lasting >6 months). The precipitating factor usually precedes shedding by 1–6 months, but identifying a specific causal event often is difficult, if not impossible. This point is especially relevant with medication use in that hair loss often will occur up to several months after initiation of a particular drug therapy. The health care provider should ascertain the start date of all medications as a part of the clinical workup for patients with telogen effluvium. This type of hair loss usually is reversible.^{2,3,5}

Hair loss may be assessed by using a variety of tests (e.g., biopsy of the scalp, daily hair loss count, hair-pull test).^{2,3} A *hair-pull test* is done by holding 40–60 hairs between the thumb and forefinger and firmly (but not forcefully) pulling the hairs away from the scalp. A positive test result, in which more than 10% of the hairs are removed, suggests types of alopecia other than AGA (e.g., effluvium, alopecia areata).³ All patients presenting with hair loss that is not considered androgenic should be referred to an appropriate health care provider for complete medical evaluation.

Treatment of Hair Loss

Treatment Goals

The goal in self-treatment for hair loss is to achieve an appearance that the patient considers acceptable with a corresponding decrease in the emotional distress experienced.

General Treatment Approach

If a self-treatment approach to hair loss is appropriate, the treatment objectives can be accomplished through nonprescription measures consisting of nonpharmacologic strategies such as cosmetic camouflage and/or the use of topical minoxidil to stimulate hair growth, if applicable. With the exception of AGA, all other types of hair loss should be referred for medical evaluation to determine the cause and proper treatment. The algorithm in [Figure 45–3](#) outlines the self-care approach to management of hair loss, with a list of specific exclusions for self-treatment.

Nonpharmacologic Therapy

Hair loss can be psychologically damaging. Camouflaging thinning hair with wigs and hair weaves may help relieve the associated emotional distress. Technological advances have made production of custom wigs that match the wearer's original hair a standard practice. Approaches to treating less severe hair loss include use of hair sprays, gels, colorants, permanents, and scalp-camouflaging products (e.g., topical hair fibers, powder cakes, scalp lotions, scalp sprays, hair crayons). Such products can create an illusion of fullness; they do not actually decrease hair loss.^{1,18}

Scalp massage, frequent shampooing, and electrical stimulation have been proposed as treatments for hair loss; however, these remedies are considered ineffective.¹⁹ Although data regarding its efficacy are inconsistent, low-level light therapy is FDA approved and marketed for hair growth.^{1,17,20,21}

If hair loss is caused by poor diet or iron deficiency, the patient may benefit from consultation with a dietitian. In iron deficiency states, increasing protein intake or taking iron supplements may be a simple solution, with subsequent reversal of hair loss.

Surgical transplantation of terminal hair follicles from another anatomic site is an alternative nonpharmacologic approach to hair loss (e.g., hair follicles from the occipital region may be implanted to the frontal and vertex scalp).²¹

Pharmacologic Therapy

Minoxidil

Minoxidil, the only FDA-approved agent for self-treatment for AGA, is available as 2% and 5% hydroalcoholic solutions and as a 5% solvent-free foam. Minoxidil can be applied by various methods ([Table 45–3](#)), depending on the applicator (i.e., spray, dropper).²² This treatment is indicated for AGA involving the scalp.²² Specifically, nonprescription topical minoxidil is labeled for baldness at the crown of the head in men and for hair thinning in the frontoparietal area in women. The 2% and 5% solutions (1 mL twice daily) and 5% foam (½ capful twice daily) are approved for use in men, whereas only the 2% solution (1 mL twice daily) and 5% foam products (½ capful once daily) are approved for use in women.²² When used orally to control hypertension, minoxidil is a potassium

channel opener and vasodilator. When used topically for hair loss, the drug appears to increase cutaneous blood flow, promote and maintain vascularization of hair follicles, directly stimulate follicular hypertrophy, and prolong the anagen phase. Minoxidil also may transform resting (*telogen phase*) hair follicles into active (*anagen phase*) hair follicles, resulting in a lower percentage of hairs in the telogen phase, which are shed more easily.^{23–25} It is proposed that minoxidil enhances hair growth by stimulating prostaglandin endoperoxide synthase-1, leading to increased production of prostaglandin E₂, which results in prolonged anagen phase.^{5,21,26}

TABLE 45–3 Administration Guidelines for Nonprescription Minoxidil

Minoxidil Solution

- Apply minoxidil to clean, dry scalp and hair.
- Rub about 1 mL of the product into the affected area of the scalp. Some products have a measuring cap with a 1-mL fill line. Do not apply the product more often than twice daily (morning and night).
- Wash and dry hands after applying the medication. If it gets into the eyes, mouth, or nose, rinse these areas thoroughly with tap water.
- Do not double the dose if you miss an application.
- Allow 2–4 hours for the drug to penetrate the scalp. Do not participate in any activity that might wash away or dilute the drug (e.g., bathing or swimming without a cap) for 2–4 hours after application.
- At night, apply the drug 2–4 hours before bedtime; if the product is not allowed to dry completely, minoxidil can stain clothing and bed linen.
- A hair dryer, on a low setting, may be used after applying the drug to speed drying of the hair.
- If applicable, apply hair grooming and styling products (e.g., sprays, mousses, gels) after the minoxidil has dried. These products usually do not affect the efficacy of topical minoxidil.
- Avoid using topical minoxidil on the day of and for 24 hours after using permanent wave or hair color products, to reduce scalp irritation.

Minoxidil Foam

- The foam may “melt” on contact with warm skin. Therefore, wash hands in cold water and dry them thoroughly before applying foam.
- Within the thinning hair area, part the hair into one or more rows to maximize contact of the foam with the scalp. The hair should be completely dry before application.
- Holding the product can upside down, apply ½ capful of the foam to the fingertips. The 5% product for men should be applied twice daily, in the morning and at night. The 5% product for women should be applied once daily.
- Using the fingertips, spread the foam over the thinning scalp area, and then massage gently into the scalp. Wash hands thoroughly after application.

- Allow the product to dry completely before lying down or applying grooming/styling products.
- Avoid using topical minoxidil on the day of and for 24 hours after using permanent wave or hair color products, to reduce scalp irritation.

Source: [References 22](#) and [28](#).

For men undergoing hair transplantation whose hair follicles may be viable but not functioning optimally in the area to be transplanted, topical minoxidil can increase hair density, speed regrowth in transplanted follicles and also can complement the surgical outcome by minimizing the likelihood of progression of hair loss.²⁷

After initiation of minoxidil treatment, an increase in hair loss may occur within the first few weeks of product usage.²⁸ Several months may elapse before hair growth is apparent. If increased hair density fails to appear after 4–6 months of minoxidil use, the patient should consider discussing other options with the treating health care provider.^{22,28} In many cases, increased hair density is minimal, and treatment response is difficult to assess. Once the drug is discontinued, hair density returns to pretreatment levels in a matter of months; therefore, the patient must continue to use the product indefinitely to maintain new growth.²²

Several studies have evaluated the safety and effectiveness of topical minoxidil 2% and 5% preparations. In a 48-week study, men using 5% minoxidil showed greater benefit, in terms of earlier response and increased hair regrowth (i.e., 45% more), than that seen in men using 2% minoxidil.²⁹ Of note, however, increased frequency of itching and local irritation also was noted in the 5% minoxidil treatment group compared with the 2% minoxidil group.²⁹ A randomized, double-blind, placebo-controlled trial evaluated the efficacy and safety of 5% topical minoxidil compared with those of 2% topical minoxidil and placebo in the treatment of FPHL.³⁰ Both 5% and 2% preparations of minoxidil were superior to placebo, and the 5% topical minoxidil group showed statistically significant benefits over the 2% topical minoxidil group.³⁰ The incidence of itching, local irritation, and *hypertrichosis* (excessive hair growth)

in the group receiving 5% minoxidil was greater than that in the 2% minoxidil and placebo groups.³⁰ In a randomized, single-blind trial studying 113 women with AGA, once-daily 5% minoxidil foam was found to be as effective as twice-daily 2% minoxidil solution; the 5% concentration also was associated with several aesthetic and practical advantages (e.g., once-daily administration; lower rates of adverse effects, such as itching and dandruff; less interference with hair styling).³¹

Some patients who require prescription treatment with finasteride may still use topical minoxidil for an adjunct therapy. Topical minoxidil solution 2% has been investigated in combination with oral finasteride 1 mg in male patients. The outcomes of this study indicate a higher percentage of responders with the combination treatment than with either agent alone.³²

The most common adverse effects associated with minoxidil—local itching, irritation, and dryness or scaling at the site of application—may be related to the hydroalcoholic/propylene glycol vehicle in the product used. Use of the 5% minoxidil topical formulation in a propylene glycol-free foam vehicle reduces the risk of local adverse effects.

Transient hypertrichosis, usually on the forehead and cheeks, is a possible adverse effect with long-term use of minoxidil. Occasionally, patients may notice hypertrichosis on the chest, back, forearms, and ear rims, which could indicate that the product has been applied excessively.³³ Rare adverse effects include acne at the site of application, increased hair loss, inflammation (with soreness) of the hair roots, reddened skin, swelling of the face, and allergic contact dermatitis.^{22,28}

Minoxidil is absorbed through the skin in relatively low concentrations; documented systemic adverse effects are rare. In the unlikely event of an accidental ingestion, the patient should seek emergency medical attention or contact a poison control center.

Although minoxidil-induced hemodynamic changes have not been detected in most controlled clinical studies, patients with preexisting cardiovascular disorders may be at increased risk for adverse cardiovascular effects (e.g., chest pain, dizziness, fainting, tachycardia).³⁴

Researchers have found little evidence of a potential effect of minoxidil on systemic endocrine functions.³⁵ Measurement of plasma testosterone and

excretion of urinary hydroxysteroids and ketosteroids in hypertensive patients who had been treated with oral minoxidil did not reveal any effects. In a study of topical minoxidil, however, the modification of follicular testosterone metabolism occurred despite unchanged serum cortisol, testosterone, and thyroid indices.³⁶

The use of topical minoxidil is not associated with any known drug–drug interactions. Topical application of corticosteroids, petrolatum, or retinoids (e.g., adapalene, tretinoin) to the scalp in combination with minoxidil should be avoided because of possible increased absorption of minoxidil and increased risk of adverse effects. In addition, minoxidil should not be used for 24 hours before or after application of any hair permanent, hair color, or hair relaxant products.^{22,28}

Patients who are allergic to minoxidil or to any component of the preparation should avoid this medication. Patients with scalp damage from psoriasis, severe sunburn, or abrasions should also avoid topical minoxidil; these conditions may increase minoxidil absorption.

The solution formulation has an alcohol base and will burn or irritate eyes, mucous membranes, and abraded skin. If the product gets into the eyes, mouth, or nose, these areas should be thoroughly rinsed with tap water. Patients should wash and dry the hands after using the product. These precautions also are intended to prevent the systemic entry of minoxidil by alternative routes. Products containing minoxidil should not be used on any other part of the body.²⁸

Product Selection Guidelines

Safety and efficacy of the product in children younger than 18 years have not been established, so the use of minoxidil in this age group is contraindicated.²²

The limited human and animal data available for topical minoxidil suggest moderate fetal risk.³⁷ Pregnant women should be advised to consult their primary care provider before using minoxidil. Minoxidil is excreted in breast milk. Even though the American Academy of Pediatrics considers minoxidil compatible with breastfeeding, patients should consult their primary care provider rather than merely initiating self-treatment with topical minoxidil.³⁷

Either the 2% solution or 5% foam formulations can be recommended for use

by women; however, men usually are advised to use the 5% concentration. One study demonstrated a lower incidence of contact dermatitis has been demonstrated with propylene glycol-free foam products than with topical solutions.^{1,21} Accordingly, the foam formulation *may* be more desirable in patients with a history of sensitive skin or dermatitis. Patient preference for method of application is a critical factor in product selection. **Table 45-4** lists examples of commercially available products.

TABLE 45-4 Selected Nonprescription Hair Regrowth Products	
Trade Name	Primary Ingredient
Hair Regrowth Treatment Men Topical Solution	Minoxidil 2%
Hair Regrowth Treatment Men Topical Solution	Minoxidil 5%
Minoxidil for Men 2% Topical Solution	Minoxidil 2%
Minoxidil for Men 5% Topical Solution	Minoxidil 5%
Men's Rogaine 5% Minoxidil Solution	Minoxidil 5%
Men's Rogaine 5% Minoxidil Unscented Foam	Minoxidil 5%
Women's Rogaine 5% Minoxidil Unscented Foam	Minoxidil 5%
Women's Rogaine 5% Minoxidil Solution	Minoxidil 2%

Complementary Therapies

In the past, FDA advisory panels have proposed removing from the market a number of ingredients that were known to be safe for external use but for

which scientific evidence was lacking for their purported efficacy in preventing hair loss or promoting hair growth.³⁸ These unsupported claims generally are no longer made, but many such ingredients are still available today in nonprescription lotions and shampoos. In addition, oral and topical dietary supplements marketed to improve the structure and function of hair growth have become more popular. Despite the lack of sufficient evidence to document effectiveness, shampoos, topical solutions, and dietary supplements for hair loss include ingredients such as amino acids, aminobenzoic acid, B vitamins, jojoba oil, lanolin, maidenhair fern (*Adiantum capillis-verneris*), polysorbates 20 and 60, royal jelly (white secretion of *Apis melliferis* worker bees), tetracaine hydrochloride, urea, and wheat germ oil.^{19,38,39} Saw palmetto administered orally was shown to increase hair growth in 6 of 10 men with AGA in one randomized, double-blind, placebo-controlled study.⁴⁰

Algorithm: Hair Loss

FIGURE 45–3 Self-care approach to management of hair loss. Key: D/C = Discontinue; PCP = primary care provider.

Assessment of Hair Loss: A Case-Based Approach

Before recommending a treatment for hair loss, the health care provider should first consider possible underlying medical causes. To assess for alopecia areata or telogen effluvium, the provider can direct the patient to perform a gentle hair-pull test. A positive result on this test is an indication for referral to a dermatologist or other appropriate specialist for further evaluation. If pathology-induced hair loss and active hair loss are ruled out, the assessment should determine whether the balding fits the criteria for AGA.

Cases 45–1 and 45–2 illustrate the assessment of patients with different forms of hair loss.

Case 45–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient seeks the pharmacist's advice regarding products to combat gradual hair loss at the temples with some thinning at the vertex; no signs of inflammation or scarring on scalp are evident.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None
c. Description of the patient's efforts to relieve the symptoms	Patient has tried various "supplements" and switched shampoos several times, with no improvements noted.
d. Patient's identity	James Kramer
e. Patient's age, gender, height, and weight	30 years, male, 6 ft 2 in., 200 lb
f. Patient's occupation	Information technology support specialist
g. Patient's dietary habits	Hard-boiled eggs or oatmeal for breakfast; eats out for lunch daily, Mondays-Fridays; has fish or chicken with vegetables for dinner.
h. Patient's sleep habits	Sleeps 6-7 hours nightly.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Men's multivitamin daily; occasional ibuprofen 200-400 mg as needed for pain associated with past sports-related knee injury or headache
j. Allergies	Sulfa antibiotics (rash)
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Mr. Kramer indicated that every male in his family eventually loses his hair. He prefers to use a topical

Relevant Evaluation Criteria	Scenario/Model Outcome
	treatment because he is concerned about adverse effects of oral medications.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 45-2).	The patient has androgenetic alopecia, as evidenced by typical male pattern hair loss: gradual hair loss at temples and vertex. He has no signs of inflammation or scarring on scalp. Eyebrows and eyelashes are normal.
3. Identify exclusions for self-treatment (Figure 45-3).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend self-care using nonprescription minoxidil topical treatment and/or camouflage measures. (2) Refer Mr. Kramer to his regular health care provider for evaluation and treatment. (3) Recommend self-care until an appropriate health care provider can be consulted. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Topical minoxidil 2% or 5% solution and 5% foam products are approved for use in men. Mr. Kramer can use either formulation along with nondrug measures to treat the alopecia. The 5% foam formulation may be preferred, as it may cause less irritation and be more effective.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Apply approximately ½ capful of 5% topical foam twice daily to a clean, dry scalp."
7. Explain to the patient or caregiver the rationale for selecting the recommended	"Minoxidil 2% or 5% solution and 5% foam are available and FDA approved for use in men with androgenetic alopecia. The foam formulation may cause less

Relevant Evaluation Criteria	Scenario/Model Outcome
therapeutic approach from the considered therapeutic alternatives.	irritation. Although either the 2% or 5% product will be effective, men using 5% minoxidil had an earlier response and greater hair regrowth than men using 2% minoxidil.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	“Apply approximately ½ capful of 5% topical foam twice daily to a clean, dry scalp.”
b. Maximum number of days the therapy should be employed	“If no new hair growth is noted within 4–6 months, discuss continued use of the product with your primary care provider. If a response is noted, treatment will need to be continued indefinitely to maintain ongoing benefits.”
c. Product administration procedures	See Table 45–3 .
d. Expected time to onset of relief	“It may take 4–6 months for you to experience increased hair growth.”
e. Degree of relief that can be reasonably expected	“Progressive hair loss will be slowed.”
f. Most common adverse effects	“Local itching, irritation, and dryness or scaling at the site of application may occur.”
g. Adverse effects that warrant medical intervention should they occur	“Contact your primary care provider if you experience increased hair growth in areas beyond the scalp, acne, reddened skin/scalp, or swelling of the face.”
h. Patient options in the event that condition worsens or persists	“If increased hair growth is not experienced within 4–6 months, contact your primary care provider. Also contact your primary care provider if adverse effects are noted.”
i. Product storage requirements	“Store this product in a cool, dry place out of children’s

Relevant Evaluation Criteria	Scenario/Model Outcome
	reach.”
j. Specific nondrug measures	“Minimize exposure to factors that may trigger hair loss, such as certain medications, stress, illness, or injury.”
Solicit follow-up questions from the patient or caregiver.	“How can I tell if I am responding to the treatment?”
Answer the patient or caregiver questions.	“Hair density is more likely to increase if the treated area is in earlier stages of hair loss. Look for fine, short hairs as a first response. Additional hair loss may occur during the first few weeks of therapy.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mr. Kramer to call you right away with significant concerns about adverse effects (skin irritation, redness). Ask him to monitor and report any hair regrowth in 1–4 months.

Key: ACE = Angiotensin-converting enzyme; FDA = U.S. Food and Drug Administration; GERD = gastroesophageal reflux disease.

Case 45–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of	The patient seeks the pharmacist’s advice regarding a

Relevant Evaluation Criteria	Scenario/Model Outcome
symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	significant increase in hair loss. She has noticed a large amount of shed hair in the shower drain and in the bathroom sink. The hair loss has resulted in noticeable diffuse thinning of the hair over the past several weeks. No signs of inflammation or scarring of the scalp are present. Hair-pull test gives a positive result (8 hairs are pulled from the scalp with gentle tugging on a group of approximately 50 hairs).
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	None
c. Description of the patient's efforts to relieve the symptoms	Patient has tried new vitamins to boost her energy and promote hair growth and switched shampoos without improvement.
d. Patient's identity	Jennifer Jones
e. Patient's age, gender, height, and weight	45 years, female, 5 ft 4 in., 180 lb
f. Patient's occupation	Graphic designer
g. Patient's dietary habits	Patient recently started a weight loss program at the local Y.
h. Patient's sleep habits	Sleeps about 10 hours a night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Daily multivitamin; recently started taking fish oil for high cholesterol; Dulcolax occasionally for constipation
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) -----	The patient states: "I have been feeling extremely tired and down lately. I have gained quite a bit of weight over the past 2 months and have been more constipated. And now my hair is

Relevant Evaluation Criteria	Scenario/Model Outcome
	falling out! Even the men in my family generally keep their hair—I don't know what's going on with me!"
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 45–2).	The patient likely has telogen effluvium secondary to hypothyroidism, as evidenced by relatively sudden onset of hair loss and a positive hair-pull test result. She also is extremely fatigued and has experienced weight gain and constipation. She has no signs of inflammation or scarring on the scalp.
3. Identify exclusions for self-treatment (Figure 45–3).	Hair loss of sudden onset with a positive result on a hair-pull test in a woman is suggestive of a possible endocrine disorder, so self-treatment is not an option.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Jones to her regular health care provider for evaluation and treatment. (2) Recommend self-care until she can see her primary care provider. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer Ms. Jones to her regular health care provider for evaluation and treatment.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult your primary care provider for evaluation and treatment."
7. Explain to the patient or caregiver the rationale for selecting the	"The other signs and symptoms you described, such as weight gain and extreme fatigue, suggest that you may have an underlying cause for your hair loss, such as hypothyroidism. Use

Relevant Evaluation Criteria	Scenario/Model Outcome
recommended therapeutic approach from the considered therapeutic alternatives.	of nonprescription products available for hair loss is not recommended for this type of hair loss. It is best to see your primary care provider for evaluation and subsequent treatment.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
Solicit follow-up questions from the patient or caregiver.	“If the cause is identified and treated, will my hair grow back?”
Answer the patient’s or caregiver’s questions.	“If the underlying cause is identified and treated, hair loss will stop or lessen and hair will regrow. It is important to see your primary care provider to be evaluated and to determine appropriate treatment.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Ms. Jones to report to you the outcome of her primary care provider’s evaluation and recommendations.

Patient Counseling for Hair Loss

Patients who want to use nonprescription minoxidil should be advised that most treatment regimens for hair loss do not alter its progression, and that the longer the hair thinning or loss has continued, the less likely it is that the agent will elicit a regrowth response. For patients who still want to use minoxidil, the health care provider should provide a careful review of product instructions, with emphasis on possible adverse effects and the signs and symptoms that

warrant medical attention. In addition, if hair regrowth is achieved, patient counseling should underscore the need for indefinite use of minoxidil to maintain the regrowth. Cosmetic products, camouflaging options, and hair transplants/surgical interventions may be acceptable alternatives if the patient is concerned about long-term use of the drug or does not obtain a desired endpoint with the minoxidil regimen. The box “Patient Education for Hair Loss” lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Hair Loss

Patients should use minoxidil for the minimum recommended period. If new hair growth does not occur after use of minoxidil 2% or 5% for 4–6 months, the patient should consider ending treatment and consulting a dermatologist or other primary care provider for further evaluation.^{22,28} If new hair growth does occur within the recommended period, the patient should be advised to continue the drug treatment indefinitely.

Patient Education for Hair Loss

The goal in self-treatment for hair loss is to achieve an appearance that the patient considers acceptable while also minimizing emotional distress. This objective can be accomplished by nonprescription methods including cosmetic camouflage and/or the use of topical minoxidil to stimulate hair growth, when appropriate. To ensure optimal therapeutic outcomes, it is essential that patients carefully follow product packaging information and consider the following measures.

Nondrug Measures

- If desired, use wigs to cover severe hair loss until hair is regrown.
- For less severe hair loss, use hair sprays, gels, colorants, permanents, or hair-building products in moderation to create the illusion of full hair. These cosmetics will not affect the rate of hair loss.
- Avoid the use of oily hair products that can cause folliculitis.

- Avoid hairstyles that pull on the hair, such as tight braids.
- Avoid heat from hair dryers and curling/flat irons because their use can make the hair more brittle.

Nonprescription Medications

- During the first few weeks of minoxidil use, continued hair loss may occur. Note that use of minoxidil must be continuous and indefinite to maintain regrowth. Up to 4–6 months may be required to obtain any results. If treatment is interrupted, regrowth typically will be lost within 4 months or less, and progression of hair loss will begin again.
- Minoxidil is not recommended in patients who are pregnant, breastfeeding, or planning to become pregnant while using this product. Women should consult a primary care provider before initiating a minoxidil regimen.
- See Table 45–3 for instructions on how to use this product.
- Do not apply the product more often than directed. More frequent applications will not achieve better regrowth or a faster response but may increase adverse effects.
- Do not use other scalp drugs or hair care products while using this drug.
- Do not apply the product to damaged or inflamed areas of the scalp, including areas with active scalp psoriasis or eczema lesions and open scalp wounds of any kind.
- Note that local itching or irritation at the site of application may occur. More rarely, allergic contact dermatitis or transient hypertrichosis (unwanted facial hair growth) may occur.
- Keep product container in a cool, dry place, but do not put it in the refrigerator.
- Keep the product out of children's reach. Ingestion of minoxidil is potentially hazardous. If the product is ingested, a poison control center should be contacted immediately.
- The solution is flammable. Keep away from fire or flame.
- Do not use on infants or children 18 years of age or younger.
- Do not use if you have heart disease except under the supervision of a primary care provider.

- If hair fails to appear within the time specified on the product (generally 4–6 months) despite consistent use of the product, consider stopping the treatment and seeing your primary care provider for further evaluation.

Source: [References 22](#) and [28](#).

Key Points for Hair Loss

- Minoxidil is not effective for everyone.
- Positive treatment results may take several weeks to be noticed. Additional hair loss may occur during the first few weeks of therapy.
- Adherence is critically important for pharmacologic treatment. Hair loss will recur if therapy is stopped.
- Offering cosmetic solutions also may be helpful.
- Patients, particularly women, are seeking treatment not only to combat the hair loss but also to bolster self-esteem, which often suffers because of the cultural association of hair loss with illness and advanced age.
- The health care provider should identify and acknowledge the limitations of the ongoing treatment and provide emotional support.

Chapter 46: Insomnia, Drowsiness, and Fatigue

Authors: Christine Eisenhower

Insomnia

Insomnia, one of the most common patient complaints, is associated with increasing age, female sex, several comorbid disorders, and night shift work.¹ Insomnia occurs when a person has trouble falling or staying asleep and/or does not feel refreshed after sleeping, despite having the opportunity to sleep for an adequate amount of time in a sufficient environment.^{1,2} Insomnia results in poor daytime productivity, impaired functional status, work absenteeism, and occupational and motor vehicle accidents.¹ Annual cost estimates for insomnia in the United States range from \$30 billion to \$107.5 billion, depending on inclusion of indirect costs such as missed workdays.³

The National Sleep Foundation recommends 7–9 hours of sleep nightly for adults ages 26–64 years, and 7–8 hours for adults 65 years and older.^{4,5} The typical American gets 6.9 hours of sleep on workdays and 7.6 hours on non-workdays.⁵ In a 2015 poll, 34% of Americans reported at least one sleep problem during the previous 7 days, and 13% reported they rarely or never get a good night of sleep.⁵ Weekly average sleep duration is lowest for those who rate their general health, quality of life, and/or physical and mental health as fair or poor.⁵ Approximately 20% of American adults use a medication for insomnia in a given month, with nearly 60% of medications used being nonprescription sleep aids, primarily antihistamines.⁶ Only a small percentage of patients with symptoms of insomnia actually consult their health care provider.⁶ The combination of frequent misuse of hypnotics and availability of nonprescription agents makes insomnia a disorder of significant concern.

Pathophysiology of Insomnia

Sleep comprises five different stages. Stages 1–4, categorized as non-rapid eye movement (REM) sleep, are important for overall health maintenance. Stage 5 is important for regulation of learning and mood.^{3,7} *Stage 1 sleep* is a transitional stage, representing the initiation of sleep.⁷ *Stage 2* is an

intermediate phase involving alpha rapid-wave sleep, as measured by an electroencephalogram (EEG). At this stage, heart rate and body temperature decrease.^{3,7} Stages 3 and 4, collectively known as *deep sleep* or *delta sleep*, are characterized by the patterns of delta or slow-frequency waves on the EEG. Stage 5, or *REM sleep*, is neither light nor deep and is characterized by an increase in dream activity. At this stage, the EEG demonstrates an increase in high-frequency waves.⁷ The whole sleep cycle takes place over 90–120 minutes, with about 3–7 cycles occurring per night.³

Sleep physiology changes with increasing age. Among older adults, total sleep time is shorter, the number of nocturnal awakenings increases, and less time is spent in stages 4 and 5. *Sleep-onset latency* (time to fall asleep) usually remains normal with increasing age. Despite these changes, older adults cannot be assumed to require less sleep.⁵

Shift workers often complain of sleep disturbances and fatigue. Night shift work can have negative impacts on the circadian rhythm and secretion of melatonin, stress hormone levels, autoimmune function, work–life balance, social interactions, and mental health. Those who work rotating night shifts with early shift changeovers and backward-rotating shifts may have an even higher risk of health problems.⁸

Insomnia can be classified on the basis of an identifiable cause. *Primary insomnia* is the term used to describe patients who have sleep difficulty that may be considered idiopathic, paradoxical, or psychophysiological.² *Paradoxical insomnia* is defined as the presence of significant sleep symptoms with poor correlation between patient report of symptoms and objective measures of sleep.^{2,6} Patients also may have primary insomnia caused by inadequate sleep hygiene or acute stressors such as medical illness, anxiety, travel, hospitalization, divorce, or death of a loved one (known as *adjustment insomnia*).¹ *Secondary insomnia* is caused by another sleep disorder, general medical or psychiatric condition, substance use disorder, or medication(s).² All underlying causes of insomnia should be identified and, if possible, managed to relieve the sleep disturbance.^{2,3}

Insomnia also can be classified as *short-term* or *chronic* according to the duration of sleep disturbance. Short-term insomnia meets the symptom criteria and persists <3 months.¹ Chronic insomnia persists ≥3 months with symptoms occurring ≥3 times per week; it can be secondary to medical problems, psychiatric disorders, or a substance use disorder.¹ Short-term

insomnia affects an estimated 30%–50% of the population, whereas chronic insomnia affects at least 5%–10% of the population in industrialized countries.¹

In addition to psychiatric disorders, several medical disorders are associated with chronic insomnia ([Table 46–1](#)). Chronic insomnia is a key complaint of patients experiencing pain syndromes. It also can be secondary to use of medications or other substances, or to *circadian rhythm sleep disorders*; the latter involves abnormalities in length, timing, and/or rigid behavior of the sleep–wake cycle relative to the day–night cycle.^{2,6} Early morning awakening often is associated with depression. Nonprescription sleep aids generally are not helpful in patients with chronic insomnia, and medical referral is indicated.

Medications, including both prescription and nonprescription drugs, can produce either insomnia or withdrawal insomnia ([Table 46–2](#)).^{2,7,9,10} Antidepressants, antihypertensive agents, and sympathomimetic amines such as pseudoephedrine and phenylephrine are commonly associated with insomnia. Alcohol can cause insomnia after acute use and as a withdrawal effect after chronic use. Some individuals also are sensitive to the stimulant effects of caffeine and nicotine. Drinking caffeinated beverages in the late afternoon or evening hours can cause insomnia. Late-night exercise, late-evening meals, and environmental distractions such as noise, lighting, uncomfortable temperatures, or new surroundings also can interfere with sleep.⁷

TABLE 46–2 Selected Drugs That Can Exacerbate Insomnia

Drugs That Can Cause Insomnia	Drugs That Can Produce Withdrawal Insomnia
Alcohol	Alcohol
Antiarrhythmics	Amphetamines
Antidepressants (e.g., bupropion, selective serotonin reuptake inhibitors, serotonin-norepinephrine reuptake inhibitors, monoamine oxidase inhibitors)	Antihistamines (first generation) Barbiturates Benzodiazepines Illicit drugs (e.g., cocaine, marijuana, phencyclidine)

Clinical Presentation of Insomnia

Patients with insomnia may have varying complaints, such as difficulty falling

asleep, frequent awakenings, early morning awakening and inability to fall back to sleep, disturbed quality of sleep with unusual or troublesome dreams, or just poor sleep quality. Their actual duration of sleep, as determined by sleep laboratory studies, may or may not differ from individuals who report normal sleep. However, these patients may report that they need more than 30 minutes to fall asleep and/or that their duration of sleep is less than 7 hours nightly.

Sleep-deprived individuals are highly symptomatic, and their quality of life is negatively affected. Most untreated patients with insomnia report symptoms of fatigue, drowsiness, anxiety, irritability, depression, decreased concentration, and memory impairment. If untreated, insomnia can be associated with a rise in morbidity and mortality rates from general medical and psychiatric disorders, such as cardiovascular disease, pain syndromes, depression, anxiety, and substance use disorder.^{2,6}

Treatment of Insomnia

Treatment Goals

Treatment goals are to improve the patient's presenting symptoms, quality of life, and functioning.² This may be achieved through modification of concomitant medications, management of related medical conditions, and use of nonpharmacologic and pharmacologic therapies for insomnia.

General Treatment Approach

For patients with transient or short-term primary insomnia, reestablishing the normal sleep cycle with good sleep hygiene practices, with or without a nonprescription sleep aid, should help to normalize sleep patterns. Patients with an average sleep-onset latency greater than 30 minutes, wake after sleep onset (WASO) greater than 30 minutes, sleep efficiency less than 85%, and/or total sleep time less than 6.5 hours are described in the literature as having significant sleep disturbances and should be referred to their health care provider. *Sleep efficiency* describes the percent of time in bed that the patient is actually asleep.^{2,7} Patients with other sleep disorders, such as sleep apnea, narcolepsy, and restless legs syndrome, also may seek relief with the use of nonprescription sleep aids. Because of the risk for potentially significant adverse effects, patients with these disorders require medical referral to a

sleep specialist. The algorithm in [Figure 46–1](#) outlines the assessment and self-treatment of transient and short-term insomnia, and also lists exclusions for self-treatment.

Nonpharmacologic Therapy

Cognitive behavioral therapy for insomnia (CBT-I), which addresses dysfunctional behaviors and beliefs that contribute to insomnia, is considered first-line therapy for all patients.^{1,6,11} CBT-I consists of a combination of cognitive therapy; behavioral interventions such as sleep restriction, relaxation, and stimulus control; and educational interventions such as sleep hygiene.¹² *Sleep restriction* is a method of reducing daytime sleepiness and improving sleep continuity that entails limiting time in bed (TIB) to just sleeping at night. Patients should be asked to record how much time they actually were asleep (total sleep time). Initially, TIB is limited to that total sleep time (no daytime napping) and then gradually increased to enhance sleep drive. For example, a patient may spend 9 hours in bed but sleep only 6.5 hours. The patient should restrict TIB to 6.5 hours and avoid daytime napping. Initially, the patient will experience daytime sleepiness, but the patient's body will adjust and the sleep drive will increase in about 1 week. The patient can then extend TIB by an additional 30 minutes each week; eventually, the total sleep time will be confined only to nighttime. This approach also will reduce nighttime awakenings.²

The use of weekly CBT-I in both group therapy at a mentalhealth care center and guided internet therapy with a sleep therapist has been evaluated in adolescents with insomnia, with improvements observed in sleep efficiency, sleep-onset latency, WASO time, and total sleep time.¹² The sleep hygiene measures in [Table 46–3](#) are recommended for all patients with insomnia.^{6,7,11,13} In most patients with sleep disturbances, these measures should be tried before starting drug therapy. If initiated, drug therapy should be accompanied by sleep hygiene and other components of CBT-I.¹ Patients should be encouraged to try one or two measures at a time. Barriers to implementation of CBT-I include cost, and patients' lack of availability or patience, and/or unwillingness to try CBT-I techniques.¹

TABLE 46–3 Principles of Good Sleep Hygiene

- Use bed for sleeping or intimacy only.
- Establish a regular sleep pattern. Go to bed and arise at about the same time daily, even on the weekends.
- Make the bedroom comfortable for sleeping. Avoid temperature extremes, noise, and light.
- Engage in relaxing activities before bedtime.
- Avoid using electronic devices (particularly television and smart devices) around bedtime.
- Exercise regularly but not within a few hours of bedtime.
- If hungry eat a light snack but avoid eating meals within 2 hours before bedtime.
- Avoid daytime napping or limit naps to 20–30 minutes.
- Avoid using caffeine, alcohol, or nicotine for at least several hours before bedtime.
- If unable to fall asleep after more than 20 minutes, do not continue to try to sleep; get out of bed and perform a relaxing activity until you feel tired.
- Do not watch the clock at night.

Source: [References 6, 7, 11, and 13](#).

Pharmacologic Therapy

When the U.S. Food and Drug Administration (FDA) issued its final monograph on nonprescription sleep aids in 1989, the antihistamine diphenhydramine, as either the hydrochloride or citrate salt, was the only sleep aid deemed to be safe and effective for self-administration.¹⁴

Antihistamines

Diphenhydramine and doxylamine belong to the ethanolamine group of antihistamines, which affect sleep by competitively blocking histamine-1 receptors.^{15,16} Although the safety and efficacy of doxylamine have not been fully established, FDA has allowed the drug to remain on the market. Few studies supporting the efficacy of doxylamine as a hypnotic are available.^{17,18}

Both diphenhydramine and doxylamine are well absorbed from the gastrointestinal tract, with similar times to maximum plasma concentrations (1–4 hours and 2–4 hours, respectively). Diphenhydramine has an elimination half-life of 2.4–9.3 hours in healthy adults compared with 10–12 hours for doxylamine.^{15,17} Diphenhydramine is metabolized in the liver through two successive N-demethylations, and its apparent half-life can be prolonged in

patients with hepatic cirrhosis.¹⁵ Studies have shown a positive relationship between diphenhydramine plasma concentrations and drowsiness and cognitive impairment. Maximum sedation with diphenhydramine occurs 1–3 hours after a dose.¹⁵

The primary indication for diphenhydramine in insomnia is the symptomatic management of transient and short-term sleep difficulties, particularly in individuals who complain of occasional problems falling asleep. The efficacy of diphenhydramine in patients with chronic insomnia is poor.¹⁸ Tolerance to the sedative effect of diphenhydramine develops in healthy volunteers within days of repeated use.¹⁸

For use as a nighttime sleep aid, the usual diphenhydramine dosage is 50 mg for patients 12 years and older, taken 30 minutes prior to bedtime. Use of a 100 mg dose is not likely to be more efficacious but will increase the risk for adverse effects.¹⁵ Intermittent use to assess sleep quality without medication may reduce tolerance to the hypnotic effect. Use of diphenhydramine as a sleep aid should be limited according to the 2017 American Academy of Sleep Medicine (AASM) guidelines.¹

Additive sedation or anticholinergic effects occur when diphenhydramine is taken with other medications having these properties.¹⁹ For example, diphenhydramine, an inhibitor of the hepatic enzyme cytochrome P450 2D6 (CYP2D6), causes more than a twofold decrease in the clearance of metoprolol, especially in women.²⁰ Table 46–4 describes clinically significant drug–drug interactions that can occur with diphenhydramine.^{16,20,21} Alterations to pharmacotherapy should be made, if indicated.

TABLE 46–4 Selected Clinically Significant Drug Interactions With Diphenhydramine

Interacting Drugs or Drug Classes	Description	Monitoring Recommendation
Acetylcholinesterase inhibitors	Acetylcholinesterase inhibitors and diphenhydramine may diminish the therapeutic effects of each other.	Monitor therapy.
Alcohol (ethyl)	Diphenhydramine may enhance the central nervous system (CNS)	Monitor therapy.

Interacting Drugs or Drug Classes	Description	Monitoring Recommendation
	depressant effect of ethanol.	
Aripiprazole	Diphenhydramine may increase serum concentrations of aripiprazole.	Monitor for increased pharmacologic effects. Dose adjustments may be required based on concomitant therapy and/or indication.
Buprenorphine	Diphenhydramine may enhance the CNS depressant effect of buprenorphine.	Consider reduced doses of other CNS depressants, and avoiding such drugs in patients at high risk of buprenorphine overuse/self-injection. Initiate buprenorphine patches at 5 mcg per hour when used with other CNS depressants.
Cannabinoids	Cannabinoids may enhance the CNS depressant effect of diphenhydramine.	Monitor therapy.
Gastrointestinal Agents (prokinetic)	Diphenhydramine may diminish the therapeutic effect of prokinetic gastrointestinal (GI) agents.	Monitor therapy.
Glucagon	Diphenhydramine may enhance the adverse and toxic GI effects of glucagon.	Monitor therapy.
Kava	Kava may enhance the adverse/toxic effects of diphenhydramine.	Monitor therapy.
Magnesium sulfate	Magnesium sulfate may enhance the CNS depressant effect of diphenhydramine.	Monitor therapy.
Metoprolol	Diphenhydramine may increase the serum concentration of metoprolol and cause negative chronotropic	Consider an alternative for one of the interacting drugs to avoid metoprolol toxicity. If the combination must be used, closely monitor response to metoprolol. Metoprolol dose reductions may be

Interacting Drugs or Drug Classes	Description	Monitoring Recommendation
	effects, particularly in women.	necessary.
Minocycline	Minocycline may enhance the CNS depressant effect of diphenhydramine.	Monitor therapy.
Mirtazapine	Diphenhydramine may enhance the CNS depressant effect of mirtazapine.	Monitor therapy.
Opioid agonists	Diphenhydramine may enhance the CNS depressant effect of opioid agonists.	Avoid concomitant use; only combine if alternatives are ineffective or unavailable.
Potassium chloride	Diphenhydramine may enhance the ulcerogenic effect of potassium chloride.	Patients on diphenhydramine should avoid using any solid oral dosage form of potassium chloride because of anticholinergic effects. Avoid combining use of these drugs.
QT-prolonging agents (e.g. antiarrhythmics, citalopram, clarithromycin, fluoxetine, levofloxacin, moxifloxacin, ziprasidone)	Additive QT-prolonging effects occur with diphenhydramine.	Unless contraindicated, coadminister with caution.
Selective serotonin reuptake inhibitors (SSRIs)	Diphenhydramine may enhance the adverse effects of SSRIs. Risk of psychomotor impairment may be enhanced.	Monitor therapy.
Tamoxifen	Histamine-1 receptor blockers may decrease serum concentrations of endoxifen, the active metabolite of tamoxifen.	When possible, consider alternatives that have less of an inhibitory effect on CYP2D6 activity. Consider therapy modification.

Interacting Drugs or Drug Classes	Description	Monitoring Recommendation
Topiramate	Diphenhydramine may enhance the adverse and toxic effects of topiramate.	Monitor therapy.

Source: [References 16, 20, and 21](#).

The primary adverse effects of diphenhydramine and doxylamine are anticholinergic.^{15,17} Dry mouth and throat, constipation, blurred vision, urinary retention, and tinnitus may occur. Older patients, patients with comorbid medical disorders, and patients taking multiple medications are particularly susceptible to developing adverse effects when taking either sleep aid.

Anticholinergic toxicity can result from excessive antihistamine dosages. Factors such as drug–drug interactions, intentional overdose, or individual sensitivity also can lead to toxicity.^{16,19} Central nervous system (CNS) anticholinergic toxicity is one of the primary presenting features of antihistamine excess. Patients exhibiting excessive anticholinergic effects can be anxious, excited, delirious, hallucinating, or stuporous. In more-severe cases, coma or seizures may occur. Other physical signs of anticholinergic toxicity include dilated pupils, flushed skin, hot and dry mucous membranes, and elevated body temperature. Tachycardia and moderate QTc prolongation on the electrocardiogram are common. In severe cases, rhabdomyolysis, dysrhythmias, cardiovascular collapse, hallucinations, seizure, and death can occur.^{16,19} In the case of diphenhydramine overdose, patients should be referred for emergency treatment, which includes gastric lavage and activated charcoal administered orally or via nasogastric tube, and additional symptomatic treatment.¹⁶

Several warnings and precautions apply to the use of diphenhydramine. Older men with prostatic hyperplasia and difficulty urinating should not use diphenhydramine because urinary retention can occur. Anticholinergic agents can increase intraocular pressure; therefore, patients with angle-closure glaucoma should avoid them. Patients with hypertension or ischemic heart

disease are advised to use diphenhydramine with caution. However, cardiovascular adverse effects such as hypotension and arrhythmias are not common and are generally associated with overdoses.^{16,19} Anticholinergic agents decrease cognitive function and increase confusion in patients with dementia; these patients should not take diphenhydramine because it is categorized as having definite anticholinergic effects on the Anticholinergic Cognitive Burden Scale.²² In addition, higher cumulative anticholinergic use is associated with an increased risk for dementia. Efforts to increase awareness among health care providers and older adults about this potential medication-related risk are important to minimize use of anticholinergic medications such as diphenhydramine over time.²³

Patients should be cautioned to avoid performing tasks that require their full attention or coordination, such as driving, cooking, or operating machinery, until their response to diphenhydramine is known. They also should be discouraged from drinking alcoholic beverages while taking diphenhydramine. Some patients can develop excitation from diphenhydramine and other highly anticholinergic antihistamines.¹⁹ This paradoxical effect occurs more often in children, older patients, and patients with organic mental disorders. Symptoms include nervousness, restlessness, agitation, tremors, insomnia, delirium, and, in rare cases, seizures.

Combination products containing diphenhydramine plus acetaminophen, ibuprofen, or aspirin are available.^{16,19} No published studies establish whether these products are of benefit in inducing sleep in patients who complain of insomnia caused by pain. Gastrointestinal adverse effects are of concern with frequent use of combination products containing ibuprofen and aspirin.

Several case reports of diphenhydramine use disorder in patients taking antipsychotic medications have been published.²⁴ Health care providers should carefully assess for misuse in individuals making repeated purchases of diphenhydramine, especially in patients being treated for psychosis. Patients taking antipsychotics may seek relief of adverse effects, such as tremor, and rewarding effects, such as elevated mood from anticholinergic medications.²⁴

Ethanol

Use of alcohol as a hypnotic is common in patients with chronic insomnia who wish to shorten time to sleep onset. However, alcohol has a short duration of action and is associated with adverse effects such as misuse, dependence, and

exacerbation of obstructive sleep apnea.² The Intraindividual Study of Affect, Health, and Interpersonal Behavior (iSAHIB) evaluated sleep quality and alcohol consumption in 150 participants 19–89 years of age. Results showed significant and negative associations between sleep quality and daily alcohol use. Use of items from the Pittsburgh Sleep Quality Index showed a decrease of 0.71 in sleep quality for each additional drink.²⁵

Alcohol is present in some liquid nonprescription combination cold products. These products can contain up to 10% alcohol by volume and are marketed to induce sleep. However, data regarding the efficacy and safety of these products as sleep aids are limited. The multiple ingredients increase the risk of adverse effects and interactions with other drugs.

Pharmacotherapeutic Comparisons

In general, diphenhydramine should not be recommended for a chronic sleep disturbance because use-related adverse effects are common, especially in older adults, and evidence of efficacy is lacking.^{2,6,11,18} AASM’s weak recommendation against the use of diphenhydramine for treatment of sleep-onset and sleep-maintenance insomnia is based on low-quality evidence in patients receiving 50 mg doses.¹

Product Selection Guidelines

Because the value of doxylamine as a sleep aid is not well established, only diphenhydramine may be suggested to appropriate patients for short-term use. To meet different patient preferences, nonprescription diphenhydramine is available as capsules, liquid-filled capsules, caplets, tablets, chewable tablets, orally disintegrating tablets, solutions, and elixirs (Table 46–5).¹⁶

TABLE 46–5 Selected Nonprescription Sleep Aid Products	
Trade Name	Primary Ingredient(s)
Single-Entity Antihistamine Products	
Unisom SleepGels Capsules (liquid filled)	Diphenhydramine HCl 50 mg
Unisom SleepMelts Tablets (orally disintegrating)	Diphenhydramine HCl 25 mg
Sominex Nighttime Sleep-Aid Tablets	Diphenhydramine HCl 25 mg

Trade Name	Primary Ingredient(s)
Sominex Nighttime Sleep-Aid Caplets	Diphenhydramine HCl 50 mg
ZzzQuil Nighttime Sleep-Aid Capsules (liquid filled)	Diphenhydramine HCl 25 mg
ZzzQuil Nighttime Sleep-Aid Liquid	Diphenhydramine HCL 50 mg/30 mL
Antihistamine/Analgesic Combination Products	
Advil PM Pain Reliever & Nighttime Sleep Aid Caplets	Diphenhydramine citrate 38 mg; ibuprofen 200 mg
Excedrin PM Headache Caplets	Diphenhydramine citrate 38 mg; acetaminophen 250 mg; aspirin 250 mg
Tylenol PM Extra Strength Caplets	Diphenhydramine HCl 25 mg; acetaminophen 500 mg
Tylenol PM Extra Strength Pain Reliever and Sleep Aid Liquid	Diphenhydramine HCl 50 mg; acetaminophen 1000 mg; per 30 mL

Note: Information is not all-inclusive. Product formulations may have changed since time of publication.

Special Populations

The safety of antihistamines during pregnancy has not been established.¹⁹ Therefore, the benefit–risk ratio of using these drugs to manage insomnia during pregnancy should be evaluated carefully. Most epidemiologic studies have not demonstrated increased risk of teratogenicity with the use of diphenhydramine during the first trimester, but one trial from 1974 reported cleft palate alone and other fetal abnormalities.¹⁵ Nevertheless, pregnant women should be referred for further evaluation.

An increased risk of CNS adverse effects can occur in breastfed neonates after maternal intake of a sedating antihistamine. Use of large dosages for sustained periods of time may inhibit lactation, causing drowsiness and irritability in breastfed infants.^{16,26} Continued use of sedating antihistamines for insomnia is not recommended for use in nursing mothers.^{16,17,19} Second-generation antihistamines are preferred for women who are breastfeeding and require

use of an antihistamine.¹⁶

Children and adolescents may present with insomnia caused by a circadian rhythm disorder. Teenagers should be asked about their use of nonprescription remedies and intake of caffeine, nicotine, alcohol, and illicit substances. Behavioral interventions and good sleep hygiene are first-line treatment for insomnia in children and adolescents. Diphenhydramine and doxylamine are not indicated to treat insomnia in children younger than 12 years. Diphenhydramine may cause paradoxical excitation in younger children and is not recommended to induce sleep in infants.¹⁵ Anticholinergic toxicity is common in children, and their symptoms may be more severe than those of adults. Diphenhydramine toxicity was reported in children administered the topical application over large areas of their bodies, as well as in those receiving topical and oral preparations simultaneously.¹⁵ FDA requires a label warning that advises consumers not to use oral nonprescription diphenhydramine with other products that contain the drug, including topical agents.¹⁵

Treatment of insomnia in older adults involves behavioral therapy and pharmacotherapy with approved agents. The 2019 AGS Beers Criteria[®] recommends avoiding the use of first-generation antihistamines in older adults (age $\geq$ 65 years) because of their anticholinergic effects.²⁷ Concerns about diphenhydramine and doxylamine use in older patients include delirium, confusion, and cognitive decline. Therefore, nonprescription antihistamines should not be recommended to treat insomnia in this age group; the patients should be referred instead to their health care provider for further evaluation.

Patient Factors

Considerations for selecting nonprescription and/or complementary therapies for insomnia include the patient's age, their participation in shift-work, and their willingness to make changes to their sleep hygiene and routine. Product cost and availability are other considerations.

Patient Preferences

Patients may prefer the use of diphenhydramine as a more effortless intervention over CBT-I measures. However, they should be reminded of the potential benefits of CBT-I, and the lack of evidence to support use of diphenhydramine and other nonprescription therapies for insomnia.

Complementary Therapies

Complementary therapies such as melatonin, valerian, and chamomile often are used for insomnia. (See [Chapter 51](#) for a thorough discussion of these first two supplements). The AASM's weak recommendation against the use of melatonin or valerian as treatment for sleep-onset or sleep-maintenance insomnia in adults is based on evidence of very low and low quality, respectively.¹ The recommendation against melatonin is based on the use of 2 mg doses, which reduced sleep-onset latency by an average of 9 minutes versus placebo, but demonstrated only small improvements in sleep quality.¹ However, a systematic review of six placebo-controlled trials concluded that both melatonin immediate-release 5 mg daily for 8 weeks and extended-release 2 mg daily for 3 weeks benefited patient-reported sleep quality, sleep-onset latency, and morning alertness. Patients receiving 2 mg doses continued to see positive effects on sleep-onset latency at 26 weeks.¹⁸ Overall, evidence of the efficacy of melatonin is conflicting and likely depends on many factors such as dosing and timing of administration. Melatonin may be given 2–3 hours prior to bedtime to shift circadian rhythm. With regard to safety, a small study of patients aged ≥55 years did not observe psychomotor or cognitive impairment with use of melatonin.¹⁸ Patients who choose to try melatonin using the aforementioned doses and formulations should be advised to contact their health care provider after 10 days if insomnia persists.

Compared with placebo, valerian (*Valeriana officinalis*) lacks benefit in insomnia.²⁸ A meta-analysis of five randomized, double-blind, controlled trials reported no statistically significant differences in sleep-onset latency, sleep duration, sleep efficiency, and wake duration.²⁸ Various doses of valerian concoctions and extracts were used in clinical trials, including 300–600 mg daily taken 30–60 minute prior to bedtime, and 100–1215 mg 3 times daily.²⁸ A higher incidence of adverse events, including diarrhea, was observed in eight trials comparing valerian with placebo.²⁸

Chamomile (*Matricaria recutita*) flower extract is considered a popular dietary supplement to induce drowsiness.^{28,29} Chamomile contains apigenin, a flavonoid that antagonizes GABA-A and GABA-C receptors.²⁹ A small study of adults with primary insomnia compared use of a placebo with 270 mg of flower extract (higher than the dose ingested in tea) twice daily for 4 weeks.^{28,29} Statistically significant differences in severity were not detected for insomnia, sleep-onset latency, WASO time, sleep duration, nocturnal

awakenings, daytime functioning, sleep quality, and sleep efficiency.²⁸

Mindfulness meditation may be a useful complementary therapy for patients with insomnia. It involves attention regulation, body awareness, emotional regulation, and self-awareness. A meta-analysis of six randomized, controlled trials that included patients with primary chronic insomnia, insomnia secondary to depression or cancer, and sleep disturbances reported significant improvements in total wake time ($P = .03$) and sleep quality ($P = .003$).³⁰

Assessment of Insomnia: A Case-Based Approach

In assessing whether to recommend a nonprescription sleep aid, the health care provider should determine whether use of such products is appropriate, what nondrug interventions should be recommended, and whether medical referral to another provider is indicated. Identifying acute causes of insomnia, poor sleep hygiene practices, or underlying medical disorders can assist the provider in making a recommendation.

Case 46–1 is an example of the assessment of a patient with insomnia.

Algorithm: Transient and Short-Term Insomnia

FIGURE 46–1 Self-care of transient and short-term insomnia. Key: CBT-I = Cognitive behavioral therapy for insomnia; WASO = wake after sleep onset.

Case 46–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	

Relevant Evaluation Criteria	Scenario/Model Outcome
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of difficulty sleeping for the past 2 months. He lies awake about 20 minutes before going to sleep and is often drowsy and irritable at work. He wakes up 2–3 times per night, for about 5 minutes each time.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient reports he previously slept well, except when stressed at work. His work schedule recently changed; he works 4 days per week from 6 AM to 2 PM and covers a nighttime shift on Saturdays as an air traffic controller. His sleep difficulties began after this change.
c. Description of the patient's/ caregiver's efforts to relieve the symptoms	He reports playing games on his smart phone if he cannot fall asleep right away. He lives with his spouse and two young children, so he finds the weekend shift to be the most challenging to his sleep routine. Sometimes, he sleeps in the basement to avoid extra noise. If he cannot get enough sleep, he will drink two cups of coffee before the next shift starts.
d. Patient's identity	Dan Rudy
e. Patient's age, gender, height, and weight	43 years old, male, 5 ft 9 in., 182 lb
f. Patient's occupation	Air traffic controller for Federal Aviation Administration
g. Patient's dietary habits	Patient reports stopping at the local coffee shop for one donut, one bagel, and two coffees most mornings. His spouse packs a lunch for him on the weekdays, usually consisting of a turkey sandwich and sometimes a leftover salad. He also will grab a large candy bar from the

Relevant Evaluation Criteria	Scenario/Model Outcome
	vending machine each afternoon and another coffee halfway through his shift. He also drinks two more coffees in the evening if he needs to be awake to drive his kids to soccer and dance.
h. Patient's sleep habits	Can get about 8 hours of sleep after weekday shifts but decreases to just under 7 hours after nighttime shift for a few days.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>High cholesterol:</i> Atorvastatin 20 mg daily; <i>pain from old knee injury:</i> ibuprofen 800 mg as needed
j. Allergies	No known drug allergies
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Drinks "a few" beers with his friends on Friday nights or when watching football games. Denies use of tobacco.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Poor sleep secondary to shift-work, which occurs in a semi-dark room. Excessive caffeine use late in day. Poor sleep hygiene due to use of smart device when he cannot fall asleep.
3. Identify exclusions for self-treatment (Figure 46-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the	Options include (1) Refer Dan to his HCP.

Relevant Evaluation Criteria	Scenario/Model Outcome
primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	(2) Recommend CBT-I techniques until Dan can make an appointment with his HCP. (3) Recommend diphenhydramine 50 mg after Saturday shift, and CBT-I measures including good sleep hygiene after all shifts, limiting daily alcohol and caffeine use, and engaging in regular physical activity. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	CBT-I measures including good sleep hygiene for 10 days, as well as limiting alcohol and caffeine consumption. May try diphenhydramine after nighttime shift.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Take 1 diphenhydramine 50 mg tablet 30 minutes before your anticipated bedtime after your Saturday shift. If symptoms persist for 10 days, seek medical evaluation."
	"Follow measures for positive sleep hygiene." (See Table 46-3.) "Limit alcohol consumption to 1-2 servings (12-24 oz) of beer, consumed no later than 2 hours before bedtime. Limit overall intake of caffeine, and at a minimum, avoid caffeine 6 hours before bedtime."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the	"A consistent sleep pattern will help resolve your insomnia. Seeing your health care provider may not be necessary if you follow good sleep hygiene measures and take the diphenhydramine. Poor sleep practices are a common cause of insomnia. If these practices are continued, they can create a chronic sleep disturbance. A medication such as diphenhydramine can facilitate falling asleep, but it must be combined with measures of good sleep hygiene. You should avoid screen time

Relevant Evaluation Criteria	Scenario/Model Outcome
considered therapeutic alternatives.	from your cell phone at night because the bright light can interfere with your ability to fall asleep. In addition, you may find mindfulness mediation as well as sleep restriction to be helpful.”
	“Alcohol in more than modest quantities can disrupt sleep and make insomnia worse. Therefore, alcohol consumption should be limited and avoided for at least 2 hours before bedtime. In addition, caffeine is a stimulant and promotes wakefulness. Caffeine intake should be limited and not occur within 6 hours of bedtime. All dietary sources of caffeine, for example, coffee, sodas, and energy drinks, as well as hidden sources of caffeine, such as chocolate, should be identified.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	“Take diphenhydramine 50 mg nightly after your Saturday shift. Do not exceed this nightly dose. Always use sleep aids in combination with good sleep hygiene measures.” (See Table 46–3). “Do not take diphenhydramine as a sleep aid for more than a few nights without seeing your health care provider.”
	“Avoid drinking alcohol with the diphenhydramine because of the risk of increased sedation and the negative effects that alcohol has on sleep patterns.”
	“Adverse effects may include sedation, next-morning hangover, and anticholinergic effects such as dry mouth, urinary retention, blurry vision, and constipation.”
Solicit follow-up questions from the patient or caregiver.	(1) “May I repeat the dose of diphenhydramine if I do not fall asleep within 2 hours?” (2) “May I take diphenhydramine with my cholesterol medication?”
Answer the patient’s or caregiver’s	(1) “No. Repeating the dose increases the risk of side effects and likely will not improve sleep.” (2) “You may take both medications at the same time because

Relevant Evaluation Criteria	Scenario/Model Outcome
questions.	diphenhydramine has no significant interaction with your cholesterol medication.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact the patient after at least 3 days and one Saturday shift to assess the efficacy of diphenhydramine and improved sleep hygiene measures. Remind the patient if the insomnia continues for longer than 10 days, he should make an appointment with his health care provider for evaluation.

Patient Counseling for Insomnia

Patients with sleep disorders should be encouraged to practice good sleep hygiene measures. For some patients, these measures alone will resolve insomnia. If use of a nonprescription sleep aid is appropriate, dosing, appropriate duration, potential adverse effects, drug–drug interactions, and precautions or warnings should be explained carefully. In addition, patient education should include the signs and symptoms that indicate the need for follow-up with the provider. Taking a combination of pharmacologic products (i.e., prescription and nonprescription drugs, or drugs and dietary supplements) concomitantly to treat insomnia should be discouraged; this approach increases the risk of adverse effects. The box “Patient Education for Insomnia” lists specific information to provide patients.

Patient Education for Insomnia

The objectives of self-treatment are (1) to improve the duration and quality of sleep, (2) to reduce fatigue and drowsiness during the day, (3) to improve daytime functioning, and (4) to minimize adverse effects of

treatment. Carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes for most patients.

Disease Information

- Insomnia is difficulty getting enough sleep or trouble sleeping without interruption. Insomnia may be described as difficulty falling asleep, waking up too early, or waking up periodically during the night and not feeling rested during the day. Insomnia can cause fatigue and drowsiness during the day. Insomnia is *chronic* when it happens 3 times or more per week for 3 or more months. Insomnia can be caused by medical or psychiatric conditions, mental stress or excitement, or certain daytime and bedtime habits. If prescribed a medication that can exacerbate insomnia (e.g., a corticosteroid), talk with your health care provider about taking the medication in the morning.

Nondrug Measures

- See Table 46–3 for nondrug measures to prevent insomnia.
- Using principles of good sleep hygiene can help improve bad sleep habits and enhance quality sleep.
- If insomnia worsens or continues after 10 days of appropriate sleep hygiene plus CBT-I, seek medical attention.

Nonprescription Medications

- Age younger than 12 years or 65 years and older are exclusions for self-treatment of insomnia.
- Do not drive or operate machinery after taking sleep aids, including melatonin and valerian.
- Diphenhydramine is not expected to harm an unborn baby; however, you should not use diphenhydramine for sleep during pregnancy unless your health care provider recommends its use. It is important to tell your health care provider if you are pregnant or plan to become pregnant during treatment.
- Diphenhydramine may pass into breast milk and may harm a

nursing baby. Antihistamines also may slow breast milk production. Do not use this medication without medical advice if you are breastfeeding.

Diphenhydramine

- Establish a regular bedtime and take diphenhydramine 30 minutes before you want to go to sleep. Do not take more than 50 mg of diphenhydramine each night.
- After 3 nights of improved sleep, skip taking the medication for 1 night to see if the insomnia is resolved.
- Longer use of diphenhydramine will cause tolerance to the medication's sleep-inducing effects but not necessarily to its side effects. If your insomnia persists, you may have an underlying disorder.
- Note that diphenhydramine can cause morning grogginess or excessive sedation, dry mouth, blurred vision, constipation, and difficulty urinating (particularly in older men).
- Do not take diphenhydramine with alcohol; alcohol can increase the effects of the medication on the central nervous system. Alcohol also disrupts the sleep cycle.
- Do not combine use of diphenhydramine with prescription sleep aids.
- Consult your health care provider before taking diphenhydramine with other medications.

Evaluation of Patient Outcomes for Insomnia

Successful outcomes include decreased sleep-onset latency, improved sleep quality, and decreased daytime fatigue and drowsiness. The patient should be advised to seek medical evaluation if sleep has not improved in 10 days.

Key Points for Insomnia

- Refer patients with chronic insomnia or sleep disturbance caused by an underlying disorder for medical evaluation.
- Advise patients who are eligible for self-treatment to contact their health care provider if symptoms worsen or do not improve after 10 days.
- Counsel patients with insomnia about nondrug measures such as good sleep hygiene (Table 46–3).
- Refer children younger than 12 years, pregnant or breastfeeding women, and adults 65 years or older with insomnia to their health care provider.
- Advise patients about the different dosage forms of nonprescription sleep aids so they can select a product best suited for them.
- Advise patients that evidence to support the use of diphenhydramine is lacking and that its benefits are likely similar to its harms.
- Counsel patients on the adverse effects of diphenhydramine and, if applicable, other sleep aids, particularly next-day sedation, drowsiness, and the additive CNS depressant effects of alcohol and other sedating drugs.
- Advise patients taking a nonprescription sleep aid that contains diphenhydramine to avoid taking other oral drugs that contain this agent.
- Advise patients against combining the use of oral and topical diphenhydramine products.
- Advise patients to discuss the potential risks and benefits of complementary therapies with their health care provider before they select an agent.

Drowsiness and Fatigue

Drowsiness or fatigue may be acute in onset or chronic and can increase the risk of occupational or motor vehicle accidents, as well as adversely impact productivity, mood, and overall health.³¹ Evidence indicates an increased incidence of sleep-related crashes in young drivers who report an average of less than 6 hours of sleep per night.³²

Caffeine is the most frequently used CNS stimulant in the world to treat drowsiness or fatigue. Men and women consume an average of 196 mg daily and 151 mg daily, respectively, through ingestion of coffee, tea, and soft drinks. Youths’ daily consumption of caffeine is lower than that of adults. Caffeine consumption averaged 61 mg in those ages 14–19 years, 26 mg in those ages 9–13 years, and 15 mg in those ages 4–8 years.³³ Energy drinks are popular with adolescents and young adults. [Table 46–6](#) lists the caffeine content of commonly consumed beverages. Many nonprescription, prescription, and dietary supplements also contain caffeine. High total daily caffeine intake leads to adverse effects, withdrawal reactions, or, rarely, interactions with drugs.

TABLE 46–6 Caffeine Content in Common Dietary Sources		
Coffees, Teas, and Soft Drinks	Ounces	Caffeine Content (mg)
Brewed coffee	8	80–135
Brewed coffee, decaffeinated	8	3–4
Starbucks coffee, dark roast, tall	12	193
Starbucks coffee, dark roast, grande	16	260
Espresso	2	100
Instant coffee	8	65–100
Instant coffee, decaffeinated	8	2–3
Brewed tea, U.S. brands	8	40
Brew Dr. Kombucha	14	<15

Coffees, Teas, and Soft Drinks	Ounces	Caffeine Content (mg)
Snapple Iced Tea, flavored	8	31.5
Mountain Dew	12	55
Diet Coke	12	45.6
Coca-Cola Classic	12	34
Dr. Pepper	12	41
Dark chocolate	1	20

Note: The listed caffeine content for the brewed coffees and teas may vary according to brewing methods. The caffeine content in kombucha drinks may vary according to the number of days of fermentation.

Pathophysiology of Drowsiness and Fatigue

Daytime drowsiness and fatigue are caused most often by *inadequate sleep*, that is, sleep of both insufficient duration and quality. The degree of sleepiness is determined by two factors that regulate sleep and wakefulness: (1) a homeostatic process involving an increase in sleepiness as time since the most recent period of sleep increases and (2) a circadian process by which the master biological clock in the suprachiasmatic nucleus varies alertness over the course of the 24-hour day.³⁴ Other possible contributing factors include the use of CNS depressants, such as antihistamines, antipsychotics, anticonvulsants, and opioids. Dopamine agonists, antibiotics, and antihypertensive agents also may increase the risk of drowsiness. Increased susceptibility to the sedating effects of these agents can be particularly troublesome in older adults. Other etiologies include depression, cancer, anemia, hypothyroidism, chronic pain, overexertion, or inconsistencies in diet and exercise.³¹

Clinical Presentation of Drowsiness and Fatigue

The subjective experience of sleepiness includes feeling foggy or woozy, being responsive but not fully alert, and having dream-like thoughts. Patients may report a moderate to high chance of dozing off at inappropriate or dangerous

times, such as at work, in public, or while driving. Self-reported measures of sleepiness include the Stanford Sleepiness Scale and the Epworth Sleepiness Scale.^{31,35,36}

Treatment of Drowsiness and Fatigue

Treatment Goals

The goal in treating daytime drowsiness and fatigue is to identify and eliminate the underlying cause, thereby improving mental alertness and productivity. The algorithm in [Figure 46–2](#) outlines the approach to self-treatment.

General Treatment Approach

Many consumers use dietary sources of caffeine to self-treat occasional symptoms of fatigue and drowsiness. Nonprescription caffeine-containing products also may be used. Caffeine as a supplement, or in dietary form, is not a substitute for adequate sleep. Before recommending any caffeine-containing nonprescription product, the health care provider should rule out any drug-induced cause of daytime drowsiness and fatigue. If symptoms are chronic, especially with 7–8 hours of sleep, medical referral is indicated.

Nonpharmacologic Therapy

Good sleep hygiene principles should be emphasized ([Table 46–3](#)).

Pharmacologic Therapy

Caffeine inhibits phosphodiesterase, leading to increased levels of 3',5' cyclic adenosine monophosphate. This effect plays a role in preventing apnea. Caffeine also is a CNS stimulant that increases sensitivity of the medullary respiratory center to carbon dioxide, stimulates central inspiratory drive, and enhances contraction of skeletal muscles including the diaphragm.³⁷ Patients will benefit from increased alertness at moderate doses, but they also may experience unfavorable stimulant effects such as decreased fine motor coordination, headache, nervousness, and dizziness. More significant adverse effects include anxiety, irritability, insomnia, and tachycardia.^{37,38}

The stimulant effects of caffeine may be felt 15 minutes after a dose, and caffeine reaches peak concentration in 30–120 minutes. It has a volume of distribution of 0.6 L/kg in adults. Caffeine is metabolized in the liver by the CYP1A2 isoenzyme; active metabolites include theophylline. The elimination half-life of caffeine is about 5 hours in adults and children older than 9 years.^{37,38}

Caffeine is the only FDA-approved nonprescription stimulant. [Table 46–7](#) lists selected trade-name products that contain caffeine. The labeled dosages of approved nonprescription supplements for adults and children 12 years and older is 100–200 mg every 3–4 hours as needed. Caffeine is marketed for occasional use to help restore mental alertness or wakefulness.³⁹

TABLE 46–7 Selected Caffeine-Containing Products	
Trade Name	Caffeine Content (mg) per Unit
Nonprescription Caffeine-Only Products	
NoDoz Maximum Strength	200
Vivarin	200
Nonprescription Combination Products	
Excedrin Migraine	65
Midol Complete Caplets	60
Prescription Combination Products	
Cafergot	100
Fioricet	40
Fiorinal	40

Note: Information is not all inclusive. Products may have changed formulations or caffeine content since time of publication.

Tolerance to the effects of caffeine on the respiratory and cardiovascular

systems is common. Habitual caffeine drinkers who routinely consume as little as 100–200 mg daily and abruptly discontinue caffeine may experience mild signs and symptoms of withdrawal. Symptoms include headache, fatigue, decreased concentration, and irritability.⁴⁰

An exaggerated pharmacologic effect can occur when nonprescription caffeine is combined with dietary sources, or with prescription or nonprescription medications containing caffeine. For example, caffeine may reduce the clearance of theophylline, causing additive sympathetic effects such as an increased heart rate. The CYP1A2 isoenzyme can be induced or inhibited by other drugs. The routine use of high dosages of caffeine (400 mg daily) could theoretically saturate the binding sites and increase the risk of interactions with drugs that share this metabolic pathway. Cigarette smoking increases the clearance of caffeine by 56%.⁴¹ Individuals who are quitting smoking should be counseled to reduce their caffeine intake by half.⁴² Conversely, hormonal contraceptives and ciprofloxacin can inhibit the CYP1A2 isoenzyme. The clinical significance of these interactions is unknown, but patients taking these drugs should be cautioned to moderate their use of caffeine. Clinically significant drug interactions with caffeine are listed in [Table 46–8](#).⁴³ Genetic polymorphisms at CYP1A2 and adenosine receptors also may influence response to caffeine.

TABLE 46–8 Selected Clinically Significant Drug Interactions With Caffeine

Interacting Drugs or Drug Classes	Description	Monitoring Recommendation
Adenosine	Caffeine may diminish the therapeutic effect of adenosine.	Monitor for decreased effect of adenosine if patient is consuming caffeine. Many cardiac facilities instruct patients to avoid caffeine 12–24 hours prior to nuclear stress tests.
Atomoxetine	Atomoxetine may increase the hypertensive or tachycardic effect of caffeine.	Monitor therapy.
Cannabinoids (except cannabidiol)	These products may increase the tachycardic effect of	Monitor therapy.

Interacting Drugs or Drug Classes	Description	Monitoring Recommendation
	caffeine.	
Ciprofloxacin (systemic)	Ciprofloxacin may increase serum concentration of caffeine.	Monitor therapy.
Linezolid	Linezolid may enhance the hypertensive effect of caffeine.	Reduce initial doses of caffeine, and closely monitor blood pressure.
Lithium	Caffeine may decrease the serum concentration of lithium.	Monitor therapy.
Norfloxacin	Norfloxacin may increase the serum concentration of caffeine.	Monitor therapy.
Theophylline	Caffeine may increase the plasma concentration of theophylline.	Avoid concomitant use of caffeine or maintain consistent intake. Monitor theophylline trough concentrations.
Tizanidine	Caffeine may increase the serum concentration of tizanidine.	Avoid concomitant use when possible. If unavoidable, initiate tizanidine at 2 mg and increase in 2–4 mg increments according to patient response. Monitor for adverse reactions.
Tobacco (smoked)	Tobacco may decrease serum concentration of caffeine.	Monitor therapy.

Source: [Reference 43](#).

Patients who take monoamine oxidase inhibitors or have existing coronary

heart disease, uncontrolled hypertension, or preexisting arrhythmias should be counseled to avoid nonprescription caffeine-containing preparations and to moderate their intake of dietary caffeine. The consumption of coffee may lead to dose-related increases in blood pressure. A systematic review identified two cohort studies of patients receiving greater than 180 mg or greater than 200 mg caffeine per day, but less than 400 mg per day. An increase in blood pressure was not observed with these quantities. However, an analysis of 13 case-control studies showed an increased risk of coronary heart disease with daily intake of 275 mg or higher.⁴⁰

Caffeine has dose-related benefits for both rested and fatigued patients. After sleep deprivation, caffeine doses of 200–600 mg can improve psychomotor performance, alertness, and reaction time.⁴⁴ Cognitive function and driving performance were evaluated in participants receiving caffeine 200 mg (n = 50) or placebo (n = 50) after a 3-day washout period. Both brake reaction time and change in position of car were measured. Participants who received caffeine performed better on the Shifting Attention Test and had a shorter brake reaction time ($P = .03$ and $P = .048$, respectively).⁴⁵

The use of caffeinated coffee to counter the effects of excessive alcohol ingestion is a common practice. Although the combination of energy drinks or caffeine with alcohol increases alertness and reduces alcohol-related fatigue, it does not reverse alcohol-induced deficits on simple psychomotor tasks.⁴⁶ In 2010, FDA issued warning letters to manufacturers of caffeinated alcoholic beverages that they were in violation of the Federal Food, Drug, and Cosmetic Act because the combination of the two substances is not approved nor generally recognized as safe.⁴⁷

Patients should be cautioned about excessive consumption of caffeine in weight-loss supplements and energy sports drinks. Natural caffeine, other methylxanthines, and caffeine-containing herbs such as guarana, green tea, yerba mate, and kola nut are common ingredients in products marketed to young consumers for energy or weight loss.³⁸ The caffeine content is not always listed on the label of energy drinks. **Table 46–9** lists the amount of caffeine contained in selected weight-loss dietary supplements and sports energy drinks.

TABLE 46–9 Caffeine Content in Selected Dietary Supplements and Energy Drinks

Trade Name	Caffeine Content per Serving (mg)
Dietary Supplements	
Dexatrim Max Daytime Appetite Control	200
Pro Clinical Hydroxycut ^a	200
Energy Drinks^b	
5-hour Energy (regular strength)	200 ^c
Monster Energy	80 ^d
Red Bull	80 ^e
Rockstar Xduration	300

Note: Data are not all inclusive. Products may have changed formulations or caffeine content since time of publication.

^a Also contains Hydroxycut Blend 441 mg (robusta coffee extract, apple cider vinegar, plum, baobab extract, and cardamom).

^b Caffeine content based on serving size and strength sold.

^c Also contains taurine, glucuronic acid, malic acid, N-acetyl L-tyrosine, L-phenylalanine, and citicoline.

^d Also contains Monster Energy Blend (glucose, taurine, L-carnitine, inositol, maltodextrin).

^e Also contains taurine.

Product Selection Guidelines

Special Populations

Caffeine freely crosses the placenta and passes through breast milk.^{48,49} The American College of Obstetricians and Gynecologists has concluded that moderate caffeine consumption (defined by the organization as less than 200 mg daily) does not contribute to miscarriages or preterm births.⁴⁸ Total daily

caffeine intake should be limited to less than 200 mg during pregnancy; however, a systematic analysis supports use up to 300 mg daily.⁴⁰ The American Academy of Pediatrics considers usual dietary amounts of caffeine (defined by the organization as 300 mg or less daily) compatible with breastfeeding.⁴⁹ Infants unable to metabolize caffeine or those who receive large quantities of caffeine through breast milk may have symptoms of nervousness, increased heart rate, sleeplessness, poor feeding, and irritability. Nursing women should consume caffeine only in small to moderate amounts (2–3 cups daily), preferably right after breastfeeding to minimize effects on the infant.

Children are more susceptible to the cardiovascular and CNS adverse effects of caffeine because of their lower body weight. Four of five controlled trials from a systematic review of children and/or adolescents using 1–5 mg/kg of caffeine found a statistically significant increase in blood pressure. Although daily caffeine intake of 2.5 mg/kg is considered safe for this age group, blood pressure increases were observed at doses below and above this threshold.⁴⁰ Use of nonprescription caffeine products is not indicated in children younger than 12 years.

Patient Factors

Health care providers should consider age, comorbid conditions, and concomitant medications when recommending treatment for drowsiness and fatigue.

Patient Preferences

Patients may prefer to consume caffeine as beverages rather than as tablets or capsules. If they choose oral formulations of caffeine, they also should be aware of the caffeine content of any consumed beverages.

Complementary Therapies

Ginseng is used frequently to boost physical and mental energy and to produce a sense of well-being. A review of randomized controlled trials reveals contradictory scientific evidence to support these claims (see [Chapter 51](#)). Caffeine-containing dietary supplements that patients may be using include kola nut, guarana, and yerba mate. Soy isoflavones and black cohosh are marketed in combination with caffeine, green tea, and yerba mate to boost

energy and manage fatigue in women who are postmenopausal. Ingredients purported to counteract fatigue that are often found in sports energy drinks include taurine and guarana, although the amounts are unlikely to produce either therapeutic or adverse effects.

Assessment of Drowsiness and Fatigue: A Case-Based Approach

When assessing a patient with a complaint of daytime drowsiness, the health care provider should determine the cause of fatigue. Evaluating the patient's medical or psychiatric problems, current medication use, dietary caffeine consumption, sleep patterns, and lifestyle will help in determining the underlying cause. Because data supporting the efficacy of caffeine are lacking and adverse effects are associated with recommended and excessive dosages, health care providers should recommend improved sleep hygiene and lifestyle modifications or medical referral before they recommend the use of a caffeine-containing product.

Case 46–2 provides an example of the assessment of a patient with drowsiness and fatigue.

Algorithm: Drowsiness and Fatigue

FIGURE 46–2 Self-care of drowsiness and fatigue. HCP = Health care provider.

Case 46–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential	

Relevant Evaluation Criteria	Scenario/Model Outcome
information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient requests advice on choosing a nonprescription product to avoid daytime sleepiness. She reports that she sleeps fairly well, but by 1 or 2 PM each day at work, she is drowsy and sometimes nods off at her desk. She estimates this problem has been occurring for about 2 months now.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She spends most of her work day on the phone, calling her patients or meeting with them in-person at the center. She finds it hard to sit for most of the day at her desk and is stressed out because she is behind on social work progress notes.
c. Description of the patient's/caregiver's efforts to relieve the symptoms	The patient starts her day with 2 cups of instant coffee and, sometime after 12 pm, purchases 2 Diet Cokes from the vending machine at the clinic.
d. Patient's identity	Samantha Glines
e. Patient's age, gender, height, and weight	55 years old, female, 5 ft 4 in., 138 lb
f. Patient's occupation	Social worker
g. Patient's dietary habits	Normal diet. Patient is working to reduce her daily salt consumption from food.
h. Patient's sleep habits	Patient reports her sleep is pretty good at nighttime, unless she comes home from work and "crashes" first.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Depression:</i> sertraline 150 mg daily (current dose for 1 year); <i>Focal seizures:</i> levetiracetam extended-release 1000 mg daily (dose increased 2 months ago); no dietary supplements.
j. Allergies	No known drug allergies.
k. History of other adverse	None

Relevant Evaluation Criteria	Scenario/Model Outcome
reactions to medications	
I. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Daytime fatigue
3. Identify exclusions for self-treatment (Figure 46-2).	Medication-induced drowsiness.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Samantha to an appropriate health care provider. (2) Recommend self-care with a nonprescription stimulant and nondrug measures. (3) Recommend self-care until Samantha can see an appropriate provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Samantha needs to see her health care provider because she has had a medication dose adjustment that corresponds with the onset of her daytime sleepiness.
6. Describe the recommended therapeutic approach to the patient or	"You should make an appointment to see your health care provider."

Relevant Evaluation Criteria	Scenario/Model Outcome
caregiver.	
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Because this problem of fatigue may be caused by the change in the dose of your medication for seizures, you should make an appointment with your health care provider for a physical examination. Stimulant medication is not indicated at this time because your provider will have to decide on the best method of treatment. Even before you see your health care provider, you should reduce your intake of soda drinks and coffee, and begin sleep hygiene measures.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply to this case.
Solicit follow-up questions from the patient or caregiver.	“Can I switch from Diet Coke to energy drinks instead?”
Answer the patient’s or caregiver’s questions.	“Energy drinks often do not list all of the ingredients and their quantities. It would be best that you do not use these products and wait to discuss your daytime drowsiness with your health care provider.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact the patient in 1-2 days to be sure she made an appointment for medical care.

Key: n/a = Not applicable.

Patient Counseling for Drowsiness and Fatigue

Counseling on the treatment of drowsiness and fatigue should focus on practicing good sleep hygiene and eliminating factors that interfere with normal sleep. If a caffeine product is indicated, the health care provider should review dosage guidelines with the patient and emphasize the potential adverse effects and drug interactions. The patient should be counseled on symptoms of excessive caffeine ingestion, such as irritability, tremor, rapid pulse, dizziness, and heart palpitations. Regular users of caffeine also should be counseled on withdrawal symptoms such as headache and anxiety, which can occur if caffeine from any source is stopped abruptly. The box “Patient Education for Drowsiness and Fatigue” lists information to provide patients.

Evaluation of Patient Outcomes for Drowsiness and Fatigue

Successful outcomes include daytime alertness, increased productivity, and peak performance with respect to psychomotor tasks and cognitive function, including attention and concentration. An individual should seek medical evaluation if, after 7–10 days, drowsiness and fatigue persist despite the limited use of caffeine and the establishment of good sleep hygiene.

Patient Education for Drowsiness and Fatigue

The objective of self-treatment is to maintain wakefulness. For most patients, improved sleep hygiene will help ensure optimal therapeutic outcomes. If the patient insists on taking a caffeine-containing product, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes for most patients.

Disease Information

- Symptoms of drowsiness and fatigue often include feeling foggy, woozy, and/or not fully alert, and having dream-like thoughts.

Nondrug Measures

- Practice principles of good sleep hygiene (Table 46–3).
- If drowsiness or fatigue persists or recurs, consult your health care provider.

Nonprescription Medications

- Do not exceed the recommended caffeine dose of 100–200 mg every 3–4 hours as needed. Note that higher doses of caffeine may cause side effects, and chronic use may result in tolerance as well as withdrawal symptoms upon abrupt discontinuation.
- Do not use caffeine tablets in combination with coffee or other caffeinated products, including dietary supplements.
- Discuss safe daily caffeine consumption with your health care provider if you are pregnant or breastfeeding.
- Do not give caffeine to children younger than 12 years.
- If you are taking atomoxetine or ciprofloxacin, consult your health care provider before using caffeine-containing products.
- If you have a history of peptic ulcer disease, psychiatric disorders, symptomatic heart disease, or uncontrolled hypertension, consult your health care provider before using caffeine products.

When to Seek Medical Attention

- Seek medical attention immediately if the following symptoms of caffeine toxicity occur at the same time:
 - Increases in heart rate and blood pressure
 - Headache
 - Symptoms of anxiety and insomnia
 - Increase in hand tremor

Key Points for Drowsiness and Fatigue

- Advise patients that caffeine appears to be safe and effective in low to moderate doses in the diet, as well as for occasional use as a nonprescription supplement during completion of tasks of short duration when enhanced alertness is desired.
- Instruct patients that caffeine is most effective when taken intermittently at dosages of 100–200 mg every 3–4 hours as needed.
- Pregnant or nursing women, children younger than 12 years, patients with heart disease, and patients with anxiety disorders should avoid use of caffeine.
- Health care providers should be aware of the patient's use of prescription and nonprescription medications and dietary supplements that contain caffeine, as well as the patient's dietary consumption of caffeine.
- Adverse effects of caffeine are more likely to occur in occasional users and patients of advanced age.
- Advise patients taking daily dosages of caffeine higher than 200 mg about possible drug interactions.
- Counsel patients against use of dietary supplements to increase energy or decrease fatigue.

Chapter 47: Tobacco Cessation

Authors: Beth A. Martin, Maria C. Wopat

In 1982, the U.S. Surgeon General C. Everett Koop stated that cigarette smoking was the “chief, single, avoidable cause of death in our society and the most important public health issue of our time.”¹ This statement remains true nearly 4 decades later. In the United States, cigarette smoking is the leading known cause of preventable death,² responsible for an estimated 480,000 deaths each year.³ In addition to lives lost, the economic impact of smoking is enormous, costing society approximately \$300 billion annually for smoking-attributable health expenditures and lost productivity.³

The negative effects of smoking are both well established and well publicized. Although cigarette smoking among U.S. adults has decreased significantly, data reported in 2017 show that an estimated 34.3 million adult Americans (14% of the overall population—15.8% of males and 12.2% of females) still smoked either every day or some days.⁴ Tobacco products have evolved to now include combustible, noncombustible, and electronic products. In 2017, the number of U.S. adults using any of these products jumped to roughly 47.4 million adults (19.3%).⁴ Among those who use tobacco products, nearly 20% (9.0 million) use two or more tobacco products.⁴ The prevalence of smoking cigarettes varies in accordance with sociodemographic factors including gender, race/ethnicity, education level, age, and socioeconomic status. The prevalence of smoking in the United States was highest among non-Hispanic American Indians/Alaska Natives (24%) and lowest among non-Hispanic Asians (7.1%). Smoking is more common among people ages 45–64 years (16.5%) and those living below the federal poverty level (21.4%).⁴ Smoking also is more prevalent for those with less than a post-secondary education, ranging from 18.7% in high school graduates to 36.8% in those who have completed a General Educational Development test).⁴ The median prevalence of smoking varies by state, with Utah exhibiting the lowest prevalence at 8.9% and West Virginia exhibiting the highest at 26%.⁵

The U.S. Food and Drug Administration (FDA) developed new cigarette health warnings in 2020 that are designed to promote greater public understanding of the negative health consequences of cigarette smoking. Beginning October 16, 2021, the warnings must appear prominently on cigarette packages and in advertisements. On the front and rear panels of cigarette packages, a warning

will occupy the top 50% of a panel. In cigarette advertisements, the warnings will occupy at least 20% of the top portion of an advertisement. Once implemented, the new warnings must be randomly and equally displayed and distributed on cigarette packages and rotated quarterly in cigarette advertisements.^{6,7}

Although tobacco control efforts have helped reduce the rate of cigarette smoking, the use of e-cigarettes, or electronic nicotine delivery systems (ENDS), is on the rise, and the statistics are alarming. Frequent use of ENDS products, defined as use that occurred more often than 20 days in the past 30 days, increased from 20% in 2017 to 27.7% in 2018 among current high school users.⁸ Data from a 2019 survey showed a further increase of 34.2% in high school students; the data also showed 18% of middle school students had used ENDS.⁹ From 2018 to 2019, use of e-cigarettes in the past 30 days by high school students increased from 20.8%⁸ to 27.5%.⁹ The 2018 survey data also showed that 4.9% of middle schoolers had used an e-cigarette in the past 30 days⁸; in 2019 this usage had increased to 10.5%.⁹ Literature also has shown that 43.9% of youth who had used e-cigarettes but not conventional cigarettes had an intention to smoke conventional cigarettes, and 21.5% of those who had never used either type of cigarette had an intention to smoke conventional cigarettes.¹⁰

Pathophysiology of Tobacco Use and Dependence

In 1988, the U.S. Surgeon General released a landmark report in which the authors concluded that tobacco products are effective nicotine delivery systems capable of inducing and sustaining chemical dependence.¹¹ The primary criteria used to categorize nicotine as an addictive substance were its (1) psychoactive effects, (2) use in a highly controlled or compulsive manner, and (3) reinforcement of behavioral patterns of tobacco use. The underlying pharmacologic and behavioral processes associated with tobacco dependence are considered to be similar to those that determine addiction to drugs such as heroin and cocaine.¹¹

As with other addictive substances (e.g., opiates, cocaine, amphetamines), nicotine stimulates the mesolimbic dopaminergic system in the midbrain,

inducing pleasant or rewarding effects that promote continued use.¹² This effect is referred to as the *dopamine reward pathway*. Nicotine binds to the $\alpha_4\beta_2$ nicotinic cholinergic receptors in the ventral mental area of the brain, triggering the release of dopamine in the nucleus accumbens. Psychosocial, behavioral, genetic, and environmental factors also play an important role in establishing and maintaining dependence.^{12,13} For example, smoking commonly is associated with specific activities such as driving, talking on the telephone, eating, drinking coffee or alcohol, and being around others who smoke. Over time, the habitual use of cigarettes under these circumstances can lead to the development of smoking routines that can be difficult to break. Indeed, specific environmental situations can become powerful conditioned stimuli or cues associated with smoking that are capable of triggering “automatic” smoking patterns.¹²

Tobacco use dramatically increases one’s odds of dependence, disease, disability, and death. Cigarettes are carefully engineered and heavily marketed products. For example, although the design of cigarettes and other tobacco products has evolved over the past 5 decades (e.g., filtered, menthol, low-tar, “light” cigarettes; e-cigarettes; dissolvable tobacco), overall disease risk has not been reduced among smokers.¹³ The tobacco industry spends nearly \$20 to market its products for every \$1 that states spend on tobacco control.¹⁴ Cigarettes are the *only* marketed consumable product that, when used persistently, will kill half or more of its users.¹⁵

The Environmental Protection Agency (EPA) classifies cigarette smoke as a Class A carcinogen (i.e., a carcinogen with no safe level of exposure for humans). Cigarette smoke is a complex mixture of thousands of compounds—including nitrogen, carbon monoxide, ammonia, hydrogen cyanide, benzene, and nicotine—in gaseous and particulate phases. The particulate fraction, excluding the nicotine and water components, is collectively referred to as *tar*. Numerous carcinogens, including polycyclic aromatic hydrocarbons (PAHs) and nitrosamines, have been identified in the tar fraction of tobacco smoke.^{13,16}

Nicotine, the addictive component of tobacco, is distilled from burning tobacco and then carried in tar droplets to the small airways of the lung, where it is absorbed rapidly into the arterial circulation and distributed throughout the body. Nicotine readily penetrates the central nervous system and is estimated to reach the brain within seconds after inhalation.¹⁷ Nicotine binds

to receptors in the brain and other organs, inducing a variety of predominantly stimulatory effects on the cardiovascular, endocrine, nervous, and metabolic systems.¹⁸ Pharmacodynamic effects associated with nicotine administration include arousal and increases in the heart rate and blood pressure. In the brain, smoking leads to the activation of nicotinic cholinergic receptors and release of numerous neurotransmitters, which induce a range of effects such as pleasure (dopamine), arousal (acetylcholine and norepinephrine), cognitive enhancement (acetylcholine), appetite suppression (dopamine, norepinephrine, and serotonin), learning and memory enhancement (glutamate), mood modulation (serotonin), and reduction of anxiety and tension (beta-endorphin and gamma-aminobutyric acid).^{12,13,17}

Clinical Presentation of Tobacco Use and Dependence

Most chronic tobacco users develop tolerance to the effects of nicotine, and abrupt cessation precipitates symptoms of nicotine withdrawal.¹² The symptoms and their severity vary from person to person but generally include irritability, frustration, anger, anxiety, depression, difficulty concentrating, impatience, insomnia, and restlessness.^{19,20} Other symptoms that patients may report include cravings, impaired performance, constipation, cough, dizziness, and increased dreaming. Typically, the physiologic symptoms of nicotine withdrawal manifest within the first 1–2 days, peak within the first week, and gradually dissipate over 2–4 weeks.²⁰ Increased appetite and weight gain may persist for 6 or more months after quitting.¹⁹

According to reports issued by the U.S. Surgeon General in 2004,² 2010,¹³ and 2014,³ smoking adversely affects nearly every organ system in the body and plays a causal role in the development of numerous diseases, including many cancers (**Table 47–1**). Furthermore, smoking cigarettes with lower machine-measured yields of tar and nicotine provides no clear benefit to health. Involuntary exposure to secondhand smoke, which includes the smoke emanating from a cigarette and then exhaled by the smoker, is associated with adverse health effects in nonsmokers, including cardiovascular disease, respiratory disease, and lung cancer.²¹ Even low levels of exposure, such as secondhand smoke exposure, are associated with rapid increases in endothelial dysfunction and inflammation, which lead to acute cardiovascular

events and thrombosis.¹³ In children, secondhand smoke exposure can increase the risk of ear infections; precipitate more frequent and severe asthma attacks; worsen respiratory symptoms (e.g., coughing, sneezing, shortness of breath); increase the risk of respiratory infections; and increase the risk for sudden infant death syndrome (SIDS).²¹ There is no risk-free level of exposure to tobacco smoke.^{13,22}

TABLE 47-1 Health Consequences of Smoking

Cancer

Acute myeloid leukemia
Bladder
Breast
Cervical
Colorectal
Esophageal
Gastric
Kidney
Laryngeal
Liver
Lung
Oral cavity and pharyngeal
Pancreatic
Prostate

Cardiovascular Diseases

Abdominal aortic aneurysm
Coronary heart disease (e.g., angina pectoris, ischemic heart disease, myocardial infarction)
Cerebrovascular disease (e.g., transient ischemic attacks, stroke)
Peripheral arterial disease

Pulmonary Diseases

Acute respiratory illnesses
 Upper respiratory tract disease (e.g., rhinitis, sinusitis, laryngitis, pharyngitis)
 Lower respiratory tract disease (e.g., bronchitis, pneumonia)
Chronic respiratory illnesses
 Chronic obstructive pulmonary disease
 Respiratory symptoms
 Exacerbation of asthma
 Reduced lung function
 Tuberculosis

Reproductive Effects

Reduced fertility in women
Pregnancy and pregnancy outcomes
 Premature rupture of membranes

Placenta previa
Placental abruption
Preterm delivery
Low infant birth weight
Ectopic pregnancy
Infant mortality
Sudden infant death syndrome (SIDS)
Erectile dysfunction

Ophthalmic Effects

Cataract
Neovascular and atrophic forms of age-related macular degeneration

Other Effects

Diabetes (30%–40% higher risk for active smokers, with a dose–response relationship between the number of cigarettes smoked and this risk)
Osteoporosis (reduced bone density in postmenopausal women, with increased risk of hip fracture)
Periodontitis
Peptic ulcer disease (in patients infected with *Helicobacter pylori*)
Rheumatoid arthritis
Surgical outcomes—suboptimal
 Poor wound healing
 Respiratory complications

Source: [References 2, 3, and 16](#).

Tobacco smoke interacts with medications through pharmacokinetic or pharmacodynamic mechanisms that can lead to reduced therapeutic efficacy or, less commonly, increased toxicity. Most of the pharmacokinetic interactions are the result of induction of hepatic cytochrome P450 (CYP) enzymes (primarily the CYP1A2 isoenzyme) by PAHs present in tobacco smoke.²³ Induction of the CYP1A2 isoenzyme can increase the hepatic metabolism of certain drugs ([Table 47–2](#)), potentially resulting in a reduced therapeutic response or a need for higher dosages in smokers; conversely, the dosages of some drugs might need to be reduced in patients who quit smoking.²³ Similarly, the clearance of caffeine is significantly increased (by 56%) in smokers. After cessation, ex-smokers who drink caffeinated beverages should be advised to decrease their usual caffeine intake to avoid higher levels of caffeine, which may induce symptoms similar to nicotine withdrawal.

TABLE 47-2 Drug Interactions With Tobacco Smoke

Drug/Class (Trade Name)	Mechanism of Interaction and Effects
Pharmacokinetic Interactions	
Alprazolam (Xanax)	Conflicting data on significance, but possible decreased plasma concentrations (up to 50%); decreased half-life (35%).
Bendamustine (Treanda) ^a	Metabolized by CYP1A2. Manufacturer recommends using with caution in smokers owing to likely decreased bendamustine concentrations, with increased concentrations of its two active metabolites.
Caffeine ^a	Increased metabolism (induction of CYP1A2); increased clearance (56%). Caffeine levels are likely increased after cessation.
Chlorpromazine (Thorazine)	Decreased AUC (36%) and serum concentrations (24%).
	Decreased sedation and hypotension possible in smokers; smokers may require increased dosages.
Clopidogrel (Plavix) ^a	Increased metabolism (induction of CYP1A2) of clopidogrel to its active metabolite.
	Clopidogrel's effects are enhanced in smokers (≥10 cigarettes/day): significant increased platelet inhibition, decreased platelet aggregation. Although improved clinical outcomes have been shown (smoker's paradox; may be dependent on CYP1A2 genotype); tobacco cessation should still be recommended in at-risk populations needing clopidogrel.
Clozapine (Clozaril) ^a	Increased metabolism (induction of CYP1A2); decreased plasma concentrations (18%).
	Increased levels may occur upon cessation; closely monitor drug levels and reduce dose as required to avoid toxicity.
Erlotinib (Tarceva) ^a	Increased clearance (24%); decreased trough serum concentrations (twofold).
Flecainide (Tambocor)	Increased clearance (61%); decreased trough serum concentrations (25%). Smokers may need increased dosages.
Fluvoxamine (Luvox) ^a	Increased metabolism (induction of CYP1A2); increased clearance (24%); decreased AUC (31%); decreased plasma concentrations (32%).
	Dosage modifications are not routinely recommended, but smokers may need

Drug/Class (Trade Name)	Mechanism of Interaction and Effects
	increased dosages.
Haloperidol (Haldol) ^a	Increased clearance (44%); decreased serum concentrations (70%); data are inconsistent; therefore, clinical significance is unclear.
Heparin	Mechanism unknown but increased clearance and decreased half-life. Smoking has prothrombotic effects.
	Smokers may need increased dosages due to PK and PD interactions.
Insulin, subcutaneous	Possible decreased insulin absorption secondary to peripheral vasoconstriction; smoking may cause release of endogenous substances that cause insulin resistance.
	PK and PD interactions are likely not clinically significant; smokers may need increased dosages.
Irinotecan (Camptosar) ^a	Increased clearance (18%); decreased serum concentrations of active metabolite, SN-38 (~ 40%), via induction of glucuronidation; decreased systemic exposure resulting in lower hematologic toxicity; may reduce efficacy.
	Smokers may need increased dosages.
Methadone	Possible increased metabolism (induction of CYP1A2, a minor pathway for methadone).
	Carefully monitor response upon cessation.
Mexiletine (Mexitil)	Increased clearance (25%; via oxidation and glucuronidation); decreased half-life (36%).
Nintedanib (OFEV)	Decreased exposure (21%) in smokers. No dose adjustment recommended; however, patients should not smoke during use.
Olanzapine (Zyprexa) ^a	Increased metabolism (induction of CYP1A2); increased clearance (98%), decreased serum concentrations (12%).
	Dosage modifications are not routinely recommended, but smokers may need increased dosages.
Pirfenidone (Esbriet)	Increased metabolism (induction of CYP1A2), decreased AUC (46%), and decreased plasma concentration (68%).
	Decreased exposure in smokers might alter efficacy profile.

Drug/Class (Trade Name)	Mechanism of Interaction and Effects
Propranolol (Inderal)	Increased clearance (77%, via side chain oxidation and glucuronidation).
Riociguat (Adempas) ^a	Decreased plasma concentrations (by 50%–60%).
	Smokers may require dosages higher than 2.5 mg 3 times a day; consider dose reduction upon cessation.
Ropinirole (Requip) ^a	Decreased maximum concentration (30%) and AUC (38%) in study with patients with restless legs syndrome.
	Smokers may need increased dosages.
Tacrine (Cognex) ^a	Increased metabolism (induction of CYP1A2); decreased half-life (50%); serum concentrations threefold lower.
	Smokers may need increased dosages.
Tasimelteon (Hetlioz) ^a	Increased metabolism (induction of CYP1A2); drug exposure decreased by 40%.
	Smokers may need increased dosages.
Theophylline ^a	Increased metabolism (induction of CYP1A2); increased clearance (58%–100%); decreased half-life (63%).
	Levels should be monitored if smoking is initiated, discontinued, or changed. Maintenance doses are considerably higher in smokers.
	Increased clearance with secondhand smoke exposure.
Tizanidine (Zanaflex)	Decreased AUC (30%–40%) and decreased half-life (10%) observed in male smokers.
Tricyclic antidepressants (e.g., imipramine, nortriptyline)	Possible interaction with tricyclic antidepressants in the direction of decreased blood levels, but the clinical significance is not established.
Warfarin	Increased metabolism (induction of CYP1A2) of R-enantiomer; however, S-enantiomer is more potent, and the effect on the international normalized ratio (INR) is inconclusive. Consider monitoring INR more closely upon smoking cessation.

Drug/Class (Trade Name)	Mechanism of Interaction and Effects
Pharmacodynamic Interactions	
Benzodiazepines (diazepam, chlordiazepoxide)	Decreased sedation and drowsiness, possibly caused by nicotine stimulation of central nervous system.
Beta blockers	Less effective antihypertensive and heart rate control effects, possibly caused by nicotine-mediated sympathetic activation.
	Smokers may need increased dosages.
Corticosteroids, inhaled ^a	Smokers with asthma may have less of a response to inhaled corticosteroids.
Hormonal contraceptives ^a	Increased risk of cardiovascular adverse effects (e.g., stroke, myocardial infarction, thromboembolism) in women who smoke and use oral contraceptives. Ortho Evra patch users have twofold increased risk of venous thromboembolism compared with oral contraceptive users, likely owing to increased estrogen exposure (60% higher levels).
	Risk increases with age and with heavy smoking (≥15 cigarettes per day) that is quite marked in women ≥35 years of age.
Serotonin 5-HT ₁ receptor agonists (triptans)	This class of drugs may cause coronary vasospasm; caution is indicated for use in smokers owing to possible unrecognized CAD.

Note: Many interactions between tobacco smoke and medications have been identified. In most cases, the tobacco smoke—not the nicotine—causes these drug interactions. Tobacco smoke interacts with medications through PK and PD mechanisms. PK interactions affect the absorption, distribution, metabolism, or elimination of other drugs, potentially causing an altered pharmacologic response. A majority of PK interactions with smoking are the result of induction of hepatic cytochrome P450 enzymes (primarily CYP1A2). PD interactions alter the expected response or actions of other drugs. The amount of tobacco smoking necessary to have an effect has not been established, and the assumption is that any smoker is susceptible to the same degree of interaction. Those exposed regularly to secondhand smoke may also be at risk.

^a Clinically significant interaction.

Key: AUC = Area under the curve; CAD = coronary artery disease; HT₁ = hydroxytryptamine (receptor) class 1; PD = pharmacodynamic; PK = pharmacokinetic.

A significant pharmacodynamic drug interaction occurs between tobacco smoke and combination hormonal contraceptives (pills, patch, and ring). Data indicate that cigarette smoking substantially increases the risk of serious adverse cardiovascular events (e.g., stroke, myocardial infarction, thromboembolism) in women using oral contraceptives.^{24–28} This risk is markedly increased in women 35 years of age or older who smoke 15 or more cigarettes per day.²⁴ Accordingly, most experts consider use of hormonal contraceptives to be a contraindication in smokers and recommend use of an alternative form of contraception.^{25,28} Additional drug–smoking interactions, with their corresponding underlying mechanisms, are listed in [Table 47–2](#).²⁹ During the course of routine patient care, it is important to assess for potential drug and smoking interactions and to make appropriate adjustments to the medication regimen.

Smoking Cessation Treatment

The 2010 Surgeon General’s Report on the health benefits of smoking cessation outlined the numerous and substantial health benefits realized when patients quit smoking.³⁰ Some health benefits are incurred shortly after quitting (e.g., within 2 weeks–3 months), and others are incurred over time ([Figure 47–1](#)). On average, cigarette smokers die approximately 10 years earlier than nonsmokers; among those who continue smoking, at least half will eventually die of a tobacco-related disease. Quitting at the ages of 30, 40, 50, and 60 years results in a gain of 10, 9, 6, and 3 years of life, respectively.^{3,16} Consequently, although it is important to educate tobacco users that it is never too late to quit to achieve many of the associated health benefits, significant benefits to quitting earlier in life also should be emphasized.

FIGURE 47–1 Health benefits of smoking cessation. (Source: [References 2, 3,](#) and [16.](#))

Treatment Goals

Tobacco dependence is a chronic disease typically characterized by multiple failed attempts to quit before long-term cessation is achieved. Because tobacco use is a complex, addictive behavior, helping patients quit and preventing relapse are best achieved by combining appropriate pharmacotherapy with counseling.³¹ For any patient who uses tobacco, the primary goal is complete, long-term abstinence from all nicotine-containing products.

General Treatment Approach

Most smokers use no cessation treatments for their quit attempts, an approach known as quitting “cold turkey,”³² and approximately 95% of all attempts to quit using this method end in relapse.³¹ Yet decades of research clearly show that patients who receive assistance have increased odds of quitting. The 2008 U.S. Public Health Service clinical practice guideline for treating tobacco use and dependence³¹ presents evidence-based recommendations and effective strategies for health care providers who provide tobacco cessation counseling. Although even brief advice from a provider is associated with increased odds of quitting,^{31,33} more intensive counseling (longer and more frequent counseling sessions, or greater overall contact time) and use of pharmacotherapy (except in patients with exclusions for self-treatment with medications, as listed in [Figure 47–2](#)) result in increased quit rates. Two particularly effective types of counseling are practical counseling (behavior change counseling, including problem-solving and skills training) and social support delivered as part of the treatment.³¹

Patients who receive a tobacco cessation intervention from a provider, either nonphysician or physician, are 1.7 or 2.2 times, respectively, more likely to quit (and remain tobacco free at >5 months after cessation), than are patients who do not receive a provider’s intervention.³¹ Self-help materials are only slightly better than no provider intervention. Although the length of an intervention increases effectiveness, even minimal interventions (<3 minutes) increase cessation rates.³¹ In a meta-analysis of 46 studies, four or more intervention sessions were found to approximately double cessation rates.³¹

Although the use of pharmacotherapy substantially increases patients' chances of quitting, the addition of counseling further increases cessation rates by a factor of 1.4.³¹ Similarly, adding pharmacotherapy to counseling increases cessation rates. When medications are not contraindicated, cessation interventions should consist of pharmacotherapy (one medication or combination therapy) and counseling (see later under "Special Populations").³¹ Figure 47–2 outlines a self-treatment approach for tobacco cessation.

Nonpharmacologic Therapy

Helping Patients Quit: The 5 A's Approach (Comprehensive Counseling)

As delineated in the U.S. Public Health Service Clinical Practice Guideline for Treating Tobacco Use and Dependence,³¹ the five key components of comprehensive counseling for tobacco cessation are (1) asking patients whether they use tobacco, (2) advising tobacco users to quit, (3) assessing patients' readiness to quit, (4) assisting patients with quitting, and (5) arranging follow-up care. These steps are referred to as the "5 A's."

Ask About Tobacco Use

A key first step in the cessation process, and in all patient interactions, is asking about tobacco use. Because tobacco use is the primary known preventable cause of mortality in the United States and because tobacco smoke interacts with multiple medications, screening for tobacco use is crucial and should be a routine component of care. The following question can be used to identify all types of tobacco use, even for infrequent users: "Do you ever smoke or use any type of tobacco?" Specifically asking about e-cigarette use may be necessary; using the specific terms of "JUULing" or "vaping" or "pods" may be necessary for the user to identify their inhaled nicotine use. In clinic or hospital settings, tobacco use status should be considered a component of vital sign assessment and collected routinely, along with blood pressure, pulse, weight, temperature, and respiratory rate.³¹ In community pharmacies, tobacco use status should be assessed, documented in the patient profile, and reassessed periodically. Asking about exposure to secondhand smoke also should be considered.

Advise to Quit

All tobacco users should be advised to quit. The advice should be clear, strong, and personalized, yet delivered with sensitivity and in a tone of voice that communicates concern for the patient and a willingness to provide appropriate assistance with quitting when the patient is ready. When possible, primary care providers should individualize the message by linking their advice to the patient's health status, current medication regimen, personal reasons for wanting to quit, or the effect of tobacco on others. The following example highlights this approach: "Ms. Bettis, I see that you now are on two different inhalers for your emphysema. Quitting smoking is the single most important treatment for your emphysema and can improve how well your inhalers work. I strongly encourage you to quit, and I would like to help you."

Assess Readiness to Quit

Because many patients will not be ready to quit when they are first approached, it is important for providers to gauge each patient's readiness to quit before recommending a treatment regimen. Patients should be categorized as (1) not ready to quit in the next month; (2) ready to quit in the next month; (3) a recent quitter, having quit in the past 6 months; or (4) a former user, having quit more than 6 months ago.³¹ This classification defines the provider's next course of action, which is to provide counseling that is tailored to the patient's readiness to quit. The following approach is an example for a current smoker: "Mr. Crosby, what are your thoughts about quitting? Is this something that you might consider doing in the next month?" Counseling a patient who is ready to quit in the next month should differ from counseling a patient who is not considering quitting in the near future.

Assist With Quitting

Important elements of the assisting component of treatment include helping patients to make the decision to quit and to set a quit date within the next month if possible. Providers should be empathetic and acknowledge that quitting is a challenge for most patients. When asked to set a quit date in the next month, patients are sometimes reluctant. A follow-up question could be "What is the worst thing that could happen if you tried to quit now?" This allows patients to consider whether any barriers to quitting exist, whether their perceptions are disproportionate, and what they may learn by attempting

to quit. Accordingly, the goal is to help maximize each patient's chances of success by designing an individualized treatment plan.

All patients attempting to quit should be encouraged to use pharmacotherapy combined with counseling. This combination will yield higher quit rates than either approach alone, except in special circumstances or in specific populations for which adequate evidence of the combined method's effectiveness is lacking (pregnant women, smokeless tobacco users, people who smoke fewer than 10 cigarettes per day, and adolescents).³¹ Counseling interventions, which focus on promoting behavior change and enhancing adherence with medication regimens, may include individualized counseling (e.g., in person or by telephone), a group cessation program, an internet-based program, or a combination of these approaches.

Arrange Follow-up Counseling

Because the patient's ability to quit increases substantially when multiple counseling interactions are provided, arranging follow-up counseling is an important, yet typically neglected, element of treatment for tobacco dependence. Follow-up contact should occur soon after the quit date, preferably during the first week. Follow-up does not have to be done in person and could be performed by telephone or electronic communication. A second follow-up contact is recommended within the first month after quitting.²⁸ Additional follow-up contacts should occur periodically to monitor patient progress (including adherence to pharmacotherapy regimens) and to provide ongoing support. Quit rates at 5 or more months after cessation are positively associated with the total number of person-to-person encounters (both individual and group): 12.4% for 0–1 contact, 16.3% for 2–3 contacts, 20.9% for 4–8 contacts, and 24.7% for more than 8 contacts.³¹ A dose–relationship has also been seen for length of contact.³¹

Counseling Interventions for Quitting

In providing counseling for quitting smoking, the goal is to facilitate the process of change by helping to ready the patient for permanent cessation. It is important to convey the view of quitting as a learning process that might take months or even years to achieve, rather than as a now-or-never event.

Counseling Patients Who Are Not Ready to Quit: Ongoing

Assessment

In counseling patients who are not ready to quit, an important first step is to encourage the patient to start thinking about quitting and to consider making a commitment to quit sometime in the foreseeable future. Sometimes patients who are not ready truly do not understand the need to quit. In general, most smokers will recognize the need to quit but are not yet ready to make the commitment to quit. Many patients will have tried to quit multiple times and relapsed; thus, they might feel too discouraged to try again.

Strategies for working with patients who are not ready to quit include increasing patient awareness of the available treatment options, having patients identify their reasons for smoking and for wanting to quit, and identifying barriers to quitting. Providers can also engage patients in thinking about quitting by raising awareness of specific drug interactions between medications and tobacco smoke ([Table 47–2](#)) and how tobacco use can induce or exacerbate medical conditions (e.g., chronic obstructive pulmonary disease, heart disease). Providers should also discuss the importance of preventive health, such as the recommendation for all adult smokers, 19–64 years of age to receive the pneumococcal vaccine to aid in the prevention of invasive pneumococcal disease.³⁴

Although it may be useful to provide patients with information about the medications available for quitting, it is not appropriate to recommend a treatment regimen until the patient is ready to quit in the near future (e.g., within the next month). A treatment goal at this stage should be to promote motivation to quit. Providers can encourage patients to seriously consider quitting by asking the following series of three questions:

1. “Do you ever plan to quit?”

If the patient responds “no,” the provider should inquire, “What would have to change for you to decide to quit?” If the patient indicates that nothing would change his or her opinion about quitting, then the provider should offer to assist if or when the patient changes his or her mind. If the patient responds “yes,” the provider should continue to question 2.

2. “How would it benefit you to quit now, instead of later?”

Quitting generally becomes more difficult the longer a patient smokes. Most patients will agree that there is never an ideal time to quit, and that postponing quitting has more negative effects than positive.

3. “What would have to change for you to decide to quit sooner?”

This question probes patients’ perceptions about quitting and can reveal specific barriers to quitting that can be discussed and addressed.

Counseling Patients Who Are Ready to Quit

The goal for patients who are ready to quit in the next month is to achieve cessation by providing an individualized treatment plan that addresses the key issues listed in [Table 47–3](#). The first step is to discuss the patient’s tobacco use history by inquiring about levels of smoking (cigarettes/day), number of years smoked, methods used previously for quitting (if any), and reasons for previous failed quit attempts. Providers should fully understand the basis for personal preferences for the different pharmacotherapies for quitting and then work with each patient in selecting the quitting methods (e.g., medications or behavioral counseling programs). It is important to recognize that pharmacotherapy might not be desirable or affordable for all patients. However, providers should educate patients that medications, when taken correctly, can substantially increase the likelihood of quitting successfully,³¹ and that the costs of continuing smoking far outweigh the costs of the medications.

TABLE 47–3 Key Topics for Individualized Tobacco Cessation Plans

Topic	Description
Assess tobacco use history	• Current use: – Type(s) and amount of tobacco used • Past use: – Duration of smoking – Recent changes in levels of use • Past quit attempts: – Number of attempts, date of most recent attempt, duration of abstinence – Previous methods: What did or did not work? Why or why not?

Topic	Description
	- Previous experience with cessation pharmacotherapy: agent used, adequacy of dose, adherence, duration of treatment - Reasons for relapse • Reasons or motivation for wanting to quit (or stay quit) • Confidence in ability to quit (or stay quit) • Triggers for smoking • Routines and situations associated with smoking • Stress-related smoking • Social support for quitting • Concerns about weight gain • Concerns about withdrawal symptoms
Facilitate the quitting process	• Discuss methods for quitting: pros and cons of the different methods • Set a quit date, ideally within the next 2 weeks • Discuss coping strategies • Discuss withdrawal symptoms • Discuss concept of a slip (occasional smoking) versus full relapse • Provide medication counseling: adherence and proper use • Offer to assist throughout the quit attempt
Arrange and provide follow-up counseling	• Monitor the patient's progress throughout the quit attempt • Evaluate the current quit attempt - Status of attempt - Slips (occasional smoking) and relapses - Medication use: ▪ Adherence with regimen ▪ Plans for discontinuation - Address temptations and triggers; discuss relapse prevention strategies - Provide encouragement throughout the quit attempt • Follow-up contacts (face-to-face, by telephone, or by e-mail): first contact during first week after quitting, second contact within the first month, additional contacts scheduled as needed

Ideally, patients will select a quit date that is within the next 2 weeks, allowing ample time to prepare themselves and their environment before the actual quit date. This preparation includes removing all tobacco products and ashtrays from the home, car, and workplace. Patients should be advised to discuss their desire to quit with their family, friends, and coworkers and to request their support and assistance. Having patients think about when and why they smoke can help them anticipate situations that might trigger a desire to smoke and contribute to relapse. Additional counseling strategies to address with patients during a quit attempt are listed in [Table 47–4](#). Patients should be counseled on proper medication use (including administration), adverse effects, and adherence, and it is crucial to emphasize the importance of receiving behavioral counseling throughout the quit attempt. Additionally, patients should be advised to adhere to the entire course of pharmacotherapy, even though most withdrawal symptoms subside within 2–4 weeks.²¹

TABLE 47–4 Cognitive and Behavioral Strategies for Smoking Cessation

Cognitive Strategies	
Cognitive strategies focus on retraining of the way a patient thinks. Often, patients mentally deliberate on the fact that they are thinking about a cigarette, and this leads to relapse. Patients must recognize that thinking about a cigarette does not mean they need to have one.	
Review commitment to quit	Each morning say, “I am proud that I made it through another day without tobacco!” Remind oneself that cravings and temptations are temporary and will pass. Announce, either silently or aloud, “I am a nonsmoker, and the temptation will pass.”
Distractive thinking	Practice deliberate, immediate refocusing of thinking toward other thoughts when cued by thoughts about tobacco use.
Positive self-talk, pep talks	Say: “I can do this,” and remind oneself of previous difficult situations in which tobacco use was avoided.
Relaxation through imagery	Center mind toward positive, relaxing thoughts.
Mental rehearsal, visualization	Prepare for situations that might arise by envisioning how best to handle them. For example, envision what would happen if offered a cigarette by a friend, mentally craft and rehearse a response, and perhaps even practice it by saying it aloud.

Behavioral Strategies

Behavioral strategies involve specific actions to reduce the risk for relapse. These strategies should be considered prior to quitting, after determining patient-specific triggers and routines or situations associated with tobacco use. Below are strategies for several of the more common cues or causes for relapse.

Stress	Anticipate upcoming challenges at work, at school, or in personal life. Develop a substitute plan for tobacco use during times of stress (e.g., use deep breathing, take a break or leave the situation, call a supportive friend or family member, use nicotine replacement therapy).
Alcohol	Drinking alcohol can lead to relapse. Consider limiting or abstaining from alcohol during the early stages of quitting.
Other smokers	Quitting is more difficult when other tobacco users are around. This is especially difficult if another tobacco user is in the household. During the early stages of quitting, limit prolonged contact with people who are using tobacco. Ask co-workers, friends, and housemates not to smoke or use tobacco in your presence.
Oral gratification needs	Have nontobacco oral substitutes (e.g., gum, sugarless candy, straws, toothpicks, lip balm, toothbrush, nicotine replacement therapy, bottled water) readily available.
Automatic smoking routines	Anticipate routines that are associated with tobacco use and develop an alternative plan. Examples: • Morning coffee: Change morning routine; drink tea instead of coffee; take shower before drinking coffee; take a brisk walk shortly after awakening. • While driving: Remove all tobacco from car; have car interior detailed; listen to an audiobook or talk radio; use oral substitutes. • While on the phone: Stand while talking; limit call duration; change phone location; keep hands occupied by doodling or sketching. • After meals: Get up and immediately do dishes or take a brisk walk after eating; call supportive friend.
Postcessation weight gain	In general, attempting to modify multiple behaviors at one time is not recommended. If weight gain is a barrier to quitting, engage in regular physical activity and adhere to a healthy diet (as opposed to strict dieting). Carefully plan and prepare meals; increase fruit, vegetable, and water intake to create a feeling of fullness; and chew sugarless gum or eat sugarless candy. Consider use of pharmacotherapy shown to delay weight gain (e.g., 4 mg nicotine gum, 4 mg nicotine lozenge, bupropion).
Cravings for tobacco	Cravings for tobacco are temporary and usually pass within 5–10 minutes. Handle cravings through distractive thinking, take a break, do something else, take deep

breaths.

Counseling Patients Who Recently Quit

Patients who recently quit will face frequent, difficult challenges in countering withdrawal symptoms and cravings or temptations to use tobacco. An important step is to help them identify situations that might trigger relapse and to suggest appropriate coping strategies. Because smoking also is a habitual behavior, patients should be advised to alter daily routines that were previously associated with tobacco use. These changes will help to disassociate the behaviors from the tobacco.

Many people who quit using tobacco will experience cravings for years and even decades after quitting. Thus, counseling for relapse prevention should be part of every follow-up contact with patients who have recently or ever quit smoking. Patients who slip and smoke a cigarette (or use any form of tobacco) or experience a full relapse back to smoking should be encouraged to think through the scenario in which smoking first recurred and identify the trigger for relapse. Identifying triggers will provide valuable information for future quit attempts.

Counseling Patients Who Are Former Smokers

The strategies to be applied for former tobacco users are similar but typically less intensive than those to be applied for recent quitters. The goal for former tobacco users is to remain tobacco-free for life. Providers should evaluate the patient's resolve for staying tobacco-free and ongoing coping strategies; in this context, it is appropriate to ascertain whether the patient has had any strong temptations to use tobacco or has occasionally used any tobacco product. Also, it is important to ensure that patients are appropriately terminating or tapering pharmacotherapy products. Patients who have been tobacco-free should be congratulated for their success. For patients who have intermittently used tobacco, situations in which tobacco use occurred should be reviewed, and additional coping strategies should be discussed.

Helping Patients Quit: The Ask-Advise-Refer Approach (Brief Intervention)

Providers should familiarize themselves with local resources for tobacco cessation, including group programs and telephone quit lines. When time or lack of expertise limits the ability to provide comprehensive cessation counseling, providers are encouraged to apply an “abbreviated 5 A’s” model whereby they *ask* about tobacco use, *advise* tobacco users to quit, and *refer* patients to other resources for additional assistance, including local services, group counseling programs, and web-based applications. Community pharmacy personnel (pharmacists and technicians) can feasibly provide brief cessation interventions that include distributing quit line materials to patients interested in quitting.³⁵ Telephone-based counseling is available throughout the United States. These services provide low-cost interventions that can reach patients who might otherwise have limited access to medical treatment because of remoteness of geographic location or lack of financial resources. In clinical trials, telephone counseling services for which at least some of the contacts are initiated by the quit line counselor were shown to be effective in promoting abstinence.³¹ Compared with medication-alone therapy, combining medication with quit line counseling significantly improves abstinence rates.³¹ The national telephone number for the toll-free tobacco quit line is 1-800-QUIT-NOW.

Pharmacologic Therapy

Although in some situations pharmacotherapy should be used with caution or only under the supervision of a primary care provider (see later under Special Populations), most patients who are attempting to quit should be advised to incorporate pharmacotherapy in their treatment plan. Currently, seven first-line agents are approved by the U.S. Food and Drug Administration (FDA) for smoking cessation³¹: five formulations of nicotine replacement therapy (NRT), sustained-release bupropion, and varenicline. Three of the NRT formulations—gum, lozenge, and transdermal patch—are nonprescription, but the nicotine inhaler and nicotine nasal spray, as well as bupropion and varenicline, require a prescription.

Nicotine Replacement Therapy

NRT is the most commonly used pharmacotherapy for smoking cessation.³² NRT products often are used to help noncigarette tobacco users to quit, but these products are FDA labeled only to help cigarette smokers quit. Similar to the nicotine present in tobacco, the active agents in NRT stimulate the release of dopamine in the central nervous system.¹³ The rationale underlying the use of NRT for smoking cessation is twofold. First, NRT provides smokers with a nontobacco source of nicotine to reduce the physiologic symptoms of nicotine withdrawal that typically occur after abstinence from tobacco. Second, by attenuating the symptoms of withdrawal, NRT assists quitters by allowing them to focus on the behavioral and psychological aspects of smoking cessation. A key advantage of NRT is that patients, as well as those in the smoker's environment, are not exposed to the carcinogens and other toxic constituents present in tobacco and tobacco smoke. Because NRT products are regulated by FDA, they contain the labeled amount of nicotine, whereas non-regulated forms of nicotine delivery systems (e.g. electronic cigarettes) may significantly vary from the labeled concentration and contain ingredients that lack sufficient safety testing. Compared with cigarettes, NRT formulations provide lower, slower, and less-variable plasma nicotine concentrations,¹⁸ thereby eliminating the almost immediate reinforcing effects of nicotine obtained through smoking.

Nicotine is well absorbed (Figure 47–3) from many sites, including the lungs, skin, and nasal and buccal (oral) mucosa. Nicotine absorption is pH-dependent, and lower systemic concentrations are achieved under acidic conditions. Nicotine also is well absorbed from the gastrointestinal tract (small intestine) but undergoes extensive first-pass hepatic metabolism, resulting in negligible systemic levels of nicotine.¹⁸

FIGURE 47–3 Plasma nicotine concentrations over time for various nicotine delivery systems. (Source: Reproduced with permission from Rx for Change: Clinician-Assisted Tobacco Cessation program. The Regents of the University of California. Copyright © 1999–2020.)

The main difference between the various NRT formulations is the site and rate of nicotine absorption (Figure 47–3). Compared with cigarettes, all of the NRT formulations deliver nicotine less rapidly and achieve lower serum nicotine

levels, thereby lowering the likelihood of developing physical dependence. Peak serum concentrations are achieved most rapidly with the nasal spray (11–18 minutes), followed by the gum, lozenge, and inhaler (30–60 minutes) and then by the transdermal patch (3–12 hours). In contrast, significantly higher peak nicotine levels are attained within 10 minutes of smoking a cigarette.¹⁸

Patients should begin NRT on their quit date and discontinue use of all forms of tobacco on initiation of the NRT regimen. Use of tobacco in combination with NRT may result in serum nicotine concentrations that are higher than those achieved from tobacco products alone, increasing the likelihood of nicotine-related adverse effects, including nausea, vomiting, hypersalivation, perspiring, abdominal pain, dizziness, weakness, and palpitations.

Nicotine Polacrilex Gum

Nicotine polacrilex gum is a resin complex of nicotine and polacrilin in a sugar-free (<3 calories/piece) chewing gum base. The product is available as 2 mg and 4 mg strengths, in original (tobacco-like, peppery), cinnamon, fruit, and mint flavors (Table 47–5). All gum formulations contain buffering agents (sodium carbonate and sodium bicarbonate) to increase salivary pH, thereby enhancing absorption of nicotine across the buccal mucosa. When the 2 mg and 4 mg gums are used properly, approximately 1.6 mg and 2.2 mg of nicotine is absorbed from each dose, respectively. Peak serum concentrations of nicotine are achieved approximately 30 minutes after chewing a single piece of gum and then slowly decline over 2–3 hours.¹⁸

TABLE 47–5 Dosages for Nonprescription Nicotine Polacrilex Gum and Lozenge		
	Gum	Lozenge
Product strength	Nicorette: 2 mg, 4 mg; original, cinnamon, fruit, mint Generic: 2 mg, 4 mg; original, fruit, mint	Nicorette (standard): 2 mg, 4 mg; mint Nicorette (mini): 2 mg, 4 mg; mint Generic (standard): 2 mg, 4 mg; mint, cherry
Dose	First cigarette ≤30 minutes after waking: 4 mg First cigarette >30 minutes after waking: 2 mg Weeks 1–6: 1 piece every 1–2 hours Weeks 7–9: 1 piece every 2–4 hours	First cigarette ≤30 minutes after waking: 4 mg First cigarette >30 minutes after waking: 2 mg Weeks 1–6: 1 lozenge every 1–2 hours Weeks 7–9: 1 lozenge every 2–4 hours

	Gum	Lozenge
	<i>Weeks 10–12: 1 piece every 4–8 hours</i>	<i>Weeks 10–12: 1 lozenge every 4–8 hours</i>

The recommended dosage of nicotine gum is based on the “time to first cigarette” (TTFC) of the day. Having a strong desire or need to smoke soon after waking is viewed as a key indicator of nicotine dependence. Therefore, patients who smoke their first cigarette of the day within 30 minutes of waking are likely to be more highly dependent on nicotine and require higher dosages than those who delay smoking for more than 30 minutes after waking. Specifically, if the TTFC is 30 minutes or less, therapy should be initiated with the 4 mg gum. If the TTFC is more than 30 minutes, therapy should be initiated with the 2 mg gum. [Table 47–5](#) provides the manufacturer’s recommended dosing schedule. During the initial 6 weeks of therapy, patients should use 1 piece of gum every 1–2 hours while awake. In general, this amounts to at least 9 pieces of gum daily, which improves the overall chances of quitting. [Table 47–6](#) provides specific instructions for proper use of the nicotine gum. The “chew and park” method described in the table allows for the slow, consistent release of nicotine from the polacrillin resin. Patients can use additional pieces of gum (up to the maximum of 24 pieces per day) if cravings occur between the scheduled doses. In general, individuals who smoke heavily will need more pieces to alleviate their cravings.

TABLE 47–6 Usage Guidelines for Nicotine Polacrilex Gum

- Begin NRT on quit date and discontinue all forms of tobacco upon initiation of NRT regimen.
- Note that nicotine gum is a nicotine delivery system, not a chewing gum.
- Proper administration technique is necessary when using this product. Nicotine from the gum is released using the “chew and park” method:
 - Chew each piece of gum *slowly* several times.
 - Stop chewing at the first sign of a peppery, minty, fruity, or citrus taste, or after experiencing a slight tingling sensation in the mouth. This usually occurs after approximately 15 chews, but the time to effect onset varies.
 - Park the gum between the cheek and gum to allow absorption of nicotine across the lining of the mouth.
 - When the taste or tingling dissipates (generally after 1–2 minutes), slowly resume chewing.

- When the taste or tingle returns, stop chewing and park the gum in a different place in the mouth. This will decrease the incidence of mouth irritation.
- The chew and park steps should be repeated until most of the nicotine is gone, which is when the taste or tingle does not return after continued chewing. On average, each piece of gum lasts 30 minutes.

- To minimize withdrawal symptoms, use the nicotine gum on a scheduled basis rather than as needed.
- Follow the dosage regimen carefully; reduce the dosage at the recommended intervals; if needed for longer than 12 weeks of treatment to keep from smoking, talk to your HCP.
- Do not chew more than 24 pieces per day.
- Acidic beverages such as coffee, juices, wine, or soft drinks may transiently reduce the salivary pH, resulting in decreased absorption of nicotine across the buccal mucosa. Do not eat or drink anything (except water) 15 minutes before or while using the nicotine gum.
- Note that chewing the gum too quickly will result in an unpleasant taste caused by too much nicotine in the saliva, and that if the nicotine is swallowed, it may cause effects similar to those produced by excessive smoking (e.g., nausea, throat irritation, light-headedness, hiccups).
- Have nicotine gum readily available at all times. Keep the nicotine gum in the same place you previously kept your cigarettes (e.g., shirt pocket, purse, desk).
- Keep this product, including used pieces, out of the reach of children and pets.

Key: HCP = Health care provider; NRT = nicotine replacement therapy.

An important point to note is that patients often do not use enough of the gum to derive its full benefit or they use it incorrectly (e.g., incorrect chewing technique or concurrent consumption of beverages or foods that alter the pH of the mouth). An adherence screening question could be “Are you able to use this medicine nine or more times a day?” Commonly, patients chew too few pieces per day or shorten the duration of treatment. For this reason, recommending a fixed schedule of administration, tapering over 1–3 months, is preferable to having the patient use the gum as needed to control cravings.³¹

The most common adverse effects associated with the use of the nicotine gum include unpleasant taste, mouth irritation, jaw muscle soreness or fatigue, hypersalivation, hiccups, and dyspepsia. Many of these effects can be minimized or prevented by using proper chewing technique.³¹ The nicotine polacrillin resin is more viscous than ordinary chewing gum and more likely to adhere to fillings, bridges, dentures, crowns, and braces. Patients should be

warned that chewing the gum too rapidly may result in excessive release of nicotine, leading to lightheadedness, nausea, vomiting, irritation of the throat and mouth, hiccups, and indigestion.

Patients with active temporomandibular joint (TMJ) disease should not use the nicotine gum because the highly viscous consistency of the formulation and the need for frequent chewing may exacerbate the jaw condition. In addition, the manufacturer recommends that patients with sodium-restricted diet, stomach ulcers, or diabetes contact their primary care provider before use of the product because these more serious conditions may potentially necessitate further monitoring.

Nicotine Polacrilex Lozenge

The nicotine polacrilex lozenge is a resin complex of nicotine and polacrillin in a sugar-free mint- or cherry-flavored lozenge ([Table 47–5](#)). The lozenges are available in 2 mg and 4 mg strengths with two different physical sizes (regular and mini); they should be used similarly to other medicinal lozenges or troches (i.e., suck and rotate it within the mouth until it dissolves). Because the mini-lozenge is smaller, it is more easily concealed and dissolves more quickly. The pharmacokinetics of the nicotine lozenge and gum formulations are comparable, but a nicotine lozenge delivers approximately 25% more nicotine than an equivalent dose of nicotine gum because of complete dissolution of the dosage form.³⁶ The lozenge form also contains buffering agents (sodium carbonate and potassium bicarbonate) to increase salivary pH, enhancing the buccal absorption of nicotine.

As with nicotine gum, dosing for the lozenge is based on the TTFC. If the TTFC is 30 minutes or less, therapy should be initiated with the 4 mg lozenge. For a TTFC of more than 30 minutes, therapy should be initiated with the 2 mg lozenge. During the initial 6 weeks of therapy, patients should use 1 lozenge every 1–2 hours while awake. In general, this amounts to at least 9 lozenges daily. An adherence screening question could be “Are you able to use this medicine nine or more times a day?” [Table 47–7](#) provides further instructions for proper use of the nicotine lozenge. Patients can use additional lozenges (up to 5 lozenges in 6 hours or a maximum of 20 lozenges per day) if cravings occur between the scheduled doses. The manufacturer recommends that patients with sodium-restricted diets, stomach ulcers, or diabetes contact their primary care provider before using the lozenges because these more serious

conditions may necessitate further monitoring.

TABLE 47-7 Usage Guidelines for Nicotine Polacrilex Lozenge

- Begin NRT on quit date and discontinue use of all forms of tobacco on initiation of NRT regimen.
- Proper administration technique is necessary when using the nicotine lozenge:
 - Place the lozenge in the mouth and allow it to dissolve slowly (20–30 minutes for standard lozenge; 10 minutes for mini-lozenge). As the nicotine is released from the lozenge, you may experience a warm, tingling sensation.
 - To reduce the risk of side effects (e.g., nausea, hiccups, and heartburn), do not chew or swallow the lozenge.
 - Occasionally rotate the lozenge to different areas of the mouth to decrease mouth irritation.
- To minimize withdrawal symptoms, use the nicotine lozenge on a scheduled basis rather than as needed.
- Follow the dosage regimen carefully; reduce the dosage at the recommended intervals; if needed for longer than 12 weeks of treatment to keep from smoking, talk to your HCP.
- Do not use more than 5 lozenges in 6 hours or more than 20 lozenges per day.
- Acidic beverages such as coffee, juices, wine, or soft drinks may transiently reduce the salivary pH, resulting in decreased absorption of nicotine across the buccal mucosa. Do not eat or drink anything (except water) 15 minutes before or while using the nicotine lozenge.
- Patients who use more than 1 lozenge at a time, continuously use 1 lozenge after another, or chew or swallow the lozenge are more likely to experience heartburn or indigestion.
- Have nicotine lozenges readily available at all times. Keep the nicotine lozenges in the same place you previously kept your cigarettes (e.g., shirt pocket, purse, desk).
- Keep this product out of the reach of children and pets.

Key: HCP = Health care provider; NRT = nicotine replacement therapy.

Adverse effects associated with the nicotine lozenge include mouth irritation, nausea, hiccups, cough, heartburn, headache, flatulence, and insomnia. Patients who use more than 1 lozenge at a time, continuously use 1 lozenge after another, or chew or swallow the lozenge are more likely to experience heartburn or indigestion.

Nicotine Transdermal Systems (Nicotine Patch)

Nicotine transdermal systems deliver continuous, low levels of nicotine

through the skin over 24 hours. The patch consists of a waterproof surface layer, a nicotine reservoir, an adhesive layer, and a disposable protective liner.

The dosing schedules for the nicotine patches vary slightly ([Table 47–8](#)). Before recommending a specific product and a dosing schedule, the provider should know how many cigarettes the patient smokes per day. In general, heavier smokers will require higher-strength formulations for a longer duration of therapy. Patients who experience adverse effects such as dizziness, perspiration, nausea, vomiting, diarrhea, or headache should consider a lower-strength patch. Additional instructions for proper use of the nicotine patch are listed in [Table 47–9](#).

TABLE 47–8 Dosages for Nonprescription Nicotine Transdermal Systems (Patch)

Dosage Feature	NicoDerm CQ and Generic Patch
Product strength	7, 14, 21 mg (24 hour)
Dose	<i>>10 cigarettes/day</i> 21 mg/day × 4–6 weeks 14 mg/day × 2 weeks 7 mg/day × 2 weeks <i>≤10 cigarettes/day</i> 14 mg/day × 6 weeks 7 mg/day × 2 weeks

TABLE 47–9 Usage Guidelines for Nicotine Transdermal Systems (Nicotine Patch)

- Begin NRT on quit date and discontinue use of all forms of tobacco on initiation of NRT regimen.
- Apply the patch to a clean, dry, hairless area of the skin on the upper body or the upper outer part of the arm at approximately the same time each day. An electric razor can be used to create a hairless application site.
- The patch should be applied to a different area of skin each day. Avoid areas with new and healing tattoos. To minimize the potential for local skin reactions, the same area should not be used again for at least 1 week.
- During application, apply firm pressure to the patch with the palm of the hand for 10 seconds. Be sure that the patch adheres well to the skin, especially around the edges; this is necessary for a good seal.
- Wash your hands after applying or removing the patch.
- The patch should not be left on the skin for more than 24 hours because prolonged use may lead to skin irritation.
- Any adhesive remaining on the skin after patch removal can be removed with rubbing

alcohol.

- Water will not reduce the effectiveness of the nicotine patch if it is applied correctly. You may bathe, swim, shower, or exercise while wearing the patch.
- Do not cut patches in half or into smaller pieces to adjust or reduce the nicotine dosage. Nicotine in the patch may evaporate from the cut edges and the patch may be less effective.
- Local skin reactions (e.g., itching, burning, redness) are common with the nicotine patch. These reactions are generally caused by adhesives; they can be minimized by rotating patch application sites and, if they occur, treated with nonprescription hydrocortisone cream.
- Remove the nicotine patch before having a magnetic resonance imaging (MRI) procedure. Burns from nicotine patches worn during MRI scanning have been reported and probably are caused by the metallic component in the backing of some patches.
- Users experiencing troublesome dreams or other sleep disruptions should remove the patch before bedtime.
- Discard the removed nicotine patch by folding it onto itself, completely covering the adhesive area.
- Keep new and used patches out of the reach of children and pets.

Key: NRT = Nicotine replacement therapy.

The most common adverse effects associated with the nicotine patch are local skin reactions (erythema, burning, and pruritus) at the application site, which generally are caused by skin occlusion or sensitivity to the patch adhesives. If the skin reaction is bothersome, the patient can apply nonprescription hydrocortisone cream to the site or try another manufacturer's product that uses a different adhesive. Other, less common adverse effects include vivid or abnormal dreams, insomnia, and headache. Sleep disturbances might be caused by nocturnal nicotine absorption. If this effect becomes troublesome, patients should be instructed to remove the patch at bedtime; of note, a new patch should be applied as soon as possible after waking the following morning because the lack of nicotine coverage throughout the night may lead to an increased urge to smoke.³¹ Additionally, a short-acting NRT could be used after waking to bridge therapy.

Prescription Medications for Smoking Cessation

Detailed information about prescription products for tobacco cessation is outside the scope of this discussion. The following information is a summary of

key information; for further details, the reader is encouraged to consult another reference that specializes in this content.

Nicotine Inhaler

The nicotine inhaler consists of a plastic mouthpiece and a menthol-flavored nicotine-containing cartridge that delivers 4 mg of nicotine as an inhaled vapor, 2 mg of which is absorbed across the oropharyngeal mucosa. The inhaler reduces nicotine withdrawal symptoms and may give some degree of comfort by providing a hand-to-mouth ritual that emulates the act of smoking. However, reinforcing the hand-to-mouth ritual can make quitting more difficult. A gradual reduction in inhaler use is recommended. The inhaler has not been evaluated for use in patients with bronchospastic diseases, such as asthma, so it should be used with caution in these patients because of the risk of exacerbation.³⁷ Adverse effects of the inhaler include mild mouth and throat irritation, cough, and rhinitis.

Nicotine Nasal Spray

The nicotine nasal spray is an aqueous solution of nicotine for administration to the nasal mucosa. Each actuation delivers a 0.5 mg bolus of nicotine that is absorbed across the nasal mucosa. Because of its rapid onset of action (relative to other NRT formulations), the spray is a potential option for patients who prefer a medication to manage withdrawal symptoms rapidly; however, in 15%–20% of patients, use of the nasal spray can result in dependence. The nasal spray is not recommended for patients with chronic nasal disorders. Some patients with asthma have reported bronchospasm after using the nasal spray, so use of this medication in patients with bronchospastic disease should be avoided.³⁷ Initially, most patients will experience nose and throat irritation (peppery sensation), watery eyes, sneezing, or coughing when using this product. This product is to be administered without sniffing (i.e., not administered using the same technique as for standard allergy nasal sprays). After the first week, most patients have minimal difficulty with the product, and tolerance generally develops with regular use. A gradual reduction in nasal spray use is recommended.

Sustained-Release Bupropion

Sustained-release bupropion was the first non-nicotine medication approved for smoking cessation. This agent is a prescription antidepressant medication

that is believed to promote smoking cessation by blocking the reuptake of dopamine and norepinephrine in the brain, thereby decreasing the cravings for cigarettes and symptoms of nicotine withdrawal.³¹

Therapy is started with a dose of 150 mg orally every morning for 3 days, followed by 150 mg twice daily for 7–12 weeks. Because steady-state blood levels are reached after approximately 7 days of therapy, patients set their quit date for 1–2 weeks after starting therapy. Insomnia and dry mouth are the most common adverse effects reported with bupropion. Because seizures have been reported in approximately 0.1% of patients, bupropion is contraindicated in patients who (1) have a seizure disorder, (2) have a current or previous diagnosis of anorexia or bulimia nervosa, (3) are undergoing abrupt discontinuation of alcohol or sedatives (including benzodiazepines), (4) are currently using or have used a monoamine oxidase inhibitor within the past 14 days, or (5) are currently being treated with any other medications that contain bupropion. Other factors that may potentially increase the odds of seizure and are classified as warnings for use of this medication include history of head trauma or previous seizure, central nervous system tumor, severe hepatic cirrhosis, and concomitant use of medications that lower the seizure threshold. A black-box warning that highlighted risks of serious neuropsychiatric symptoms was removed from product labeling in 2016.³⁸ This labeling change was made when results of a large trial of smokers with comorbid psychiatric disorders suggested that bupropion and varenicline have no higher risk of associated adverse psychiatric events than NRT.³⁹ Pharmacotherapy should ideally be coordinated with the patient's behavioral health team to promote appropriate monitoring. Although reports are rare, FDA still recommends that providers and patients monitor for changes in mood and behavior during treatment with bupropion.³⁸

Varenicline

Varenicline (Chantix) is a partial agonist and is highly selective for the alpha-4 beta-2 nicotinic receptor. The efficacy of varenicline in smoking cessation is believed to be the result of sustained, low-level agonist activity at the receptor site that is combined with competitive inhibition of nicotine binding. The partial agonist activity induces modest receptor stimulation, leading to increased dopamine levels that attenuate the symptoms of nicotine withdrawal. In addition, by competitively blocking the binding of nicotine to nicotinic acetylcholine receptors in the central nervous system, varenicline

inhibits the surges of dopamine release that occur immediately after inhalation of tobacco smoke. The latter mechanism may be effective in preventing relapse by reducing the pleasure associated with smoking.⁴⁰

As with sustained-release bupropion, treatment with varenicline should be started 1 week before the patient stops smoking. This regimen allows for gradual escalation of the dose to minimize treatment-related nausea and insomnia. Therapy is generally started at 0.5 mg daily on days 1–3; 0.5 mg twice daily on days 4–7; and 1 mg twice daily for weeks 2–12. For patients who are not able to quit abruptly, an approved regimen suggests that they begin varenicline dosing and reduce smoking by 50% within the first 4 weeks, then by an additional 50% in the next 4 weeks, and continue reducing with the goal of complete abstinence by 12 weeks; they may continue treatment an additional 12 weeks for a total of 24 weeks.⁴¹ Nausea, insomnia, abnormal dreams, and headache are the most commonly reported adverse effects. Some people have experienced increased drunkenness (intoxication), unusual or sometimes aggressive behavior, and/or having no memory of things that have happened while drinking alcohol and using this medication.⁴² Similarly to bupropion, a black-box warning that highlighted risks of serious neuropsychiatric symptoms was removed from product labeling in 2016. This labeling change was made when results of the EAGLES trial of smokers with comorbid psychiatric disorders suggested that bupropion and varenicline have no higher risk of associated adverse psychiatric events than NRT.³⁹ Pharmacotherapy should ideally be coordinated with the patient's behavioral health team to promote appropriate monitoring. Although reports are rare, the FDA still recommends that providers and patients monitor for changes in mood and behavior during treatment with varenicline.⁴³

A small increased risk of cardiac events has been reported in some patients with existing cardiovascular disease.⁴⁴ In 2012, FDA shared results of a meta-analysis conducted by the manufacturer of varenicline, reporting that a higher occurrence of major adverse cardiovascular events was observed in patients using varenicline than in persons taking a placebo (although the increased risk was not statistically significant).^{45,46} The warnings and precautions labeling was updated to include the results of the meta-analysis and included instructions to patients to notify their health care providers of new or worsening cardiovascular symptoms and to seek immediate medical attention if they experience signs and symptoms of myocardial infarction or stroke. The labeling also suggests that the known benefits of varenicline for smoking

cessation should be weighed against the potential harms in patients with cardiovascular disease.⁴¹

Pharmacotherapeutic Comparison

Few trials have directly compared the various agents for smoking cessation. In general, compared with placebo, regimens with the first-line agents approximately double the long-term quit rates^{31,47} (Table 47–10). An open-label comparison of varenicline, nicotine patch, and combination therapy produced no significant differences in abstinence rates at 26 weeks for motivated adults.⁴²

TABLE 47–10 Methods for Smoking Cessation: Estimates of Treatment Efficacy for First-Line Agents Compared With Placebo at 6 Months After Quitting

Pharmacotherapy	Estimated Odds Ratio ^a (95% CI)	Estimated Abstinence Rate ^b (95% CI)
Placebo	1.0	13.8
Monotherapy (first-line agents)		
Sustained-release bupropion	2.0 (1.8–2.2)	24.2 (22.2–26.4)
Nicotine gum (6–14 weeks)	1.5 (1.2–1.7)	19.0 (16.5–21.9)
Nicotine inhaler	2.1 (1.5–2.9)	24.8 (19.1–31.6)
Nicotine lozenge (2 mg)	2.0 (1.4–2.8)	24.2 ^c
Nicotine patch (6–14 weeks)	1.9 (1.7–2.2)	23.4 (21.3–25.8)
Nicotine nasal spray	2.3 (1.7–3.0)	26.7 (21.5–32.7)
Varenicline (2 mg/day)	3.1 (2.5–3.8)	33.2 (28.9–37.8)
Combination Therapy (first-line agents)		
Nicotine patch (>14 weeks) + as-needed NRT (gum, nasal spray, or lozenge ^d)	3.6 (2.5–5.2)	36.5 (28.6–45.3)
Nicotine patch + bupropion SR	2.5 (1.9–3.4)	28.9 (23.5–35.1)
Nicotine patch + nicotine inhaler	2.2 (1.3–3.6)	25.8 (17.4–36.5)

^a Estimated relative to placebo.

^b Abstinence percentages for specified treatment.

^c One qualifying randomized trial; 95% CI not reported in the 2008 clinical practice guideline.

^d A recent trial, not included in the clinical practice guideline, supports the combination of the nicotine patch and nicotine lozenge.⁴²

Key: CI = Confidence interval; NRT = nicotine replacement therapy; SR = sustained release.

Product Selection Guidelines

Because all first-line, FDA-approved cessation medications enhance quit rates, the choice of therapy is based largely on contraindications or precautions, patient preference, tolerability of the available dosage forms, use during previous quit attempts (i.e., what worked well and what did not, regardless of whether or not the medication was being used correctly), and cost. For whatever regimen selected, the cost of treatment will be insignificant compared with the costs of continued smoking and the costs of managing the resultant complications.

The number of smokeless tobacco products available on the market, including dissolvable tobacco and electronic cigarettes, is on the rise. Currently no guidelines exist for the treatment of tobacco cessation for people using these products. A review and meta-analysis supports the use of varenicline for smokeless tobacco users, although product labeling has not been changed.⁴³

Since 2016, FDA has increased its regulatory oversight of all tobacco products, including cigars, electronic cigarettes, and hookah and pipe tobacco. On December 20, 2019, the President signed legislation raising the federal minimum age to purchase tobacco products from 18 to 21 years of age.⁴⁸ In January 2020, FDA issued a policy that restricts any flavored pod or cartridge-based ENDS product other than menthol or tobacco-flavors. Of note, this

restriction does not include e-liquids sold in vape shops; however, these operations may be considered manufacturers.⁴⁸ Finally, manufacturers now have to comply with all FDA requirements, including reporting all ingredients and listing health warnings on packaging and advertising.

Special Populations

NRT should be used with caution in patients with serious underlying cardiovascular disease, including those who have had a recent myocardial infarction (i.e., within the preceding 2 weeks), those with serious arrhythmias, and those with serious or worsening angina pectoris.³¹ Nicotine may increase the myocardial workload by increasing the heart rate and blood pressure and also may constrict coronary arteries, leading to cardiac ischemia.⁴³ Although most experts believe that the risks of NRT in patients with cardiovascular disease are small relative to the risks of continued smoking,^{49,50} patients with serious underlying cardiovascular disease are advised to use NRT only while under the supervision of a health care provider.

Evidence exists for risk to the human fetus when prescription formulations of nicotine are used during pregnancy.⁵¹ (See the Preface for a detailed explanation of the pregnancy data.) Although NRT may pose a risk to the developing fetus, some experts have argued that NRT use during pregnancy is safer than continued smoking.^{51,52} However, because data showing effectiveness of NRT in pregnancy are inconclusive and because nicotine has the potential to cause fetal harm, the 2008 clinical practice guideline states that pregnant women should be encouraged to quit without the use of medication. Instead, providers are advised to offer interventions of person-to-person behavioral counseling for their pregnant patients who smoke.³¹

The efficacy of NRT, sustained-release bupropion, and varenicline has not been established in pediatric or adolescent smokers, and no NRT product is currently indicated for use in these populations.³¹ Accordingly, counseling is the recommended treatment method for smokers younger than 18 years.

People older than 65 years can benefit greatly from quitting smoking. Pharmacologic therapy and counseling are recommended. If mobility is an issue, referral to a quit line may be useful.^{16,31}

The manufacturers of nicotine gum, lozenge, and patch products recommend that patients taking a prescription medicine for asthma or depression speak

with their primary care provider before using nonprescription NRT. Fluvoxamine and theophylline (both now used infrequently) and inhaled corticosteroids have known clinically significant interactions with tobacco smoke ([Table 47–2](#)).

People who are lesbian, gay, bisexual, or transgender (LGBT) have more risk factors for cigarette use including increased second-hand smoke exposure and daily stressors due to perceived stigma.⁵³ In 2016, LGB adult cigarette use in the US was reported as higher than that of heterosexual/straight individuals (20.5% vs. 15.3%, respectively).⁵³

For light smokers (those who smoke fewer than 10 cigarettes per day and those who do not smoke every day), counseling is the recommended treatment method.³¹ However, the nicotine patch is approved for use in light smokers, and the nicotine lozenge was shown to be effective in individuals who smoke 15 or fewer cigarettes daily.⁵⁴ Use of smokeless tobacco (e.g., snuff, moist snuff, chewing tobacco, dissolvable tobacco), cigars, and pipes can produce nicotine addiction and lead to serious health consequences. Behavioral counseling is the recommended treatment method for these tobacco users.³¹

Patient Factors

When recommending a nonprescription agent for smoking cessation, primary care providers should determine the patient's smoking patterns, lifestyle habits, and coexisting medical conditions. In general, higher levels of smoking will require higher dosages of NRT and longer durations of treatment.

Some patients might need to use their smoking cessation medication longer than the usual recommended treatment duration. Although the general goal is complete—long-term abstinence from all nicotine-containing products—some smokers may benefit from long-term medication use.³¹ If continued use helps prevent relapse, this approach is considered preferable to the patient returning to smoking.³¹

Patients who smoke continuously throughout the day may have better success with a nicotine patch because it provides a sustained, steady release of nicotine. Conversely, patients who smoke intermittently throughout the day or who smoke intensely for short periods of time, followed by long periods of abstinence, might prefer a relatively short-acting formulation, such as a

nicotine gum or lozenge, to more closely mimic their tobacco use patterns. For some quitters, frequent gum chewing may not be feasible or socially acceptable. The nicotine patch, which can be concealed under clothing, might be a reasonable choice for these patients. Others may find nicotine lozenges, which can be used more discreetly, to be an acceptable alternative. Patients with underlying dermatologic conditions (e.g., psoriasis, eczema, atopic dermatitis) or allergy to adhesive tape are more likely to experience skin irritation and should not use the nicotine patch. The nicotine lozenge or patch is more appropriate than the nicotine gum for patients with TMJ disease or dentures. Finally, patients with serious cardiovascular disease, women who are pregnant or nursing, light smokers, and adolescents should be referred for further evaluation by their primary provider before starting treatment with NRT.

Patient Preferences

Identifying the patient's perceptions and expectations about pharmacotherapy, including the ability to adhere to the regimen, previous experience with smoking cessation medications, and concern about weight gain, is particularly important. Because NRT formulations require frequent dosing or nontraditional routes of administration, patient education about proper use of these products is essential. Patients who have difficulty taking multiple doses of medications throughout the day or those who want a simplified regimen might achieve greater success with the nicotine patch. By contrast, the gum or lozenge may be preferable for patients who want to titrate nicotine levels to manage withdrawal symptoms. Some people may find that they need an oral substitute for tobacco; the oral gratification given by the nicotine gum, lozenge, or inhaler might be beneficial in these patients. Others may prefer the idea of using a combination of medications, such as the nicotine patch plus gum or lozenge, on an as-needed basis, as discussed later in this section.

All smokers making a repeat quit attempt should be queried about their previous use of pharmacotherapy and their perceptions of available treatment options. For patients reporting a favorable past experience with a given product, repeated treatment with the same agent may be appropriate, with consideration given to increasing the dose, frequency of dosing, or duration of therapy. For patients who report a negative experience with a particular medication (e.g., poor adherence, adverse effects, palatability issues, cost), a

different regimen should be considered. For example, for a quitter who had short-term success with the patch but discontinued therapy because of intolerable nightmares, a second trial of the patch that is removed at bedtime is more likely to be successful. A patient who is unable to tolerate nicotine gum because of jaw muscle ache could be advised to switch to the nicotine lozenge or patch. For a patient who expresses concern about postcessation weight gain, use of the 4 mg nicotine gum or lozenge or sustained-release bupropion may be particularly helpful in that these products were shown to delay weight gain after quitting.³¹ Among patients for whom the out-of-pocket expense poses a potential barrier to pharmacologic treatment, use of the generic formulations is preferable.

Combination therapy should be considered a first-line treatment and might be particularly appropriate in patients who have experienced numerous failed attempts using monotherapy. Combination therapy generally involves the use of a long-acting medication (nicotine patch or sustained-release bupropion) in combination with a short-acting nicotine formulation (nicotine gum, lozenge, inhaler, or nasal spray). The long-acting nicotine formulation, which delivers relatively constant concentrations of drug, is used to prevent the onset of severe withdrawal symptoms, whereas the short-acting nicotine formulation, which delivers nicotine more rapidly, is used as needed to control withdrawal symptoms that may emerge during potential relapse situations (e.g., after meals, during episodes of stress, being around other smokers). Research suggests that combination therapy may be somewhat more efficacious than monotherapy.^{31,55} Disadvantages of combination therapy are the possibility of additional adverse effects (e.g., nicotine toxicity), difficulty with adherence, and increased cost. For other combination regimens, patients should be referred to their primary care provider to determine the most appropriate option.

Complementary Therapies

Although a variety of herbal and homeopathic products are available to aid cessation, data supporting their safety and efficacy are lacking. Many herbal preparations for cessation contain lobeline (derived from *Lobelia inflata*), an herbal alkaloid with partial nicotinic agonist properties. A meta-analysis⁵⁶ and a multicenter trial⁵⁷ found no evidence to support the role of lobeline as an aid for smoking cessation. Similarly, controlled trials did not find hypnosis or acupuncture to be an effective treatment for smoking cessation.^{31,58}

Electronic Cigarettes

Electronic cigarettes (e-cigarettes or ENDS) continue to gain popularity in the United States. These devices were initially marketed as a substitute for cigarettes in situations that do not allow smoking; however, many places have now also banned their use. Although found to be less harmful than regular cigarettes, e-cigarettes produce a breathable aerosol that still contains the highly addictive substance nicotine as well as other harmful chemicals and carcinogens, such as nitrosamines and diethylene glycol.⁵⁹ Specific to a potentially serious side effect, seizures may be associated with e-cigarette use.⁶⁰ Although compelling, data remain insufficient to support the safety or efficacy of these products in reducing or stopping smoking.⁶¹ The ACC consensus review offers suggestions on how to use e-cigarettes for those motivated to quit smoking.⁶² In a multicenter randomized study, e-cigarettes were found to increase smoking abstinence rates compared with traditional nicotine replacement therapy (NRT) (1 year abstinence rates: 18% and 9.9%, respectively).⁶³

E-cigarettes or vaporizers come in a variety of shapes and flavors, making them more marketable to children and young adults. For example, some products are pod- or cartridge-based and shaped like USB drives, making them easier to conceal, and were marketed in flavors like chocolate, mint, and multiple fruity flavors, to name just a few. The January 2020 restrictions on sale of those flavors is being enforced. E-cigarettes are the most commonly used tobacco product among youth, and youth are more likely than an adult to use an e-cigarette.⁵⁹ In April 2018, FDA introduced the Youth Tobacco Prevention Plan, an initiative that is focused on stopping youth use of tobacco products, and in particular, e-cigarettes. It includes a series of enforcement and regulatory steps as well as an educational campaign.⁶⁴ As this field continues to rapidly evolve, parents, teachers, and health care workers can help to prevent and reduce young people's use of e-cigarettes by staying updated on current trends and learning about what products are available, the harmful and potentially harmful ingredients, and the many emerging health risks.

Algorithm: Tobacco Cessation

FIGURE 47–2 Self-care for tobacco cessation. Key: 5 A's = Ask, advise, assess,

assist, arrange; MI = myocardial infarction; NRT = nicotine replacement therapy; OTC = over-the-counter; PUD = peptic ulcer disease; Rx = prescription; TMJ = temporomandibular joint.

Assessment of Tobacco Cessation: A Case-Based Approach

To help patients succeed at tobacco cessation, the provider must assist them in evaluating their patterns of smoking, identify medications and quitting methods they have or have not tried in the past, and determine appropriate cessation therapies. Analysis of smoking patterns and triggers for smoking will help the provider work with the patient to develop an appropriate treatment plan.

Cases 47–1 and 47–2 illustrate the assessment of two patients in different phases of quitting smoking.

Case 47–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient would like information about the various nonprescription medications for tobacco cessation. He is noticing that he gets more "winded" when he walks, and he is concerned about the effects of smoking on his health. He has smoked one pack per day (or 20 cigarettes) for 21 years. He smokes 2 cigarettes with his morning coffee and smokes in social situations such as when having a few drinks with coworkers. He has not received cessation counseling from a provider. He has tried the nicotine patch and gum in the past

Relevant Evaluation Criteria	Scenario/Model Outcome
	and wants to try Chantix (varenicline).
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	He is in a rush because he has to get back to work. He smokes mostly on work breaks and at home in the morning and in the evenings after dinner.
c. Description of the patient's efforts to relieve the symptoms	He has tried to quit smoking approximately 5 times to date, 3 times using NRT.
d. Patient's identity	Kevin Stills
e. Patient's age, gender, height, and weight	61 years old, male, 5 ft 8 in., 170 lb
f. Patient's occupation	Accountant
g. Patient's dietary habits	Reasonably healthy diet; walks 30 minutes daily during his lunch break.
h. Patient's sleep habits	Sleeps 7 hours/night during the workweek; does not have trouble sleeping.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension: controlled on lisinopril 10 mg daily
j. Allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe)	Mr. Stills is married, with no children. His wife is supportive of his attempt to quit. Some close friends and coworkers also smoke.

Relevant Evaluation Criteria	Scenario/Model Outcome
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Patient is a middle-aged man who would like to quit smoking to improve his breathing and overall health.
3. Identify exclusions for self-treatment (Figure 47-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend pharmacotherapy and counseling. Pharmacotherapy options include • Nicotine patch • Nicotine gum • Nicotine lozenge • Combination therapy with the nicotine patch plus a short-acting NRT formulation • Referral to PCP for prescription pharmacotherapy (nicotine inhaler, nicotine nasal spray, bupropion SR, varenicline) (2) Refer Mr. Stills to telephone counseling (1-800-QUIT-NOW) or text-based services and applications because he is in a hurry. (3) Recommend that he set a quit date in 1-2 weeks. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account	Mr. Stills expressed interest in taking varenicline. Refer him to his PCP for a prescription.

Relevant Evaluation Criteria	Scenario/Model Outcome
patient preferences.	
	For behavioral counseling, refer him to the quit line. (See Tables 47-3 and 47-4.)
6. Describe the recommended therapeutic approach to the patient or caregiver.	“Medication is recommended. Although you have no contraindications or precautions for medication use as part of a self-care quit program, varenicline is available only by prescription.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Use of Chantix, or varenicline, is considered a first-line treatment for smoking cessation. Because you would like to take this medication and it is available by prescription only, you will need to contact your PCP to obtain a prescription. I can also call your provider for you now if you would like. Receiving counseling, in addition to taking Chantix as directed, will increase your chances of success with quitting.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“What should I do if I am tempted to smoke when I am around my friends?”
Answer the patient's or caregiver's questions.	“The quit line counselor will be able to talk to you about problem-solving and coping skills for your smoking triggers. It is important that your friends and wife support you when you quit. To minimize relapse, reduce or avoid use of alcohol during the first 2 weeks of your quit attempt. The counselor will arrange follow-up contacts after your quit date.”

Relevant Evaluation Criteria	Scenario/Model Outcome
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Mr. Stills plans to contact his PCP and will return to the pharmacy to fill his prescription. He also set a quit date in 2 weeks with plans to follow up with the quit line.

Key: NKA = No known allergies; NRT = nicotine replacement therapy; PCP = primary care provider; SR = sustained release.

Case 47–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient quit smoking 7 days ago and is using the generic 21 mg nicotine patch. She complains of trouble sleeping and is experiencing disturbing dreams since starting to use the patch. She had been smoking approximately 1.5 packs per day (approximately 30 cigarettes daily) for 10 years before quitting.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Before quitting, patient used to have a cigarette before even getting out of bed because she had such intense cravings.

Relevant Evaluation Criteria	Scenario/Model Outcome
c. Description of the patient's efforts to relieve the symptoms	Patient has been using the 21 mg nicotine patch for 7 days. She had not previously tried pharmacotherapy for quitting. She purchased the patch after speaking to an HCP. She has not received any formal counseling from a provider. She feels a bit agitated and irritable from time to time during the day; she is very tempted to smoke in the morning when she wakes up. Overall, she likes the patch and is not experiencing any significant skin reactions.
d. Patient's identity	Kristen Brady
e. Patient's age, gender, height, and weight	28 years old, female, 5 ft 6 in., 140 lb
f. Patient's occupation	Web designer
g. Patient's dietary habits	Tries to "eat healthy"; drinks approximately 8 cups of caffeinated coffee per day.
h. Patient's sleep habits	Sleeps 7-8 hours a night. Since using the patch, she has experienced trouble sleeping and disturbing dreams.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Ms. Brady is not pregnant or lactating.
	She has TMJ disease, for which she takes acetaminophen 325 mg every 6 hours as needed for pain, but she rarely takes it.
j. Allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe)	Patient is single. Her boyfriend and her roommate are supportive of her desire to quit.
Assess	

Relevant Evaluation Criteria	Scenario/Model Outcome
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Patient quit smoking 1 week ago and is experiencing "intolerable" adverse effects from the nicotine patch (i.e., sleep disturbances), daily withdrawal symptoms (i.e., agitation, irritability), and morning cravings.
3. Identify exclusions for self-treatment (Figure 47-2).	None
4 Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend continued pharmacotherapy and counseling. Pharmacotherapy options include • Removal of nicotine patch at night and addition of a lozenge as needed (particularly in the morning upon waking). • Alternative NRT agent, such as lozenge alone. • Referral to PCP for prescription pharmacotherapy (nicotine inhaler, nicotine nasal spray, bupropion SR, varenicline). (2) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because Ms. Brady has expressed that she thinks the patch is working well to manage her withdrawal symptoms, continue the nicotine patch, but advise her to take the patch off before bedtime. This change should help reduce the sleep disturbances and disturbing dreams. She can use combination therapy with a nicotine lozenge, as needed. The nicotine gum would not be a good choice because she has TMJ disease. A 2 mg lozenge dose to be used on an as-needed basis is reasonable.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"It's great that the patch is working for you so far. You have no contraindications or precautions for use of the nicotine patch and as-needed 2 mg lozenge. I have some ideas that should help you with your sleep problems and some other information for you, including how to manage morning cravings."

Relevant Evaluation Criteria	Scenario/Model Outcome
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“You do not have any medical conditions for which nicotine replacement medications should be used with caution (e.g., recent heart attack, serious arrhythmias, angina). The nicotine patch provides a low, constant level of nicotine to help reduce nicotine withdrawal symptoms. By taking it off at night, you should no longer experience sleep disturbances. The nicotine lozenge should be used only when you experience situations in which you are craving a cigarette, such as when you wake up. Receiving counseling, in addition to taking your medications as directed, will increase your chances of quitting.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	“Use the 2 mg nicotine lozenge if you experience situations in which you are craving a cigarette, such as when you wake up.” (See Tables 47-5 and 47-8 .)
b. Maximum number of days the therapy should be employed	See Table 47-8 .
c. Product administration procedures	See Tables 47-7 and 47-9 .
d. Expected time to onset of relief	“With the lozenge, nicotine levels will peak 30-60 minutes after you start using it. You are already using the nicotine patch, which provides a steady amount of nicotine throughout the day. The blood nicotine levels from the patch and lozenge are lower than those from smoking, but they should be sufficient to help control your nicotine withdrawal. Most patients find that nicotine withdrawal symptoms peak in the first few days after the last cigarette; withdrawal symptoms then gradually diminish over the next 2-4 weeks.”

Relevant Evaluation Criteria	Scenario/Model Outcome
e. Degree of relief that can be reasonably expected	“Over time, you may find you need to use the lozenge less often. Be sure to stick with the recommended daily dosing schedule for the patch and the duration of use needed for the best chance of success. This will help you to be more comfortable while you are quitting.”
f. Most common adverse effects	“The most common adverse effects of the nicotine patch are skin reactions (redness, burning, and itching) at the application site and headaches. The sleep disturbances (vivid dreams and insomnia) that you are currently experiencing from the patch should resolve when you remove it before bedtime. The most common adverse effects of the nicotine lozenge are nausea, hiccups, and heartburn.”
g. Adverse effects that warrant medical intervention should they occur	“If you find that reducing your caffeine intake and using the nicotine lozenge do not help relieve your morning cravings and irritability during the day, contact your PCP. If you experience symptoms of nicotine excess (e.g., nausea, vomiting, dizziness, weakness, rapid heartbeat), also contact your PCP.”
h. Patient options in the event that condition worsens or persists	“Contact your PCP for the following reasons: You experience withdrawal symptoms or severe cigarette cravings. You may need a higher dosage of nicotine. You have adverse effects related to nicotine excess.” (see outcome in 8g.)
i. Product storage requirements	“Store the patches and lozenges at room temperature. Keep unused patches in the closed, protective pouch. Keep all new and used patches and lozenges out of the reach of children and pets.”
j. Specific nondrug measures	“Reduce caffeine use by half to minimize agitation and trouble sleeping. In addition to the counseling I can provide, other counseling programs are available, including the telephone quit line (1-800-QUIT-NOW), group classes, and internet-based programs. We can discuss which options you feel might be useful to you.”
Solicit follow-up questions from the patient or caregiver.	“How often can I use the lozenge?”
Answer the patient's or caregiver's questions.	“You should use the lozenge when you feel a strong craving to smoke, such as when you wake up in the morning. The patch will provide a consistent low level of nicotine to help reduce withdrawal symptoms. You should use the nicotine lozenge only when you feel a need, or urge, to smoke. Even though the box says you can use up to 20 lozenges a day, you should not need this many when you use them

Relevant Evaluation Criteria	Scenario/Model Outcome
	with the patch. Also remember to switch to the lower-strength 14 mg patch after 6 weeks; use it for 2 weeks, and then use the 7 mg patch for 2 weeks.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Confirm that Ms. Brady will reduce caffeine use, remove the patch before bedtime, and use the lozenge as needed for cravings. Call patient in 1 week to assess quit plan.

Key: NKA = No known allergies; NRT = nicotine replacement therapy; PCP = primary care provider; SR = sustained release; TMJ = temporomandibular joint.

Patient Counseling for Tobacco Cessation

Substantial benefits of quitting can be realized at any age. Although approximately 70% of adult smokers would like to quit,⁴ few are able to do so on their own. Research has shown that tobacco cessation rates can be substantially improved with treatment that includes counseling and pharmacotherapy.³¹ (See “Nonpharmacologic Therapy” for a detailed discussion of counseling.) Health care providers are in an ideal position to identify tobacco users and to either provide assistance throughout the cessation attempt or refer the patient to a tobacco cessation resource. The box “Patient Education for Tobacco Cessation” describes specific information to include in patient counseling.

Patient Education for Tobacco Cessation

Tobacco dependence is a chronic disease optimally treated with a

combination of counseling and medications. The primary goal of tobacco cessation treatment is to attain complete, long-term abstinence from all nicotine-containing products. For most people, carefully following product instructions and the self-care measures listed here will help ensure optimal treatment outcomes.

Nondrug Methods

- Receiving counseling from a health care provider will increase the success of tobacco cessation. A provider can help develop a tailored tobacco cessation treatment plan.
- Telephone quit lines (e.g., 1-800-QUIT-NOW) also are available to provide comprehensive counseling services at no cost.
- Internet-based resources and mobile apps also are available, many at no cost.

Nonprescription Medications

Nicotine Replacement Therapy (NRT)

- NRT helps relieve and prevent symptoms of nicotine withdrawal by partially replacing the high levels of nicotine that your body is used to obtaining from cigarettes. Use of NRT helps you to focus on changing your smoking routines and to practice new coping skills while decreasing your withdrawal symptoms.
- NRT does not contain any of the harmful tars and other toxins present in tobacco smoke.
- Symptoms of nicotine withdrawal are common and should subside over 2–4 weeks.
- Recommended daily dosages for NRT are shown in [Tables 47–5 and 47–8](#).
- See [Table 47–6](#) for usage guidelines for nicotine gum, [Table 47–7](#) for the nicotine lozenge, and [Table 47–9](#) for the nicotine patch.
- Carefully follow the dosage regimen for the selected product. Failure to do so will increase the chance of having withdrawal symptoms. Discontinuing therapy early might lead to relapse.
- Signs and symptoms of nicotine excess include nausea, vomiting,

dizziness, diarrhea, weakness, and rapid heartbeat.

- Do not eat or drink (except water) 15 minutes before or while using the nicotine gum or lozenge.
- Store NRT products at room temperature and protect from light.
- Keep new and used products out of the reach of children and pets.
- For all forms of NRT, consult your primary care provider before use if you have had a recent (in the past 2 weeks) heart attack, experience frequent pain caused by severe angina, have an irregular heartbeat, are pregnant or lactating, are younger than 18 years, or smoke fewer than 10 cigarettes a day.
- You may consider use of nicotine gum with the patch (gum used only on as-needed basis). For other possible medication combinations, speak to your primary care provider first.

When to Seek Medical Attention

- For all forms of NRT, stop use and seek medical attention if irregular heartbeat or palpitations occur, or if you have symptoms of nicotine overdose, such as nausea, vomiting, dizziness, diarrhea, or weakness.
- For nicotine gum: Stop use if mouth, teeth, or jaw problems develop.
- For nicotine lozenge: Stop use if mouth problems, persistent indigestion, or severe sore throat develops.
- For nicotine patch: Stop use if the skin swells, a rash develops, or skin redness caused by the patch does not subside with use of nonprescription hydrocortisone cream or does not go away after 4 days.

Evaluation of Patient Outcomes for Tobacco Cessation

Follow-up contact is an essential component of treatment for tobacco use and dependence.³¹ At each follow-up encounter, the provider should do the

following:

- Assess a patient's tobacco use status and, if appropriate, evaluate and monitor pharmacotherapy use.
 - Congratulate abstinent patients and encourage them to remain tobacco free.
 - In cases of relapse, review the specific circumstances, reassess the commitment to abstinence, encourage the patient to learn from identified mistakes, and identify strategies to prevent future lapses.
 - Determine whether the patient is experiencing nicotine withdrawal symptoms or adverse effects from the pharmacotherapy.
 - Offer ongoing support. If providing that level of support is not possible, refer the patient to a specialist for more intensive treatment.
-

Key Points for Tobacco Cessation

- Apply the 5 A's approach in providing tobacco cessation counseling: ask, advise, assess, assist, and arrange.
- For a patient who is not ready to quit, provide brief counseling, and emphasize that the pharmacist will be available when the patient is ready to quit smoking.
- For a patient who is ready to quit, offer counseling and pharmacotherapy. If time is limited, ask about tobacco use, advise the patient to quit, and refer the patient to the toll-free quit line (1-800-QUIT-NOW), web-based resources, mobile apps, and texting services.
- Numerous effective medications are available for tobacco dependence; encourage their use by all patients attempting to quit smoking—except when medically contraindicated or in specific populations for which evidence of effectiveness is insufficient (i.e., pregnant women, smokeless tobacco users, light smokers, adolescents). For patients with exclusions for self-treatment with NRT, referral to a primary care provider for further assessment is warranted.
- Advise patients that it is never too late for them to quit, but that

quitting earlier in life is clearly advantageous. Quitting smoking at any age has immediate as well as long-term benefits by reducing the risk for smoking-related diseases and improving health in general.

- The combination of counseling and medication for tobacco cessation is more effective than either alone.
- Smokers who quit can experience side effects from increased drug levels of several medications due to pharmacokinetic and pharmacodynamic interactions with tobacco smoke.
- It is essential that health care providers use the 5 A's counseling process to guide their patients through a quit attempt: ask, advise, assess, assist, and arrange. Patients also can be referred to the national quit line: 1-800-QUIT-NOW.
- Self-treatment is not recommended for those under the age of 18 years, someone who is pregnant or breastfeeding, and those with serious heart disease.
- Assess the tobacco user's smoking patterns and preferences to help determine an appropriate self-care strategy.
- Instruct patients on how to use the various nicotine replacement products, including application of the patch and the special chew and park technique for the gum.

Chapter 48: Home Testing and Monitoring Devices

Authors: Daniel L. Krinsky

The home testing market continues to grow, offering an expanded array of products that are more user friendly and comprehensive. The global home diagnostics market is expected to increase from \$4.78 billion in 2017 to \$6.53 billion by 2025. The use of new technologies and wearable devices is fueling growth in several sectors. These tests typically are available as strips, cups, dip cards, cassettes, and, more recently, as digital monitoring devices. Blood, urine, and saliva are the primary testing media.¹

Forces driving the growth in home diagnostics include (1) increased public interest in health and preventive medicine; (2) reduced health care costs because patients can avoid unnecessary visits to health care providers and can seek earlier treatment of a medical condition; (3) reduced access and availability of health care resources; (4) increased number of available tests; and (5) important advances in technology that have led to simplified, accurate tests that can be easily performed at home.

Home testing and monitoring kits are designed to detect the presence or absence of a medical or physiologic condition and to monitor disease therapy. Recent growth in this market has been in the area of preventive health. Individuals with a family history of certain disorders, such as hypertension and diabetes, are using wearables and other devices as a proactive approach to monitoring the results of a wellness routine. Others who are interested in monitoring certain aspects of their health also are using wearables to obtain more personalized, individualized information to guide lifestyle and health decisions.

The Food and Drug Administration (FDA) requires home tests to perform as well as their professional-use equivalent. However, home tests must be used properly to achieve accurate results. The primary criterion for FDA approval of a direct-to-consumer test is the consumer's ability to obtain an accurate result and to interpret the result correctly; ultimately the test's benefits must outweigh its risks.² Throughout the approval process, the agency is looking for data and evidence that support the test's efficacy and its usability.³ FDA

maintains a website that provides information on approved nonprescription medical devices.²

This chapter discusses home test kits that aid in detecting the following disorders or conditions: pregnancy, female fertility; male fertility; colorectal cancer (fecal occult blood tests); high cholesterol levels; urinary tract infections; human immunodeficiency virus; hepatitis C; and drug abuse. This chapter also covers proper selection and use of blood pressure monitors, and provides a table of miscellaneous tests at the end of the chapter. For other products used in self-monitoring of disorders, see [Chapter 8](#) for discussion of self-treatment for vaginal fungal infections. Future home tests and diagnostics will be more complex and provide more data. These advances likely will lead to some patients feeling more empowered, others more confused, and many wanting guidance from a medical professional.

Selection Criteria

With the variety of diagnostic and monitoring products available, deciding which test to recommend to a given patient can be challenging. The major product variables to consider include test complexity, ease of reading results, presence of a control, and cost. [Table 48–1](#) addresses considerations for patients regarding the selection and use of home tests.

TABLE 48–1 Selection and Use of Home Tests and Devices

- Not all available tests are FDA-approved for home use. Check the status of a particular test at www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfiVD/Search.cfm.
- Always check the expiration date before purchasing a product to ensure that reagents are not outdated. For example, a test that has an expiration date of 04/2023 expires at the end of the designated month (April 30, 2023).
- Follow the manufacturer's instructions for storing the tests to ensure that reagents remain stable.
- When selecting a test, consider simplicity of use. Single-step tests usually are desirable because each step is a potential source of error.
- When considering cost, determine the cost per test unit and whether kits with multiple tests are needed. Generic or store-brand kits may cost significantly less.
- When possible, select a test that includes a control to ensure that the test is functioning correctly.
- Read all instructions carefully and completely before attempting to perform a test.

- Before scheduling or performing the test, note the time of day that the test is to be conducted, the length of time required, and any necessary supplies or equipment; then schedule the best time and place to conduct the test.
- Follow instructions exactly as described and in the order described. If you have questions about the testing procedure or interpretation of the results, consult a health care provider, or call the test manufacturer's toll-free number, if provided, for customer assistance.
- Use an accurate timing device that measures seconds to ensure that you wait the specified length of time between steps. Note that waiting longer than the specified time to read test results could affect test reliability.
- If the selected test requires observation of a color change, read the test in good lighting. If you have color-defective vision or other visual impairment, ask someone without vision difficulties to observe the color change and/or read the test results.
- If you have physical limitations that could interfere with performing the test, ask someone to help you perform the test.
- If the test requires a fingerstick and you have a medical condition or take medications that may cause excessive bleeding, consult your health care provider before performing the test.
- Food, medications, and certain diseases or conditions sometimes can interfere with test results.
- Many manufacturers offer the ability to navigate and interpret test results through portals. They also provide access to counselors/advisors/medical experts who can help with data interpretation and application.
- Discuss test results with your health care provider to ensure you take the appropriate actions based on your information and health status.

Key: FDA = U.S. Food and Drug Administration.

When recommending a test or device, the pharmacist must weigh the following potential variables:

- Is self-testing appropriate based on the patient's signs and symptoms?
- What is the patient's ability to accurately conduct the test? Interpret the results? Take appropriate actions based on the results?
- What happens if the test strip turns a specific color for a positive result, but the user is color blind?
- Is a "negative" result good or bad? Is a "positive" result good or bad?
- When should users contact their physician?
- What if a patient misinterprets the test results?
- What are potential interferences in obtaining accurate test results?
- Is there liability? Where/when does the manufacturer's responsibility

begin and end?

- What if patients take action on a result that leads to a poor outcome, uses an unapproved therapy, or seeks care from an unorthodox source that results in a negative outcome?
-

Pregnancy Detection Tests

Women now are able to detect pregnancy early, including before the day of the missed period because of the heightened sensitivity of at-home pregnancy tests. Early detection of pregnancy is desirable for many reasons, including allowing the woman to make decisions regarding prenatal care and lifestyle changes to avoid potential harm to the fetus.

Physiology of the Female Reproductive Cycle

The female reproductive cycle lasts approximately 28 days and is hormonally controlled. At the beginning of the cycle (day 1 through approximately day 12), low levels of circulating estrogen and progesterone cause the hypothalamus to secrete gonadotropin-releasing hormone (GnRH). In turn, GnRH stimulates release of the follicle-stimulating hormone (FSH) and low levels of luteinizing hormone (LH) from the anterior pituitary gland. This combination of hormones promotes development of several follicles within an ovary during each cycle. One follicle continues to mature while the others regress. At midcycle (approximately day 14 or 15), circulating and urinary LH levels significantly increase and cause final maturation of the follicle. *Ovulation* (rupturing of the follicle and release of the ovum) occurs approximately 20–48 hours after the LH surge. Cells in the ruptured follicle form the corpus luteum, which begins to secrete progesterone and estrogen. For approximately 7–8 days after ovulation, the corpus luteum continues to develop and secrete estrogen and progesterone, inhibiting further secretion of FSH and LH.

Once ovulation occurs, the ovum remains viable for fertilization for only 12–24 hours. Because sperm may live up to 72 hours, optimal days for fertilization to occur include the 2 days before ovulation, the day of ovulation, and the day after ovulation. For the greatest chance of achieving pregnancy, intercourse should take place within 24 hours after the LH surge.

If fertilization occurs, trophoblastic cells produce the human chorionic

gonadotropin (hCG) hormone. This hormone causes the corpus luteum to continue to produce progesterone and estrogen, forestalling the onset of menses while the placenta develops and becomes functional. As early as day 7 after conception, the placenta produces hCG, some of which is excreted in the urine. The concentration of hCG continues to increase during early pregnancy, reaching maximum levels 6 weeks after conception. The levels of hCG decline over the following 4–6 weeks and then stabilize for the remainder of the pregnancy.

If fertilization does not occur during a cycle, the corpus luteum degenerates, circulating levels of progesterone and estrogen diminish, and menstruation occurs (days 1–5). Resulting low levels of progesterone and estrogen cause release of GnRH from the hypothalamus, and the hormonal cycle begins again.

Usage Considerations

Numerous pregnancy tests with different reaction times and hCG sensitivity are available for home use. [Table 48–2](#) lists some available products that have been tested for accuracy.^{4–6} The most sensitive tests are capable of detecting hCG levels at the 20–25 mIU/hCG threshold. Factors to consider include accuracy based on testing a certain number of days before a missed period, time to obtain results, and how results are displayed.

TABLE 48–2 Selected Nonprescription Pregnancy Tests and Product Features

Trade Name (Website)	hCG Sensitivity ^a	Product Features
First Response Early Result ^b (www.firstresponse.com/en/product-listings/early-result-pregnancy-test)	<6.3 mIU/mL	• Uses test stick; digital display test also available • Best combination of sensitivity and reliability • Can test up to 6 days before missed period • Results obtained in 1 minute
Clearblue Plus/Advanced/Digital ^c	25 mIU/mL	• Uses test stick • Can test up to 5 days before missed period

Trade Name (Website)	hCG Sensitivity ^a	Product Features
		• Color-change tip indicates urine has been absorbed • Digital display test (50 mIU/mL) also available • Clearblue Advanced provides estimate of weeks since ovulation (1–2 weeks, 2–3 weeks, 3+ weeks) • Test strip technology prevents excess urine from causing error
Store-brand Products	25–50 mIU/mL	• Uses test sticks • Usually less expensive and possibly less reliable than brand-name products
E.P.T.	25–50 mIU/mL	• Uses test sticks • Digital display test also available
ClinicalGuard HCG Pregnancy Test Strips ^d (www.clinicalguard.com/pregnancy-test-guide)	25 mIU/mL	• Uses test strips (dip method) • Good option for those wanting to do multiple testing • Works well for women undergoing IVF
AccuMed Pregnancy Test Strips ^e (accumed.com/accumed-pregnancy-test-strips-25-count.html)	25 mIU/mL	• Uses test strips (dip method) • Works well for women with irregular periods • Can test as early as 5 days before missed period
Pregmate Pregnancy Urine Test Strips	25 mIU/mL	• Uses dip method for wide strip that is easy to use and read • Good option for multiple testing

Trade Name (Website)	hCG Sensitivity ^a	Product Features
		• Best if used no sooner than 1 day prior to missed period • Results obtained in 5 minutes
VeriClear Digital Early Result Pregnancy Test	10 mIU/ml	• Claims to detect pregnancy 6 days before missed period • Uses dip or midstream technique, with results provided in 3 minutes • Links to proprietary digital platform provided

^a Manufacturer's claimed sensitivity.

Key: hCG = Human chorionic gonadotropin [hormone]; IVF = in vitro fertilization.

Mechanism of Action

Home pregnancy tests detect hCG in the urine by using monoclonal or polyclonal antibodies in an enzyme immunoassay. The antibodies are bound to a solid surface of the stick. If urinary hCG is present, it will form a complex with

the antibodies. Another antibody that is linked to an enzyme and that will react with a chromogen to produce a distinctive color is added. The hCG is sandwiched between the antibody linked to the enzyme and the antibodies bound to the solid surface. Filtering within the testing device removes unbound substances; a chromogen then reacts with the enzyme, causing a color change. Digital devices contain optical readers that provide results in words or icons.

Accuracy Rate

A pregnancy cannot be detected before implantation. Because of natural variability in the timing of ovulation, implantation does not necessarily occur before the expected onset of the next menses. One of the challenges with any home test is the ability for the user to accurately execute the testing process and evaluate the results. A study of 72 patients who used one of eight home-based pregnancy tests found that certain tests provided a greater chance of the user and a technician obtaining the same result. Clearblue Digital and Clearblue PLUS demonstrated >90% agreement; the percentage decreased for the products that are no longer available.⁷ An evaluation of test usability found most women preferred to use branded midstream digital and easy-use visual tests. Those ranking lower included store-brand tests, branded midstream visual tests, and cassette or strip tests.⁸

Another study found that 90% is the highest possible screening sensitivity for an hCG-based pregnancy test conducted on the first day of a missed period because 10% of women may not have an implanted embryo at that point. Although most pregnancy tests are advertised as 99% accurate on the day of the expected period, studies estimate that 97% is the highest possible screening sensitivity of a home pregnancy test performed by 1 week after the first day of the missed period.⁹ A test sensitivity for hCG of 12.4 mIU/mL is needed to detect 95% of pregnancies on the expected day of a missed period.¹⁰ The package insert for many tests now include a table that lists the accuracy rate based on the number of days before the expected period. The actual accuracy rate of these tests is lower because users do not carefully follow the directions; digital readouts, which are rated highly by users, appear to improve the patient's ability to use home pregnancy tests and to accurately interpret results.^{7,11}

The following recommendations are key to patients accurately performing the

test and interpreting the data:

1. Use first morning urine for the most accurate results.
2. Try to avoid getting up during the night to urinate. The test works best with “full bladder” urine because it will not be diluted.
3. Follow the guidelines for the test reaction time. Results read after the recommended time should be considered invalid because “false” lines may be present for a number of reasons after the specified reaction time. In this event, the results should be considered inaccurate, and the test should be repeated.

Interferences

A false-positive result may occur if the woman has had a miscarriage or given birth within the previous 8 weeks because hCG may still be present in the body. Medications such as Pergonal (menotropins for injection) and Profasi (chorionic gonadotropin for injection) can produce false-positive results. Unreliable results may occur in women who are perimenopausal or who have ovarian cysts or ectopic pregnancy. Oral contraceptive use does not affect test results.

A false-negative result typically is due to the user testing too early or the urine sample containing an inadequate level of hCG. If a test completed prior to a missed period yields a negative result, the woman should repeat the test in a week to verify the results.

Usage Guidelines

See the box “Patient Education for Pregnancy Tests.”

Product Selection Guidelines

Selecting the best test is based on three key benchmarks: test sensitivity, the ease of use/interpretation, and price. Product labeling for most tests states that women may use the test as early as the first day of a missed menstrual period. Some tests that can detect hCG levels at ≤ 20 –25 mIU/mL can be used 3 days before the missed period. The earlier a pregnancy test is used, the greater is the likelihood of a false-negative result. Most pregnancy tests are one-step procedures. Some tests have clear test sticks or a color change indicator that

allows the woman to see the reaction as it occurs; this feature serves as a check that the stick absorbed sufficient urine. Other products include two tests, which can be helpful if the first test is negative. The newest tests are digital and display the results as “Pregnant” or “Not pregnant,” or “Yes” or “No,” instead of showing colored lines, which eliminates the need to interpret the results. Test results generally are obtained in 3 minutes.

A study of seven nonprescription pregnancy tests found that First Response Early Result was the most sensitive and most reliable test. It detected hCG at concentrations as low as 6.3 mIU/mL. In addition, this product is expected to detect >95% of pregnancies on the first day of a missed period.¹²

Assessment of Pregnancy Test Use

Whether a pregnancy test is appropriate for a patient should be determined first by asking questions about her menstrual cycle and the number of days since intercourse. If product use is appropriate, the patient should be asked about her previous use of pregnancy tests and any difficulties she had with the tests. Questions about medical disorders and medication use also should be asked to determine whether inaccurate test results are possible or whether special measures may be required to protect the fetus.

Patient Counseling for Pregnancy Tests

During counseling on the use of pregnancy tests, the health care provider should emphasize the importance of following package instructions carefully, especially the instruction for when to begin testing. Pregnancy tests are very sensitive; therefore, the patient should be advised of medical and environmental factors that can cause inaccurate test results. It also is important for patients to pay close attention to expiration dating on the packaging, especially if the product has multiple test strips. The box “Patient Education for Pregnancy Tests” lists specific information to provide patients.

Patient Education for Pregnancy Tests

Usage Guidelines

- Unless package instructions specify otherwise, use the first morning urine because the levels of hCG, if present, will be concentrated at that time.
- If testing occurs at other times of the day, restrict fluid intake 4–6 hours before urine collection.
- Check the expiration date of the packaging. Remove test stick from packaging just before use. Remove cap from absorbent tip.
- Apply urine to testing device using whichever of the following methods is specified in package instructions: Hold test stick in the urine stream for designated time, or collect urine in a clean collection cup and dip the stick in the urine.
- After the urine is applied to the stick, lay the testing device on a flat surface. Wait the recommended time (1–5 minutes) before reading the results. Waiting the maximum allowed time may improve the sensitivity of the test.
- After reading the results, discard the testing device. If the test result is negative, test again in 1 week if menstruation has not started.
- Read all package labeling and inserts carefully for guidelines on how to complete the test, how many days before a missed period the test can be used, and how results are displayed.

Avoidance of Incorrect Results

- The most accurate results will be obtained by waiting at least 1 week after the date of the expected period. Performing the test earlier may produce false-negative results.
- Try to test the urine sample immediately after collection.
- If the sample must be tested later, store it in the refrigerator, but allow the sample to warm to room temperature for 20–30 minutes before testing. Chilled urine may produce false-negative results. Be careful not to redisperse or shake up any sediment present in the sample.

When to Seek Medical Attention

- If the second test is negative and menstruation has not begun, consult a health care provider.

- If you test positive, contact your health care provider as soon as possible to determine next steps.

Evaluation of Patient Outcomes With Pregnancy Tests

If the pregnancy test result is positive, the woman should assume that she is pregnant and contact her provider as soon as possible. In addition, if the patient is taking a medication that has teratogenic potential (e.g., Accutane, methotrexate) or any medications for chronic conditions, she should be advised to discuss with her provider any possible effects the medications may have on the fetus. If the test result is negative, the woman should review the procedure and make sure she performed the test correctly. She should test again in 1 week if her menses has not begun. If the results of the second test are negative and menses still has not begun, she should seek the advice of an appropriate health care provider.

Female Fertility Tests

Infertility is defined as the inability to become pregnant after having regular intercourse without birth control for 1 year in women younger than 35 years and for 6 months in women ages 35 years and older. *Primary infertility* is infertility in a woman who has never had a pregnancy. *Secondary infertility* is infertility in a woman who has had one or more pregnancies but cannot become pregnant again. Approximately 10% of women in the United States ages 15–44 years have difficulty becoming pregnant or staying pregnant, according to the Centers for Disease Control and Prevention. One-third of infertility cases are caused by fertility problems in women, another third are due to fertility problems in men, and the remaining cases are caused by a mixture of male and female problems or by problems that cannot be determined.^{13,14}

Basal body temperature (BBT) thermometers, ovulation prediction kits (OPKs), and devices to time sexual intercourse to coincide with optimal fertility can assist women in becoming pregnant. These tests and devices also are useful

for women who want to be more aware of their time of ovulation. However, they are not reliable methods for birth control.

Available nonprescription products for ovulation prediction include ovulation detection devices, BBT thermometers, and urine tests.^{15–20} Each detection method has a different mechanism of action and method of use. Many of the newer products are accompanied by a mobile app that downloads information and allows the user to analyze data compiled from built-in algorithms. More information about selected products and key features is provided in **Table 48–3**. Women should select their preferred method, but health care providers are encouraged to become actively involved in educating women on the pros and cons of each option and in assisting with the selection process.

TABLE 48–3 Selected Nonprescription Ovulation Prediction Tests and Devices and Features

Trade Name (Website)	Product Features
OvuSense vaginal temperature sensor ¹⁵ (www.ovusense.com/us)	• Ovusense sensor inserted into vagina overnight; measures CBT every 5 minutes • Sensor removed and cleaned in the morning before downloading of data to the Ovusense App • Data uploaded to secure cloud database • Used for two cycles to obtain data for “short range” 4-day ovulation window • Can alert user up to 24 hours before ovulation based on in-cycle data • Can compare ovulation dates and cycle pattern by scrolling on app • Real-time data shared through app • 99% claimed accuracy rate for detecting ovulation date
NaturalCycles ¹⁶ (www.naturalcycles.com)	• Thermometers and mobile application • Pairs BBT monitoring with algorithm that uses patient cycle information to predict fertile window • Patient takes AM temperature; enters data into app • Can add menstrual period data for more accurate prediction • Can add extra information, including cycle symptoms, mood changes, sexual intercourse data

Trade Name (Website)	Product Features
	• 99.5% accuracy in identifying fertile days
Ava Sensor Bracelet¹⁷ (www.avawomen.com)	• Patient wears Ava Sensor Bracelet to bed • Measures skin temperature changes, pulse rate, heart rate, perfusion, respiratory rate • Measures datapoints 25 times per second • Device synced each morning • App takes data and identifies 5 best fertile days • Tested for women who have cycles of 24–35 days • Not to be used in patients with PCOS or irregular cycles • 12-hour rechargeable battery • 50% more accurate than traditional calendar method
OvaCue Fertility Monitor¹⁸ (www.fairhavenhealth.com/product-category/fertility/ovulation-prediction/)	• Hand-held fertility monitor with saliva and cervical mucus sensors; requires a few seconds for each daily test • Measures estrogen-induced changes in the electrolyte levels in saliva and cervical mucus • Monitor tracks trends and attempts to identify a specific trend (“cue peak”) that marks the beginning of the fertile window • Once cue peak detected, monitor identifies dates of low to peak fertility, providing 5–7 days advance notice of ovulation • Data uploaded to OvaGraph using USB cable (included); stores up to 4 months of readings • Can be used by women with irregular cycles and PCOS • Interprets each user reading in relation to previous user readings • Comes with access to OvaGraph, a full-featured fertility charting tool • Access to OvaCue specialists at Fairhaven Health provided to assist with data interpretation • Can share charts with health care providers • Technology shown to be >98% accurate in NIH-funded studies

Trade Name (Website)	Product Features
iFertracker Smart Fertility Tracker¹⁹ (www.ifertracker.com)	• Wearable fertility tracker • Synced via Bluetooth with app; device gathers continuous BBT data while user sleeps • Automatically charts data and provides user with daily fertility snapshot • Built-in algorithm filters out events that have thermal impact on BBT • Sensor placed directly beneath crease of armpit; daily site rotation recommended • Device identifies invalid data (e.g., mid-night arisings) and accommodates variations in sleeping schedules • Collects 20,000 data points per night • Notifications provided for optimum times for conception • BBT chart can be exported directly from app • Testers encouraged to use mobile app's health log to record moods, stress, sexual activity, cervical mucus quality, and sleep to increase accuracy of ovulation prediction feature • Temperature accuracy within 0.05°C and 0.09°F
Mira Analyzer and App²⁰ (www.miracare.com)	• Combines tracking of hormonal and menstrual patterns with learning algorithm and smartphone connectivity • Provides quantitative hormone measurements and predicts ovulation/fertility window • Tracks LH and estrogen levels • Works in women with irregular cycles, PCOS, or hormone imbalance • Allows entry of full suite of additional fertility tracking data (e.g., intercourse and menstrual period dates, cervical mucus levels, cervical anatomy, BBTs) • Offers advanced algorithm that provides personalized and accurate insight for fertility window • 99% accuracy rate
Clearblue Fertility Monitor with Touch Screen (www.clearblue.com/ovulation-tests/fertility-monitor-with-touch-screen)	• Designed to identify all fertile days • Used with Clearblue Test Sticks (sold separately)

Trade Name (Website)	Product Features
	• Urine collection via midstream or dip (suggested) methods • Test stick inserted into device; results provided in 5 minutes • Touch Screen technology with alarm reminder, calendar, and ability to record other data (e.g., dates for menstrual cycles and sexual intercourse) • Measures LH and E3G levels • Provides three ranges for fertility status: low, high, peak • Stores up to six cycles of data that can be shared with physician • 97% consistency with ultrasound
Clearblue Connected Ovulation Test System (www.clearblue.com/ovulation-tests/connected-ovulation-test-system)	• Measures LH and E3G levels • Identifies ≥ 4 fertile days • Reusable holder for test sticks • Results provided in 5 minutes • Urine collection via midstream or dip (suggested) method • Connects via Bluetooth to smartphone • Smart reminders for best days to test based on personal data
Clearblue Advanced Digital Ovulation Test (www.clearblue.com/ovulation-tests/advanced-digital)	• Urine collection via midstream or dip (suggested) method • Test stick inserted into device; results provided in 5 minutes • Measures both LH and E3G levels • Identifies ≥ 4 fertile days • Reusable holder/reader for the test sticks • Algorithm adapts to user's hormone profile
Clearblue Easy Ovulation Kit (www.clearblue.com/ovulation-tests/easy-ovulation-kit)	• Urine collection via midstream or dip (suggested) method • Test stick (absorbent tip) plus result window included • Results provided in 3 minutes • Measures only LH level • Identifies 2 most fertile days

Trade Name (Website)	Product Features
	• Results indicate “Yes” or “No” for LH surge • Includes one pregnancy test
Clearblue Digital Ovulation Test (www.clearblue.com/ovulation-tests/digital)	• Urine collection via midstream or dip (suggested) method • Test stick inserted into device; results obtained in 3 minutes • Measures only LH level • Identifies 2 most fertile days • Digital smiley face technology to identify LH surge • Reusable holder/reader for test sticks
First Response Ovulation Plus Pregnancy (www.firstresponse.com/en/product-listings/ovulation-plus-pregnancy-test)	• Urine collection via midstream or dip method • Identifies 2 most fertile days • Measures LH level only • Results provided in 5 minutes • Includes one pregnancy test

Key: BBT = Basal body temperature; CBT = core body temperature; E3G = estrone-3-glucuronide; LH = luteinizing hormone; NIH = National Institutes of Health; PCOS = polycystic ovarian syndrome; USB = universal serial bus.

Basal Thermometry

For many years, women have measured their BBT to predict the time of ovulation. Resting BBT usually is between 97.0°F (36.1°C) and 97.5°F (36.4°C) during the first part of the female reproductive cycle. Approximately 24–48 hours after ovulation, it rises to a level closer to normal (i.e., 98.6°F [37.0°C]).²¹

Usage Considerations

Mechanism of Action

When using basal thermometry, women take their temperature (orally, rectally, or vaginally) with a basal thermometer each morning before arising. These temperature measurements are then plotted graphically. A rise in

temperature signals that ovulation has occurred. When the increase occurs, women who want to become pregnant should have intercourse as soon as possible to maximize their chances of conception.

Accuracy Rate

The only equipment necessary for monitoring BBT is a basal thermometer, which has smaller gradations than a regular thermometer (i.e., 0.1 degree vs. 0.2). Although basal thermometry is a relatively simple method of ovulation prediction, interpreting temperature data can be confusing. The temperature increase that follows ovulation is small (0.4°F–1.0°F [0.2°C–0.6°C]). Women who have trouble reading a thermometer may miss the rise altogether; in this case, a digital model should be used.

Interferences

Several factors, such as emotions, movements, and infections, can influence the BBT. Eating, drinking, talking, and smoking within 30 minutes of checking one's temperature should be postponed until after a measurement is obtained.

Usage Guidelines

See the box “Patient Education for Ovulation Prediction Tests and Devices.”

Product Selection Guidelines

Digital thermometers that track multiple temperature readings for the user are available, although they are more expensive than digital thermometers that lack this feature.

Urinary Hormone Tests

Ovulation prediction tests that use urine samples to estimate the time of ovulation are marketed to women who are having difficulty conceiving and need to pinpoint ovulation. Most of these products determine ovulation by detecting the urinary LH level, and some also have the ability to assess the presence of estrone-3-glucuronide (E3G), a component of estrogen. E3G levels rise and fall in a pattern similar to that of LH but peak sooner, thus expanding the window of detection.

Usage Considerations

Mechanism of Action

Urine-based ovulation prediction tests use antibodies specific to LH to detect the surge in its level. An enzyme-linked immunosorbent assay (ELISA) elicits a color change that indicates the level of LH in the urine. The LH surge is revealed by a difference in color or color intensity from that noted on the previous day of testing. The intensity of color on the test stick is directly proportional to the quantity of LH in the urine sample. The standard digital test has a similar mechanism of action: When LH is detected in urine, the test stick shows a blue surge line that is read by the digital device. The digital device will display a smiley face, which means that LH has been detected and that a woman's chances for conceiving are increased over the next 48 hours. This device also sets an individualized threshold for measuring the user's LH readings and compares them from baseline. The digital device helps to decrease human error. Generally, early morning collection of urine is recommended because the LH surge usually begins early in the day, and the urine concentration is relatively consistent at this time. Some products do not specify a time of day and require only that a consistent time of day be used.

Testing should begin 2–4 days before the estimated day of ovulation. The kit contains directions to determine when to begin testing; the starting date is based on the average length of the past three menstrual cycles. If the cycle varies by >3–4 days each month, the woman should use the shortest menstrual cycle to determine the starting date.

A study comparing pregnancy rates in women who used an ovulation prediction system with those who did not use a system was conducted. The proportion of women who used an application-connected ovulation test system that measured both LH and an estrogen metabolite and who became pregnant after one cycle was significantly greater (25.4%) than for women who did not use a testing system (14.7%; $P < 0.001$). After two cycles this trend continued: 36.2% for those using the system versus 28.6% for those not testing; $P = 0.026$.²²

Surveys of those who used a home digital ovulation test reported positive experiences (ovulation confirmation, better understanding of the menstrual cycle) and negative experiences (uncertainty about results, changes in their

relationship with their partner, emotional consequences). The survey also found that women trying to conceive want access to high-quality information about the use of these tests and the results.²³ Other studies found that use of these tests did not significantly impact the user's stress levels. (See the section "Product Selection Guidelines" for further information.)

The Clearblue Advanced Digital Ovulation Test and the Clearblue Fertility Monitor test increase the window for ovulation detection by measuring the hormones LH and E3G, a component of estrogen. The advanced digital product uses a test holder and disposable test sticks that are inserted into the holder for reading. The test holder contains special software that tracks changes in a woman's hormone levels from baseline to display peak and high fertility trends. The Clearblue Fertility Monitor with Touchscreen is a palm-size device with a light-emitting diode screen that allows the woman to insert a test stick into the monitor to obtain results. To accurately predict ovulation, the patient must establish a baseline using data about fluctuations in her hormone levels. For the first month, the test monitor will instruct the woman to test daily for 10–20 consecutive days, starting on approximately the sixth day after the beginning of menstruation. Using these data, the monitor calculates the time window for optimum chances of conception. After establishing her baseline, the woman tests for 10–20 days each month, depending on her cycle length. Each day's results are displayed as "low," "high," or "peak fertility." A low result indicates a small chance of conception; a high result indicates an increased chance of conception. The reading typically is displayed for 1–5 days, leading up to the peak fertility period for each cycle. A peak fertility reading indicates the highest chance of conception and usually is observed 2 days before ovulation.

When compared with no use of a detection method for ovulation, another test, the Clearblue Connected Ovulation Test System, was shown to double a woman's chances of getting pregnant in the first cycle of use. The product identifies 4 or more fertile days each cycle and tracks two key fertility hormones (E3G and LH). During testing, the product connects via Bluetooth to a smart phone, and the results are synced and displayed on the phone. The provided calendar and cycle comparison charts allow the user to set smart reminders.²⁴

Data evaluating common devices showed that the Clearblue Easy Fertility Monitor with Touch Screen reported a significantly higher pregnancy rate

during the first two cycles in women using this product compared with control groups (22.7% vs. 14.4%). The manufacturer claims this testing device and the Clearblue Digital Ovulation Test, which features a dual hormone indicator, can identify 4 or more fertile days with an accuracy rate of >99% and with a sensitivity to determine ovulation of 97%. Both monitors are digital immunoassays incorporating a disposable microspectrophotometer.²⁵

Interferences

Medications used to promote ovulation (e.g., menotropins) artificially elevate LH levels and may cause false-positive results in ovulation prediction tests that measure only LH. The true LH surge can be detected in patients receiving clomiphene as long as testing does not begin until the second day after the drug therapy ends. Medical conditions associated with high levels of LH, such as menopause and polycystic ovarian syndrome (PCOS), may cause false-positive results for ovulation. Pregnancy also can cause a false-positive result for ovulation. If the patient has recently discontinued using oral contraceptives, the start of ovulation may be delayed for one to two cycles. Therefore, it would not be appropriate to use a home ovulation prediction test until fertilization has been attempted unsuccessfully for 1–2 months after discontinuation of the use of oral contraceptives.

The presence of PCOS; medications that affect the cycle (e.g., oral contraceptives, certain fertility treatments, estrogen-containing medications); impaired liver or kidney function (which alters levels of E3G); breastfeeding; tetracycline; and perimenopause may produce false-positive results with the Clearblue Fertility Monitor. Women who have been pregnant recently, stopped breastfeeding, or stopped using hormonal contraception should consider waiting until they have at least two consecutive natural menstrual cycles (lasting 21–42 days) before using this product.

Usage Guidelines

See the box “Patient Education for Ovulation Prediction Tests and Devices.”

Product Selection Guidelines

The available ovulation prediction tests vary in the length of time needed to complete the test, method of applying urine to the test stick, number of individual tests provided, and method for reading results. Patients with longer

cycles may benefit from purchasing kits that contain more testing sticks. One of the concerns expressed by some patients and providers is the added stress involved with using an ovulation testing system. Two studies determined that the use of a digital home ovulation test did not increase the level of stress in women trying to conceive. Of note, the authors did attempt to remove the potential bias related to the percentage of women in each group (study and control) who conceived.^{26,27}

The advantages of OPKs include

- They are easy to use.
- They provide information about the approach of ovulation.
- They accurately predict ovulation: 80% accurate with 5-day testing; 95% accurate with 10-day testing.
- They can be combined with other methods, such as BBT.
- Although ideal, they do not require testing of the first urine in the morning. Directions suggest testing within the same 6-hour window each day to obtain the most accurate results.²⁸

The disadvantages of OPKs include

- Regular testing is costly.
- Results could be difficult to interpret if the LH surge is low.
- They are not the most accurate system for women with PCOS.
- They cannot be used to confirm ovulation because an LH surge with no egg release can occur.
- No results are provided if testing is done too early or when the woman is not ovulating.

The Clearblue Fertility Monitor and Clearblue Advanced Digital Ovulation Test have some possible advantages over the traditional ovulation prediction kits, which detect only LH levels. The traditional kits identify the 24- to 48-hour window around ovulation. Both Clearblue products identify a larger window of several days and do not require that patients interpret color changes. In addition, these products measure both LH and E3G levels, increasing the specificity of ovulation prediction. However, no studies have proved that these advantages increase a woman's chance of accurately identifying ovulation and, ultimately, conceiving. Compared with the traditional ovulation prediction kits, which detect only LH levels, the initial cost of the Clearblue Fertility Monitor with Touchscreen is higher, but it is reusable for an indefinite period, with only

the additional expense of purchasing more test sticks.

Assessment of Female Fertility Test Use

The patient should be asked privately about her reasons for using an ovulation prediction test. If the reason is difficulty in conceiving, the patient should be asked whether she has consulted a health care specialist about a possible fertility problem and whether she has previously used ovulation prediction tests or devices. Questions about other possible pathology and medication use are appropriate to determine possible interferences with test results or temperature measurements. Case 48–1 illustrates assessment of a patient who wishes to become pregnant.

Case 48–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has been trying to become pregnant for 2 months. She asks if the ovulation kits can help.
b. Medical history, including family history	Menstrual cycle: 29 days; regular cycle in the past. She has regular intercourse with her husband of 3 years.
c. Patient's identity	Cherise Turner
d. Patient's age, gender, height, and weight	31 years old, female, 5 ft 6 in., 145 lb
e. Patient's occupation	School assistant principal
f. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No current medical conditions; multivitamin and probiotic daily

Relevant Evaluation Criteria	Scenario/Model Outcome
g. Prior use of diagnostic/monitoring test	Has never used any home diagnostic tests.
h. Potential problems with performing/interpreting test	Cherise does not know how to use an ovulation prediction test.
Assess	
2. Determine whether self-testing is appropriate.	Self-testing is appropriate.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend an ovulation test today. Educate the patient to follow all manufacturer's instructions when performing the self-test. (2) Advise the patient to make an appointment with her HCP if she does not become pregnant within 1 year. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because the patient likes technology, she is interested in trying a fertility monitor.
Implement	
6. Describe the testing procedure to the patient.	
a. Specific instructions	"When you perform the test, follow the instructions carefully."
b. How to avoid incorrect results	See the box "Patient Education for Pregnancy Tests."

Relevant Evaluation Criteria	Scenario/Model Outcome
Solicit follow-up questions from the patient or caregiver.	“How long should I do the tests before seeing a doctor?”
Answer the patient’s or caregiver’s questions.	“It can take up to a year for couples to conceive without the help of ovulation prediction. If you are able to predict ovulation consistently with the monitor for 3 months and have not become pregnant, you should make an appointment with your health care provider.”
Follow-up: Monitor and Evaluate	
7. Assess patient outcome.	“You can call if you have any questions while doing the test or are concerned about the results.”

Key: HCP = Health care provider.

Patient Counseling for Female Fertility Tests

To use ovulation prediction products effectively, a woman must know approximately when ovulation occurs or be willing to track three menstrual cycles to determine when it occurs. The health care provider should explain hormonal fluctuations during the cycle and how they relate to the use of ovulation prediction tests and devices. The provider also should explain the reason for the number of tests or measurements that must be performed with each type of product. Finally, counseling should emphasize consistent use of the products for at least 3 months to achieve accurate results. The box “Patient Education for Ovulation Prediction Tests and Devices” lists specific information to provide patients.

Evaluation of Patient Outcomes With Female Fertility Tests

Ovulation prediction products should not be used for >3 months. If conception does not occur within this period, the woman should see a health care provider.

Patient Education for Ovulation Prediction Tests and Devices

Basal Body Temperature (BBT) Thermometers

Usage Guidelines

- Read the instructions thoroughly before using the thermometer.
- Choose one method of taking temperatures (orally, vaginally, rectally; review product labeling for specific recommendations), and use that method consistently.
- Take temperature readings at approximately the same time each morning. Take temperature just before rising each morning after at least 5 hours of sleep. If using a regular basal thermometer, plot the temperatures on a graph. A rise in temperature indicates that ovulation has occurred.

Avoidance of Incorrect Results

- Do not move while taking temperature measurements.
- Note that emotions can affect temperature measurements.
- If fever is present, discontinue the measurements until the fever is resolved. Resume measurements on the first day of the menstrual cycle that occurs after the fever is gone.
- Do not eat, drink, talk, or smoke within 30 minutes of taking temperature measurements.

Ovulation Prediction Tests

Usage Guidelines (Except Clearblue Fertility Monitor With Touch Screen)

- Start using the test 2–3 days before ovulation is expected.

- Follow the manufacturer's specific directions for the timing of urine collection. If the first morning urine is not tested, restrict fluid intake for at least 4 hours before testing. Avoid urinating until you are ready to test the urine so that the urine will not be diluted.
- Test the urine sample immediately after collection.
- If immediate testing is not feasible, refrigerate urine for the length of time specified in the product's directions. Allow refrigerated sample to stand at room temperature for 20–30 minutes before beginning the test.
- Do not shake up any sediment that may be present in the sample.
- Either hold a test stick in the urine stream for the specified time, or collect urine in a collection cup and dip the stick in the urine.
- After the urine is placed on the testing device, read the results in 3–5 minutes, depending on the manufacturer's instructions.
- Watch for the test's first significant increase in color intensity or, if using a digital test, the display of an indicator, such as a 'smiley face', suggesting a result. Either result indicates that the surge of LH has occurred and that ovulation will occur within 1 or 2 days.
- Once the LH surge is detected, discontinue testing. Remaining tests can be used later, if necessary.
- If the LH surge is not detected, carefully review the testing instructions to ensure that they were performed properly.
- If the testing procedure was accurate, ovulation may not have occurred or testing may have occurred too late in the cycle. Consider testing for a longer period and earlier in the next cycle to increase the chances of detecting the LH surge.
- Many tests now come with an app or other technology that complements the actual test to improve predictability.

Usage Guidelines for Clearblue Fertility Monitor With Touch Screen test

- For the first month, begin testing on the sixth day after menstruation starts; the monitor will indicate how many total days you should test.
- For subsequent months, test the number of days indicated by the monitor.
- Remove test stick from packaging just before use.

- Hold the test stick in the urine stream; insert stick in monitor.
- Discard test stick after use.

Avoidance of Incorrect Results

- Fertility medications, PCOS, menopause, and pregnancy can cause false-positive results for ovulation. Note: Some tests can be used by patients who have PCOS. If applicable, package labeling should provide this information.
- With the Clearblue Fertility Monitor With Touch Screen, estrogen-containing medications, impaired liver or kidney function, breastfeeding, tetracycline, and perimenopause can cause false-positive results.
- Recent pregnancy or discontinuation of oral contraceptives or breastfeeding will delay ovulation for one or two cycles. Start testing after two natural menstrual cycles have occurred.

When to Seek Medical Attention

- If a negative test is obtained or there are questions about any test result, see a health care provider for evaluation and further testing.

Key: LH = Luteinizing hormone; PCOS = polycystic ovarian syndrome.

Male Fertility Tests

Infertility affects an estimated 15% (48.5 million) of couples globally. Males are found to be solely responsible for 20%–30% of infertility cases and contribute to 50% of cases overall; 12% of men worldwide are infertile and may not know it.²⁹ Sperm concentration is one of the many factors used to determine male fertility. Because many additional factors play a role in male infertility, a positive test for sperm count is not a guarantee of fertility. A decreased sperm concentration is known to result from epididymitis, orchitis, hormone imbalances, anabolic steroid use, smoking, heavy alcohol use, and diabetes. A systematic review and meta-regression analysis of data from 1973 to 2011 that

looked at recent trends in sperm counts (concentration and total count) found a significant decline in both measures. Specifically, there was a 50%–60% decline among men unselected by fertility from the following geographic areas: Australia, Europe, New Zealand, and North America.³⁰

Usage Considerations

The available male fertility tests measure sperm concentration within ranges, usually low (<15 million [M]/mL), moderate (15 M/mL–55 M/mL), and optimal (>55 M/mL). The low fertility range differs slightly from the World Health Organization (WHO) cutoff value of 20 M/mL.³¹ Test results suggesting male infertility are manufacturer specific, so users are encouraged to review the manufacturer packaging and insert information carefully. In most cases, at least two test results are needed to validate a man’s status. Some tests also assess sperm volume, motility, and morphology, which may be important variables in assessing fertility status.

Mechanism of Action

Multiple tests are available to assess sperm count (Table 48–4). The Spermcheck Fertility semiquantitative test works by detecting the concentration of a sperm-specific protein (antigen SP-10) in the semen, which is then used to determine the sperm count. The semen is mixed with a buffer to help release the specific protein from the sperm. The mixture then binds to a colloidal gold compound in the test well and flows through the test. If the sample contains 20 million or more cells per milliliter, a reddish line appears, indicating a positive result. The test kit contains all the necessary supplies for the test: a testing device, testing solution, transfer device, and sperm collection cup.³²

TABLE 48–4 Selected Nonprescription Male Fertility Tests and Devices	
Trade Name (Website)	Product Features
Trak Male Fertility Testing System (trakfertility.com/)	• Tests for sperm count and semen volume • Measures sperm count as Optimal: >55 M/mL; Moderate: 15–55 M/mL; or Low: <15 M/mL • Includes reusable Trak Engine, two sperm count tests, and two semen volume tests.

Trade Name (Website)	Product Features
	• Semen sample collected in provided cup • Sample loaded into a test Prop and attached to Engine • Sample “spun”; sperm count results provided after 6 minutes • Sperm volume also assessed based on comparison of actual results to WHO standards
myLab At Home Male Fertility Test www.mylabbox.com/at-home-std-kits/fertility/; www.yospermtest.com/#)	• Includes two rapid tests • Measures motile sperm concentration, motility, and morphology • Provides results in one of three ranges: Optimal: >55 M/mL; Moderate: 15–55 M/mL; or Low: <15 M/mL • Quality score and fertility improvement app • Video provided • YO Home Sperm Test Kit provided via partnership between myLab and Medical Electronic Systems • Takes approximately 30 minutes to obtain results • Testing twice recommended to establish baseline for measuring progress; then testing at least monthly outside partner’s fertile window recommended • >97% accuracy rate in clinical trials
SpermCheck Fertility Home Sperm Test www.spermcheck.com/fertility/product-info/)	• Sample collected at home; must sit for 20 minutes • All necessary supplies included • Semen sample mixed with proprietary solution; mixture is added to SpermCheck Fertility Device for analysis • Takes approximately 10 minutes to complete remaining steps and receive results • Positive (normal) results: sperm count ≥ 20 M/mL; negative (low) results: sperm count <20 M/mL
Fellow Kit for semen analysis³⁷ www.meetfellow.com)	• Test purchased from manufacturer’s website

Trade Name (Website)	Product Features
	• Physician network reviews and approves purchase • Test completed at home; results sent to patient and, if requested, patient's physician • Tests for sperm motility, morphology, count, volume, and concentration • Completed test mailed to CLIA-certified laboratory • Results provided within 10 days of laboratory's receipt of completed test • Lifestyle recommendations provided to ensure accuracy of test results

The Trak Male Fertility Testing System is a quantitative assessment of sperm concentrations of ≥ 15 M/mL, which is within the three ranges specified earlier. Semen is collected and loaded into the proprietary centrifugal device that uses density gradient separation to isolate sperm from the sample. The sample is spun to filter contaminants; then it is sent to a metering chamber where results are visible in a column corresponding to one of the three concentration ranges. The Trak Testing System contains all necessary supplies for the user to complete two tests; supplies can be purchased for additional tests.^{33,34}

The YO Home Sperm Test Kit, the test kit promoted by myLab as the myLab At Home Male Fertility Test, is used with the proprietary software application to provide a qualitative assessment of motile sperm concentration (MSC). A semen sample is collected, liquefied with eosin and chymotrypsin, and then pipetted onto a cover-slipped slide. This slide is inserted into the YO clip that is attached to the user's smartphone. The test measures MSC as either low (< 6 M/mL) or moderate/normal (≥ 6 M/mL). The kit comes with all the necessary supplies to conduct two tests; additional supplies can be purchased and used with the already-purchased technology.^{35,36}

The Fellow Kit for Semen Analysis is a system for at-home sample collection that is mailed to a Clinical Laboratory Improvement Act (CLIA)-certified laboratory for analysis. The sample is analyzed for sperm motility, morphology, concentration, volume, and count. Results usually are provided within 10 days

of sample receipt, and the manufacturer's physician network is available to assess the data and provide recommendations.³⁷

Accuracy Rate

Testing performed by the various manufacturers and independent researchers found the overall accuracy of the various tests to be between 82.4% and 98%.^{32,34-36}

Interferences

No interferences that can cause false positive or negative results are known.

Usage Guidelines

See the box "Patient Education for Male Fertility Tests."

Product Selection Guidelines

Multiple male fertility tests are currently on the market. Because some tests require the user to determine visually whether a line is present, patients with visual difficulties should seek assistance in interpreting the test results. Those more comfortable with a process completed entirely in their home can select one of several products; others who wish to use a CLIA-certified laboratory have that option.

Assessment of Male Fertility Test Use

The patient should be asked privately whether he has consulted a health care provider about a possible fertility problem and whether he has previously used male fertility tests.

Patient Counseling for Male Fertility Tests

The patient should be advised that most of these tests do not account for sperm motility, morphology, and other factors that contribute to male fertility. The box "Patient Education for Male Fertility Tests" lists specific information to provide patients.

Evaluation of Patient Outcomes With Male Fertility Tests

If a negative result is obtained, the patient should contact his health care provider or a fertility specialist. If a negative result is obtained but the patient is trying to increase his sperm count, he can test his fertility on a more regular basis, usually recommended as every 3 months.

Patient Education for Male Fertility Tests

Usage Guidelines

- The semen sample is collected by masturbation, with semen directed into the provided collection cup or container.
- Each manufacturer has very specific processes that must be followed. The following are for the more commonly used male fertility tests:

SpermCheck Kit

- Because freshly ejaculated semen is gel-like, the sample must be allowed to sit for 20 minutes, during which it will thin to a liquid consistency for testing.
- Gently stir the cup with the semen transfer device at least 10 times.
- Insert the semen transfer device into the sample cup, and withdraw semen to the level of the black line, while trying to avoid creating any air bubbles.
- Gently add the semen to the upright SpermCheck solution bottle. Gently mix the solution by turning the bottle upside down at least 5–10 times. Let the solution bottle stand for 2 minutes before completing the next step.
- Add 6 drops of the solution to the sample well on the SpermCheck device that is labeled “S.”
- Read results exactly 7 minutes after adding the solution.
- To read the test, make sure there is a reddish line beside the “C” (Control) position on the device. If a control line is not present, the

test did not work accurately. If a reddish line appears next to the “T” (test) position on the device, the result is positive (sperm ≥ 20 million/mL). If no line is present at the test position, the sample is negative (sperm ≤ 20 million/mL). Do not compare the faintness or darkness of the lines between the control and test positions. The presence of a line is a positive test result.

YO Sperm Kit

- Collect semen sample in the provided cup.
- Add liquifying powder to the sample; sample may turn a pinkish color.
- Wait 10 minutes to ensure that the liquification process is complete.
- Attach the YO Clip (provided in the kit) to your smartphone.
- Withdraw some of the sample from the cup using the pipette provided.
- Apply the sample onto the YO slide in the designated area.
- Insert the slide into the YO Clip.
- Tap “Start Testing” and results will be provided in 2–3 minutes.
- Provides results in 1 of 3 ranges: Optimal: >55 M/mL; Moderate: 15–55 M/mL; or Low: <15 M/mL.

Trak Male Fertility Testing System

- Collect a semen sample in the cup provided in the kit.
- Load sample into the test Prop, and attach the Prop to the Engine.
- Sample will be “spun”: after 6 minutes, the sperm count results are provided.
- Test measures sperm count as Optimal: >55 M/mL; Moderate: 15–55 M/mL; or Low: <15 M/mL.

Avoidance of Incorrect Results

- Collect a semen sample between 2 and 7 days after the last ejaculation.
- Test as soon as possible after sample collection.

When to Seek Medical Attention

- If a negative test is obtained, see a health care provider for evaluation and further testing.
- If an optimal test result is obtained but pregnancy is not achieved after 1 year, see a health care provider.

Fecal Occult Blood Tests

Colorectal cancer (CRC) is the second most common cause of cancer death in the United States. Every 3 years, the American Cancer Society provides an update of CRC occurrence based on incidence data (available through 2016) from population-based cancer registries and mortality data (through 2017) from the National Center for Health Statistics. In 2020, approximately 147,950 individuals will have been diagnosed with CRC, and 53,200 will have succumbed to the disease. Data suggest that those in the screening-age groups (see the section “Assessment of Fecal Occult Blood Test Use”) saw declines in incidence and mortality. An increase in access to guideline-recommended screening will enhance progress against CRC.³⁸

One early and common symptom of CRC is bleeding. Checking for hidden (occult) blood in the stool is an easy way to screen for a potential colon problem. Fecal occult blood tests (FOBTs) can be used as an adjunct to more invasive tests to detect CRC and other causes of gastrointestinal (GI) bleeding.

CRC occurs most commonly in patients with a history of this type of cancer in a first-degree relative, adenomatous intestinal polyps, certain inherited genes, or inflammatory bowel disease. The incidence of CRC has been associated with advancing age, consumption of high amounts of red and processed meat, overweight/obesity, physical inactivity, smoking, and heavy alcohol use.³⁹

Usage Considerations

Two types of nonprescription FOBTs are available: pseudo-peroxidase-based toilet test (referred to as FOBT in the following discussion) and immunochemical-based FOBT (iFOBT), also referred to as the fecal immunochemical test. Both kinds of tests are noninvasive and easy to use in

the privacy of the home. A systematic review and meta-analysis of studies comparing guaiac-based FOBTs (gFOBT) with new-generation iFOBTs in CRC screening were performed. Data showed a statistically significant difference in the performance of gFOBT and iFOBT tests, with areas under the curve values of 0.77 and 0.87, respectively. Compared with the gFOBTs, the newer-generation iFOBTs were found to have a significantly higher diagnostic performance, suggesting that only fecal immunochemical tests should be used for CRC screening programs.⁴⁰

Accuracy Rate

The sensitivity and specificity values of FOBT for CRC detection obtained with guaiac tests (Hemocult cards) vary from 0.13 to 1 and from 0.69 to 0.99, respectively.⁴¹ The values for the iFOBT range from 0.42 to 0.94 and 0.4 to 1, respectively. FOBTs have better diagnostic performance for detecting distal colon cancer than proximal disease.⁴²

Mechanism of Action

Blood may be present on the surface of or contained within the stool matrix. In general, matrix blood originates in the upper GI tract, whereas surface blood comes from the lower tract. FOBT kits are more likely to detect blood from lower GI abnormalities. The FOBT toilet test detects blood in feces by a pseudoperoxidase reaction utilizing a chromogen that, when oxidized by hemoglobin, produces a blue-green color. The appearance of this color indicates a positive test.^{43,44} This type of kit is based on the premise that a significant amount of fecal blood from stool will remain on the surface of the toilet bowl water after a bowel movement.

The iFOBT uses antibodies to detect human hemoglobin protein in stool. This test reacts to heme, a part of the human hemoglobin protein, which is found in red blood cells; the test also is less likely to react to bleeding from parts of the upper digestive tract, such as the stomach. With this test, stool is sampled from toilet tissue after a bowel movement.

Interferences

In addition to cancer of the colon and rectum, blood in the stool can signify a number of conditions, including ulcers, Crohn's disease, colitis, anal fissures,

diverticulitis, and hemorrhoids. Any of these conditions can give a positive result to an FOBT.

Women who are menstruating should delay testing until menses has ceased. Menstrual blood that is present in the toilet bowl water or contaminates the stool sample can produce a positive result.

Aspirin, nonsteroidal anti-inflammatory drugs (NSAIDs), and steroids may cause sufficient gastric bleeding to produce positive results. These medications ideally should be avoided for at least 2–3 days before testing and during the test period. However, available studies have not suggested a benefit in withholding these agents and have not directly assessed their impact on sensitivity or specificity.⁴⁵ Rectally administered medications also should be avoided.

False-Positive Guaiac FOBT

False-positive gFOBT results may be caused by the presence of animal-derived heme; consumption of large amounts of green vegetables that may have chlorophyll-mediated pseudoperoxidase activity; consumption of foods that have naturally high levels of peroxidase (e.g., broccoli, cauliflower, cantaloupe, carrots, squashes, figs, horseradish, grapefruit, melons, tomatoes, pumpkins, courgettes); or medications including NSAIDs, vitamin C, and iron. Chemical FOBTs could be positive if any bleeding is present in the GI tract. Of note, the diagnostic value of iFOBT is limited to the detection of bleeding from the lower GI tract because globin from the upper GI tract is readily degraded by digestive proteolytic enzymes.⁴⁶

The FOBT toilet tests are not specific for human blood and, theoretically, may produce false-positive results if red meat is consumed. However, a meta-analysis of dietary restriction studies found no difference in response rates between restricted and nonrestricted meat consumption before physician-based testing.⁴⁷ The manufacturer's instructions say no dietary restrictions are necessary.⁴³ Toilet bowl cleaners also may produce false-positive results in the toilet tests. The box "Patient Education for Fecal Occult Blood Tests" lists measures for avoiding inaccurate test results.

Usage Guidelines

See the box "Patient Education for Fecal Occult Blood Tests."

Patient Education for Fecal Occult Blood Tests

Toilet Test Products (EZ-Detect)

- Remove toilet tank cleansers or deodorizers, and flush toilet twice before testing.
- Keep test pads in original foil pouch until time of testing.
- Before testing, use one test pad to perform a water quality check. Hold the pad by its corners and drop it into the toilet bowl. If any trace of blue/green appears in the in the test area of the pad when the pad is placed in the toilet water, use another toilet to complete the testing. Perform this water quality check on the second toilet as well.
- Immediately after a bowel movement, place a pad in the toilet bowl, printed side up. After 2 minutes, check for the appearance of a color change (blue/green) on the test pad (positive result).
- If color changes differ from blue/green, discard the pad and repeat the test after the next bowel movement.
- Repeat the test on the next two bowel movements.
- If results are negative for all three tests, use remaining pad to perform a quality check of the test pads using the positive control chemical package that is provided. Flush the toilet and empty the contents of the package into the bowl as it refills. Float the remaining test pad in the water, printed side up. After 2 minutes, check for a blue/green color change, which indicates the test pads are working properly. If the color change does not appear, call the product manufacturer's assistance line provided with the product.

Source: EZDetect.com. ColoRectal Cancer Information Center: Screening Can Save Lives. Available at: <https://www.ezdetect.com/index.html>; accessed August 26, 2020.

Stool Application Product (Second Generation FIT)

- After a bowel movement, wipe the anal area as you normally do, and retain a small amount of stool on toilet paper.
- Unscrew cap/wand from buffer tube.

- Collect a small sample of stool onto the grooves of the buffer tube cap/wand.
- Return cap/wand to tube and screw tightly. Shake tube for 3 seconds. Unscrew smaller clear cap at top of tube.
- Apply 3 drops from tube to sample well.
- Read results after 5 minutes. There should be a red line at “C,” which indicates the test is working. A positive test also will have a line at “T.” Do not read results if 10 minutes has elapsed.

Source: Pinnacle BioLabs. Fecal Immunochemical Test. Available at: <https://www.pblabs.com/collections/fit-fecal-immunochemical-test>. Accessed August 26, 2020.

Avoidance of Incorrect Results

- Do not perform test during times of known bleeding, such as hemorrhoidal or menstrual bleeding.
- Increase dietary fiber intake for several days before testing. Roughage increases the accuracy of the test by stimulating bleeding from lesions that might not otherwise bleed.
- Because bleeding from cancerous lesions may be intermittent, perform the test on three consecutive bowel movements to increase the chance of detecting a possible lesion.
- Complete all three stool tests, even if the first two produce negative results.
- Do not take nonprescription medications such as aspirin and NSAIDs for 2–3 days before testing or during testing.
- Some prescription medications can cause bleeding and may need to be discontinued before testing. Consult a health care provider about which medications to stop taking before performing the test.

When to Seek Medical Attention

- Notify a health care provider if any of the tests are positive.

Product Selection Guidelines

All FOBT tests are similar in cost. Patients who do not want to use sample stool from toilet paper may wish to use the toilet test kits.

Assessment of Fecal Occult Blood Test Use

As with most health care scenarios that encompass many specialties, guidelines for colon cancer screening differ slightly between expert groups. For most patients, colon cancer screening should start at 50 years of age and be conducted every 5–10 years. Key stakeholders have made the recommendations in the following sections.

The U.S. Preventive Services Task Force recommends the use of FOBT, sigmoidoscopy, or colonoscopy for screening. This group recommends that adults ages 50–75 years be screened for CRC. The decision to be screened after age 75 should be made on an individual basis.⁴⁸ Because of better sensitivity, the American College of Gastroenterology recommends that colonoscopy rather than FOBT be used to screen for colon cancer.⁴⁹

The American Cancer Society's screening guidelines recommend that people at average risk of CRC start regular screening at age 45 years. People who are in good health and with a life expectancy of >10 years should continue regular CRC screening through the age of 75. People at increased or high risk of CRC, as defined in the guidelines, might need to start screening before age 45, be screened more often, and/or undergo specific tests.⁵⁰ Other screening guidelines have similar recommendations.⁵¹

For those at increased risk for colon cancer, FOBT is not recommended. Patients seeking information about FOBT should be assessed for risk factors for colon cancer. Those with risk factors should be encouraged to have a screening test other than FOBT. Determining the potential for false test results is an important consideration. False-negative tests could delay necessary treatment, whereas false-positive tests could cause unwarranted anxiety and expensive follow-up testing.

Patient Counseling for Fecal Occult Blood Tests

When counseling a patient on the use of FOBTs, the health care provider

should emphasize the importance of following package instructions carefully. The box “Patient Education for Fecal Occult Blood Tests” lists specific information to provide patients.

Evaluation of Patient Outcomes With Fecal Occult Blood Tests

A patient evaluating the results of an FOBT must remember that the test is a screening method and is not specific to a particular disease. A positive test result may indicate any medical condition that causes a loss of blood through the GI system. The primary value of FOBT is to alert patients and their providers that a thorough workup may be needed. The kits are not intended to replace other diagnostic procedures. Patients should be advised to contact their provider if a positive test result is obtained.

Cholesterol Tests

Elevated levels of low-density lipoprotein cholesterol (LDL-C) and triglycerides, along with low levels of high-density lipoprotein cholesterol (HDL-C), are major contributors to the development of atherosclerotic heart disease, which can result in heart attack and stroke. Data from the Centers for Disease Control and Prevention (CDC) suggest that high cholesterol continues to be a concern for a significant number of Americans⁵²:

- In 2015–2016, more than 12% of American adults ages 20 years or older had total cholesterol (TC) levels >240 mg/dL, and more than 18% had high-density lipoprotein (HDL, or “good”) cholesterol levels <40 mg/dL.
- Of U.S. adults ages 20 years or older, 95 million have total cholesterol levels >200 mg/dL. Nearly 29 million adult Americans have total cholesterol levels >240 mg/dL.
- Of U.S. children and adolescents ages 6–19 years, 7% have high total cholesterol.⁵²

A multi-organizational task force suggests that most healthy adults should have their cholesterol checked every 4–6 years. Those who have heart disease, diabetes, or a family history of high cholesterol should be tested more frequently. Children and adolescents should have their cholesterol checked at

least once between ages 9 and 11 years and again between ages 17 and 21.^{53,54}

A home cholesterol test is one means of achieving this critical step to minimize the risk for cardiovascular disease. However, this test should not replace a complete lipid panel conducted by a health care provider. Because elevated cholesterol is a chronic condition that requires lifestyle modification and, frequently, medication for treatment, adhering to a treatment plan can be difficult for patients. Home cholesterol tests can help them monitor the efficacy of and adherence to diet, exercise, and medication plans.

Usage Considerations

Some nonprescription cholesterol tests measure only total cholesterol, whereas others also measure LDL-C, HDL-C, and triglyceride levels (Table 48–5).^{55–61} Individuals with diabetes might want to consider a device that measures glucose levels in addition to cholesterol and triglyceride levels. The kits CardioChek Plus Analyzer,⁵⁵ Mission Cholesterol Monitoring System,⁶¹ Curo L5 Cholesterol Test Kit,⁵⁹ and First Check Cholesterol Home Test⁵⁶ allow patients to measure their total blood cholesterol levels at home. The Check Up America,⁶⁰ LetsGetChecked,⁵⁷ and the EverlyWell⁵⁸ tests offer a self-collected, laboratory-performed test for a complete lipid profile.

TABLE 48–5 Selected Nonprescription Cholesterol Tests and Features	
Trade Name (Website)	Product Features
CardioCheck ⁵⁵ (ptsdiagnostics.com/ cardiochek-home-use-analyzer/)	• Fingerstick blood sample collection • Portable, palm-sized • Large digital readout • Accuracy relied upon by health/wellness programs and physicians • Provides TC, HDL cholesterol, TG, and blood glucose levels in ≤90 seconds; provides estimated LDL level • Can be programmed to display in nine languages: English, Spanish, German, French, Italian, Portuguese, Dutch, Chinese, and Russian (not all languages are available in all locations) • Blood sample placed on test strip; analyzer uses reflectance photometry to read color changes
First Check Cholesterol Home Test ⁵⁶	• Total cholesterol and HDL values provided; estimated LDL value

Trade Name (Website)	Product Features
	provided • Fingerstick blood sample collection • Results provided in 5 minutes • Fasting before testing not required • Test available only through third-party retailers • Whole blood sample is applied to receiving pad on reverse side of test strip. Blood sample is absorbed and reacts with reagents found on front side of test strip, producing a color that is compared with the supplied color chart to identify TC or HDL level in sample (Dixita Amin, Technical Support Associate, Abbott Rapid Diagnostics, San Diego, California, personal communication, August 12, 2020).
Curo L5 – Cholesterol Test Kit – At Home Blood Testing Meter & Strips⁵⁹ (www.curofit.com/s/blood-cholesterol/)	• Fingerstick blood sample collection • Measures via enzyme chromophoric spectroscopy • Capable of screening lipid profile, including LDL, HDL, TC, TG levels • Specific strips required for more-comprehensive test results • Results available in <2 minutes • Instant auto-coding with RFID chip recognition. • User-selectable, average measurement range (customizable ≤99 days) • PC/printer connection port for easy data transfer
EveryWell Cholesterol and Lipids Test⁵⁸ (www.everlywell.com/products/cholesterol-and-lipids-test/)	• Fingerstick blood sample collection • Sample sent to and analyzed in CLIA-certified laboratory • TC, HDL, TG, and calculated LDL levels • Independent board-certified physician reviews results • Results provided via secure platform within days
CheckUp America Cholesterol Panel⁶⁰ (www.homeaccess.com/product/checkup-america-cholesterol-panel/)	• FDA-approved mail-in test • Fingerstick blood sample collection • Tests done in CLIA-approved laboratory • TC, HDL, TG, calculated LDL levels provided • Results provided 5 days after sample receipt via USPS or manufacturer's secure website • Counseling and assistance available via phone

Key: CLIA = Clinical Laboratory Improvement Act; FDA = U.S. Food and Drug Administration; HDL = high-density lipoprotein; LDL = low-density lipoprotein; RFID = radio-frequency identification; TC = total cholesterol; TG = total triglyceride; USPS = U.S. Postal Service.

Mechanism of Action

CardioChek and the Mission Cholesterol Monitoring System use a reflectance photometer to read the color intensity of the chemical test reaction on the test strip.^{55,61} The Curo L5 Cholesterol Test Kit uses enzyme chromophoric spectroscopy⁵⁹; as with a glucose meter, test results are displayed on a screen. The First Check Cholesterol Home Test includes test strips that are treated with chemical reagents. A whole blood sample is absorbed on a receiving pad on the back of a test strip. The blood sample absorbs through to the front of a test strip and reacts with the reagents. The reaction area produces a color that can be compared with a supplied color chart for TC or HDL concentrations.⁵⁶ LetsGetChecked, EverlyWell, and Check Up America's lipid profile tests are performed by a CLIA-certified laboratory.^{57,58,60}

Accuracy Rate

The accuracy rate of home cholesterol tests is debated. Except for the tests that are mailed to a laboratory, the remaining products described here are FDA approved for home use, are CLIA-waived devices, and are rated substantially equivalent to a laboratory-based cholesterol test. Health care providers should emphasize to patients the importance of following a specific test's directions to ensure accurate results.

Interferences

Good fingerstick technique is necessary to avoid erroneous results from cholesterol tests. Two or three hanging drops of blood are needed, but excessive squeezing and milking of the finger will negatively affect the quality of the blood sample. If sufficient blood cannot be obtained from the first fingerstick, the patient should use a different finger. A low cholesterol value may result if the blood sample is too small or if it takes >5 minutes to collect the necessary amount of blood.

The patient should avoid doses of ≥ 500 mg of vitamin C before the test to avoid obtaining an artificially low result. Vitamin C slows the development of the color reaction by slowing the rate at which peroxide is produced and has been shown to interfere with all home-based tests.

Usage Guidelines

See the box “Patient Education for Cholesterol Tests.”

Patient Education for Cholesterol Tests

Usage Guidelines

- Before starting the test, wash your hands thoroughly with soap and warm water, and then dry them.
- To stabilize the cholesterol level, sit and relax for 5 minutes before performing the test.
- CardioChek Test: Insert the memory chip corresponding to the desired test into the meter; then turn on the meter.
- To obtain the blood sample, use the provided lancet to lance the outside of one fingertip, and wipe away the first drop of blood with the provided gauze pad, wipe, or tissue.
- Apply blood to the test strip or pad as quickly as possible. For cholesterol meters, apply enough blood to cover the testing area of a strip.
- Cholesterol meter: A test strip may need to be inserted before applying blood for the meter to read the bar code. The test strip can be removed to apply the blood sample. The meter displays the test results in approximately 1–5 minutes.
- For kits that require a sample test be sent to a laboratory, be sure to follow the detailed instructions to register your kit, collect the blood sample properly, and mail it to the laboratory. Each manufacturer has a detailed video explaining these processes.

Avoidance of Incorrect Results

- If two or three hanging drops of blood cannot be obtained, or if it

takes longer than 5 minutes to collect this amount of blood, do not perform the test.

- Do not excessively squeeze or milk the finger.
- If taking vitamin C in doses of ≥ 500 mg, do not take the dose within 4 hours of testing.
- The lancet is a biohazard; dispose of it in a puncture-resistant container.

When to Seek Medical Attention

- If the total cholesterol reading is ≥ 200 mg/dL, HDL-C is ≤ 40 mg/dL, or triglycerides are ≥ 150 mg/dL, see a health care provider for evaluation and further testing.

Key: HDL-C = High-density lipoprotein cholesterol.

Product Selection Guidelines

Although significantly more expensive than individual total cholesterol test cassette kits, the cholesterol meters are reusable with the purchase of additional testing materials and will store test results. Some of the meters have the ability to test for HDL-C and triglycerides, whereas the other home tests measure only TC. Some companies provide a lipid profile performed in a CLIA-certified laboratory, but the results are not immediately available.

Assessment of Cholesterol Test Use

Whether the patient has been diagnosed with or has some reason to be concerned about hypercholesterolemia should be determined before a cholesterol test is recommended. Any factors that could affect the test results also should be determined.

Patient Counseling for Cholesterol Tests

Counseling about cholesterol tests should emphasize the importance of properly collecting blood samples. If needed, patients should be advised to seek assistance with the fingerstick. As further assurance of accurate test

results, patients should be advised of factors that can cause inaccurate test results. The box “Patient Education for Cholesterol Tests” lists specific information to provide patients.

Evaluation of Patient Outcomes With Cholesterol Tests

Any patient who obtains a total cholesterol result of ≥ 200 mg/dL, an HDL-C ≤ 40 mg/dL, or triglycerides ≥ 150 mg/dL should see a health care provider for a full lipid profile and appropriate medical workup. Patients should not adjust their cholesterol-lowering medications based on results of a home test without consulting their provider.

Urinary Tract Infection Tests

Urinary tract infections (UTIs) are the most common outpatient infections in the United States, resulting in more than 8.5 million health care visits and accounting for more than \$1.6 billion in health care expenses. Although diagnostic symptoms such as change in frequency, urgency, dysuria, and blood in the urine may suggest a UTI, elderly women may present with all, some, or none of these symptoms. In those with a high probability of infection, a negative test result should not be considered confirmatory, and subsequent assessment is warranted. Urine culture remains the gold standard for diagnosing a UTI.⁶²

The prevalence of UTIs is much greater in women than in men and typically increases with age, although women ages 14–24 years also have a high incidence. The overall incidence in adult women is approximately 11%, whereas the incidence in women ages 65 years or older is roughly 20%. More than half of all adult women will have at least one UTI in their lifetime. The most common pathogens for uncomplicated UTIs include UroPathogenic *Escherichia coli* (UPEC) (75%), *Klebsiella pneumonia* (6%), and others collectively (19%).⁶³

Women have a shorter urethra compared with men and therefore are more likely to contract UTIs because of retrograde migration of bacteria from the skin. Conditions that increase risk of UTIs include pregnancy, diabetes, urinary

stones, urinary obstructions such as those caused by an enlarged prostate, presence of urinary catheters, and a history of UTIs.⁶⁴

Two primary uses for UTI tests are (1) early detection of an infection in patients with a history of recurrent UTIs or risk factors associated with UTIs and (2) confirmation that an infection has been cured by antibiotic therapy.

Usage Considerations

A number of home UTI tests are available, and all involve the use of a test strip and a patient's urine sample. The primary difference is whether the strip is used "midstream" or dipped in a urine collection cup.

Mechanism of Action

The EasyHome Urinary Tract Infection test strips, AZO test strips, and store-brand strips detect both nitrite and leukocyte esterase (LE), an enzyme unique to *leukocytes* (white blood cells).^{65,66} White blood cells may be found in the urine when a UTI is present. Gram-negative bacteria reduce nitrate in the urine to nitrite. Arsanilic acid in the test strip reacts with urinary nitrite to form a diazonium compound, which in turn reacts with another chemical on the strip to produce a pink color. A positive test requires a bacterial concentration of 10^5 per milliliter of urine. LE detection helps identify infections with gram-positive organisms that would be missed with testing for only nitrites.

Accuracy Rate

Combining nitrite and LE in one test increases overall sensitivity compared with either alone.

A study assessing the sensitivity of dipstick testing for nitrites, LE, and blood in 635 culture-positive patients showed poor predictability. The least sensitive test was nitrite (23.3%), followed by LE (48.5%), and blood (63.9%); combining all three parameters in one test provided 74% sensitivity.⁶⁷

Another study found testing for nitrite and LE provided more sensitive and predictive results. Nitrite has the best sensitivity (95%), followed by LE (73%); predictive values for each were 84% and 51%, respectively. Interestingly, a combination of clinical symptoms (fever, lower abdominal pain, and dysuria)

had a 92% specificity.⁶⁸

Interferences

A strict vegetarian diet that provides insufficient urinary nitrates can cause false-negative nitrite results for a UTI test. Tetracycline and vitamin C in excess of 250 mg also may produce a false-negative reading for nitrites by blocking the nitrite test reaction. Doses of vitamin C in excess of 500 mg within 24 hours of testing may result in a false-negative result for the LE test by blocking the development of the color reaction.⁶⁹ The patient should allow 10 hours between the last dose of vitamin C and the test procedure. Dyes or medications such as phenazopyridine, occasionally used by patients with UTIs, may cause a false-positive result by changing the sensor pad to pink.

Usage Guidelines

See the box “Patient Education for Urinary Tract Infection Tests.”

Patient Education for Urinary Tract Infection Tests

Usage Guidelines

- Clean the genital area thoroughly before collecting a urine sample.
- Test the first urine of the morning or, for later testing, use urine held in the bladder for at least 4 hours.
- To improve sensitivity, test on 3 consecutive days if the test on the previous day was negative.
- Pass the test strip through the urine stream, or immerse sensor pad for 1–2 seconds in urine collected in a clean cup.
- Do not touch the sensor pad with your fingers because skin oils can interfere with the test reaction.
- Make sure urine completely covers the pad.
- Most tests provide results for 2 chemicals that indicate a possible infection: leukocytes and nitrites.
- Wait the indicated time (1–2 minutes to account for testing for both chemicals); then compare the color on the sensor pad with the color chart provided.

- Wait no longer than 3 minutes to read the test strip, and ignore any color changes that occur after that time.

Avoidance of Incorrect Results

- Persons on a strict vegetarian diet or tetracycline may not obtain accurate results.
- Certain dyes or medications, such as phenazopyridine, may cause a false-positive result by changing the sensor pad to pink.
- Do not take 250 mg or more of vitamin C within 24 hours of testing; this may cause a false-negative result.
- Women should not use the test during menses because menstrual blood will cause a false-positive result.

When to Seek Medical Attention

- Contact a health care provider immediately for evaluation and treatment of any positive test.
- If the test is negative but symptoms persist, see a health care provider immediately for evaluation and treatment.

Product Selection Guidelines

UTI tests have small test strips. The EasyHome Urinary Tract Infection Test Strips can be used midstream or after urine is collected in a cup. The AZO test strips have a small, attached handle that may make it easy to hold the strip in the urine stream. Some patients will prefer one option over the other, so it is important that they know both options are available.

Assessment of Urinary Tract Infection Tests

The patient's reason for using a UTI test should be determined before a test is recommended. If the patient is testing for a suspected UTI, the patient's symptoms and risk factors for UTIs should be evaluated. If symptoms of a UTI are present, the patient should be referred to his or her health care provider immediately for evaluation and treatment. If the patient is testing to find out

whether a treated UTI has been cured, the patient's adherence to the therapy should be assessed. The patient's diet and medication use are important factors to evaluate for possible interference with test results.

Patient Counseling for Urinary Tract Infection Tests

If the sensor pad is to be immersed in a cup of urine, counseling on the use of UTI tests should emphasize the importance of collecting a clean sample of midstream urine in the provided cup or in a clean, unwaxed container. A patient with visual difficulties should be advised to seek assistance in interpreting test results. As further assurance of accurate test results, patients should be advised of medical and dietary factors that can cause inaccurate test results. The box "Patient Education for Urinary Tract Infection Tests" lists specific information to provide patients.

Evaluation of Patient Outcomes With Urinary Tract Infection Tests

Because UTI tests will detect only about 90% of infections, the patient should contact a health care provider if a negative result is obtained but UTI symptoms persist. If the result is positive, the patient should contact a health care provider immediately for evaluation and treatment.

Human Immunodeficiency Virus Tests

In 2016, the WHO published the first global guidelines on HIV self-testing. The guidelines recommend that HIV self-testing be offered as an additional approach to HIV testing services.⁷⁰ Data from 2018 in the United States show that approximately 1.2 million people were living with HIV, with just over 36,000 new cases that year. It is estimated that 14% (1 in 7) of persons with HIV do not know they are infected and need testing. HIV continues to have a disproportionate impact on certain populations, particularly racial and ethnic minorities and gay and bisexual men. Although annual infections have been

reduced by more than two-thirds since the height of the epidemic in the mid-1980s, CDC data indicate that progress has stalled in recent years. Home HIV tests allow a person to test in privacy.⁷¹

Acquired immunodeficiency syndrome (AIDS), an incurable disease caused by HIV infection, destroys the body’s immune system. HIV infection can be contracted by contact with infected body fluids such as blood or semen. People at risk for contracting the virus include those who (1) share needles or syringes for the purpose of injecting drugs, including steroids; (2) have sexual intercourse with a person infected with HIV, with someone who injects drugs, or with multiple partners; (3) had a blood transfusion anytime between 1978 and May 1985; and (4) were born to a mother infected with HIV.

Usage Considerations

Home test kits that require saliva or blood samples for HIV detection are currently available (Table 48–6). Kits that use a blood sample require the sample to be mailed off for testing. In contrast, OraQuick, a saliva-based kit, provides a result in approximately 20 minutes.

TABLE 48–6 Selected Nonprescription HIV Tests and Features	
Trade Name (Information Source)	Product Features
Let’s Get Checked Home STD Test Kit (www.letsgetchecked.com/us/en/home-std-test/)	• Tests for presence of antibodies to HIV-1, HIV-2, and P24 antigen • Test activation required online • Morning fingerstick blood sample collection recommended • Sample sent to company for analysis in CLIA-certified laboratory • Online results obtained 2–5 days after sample received • Medical experts contact user to explain results and provide treatment options
NURX Sexually Transmitted Infection (STI) Home Test Kit (www.nurx.com/sti-testing/)	• Offers multiple test kits,

Trade Name (Information Source)	Product Features
	including HIV (type not specified) testing • User downloads NURX app or visits website • User answers questions about health history, and then selects appropriate STI test kit • Data reviewed by NURX medical provider team to help determine appropriate test kit • After review, test shipped to patient • For HIV, fingerstick blood sample applied to blood spot card • Mailed blood sample analyzed in CLIA-certified laboratory • Within 7 days, NURX medical team contacts patient to discuss results • NURX experts can prescribe therapy, if needed
Everlywell HIV Test (www.everlywell.com/products/hiv-test/)	• Tests for presence of antibodies to HIV 1 and 2 • Each kit has unique ID to allow user to register kit and establish account where confidential results will be posted • Fingerstick blood sample collection • Sample returned to company for analysis in CLIA-certified laboratory • Results reviewed by independent board-certified physician • Data posted within days on manufacturer's secure platform
myLabBox HIV Home Test Kit (www.mylabbox.com/product/hiv-home-test-kit/)	• Mail-in kit tests for HIV-1 and

Trade Name (Information Source)	Product Features
	HIV-2 • Combo antigen/antibody ELISA for qualitative detection of HIV p24 antigen and antibodies to HIV-1 groups M and O and HIV-2 in human blood. • Fingerstick blood sample collection • Test conducted in CLIA-certified laboratory • Results received in 2-5 days • FDA-approved technology • Free telemedicine physician consultations for those who test positive • >99.9% accuracy rate
Health Testing Centers Complete STD Test Kit (HIV; type not specified) and Total STD Test Kit (HIV; type not specified); HIV Test Kit (HIV-1, HIV-2, p24 antigen) (www.healthtestingcenters.com/std-testing/)	• Fingerstick blood sample collected • Sample mailed to CLIA-certified laboratory • Results provided in 3-4 business days • Medical provider consultation available for those who test positive
OraQuick: In-Home HIV Test (www.oraquick.com/)	• Oral swab of upper and lower gums required • Swab inserted into provided test tube, where sample fluid mixes with liquid reagent; mixture migrates up test stick • Results (positive or negative for antibodies) available in 20 minutes • HIV infection unlikely if negative result is obtained, at least 3 months has passed since the risk event, and patient followed test directions carefully

Trade Name (Information Source)	Product Features
	• Regular testing recommended if negative test result obtained but patient engages in high-risk activities for HIV infection • For positive results, discussion of results and options with health care provider recommended • Website links provided to locate health care professionals, clinics, local health departments, and other resources based on geographic location

Key: CLIA = Clinical Laboratory Improvement Act; ELISA = enzyme-linked immunosorbent assay; FDA = U.S. Food and Drug Administration; HIV-1 = human immunodeficiency virus type 1; HIV-2 = human immunodeficiency virus type 2; STD = sexually transmitted disease; STI = sexually transmitted infection.

Mechanism of Action

The HIV tests detect antibodies to the virus. Because 3 weeks to 6 months may be required for an exposed individual to develop sufficient antibodies for detection, the time of possible exposure to the virus must be considered in determining when to perform the test.

The saliva test detects antibodies to both HIV-1 and HIV-2 using technology similar to that used in home pregnancy tests.⁷² Through a lateral flow process, the saliva specimen is wicked up by the device; HIV antibodies, if present, bind to the colloidal gold particles. The bound HIV antibodies then bind to an HIV antigen “T” line, forming a visible red band.

After collection, the home HIV test blood samples are mailed to a certified laboratory for processing. Positive samples are rescreened twice. Repeated positive samples are confirmed with an immunofluorescent assay.⁷³

Interferences

Providing an inadequate blood sample (i.e., incompletely filling the circle on the blood sample card) or inadequately swabbing the gums to provide an adequate saliva sample may cause inaccurate results. Patients taking immunosuppressant therapy may not be able to produce sufficient levels of antibodies and may obtain a false-negative result.

Usage Guidelines

See the box “Patient Education for HIV Tests.”

Patient Education for HIV Tests

Usage Guidelines—Blood Tests

- Call the product manufacturer’s toll-free number to register and receive pretest counseling. The manufacturer’s customer representative will ask for the confidential code included in the kit. Some test kits can be obtained and registered online.
- Once you have the kit, review the detailed instructions before beginning the sample collection process.
- Using the alcohol swab provided, clean the fingertip chosen for puncture. Allow alcohol to dry.
- Prick the cleaned fingertip using the lancet provided.
- Wipe away the first drop of blood with the provided gauze or tissue.
- Collect the blood sample in the provided collection device. This device may be a tube or a card. If a card is supplied, examine the back of the card to ensure that the blood soaked through. If not, place more blood on the front of the card. If a second fingerstick is needed, use the second lancet provided in the kit.
- Manufacturers have videos on their websites that illustrate exactly how samples should be collected.
- For cards, allow blood sample to air dry for 30 minutes, place the sample in the specimen return pouch; and seal the pouch in the prepaid and addressed shipping package. Be sure that the processing laboratory receives the specimen within 10 days of

sampling.

- To obtain the results, call the manufacturer's toll-free number 3–7 business days after mailing the specimen, depending on which test kit was used. Many companies also have secure websites where results can be obtained via a secure login.
- Note that counseling is available 24 hours a day, for both negative and positive results, and counseling is included in the cost of the testing unit.

Precautions—Blood Tests

- Do not share the test lancet with other individuals. Do not allow the blood being tested to contact other individuals.
- The lancet is a biohazard; dispose of it in a puncture-resistant container.

Usage Guidelines—Saliva Tests

- A timer or watch is needed.
- Remove the test tube from packaging, keeping it upright because it contains liquid that must not be spilled.
- Pop the top of the tube off, and insert it into the holder located inside the lid of the packaging.
- Remove the test stick from packaging. Do not touch the test pad.
- Swipe the test pad along upper and lower gums. Swipe each gum only once.
- Insert the test stick into the test tube with the test window facing forward. Start timing.
- Read the test result in the test window at 20 minutes. After 40 minutes, the results may be invalid.
- The test kit provides guidelines for how to read the results and what the results mean. The appearance of a line at C is a negative result. A line appearing at C and T is a positive result.
- Note that counseling on performing the test is available 24 hours a day from the company.

Avoidance of Incorrect Results—Saliva Test

- Do not open any of the packets until you are ready to begin the test.
- Do not eat, drink, or use oral care products (such as mouthwash, toothpaste, or whitening strips) for 30 minutes before starting the test.
- Remove dental products such as dentures or retainers that cover gums.
- To prevent a false-positive result, swab each gum only once.

When to Seek Medical Attention

- If the test is positive, see a health care provider immediately for evaluation and treatment. Avoid activities that can result in transfer of blood or other body fluids to other individuals.

Product Selection Guidelines

Many people will prefer to use the saliva test because it gives faster results, does not require a fingerstick, and has a price similar to that of some of the other mail-in tests. The two available HIV blood tests differ in price and turnaround time to obtain results. Most manufacturers provide results in 2–7 days and have physicians on staff to interpret the results, and if requested, to provide a consultation.

Assessment of HIV Test Use

The elapsed time since possible exposure to the HIV virus should be determined before an HIV test is recommended. The patient may not know all the risk factors for HIV infection; therefore, whether the patient has engaged in any activities that increase risk for contracting HIV should be determined tactfully. The patient should be asked about medical disorders that might rule out the use of a fingerstick-based test, such as use of an anticoagulant or antiplatelet agent, presence of a bleeding disorder, or physical limitations that might interfere with performing the test.

Patient Counseling for HIV Tests

Counseling on the use of HIV blood tests should emphasize the importance of

applying enough blood on the specimen card to ensure an accurate reading. Patients also should be advised of the fragility of blood samples and not to delay mailing the specimen card. Counseling for the saliva test should emphasize the importance of adequately swabbing the gums with the test stick. The box “Patient Education for HIV Tests” lists specific information to provide patients.

Evaluation of Patient Outcomes With HIV Tests

A patient with a positive result should see a health care provider to be retested for confirmation of HIV infection. Infected patients should be counseled on precautions to avoid infecting others. Patients with negative results should confirm that sufficient time has passed since the potential exposure.

Hepatitis C Tests

Hepatitis C is one of six identified hepatitis viruses. Hepatitis C is the most commonly reported bloodborne infection in the United States. Surveys conducted during 2013–2016 indicated an estimated 2.4 million persons were living with hepatitis C. The CDC recommends that the following groups be tested for hepatitis C⁷⁴:

- Patients ages 18 years or older
- Pregnant patients
- Current and former IV drug users
- HIV-positive patients
- Patients with abnormal liver tests or liver disease
- Patients on hemodialysis
- Patients who received donated blood or organs before July 1992
- Patients who received clotting factor concentrates before 1987
- Patients who have been exposed to blood from a person who has hepatitis C
- Patients who were born to a mother with hepatitis C

FDA provides consumer information about the home test, high-risk groups, the value of testing, and actions to take after the results are obtained.⁷⁵

Hepatitis C induces liver damage by causing hepatic cell necrosis and

inflammation, which over time may progress to fibrosis, cirrhosis, and hepatocellular carcinoma. Of people infected with hepatitis C, a significant number are likely to progress to the chronic disease state. Clinically, hepatitis C may go undetected for many years, and liver disease may be advanced by the time symptoms arise. This is one reason why the groups recommended for testing have expanded over the last several years.

Usage Considerations

Each of the available kits (Table 48–7) provide the necessary supplies for obtaining a sample that is mailed to a CLIA-certified laboratory for analysis. Results are typically available 2–7 days after the sample is received at the laboratory. Most manufacturers have medical experts that review the results and provide guidance on treatment options and the next steps to take.

TABLE 48–7 Selected Nonprescription Hepatitis C Tests and Features

Trade Name (Website)	Product Features
myLAB Box Hepatitis C Home Test Kit (www.mylabbox.com/product/hepatitis-c-home-test/)	• Fingerstick blood sample is collected. • Sample is mailed to laboratory. • Results are available in 2–5 days. • Sample is analyzed by CLIA-regulated clinical laboratory affiliates. • Free telemedicine physician consultations are available for those who test positive. • Test is >99.9% accurate and is as reliable as tests used by physicians and hospitals.
Let's Get Checked Home Hepatitis C test kits (www.letsgetchecked.com/us/en/home-hepatitis-c-test/)	• Tests are available for hepatitis C only and for hepatitis B and C. • Online test activation is required. • Fingerstick blood sample should be collected in the morning. • Sample is returned to company. • Sample is analyzed in CLIA-certified laboratory. • Online results are available within 2–5 days of receipt of sample. • Medical experts are available to contact

Trade Name (Website)	Product Features
	user to explain results and provide treatment options.
Everlywell Hepatitis C Test (www.everlywell.com/products/hepatitis-c-test/)	• Unique ID for each kit allows user to register kit and establish account for confidential posting of results. • Fingerstick blood sample is collected. • Sample is analyzed in a CLIA-certified laboratory. • Test results are reviewed by an independent board-certified physician. • Data are posted on company's secure platform within days.
NURX Sexually Transmitted Infection (STI) Home Test Kit (www.nurx.com/sti-testing/)	• Multiple test kits are offered: Full Control Test Kit includes hepatitis C testing. • Users download Nurx app or visit Nurx website. • Users answer questions about health history and select home STI test kit of interest. • NURX medical provider team reviews data and helps determine best test kit option. • Test kit is shipped after purchase is finalized. • For Hep C test, fingerstick blood sample is applied to blood spot card. • Sample is mailed to NURX and analyzed in CLIA-certified laboratory. • Within 7 days, NURX medical team contacts patient to discuss results. • NURX experts can prescribe therapy, if needed.
Health Testing Centers STD test kits (www.healthtestingcenters.com/std-testing/)	• Company offers multiple test kits that include an option to test for hepatitis C. • Fingerstick blood sample is collected. • Results are available in 3-4 business days. • Tests are performed in CLIA-certified

Trade Name (Website)	Product Features
	laboratory. • Users who test positive can discuss treatment options with a medical provider.

Mechanism of Action

The available kits test for presence of antibodies to the hepatitis C virus (HCV), not the virus itself. The HCV antibody test is used for initial screening for hepatitis C. The test is performed by enzyme immunoassays (EIAs), which detect the presence of hepatitis C antibodies in serum. The test result is reported as positive or negative. Third-generation EIAs have a sensitivity/specificity of approximately 99%. However, the presence of HCV antibodies does not indicate whether the infection is acute, chronic, or resolved. A positive antibody test result should be followed up with an HCV RNA test to confirm that viremia is present.⁷⁶ Because 6 months may be required to develop sufficient antibodies for detection, the time since possible exposure to the virus must be considered in determining when to perform the test.

Interferences

Providing an inadequate blood sample (i.e., incompletely filling the circle on the blood sample card) may cause inaccurate results. Patients taking immunosuppressant therapy may not be able to produce sufficient levels of antibodies and, therefore, may obtain a false-negative result.

Usage Guidelines

See the box “Patient Education for Hepatitis C Tests.”

Patient Education for Hepatitis C Tests

Precautions

- Do not share the test lancet with other individuals.

- Do not allow the blood being tested to contact other individuals.
- The lancet is considered a biohazard; dispose of it in a puncture-resistant container.

Usage Guidelines

- Register the PIN (personal identification number) with the manufacturer by calling the provided toll-free telephone number and following the automated directions. Some manufacturers allow for secure online registration.
- Remain seated during the testing process to prevent falling if dizziness occurs.
- Date the blood sample card.
- Before starting the test, wash your hands thoroughly with soap and warm water, and then dry them.
- Prick the cleaned fingertip using the lancet provided.
- Wipe away the first drop of blood with the provided gauze or tissue.
- Collect the blood sample in the provided collection device. This may be a tube or a card. If a card is supplied, examine the back of the card to ensure that the blood soaked through. If not, place more blood on the front of the card. If a second fingerstick is needed, use the second lancet provided in the kit.
- Manufacturers have videos on their websites that illustrate exactly how samples should be collected.
- Allow cards to air dry for 30 minutes; place the sample in the specimen return pouch; and seal the pouch in the prepaid and addressed shipping package.
- Within 4–10 business days after mailing the sample, call the toll-free number provided or log into the secure portal, using your personalized PIN, to access your test results.
- Note that counseling is included in the cost of the testing unit and is available 24 hours a day, for both negative and positive results.

When to Seek Medical Attention

- If the test is positive, see a health care provider immediately for evaluation and treatment. Avoid activities that can result in transfer

of blood or other body fluids to other individuals.

Product Selection Guidelines

Multiple hepatitis C test kits are available ([Table 48–7](#)). They have similar processes for sample collection and testing.

Assessment of Hepatitis C Test Use: A Case-Based Approach

A patient who has been infected recently may receive a false-negative result because antibodies to the virus have not had sufficient time to form. Clinical studies on file with the manufacturer of Hepatitis C Check report no false-positive results.⁷⁷ The patient may not know all the risk factors for hepatitis C; therefore, whether the patient has engaged in any activities that can cause the disease should be determined tactfully. The patient should be asked about medical disorders that might rule out use of a fingerstick-based test or physical limitations that could interfere with performing the test. Case 48–2 is an example of assessment of a patient who wishes to test for hepatitis C infection.

Patient Counseling for Hepatitis C Tests

Patients should be advised of the fragility of blood samples and not to delay mailing the specimen card. The box “Patient Education for Hepatitis C Tests” lists specific information to provide patients.

Evaluation of Patient Outcomes With Hepatitis C Tests

Patients who test positive should be referred to a health care provider because treatment options are available only by prescription. Infected patients should be counseled on precautions to avoid infection of others. These patients also should be advised to avoid using alcohol and other drugs that may advance the progression of liver disease. Finally, they should be tested for and

vaccinated against other forms of hepatitis, such as the hepatitis A and B viruses.

Case 48–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient recently read an article about the high rate of hepatitis C infections in Baby Boomers.
b. Medical history, including family history	He has heart disease, high cholesterol, GERD, rheumatoid arthritis, and hypertension. He did have a blood transfusion years ago but is evasive when asked about other risk factors.
c. Patient's identity	Jose Martinez
d. Patient's age, gender, height, and weight	64 years old, male, 5 ft 9 in., 191 lb
e. Patient's dietary habits	n/a
f. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Atorvastatin 20 mg, lisinopril 10 mg, pantoprazole 40 mg, Xeljanz XR 11 mg, and an eye vitamin, all once daily; methotrexate 7.5 mg once weekly. Adherence to medications verified by refill records. Just completed a 7 day course of prednisone.
g. Prior use of diagnostic/monitoring test	Jose has never used any home tests.
h. Potential problems with performing/interpreting test	He wears reading glasses to read fine print. His wife could help him read the instructions and complete the test.
Assess	

Relevant Evaluation Criteria	Scenario/Model Outcome
2. Determine whether self-testing is appropriate.	Although he should be screened for hepatitis C because of his age group, self-testing is not appropriate.
3. Identify exclusions for self-treatment.	Immunosuppressant therapy and unknown immune system status
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a medical provider is required, and share this information with the patient or caregiver.	Options include (1) Refer patient for hepatitis C testing. (2) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The patient understands why self-testing is not appropriate. He has an appointment with his HCP in 3 weeks and will ask for the test at that time.
Follow-up: Monitor and Evaluate	
6. Assess patient outcome.	Pharmacist will check with the patient at his next pharmacy visit to see if the test was performed or is scheduled.

Key: HCP = Health care provider; GERD = gastroesophageal reflux disease; n/a = not applicable.

Drug Abuse Tests

Data from the 2017 National Survey on Drug Use and Health (NSDUH)⁷⁸ show that

- 30.5 million people ages 12 years or older had used an illicit drug in the past 30 days (i.e., current use), which corresponds to about one in nine

or 11.2% of Americans.

- About one in four young adults ages 18 to 25 were current illicit drug users.
- Of Americans ages 12 years or older, 19.7 million battled a substance use disorder. Of those, approximately 74% of adults struggled with an alcohol use disorder, and 38% battled an illicit drug use disorder.
- One of every eight adults struggled with alcohol and drug use disorders simultaneously.

The cost of substance abuse (tobacco, alcohol, illicit drugs, prescription opioids) to society, including the costs related to health care, crime, and lost work productivity, exceeded \$820 billion (based on data from 2007–2013).⁷⁹

FDA has a website that lists consumers' frequently asked questions about home test kits for drugs of abuse: www.fda.gov/medical-devices/drugs-abuse-tests/drugs-abuse-home-use-test. This resource can be recommended to patients and, if applicable, their parents.⁸⁰

The symptoms of drug use are varied but may include withdrawal from normal activities, fatigue, red eyes, drowsiness, slurred speech, and chronic cough. The National Institute of Drug Abuse (www.nida.nih.gov) is a good resource for specific symptoms for the various drugs of abuse. Drug abuse tests may allow parents and caregivers to detect drug use early enough to affect the course of addiction.

Usage Considerations

Numerous products for detecting use of drugs are available in retail stores and pharmacies and through the internet. **Table 48–8** lists examples of tests and the substances that each test identifies.

TABLE 48–8 Selected Nonprescription Home Drug Abuse Tests				
TABLE 48–8 Selected Nonprescription Home Drug Abuse Tests				
Trade Name (Website)	Result Time to	Sample Collection	Testing Location	Detected Substances
At Home Drug Test (www.phamatech.com)	10 minutes	Urine	Home; send away for confirmation	Single-substance kits for cocaine and marijuana Multiple-substances kits

Trade Name (Website)	Time to Result	Sample Collection	Testing Location	Substances Detected
	Laboratory confirmation			12-panel kit: amphetamine, barbiturates, benzodiazepines, cocaine, marijuana, methadone, opiates, PCP, propoxyphene, valium 25-panel kit: amphetamine, barbiturates, benzodiazepines, cocaine, marijuana, methadone, opiates, PCP, propoxyphene, valium
				oxycodone, PCP
EZ Level Drug Test (www.ezlevel.com/collections/elttests) / (www.ezlevel.com/collections/drug-tests)	5 minutes 5 minutes	Urine. Testing device immersed in urine for 10 seconds. Strips absorb and test sections.	Home; qualitative results (Yes/No) for tested drugs based on color bands on test strip if negative or positive or detection limit of test.	Marijuana drug test; 5-panel drug test: amphetamine, barbiturates, benzodiazepines, cocaine, marijuana, opiates, PCP 12-panel drug test: amphetamine, barbiturates, benzodiazepines, cocaine, marijuana, opiates, PCP, propoxyphene
				propoxyphene
HomeTestNow (www.hometestnow.com)	5 minutes	Urine. Testing device immersed in urine for 30 seconds. Strips absorb and test control	Home; qualitative results (Yes/No) for tested drugs. Color bands appear on test strip if result is	12-panel instant urine dipstick test: amphetamine, barbiturates, benzodiazepines, cocaine, marijuana, methadone, opiates, PCP, propoxyphene

Key: MDA = 3,4-Methylenedioxyamphetamine; MDEA = 3,4-methylenedioxy-N-ethylamphetamine; MDMA = methylenedioxymethamphetamine; PCP = phencyclidine.

Home drug tests are marketed primarily to parents as an aid for determining drug use in their children. These tests are a means of obtaining results anonymously when drug use is suspected. Home drug testing, however, is not a substitute for open communication between parents and children regarding drug use.

Users of these tests may have questions about how soon and how long after its use can a drug be detected. Clearance rates for common drugs of abuse are given in [Table 48–9](#).⁸⁰ These data are only guidelines, and the times can vary significantly from these estimates based on how long the person has been taking the drug, the amount used, and the person’s metabolism.

TABLE 48–9 Examples of Estimated Times for Positive Drug Test		
Drug	How soon after taking drug will a positive drug test occur?	How long after taking drug will a drug test continue to be positive?
Amphetamine, methamphetamine	4–6 hours	2–3 days
Barbiturates	2–4 hours	1–3 weeks
Benzodiazepine	2–7 hours	1–4 days
Cocaine	2–6 hours	2–3 days
Ecstasy	2–7 hours	2–4 days
Marijuana	1–3 hours	1–7 days
Methadone	3–8 hours	1–3 days
Opiates	2–6 hours	1–3 days
Oxycodone	1–3 hours	1–2 days

Drug	How soon after taking drug will a positive drug test occur?	How long after taking drug will a drug test continue to be positive?
Phencyclidine	4–6 hours	7–14 days

Source: [Reference 81](#).

Samples of urine or hair are collected at home. The hair tests and some of the urine tests are mailed to a CLIA-certified laboratory, with results obtained by telephone or over the internet via a secure portal. For some of the urine tests, the user conducts a preliminary screening test in the home and then mails positive samples to a laboratory for confirmation. Other urine tests are performed only at home. Saliva tests are available, but they are currently marketed only to drug testing programs and employers.

Some of the test kits include telephone counseling (1) to help parents recognize the signs of drug use, (2) to assist in creating a family drug policy, and (3) to emphasize that parents should use the test to develop trust and open communication within their family members, rather than to intimidate them with the threat of random testing. Some telephone counseling programs provide referrals to rehabilitation and counseling services in the family's community.

Mechanism of Action

For the home urine tests, an immunochromatographic assay similar to the home pregnancy and ovulation tests is used for initial screening of a sample. Available testing devices include (1) a test cassette to which urine is applied and (2) a test device that is placed in the urine sample. In each test, a positive result for a particular drug is the absence of a line next to the drug name in the testing area. For a negative test, a line appears by the drug name and in the control area.

The laboratories use an enzyme-multiplied immunoassay technique to detect drugs in the urine samples. Gas chromatography–mass spectrometry is then used to identify the specific drug. Positive home urine samples sent to clinical laboratories for confirmation are checked for evidence of adulteration.

Substances such as water or household chemicals can be added to urine samples in an attempt to mask drug use.

Home urine tests detect drug use that occurred from several hours before testing to within 2–3 days of testing. The amount of drug found in the urine is affected by the time since consumption, the amount taken, and the amount of water consumed before sampling. Test results are reported as only positive or negative for a drug. Quantity or route of ingestion is not determined.

Hair testing detects trace amounts of ingested drugs that become trapped in the core of the hair shaft as it grows at an average rate of 1/2 inch per month. Drug use over a 90-day period can be determined from a hair sample of 1 1/2 inches.⁸¹ The presence of drugs is determined by radioimmunoassay techniques, followed by gas chromatography–mass spectrometry analysis to identify the specific substance. Hair tests report positive or negative results for a drug. For some tests, positive results are reported as a number that indicates low, medium, or high levels of use for all drugs except marijuana; the latter is reported only as positive or negative.

Usage Guidelines

See the box “Patient Education for Drug Abuse Tests.”

Interferences

Ingestion of decongestants, dextromethorphan, antidiarrheals, or cough medications containing codeine may cause false-positive results for home drug abuse tests. These items contain substances structurally related to certain drugs of abuse. Consumption of large quantities of poppy seeds or poppy seed paste may or may not cause a false-positive result for opiates, depending on the test’s sensitivity. Sensitivity standards for opiates have been raised to reduce the possibility of false-positive results.

Product Selection Guidelines

The criteria for selecting one drug abuse test over another include the drugs that are suspected of being used, the type of suspected use (i.e., casual vs. chronic), the length of time since last use, and the possibility that the suspected drug user tampered with the sample. The list of drugs that may be

identified varies with each kit. These tests can test for a single drug or up to 14 drugs.

In general, urine tests are better for detecting low-level, casual drug use. Hair testing detects longer-term use. It takes at least 5–7 days for hair to grow far enough from the scalp for testing purposes. Urine samples are subject to tampering by adding chemicals, diluting with water, or substituting someone else's urine sample. Some of the test kits include a temperature strip on the urine collection cup to ensure the sample is at body temperature. Parents may accompany their child to the bathroom to collect the urine sample. Hair samples, if taken directly from the person being tested, are not subject to tampering. Parents should weigh the possibility of tampering when deciding which type of test to choose.

Assessment of Drug Abuse Test Use

The length of time of suspected drug use and the types of drugs that are suspected will determine which type of drug abuse test to recommend. Whether the suspected user is likely to tamper with urine samples also should be considered. Finally, whether the suspected user takes legal prescription or nonprescription medications that may interfere with the test should be determined.

Patient Counseling for Drug Abuse Tests

When parents or caregivers ask for assistance in selecting a drug abuse test, health care providers should offer clinical advice and information about family counseling agencies. Counseling should emphasize the limitations of the tests for confirming drug use and, in the case of urine tests, for identifying anything more than the type of drug that is being abused. The box “Patient Education for Drug Abuse Tests” lists specific information to provide patients.

Patient Education for Drug Abuse Tests

Usage Guidelines for Urine Drug Abuse Tests

- Collect urine using the collection device included with the test. Do

not take urine from the toilet.

- Check the temperature of the urine sample immediately after collection using the temperature strip, if included. If the sample is not between 90°F (32°C) and 100°F (38°C), adulteration may have occurred.
- Immerse the test card in the urine sample for time specified in the instructions, usually 10–15 seconds, or until visible migration across the test panels has occurred. Place the device on a flat surface or leave it immersed in the sample. Do not allow urine to exceed the “max line.”
- Read the results when the “results ready” indicator changes to a pinkish red. Do not read the results 15 minutes or more after this indicator changes color or after the “results expired” indicator changes color.
- If no line appears in the control region, the test is invalid and should be repeated with a new card.

Usage Guidelines for Hair Drug Abuse Tests

- Follow manufacturer guidelines for proper hair sample collection for the specific test being use. For most tests, collect a hair sample, ½-inch wide and 1½ inches in length from the crown of the head, as close to the scalp as possible.
- Align the cut ends of the hair sample and place the sample in the collection package as directed. Do not collect hair from a hairbrush, comb, or clothing; there is no guarantee that the hair is actually from the person to be tested.
- Results are available approximately 3–9 days after receipt by the laboratory. To access results, call the manufacturer’s toll-free number and provide the code number accompanying the kit, or log into the secure portal to obtain the results.

Avoidance of Incorrect Results

- Drug tests on urine samples report only a positive or negative outcome. Neither the quantity of drug taken nor the method in which it was taken is determined.

- Drug tests on hair samples can report a low-, medium-, or high-level of drug use, but the use could have occurred as long as 90 days before testing.
- Cough medications that contain codeine or dextromethorphan, decongestants, antidiarrheals, narcotic analgesics, and possibly poppy seeds may cause false-positive test results.

When to Seek Medical Attention

- If the test is positive, seek the services of a drug rehabilitation organization, or contact a health care provider.

Evaluation of Patient Outcomes With Drug Abuse Tests

If a positive result is obtained with a drug abuse test in a minor, parents or caregivers need to consider potential problems with the test itself before concluding that drug use is confirmed. In addition, they must not assume that a negative result is accurate. Parents also should consider the testing window when evaluating results. For tests completed in adults, similar issues regarding how to address positive and negative results should be considered.

Blood Pressure Monitors

Hypertension, often an asymptomatic disease, affects tens of millions of Americans and provides an opportunity for home monitoring to improve outcomes. In 2017, the American College of Cardiology and the American Heart Association published new guidelines for hypertension management and defined the categories of blood pressure, as shown in [Table 48–10](#).^{82,83}

TABLE 48–10 ACC–AHA Categories for Blood Pressure

BP Category	Systolic BP (mm Hg)		Diastolic BP (mm Hg)
Normal	<120	AND	<80

BP Category	Systolic BP (mm Hg)		Diastolic BP (mm Hg)
Elevated	120–129	AND	<80
Stage 1 HTN	130–139	OR	80–89
Stage 2 HTN	≥140	OR	≥90

Key: ACC = American College of Cardiology; AHA = American Heart Association; BP = blood pressure; HTN = hypertension.

Source: [References 82](#) and [83](#).

When these guidelines were applied to the National Health and Nutrition Examination Survey (NHANES) data, the prevalence of hypertension among U.S. adults between 2013 and 2016 was shown to be 45%.⁸⁴ It has been demonstrated that pharmacists, using patient's home blood pressure results and telemonitoring, can individualize drug therapy regimens and help more patients reach their blood pressure goal.⁸⁵ A study that used traditional methods to compare the accuracy of home blood pressure devices with reference measures found differences between the two sets of blood pressure values. Specifically, the home devices were less accurate for systolic measures and in patients with a large arm circumference. Most of the values obtained with home blood pressure devices were not within 5 mm of readings obtained by the traditional method.⁸⁶

Many pregnant women are asked to monitor their blood pressure regularly to detect preeclampsia or other potential complications. Use of a home device provides both convenience and, if needed, multiple readings to guide interventions. An analysis of various automated home blood pressure devices found that very few have been validated officially for use in pregnancy. Nonetheless, one study found the reliability of data obtained with home blood pressure monitors was similar between validated and nonvalidated devices in this population.⁸⁷

Some of the advantages of home blood pressure monitoring are due primarily to the use of automated electronic devices. These devices are widely available and are cost effective. They also reduce user error and have been shown to

improve blood pressure control, improve medication adherence, and allow for more frequent measuring. Some disadvantages include lack of validation to ensure consistent accuracy and reliability, possible self-modification of drug therapy, and lack of medical supervision.⁸⁸ An assessment of hundreds of home blood pressure devices available worldwide found that <20% of those used on the upper arm, <9% of wrist cuff devices, and none of the >500 wearable devices had been validated (see the section “Digital Devices” for discussion of the validation process).⁸⁹ A number of resources are available to assist health care providers and to guide patients in determining which home blood pressure monitoring device is best for a given patient. Space prohibits the inclusion of details for each of these devices, and readers are encouraged to visit the referenced sites for the most recent information.

The reasons for inadequate control of blood pressure are multiple, but a significant factor is lack of patient motivation to take steps to control blood pressure, especially if the patient is asymptomatic, which leads to nonadherence with treatment strategies.

The consequences of untreated hypertension are well documented. Long-standing elevations in blood pressure can lead to damage to the heart, kidneys, lungs, eyes, and blood vessels, and to an increase in morbidity and mortality.

Treatment of high blood pressure often involves significant lifestyle changes (e.g., diet, exercise). Medications may cause adverse effects that impact adherence. Patient education and empowerment play a large role in improving patient adherence with efforts to control hypertension. Adherence, in turn, helps reduce morbidity and mortality, maintains or improves the patient’s quality of life, and improves the patient’s use of health care resources.

Teaching patients to take their own blood pressure at home is an excellent means of achieving blood pressure control. Home blood pressure monitoring gives patients a sense of control over their health and allows them to measure their progress toward a target blood pressure. Three general advantages of measuring blood pressure at home are the ability (1) to distinguish sustained hypertension from “white-coat hypertension” (i.e., measurements affected by being in the provider’s office); (2) to assess response to antihypertensive medication; and (3) to improve patient adherence to treatment.

Usage Considerations

The most popular choices for home blood pressure monitors are aneroid and digital. Monitors that measure pressure at the wrist and fingers have become popular, but the systolic and diastolic pressures vary substantially in different parts of the arterial tree. Finger monitors have so far been found to be inaccurate and are not recommended. Wrist monitors are typically smaller than the arm devices and can be used in obese people because wrist diameter is little affected by obesity.⁹⁰

Mechanism of Action

Blood pressure readings include two types of pressures: *systolic*, which indicates pressure at the time of contraction of the heart cavities, and *diastolic*, which indicates pressure at the time of dilation of the heart cavities. Blood pressure is measured indirectly by two methods: *auscultatory* (measurement of sound) and *oscillometric* (measurement of vibration). Aneroid meters involve auscultation with the use of a stethoscope to detect *Korotkoff's sounds*, which are produced by the motion of the arterial wall in response to changes in arterial pressure. *Oscillometric sensors*, which often are used with digital meters, measure blood pressure by detecting blood surges underneath the cuff as it is deflated. The detection device, which is usually indicated on the cuff with a tab or other marking, is placed directly over the brachial artery. The brachial artery can be found by palpating 1–2 inches above and just to the inside of the antecubital space. As cuff pressure increases during the measurement procedure, the brachial artery is compressed and blood flow is obstructed. As cuff pressure is gradually released, blood flow is reestablished and Korotkoff's sounds can be heard in different phases. Phase I, which corresponds to systolic pressure, can be identified when at least two consecutive "beats" are heard as cuff pressure is decreased. The nature of the sounds changes over the next three phases. Diastolic pressure is identified at the point the sounds disappear (phase V).

Interferences

Stress, tobacco smoking, and ingestion of caffeine-containing beverages can increase blood pressure. Some medications (e.g., pseudoephedrine) also may increase blood pressure.

Usage Guidelines

The actual measurement of blood pressure is a relatively simple procedure; however, many people consistently do it incorrectly. Blood pressure is naturally variable; therefore, proper technique is essential to reduce measurement variability and improve the quality of results. The normal range for blood pressure is established in patients seated in the resting state; any variation from this setting can produce inaccurate results.

Using the appropriate size cuff is essential to accurately measure a patient's blood pressure ([Table 48–11](#)). If the cuff is too small, blood pressure readings can be overestimated significantly by as much as 20–30 mm Hg. Several monitors are supplied with a large cuff; many others allow a large cuff to be purchased separately. For patients with arms too large for the largest size cuff, a wrist monitor may be a useful alternative. To obtain accurate readings with wrist cuffs, the patient must hold the wrist at heart level during the reading. Because these devices also are highly sensitive to changes in the wrist level, it is best to support the arm on a table with a pillow that will raise the wrist to the appropriate level. For the person who is doing the actual monitoring, following the steps outlined in the box “Patient Education for Self-Monitoring of Blood Pressure” will help improve the accuracy of blood pressure readings, regardless of whether they are taken in the health care provider's office, the pharmacy, or the home.

TABLE 48–11 Arm Circumferences to Determine Appropriate Blood Pressure Cuff Size

Arm Circumference (adult) ^a	Cuff Size
22–26 cm	Small adult cuff
27–34 cm	Regular adult cuff
35–44 cm	Large adult cuff
≥45 cm	Thigh cuff ^b

^a Determine arm circumference by measuring around the midpoint of the upper arm. Remeasure the patient's arm periodically, especially if he or she has recently gained or lost significant weight.

^b Consider a wrist monitor for patients whose arm circumference is >45 cm.

Source: [Reference 92](#).

Product Selection Guidelines

Of the two primary types of blood pressure–measuring devices, no single type is best for every patient. The choice of device is individualized according to characteristics such as the patient’s ability and willingness to learn, physical disabilities, patient preference, and the cost of the device. In general, aneroid devices are the least expensive. Depending on its features, a digital device can cost as much as a mercury column device. A discussion of the pros and cons of all three types of devices follows.

Aneroid Devices

Aneroid devices are the most accurate and reliable. They are lightweight, portable, and very affordable, and they pose no risk from mercury toxicity. They include several features that make patient instruction much easier. First, most devices come with a stethoscope attached to the cuff, which frees the patient from having to hold the bell of the stethoscope in place. Second, a D-ring on the cuff allows a single user to easily place the cuff on the arm. Third, a few manufacturers offer a gauge that is attached to the inflation bulb, making it easier to manipulate the equipment because there are fewer pieces to control. These monitors are considered the option of choice for home use, but they do require careful patient instruction and follow-up. Good eyesight and hearing are necessary for accurate readings with standard models. For patients with reduced visual capacity, however, devices with large-type print on the face of the gauge are available.

At the bottom of the face of each aneroid device is a small box. When the cuff is completely deflated and lying on the table, the needle of the gauge should rest in the box. If the needle is outside the box, the gauge needs recalibration. Many manufacturers sell recalibration tools to allow health care providers to adjust the devices.

Digital Devices

With advancing technology, digital devices have become more accurate, reliable, and easy to use; as a result, they have skyrocketed in popularity. These devices include *semiautomatic* (manually inflating), *fully automatic* (autoinflating), wrist, and finger blood pressure monitors. Features such as printouts, pulse monitor, digital clock, automated inflation and deflation, memory, large display, and D-ring for the cuff differentiate many of the devices. These features significantly affect the price.

A major drawback to digital monitors is the user's inability to determine whether the device is out of calibration. Patients should be advised to have their monitors checked at least annually by a health care provider for accuracy and to purchase a device that has been validated. The American Medical Association (AMA) assembled experts to establish criteria to determine which automated blood pressure devices used in clinics, communities, and the home setting are clinically accurate. These Validated Device Listing (VDL) criteria were fine-tuned with input from manufacturers, FDA, additional clinicians, and health care organizations. AMA maintains an updated list of validated devices on its website.⁹¹

If recommending a digital device, the provider should check the manufacturer's specifications to ensure that the monitor meets at least the accuracy standards set by the American National Standards Institute (ANSI). The ANSI standards for digital sphygmomanometers state that blood pressure readings between 20 and 250 mm Hg must not differ by >3 mm Hg or 2%, whichever is greater.⁹²

Assessment of Blood Pressure Self-Monitoring

Assessment should include determination of (1) why a patient wants to use a blood pressure monitor, (2) whether the patient has physical impairments that can interfere with proper use of the monitor, and (3) whether the patient can comprehend and follow instructions.

Patient Counseling for Blood Pressure Self-Monitoring

The health care provider should emphasize the importance of tracking blood

pressure values to monitor control of hypertension. Regular self-monitoring of blood pressure will illustrate positive effects of lifestyle changes and medication use in controlling the disorder. This reinforcement can improve patient adherence with prescribed therapies. The patient should be shown the proper technique for blood pressure monitoring and then be encouraged to return for a follow-up evaluation of his or her technique. Because of white coat hypertension, patients who measure blood pressure at home usually obtain lower results than those taken at the provider's office. The box "Patient Education for Self-Monitoring of Blood Pressure" lists specific information to provide patients.

Evaluation of Patient Outcomes for Self-Monitoring of Blood Pressure

Patients who measure blood pressure for diagnostic and monitoring purposes should be instructed on how to track values and how to discuss the values with their health care provider. Patients monitoring their blood pressure should be cautioned not to adjust their medications unless their provider instructs otherwise. Patients should be instructed to immediately contact their provider if they obtain elevated values and have any symptoms of high blood pressure, such as headache or blurred vision. Patient counseling and follow-up can improve outcomes in hypertensive patients by (1) motivating them to perform home monitoring of blood pressure; (2) guiding them in product selection; (3) training them to use devices appropriately; and (4) facilitating communication between the patient, the patient's family, and the patient's provider regarding any antihypertensive therapy.

Patient Education for Self-Monitoring of Blood Pressure

Precautions and Avoidance of Incorrect Results

- Keep a log of blood pressure readings and any circumstances that might have affected the reading (e.g., feeling nervous or being late for work).
- If home readings are being performed for diagnostic purposes, take readings at different times throughout the day and under different

circumstances.

- If readings are being done to determine adequacy of antihypertensive therapy, take the reading at the same time of day, preferably in the early morning soon after arising from bed.
- Allow plenty of time to relax before taking a blood pressure reading. Feelings of stress or pressure can elevate the blood pressure.
- Do not use tobacco products or drink caffeine-containing beverages for at least 30 minutes before taking a measurement. These activities can increase blood pressure.
- Wait 10–15 minutes after a bath and 30 minutes after eating to take a measurement. These activities can lower blood pressure.
- Some medications may increase blood pressure. Be alert for possible changes in blood pressure readings when starting or stopping medications.

Usage Guidelines

- Make sure the room is at a comfortable temperature.
- Sit in a comfortable chair, with your back supported and your feet facing straight ahead and placed flat on the floor.
- If using an arm cuff, place the arm to be measured on a table, making sure your upper arm is at heart level. Remove restrictive clothing from the arm.
- If using a wrist cuff, place pillows under the arm to be measured to bring the wrist up to heart level.
- Place the cuff on the arm to be measured. The cuff should be snug but not tight enough to restrict blood flow. Use the guidelines in Table 48–10 for selecting cuff size.
- Rest for at least 5 minutes in this position.
- Measure the blood pressure as directed in the product instructions. If using a stethoscope, listen for the Korotkoff's sounds as described here:
 - Phase 1: Sound begins as a soft tapping. Record the systolic pressure when two taps are heard in sequence.
 - Phase 2: Tapping sound becomes louder and is accompanied by a swishing sound or murmur.
 - Phase 3: Tapping sounds persist, but the swishing or

murmur sound stops.

- Phase 4: Tapping sounds are muffled or softened.
- Phase 5: Tapping sound stops. Record the diastolic pressure when the sound stops.

- Using the same arm, take two to three measurements separated by at least 2 minutes.
- Record the results, arm used, time and date of measurement, and name and time of last dose of any medications, including antihypertensive medications.
- Do not adjust blood pressure medications based on home measurements unless specifically instructed to do so by a health care provider.

When to Seek Medical Attention

- See a health care provider immediately for evaluation and treatment if readings are above limits set by your health care provider or above the limits stated in national guidelines, and if you are having symptoms such as headache or blurred vision.

Miscellaneous Home Tests and Technologies

As the market for home test products and wearable devices and shopping on the internet have exploded, new tests and technologies are becoming available with increasing frequency. Some newer technologies and devices provide patients with an opportunity to assess various parameters as part of a disease management program or from a preventive perspective. The growth of mobile phone apps and smartphone technologies for all current and future platforms enhances consumers' ability to self-diagnose and treat many health disorders.⁹³ Currently these mobile health apps are having positive and negative impacts on self-care. Concerns include development of apps with no expert involvement, lack of high-quality evidence to support and validate the app, incomplete features, and incorrect responses that lead to negative outcomes and patient harm.⁹⁴

A number of smart devices are available to monitor various parameters, such as blood pressure, blood oxygenation, and heart rate. Biobeat's wrist monitor provides an opportunity for continuous monitoring of these parameters along with cloud software and a mobile app for real-time data review by patients and their providers.⁹⁵

Devices such as the Apple Watch can be paired with a monitor such as the QardioArm Smart Blood Pressure Monitor to provide wireless data regarding systolic and diastolic blood pressure, heart rate, and detection of irregular heartbeat via the Qardio App. Some Apple Watches have the ability to monitor heart rate and generate an electrocardiogram. The Apple Heart Study, conducted by researchers at Stanford University School of Medicine, compared Apple Watch readings with electrocardiographic patch readings and found that the Apple Watch had a 71% positive predictive value for detecting cardiovascular irregularities that were confirmed to be atrial fibrillation.⁹⁶ SmartBP is a blood pressure management app from Evolve Medical Systems, LLC, that allows individuals to record, track, analyze, and share their blood pressure information using their iPhone/iPod touch/iPad devices and some Apple Watches.⁹⁷ A comparison of a wearable blood pressure device to industry standard devices for measuring blood pressure found an acceptable correlation between the two types of devices.⁹⁸

Many blood glucose monitoring devices are available without a prescription, yet a vast majority are obtained with a prescription because the device and necessary supplies are covered under prescription insurance. This process provides opportunities for health care providers to work with patients, review data stored on the device, and adjust therapies to achieve better outcomes. More recently, apps have been developed to add a more sophisticated layer of monitoring that includes incorporation of additional information such as medications, nutrition, exercise, and other health and lifestyle data points. However, many apps focused on self-management of diabetes have been shown to be lacking in timely and accurate education, adequate quality assurance processes, and appropriate advice for managing hypoglycemic and hyperglycemic results and for dealing with necessary alerts and warnings.⁹⁹ If patients are interested in using or are currently using one of these apps, they should discuss the advantages and disadvantages of this additional resource with their providers. Numerous websites evaluate these and many other health apps. Providers should help patients find the apps that best fit their needs and advise them to monitor their blood pressure regularly.

Technology and devices to assess sleep are another area of self-testing that is undergoing significant growth. The American Academy of Sleep Medicine (AASM) published clinical guidelines that provide recommendations for appropriate evaluation of obstructive sleep apnea and other sleep disorders. These guidelines specify that portable sleep-assessment monitoring devices record the following information: pressure-based airflow, pulse oximetry, heart rate, and respiration effort. AASM also suggests that other measures such as snore, body position to assess for estimation of positional apnea, and temperature-based airflow be included.¹⁰⁰

SleepView is a monitor that assesses airflow, respiratory effort, blood oxygenation, heart rate, snore, event detection, sleep time, and other assessments based on various body positions (supine, prone, left, right, and upright). Individuals interested in using the device need to work with their health care provider to obtain the SleepView kit. Data obtained with the device are uploaded to a secure portal so patients and providers both have access to and can discuss results and options for management of any issues identified.¹⁰¹ Other devices with similar technologies include Alice NightOne and the Watch PAT One.^{102,103} WatchPAT One collects sleep data and pairs with a patient's smartphone to transmit the data to a secure server. Through a series of algorithms, the data are analyzed and reported to the prescribing physician. The device is discarded once the testing is completed.¹⁰³

Test MyAllergy, an at-home allergy test kit that offers an opportunity to test for the presence of blood immunoglobulin E (IgE), is one way to assess whether symptoms are related to an allergen. Results, either positive or negative for the presence of elevated levels of IgE, are available within 30 minutes of obtaining a fingerstick blood sample. If the user wants more-specific information, the company also offers an Allergy 35 IgE antibody test. This test entails collection of a blood sample that is sent to the company's CLIA-certified laboratory for analysis, which usually is completed within 10 days. Per the manufacturer, this immunoassay determines the levels of antibody reactivity against specific allergens such as various grasses, ragweed, mold, foods, animal dander, dust mites, and many other substances. The process, which involves a test blotting procedure and a 2-spot blood card, is very similar to the ELISA tests offered by many laboratories. Medical experts are available to assist with data assessment and to develop an allergy management plan.¹⁰⁴

A home thyroid-stimulating hormone (TSH) test kit is available to provide

patients with data on their TSH level. The pituitary gland produces TSH, which in turn stimulates the thyroid to produce specific hormones. Hypo- and hyperthyroidism pose significant health risks, so identifying these disorders will lead to better treatments and outcomes. A fingerstick blood sample is applied to the provided collection card, which then is sent to a CLIA-certified laboratory. Results are typically available within 3 weeks via a secure online portal that can be accessed by the patient and any designated health care providers.¹⁰⁵

Selected miscellaneous home tests and wearable devices are described in [Table 48–12](#). Instructions for use are generally available from the manufacturer’s website or a site that sells the product. Following the general guidelines provided in this chapter also will help patients obtain accurate results.

TABLE 48–12 Selected Miscellaneous Nonprescription Home Tests			
Most of these products are sold by multiple manufacturers, retailers, and website marketplaces, and the vendors change regularly. Readers are encouraged to research each topic and identify options that best fit their practice or patient needs.			
Test (Website)	Purpose	Important Points	Additional Information
Alcohol screening tests (breath, saliva)	Prevents inappropriate alcohol consumption	Put nothing in mouth 15 minutes before or during the test. Follow timing directions carefully and use a timing device.	Semiquantitative BAC; saliva test strips can be used to detect alcohol in drinks.
Breast Self-Examination Aid	Makes breast self-examination easier and more comfortable	Examine breasts monthly. Self-examination does not take place of mammogram and professional examination.	Two-layer polyurethane breast shield or glove contains a small amount of silicone lubricant to reduce friction. Some kits come with instructional video (e.g., Aware, Sensa Touch).

Monistat Complete Care Vaginal Health Test ^a (www.monistat.com/vaginal-complete-care-products/vaginal-health-test)	Detects pH of vaginal secretions. (Color change based on vaginal acidity. Result is either normal or abnormal.)	pH ≥ 4.5 plus symptoms suggest yeast infection. pH ≥ 5 + symptoms suggest bacterial vaginosis or trichomoniasis.	Those with first-time yeast infection and those with pH ≥ 5 should see HCP for diagnosis. See chapter 8 for additional information.
TobacAlert (www.tobacalert.com , www.nymox.com) and Accutest NicAlert for saliva and urine (www.jantdx.com/product/accutest-nicalert-urine-screen/)	Detects tobacco use or exposure	Test detects cotinine, a metabolite of nicotine; test detects nicotine use or exposure in previous 48–72 hours. Dip strip in urine (TobacAlert, NicAlert) or saliva (NicAlert) sample, and read results in specified time.	Use of nicotine patch or gum can affect results. Secondhand smoke exposure may cause a positive result.
Test Me DNA Home DNA Paternity Testing Kit ^a (testmedna.com/home-dna-paternity-testing/); Home DNA Paternity Test (formerly IDENTIGENE DNA Paternity Test Collection Kit) (homedna.com/product/homedna-paternity;dnatesting.com/). Store-brand tests also are available.	Checks paternity of a child	Collect cheek cell samples from each participant: alleged father, child, and biological mother. Swabs are mailed to laboratory.	Kit is not available in all states. Results are available 2–5 days after sample is received by laboratory. Results are not valid for legal purposes (requires verified collection procedure and additional costs).
Reveal Home Menopause Test (urine) (www.americanscreeningcorp.com/drug-testing/reveal-menopause-test.asp); Thorne Menopause Test (saliva) (www.thorne.com/products/dp/menopause). Other saliva, urine, and blood test kits are	Urine test: detects FSH in urine Saliva test: measures various hormone levels	Urine positive test = FSH level >25 IU/L, which may indicate a woman is menopausal. FSH levels change during the menstrual cycle, so	Not a definitive diagnostic test for menopause. Diagnosis requires confirmation by HCP. Test kit is purchased, sample collected, sent to

available.	(cortisol, testosterone, estradiol, progesterone, DHEA)	the test should be done twice 1–2 weeks apart to confirm results.	laboratory for analysis and review by on-staff physicians.
Perimenopause test (www.everlywell.com)	Measures FSH, estradiol, and LH in blood sample	User purchases kit, registers kit on website, collects fingerstick blood sample, and sends sample to CLIA-certified laboratory.	Personalized results provided on portal and should be discussed with user's HCP to determine action steps.
Strep A tests ^b (Many brand-name and store-brand products are available.)	Detects strep throat infections	Same rapid test kit as that used in medical settings. Includes positive and negative control. Results provided in 5–10 minutes.	Positive test needs to be confirmed by HCP. Those with a negative test who are symptomatic also likely require follow-up with an HCP.
Home electrocardiogram monitors: Different manufacturers offer products (omronhealthcare.com/ekg/ ; www.theheartcheck.com ; www.alivecor.com/ ; www.pocketecg.com/pocketecg/).	Detects and records heart rhythm	Consumer and prescription versions. Device electrodes are placed on either one or both thumbs, or on the chest near the heart. Most devices come with an app for recording and storing data.	Device should be used in conjunction with HCP monitoring.

^a Store-brand product also are available.

^b Many brand-name and store-brand products are available.

Key: BAC = Blood alcohol concentration; FSH = follicle-stimulating hormone; LH = luteinizing hormone; DHEA = dehydroepiandrosterone; HCP = health care provider.

Key Points for Home Testing and Monitoring Devices

- To advise patients properly on selecting and using home testing or monitoring products, health care providers must be familiar with the procedures for each available product.
- Manufacturers continually introduce new products and modify current ones to provide more user-friendly versions. To keep up to date, providers should request product information from manufacturers by calling their toll-free numbers, visiting their websites, or contacting their sales representatives.
- FDA's website also should be checked frequently for problem reports, updates, and news on home tests.
- Patients who are using home tests or devices should be encouraged to follow instructions carefully and, if needed, to contact either their provider or the manufacturer's toll-free number for assistance.
- Health care providers should stress that the patient is self-testing, not self-diagnosing. Positive test results should be reported immediately to a provider for a definitive diagnosis and management of the disorder. Negative test results should be questioned when the patient is experiencing symptoms of a suspected disorder.
- If there is any question about the results, the patient should seek the advice of a health care provider.

Chapter 49: Adult Urinary Incontinence and Supplies

Authors: Christine Karabin O'Neil

Urinary incontinence (UI) is defined as the symptom of any involuntary leakage of urine.¹ Although most common in older adults, UI affects people of all ages, socioeconomic backgrounds, and ethnicities.² An estimated 25 million people in the United States are affected by UI,³ whereas more than 50 million may suffer from *overactive bladder* (OAB), whose primary symptom is a strong desire to void.⁴

UI is an underdiagnosed and underreported condition that has major psychosocial and economic effects. Feelings of embarrassment, denial, and misinformation prevent many people from seeking help, which may lead to anxiety, depression, and, possibly, social isolation.² Severe UI usually results in a loss of self-esteem and the ability to maintain an independent lifestyle. UI generally is recognized as a strong predictor of nursing home admission of older people.²

Direct costs associated with UI include the expenses for diagnosis, specific treatment, routine care, rehabilitation, and hospital and nursing home admissions. The direct costs of treating OAB with UI in adults older than 25 years were estimated at \$65.9 billion in 2007 with projected costs of \$82.6 billion in 2020.⁵

Despite the high prevalence of UI, fewer than half of community-dwelling adults with UI consult their health care provider.⁶ Many of these people accept the symptoms as a natural part of aging and use self-care strategies with little or no health professional guidance. Although they are reluctant to talk about UI, Americans spend \$2.3 billion annually on disposable incontinence products (e.g., pads, shields, guards, undergarments, briefs).⁷

Pathophysiology of Urinary Incontinence

Urination is a complex process, involving a coordinated effort by the bladder, urethra, and muscular components of the lower urinary tract, brain, and spinal

cord.⁸ Urine produced by the kidneys is propelled through the ureters to the bladder. The *detrusor muscle*, the smooth muscle layer of the bladder, gives tone to the bladder, relaxing as the bladder fills with urine and contracting during urination. The *bladder neck*, which joins the bladder and the urethra, is surrounded by smooth muscle, referred to as the internal sphincter, which either constricts to hold urine in the bladder or relaxes, permitting urine to flow through the urethra. *Micturition*, or voluntary control of urination, is maintained by contraction of the *external sphincter*, a striated muscle located at mid-urethral length. When relaxed, the urethra, which is surrounded by both smooth and striated muscle, allows urine to leave the body.

The bladder and the internal sphincter are innervated by the autonomic nervous system, and the external sphincter is innervated by the somatic or voluntary nervous system. Parasympathetic and sympathetic nerves innervate the smooth muscle of the bladder and urethra. Both α -adrenergic and β -adrenergic receptors are present in the urinary structures. The alpha receptors are located in the base of the bladder and the proximal urethra, and the beta receptors are found primarily in the body of the bladder detrusor. Stimulation of the alpha receptors causes contraction of the smooth muscles in the bladder neck and urethra, thus closing the bladder outlet. Stimulation of the beta receptors results in smooth muscle relaxation and allows the bladder to fill. As a result, sympathetic stimulation causes the bladder to retain urine. Parasympathetic cholinergic receptors are located throughout the bladder. Stimulation of these receptors causes the detrusor to contract, emptying the bladder. The *sacral center*, lying between vertebrae S2 and S4, acts as the relay center for information to and from the bladder, pelvic floor, and brain.

The capacity of the bladder is approximately 400–500 mL. When the bladder fills, stretch receptors in the detrusor wall transmit signals to the brain through the spinal cord, initiating the urge to urinate when the bladder is approximately half full. Under normal circumstances, adults can delay voiding for 30–60 minutes as a result of the short sacral reflex, which diminishes the urge to urinate by increasing contraction of the external sphincter and relaxing the detrusor muscle of the bladder. Bladder emptying usually is initiated voluntarily, causing relaxation of the external sphincter and contraction of the detrusor. Normal urination results in complete emptying of the bladder, with little or no residual urine (≤ 50 mL). Any disruption in the integration of musculoskeletal and neurologic function can lead to loss of control of normal bladder function and UI.⁹

Clinical Presentation of Urinary Incontinence

UI is a symptom that can be caused by external factors and by anatomic, physiologic, and pathologic factors that affect the urinary tract.^{2,10–12} In many cases, multiple and interacting factors contribute to UI. The risk of UI is strongly associated with aging. Additional risk factors for UI, some at least partially reversible, have been identified ([Table 49–1](#)).^{2,10–12} Identification of the cause(s) of UI is essential for its assessment and successful management.

TABLE 49–1 Risk Factors for Urinary Incontinence

Medical Disorders or Procedures
Benign prostatic hyperplasia (BPH)/transurethral resection of the prostate (TURP)/prostatectomy
Childhood nocturnal enuresis
Diabetes
Fecal impaction
Immobility/chronic degenerative disease
Impaired cognition, acute or chronic
Metabolic disorders (hyperglycemia, hypercalcemia)
Neurologic disorders (spinal cord injury, neuropathy)
Obesity (moderate–morbid)
Pregnancy/vaginal delivery/episiotomy
Stroke
Physiologic Factors
Estrogen depletion
High fluid intake (leading to polyuria and bladder capacity overload)
Low fluid intake (leading to concentrated urine and bladder irritation that worsen symptoms)
Pelvic floor muscle weakness

Lifestyle Factors
High-impact physical activities (e.g., running, jumping jacks)
Smoking
Other Factors
Caucasian race
Environmental barriers
Medications (Table 49–2)

Source: Adapted from [references 2](#) and [10–12](#).

Age-related changes in the bladder and urinary tract may contribute to an older person's vulnerability to UI. With age, the kidney's ability to concentrate urine diminishes, resulting in larger urine volumes. In addition, age-related hypotrophic changes in bladder tissue lead to frequent urination and nocturia, whereas decreased muscle tone of the bladder, as well as the bladder sphincters and pelvic muscles, contributes to the potential for reduced urine control. This loss of control, combined with diminished mobility and reaction time, predisposes older people to UI.¹³

In women, the loss of estrogen causes a decrease in bladder outlet and urethral resistance, as well as a decline in pelvic musculature, all of which increase the likelihood of UI. In addition, estrogen loss results in atrophic changes in the vaginal and urethral mucosa, disrupting the vaginal flora and leading to atrophic vaginitis and chronic urethritis. These conditions, in turn, may cause urinary frequency and urgency, dysuria, urinary tract infections, and UI. Compared with the male urethra, the female urethra is shorter and exerts less resistance to intravesicular pressure. Consequently, obesity, chronic cough, and jarring exercise, which all increase intra-abdominal pressure, result in an extra load on the bladder. As such, these factors can overwhelm the relatively low resistance offered by the short female urethra. Childbirth, gynecologic procedures, and muscle atrophy from aging also weaken the female pelvic floor muscles, thereby decreasing support for the bladder.

Without adequate support, positioning of the bladder becomes distorted (known as *cystocele* or *anterior wall prolapse*) and can result in urethral kinking, with subsequent poor bladder emptying. These conditions may result in chronic obstruction of the bladder, again leading to UI from urine volume overload.

Men often develop prostatic enlargement beginning in their middle to late 40s, which results in urethral obstruction, leading to decreased urinary flow rates, increased residual volumes, detrusor instability, and possibly overflow incontinence. Paradoxically, prostatectomy to relieve bothersome symptoms related to benign prostatic hyperplasia (BPH) can result in stress urinary incontinence (SUI) caused by incidental injury to the internal sphincter.

UI can be described broadly as transient or chronic. *Transient UI* usually is of sudden onset and secondary to acute illness (e.g., urinary tract infections) or to any disease that causes acute confusion (e.g., respiratory disease, myocardial infarction, septicemia) or immobility (e.g., fracture, injury), preventing the person from reaching a toilet independently or in time. Many other conditions and medications can cause or contribute to transient UI ([Table 49–2](#)).^{2,9} Managing these conditions may resolve UI in some patients but only reduce the severity of symptoms in others. Chronic UI often is related to neurologic or other chronic conditions, such as intrinsic sphincter deficiency, BPH, or cystocele.¹⁴ UI can be classified as overactive bladder (OAB), SUI, mixed incontinence (OAB plus SUI), overflow incontinence, or functional incontinence, depending on the underlying etiologies.

TABLE 49–2 Reversible Conditions That Cause or Contribute to Urinary Incontinence

Conditions Affecting the Lower Urinary Tract
Urinary tract infections, atrophic vaginitis/urethritis, fecal impaction, pelvic floor prolapse, hyperglycemia, hypercalcemia
Drug Adverse effects
Polyuria, frequency, urgency: caffeine, diuretics, alcohol, acetylcholinesterase inhibitors
Urinary retention: anticholinergics, antidepressants, hypnotics/sedatives, antipsychotics, narcotics, muscle relaxants, antihypertensives (calcium channel blockers), β -adrenergic agonists, α -adrenergic agonists
Urethral relaxation: α -adrenergic blockers

Urethral pressure imbalance (SUI): cough from ACE inhibitors
Increased Urine Production
Metabolic disorders (e.g., hyperglycemia, hypercalcemia), excessive fluid intake, volume overload, venous insufficiency with edema leading to nocturia
Inability or Unwillingness to Reach a Toilet
Dementia, delirium, illness/injury that interferes with mobility, psychological conditions

Key: ACE = Angiotensin-converting enzyme; SUI = stress urinary incontinence.

Source: [References 2](#) and [9](#).

Recognition of signs and symptoms of UI is an essential first step in providing treatment advice. Patients often delay discussion or do not seek medical evaluation of UI with their health care providers. Therefore, it is important for providers to inquire about potential UI symptoms when clinical evidence or patient inquiries indicate existence of such conditions. Open-ended questions such as “What problems are you having, if any, with your bladder?” and “How often do you experience urine leakage?” can be used to begin this dialogue. An awareness of signs such as the odor of urine or appearance of wetness also is necessary to identify potential patients suffering from UI. [Table 49–3](#) lists observed and reported signs and symptoms commonly associated with particular types of UI. Encouraging the use of a 24-hour voiding diary, paper or electronic, is a helpful tool in diagnosing and managing UI.^{15,16} In a voiding diary, patients can document fluid intake, amount of urine voided, episodes of urine leakage, urge to urinate, and activity at the time of leakage or sense of urgency.

TABLE 49–3 Common Signs and Symptoms of Urinary Incontinence (UI) by Type

Type of UI	Urgency	Frequency	Volume of Loss	Nocturia	Other
Urge	Frequent	>8 times per day	Large amount of urine loss: >100 mL and	>1 time per night	Inability to reach toilet following urge

Type of UI	Urgency	Frequency	Volume of Loss	Nocturia	Other
			may empty completely		to void
Stress	Occasional	Urine leakage during physical activity, lifting, coughing, sneezing; if severe, urine loss on ambulating	Small-moderate urine loss, depending on level of activity	Rare	Ability to reach toilet in time to complete void
Overflow	Hesitancy	Straining to void	Decreased or incomplete urine stream; dribbling	Frequent	Sensation of bladder or abdominal fullness, and incomplete bladder emptying

OAB occurs in both men and women, and its incidence increases with age. This condition is characterized by sudden and profound urinary urgency, usually accompanied by frequency (urinating more than 8 times daily) and nocturia (two or more awakenings at night to pass urine). The condition often, but not always, is accompanied by *urge incontinence* (UI; involuntary urine leakage with urgency).^{2,9,13} OAB usually, but not always, is attributable to uninhibited contractions of the detrusor muscle, referred to as *detrusor instability*. Other terms describing detrusor instability are *detrusor hyperreflexia*, *detrusor hyperactivity with impaired bladder contractility*, and *bladder instability*.

Neurogenic causes of detrusor instability include dementia, stroke, Parkinsonism, suprasacral spinal cord injury, multiple sclerosis, and medullary lesions. Detrusor instability of neurologic origin is referred to as *hyperreflexia*. Nonneurogenic causes of detrusor instability include bladder irritation caused by infection or interstitial cystitis (*bladder pain syndrome*), obstruction (e.g., BPH, cystocele), bladder stones, and tumors. Excessive beverage intake and some therapeutic agents (e.g., diuretics, alcohol) can exacerbate symptoms of UI as a result of increased filling of the bladder. Bethanechol also can lead to UI through cholinergically mediated contraction of bladder smooth muscle.

SUI is characterized by involuntary leakage of urine with sudden increases in abdominal pressure associated with sneezing, laughing, coughing, exercising, and lifting. SUI is the most frequently encountered type of UI in women, except in the very old (>75 years), in whom OAB is most common. Symptoms of SUI may occur in some men after transurethral resection of the prostate and radical prostatectomy.¹³ Symptoms in women are exacerbated by pregnancy and obesity, which also increase intra-abdominal pressure. This involuntary leakage is believed to be caused by hypermobility of the bladder neck or weakness of the urethral sphincter and pelvic floor muscles. *Hypermobility* refers to displacement of the bladder neck and urethra during physical exertion; it occurs when the supporting pelvic muscles have been weakened as a result of vaginal childbirth and aging. The weakening of the urethral sphincter can be secondary to vaginal or urologic surgery, trauma, aging, or inadequate estrogen, or it may be neurologic in etiology.¹⁷ Drug-related causes of SUI include α -adrenergic antagonists such as prazosin, terazosin, doxazosin, tamsulosin, and alfuzosin, which cause urethral relaxation ([Table 49–2](#)).

Overflow incontinence, an involuntary urine loss associated with overdistention of the bladder, is observed in 7%–11% of incontinent older patients.² Symptoms include dribbling, reduced force and caliber of urinary stream, urgency, and a sensation of incomplete voiding. The two main causes are outlet obstruction and/or an underactive bladder (detrusor) muscle. Outlet obstruction can be caused by BPH, urogenital tumors, pelvic organ prolapse, or previous anti-incontinence surgery. Dysfunctional bladder contractility can result from diabetic or alcoholic neuropathy, lower spinal cord injury, radical pelvic surgery, or medications that have anticholinergic properties, such as antihistamines, antipsychotics, narcotics, tricyclic antidepressants, muscle relaxants, and medications used to treat UI. These medications can cause overflow incontinence by blocking cholinergically mediated bladder contractions, thereby inhibiting normal bladder function.

Mixed incontinence, most common in women, consists of the combination of OAB and SUI.² Although the term *mixed UI* generally is applied to women, men with outlet obstruction resulting from BPH may exhibit mixed symptoms of OAB and overflow incontinence. Men also may exhibit mixed symptoms as a result of SUI attributable to radical prostatectomy or transurethral resection of the prostate combined with OAB.

Functional incontinence is described as urine loss caused by factors such as

physical or cognitive impairment, which interfere with a person's ability to reach toilet facilities in time or to perform toileting tasks.² Causes of this type of UI are many and include stroke, diminished mobility, impaired cognitive function or perception, environmental barriers, use of sedative and hypotensive agents, poorly controlled severe pain, and psychological unwillingness to release urine in the proper place. Because many functionally impaired people may have other types of UI, functional incontinence should be a diagnosis of exclusion.

The consequences of UI are considerable. Many people are embarrassed by such a condition and refrain from discussing their urinary problems with their primary care providers. Some people with UI believe it is a normal consequence of aging, rather than a symptom of underlying disease or anatomic change. Social isolation occurs because the incontinent patient avoids social interaction to prevent the embarrassment and rejection that often accompany UI. In turn, social isolation leads to depression. Intimate contact and sexual activity with the patient's partner also can decrease. Attempts to limit episodes of involuntary urine loss by restricting fluid intake can cause dehydration and hypotension, whereas skin irritation and ulceration caused by long exposure to urine result in "diaper rash" and possibly pressure injuries.²

The caregivers of incontinent older patients are under stress because of the tedious and time-consuming care needed to deal with the problems of UI at home. Often, the loss of urine control leads to a drastic reduction in quality of life, and in some cases, placement in a long-term care facility.^{2,18} Falls and fractures may be potential risks associated with repeated trips to the bathroom caused by UI or urgency symptoms in the absence of incontinence.¹⁹

Treatment of Adult Urinary Incontinence

Treatment Goals

The goals of treatment of UI are to cure incontinence or to reduce the severity of symptoms, avoid complications, and improve the patient's quality of life. When incontinence aids are used as part of self-management in UI treatment, additional goals are to control or treat skin breakdown (diaper rash), control

the odor of leaked urine, and contain urine in the undergarment.

General Treatment Approach

Treatment is individualized for the type of UI. The four major categories of intervention are behavioral modification, use of devices, pharmacologic treatment, and surgical treatment. [Figure 49–1](#) outlines the self-management of adult UI.

Nonpharmacologic Therapy

Behavioral techniques decrease the frequency of UI in most patients, have no reported adverse effects, and do not limit future therapies.² These techniques generally require patient and caregiver involvement and continued practice to be most successful. Three types of behavioral techniques, listed in order of increasing need for patient involvement, are toileting assistance, bladder training, and pelvic floor muscle training. Behavioral techniques now are the accepted first-line therapy in treating all forms of UI, except overflow incontinence.²⁰ A behavioral modification program involving pelvic floor muscle training and behavioral techniques was found to prevent the development of UI in continent older women.²¹ Providers should educate patients about the role of behavioral therapy in the prevention and management of UI.

Toileting assistance includes routine or scheduled voiding performed at fixed, regular intervals (every 2–4 hours); habit training, or scheduling voiding to match patterns in those who have natural voiding patterns; and prompted voiding. In prompted voiding, patients are trained to void only if the need is voiced on direct questioning. They are checked for wetness and praised for maintaining continence and trying to void.

Bladder training consists of education, scheduled voiding with systematic delay, and positive reinforcement. Patients are taught to delay voiding when the urge occurs and to use tactics to increase urine volume and the interval between voids. Bladder training is recommended for urge or mixed incontinence but often is difficult to achieve in cognitively impaired or frail older people.

Training of pelvic floor muscles aims to improve urethral closure pressure by

activating the striated muscles of the urethra and the underlying pelvic floor muscles. Two components of training have been established. Early improvement (reduction of urine leakage within 1 week of beginning pelvic floor muscle exercises) may be achieved by some women who learn “the knack maneuver,” or volitional precontraction. The *knack maneuver* describes learning to contract pelvic floor muscles in anticipation of and during increases in intra-abdominal pressure (e.g., coughing). This maneuver alone has demonstrated the capacity to reduce SUI.²² In addition, pelvic floor muscle training, also known as Kegel exercises or pelvic floor exercises, is designed to strengthen the voluntary periurethral and perivaginal muscles, giving the patient more control of micturition, thereby reducing UI.² Kegel exercises, which have been used successfully for SUI and OAB, are performed by squeezing the pelvic muscles as if to stop the flow of urine. The contractions should be held for about 10 seconds and then released for 10 seconds; 3–4 sets of 10 contractions per day are generally recommended.^{2,23} It is important to advise patients that the response to pelvic muscle exercises is delayed.

The exercises may be augmented by the use of vaginal weights or biofeedback techniques. Biofeedback can facilitate learning pelvic muscle exercises. Direct electrical stimulation of the pelvic floor muscles with vaginal or anal probes or surface electrodes has been used with limited success in SUI, urge UI, and mixed UI. FDA has recently approved several nonprescription devices that utilize electrical stimulation and/or biofeedback. ApexM, designed for home use, treats SUI, urge UI, and mixed UI in women. After 90 days of proper use, women experienced a 90 percent reduction in bladder leakage. On average, SUI symptoms are resolved within 12–14 weeks, whereas complete resolution of symptoms of urgency/OAB may take longer.²⁴ Attain, similar in design to ApexM, includes visual biofeedback and a guided exercise program.²⁵ Innovo, another FDA-cleared, nonprescription device for SUI, is a noninvasive device similar in appearance to exercise shorts.²⁶ The device delivers 180 pelvic floor contractions in 30 minutes; when used 5 times per week, this device resolved dryness in 87% of users after 12 weeks.²⁷

Radiofrequency energy treatment (Lyrette, formerly Renessa), a nonsurgical approach to SUI, is available in a urologist’s office.²⁸ The treatment, which uses low temperature to cause natural collagen to become firmer, produced improvements in 3 of 4 women and nearly 60% eliminated the use of pads.²⁹ Another option available only through a provider’s office is the NeoControl pelvic floor therapy system.³⁰ This is a pulsating magnetic chair that uses

directed magnetic fields to induce pelvic muscle contractions. Patients generally require 20- to 30-minute treatments twice a week for 8 weeks or longer. FDA approved this device for treatment of SUI incontinence, OAB, and mixed UI. Application of mechanical pressure to support the urethra is evident in the age-old advice to women with SUI to cross their legs before coughing or sneezing to prevent urine leakage.³¹ Similarly, various devices have been used by prescription for UI, including elevating devices to support the bladder neck (pessary, tampon, prosthesis); urethral occlusive devices (urethral plug or insert, caps, expandable urethral devices, urethral shields); external collection systems (condom catheters, female urinals); penile compression devices; and catheterization (intermittent, indwelling, suprapubic).² Poise Impressa Bladder Supports³² and Revive Reusable Bladder Supports³³ are nonprescription internal products cleared by FDA for the temporary management of SUI. The core of Impressa bladder support is made from flexible, medical-grade silicone, surrounded by a soft, nonabsorbent polypropylene covering with a polyester and rayon string to help make insertion and removal easy. Revive is a reusable silicone ring that comes with 31 strings; after 31 uses, the device should be discarded. Similar to a tampon, each bladder support comes in a smooth plastic applicator and is inserted into the vagina to gently lift and give support to the urethra. Designed to reduce or stop urine leakage in women with SUI, Impressa is available in three sizes to adapt to a woman's unique internal shape; Revive is available in one size. A recent review of mechanical devices found inconsistent results, insufficient evidence to compare one device with another, and no evidence to compare mechanical devices with other forms of treatment.³⁴

Although uncommon in the treatment of OAB, surgery can successfully treat SUI and overflow incontinence. Surgery is an option when nonpharmacologic and pharmacologic therapies have failed or the patient wants definitive treatment. The aims of continence surgery are to elevate the bladder neck, support the urethra, and increase urethral resistance.^{2,35} Some surgical options include urethral bulking agents (collagen), sling operation, tension-free vaginal tape, artificial sphincter insertion, needle bladder-neck suspension, retropubic suspension, urinary diversion, and bladder denervation. It should be noted that surgical treatment for SUI can instigate or exacerbate symptoms of urgency.

Pharmacologic Therapy

The type of UI influences the choice of treatments, making a prior medical

evaluation essential. Inappropriate use of systemic nonprescription products and incorrect use of absorbent undergarments and pads before a proper evaluation may result in unnecessary expense, inappropriate treatment, and possibly unnecessary changes in the patient's lifestyle and psychological well-being. For that reason, an overview of the pharmacologic measures for specific types of UI is presented here. Most medications used to treat these disorders are prescription products; however, a nonprescription form of oxybutynin, Oxytrol for Women, was approved in 2013. OAB or UI may be treated with anticholinergic medications, which facilitate urine storage by decreasing uninhibited detrusor contractions. Oxybutynin (Oxytrol for Women) provides a nonprescription option for women ages 18 years and older with urinary symptoms consistent with OAB (e.g., two of the following three symptoms for at least 3 months: frequency, urgency, and incontinence). The transdermal patch is applied every 4 days to a clean, dry, and smooth area of the skin on the abdomen, hips, or buttocks. Application sites need to be rotated with each patch. Common adverse effects include skin irritation at the patch application site, constipation, and dry mouth. Sleepiness, dizziness, and blurry vision also may occur. Thus, driving or operating machinery is not advised until patients know how they will react to the patch. If symptoms do not improve, women should seek a medical referral.³⁶

Prescription anticholinergic medications such as darifenacin, oxybutynin chloride, solifenacin, tolterodine, fesoterodine, and trospium are used frequently for OAB and urge UI. Mirabegron, a beta-3 adrenergic agonist approved for the treatment of both conditions, is an alternative to anticholinergic medications. For patients who do not respond or who cannot take anticholinergic medication, onabotulinumtoxinA offers significant relief from symptoms of OAB and urge UI.³⁷

Other prescription medications that have less evidence of clinical efficacy and raise concerns about risks of adverse effects include propantheline, imipramine, hyoscyamine, and nifedipine. Flavoxate, FDA approved for urinary tract symptoms, is not effective according to the results of four placebo-controlled trials.³⁵ Diphenhydramine (see [Chapter 11](#)) and dicyclomine are used occasionally for UI. Providers should counsel patients about the potential adverse effects that occur more frequently with diphenhydramine than with the prescription products. Sedation, dry mouth (a problem for denture users and patients with gastroesophageal reflux disease, dysphagia, or stroke), dizziness, constipation, and confusion can be significant problems in older

patients. Contraindications to the use of diphenhydramine and other anticholinergic medications include many conditions (e.g., narrow-angle glaucoma, peptic ulcer, urinary tract obstruction, gastroesophageal reflux disease, uncontrolled hyperthyroidism) that occur more often in older patients. Because of these concerns, diphenhydramine and other anticholinergic medications are considered potentially inappropriate medications in older patients and are included in the most recent release of the Beers list.³⁸

SUI often is treated with agents that increase outflow resistance through alpha-receptor stimulation that enhances contraction of the bladder-neck muscles.² A commonly recommended nonprescription drug is pseudoephedrine (see [Chapter 11](#)).^{2,17} The dose of pseudoephedrine is 15–30 mg 3 times daily, starting with the lowest dose, especially in older people. Use of nonprescription medications for UI is an off-label indication and must be approved by a primary care provider. Caution should be used, however, when initiating such therapy in patients with hypertension and/or cardiac arrhythmias. Providers should advise patients to monitor their blood pressure and pulse, and to report any new occurrences of heart palpitations or fainting. Common adverse effects of pseudoephedrine include insomnia, headache, tachycardia, elevated blood pressure, dizziness, nervousness, agitation, and tremor.

Topical vaginal estrogen therapy is most useful in SUI with underlying vaginitis and urethritis caused by estrogen deficiency; several randomized controlled trials of vaginal estrogen have shown a decrease in urgency and incontinence.^{39,40} Therapy with estrogen vaginal cream usually is initiated with daily application and tapered to several times weekly applications; benefits are usually seen in 4–6 weeks. Other vaginal estrogen options include the vaginal ring and vaginal tablets. In women, only topical estrogen should be advised because placebo-controlled studies have shown that oral estrogen therapy is not effective and that systemic therapy is associated with potentially serious adverse effects, including venous thromboembolism, heart attack, stroke, and breast cancer. Estrogen can be used in combination with α -adrenergic agonists; however, the combination is only slightly more effective and can be associated with more adverse effects and increased therapy cost. The antidepressant imipramine, which also acts as an adrenergic agonist, has been suggested when α -adrenergic agonists and estrogens have failed. Duloxetine, a selective serotonin and norepinephrine reuptake inhibitor currently approved for the treatment of depression, post-herpetic neuropathy, and

diabetic neuropathy, is moderately effective in managing SUI.⁴¹ The treatment of overflow incontinence is directed by the underlying cause. In BPH, prescription α -adrenergic antagonists (terazosin, doxazosin, tamsulosin, alfuzosin, silodosin, prazosin) or 5-alpha-reductase inhibitors (finasteride, dutasteride) can be used to reduce the degree of outlet obstruction. Compared with 5-alpha-reductase inhibitors, α -adrenergic antagonists have a much faster onset of effect (several days). Because of a relatively high rate of orthostatic hypotension, prazosin is not recommended for therapy of UI. Prescription agents, such as bethanechol chloride, may be initiated if the bladder has insufficient contractile strength, such as after receiving general anesthesia. Its efficacy is not well established in long-standing hypotonic bladder, however, and it is associated with potentially serious adverse effects. In neurogenic bladder, bethanechol appears to be most effective when starting therapy as soon as possible after the occurrence of neurologic-induced incontinence. Surgery for BPH often is necessary. Catheterization, usually intermittent, is combined with frequent attempts to void as a last resort when medical and surgical corrections have failed.

Treatment of functional and iatrogenic incontinence requires evaluating the patient's entire medical status, medication history, and environment. UI resulting from medications can be resolved by initiating alternative treatments. Underlying dysfunctions, such as pain related to rheumatoid arthritis and decreased mobility, can be remedied by medical and environmental changes that make using the toilet possible or easier within the limitations of the patient's functional status. Often an assessment by physical or occupational therapists can be useful in enhancing physical function.

Use of Urinary Incontinence Supplies

Absorbent undergarments and pads are used to protect clothing, bedding, and furniture while allowing the patient to have independence and mobility. Although absorbent products are beneficial, they should be used only after a thorough and complete physical examination. Medicare, Medicaid, and other private insurers typically cover catheters and related supplies, but Medicare does not cover absorbent undergarments or pads, except during hospital and skilled long-term care visits. Medicaid will cover such bladder control supplies, but coverage varies by state. Prematurely initiating the use of absorbent protective products relieves the discomfort and obscures the cause of UI. Because correction of the cause may be possible, the premature acceptance of

UI may have significant financial, social, and psychological consequences.

Product Selection Guidelines

The type of absorbent product selected depends on several factors²:

- Type and severity of UI
- Functional status
- Gender
- Availability of caregivers
- Patient preference
- Cost
- Convenience

Health care providers need to discuss these factors with patients and their caregivers when helping them select absorbent garments and pads, which are available as reusable or disposable products ([Table 49–4](#)). This discussion is particularly important for low-income patients who often do not have the economic flexibility to purchase absorbent products; they may be forced to resort to ineffective substitutes such as toilet paper or tissue products. Many people attempt to extend the life of disposable products by layering flushable tissue over the pad. The tissue also is easier to dispose of in public places. However, its reduced wicking capacity can expose the skin to more moisture, creating the potential for breakdown. Some patients may be inclined to use low-cost menstrual pads that may be effective in some cases; however, these products contain materials that are specific to absorbing blood, not urine. Given the wide variety of available products, a resource guide published by the National Association for Continence (NAFC) may be invaluable in helping patients select a product.⁴²

TABLE 49–4 Selected Adult Incontinence Product Features^a

Trade Name	Absorbency	Size	Characteristics
Undergarments			
Assurance Slip-On Protective Undergarment ^b	Moderate-heavy leakage	One size	One-piece design; no buttons or tapes
Attends Undergarments Super Absorbency	Moderate leakage		Reusable elastic belts

Trade Name	Absorbency	Size	Characteristics
Depend Undergarments Easy Fit Elastic Leg/Adjustable Straps Regular & Extra Absorbency	Moderate leakage	One size; fits hip sizes up to 65 in.	Soft, cloth-like outer cover; reusable hook and loop strap tabs
Depend Undergarments Elastic Leg/Button Straps Regular & Extra Absorbency	Moderate leakage	One size; fits hip sizes up to 65 in.	Soft, cloth-like outer cover; reusable button strap tabs
Depend Undergarments Elastic Leg Extra Absorbency	Moderate leakage	One size	Soft, cloth-like outer cover; reusable button strap tabs
Depend Underwear Extra & Super Plus Absorbency	Heavy leakage	S/M, L	Feels and wears like underwear
Depend Refastenable Underwear Extra & Super Plus Absorbency	Heavy leakage	S/M, L/ XL	Feels and wears like underwear; 4 refastenable tabs
Prevail Underwear	Heavy leakage	S, M, L	For men and women; look and feel like underwear; pull-on
Briefs			
Attends Briefs	Heavy leakage	Y, S, M, L	Refastenable tapes
Attends Briefs with Waistband	Heavy leakage	M, L	Waistband
Depend Fitted Briefs Regular & Overnight Absorbency	Heavy leakage; overnight absorbency absorbs 30% more urine than regular absorbency	M, L	Six refastenable tapes plus elastic leg and waist; wetness indicator
TENA Briefs	Heavy leakage	Y, S, M, L	Refastenable tabs
Pads			
Attends Pads	Light leakage; medium-, extra-, super absorbency	8.5, 10.5, 12.5 14.5, 18 in. long	

Trade Name	Absorbency	Size	Characteristics
Poise Liners	Very light absorbency	6.5 in. long	
Poise Extra Coverage Liners	Very light absorbency	7.5 in. long	
Poise Thin Pads Light Absorbency	Light leakage	8.5 in. long	Elasticized sides
Poise Pads Regular Absorbency	Light leakage	8.5 in. long	Elasticized sides
Poise Pads Extra Absorbency	Light leakage	9.5 in. long	Elasticized sides; one end wider
Poise Pads Extra Plus Absorbency	Light-moderate leakage	11 in. long	Elasticized sides; one end wider
Poise Pads with Side Shields Ultra Absorbency	Light-moderate leakage	11 in. long	
Poise Pads with Side Shields Ultra Plus Absorbency	Moderate leakage	13 in. long	Pad-like comfort with guard-like absorbency; one end wider
Serenity/TENA Dry Active Liners	Light leakage	Regular and long	
Serenity/TENA Active Ultra Thin Pads	Light-moderate leakage	Regular and long	
Serenity/TENA Stylish Ultra Thin Pads with Wings	Light leakage	One size	Form fitting, sleek, and super absorbent
Serenity/TENA Anywhere Ultra Thin Pads	Heavy leakage	Long	
Serenity/TENA Anywhere Ultra Thin Pads	Moderate leakage	Regular	
Serenity/TENA Pads Moderate	Moderate leakage	Regular and long	
Serenity/TENA Pads Heavy	Heavy leakage	Regular and long	

Trade Name	Absorbency	Size	Characteristics
Serenity/TENA Ultimate Pads	Heavy leakage	One size	
Serenity/TENA Overnight Pads	Heavy leakage; overnight use	One size	Longest pad
Serenity/TENA InstaDRY Heavy Pads	Heavy leakage	One size	Fast-absorbing pad
Guards			
Attends Guards Super Absorbency	Light-moderate leakage	One size	Curved fit
Conveen Drip Collector	Dribbling or light leakage; adheres to underwear; designed for men	3- and 4-oz capacity	
Depend Guards for Men	Light-moderate leakage	One size	Anatomic design with elasticized pouch and cup-like fit
Serenity/TENA Guards Super Absorbency	Moderate-heavy leakage	One size	
Serenity Guards Super Plus Absorbency	Heavy leakage	One size	

^a Products change often; for current product availability, refer to these websites: www.depend.com, www.poise.com, www.serenity.com.

^b Manufacturer markets other products similar to the Depend line but offers a lower price point.

Key: Y = Youth; S = small; M = medium; L = large.

In 2012, NAFC recommended the following eight national quality performance standards for disposable adult absorbent products⁴³:

1. *Rewet rate*: a measure of a product's ability to withstand incontinent

episodes between changes

2. *Rate of acquisition*: a measure of the speed at which urine is drawn away from the skin
3. *Retention capacity*: a measure of a product's capacity to hold fluid
4. Sizing options: availability of sizes ranging from youth and small adult to extra-large and double-extra-large adult
5. Safety: absence of components, including additives, that are listed in any federal regulatory agency as being considered "unsafe"
6. Presence of a *closure system*: mechanism that allows the product to be opened and refastened
7. *Breathable zones*: an acceptable minimum air flow in side "wings" of the product sufficient to release trapped body heat and gaseous body perspiration in the pelvic region
8. *Performance of elastics*: provision of evidence of fit and functionality of containment of body waste, without sacrificing comfort

The disposable product market has been a multimillion-dollar industry since the 1990s. These products work in the same manner as children's disposable diapers. They are designed to absorb urine; provide a moisture barrier to protect clothes, bedding, and furniture; and minimize skin contact with urine. For maximum absorbency, products containing an absorptive gel of superabsorbent polymers may be preferable. Urine is jelled in the matrix of the absorbent layer, minimizing its contact with skin. Reusable incontinence undergarments may offer a more affordable option. These products resemble underpants with a waterproof crotch and are designed to hold a reusable panty liner. The newest option is reusable incontinence undergarments that resemble standard underwear but have the absorbency of disposable briefs. These undergarments have a unique crotch design made of several layers of wicking fabric that quickly pulls moisture away from the skin. They are available for men and women in a variety of leakage control levels. Reusable incontinence underwear is constructed of waterproof outer fabrics ranging from lace to nylon floral prints, making them an attractive and affordable option for patients with an active lifestyle. A comparative evaluation of the performance and cost-effectiveness of four key absorbent product designs demonstrated significant and substantial differences between products and considerable individual variability in preference. Cost-effective management with absorbent products may best be achieved by allowing users to choose combinations of designs for different circumstances.⁴⁴

The capacity of each disposable product corresponds to the needs of the patient:

- Guards/shields: 2–12 oz. (60–360 mL), light–heavy capacity
- Undergarments: 12–18 oz. (360–540 mL), moderate–heavy capacity
- Briefs: 28–36 oz. (840–1100 mL), moderate–heavy capacity

Patients with small amounts of leakage (e.g., dribbling), as occurs in SUI or overflow incontinence and after urologic surgical procedures, may require only a pad or a shield.^{45,46} A recent systematic review of absorbent products suggests that disposable insert pads are best for leak-through prevention; they also are the most acceptable and preferred design for women with light UI.⁴⁷ In a similar study, guards were preferred for light UI in men.⁴⁸ If larger amounts of urine are lost with UI, as often occurs with detrusor instability, products with a larger capacity would be more appropriate. Many products designed for overnight (heavy) use tend to have the largest capacities.⁴² Booster or doubler pads or inserts also are available to prevent leaks and increase the absorbency of current absorbent products.

Another important issue is the functional capacity of the patient. If the patient needs assistance with absorbent garments, the caregiver may find that briefs or diapers with “roll-on” bed application and adhesive closures are useful. Securing the product may be an important issue. Close-fitting underwear is recommended. Some garments or shields have adhesive strips or belts to hold them in place. The use of belts may require assistance from a caregiver. Of course, comfort and leg security from urine leakage are important. Many product lines offer elastic legs or contoured shapes. Caregivers and patients should consider products designed for the differences between male and female anatomy when selecting large-capacity products.^{45,46}

Protective underpads often are used in conjunction with briefs and undergarments for extended duration activities, such as sleeping and sitting. Both bed and chair pads are available, and the provider should inquire about the need for additional protection. The underpad should have a known capacity, a waterproof duration of several hours, and an ability to remain intact when wet. Bed pads are available in sizes from 16 by 24 in. to 30 by 36 in. For chairs, a 16- by 18-in. pad should be used.⁴⁶

Complications From Absorbent Products

Because the use of absorbent products increases the risk of skin irritation and maceration, these products should be checked every 2 hours. With continual urine loss, it is recommended that the absorbent material be changed every 2–4 hours. The use of skin protectants (barrier creams, ointments), as in diaper rash, is appropriate. If a rash occurs, the same treatment as that described for infants is indicated (see [Chapter 36](#)).

Urine odor is an embarrassing problem. Nonprescription products containing chlorophyll (e.g., Derifil, Pals, Nullo) or vitamin C can be recommended to help decrease urine odor. However, frequent checks for wetness and prompt changes of soiled pads and garments are preferable to efforts to mask the odor.

The healing of skin wounds may be delayed in the patient with skin wetted by urine. Any skin breakdown needs to be reported to the primary care provider. This serious complication should not be treated with nonprescription products without medical supervision.

UI products that are not available from the pharmacy or specialty supply store may be obtained by contacting the National Association for Continence (NAFC), PO Box 1019, Charleston, SC 29402-1019; 1-843-377-0900, 1-800-BLADDER; fax: 1-843-377-0905; or www.nafc.org.

Complementary Therapies

Nutritional deficiencies of protein, calcium, vitamin C, zinc, magnesium, and vitamin B₁₂ have been proposed as possibly contributing to the development of UI.⁴⁹ Of these, the relationship between vitamin B₁₂ deficiency and UI has been established.⁵⁰ A B₁₂ deficiency may lead to diminished neurosensory input regarding bladder fullness or to inappropriate neurologic stimulation of the bladder, causing detrusor instability. Many factors, such as spicy and acidic foods (e.g., caffeine, alcohol, citrus fruits), tobacco, dyes (e.g., Federal Food, Drug, and Cosmetic Yellow No. 5), food preservatives, and sugar substitutes (i.e., aspartame), may cause urinary frequency and urgency with the potential for UI. Cranberry may be effective in preventing UTI recurrence in generally healthy women,⁵¹ but it can worsen overactive bladder symptoms. The acidity of cranberry can irritate the bladder, and its diuretic action may increase

urinary frequency.

Several herbal products have been suggested to support patients with UI, including phytoestrogens (e.g., soybean, flaxseed), saw palmetto and pygeum (African plum), St. John's wort, and bearberry (uva-ursi) teas. Good clinical evidence from recent rigorous studies showed that saw palmetto is not effective in improving lower urinary tract symptoms related to BPH.^{52,53} In addition, there is no evidence from controlled studies that other aforementioned herbal products significantly improve lower urinary tract symptoms.⁵⁴ Patients should be advised to consult with their PCPs before using any of these products for UI. An in-depth discussion of saw palmetto and pygeum is presented in [Chapter 51](#).

Algorithm: Adult Urinary Incontinence

FIGURE 49–1 Self-care for adult urinary incontinence. Key: OAB = Overactive bladder; PCP = primary care provider; SUI = stress urinary incontinence; UI = urinary incontinence.

Assessment of Adult Urinary Incontinence and Supplies: A Case-Based Approach

Because of the public's general lack of sufficient medical knowledge about the different types of UI, some patients (or their caregivers) may attempt self-diagnosis and treatment without consulting their primary care providers. Self-diagnosis could lead to inappropriate treatment. Therefore, it is imperative that providers inquire about a proper medical evaluation before recommending nonprescription products, including absorbent products. Use of nonprescription medications for off-label indications must be recommended by a primary care provider.

Armed with the patient's history and proper diagnosis, the provider can answer questions appropriately and aid in the selection and proper use of devices and medications that treat this disorder.

Cases 49–1 and 49–2 illustrate the assessment of adult patients with UI.

Case 49–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Information Gathering	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of episodes of a “weak bladder,” and “I have the urge to go more than 8 times in a day, and sometimes I don't make it to the bathroom in time.” The first incident occurred 3 months ago. As a result, she has restricted her fluids and limited her activities. She has not seen her primary care provider.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	“The ‘leakage’ occurs unexpectedly at no particular time. It is really causing issues at work.”
c. Description of the patient's efforts to relieve the symptoms	“I have been using extra absorbent feminine pads. I usually can get to the bathroom in time, but when leakage does happen, the urine soaks the pads.”
d. Patient's identity	Jamie Scott
e. Patient's age, gender, height, and weight	43 years old, female, 5 ft 2 in., 146 lb
f. Patient's occupation	High school gym teacher
g. Patient's dietary habits	Vegetarian diet, 3 cups of coffee/tea per day, 1 glass of wine daily
h. Patient's sleep habits	Usually get 7–8 hours of uninterrupted sleep.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Occasional use of acetaminophen for headaches multivitamin daily.

Relevant Evaluation Criteria	Scenario/Model Outcome
j. Allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Lives with partner
Assessment and Triage	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Characteristics of Ms. Scott's urine leakage are consistent with overactive bladder with urge incontinence.
3. Identify exclusions for self-treatment.	None. However, Ms. Scott should be encouraged to seek a diagnosis for her UI before relying on incontinence products.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend a trial of Oxytrol for Women 3.9 mg/day patch. If symptoms do not improve within 2 weeks, patient should seek medical referral. (2) Refer Ms. Scott to her primary care provider or gynecologist for evaluation of urge incontinence. (3) Recommend a pad or shield for light urine leakage. Reusable incontinence underwear also may be an option for her active lifestyle. (4) Suggest avoidance of frequent use of caffeine.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	See Figure 49-1 .

Relevant Evaluation Criteria	Scenario/Model Outcome
	Ms. Scott should be offered a trial of Oxytrol for Women 3.9 mg/day patch. She should be advised to consider using pads, shields, or reusable incontinence underwear, as needed, for light urine leakage. These products would offer more protection than feminine pads. She should be counseled on the benefits of alcohol reduction.
6. Describe the recommended therapeutic approach to the patient or caregiver.	“Oxytrol for Women is recommended for the self-care of symptoms of overactive bladder, specifically the sudden and urgent need to urinate. If symptoms persist, a medical referral will be necessary.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Oxytrol for Women has been shown to be a safe and effective treatment for overactive bladder. Medical evaluation may be necessary for persistent symptoms to determine the type of incontinence and the need for a prescription medication or device.”
Patient Education	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	“Oxytrol for Women is recommended for the self-care of symptoms of overactive bladder, specifically the sudden and urgent need to urinate.”
a. Appropriate dose and frequency of administration	“Apply one 3.9 mg/day Oxytrol for Women patch to the skin every 4 days. It is a thin clear patch.”
b. Maximum number of days the therapy should be employed	“Apply the patch no more than 2 days per week. Select 2 days of the week (e.g., Sunday and Wednesday) and maintain a consistent schedule.”
c. Product administration procedures	“Remove the patch every 4 days and apply a new patch to a different area. The patch may be applied to the abdomen, hip, or buttock. Contact with water during bathing, swimming, showering, or exercising will not change the way Oxytrol works.
	If an Oxytrol patch falls off, try sticking it back into place. If it does not stick well, put on a new patch and leave it on only for the rest of your wearing time. Do not change your patch removal schedule.

Relevant Evaluation Criteria	Scenario/Model Outcome
	Do not wear more than one Oxytrol patch at a time. Using extra skin patches will not make the medicine more effective. Never cut a skin patch.
	Use baby oil or mild soap and water to remove any adhesive residue that stays on your skin. Avoid using harsh soaps, alcohol, nail polish remover, or other solvents that could irritate your skin.
	After removing a patch, fold it in half so that it sticks together. and throw it away in a place where children or pets cannot get to it."
d. Expected time to onset of relief	"Symptoms may improve within 3-4 weeks but could be seen as early as 2 weeks. Results are generally seen by 12 weeks."
e. Degree of relief that can be reasonably expected	"Usage may result in reduction of symptoms by as much as 75%."
f. Most common adverse effects	"The Oxytrol for Women patch may cause skin irritation where the patch was applied, dry mouth, and constipation.
	The Oxytrol patch may burn your skin if you wear the patch during an MRI procedure. Remove the patch before undergoing the MRI.
	Incontinence pads: may cause skin irritation, rash, maceration, and breakdown."
g. Adverse effects that warrant medical intervention should they occur	"If skin irritation near patch is severe, discontinue product use."
h. Patient options in the event that condition worsens or persists	"If symptoms persist, see your primary care provider or urologist for further follow-up. If urine loss is continual, change absorbent undergarments every 2-4 hours."
i. product storage requirements	n/a
j. specific nondrug measures	See the box "Patient Education for Adult Urinary Incontinence and Supplies" for behavioral measures to reduce and improve incontinence symptoms.

Relevant Evaluation Criteria	Scenario/Model Outcome
Solicit follow-up questions from patient or caregiver.	(1) “What if the symptoms don’t improve?”
	(2) “What if the incontinence product does not provide enough protection?”
Answer patient’s or caregiver’s questions.	(1) “If symptoms do not improve, see your primary care provider.”
	(2) “You may select a product with higher absorbency according to the amount of urine leakage.” (See Table 49–4.)
Evaluation of Patient Outcome	
9. Assess patient outcome.	“If symptoms do not improve within 2 weeks of using Oxytrol, consult with your primary care provider for further treatment and evaluation.”

Key: MRI = Magnetic resonance imaging; n/a = not applicable; NKA = no known allergies; UI = urinary incontinence.

Case 49–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Information Gathering	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient wants to use cranberry capsules for a recent problem of “inability to empty my bladder.” He heard about a product for urinary heath during a recent radio broadcast. He has been quite healthy,

Relevant Evaluation Criteria	Scenario/Model Outcome
	and this new problem is affecting his social life.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	He often wakes up 2-3 times per night to urinate.
c. Description of the patient's efforts to relieve the symptoms	Frequent trips to the bathroom
d. Patient's identity	Joe Thomas
e. Patient's age, gender, height, and weight	56 years old, male, 5 ft 10 in., 220 lb
f. Patient's occupation	School bus driver
g. Patient's dietary habits	Beer, 2-3 drinks on weekends
h. Patient's sleep habits	Frequent nighttime awakenings to urinate
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension: currently takes lisinopril 10 mg daily.
	Diabetes type II: metformin 500 mg BID
j. Allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	n/a
Assessment and Triage	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Mr. Thomas's urine leakage may be consistent with overflow incontinence. He is currently taking no medications for urinary symptoms; he should see his PCP or urologist for reevaluation of the therapy prior to starting any dietary supplement or other nonprescription treatment.
3. Identify exclusions for self-treatment.	Mr. Thomas is a male who has not been evaluated by a PCP or a urologist.

Relevant Evaluation Criteria	Scenario/Model Outcome
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mr. Thomas for further evaluation of overflow incontinence. (2) Recommend nondrug measures and products to control his symptoms. (3) Recommend nondrug measures and products until he can see his PCP. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Thomas should consult a PCP or other health care provider for further evaluation prior to using any nonprescription medication, prescription medication, or incontinence product.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Once current therapy has been evaluated and other causes eliminated, alternative prescription drug therapy may be suggested for reducing the symptoms of overflow incontinence. An absorbent guard may be appropriate for persistent symptoms."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Medical evaluation is necessary to assess the cause of your symptoms prior to starting any drug therapy."
Patient Education	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver:	See the box "Patient Education for Adult Urinary Incontinence and Supplies."
a. Appropriate dose and frequency of administration	See the box "Patient Education for Adult Urinary Incontinence and Supplies."

Relevant Evaluation Criteria	Scenario/Model Outcome
b. Maximum number of days the therapy should be employed	See the box “Patient Education for Adult Urinary Incontinence and Supplies.”
c. Product administration procedures	See the box “Patient Education for Adult Urinary Incontinence and Supplies.”
d. Expected time to onset of relief	n/a
e. Degree of relief that can be reasonably expected	See the box “Patient Education for Adult Urinary Incontinence and Supplies.”
f. Most common adverse effects	“You may experience irritation, rash, maceration, and breakdown of the affected skin.”
g. Adverse effects that warrant medical intervention should they occur	“You should check for skin irritation every 2 hours.” See the box “Patient Education for Adult Urinary Incontinence and Supplies.”
h. Patient options in the event that condition worsens or persists	“If urine loss is continual, change absorbent undergarments every 2–4 hours. See your primary care provider or urologist for further follow-up.”
i. Product storage requirements	n/a
j. Specific nondrug measures	See the box “Patient Education for Adult Urinary Incontinence and Supplies.”
Solicit follow-up questions from patient or caregiver.	“What if the incontinence product does not provide enough protection?”
Answer patient’s or caregiver’s questions.	“You may select a different product with higher absorbency based on the amount of urine leakage.” (See Table 49–4.)
Evaluation of Patient Outcome	
9. Assess patient outcome.	Contact the patient in a couple of days to ensure that he made an appointment and sought medical care

Key: n/a = Not applicable; NKA = no known allergies; PCP = primary care provider.

Patient Counseling for Adult Urinary Incontinence and Supplies

The health care provider's role in self-treatment of UI includes educating patients about the condition; recommending medical evaluation, as appropriate, that is based on an initial evaluation of signs and symptoms; assisting patients and caregivers in selecting products to reduce the risk of urine leaking to outer garments; and avoiding factors that can aggravate the condition. Patients should be provided with information to help them understand UI. The box "Patient Education for Adult Urinary Incontinence and Supplies" lists specific information to provide patients regarding the use of incontinence supplies. An excellent resource for patient education is the Simon Foundation for Continence, PO Box 815, Wilmette, IL 60091; 1-800-23Simon; or www.simonfoundation.org.

Patient Education For Adult Urinary Incontinence and Supplies

The objectives of self-treatment are (1) to reduce or eliminate symptoms of urinary incontinence (UI), (2) to control or treat skin irritation caused by contact with urine, (3) to control the odor of urine leaked from the bladder, (4) to control leakage of urine to outer garments, and (5) to prevent other complications such as falls and social isolation. For most patients, carefully following product instructions and the self-care measures listed here will help to ensure optimal therapeutic outcomes.

- Consult a primary care provider or urologist for a thorough examination before resorting to permanent use of absorbent undergarments or shields. Many cases of UI are reversible with treatment.
- Absorbent products are designed to absorb urine; to provide a moisture barrier to protect clothes, bedding, and furniture; and to minimize skin contact with urine.
- Base selection of absorbent products on the amount of leaked

urine:

- Guards/shields: 2–12 ounces (60–360 mL), light–heavy capacity
- Undergarments: 12–18 ounces (360–540 mL), moderate–heavy capacity
- Briefs: 28–36 ounces (840–1000 mL), moderate–heavy capacity

- Choose briefs or diapers with roll-on bed application and adhesive closures (for patients who are unable to change themselves).
- If additional protection is needed during sleeping and sitting, select absorbent bed or chair pads to use with absorbent undergarments.
- Check skin for irritation or maceration every 2 hours, even when absorbent garments are used.
- If urine loss is continual, change absorbent undergarments every 2–4 hours, and consult your primary care provider or urologist if UI symptoms worsen.
- If desired, use skin protectants labeled for diaper rash to protect the skin (see [Chapter 36](#)).
- If desired, use products containing chlorophyll, such as Derifil, Pals, and Nullo, to help decrease odor. However, continue frequent skin checks and frequent changes of absorbent undergarments.
- If pressure injuries (open sores) occur in an immobile patient, the caregiver should not attempt to treat the ulcers with nonprescription products and should instead consult a primary care provider.
- Identify and eliminate foods, liquids, or other substances that can irritate the bladder (e.g., coffee, tea, soda, alcohol, chocolate, acidic juices, tomato-based sauces, spicy food, artificial sweeteners, nicotine).
- Avoid excessive intake of liquid. Drink enough to produce about a cup of urine every 3–4 waking hours on average. Do not drink large amounts of liquid after 5 PM.
- Avoid products that irritate the urethra and bladder. Use cotton underwear, avoid scented powders or bath products, and use white toilet paper.
- Follow instructions for behavioral therapy and medications for

incontinence if prescribed by your primary care provider or urologist.

Evaluation of Patient Outcomes for Adult Urinary Incontinence and Supplies

At follow-up, the provider should find out whether the pharmacologic therapy is effective, whether the recommended incontinence product is comfortable and easy to use, and whether leakage from the undergarment or odor is a problem. If leakage is occurring, the absorbency and/or type of product should be reassessed. Patients who have problems with odor may need to use deodorizers. The patient or caregiver also should be asked whether the skin, especially in the perivaginal and perianal areas, is being checked for breakdown. Redness or skin irritation call for the use of skin protectants. Questioning about occurrence of urinary tract or vaginal infections also is appropriate. Such infections may indicate a need to change undergarments more often or to use another type of incontinence product. These measures will prevent prolonged skin contact with urine. In addition, the provider should monitor the effectiveness of other prescription medications and behavioral therapies for UI. The patient should be asked about adverse effects associated with the specific medication he or she may be prescribed.

Providers also should evaluate whether the use of incontinence products and other treatments has allowed patients to resume their normal lifestyles and social interactions. If these objectives are not being met after an adequate duration of any pharmacotherapy, the medication dose and type should be reviewed. Alternative absorbent products also should be considered. The patient should be encouraged to seek further advice from his or her primary care provider on treatment options.

Key Points for Adult Urinary Incontinence and Supplies

- UI is a common treatable condition that is often cured or improved with therapy.
- Because the cause of UI may be multifactorial, the patient should receive a comprehensive medical evaluation before a therapy plan is developed.
- A variety of treatment options, including drug therapy, behavioral therapies, devices, incontinence aids, and surgery, are available.
- Currently only one nonprescription pharmacologic option, Oxytrol for Women, a 3.9 mg daily patch, is available for overactive bladder and UI.
- Incontinence aids are designed to absorb urine; to provide a moisture barrier to protect clothes, bedding, and furniture; and to minimize skin contact with urine.
- The selection of absorbent products is based on the amount of urine leakage.
- Providers can play an important role in educating patients about UI; performing assessment and triage and referring for medical evaluation, if needed; counseling on the selection and appropriate use of prescription and nonprescription incontinence products and the avoidance of aggravating factors; and monitoring patient response.

Chapter 50: Introduction to Dietary Supplements

Authors: Candy Tsourounis, Cathi Dennehy

The Food and Drug Administration (FDA) defines *dietary supplements* (DS) as vitamins, minerals, herbs or other botanicals, and amino acids; dietary substances used to supplement the diet by increasing dietary intake or concentrates, metabolites, constituents, and extracts; or any combination of these stated ingredients.¹ Many terms have been used to describe DS, including *nutraceuticals*, *natural products*, *supplements*, *herbs*, *botanicals*, and *phytochemicals*. DS most often are grouped into the natural products category of complementary and alternative medicine (CAM) or integrative health (IH), according to the National Institutes of Health (NIH).² The term *complementary* refers to the use of natural products in addition to conventional medicine; *alternative* is the use of natural products in place of conventional medicine; *integrative* combines both natural and conventional approaches in a coordinated and purposeful way.² For the purposes of this chapter, herbs, vitamins, and similar products will be referred to as DS. FDA also uses this designation, because it relates to the intended use, namely for oral use only and for supplementing the diet. Indeed, consumers use DS not only to supplement the diet but also to maintain health and wellness. Some consumers also use DS to treat symptoms of medical conditions, despite FDA legislation that prohibits DS manufacturers from marketing products for this purpose unless the specific DS have undergone extensive review and been preapproved by FDA for a specified health claim.

Use of Dietary Supplements

Prevalence and Indications for Use

The National Health Interview Survey (NHIS), which is administered every 5 years to approximately 34,000–40,000 U.S. citizens, includes questions on complementary health approaches. The 2012 survey listed the use of non-vitamin and non-mineral natural products as 17.7% in adults older than 18 years and 4.9% in children ages 4–17 years.^{3,4} As shown in [Table 50–1](#), therapeutic use

of vitamin and mineral products in adults with multiple chronic conditions is more prevalent than use of the top 10 CAM approaches.⁵ In children ages 2–8 years, about 40% are given DS containing vitamins or minerals, despite their generally having adequate nutrient intake.⁶ All statistical data for DS use collected by the 2017 NHIS have yet to be published; partial results were released in November 2018. A significant increase in the use of yoga and meditation practices in children and an increased use of yoga, meditation practices, and chiropractors in adults have been preliminarily reported.⁷

TABLE 50–1 Top 10 Complementary and Alternative Medicine Practices Used by Adults With Multiple Chronic Conditions

Therapy Type	Total Study Population (n = 33,557)	Percent Use
Multivitamin or multimineral	17,493	52.7%
Vitamin	11,662	34.8%
Mineral	9891	28.4%
Non-vitamin or herbal therapy	5974	17.9%
Mind-body therapy	4127	12.5%
Chiropractic or osteopathic	2993	9.1%
Massage	2951	8.8%
Movement therapy	2162	6.6%
Special diets	1027	3.0%
Homeopathy	718	2.2%

Source: [Reference 5](#).

The National Health and Nutrition Examination Survey assessed adults' motivations for using DS.⁸ The primary reasons cited were to improve overall health (45%), maintain health (33%), and promote bone health (25%). Among adults ages 60 years and older, DS were used for site-specific conditions involving the bones, heart, and joints, whereas younger adults, ages 20–39

years, used DS to provide energy and immunity. Women frequently used calcium for bone health, whereas men used DS for heart health and lowering of cholesterol levels. The use of DS in the form of vitamin and mineral supplements also has been reported to contribute substantially to meeting the dietary reference intakes (DRIs) of key nutrients. Despite this use, some key nutrients such as vitamins C, D, and K and magnesium remain below the estimated average requirement for almost half of the U.S. population.⁹

The 2012 NHIS cited the following indications for CAM use in children (listed in order of prevalence): back or neck pain, other musculoskeletal disorders, head or chest cold, anxiety or stress, attention-deficit/hyperactivity disorder, and insomnia.⁴ When DS were considered as a separate CAM modality, indications for their use in children were less specific and involved diverse health conditions.⁴

Commonly Used Dietary Supplements

By 2024, the DS market is projected to generate approximately 57 billion US dollars, an increase of 18 billion dollars since 2019. Annual increases in market size have been steady, rising approximately 2–4.5 billion US dollars each year since 2016.¹⁰

Reported sales data for top DS differ according to the purchase location and may differ from actual consumer-use data. The most commonly used non-vitamin, non-mineral supplements in adults include fish oil, glucosamine, and chondroitin or a combination of these DS; pre- or probiotics; melatonin; and coenzyme Q10.³ In children, the most commonly used non-vitamin, non-mineral products are fish oil, melatonin, pre- and probiotics, echinacea, and garlic.⁴ Popular single-ingredient vitamins and minerals include vitamin D, calcium, and vitamin C.

Among all DS, vitamins and minerals remain the top-selling supplements, primarily because they are used across all life stages. Many Americans do not consume sufficient nutrient-dense foods, such as fruits and vegetables, resulting in inadequate intake of several vitamins and minerals relative to the Institute of Medicine's estimated average requirements or adequate intake levels.⁹ Even with DS use, some adults do not meet the estimated average intake of some nutrients.⁹ Knowing which DS are commonly used by adults and children will benefit pharmacists who are likely to be asked to assist with

product selection, provide directions for proper use, and counsel on safety considerations.

Attitudes and Predictors of Use

Many studies have measured predictors of CAM use and, more specifically, use of natural products such as DS.^{3,7} For most U.S. adults, common predictors for DS use include being female; being 45–64 years of age; having a college or higher degree; being of White, Asian, Pacific Islander, American Indian, or Alaskan Native descent; living in the western United States (i.e., West North Central, Mountain, and Pacific states); and having a current self-rated health status of very good to excellent.^{3,7} Having a higher socioeconomic status, defined as “not poor” or “near poor,” and having private health insurance also are predictors of high DS use.⁷ Users of DS also are more likely to be physically active and are less likely to smoke.⁷

Among children, use of non-vitamin, non-mineral natural products was twice as likely to be reported if the parent also used a CAM modality (9% vs. 4%).⁴ When vitamins and minerals were included, predictors of their use in children included being from a family with a higher level of parental education and family income, being from a family with private health insurance, living in the western United States, and being non-Hispanic white.⁴ DS use was more common in children who have a higher disease burden, a greater number of health conditions, and a greater number of primary care provider visits in the preceding 12 months.⁴

Older adults, ages 61–69 years, are frequent DS users and are more likely to have chronic conditions and to use concomitant prescription medications.¹¹ As such, this population is at an increased risk for drug–drug and drug–disease state interactions with DS. Individuals who cited general wellness as their rationale for use were 16 times more likely to consume DS. Other factors that appear to be highly predictive of DS use include having an attitude that the DS will work and having a history of receiving health care from CAM providers, such as acupuncturists, chiropractors, faith healers, herbalists, or homeopaths.¹¹ The findings suggest that the most important predictor of DS use is preservation of health, regardless of an individual’s assessment of his or her own health status, medical history, or use of concomitant medications.¹¹

Television was the most commonly reported source of DS information (73%),

followed by magazines and radio (both 30%), newspapers (13%), friends (8%), and store displays (5%).¹¹ Data on DS advertising spending, by media, support the highest prevalence of spending on magazine (46.6%) and television (43.7%) advertisements.¹² Segmentation of advertising by gender, age, and performance has been observed. Examples include advertisements targeting stamina and improved sexual well-being in men, hormone balance and physical appearance in women, brain health and vitality in seniors, and strength and endurance in bodybuilders.¹² DS sellers use marketing methods that target consumers in their home, where promotional material with claims about what a supplement can achieve is difficult to dispute or even scientifically investigate. A consumer simply needs to view or read the advertisement and then proceed to a store or the internet to attain it. A consumer may not realize that a DS differs from an FDA-regulated drug. Because marketing methods for drugs also occur through television, magazines, and radio, some consumers likely will not be able to distinguish a drug from a DS. Of high concern is that DS users may not report this use to their health care providers; this nondisclosure is estimated to be 24.9% for DS, with the most common reasons for nondisclosure being failure of the provider to ask and feeling that the provider did not need to know.¹³ These data confirm the importance of obtaining a complete medication history that includes use of DS as well as prescription and nonprescription drugs. The nondisclosure rate is reported to increase if the provider seems disinterested, appears judgmental of IH use, or lacks sufficient knowledge about these therapies.¹³

Legislation and Regulatory Issues

FDA regulates both finished (ready to be sold) DS products and individual dietary ingredients that are used to make DS products. Importantly, FDA regulates DS under a different set of regulations than those covering conventional foods and medications.

Dietary Supplement Health and Education Act

In 1994, the Dietary Supplement Health and Education Act (DSHEA) was approved by Congress and signed into law.¹ This act allowed FDA to regulate DS under the purview of the Center for Food Safety and Applied Nutrition. As a result, DS were excluded from the strict purity and potency standards that are

applied to prescription and nonprescription drugs by the Center for Drug Evaluation and Research. DS had to meet only the standards that applied to food preparation. Any additional standards regarding purity and potency were the sole responsibility of the manufacturer. The lack of strict good manufacturing practice standards created problems with DS content, purity, potency, consistency, and actual identity, as well as contamination, herb misidentification, and sub- and supratherapeutic effects. The lack of strict standards and limited oversight of the manufacturing process created a buyer-beware market, placing the consumer at risk and often alienating conventional health care providers to the use of IH therapies, and also led to the misconception that DS are not regulated by FDA.

Another major difference between DS and prescription and nonprescription drugs is the level of evidence required to demonstrate safety and efficacy. For prescription and nonprescription drugs, clinical trials are required to demonstrate evidence of a drug's safety and efficacy prior to its marketing. Although DS manufacturers are prohibited from marketing unsafe or ineffective products, clinical trials are not generally required to prove the safety and efficacy of DS products prior to their marketing. Some exceptions do exist such as new DS ingredients or DS with health and nutrient content claims. The DS manufacturer is responsible for the product's safety and efficacy; FDA assumes a postmarketing surveillance role and must prove that a particular DS is not safe in order to restrict its use or remove it from the market.

New Dietary Supplement Ingredients

DS ingredients that were sold in the United States prior to October 15, 1994, are not required to be reviewed for safety by FDA before they are marketed; they are assumed to be safe on the basis of a history of use in humans. For any new DS ingredient that was not on the market prior to October 15, 1994, a manufacturer must notify FDA 75 days in advance of its intent to market the product.¹ The manufacturer also must provide FDA with evidence that the DS is safe in humans when used as directed.¹ Unfortunately, a comprehensive list of DS ingredients that were sold prior to this date is not available. As a result, the decision of whether a product contains a new ingredient is left up to the manufacturer. In 2011, FDA issued comprehensive guidance that outlines specific recommendations that must be submitted in new dietary ingredient notifications. The guidance document outlines the specific materials that should be submitted to FDA and makes recommendations for the types of

safety evidence that should be submitted for new DS ingredients taken short term, long term, or intermittently. Submission of available information on genotoxicity, teratogenicity, mutagenicity, and toxicology for a dietary ingredient also is recommended.¹⁴

Current Good Manufacturing Practice

Enactment of the DSHEA required the establishment of current good manufacturing practice (cGMP) standards for the DS industry. In 2007, FDA issued a final rule on proposed changes to cGMP standards for DS.¹⁵ Some of the changes require that DS be manufactured in a quality manner without adulterants or impurities; that they be labeled accurately; and that raw materials be evaluated by the manufacturer. These changes have helped to better regulate manufacturing practices, especially with regard to setting limits on the presence of bacteria, pesticides, and heavy metals. In 2013, researchers used DNA barcoding technology to test 44 DS products marketed in both the United States and Canada; in many products that contained herbs, they found content discrepancies, herb substitution, and contaminants or use of fillers in place of active ingredients.¹⁶ These findings were of concern, because DS products marketed in the United States are required to meet cGMP standards as outlined in DSHEA. Most manufacturers achieve this requirement through their manufacturing and production processes. To address concerns about meeting cGMP standards, some manufacturers also have their DS products tested by external quality assurance programs so that their product can carry a seal of approval that verifies compliance with cGMP standards. These programs are discussed in the section “Quality Assurance Programs.”

Labeling

FDA has primary responsibility for regulating claims found on packaging, package labeling, package inserts, and other promotional materials that are distributed at the point of sale. The Federal Trade Commission (FTC) has primary responsibility for advertising claims made through print and broadcast advertisements, infomercials, catalogs, and other direct marketing materials.¹⁷ FTC requires DS claims of safety and efficacy to be supported by “competent and reliable scientific evidence.” This evidence is defined as “tests, analyses, research, studies or other evidence based on the expertise of professionals in the relevant area that have been conducted and evaluated in

an objective manner by qualified individuals, using procedures generally accepted to yield accurate and reliable results.”¹⁷ Complaints against DS advertising may be filed with FTC online.

All DS marketed in the United States must meet supplement labeling requirements.¹ The labels must list (1) the name of the product as well as the word *dietary supplement*; (2) the net quantity of contents; (3) the manufacturer’s, packer’s, or distributor’s name and place of business; and (4) directions for use. In addition, each label also must contain a supplement facts panel that describes the serving size, the list of dietary ingredients, amount per serving size, and the percent daily value, if one has been established (Figure 50–1).

FIGURE 50–1 Statutory labeling format for certain dietary supplements. (Source: Food and Drug Administration. Dietary supplement labeling guide. Available at: <http://www.fda.gov/Food/GuidanceRegulation/GuidanceDocumentsRegulatoryInformation/DietarySupplements/ucm2006823.htm>. Accessed June 26, 2019.)

Plant-based DS should indicate the plant’s scientific name, or Latin binomial (i.e., genus and species), and the specific plant part used. Manufacturers may market a combination of DS ingredients as a proprietary blend. Although the individual ingredients in the proprietary blend are listed, the actual quantity of each ingredient is not disclosed. Under DSHEA, listing the total weight of the blend and the components of the blend, in order of predominance by weight, is required. Fillers, artificial colors, sweeteners, flavors, or binders also should be listed in descending order of predominance. Consistent with the trend in formulating proprietary blends, many multivitamin products are being combined with additional non-vitamin, non-mineral DS ingredients.

When a DS does not follow labeling requirements, the product is considered misbranded.¹ DS manufacturers are not allowed to make claims that their product will diagnose, cure, mitigate, treat, or prevent disease.¹ These claims would require the product to adhere to the regulations related to a drug, and the product would be subject to all the regulatory processes necessary to demonstrate safety and efficacy. Other examples of misbranding include DS that do not conform to labeling requirements; that fail to contain the name or place of business of the manufacturer, packer, or distributor; or that fail to include accurate statements regarding the quantity of the contents.

The claims for all DS products fall under one of three types: (1) health claim, (2) nutrient content claim, or (3) structure–function claim.¹⁸ Health claims and nutrient content claims require FDA approval, whereas structure–function claims do not. A manufacturer must notify FDA of the exact wording of any structure–function claim within 30 days after the product is marketed. Product labels that contain these claims also must carry a disclaimer: “This statement has not been evaluated by the FDA. This product is not intended to diagnose, treat, cure or prevent disease.”

Health claims describe the relationship between a food, food component, or DS ingredient and the resulting reduction in risk of a disease or health-related condition. An example of an approved health claim is claiming that a diet low in saturated fat and cholesterol that includes 25 g of soy protein daily may reduce the risk of heart disease. Nutrient content claims describe the relative amount of a nutrient or dietary substance in a product. For example, “very low sodium” means the product is required to have 35 mg or less of sodium per reference amount. Finally, a structure–function claim describes how a product may maintain the normal healthy structure or function of the body without discussing a specific disease state. A supplement manufacturer may claim that the product “supports healthy cholesterol levels” but is prohibited from indicating that the supplement may “reduce high cholesterol levels.”

Dietary Supplement and Nonprescription Drug Consumer Protection Act

One of the most important changes to the supplement industry involves the Dietary Supplement and Nonprescription Drug Consumer Protection Act (Public Law 109–462), which was signed into law on December 22, 2006.¹⁹ This law requires manufacturers, packers, or distributors of DS to submit to FDA reports of serious adverse events that are based on specific information received from the public. Serious adverse events are defined as death, a life-threatening situation, a hospitalization, a persistent or significant disability or incapacity, a congenital anomaly or birth defect, or an adverse event that, based on reasonable medical judgment, requires medical or surgical intervention to prevent such serious outcomes. Increased reporting of adverse events may better characterize the frequency and type of serious adverse events associated with DS. FDA actively evaluates trends in serious adverse events so that appropriate corrective action may be taken. Consumers and

health care providers also are encouraged to report DS-related adverse events through FDA's MedWatch adverse event reporting program (www.fda.gov/medwatch).²⁰

Production Issues

Plant Species and Parts

A health care provider should explain that herbal products typically carry two names, the common name and the Latin binomial. An example would be a product such as St. John's wort (common name), which also is known as *Hypericum perforatum* (Latin genus and species name). Some product labels may list only the Latin name, which can be confusing to a consumer who is unfamiliar with this terminology. When consumers enter a pharmacy and search for an echinacea product, they may encounter single-ingredient products that contain any of three echinacea species, *Echinacea pallida*, *Echinacea purpurea*, or *Echinacea angustifolia*; products that contain a mixture of two or all of these species; and products that contain echinacea as one of many listed supplement ingredients. In the case of echinacea, single-ingredient products involving the above-ground parts of *E. purpurea*, formulated as an alcohol extract of the fresh pressed juice, have been the most widely studied. The most recent systematic review and meta-analysis noted no reduction in cold duration for echinacea species (general to all species) in treating upper respiratory infections, but provided promising evidence, compared with placebo, in prevention of colds [risk ratio 0.77 (95% confidence interval [CI] 0.71–0.85), 9 studies].²¹

Common Product Formulations

The content of any DS is based on the raw starting material and how the material subsequently is processed or formulated. Plant-based DS such as echinacea and ginseng have greater variability in their composition than single-ingredient non-botanical products such as creatine or melatonin. This variability is caused by the chemical composition of botanical DS, which is influenced by the plant's growing conditions, the plant species, the specific plant part used, and the time of harvest.

When clinical trial data are lacking, knowing which plant species is preferred or which part of the plant should be used can be based on historical precedent. In developing countries, plant-based medicine is common, and information regarding preferred plant species, preferred plant part, and proper use is handed down from generation to generation, setting a historical precedent for use. When it comes to drug discovery, natural products are the most successful drug leads that we have as a resource. An estimated 25% of modern drugs are plant derived, and 50% are derived from natural products (e.g., plants, animals, microbes, and their derivatives).²² In developing countries, such as those in Africa, the use of plants as drugs is as high as 80%.²² The isolation of new drug compounds from natural resources is one of many reasons to extend environmental preservation and protection to biodiverse landscapes (e.g., rainforests, oceans). Use of herbs based on historical precedent also is common in the practice of midwifery. Few clinical trials exist on the use of DS in pregnant and lactating women and in children. The decision to use DS on the basis of historical precedent is something providers must discuss with their patients.

Method of Preparation

The method in which a DS is manufactured will ultimately affect its final chemical composition and potential efficacy. Some formulations may be well studied, whereas others may not have been studied at all. The most common herbal formulations that a consumer will encounter are made either directly from the fresh plant (e.g., expressed juice, tincture, tea) or from the dried plant (e.g., fluid extract or tincture, evaporated extract [capsules, tablets], tea).²³ Tinctures are most commonly prepared by combining chopped herbs with alcohol. This type of formulation should be avoided in persons taking sedating medications or medications that carry disulfiram reaction warnings. Tinctures also should be used cautiously in special populations such as infants, children, and older people. Most of the common non-plant-based DS, such as vitamins, minerals, glucosamine, creatine, coenzyme Q10, and melatonin, are manufactured as tablets or capsules; these DS represent compounds that are structurally similar to or identical to compounds naturally found in the human body.

Freshly pressed juice formulations are prepared by pressing the herb and collecting the liquid that is removed.²³ This type of preparation often takes a large amount of the herb to create a substantial portion of juice. In the case of

E. purpurea, the best-studied formulation is an alcohol extract of the freshly pressed juice.²¹ A potential advantage of the alcohol extract is that the presence of alcohol increases the product's shelf life.

Tea formulations can be prepared from the root, leaf, bark, and/or fruit of a plant. Most often they are prepared as an *infusion* by pouring boiling water over the fresh or dried leaf portions of one or more plant species and then letting the herb steep for a small amount of time.²² This process releases the water-soluble constituents into the tea. The potency is determined by the steeping time and the amount of herb used. The term *decoction* may be used when the plant parts are placed in cold water, brought to a boil, and then simmered for a period of time.²³ Common single-herb tea formulations include chamomile, ginger, peppermint, green tea, or black tea. Multi-ingredient blends that are customized to a specific person's ailment commonly are used in traditional Chinese medicine and also may be administered as teas.

Extracts are intended to concentrate the effects of an herb and can be prepared by soaking fresh or dried plant parts in alcohol, water, alcohol/water mixtures, or oil.²³ The extraction liquid is then reserved and the plant material discarded. Tinctures are fluid extracts in which alcohol is typically used as the extraction medium.²³ Chemicals that seep into the extraction liquid are specific to the solution used. If the extracted liquid is evaporated and dried, it can be formulated into tablets or capsules.²³ Extracts and tinctures may list the extraction ratio on the package label. For example, a 5:1 ratio would indicate that 5 parts of herb were used to prepare 1 part of the extract. *Ginkgo biloba* is prepared as a dried extract in tablet form. Ginkgo is typically standardized to a 50:1 extract ratio, meaning that 50 parts of the ginkgo leaf were used to prepare 1 part of the extract.²³ Garlic is available in multiple formulations, the most popular being a dried powdered extract in tablet or capsule form and an aged garlic extract. The chemical composition of the powdered extract will differ from that of the aged extract because of the differences in method of preparation. This variance in composition, in turn, may influence the efficacy of each product.

Standardization

The process of standardization is reserved primarily for plant-based DS, because herbs contain many active and inactive constituents.²³ For specific DS, standardization involves identifying specific chemicals or "markers" that

may possess therapeutic activity, isolating them, and then formulating them into a final and consistent product. Standardization can occur only if the chemical markers that contribute to the pharmacologic effect have been identified. For example, a *G. biloba* product may be standardized to contain 6% terpene lactones and 24% flavonoid glycosides, whereas a chastetree berry product may not list any standardized markers at all. The identified active chemical markers may change over time as new research is performed. For example, the active antidepressant marker for St. John's wort initially was thought to be hypericin but is now considered to be hyperforin. Bottles of St. John's wort may list one or both of these standardizations on the package label. Interestingly, no legal or regulatory definition is accepted as it relates to standardization of DS. Claiming that a product is standardized does not necessarily mean a uniform manufacturing process was used. DS verification programs (discussed later) however, may be helpful in determining compliance with package labeling and actual product composition.

Common Quality Control Issue: Adulteration

According to DSHEA, adulteration of a DS occurs when (1) the DS presents a significant or unreasonable risk of illness or injury when used in accordance with the suggested labeling, (2) the DS is a new entity and lacks adequate evidence to ensure its safety of use, (3) the DS has been declared an imminent hazard by the Department of Health and Human Services Secretary, or (4) the DS contains a dietary ingredient that is present in sufficient quantity to render the product poisonous or deleterious to human health, as described for adulterated foods in the Federal Food, Drug, and Cosmetic Act.¹ Adulteration of DS has occurred both intentionally and unintentionally. Examples of unintentional adulterants include heavy metals introduced at the time of cultivation or during the manufacturing process.²⁴ Heavy metals from environmental pollution can leach from contaminated soil into a plant as the plant grows.²⁵ In an analysis of 230 Ayurvedic medicines purchased over the internet, 21% of the Indian-manufactured medicines and 22% of the U.S.-manufactured medicines contained lead, mercury, or arsenic.²⁴ Heavy metals also may be added to traditional medicine products with the intent of promoting good health. In traditional *rasa shastra* Ayurvedic medicine, addition of heavy metals is standard practice.²⁵ In this instance, the presence of heavy metals would not be considered adulteration, because they were

added intentionally and with the goal of promoting good health. However, this practice still could lead to heavy metal toxicity for the product user if the content exceeds recommended levels for heavy metal exposure set by state or national health standards.²⁵

Intentional adulteration can occur when a manufacturer substitutes a different DS for an ingredient that is in short supply or is too expensive (e.g., economic adulteration). It also can occur when a prescription drug is added to the product to enhance its efficacy. Traditional Chinese medicines frequently have been found to contain heavy metals and undeclared drugs.²⁶ A survey of FDA Class I drug recalls performed between 2004 and 2012 found that 50% of all drug recalls involved DS products.²⁷ A Class I drug recall involves products containing a drug compound that is likely to result in serious health consequences or death.²⁷ These recalls most commonly involved products manufactured in the United States and marketed for sexual enhancement, bodybuilding, and weight loss. DS used for weight loss and energy are problematic, causing 71.8% of emergency department visits related to DS and resulting in palpitations, chest pain, or tachycardia in predominantly young patients, ages 20–34 years.²⁶ Violations of cGMP standards have been documented for nearly half of the DS manufacturing firms inspected by FDA.²⁷ The agency is addressing this issue by issuing targeted marketing about adulterated supplements to both consumers and health care providers and by creating multinational enforcement groups who target suppliers of commonly adulterated supplements.²⁷

Quality Assurance Programs

Several organizations have developed quality assurance programs to assess analytical reference standards and to certify DS composition. These programs indicate whether the DS product contents match the label contents; however, the safety or efficacy of the DS cannot be ensured. Because only a single batch is tested at any one time, these programs also do not address product quality between different batches or lots. Most quality assurance programs offer a “voluntary third party verification program” to manufacturers who pay to have their products tested. Products that pass are then allowed to carry a verification seal on the product label.

U. S. Pharmacopeia Dietary Supplement

Verification Program

In 2002, the U.S. Pharmacopeia (USP) initiated a voluntary Dietary Supplements Verification Program.²⁸ The purpose of the program is to provide consumers with a method for identifying DS that have passed rigorous standards for purity, potency, performance, and consistency in agreement with cGMP. Products earning USP certification carry a distinctive seal of approval on the product label called the “USP Verified Mark.” These products are certified to contain the listed ingredients in the indicated potency and amounts, to be bioavailable and free of contaminants, and to have been manufactured under appropriate sanitary and well-controlled conditions. As of 2019, over 100 different DS formulas representing different brands and retailers have received the USP Verified Mark. To ensure continuing adherence to quality standards, USP conducts yearly facility audits and initiates surveillance of certified products by testing products sold on store shelves. Approved products can be found at the USP website (<https://www.quality-supplements.org/verified-products>).

ConsumerLab.com

ConsumerLab.com (CL) is an independent company that tests products related to health, wellness, and nutrition, such as DS.²⁹ Products are tested on the basis of identity, purity, and consistency with the labeled ingredients. The test results are posted on CL’s website, https://www.consumerlab.com/results/brands_vitamins_supplements_list.asp, with new results available every 4–6 weeks. Manufacturers are allowed to license the CL seal of approval for a product that passes the review. To continue to carry the approval seal, a product must pass random sample testing every 12 months. The site provides free access to some information, but full access to DS testing results and product reviews requires a subscription of \$47 for 1 year or \$78 for 2 years. The specific DS products that have passed testing may not represent testing approval for the entire product line from a given DS manufacturer. The names of DS products that fail testing are available only to subscribers. The company is not affiliated with manufacturers of any DS, health, or nutrition products.

NSF International

NSF was established more than 66 years ago to standardize sanitation and

food safety requirements. Today, NSF International (<http://www.nsf.org/consumer-resources/health-beauty/supplements-vitamins/supplement-vitamin-certification>) is an independent, nonprofit organization that provides certifications of food, water, and DS quality.³⁰ This organization verifies the DS product formulation, and that it contains the labeled ingredients and that contaminants and unlisted ingredients are not present. NSF also certifies DS intended for use by athletes under the NSF Certified for Sport program. DS are screened to ensure that they contain none of the 270-plus substances banned for use by major athletic organizations nor any undeclared ingredients, including stimulants, narcotics, steroids, diuretics, beta-2 agonists, masking agents, and other substances. This program is recognized by sporting organizations including the National Football League, Major League Baseball, Professional Golfers' Association, Ladies Professional Golf Association, and the Canadian Centre for Ethics in Sports. Any DS product that meets certification standards is allowed to carry the NSF certification seal of approval on the label.

Hazards From Dietary Supplements

False Advertising and Quackery

Manufacturers who make DS health claims sometimes ignore the regulations established by FDA and FTC and market products using false or misleading claims. FTC requires all advertising to be truthful, not misleading, and based on sound scientific evidence. The weight-loss DS market is one example in which false or misleading health claims commonly are identified.³¹ Historically, this type of practice might be considered *quackery*, which implies that the person promoting use of the product knows it to be ineffective and is still promoting its use. In the case of some DS, manufacturers may believe, with or without strong clinical support, that their products are effective for a wide variety of ailments.

Consumers and providers should be wary of information found on online sites that market DS products. Some retail sites have been shown to be unreliable and may list disease claims, may fail to cite the standard disclaimer, and may lack referenced information.³² Consumers should be wary of products that contain any of the characteristics listed in [Table 50–2](#).^{31,33} In addition, consumers should consult a reliable drug information resource, as well as their health care provider, to confirm whether the health claims have a scientific

basis. Consumers and providers can go to the NIH Office of Dietary Supplements site and sign up to receive FDA and FTC press releases for products that have been identified as containing adulterants, such as prescription drugs, or for manufacturers that have been issued warnings or recalls for product quality.³¹ This online site also provides tips on how to evaluate health information on the internet.³¹ FDA also has created supplement categories that should be viewed with scrutiny because of a history of prior violations or problems.³³ These supplement categories are listed in [Table 50–3](#). A consumer or provider who wishes to file a complaint related to false advertising should contact FTC.¹⁷

TABLE 50–2 Characteristics of DS Fraudulent or Misleading Claims

- List specific disease states or allude to the product’s use for a disease usually treated with prescription drug therapy.
- State that supplement’s efficacy is similar to, or supplement can be used as an alternative to, a prescription or nonprescription drug.
- List a wide variety of unrelated clinical conditions for use.
- State only benefits and no harmful effects.
- Neglect to provide expiration date, lot number, and contact information for the manufacturer on the package label.
- Use pseudo-medical terminology such as *detoxify*, *purify*, or *improves body chemistry*.
- Use terms such as *miraculous discovery*, *revolutionary therapy*, or *breakthrough treatment*, which suggest that the product has superior efficacy to standard care.
- Suggest that the product is more expensive, because it works so well.
- Use personal testimonials in place of sound scientific evidence to support product claims.
- Promise quick relief of a health condition.
- Promote natural content as being superior to conventional medicine.
- Provide a money-back guarantee or satisfaction guarantee, but marketers of fraudulent products often change their business location.
- Make accusations that pharmaceutical drug manufacturers and health care providers are working together to defraud consumers and steer consumers away from healthier dietary supplement options.

TABLE 50–3 Categories of Supplements That FDA Cites as “Clearly Problematic”

- Treatments of potentially life-threatening diseases (e.g., HIV, cancer) or serious medical conditions such as Alzheimer disease
- Weight-loss products
- Chelation products^a
- Treatments for behavioral disorders such as attention-deficit/hyperactivity disorder or

autism

- Treatments for intellectual disability or Down syndrome
- Colloidal minerals and silver products^b
- Supplements for addiction (e.g., smoking, drinking, opiate use)
- Supplements for body building or athletic performance enhancement
- Supplements for sexual enhancement (e.g., impotence)

^a FDA has not approved any nonprescription chelation products (only prescription). Unapproved chelation products in supplement form can pose a serious risk of harm.

^b FDA has not approved any nonprescription or prescription oral silver products. Taken orally, colloidal silver may pose serious risk of harm.

Key: FDA = Food and Drug Administration; HIV = human immunodeficiency virus.

Hazards Introduced by the Consumer

Exceeding the recommended dietary allowance for a vitamin or mineral supplement or taking more of a supplement than is directed on the label can occur intentionally or accidentally. Accidental over-supplementation is more likely to occur when a consumer is taking more than one multi-ingredient product containing similar ingredients. Regardless of how it occurs, over-supplementation should be discouraged, because an adverse event may result. Overuse of some DS has serious consequences. For example, overuse of colloidal silver has led to irreversible blue-gray skin discoloration.³⁴ Overuse of calcium or vitamin D supplements over short periods may cause hypercalcemia. In addition, concern exists that excessive calcium supplementation over long periods of time may contribute to coronary artery calcification.³⁵ As mentioned previously, adverse events should be reported by consumers and health care professionals to MedWatch.²⁰ For most DS, individual case reports and postmarketing surveillance provide the best means of identifying adverse events and drug interactions. Consumers should be advised to monitor for acute adverse events for up to 2 weeks after initiating a new DS and to continue monitoring while using the product.

Product Hazards: Adverse Effects and Drug Interactions

The fact that herbal DS are derived from a natural source does not guarantee safety. Adverse effects often are linked to the pharmacology of the supplement, as was noted when products containing ephedra were removed from the market because of their association with stroke and myocardial infarction.³⁶

Some DS contain chemicals that are toxic when ingested. Pyrrolizidine alkaloids present in *Symphytum officinale* (comfrey), *Borago officinalis* (borage), *Tussilago farfara* (coltsfoot), and *Senecio aureus* (golden ragwort or life root) have been associated with case reports of hepatotoxicity.³⁷ If an adverse event is suspected, product testing is essential to rule out possible plant misidentification; adulteration with prescription or nonprescription drugs; or contamination with heavy metals, microbial contaminants, and pesticides that can occur during production.

Interactions between DS and conventional medications may have a pharmacodynamic or pharmacokinetic basis. Pharmacodynamic interactions can occur when a supplement's pharmacology is similar to or opposite that of a drug the consumer is taking. For example, both St. John's wort and L-tryptophan have been linked to case reports of serotonin syndrome in persons taking these products with prescription psychotropic drugs.^{38,39} Additive effects have occurred, or theoretically could occur, in persons combining central nervous system depressants with DS that have sedative properties, such as melatonin or valerian, or in persons combining drugs that have antithrombotic activity with DS that have antiplatelet properties, such as garlic, ginkgo, and ginger.⁴⁰ Case reports of a DS opposing the effect of a drug or adversely influencing an existing disease state have been reported infrequently in the literature. Theoretical concerns are cited as a reason to avoid DS that enhance immune system activity such as echinacea in persons who have autoimmune disorders or require immunosuppressants.⁴⁰ Finally, DS may have pharmacokinetic interactions. St. John's wort induces multiple cytochrome P450 isoenzymes, as well as the P-glycoprotein drug transporter system.⁴⁰

Communication Issues

Counseling on Dietary Supplements

The primary consideration in counseling consumers on DS is to recognize the importance of respecting the person's beliefs and values so that a trusting, nonjudgmental relationship can develop. The person must feel comfortable telling the provider about any use of DS. Providers should ask about all therapies being used, including DS, because consumers often may not disclose this information. Providers also must be able to provide recommendations regarding DS, when information is available. The risk of adverse effects versus the potential for positive effects must be considered and clearly explained. As an example, if a consumer wishes to take a DS that *has demonstrated both positive and negative outcomes in clinical trials, but lacks* documented adverse effects or drug interactions, a provider may support DS use with the caveat that it may or may not be of benefit. The consumer should be advised to monitor for perceived benefit and adverse effects. If no benefits are observed within the expected time frame, the DS should be discontinued. Providers should be less inclined to support use of a DS whose efficacy is not supported by evidence and should discourage the use of unsafe products and practices. Importantly, providers do not control access to DS, and consumers may choose to use any available DS. In many instances, providers may be in the position of educating a consumer about DS even though they believe that the product should not be used. In these situations, counseling on expectations and adverse effects is essential. For example, educating consumers on the early signs of a serious adverse effect will enable them to recognize a problem and discontinue the DS to minimize harm. Consumers always should be advised to seek medical care for serious conditions.

Health care providers should encourage consumers to read labels carefully and ask questions. Providers should be aware of the potential for confusion related to DS labels and claims, and counsel consumers in a way that lessens confusion. *Thymus* is an example of a term that might be dangerous if misunderstood. *Thymus vulgaris* is the Latin name for garden thyme. On a supplement label, "*Thymus extract*" may refer to an extract of the herbs thyme, Spanish thyme, or wild thyme, products with relatively few adverse effects when used in small doses. However, "thymus extract" may refer to a

preparation made from animal thymus gland that is marketed to enhance immune function, a product with considerable quality and safety concerns.

In addition to these broad counseling issues, the following points should be emphasized. First, providers should emphasize that most self-care with DS should be for a limited period. If a problem persists, the consumer should seek medical care. Second, consumers should inform their provider before taking DS for a condition that also is being treated with a prescription drug. Third, consumers should be informed that FDA does not require DS manufacturers to submit data demonstrating efficacy or safety before the product is marketed, unless the product contains a new dietary ingredient that was not on the market prior to October 15, 1994. Quality and consistency of DS products remain a concern but may improve with the new cGMP standards. The following points should be used in counseling consumers who wish to use a DS:

- Purchase products that have either a seal of quality on the label, acquired through a program such as the USP's Dietary Supplements Verification Program or NSF International's certification program, or that meet their content claim as assessed by ConsumerLab.com.
- Purchase from large, reputable companies. These companies have the resources to meet strict manufacturing standards, have a reputation to uphold, and are more likely to follow quality assurance procedures. Companies that also manufacture prescription or nonprescription drugs (e.g., drugstore chain brands) are more likely to have cGMP standards in place and to follow those procedures when producing DS.
- Once a quality DS has been selected, continue to use the same brand and formulation. Although this approach does not guarantee a lack of potential quality issues, given that variability between batches can occur, it does increase the likelihood of a consistent product and dose. Providers working with consumers who have not had positive results with use of a DS might consider a trial of a different brand that is appropriate for the specific symptom before determining that the supplement is ineffective for that consumer.
- Know the DS products that you are using and tell your health care provider about them to ensure your provider can identify potential safety concerns with your health conditions and potential interactions with your current medications.
- Report any adverse effects related to DS use to your health care

provider.

Additional recommendations for counseling can be found in [Table 50–4](#). Cases 50–1 and 50–2 provide examples of how to counsel consumers who wish to use DS.

TABLE 50–4 General Recommendations for Consumers

Appropriate Use

- Read all labels carefully; never take more than the recommended amount.
- Never share DS with others.
- Do not select a product that lacks dosing recommendations on the label.
- Avoid products that do not carry a lot number or expiration date.
- Discard products 1 year from the date of purchase if no other expiration date is present.
- Select products that list the manufacturer's name, address, and telephone number.
- Store products in a dry environment out of direct sunlight and away from young children and pets.

Special Groups

- Always seek the advice of a pediatrician before giving a DS to a child.
- Avoid DS if you are pregnant or breastfeeding or are trying to become pregnant.
- Ask adolescents about DS use, especially products used for weight loss, mood, sexual health, and energy.
- Speak to your health care provider if you are trying to treat a life-threatening condition, such as cancer or HIV.

Adverse Effects

- The term *natural* does not mean safe; be diligent and report any unusual experiences to your health care provider.
- If you are allergic to plants, weeds, and/or pollen, ask your provider before using a DS.
- Never take more than the amount recommended on the DS label.

Interactions

- If you are taking a prescription medication, do not take a DS or the same condition.
- When possible, avoid taking multi-ingredient preparations; select single-ingredient products that list the strength per dose.
- Do not take these products with alcohol.
- Check with your health care provider if you are taking “blood-thinning” drugs; some DS may interact with these drugs.
- Always inform your health care provider of the products you are taking; keep a list or bring them with you to your appointment.

Expectations

- Never use these products in place of proper rest and nutrition; eat a balanced diet.
- Do not expect a cure or unrealistic results; these agents are not cure-alls.
- If a claim sounds too good to be true, it probably is; use discretion when evaluating product claims.
- Keep a diary to track the effectiveness and adverse effects of DS.

Key: DS = Dietary supplements; HIV = human immunodeficiency virus.

Case 50-1

Patient Symptoms and History

Mr. McAllister is 68 years old and would like to select a joint care DS for his osteoarthritis. He was diagnosed with knee osteoarthritis 15 years ago. He describes his pain as transient: he has severe pain some weeks and no pain during other weeks. He has been using acetaminophen 500 mg every 6 hours when he is in pain as his primary care provider (PCP) recommended. His last examination showed that he has cartilage damage, and his orthopedic doctor recommended that he try glucosamine. He has high blood pressure that is stable, managed with 20 mg lisinopril daily. Mr. McAllister is an avid cyclist, walks his dog three times a day, and is in otherwise excellent health. He noticed that many different types of glucosamine products are available and would like assistance in selecting the best product.

Clinical Considerations

Mr. McAllister appears to be a great candidate for glucosamine given his history of damaged knee cartilage, a condition for which glucosamine sulfate has been shown to have some effect. Mr. McAllister is taking only lisinopril, so drug interactions with glucosamine are not likely. Mr. McAllister should select a glucosamine supplement that has been approved by one of the three DS quality assurance programs: the United States Pharmacopoeia Dietary Supplement Verification Program, ConsumerLab, or NSF International. Glucosamine products that carry a seal of approval on the label would be preferable. If the label does not bear a seal of approval, a good way to verify the quality of the product is to visit the website of a quality assurance program to verify whether the product is recommended.

Mr. McAllister also should evaluate the supplement's facts panel to help him select a product that follows appropriate DS labeling recommendations. The product he selects should list the name of the DS, its active ingredients, and the strength of each ingredient contained in each pill. The manufacturer's name and address and the recommended daily dose also should be listed. He should review and consider all of the DS ingredients listed on the label, paying special attention to the ingredients that are not necessary, included added salt (e.g., sodium chloride). This is important as increased salt intake may contribute to Mr. McAllister's high blood pressure.

If the DS label bears any statements regarding the structure or function of the body (e.g., “strengthening cartilage”) the DS product also must carry the FDA disclaimer, “This statement has not been evaluated by the Food and Drug Administration. This product is not intended to diagnose, treat, cure or prevent any disease.”

Mr. McAllister should select a glucosamine sulfate formulation, not N-acetyl glucosamine or glucosamine hydrochloride, because the sulfate formulation has been the most widely studied and has the most clinical support. He should follow the dosing recommendations on the label and keep a diary of how he is feeling while taking the supplement. He should document his knee pain, joint mobility, and stiffness over time. He also should document any side effects, including when they began and dissipated. Keeping a glucosamine diary is important, because the supplement may take several months to work. He should continue to take acetaminophen as his doctor recommended during his acute flare ups, because glucosamine is not an analgesic. Before undergoing any surgical procedures, Mr. McAllister should be instructed to let his provider know that he is taking glucosamine. Finally, Mr. McAllister should be instructed to purchase his supplements from a reputable company. This will help ensure that the company has the resources to meet strict manufacturing standards, has a reputation to uphold, and would be more likely to follow strict quality assurance procedures. Companies that also manufacture prescription and nonprescription drugs are more likely to have good manufacturing practices in place and to follow these procedures when producing DS.

Case 50–2

Patient Complaint and History

Ms. Feldman is a 67-year-old female who just came from visiting her PCP for symptoms of chest pain and forgetfulness. She was diagnosed with angina, early-onset dementia from Alzheimer disease, and constipation. Her past medical history is significant for osteopenia and lower back pain, but she is able to walk without an assistive device and to maintain a steady gait. She and her PCP are in favor of using an integrative health approach and have decided to start *Ginkgo biloba*, standardized extract, 240 mg daily, instead of an acetylcholinesterase inhibitor for her dementia. She also is picking up a new prescription for metoprolol succinate (Toprol XL 100 mg once daily) and brings a laxative called “Bowel Balance” to the counter. She routinely picks up refills of her medications for bone health (calcium and vitamin D), blood pressure (hydrochlorothiazide), and pain relief (scheduled Tylenol and as-needed Vicodin, with increased use of Vicodin over the past 2 weeks). She would like your help in selecting the best *Ginkgo biloba* DS and a laxative that meets her PCP’s recommendations. She also is seeking reassurance that the new supplement is safe to use with her prescription drugs.

You evaluate the label on the Bowel Balance laxative product and find that it is a proprietary blend of 10 ingredients with psyllium seed husks, dandelion root and leaf extract 5:1, aloe vera gel (from concentrate), ginger, and senna extract as the first five ingredients. Is this a good product for this patient? Her PCP also has recommended a standardized *G. biloba* DS. Where do you find the optimal standardization information and check for potential drug-herb

interactions?

Clinical Considerations

The ingredient listed first in a proprietary blend is present in the greatest quantity. In general, the actual amount of each ingredient in a proprietary blend is not listed, but the total weight of the blend is listed. In addition, the ingredients are listed in the order of most predominant by weight to least predominant. Evaluating the first three ingredients in a blend is a good place to start. If the ingredients listed are unfamiliar, one of the drug information resources listed in this chapter can be used to evaluate the ingredients. Psyllium is a fiber laxative; dandelion root has some digestive benefits and may help with constipation; dandelion leaf is a diuretic; aloe gel is a laxative; ginger relieves nausea or motion sickness and may help with indigestion. In light of the patient's constipation and current opiate use, it would be best to avoid use of this proprietary blend, because it is likely to have laxative and diuretic properties. Because she is using Vicodin, the best approach is recommending concomitant use of a single-ingredient stimulant laxative, such as senna, and a stool softener, along with dietary recommendations to increase intake of fiber and water. In light of her recent diagnosis of dementia, limiting the use of opiates, drugs with sedating or central nervous system actions, and anticholinergics is preferred. Using the Lexicomp natural products database, you see that a standardized extract of ginkgo biloba should be prepared from the leaf of the tree and standardized to contain 24% flavone glycosides and 6% terpene lactones. By reviewing the Supplement Facts panel of the ginkgo products in stock, you should be able to select a single-ingredient preparation that contains the correct plant species and plant part(s) and also provides evidence of this standardization. The label also should be checked for the listing of a third-party verification quality assurance program, such as U.S. Pharmacopeia Dietary Supplement Verification Process, ConsumerLab.com, or NSF International. Dosing is 120 mg orally twice daily. The database does not list any drug-herb interactions that would be significant given Ms. Feldman's medication profile. If she develops an arrhythmia in the future and is placed on warfarin or a newer oral anticoagulant, the use of ginkgo should be reassessed, because this herb has antiplatelet properties.

Considerations for Special Population Groups

This section provides a brief overview of issues regarding the use of DS by different consumers. The lack of data on safety and efficacy of DS in these groups, as well as the current regulatory issues, underscores the need for comprehensive assessment of the consumer's health status and for knowledgeable counseling.

Older Adults

Although many older adults are healthy and living independently, some may

have a significant burden of disease. The latter may have age- and disease-related physiologic declines such as impaired kidney function. Older individuals may be chronically taking multiple prescription and nonprescription drugs, making a thorough medical history essential. The potential for drug–food and drug–DS interactions, age-related functional declines, and concomitant diseases should be considered in counseling older adults about DS.

Children

Use of DS by children presents unique challenges. The central nervous system of a child may be sensitive to many drugs and chemicals, especially when they are administered at an adult dose. Little research regarding the safe and effective use of DS in children is available, making evidence-based recommendations difficult. In addition, from a practical perspective, an appropriate pediatric dosage of a DS product cannot be determined if the content of the product is in question. Finally, DS should have childproof safety closures to avoid possible accidental ingestions by young children.

Adolescents

DS use among adolescents has expanded beyond vitamin supplementation to include losing weight, building muscle, and increasing energy levels.⁴¹ Data on the safety of use of these types of DS by adolescents are limited. However, research has shown that, compared with the use of vitamins, DS used by adolescents for losing weight, building muscle, and increasing energy were associated with an almost three times greater risk for severe adverse events (e.g., emergency room visit, hospitalization, death, disability). Counseling about DS use is critical among adolescents in whom body image, peer pressure, and societal norms may be powerful drivers of DS use.

Pregnant and Lactating Women

Use of DS by a woman who is planning to become pregnant or is already pregnant presents several dilemmas. Throughout the world, herbal DS have been used to maintain health during pregnancy, prevent miscarriages, and induce labor. In the United States, concern has focused on minimizing fetal exposures to prescription and nonprescription drugs, as well as to DS. Although many natural products have been used in pregnancy, published data

on their effect on the developing embryo and fetus are sparse. As part of standard preconception care, a woman should be asked about her use of DS, especially if her nutritional status might be affected at the time of conception (e.g., folic acid intake) or her ability to become pregnant might be affected (e.g., DS effects on ovulation). The most important issue concerning DS use during pregnancy and lactation is the uncertainty about the exact content in any given product batch or brand. Currently, providers should advise women to limit their use of DS to products that have reasonable proof of safety and efficacy for use during pregnancy and lactation.

Kidney Disease

Many Americans have chronic kidney disease (CKD) caused by diseases such as diabetes. CKD presents many challenges to the safe use of many prescription and nonprescription drugs. Most commonly, the individual may be unable to eliminate the drug appropriately, potentially resulting in supratherapeutic concentrations. This effect also is true for hepatically metabolized drugs with active, renally eliminated metabolites. When a patient with CKD requires dialysis, the absorption, distribution, and hepatic metabolism of drugs also may be altered. The effects of kidney disease on DS pharmacokinetics have not been studied adequately. In addition, many herbs possess antiplatelet properties that might increase the risk of bleeding in CKD.⁴⁰

Liver Disease

The effects of liver disease on DS pharmacokinetics have not been studied adequately. Many DS products contain combination ingredients; studying and evaluating the effects of liver disease on the pharmacokinetics of combination DS present unique challenges. For this reason, DS should be avoided or used cautiously in patients with compromised liver function. Some DS products can affect the ability of the liver to metabolize other medications, which can lead to drug–DS interactions. DS products containing known hepatotoxic ingredients should be avoided. No DS have been found to be clinically effective in reversing liver disease or in preventing liver damage. However, empiric use of DS-like milk thistle and its silymarin flavonolignans (with silybin being the primary component) have been used empirically in the treatment of mushroom poisoning and in cases of nonalcoholic fatty liver disease, with some evidence of efficacy.

Surgery

A detailed preoperative history that includes questions related to DS use should be obtained from all patients undergoing surgery. If applicable, supplements that are known to affect sedation or platelet function or that might possibly affect the metabolism of anesthetic agents should be discontinued 2 weeks prior to the procedure. Any other DS that the patient is taking should be reviewed by the provider to avoid potential harm.

Reliable Information Resources

The following resources may be used for general information, ongoing research, regulatory updates and alerts, and information on DS composition. Among these, Micromedex (Alternative Medicine section), Natural Medicines, and ConsumerLab.com require a paid subscription.

Micromedex, Alternative Medicine

Micromedex, Alternative Medicine (IBM Watson Health, Greenwood Village, CO) provides drug information on all types of DS, including herbs, vitamins, minerals, Chinese medicine, homeopathy, and acupuncture. This resource provides information about DS dosing, pharmacokinetics, interactions, and clinical use, along with primary literature citations. The content undergoes extensive review and is updated quarterly. The database is searchable by DS ingredient(s) and trade name.⁴²

CARDS, NIH Office of Dietary Supplements

The Computer Access to Research on Dietary Supplements (CARDS) database contains federally funded research specific to DS. Information found in CARDS is provided from many government agencies that sponsor DS research, including but not limited to the NIH Office of Dietary Supplements. The database is searchable by DS ingredient, health outcome, study type, or names of research investigators. A record of completed and published research studies on DS is maintained within the database.⁴³

Cochrane Database of Systematic Reviews

The Cochrane Database of Systematic Reviews is accessible through PubMed and offers evidence-based analyses of DS. These reports provide detailed information on trials that were included and excluded from the analysis and on the review methodology used.⁴⁴ One advantage of this database is that statements that support or refute the use of a specific DS are expressed clearly. This database requires a subscription for access. Many providers may have difficulty understanding the style and arrangement of the information that supports the analyses. In response to this concern, each review now contains a plain language summary to help improve interpretation and to allow for translation into other languages.

ConsumerLab.com

ConsumerLab.com provides access to an encyclopedia of *Natural and Alternative Treatments*. The information in this encyclopedia is evidence based and well referenced. It is a useful resource for both consumers and health care providers.²⁹

Dietary Supplement Ingredient Database

The Dietary Supplement Ingredient Database (DSID) was created by a group of federal agencies and research organizations to estimate the levels of ingredients found in DS products. DSID provides information on analyzed levels of nutrients found in adult multivitamins and minerals used in the United States. The database is intended for use in research applications that are appropriate for conducting population-based studies on nutrient intake, as opposed to assessing individual products. The data are grouped by nutrient levels rather than by product name.⁴⁵

Dietary Supplement Label Database

The Dietary Supplement Label Database (DSLDB) was created by the National Library of Medicine and includes information from the labels of more than 76,000 DS products. DSLDB is intended to help consumers and health care professionals identify ingredients found in brand-name DS. Information in this database is based on the ingredients declared by the DS manufacturer and

includes both active and inactive ingredients. DS ingredients are linked to MedlinePlus and PubMed to allow users to investigate the dietary ingredients and evaluate related primary literature. For each DS product listed, the database provides the manufacturer's name and contact information. DSLD also provides links to fact sheets published by FDA, the NIH Office of Dietary Supplements, National Center for Complementary and Integrative Health (NCCIH), and the National Cancer Institute.⁴⁶

Lexicomp, Natural Products

The Natural Products database can be searched for more than 415 commonly used DS and is intended for use by health care providers. It is peer reviewed by an expert panel and is fully referenced to the primary literature. It contains a wide variety of information on efficacy, safety, interactions, formulations, and dosing, which can be provided as printable patient education information. The database is searchable by ingredient (both vitamin and mineral ingredients and non-vitamin and non-mineral ingredients). Brand names can be used to search for some vitamin and mineral products. Plant-based supplements are best searched using the Latin name or the scientific name.⁴⁷

MedlinePlus

MedlinePlus, published by NIH, is designed for consumers and contains information regarding diseases, conditions, and wellness. It provides consumer-friendly information about plant-based and other DS, including a summary of the science that supports an ingredient. Directories, a medical encyclopedia, and a medical dictionary are available in several languages.⁴⁸

Natural Medicines

Natural Medicines is published by the Therapeutic Research Center (Stockton, CA).⁴¹ This resource is an international research collaboration of providers from many disciplines, including those trained in Western- and Asian-based forms of care. The database provides a comprehensive listing of single-ingredient and combination DS products and their associated adverse effects, drug-supplement interactions, and more. Commercially available DS products are listed for both the United States and Canada. Recommendations for DS efficacy are graded to reflect the type and quality of the clinical evidence on

which they are based. In addition to reviews of DS, the database includes monographs on other IH modalities (e.g., acupressure, Ayurveda, biofeedback, aromatherapy), as well as a dictionary of IH terms. Each monograph has an accompanying consumer handout that is available in Spanish, French, and English.

National Center for Complementary and Integrative Health (NCCIH)

NCCIH is part of NIH and is one of the federal government's leading agencies in promoting evidence-based research on IH therapies. This online site provides information on clinical trials, opportunities for research and funding, training opportunities for IH providers, and health information on IH modalities. Links to clinical practice guidelines for vitamins and other complementary therapies also are provided.⁴⁸

Office of Dietary Supplements, National Institutes of Health

The NIH Office of Dietary Supplements is a comprehensive site for general information on DS. The online site contains information regarding health and nutrition and decision-making approaches for DS treatment options and nutrient recommendations. Importantly, the site provides evidence-based fact sheets on many DS, including vitamins and botanicals. In addition, the site provides resources for researchers of DS as well as information on DS training and career development opportunities.⁴⁹

PubMed Subset for Dietary Supplements

The NIH Office of Dietary Supplements instituted a joint project with the National Library of Medicine to create the PubMed subset for DS. This subset succeeds the International Bibliographic Information on Dietary Supplements database, which was a collaboration between the Office of Dietary Supplements and the U.S. Department of Agriculture National Agricultural Library. The subset was created to improve access to DS-related literature and incorporates journals indexed in Medline that contain this content.⁵⁰

Key Points for Dietary Supplements

- DS use is common among consumers, making it essential for all providers to be knowledgeable about the most frequently used products. This education should include information about evidenced-based resources and where to report adverse effects, drug interactions, or suspected fraudulent health claims.
- Regulation of DS under DSHEA has created a marketplace in which product safety, efficacy, and quality can vary or be unknown.
- Health care providers are in a unique position to counsel consumers on DS and should take an open, nonjudgmental, evidence-based approach.
- Obtaining a history of DS use should be part of the overall drug history.
- Counseling recommendations for DS use should include consideration of overall scientific support, historical use, specific patient groups, potential for adverse effects, and potential for interactions with other medications or medical illnesses.

Chapter 51: Natural Products

Authors: Cydney E. McQueen, Katherine Kelly Orr

This chapter's discussion of natural products follows an organ system approach, as outlined in [Table 51-1](#). The chapter content is based on a review of natural products of importance in pharmacy practice. Selection of products to discuss is based on whether they have evidence to support their use, are widely promoted either with or without evidence supporting their use, or present known or theoretical safety concerns.

TABLE 51-1 Chapter Supplements Grouped by Organ Systems	
System/Systemic Effect or Action	Supplement
Cardiovascular system	Coenzyme Q10
	Fish oil
	Garlic
	Red yeast rice
	Resveratrol
Central nervous system	Butterbur
	Feverfew
	Ginkgo
	Melatonin
	St. John's wort
Digestive system	Valerian
	Ginger
	Milk thistle
	Peppermint
Endocrine system	Alpha lipoic acid

System/Systemic Effect or Action	Supplement
	Cinnamon
Immune modulators	Echinacea
	Elderberry
Physical and mental performance enhancers	Eleuthero
	Asian ginseng
	Green tea
Kidney, urinary tract, and prostate	African plum
	Cranberry
	DHEA
	Saw palmetto
Musculoskeletal system	Glucosamine and chondroitin
	MSM
	SAMe
	Turmeric/curcumin
Skin conditions	Aloe vera
	Tea tree oil
Women's health	Black cohosh
	Chaste tree berry
	Evening primrose oil
	Fenugreek
	Phytoestrogens

Key: DHEA, Dehydroepiandrosterone; MSM, methylsulfonylmethane; SAMe, S-adenosyl-L-methionine.

Cardiovascular System

Coenzyme Q10

Therapeutic Uses

Consumers primarily use coenzyme Q10 (CoQ10) for cardiovascular conditions, as a general antioxidant, and for reduction of statin-associated adverse effects. It also has been investigated for use in migraine prevention, improvement of dyslipidemias, Parkinson's disease, and reduction of chemotherapy-associated adverse effects.

Physiologic Activity

Coenzyme Q10 (CoQ10 or ubiquinone) is converted to ubiquinol in the body. Ubiquinol is found in every cell, primarily in mitochondria; the greatest concentrations are in the heart, kidney, liver, and muscle.¹ As the rate-limiting cofactor in mitochondrial adenosine triphosphate (ATP) formation, CoQ10 is involved in many energy production functions and regeneration of antioxidants, such as vitamin E. Low plasma CoQ10 levels are common in migraineurs and may be predictive of mortality in patients with chronic heart failure (HF).² Statins decrease CoQ10 biosynthesis and lower its concentrations in serum, but not always in muscle tissue. The extent to which this effect occurs differs among statins.³ CoQ10 also stabilizes membranes and may have vasodilatory and inotropic effects.⁴

Dosage and Product Considerations

For heart failure, cardiomyopathy, or hypertension, a common dosage is 100 mg taken 2–3 times daily with meals to aid absorption. Dosages up to 1200 mg daily have been used safely for some neurologic conditions.⁵ The dosage to counteract depletion of CoQ10 by statins is 50–100 mg daily. For prevention of migraine, the dosage is 100 mg daily for children and 300 mg daily for adults. Products meeting United States Pharmacopeia (USP) standards are available and should be recommended.

Safety Considerations

Gastrointestinal (GI) effects from CoQ10 use may be minimized by splitting large (>100 mg) doses. Adverse effects are mild and include nausea, GI distress, anorexia, headache, irritability, and dizziness in less than 1% of patients.⁵⁻⁷ Mild increases in liver enzyme levels have been reported. CoQ10 use should be avoided in pregnancy and lactation, because safety information is lacking. Potential drug interactions with CoQ10 are listed in [Table 51-2](#).

TABLE 51-2 Examples of Dietary Supplement–Drug Interactions*

Dietary Supplement	Known Interactions/Results^a	Theoretical Interactions/Results^b
African plum (pygeum)	n/d	Potential risk of increased adverse effects when combined with finasteride or dutasteride
Alpha-lipoic acid	Increased bioavailability of valproate	SMBG recommended in patients taking antihyperglycemic drugs
		Potential chelating activity with minerals and antacids
		Possible interference with conversion of thyroxine to triiodothyronine
		Possible reduction of effectiveness of some chemotherapy agents
Black cohosh		Possible potentiation of antihypertensive agents
		May increase toxicity of doxorubicin and docetaxel
		May decrease effectiveness of cisplatin
		Avoid with hepatotoxic

Dietary Supplement	Known Interactions/Results^a	Theoretical Interactions/Results^b
		drugs
		Possible inhibition of CYP450 and CYP2D6
Butterbur		Possible interaction with anticholinergic drugs or antimigraine medications
		Avoid with known inducers of CYP3A4; possible pyrrolizidine increases
Chasteberry		Possible interference with HT or OCPs
		Possible interaction with antipsychotics, dopamine agonists and antagonists, and metoclopramide due to dopaminergic activity
Cinnamon		Additive effects with antihyperglycemic agents
		Avoid large doses in combination with hepatotoxic agents due to coumarin content
Chondroitin		Possible increased risk of bleeding if taken with antithrombotic agents; may increase INR in combination with warfarin
Coenzyme Q10		Possible vitamin K-like procoagulant effects if taken with warfarin; monitor INR initially
		Possible additive effects with antihypertensive

Dietary Supplement	Known Interactions/Results^a	Theoretical Interactions/Results^b
		agents
Cranberry	Atorvastatin: increased adverse effects from concomitant daily cranberry juice	Possible increased levels of CYP3A4 substrates
		Possible increased INR and risk of bleeding in people taking warfarin
		Possible CYP2C9 inhibition
		May alter excretion of weakly alkaline drugs or neutralize effects of antacids
DHEA	Triazolam: increased blood levels	Interference with hormonal or antihormonal therapies
	Antidepressants; increased risk of mania	May increase risk of thromboembolism with OCPs
		Possible increased levels of CYP3A4 substrates
		Possible reduction of tuberculosis vaccine efficacy (animal data)
Echinacea	Caffeine: increased levels	Possible interaction with immunomodulating therapies.
		Caution with CYP3A4 substrates that have low oral bioavailability: verapamil, cyclosporine, tacrolimus.
		Effects on CYP1A2, CYP2C9, or CYP3A4 are likely to be clinically

Dietary Supplement	Known Interactions/Results^a	Theoretical Interactions/Results^b
		insignificant. Effects on hepatic and intestinal CYP3A4 can be opposing.
Elderberry		Possible decrease in effects of immunosuppressant agents due to immunostimulation
		Possible additive effects with antihypertensive and antihyperglycemic agents; increased monitoring recommended
Eleuthero ("Siberian ginseng")	Digoxin: possible false elevation in plasma levels (assay dependent)	SMBG recommended in patients taking antihyperglycemic agents due to unpredictable effects.
	Caffeine: increased CNS stimulation	Possible inhibition of CYP1A2 and CYP2C9
		Possible inhibition of P-glycoprotein
		Possible additive effects with antithrombotic agents
Evening primrose oil	Lopinavir: increased levels (case report)	Antithrombotic agents: possible additive effects
		Possible increased risk of seizure possible with phenothiazines
		Potential additive effects to antihypertensives
Fenugreek		Antithrombotic agents: possible additive effects

Dietary Supplement	Known Interactions/Results^a	Theoretical Interactions/Results^b
		Avoid with antihyperglycemic drugs due to additive effects.
Feverfew		Possible additive effects if taken with other antithrombotic agents or herbs
		Possible inhibition of CYP1A2, CYP2C8, CYP2C9, CYP2C19, CYP2D6, and CYP3A4
Fish oil		Antithrombotic agents: possible additive effects primarily at dosages >4 g daily
		Antihypertensives: possible additive effects
Garlic	Warfarin: increased INR in case reports	Contradictory evidence regarding induction of drugs metabolized through CYP3A4 and CYP2D6
	Saquinavir: 50% decrease in levels	
	OCPs: decreased effectiveness	Possible inhibition of CYP2E1
	Isoniazid: significantly decreased levels	
Ginger	Antithrombotic agents: possible additive effect	Avoid with antihyperglycemic drugs because of additive effects.
	Nifedipine: decreased platelet aggregation	Possible increased effects of warfarin; monitor INR
Ginkgo	Antithrombotic agents: possible additive effect (contradictory evidence)	Excessive ingestion associated with seizures;

Dietary Supplement	Known Interactions/Results^a	Theoretical Interactions/Results^b
		avoid in patients with a history of seizures or on drugs that may lower seizure threshold
	Atorvastatin: decreased clearance, though efficacy does not seem to be decreased	Potential additive effects with antihypertensive drugs, although paradoxical hypertension has been reported with HCTZ
	Efavirenz: decreased levels	Possible reduction concentrations of ritonavir, lansoprazole, and tolbutamide
	Omeprazole: decreased levels	
	Trazodone: case report of coma in patient taking low-dose trazodone	
Ginseng (<i>Panax ginseng</i>)	Glucose-lowering drugs: possible lowered BG levels in type 2 diabetes mellitus; SMBG levels required	Unpredictable effects on concurrent antithrombotic agents
		Possible interference with antipsychotics and immunosuppressants
	Phenelzine: possible headache, tremor, and mania in case report	Possible inhibition of CYP1A1, CYP2D6
	Imatinib: increased toxicity	Unpredictable effects on metabolism of CYP3A4 substrates
		Possible additive effects when used with medications that prolong the QT interval
Glucosamine	Warfarin: increased bleeding risk in individuals with variant CYP2C9 alleles	SMBG recommended for first few days of use in patients taking

Dietary Supplement	Known Interactions/Results^a	Theoretical Interactions/Results^b
		antihyperglycemic drugs
		Coadministration with acetaminophen may decrease pain control
Green tea	Decongestants, amphetamines: additive stimulant effects	Possible antagonism of warfarin's effect
	Cimetidine: increased effects of caffeine content	Possible antagonism of concurrent sedatives related to caffeine content
	Nadolol: clinically significant reductions in drug levels	Possible reduction in serum folate levels
Melatonin	Nifedipine: reduced delivery by GITS via unknown mechanism	Caffeine or OCP use: various effects on melatonin levels
		Verapamil may decrease melatonin
	Fluvoxamine, MAOIs, and tricyclic antidepressants: increase melatonin	Possible interaction with immunosuppressant drugs related to immunostimulating properties
	BZDPs, sodium valproate, and beta blockers: decrease nighttime levels	May increase seizures due to inhibition of anticonvulsant effects
Milk thistle		Inhibition of CYP2C9, CYP2D6, and CYP3A4 is unlikely; evidence is contradictory
		Possible additional decreases in blood glucose; use caution with antidiabetic medications
		Possible inhibition of

Dietary Supplement	Known Interactions/Results^a	Theoretical Interactions/Results^b
		drugs that undergo glucuronidation
Peppermint	Decreased absorption of iron salts	Possible inhibition of CYP3A4, CYP2C9, and CYP2C19
	Antacids or other drugs increasing gastric pH: early dissolution of enteric-coated capsules	
Phytoestrogens (red clover, others)		Red clover-based products: possible increased risk of bleeding in patients taking antithrombotic agents
		Phytoestrogens: possible interference with antitumor effects of tamoxifen
Red yeast rice	Additive activity and risk of adverse effects when used with statins	CYP3A4 inhibitors: possible increased levels and adverse effects
		Gemfibrozil: possible increased adverse effects
SAMe	Antidepressants and 5-HT ₁ agonists: greatly increased risk of serotonin syndrome	Risk of additive adverse effects with monoamine oxidase inhibitors
		Risk of decreased effects of levodopa due to methylation
		Avoid concomitant use with corticosteroids due to possible effects on glucocorticoid concentrations
Saw palmetto		Potential interaction with hormonal or antihormonal therapies in

Dietary Supplement	Known Interactions/Results^a	Theoretical Interactions/Results^b
		men and women
		Possible additive effects when used with antithrombotic agents
St. John's wort	CYP3A4 substrates: significantly decreased drug levels and effects (e.g., alprazolam, amitriptyline, atorvastatin, erythromycin, finasteride, imatinib, irinotecan, methadone, nifedipine, simvastatin, tacrolimus, verapamil, voriconazole, warfarin, zolpidem)	Possible increased risk of serotonin syndrome if taken with 5-HT ₁ agonists, dextromethorphan, meperidine, and tramadol
		Digoxin: decreased intestinal absorption, decreased levels
	Antidepressants: increased risk of serotonin syndromes	Possible decreased levels and effect of amiodarone, theophylline, and proton pump inhibitors
	Cyclosporine: decreased blood levels of immunosuppressant leading to transplant graft rejection	Monitoring for fexofenadine toxicity recommended if taken concomitantly
	OCPs and HT: decreased activity	Morphine: increased narcotic-induced sleep time in animal studies
	Protease inhibitors, nonnucleoside reverse transcriptase inhibitors, and nonstructural protein 5A or 5B inhibitors: decreased serum levels	Use with other photosensitizing agents contraindicated
Turmeric	Sulfasalazine and tacrolimus: significantly increased blood levels	Possible increased effects with antithrombotic agents
	Glyburide: decreased post-prandial glucose	Possible P-glycoprotein inhibition
Valerian		Possible increased sedative effect if taken with alcohol or other CNS

Dietary Supplement	Known Interactions/Results^a	Theoretical Interactions/Results^b
		depressants (i.e., BZDPs)
		Possible inhibition of CYP3A4
		Possible decreased metabolism of UGT1A1 and UGT2B7 substrate drugs

* Table is not all-inclusive. Additional resources should be consulted for clinical use.

^a Based on human studies and/or validated case reports.

^b Extrapolated from animal or in vitro studies.

Key: BG = Blood glucose; BZDP = benzodiazepine; CNS = central nervous system; CYP = cytochrome P450; DHEA = dehydroepiandrosterone; GITS = gastrointestinal therapeutic system; HCA = hydroxycitric acid; HCTZ = hydrochlorothiazide; HT = hormone therapy; 5-HT₁ = 5-hydroxytryptamine; INR = international normalized ratio; MAOI = monoamine oxidase inhibitor; OCP = oral contraceptive pill; SAME = S-adenosyl-l-methionine; SMBG = self-monitoring of blood glucose; SSRI = selective serotonin reuptake inhibitor; UGT = UDP-glucuronosyltransferase

Summary of Clinical Evidence

Evidence for CoQ10 in HF is contradictory. Studies have shown excellent results on cardiovascular health markers such as endothelial function and C-reactive protein levels, whereas trials examining symptoms or ejection fraction have demonstrated improvements or no effects when CoQ10 was added to standard therapies.^{8,9}

One large, well-designed 2-year study examined short- and long-term effects in patients with HF taking 300 mg daily CoQ10 or placebo.¹⁰ The groups had similar improvements in symptoms and function at 16 weeks; however at 106 weeks, 58% of patients taking CoQ10 had improved at least one New York Heart Association (NYHA) class compared with 45% of patients taking placebo. At 106 weeks, risk of cardiovascular events was reduced by 43% in the CoQ10

group compared with placebo, as was the risk of cardiovascular death at 9% versus 16%.

Whether supplemental CoQ10 can reduce adverse effects associated with statins remains controversial. Some studies support CoQ10's effects to reverse statin-associated adverse effects with or without statin discontinuation.^{11,12} A 2015 meta-analysis of six trials concluded that myalgia or other adverse effects were not reduced significantly; an additional trial in patients with confirmed simvastatin-induced statin myopathy found no differences between CoQ10 600 mg daily and placebo after 8 weeks.¹³ In a 2019 meta-analysis specifically focused on fatigue associated with multiple conditions, CoQ10 was shown to be beneficial for statin- and fibromyalgia-related fatigue, but not fatigue from other causes.¹⁴ Genetic differences may contribute to the variable responses to CoQ10 treatment.¹⁵

Although its true efficacy is unknown, CoQ10's favorable adverse effect profile does support a trial of adjunctive use in HF or for reduction of statin-induced adverse effects. Patients should discuss these indications, as well as the dose and duration for the trial period, with the health care provider before they add CoQ10 to the standard treatment regimen.

Fish Oil

Fish oil is a source of omega-3 fatty acids, primarily docosahexaenoic acid (DHA) and eicosapentaenoic acid (EPA).

Therapeutic Uses

Fish oil is used to lower triglyceride (TG) levels, improve cardiac health, aid in the treatment of depression, and relieve inflammatory conditions such as rheumatoid arthritis and psoriasis. American diets tend to be low in omega-3 fatty acids and high in omega-6 fatty acids. The American Heart Association recommends a minimum intake of a serving of fatty fish twice weekly for heart health.¹⁶ Consumers who do not eat fish can take fish oil supplements or plant-based omega-3 supplements to improve the omega-3:omega-6 ratio; however, less clinical evidence is available for plant-based supplements.

Physiologic Activity

Omega-3 fatty acids may decrease intestinal absorption of cholesterol and inhibit enzymes involved in synthesis, excretion, and degradation of very low-density lipoproteins, thereby decreasing levels of other lipoproteins, including low-density lipoproteins.¹⁷ The mechanism of hypotriglyceridemic action through peroxisome proliferator-activated receptors also may be responsible for improvements in glucose concentrations and insulin resistance.¹⁸ Hypotensive effects may result from decreased vasoconstriction triggered by angiotensin II.¹⁹

Intake of EPA and DHA in fish oil influences the production and concentrations of inflammatory response cytokines. Competitive inhibition of arachidonic acid decreases production of thromboxane A₂ and leukotriene B₄, whereas effects at another part of the production cascade increase levels of thromboxane A₃ and prostaglandin E₃. Fish oil's mechanism of action can be summarized as increasing levels of noninflammatory cytokines while decreasing proinflammatory cytokine levels. Plaque inflammation is decreased through the chemical mediators, resolvins, and protectins, which are derived solely from omega-3 fatty acids.²⁰

Dosage and Product Considerations

The usual recommendation for balancing the omega-3 and omega-6 ratio is 1–2 g daily of fish oil. For hyperlipidemia, dosages of 2–4 g daily in divided doses are common, but trials have used higher doses that may be considered for individual patients to reach desired lipid goals. Most studies have used products with an EPA:DHA ratio of 1.2:1 or 1.5:1. The actual quantities of EPA and DHA may not equal the stated total dose per capsule because of added excipients and other components; however, quantities of these ingredients in high-quality products will be close to the stated dose. For example, a “1 gram fish oil” product labeled to contain “480 mg EPA and 370 mg DHA” per capsule would be within the acceptable ratios, whereas a “1 gram fish oil” product with “250 mg EPA and 180 mg DHA” per capsule would not. For vegetarian/vegan patients, DHA and DHA/EPA products made from algae are available. DHA/EPA quantities may be lower though, so the total dosage of the algal oil may need to be higher.

Enteric-coated capsules taken with meals or at bedtime are recommended to

minimize the common “fish burp” effect. Anecdotally, some patients have success with freezing capsules. Data on mercury and other toxin levels in fish have increased concerns about the quality of fish oil supplements. Because mercury is insoluble in oil, it collects primarily in flesh, whereas most of the ingested fish oil is extracted from the skin. Tests of mercury levels in fish oil supplements showed no or barely detectable concentrations of mercury.²¹ However, dioxin and pesticides can accumulate in the oil. To limit exposure to these toxins, patients should be advised to purchase high-quality products that meet USP standards.²²

Supplements made from the more expensive krill oil often are marketed as superior to fish oil. Although both types of oil have demonstrated similar effects in animal studies and some human studies, human clinical trials are needed before a recommendation can be made.²³

Safety Considerations

In general, fish oil products are safe; the most common adverse effects are belching with fishy halitosis and GI distress. Because fish oil does decrease platelet aggregation in healthy individuals, cautions to stop its use before surgical procedures are common. However, a recent systemic review found no increased risk of bleeding in patients undergoing surgery and noted that some trials demonstrated a decreased need for postoperative red blood cell transfusions.²⁴ Additionally, trial evidence has demonstrated that even higher doses, up to 6.9 g daily in combination with aspirin and heparin or with warfarin, did not result in an increased risk of bleeding events.^{20,24}

Summary of Clinical Evidence

Evidence discussed in this chapter pertains to dietary supplement forms of fish oil; study results for prescription omega-3 supplements, such as Vascepa, or other sources of omega-3s, such as flax oil, cannot be applied to these products. Fish oil’s greatest effect is on TG levels. A meta-analysis of 38 trials found dietary fish oil intake of 4 g daily or greater to be associated with reductions of 9%–26% in TG levels, whereas 1–5 g daily of fish oil supplements were associated with reductions of 4%–51%.²⁵ The Agency for Healthcare Research and Quality (AHRQ) conducted an evidence review of omega-3 fatty acids in 2016. Study data showed that the strength of evidence for fish oil’s ability to lower TG levels was high (–24 mg/dL, 95% CI –31 to –18). The data also

showed modest increases in high density lipoprotein (HDL) (0.9 mg/dL, 95% CI 0.2–1.6) and reduction of the total cholesterol (TC)/HDL ratio (–0.17, 95% CI –0.26 to –0.09) in patients with lower CVD risks.²⁶ Data for the effects of omega-3 fatty acids on LDL levels are variable, with some studies noting small increases and others noting small decreases.^{25–27}

After significant cardiovascular risk reduction was noted in the landmark GISSI-Prevenzione trial, many studies evaluated cardiovascular measures. Disease management has changed considerably since that time, which may explain the conflicting results reported in newer trials. Over the last decade, meta-analyses of fish oil trials have come to conflicting conclusions regarding its cardiovascular risk reduction.²⁸ Several trials have demonstrated increased lipid lowering when fish oil was added to statin therapy, and one large ($N = 18,645$) study demonstrated a 53% reduction in heart disease in patients with elevated TG and low HDL.²⁹ Other studies found no additional benefit either for decreasing lipid levels or for reducing cardiovascular risk.³⁰ One in-depth analysis suggests that fish oil may reduce cardiovascular risk in only patients who have low omega-3 fatty acid levels, and that no additional protective effects occur in patients already taking statins. These findings may be related to competitive interference caused by increased levels of arachidonic acid.³⁰

Patients on hemodialysis experience an increased risk of thrombosis due to arteriovenous (AV) grafts for vascular access. A meta-analysis of 13 controlled trials using doses of 1.3–6 g daily of fish oil in these patients revealed a decreased risk of AV graft thrombosis (RR 0.71, 95% CI 0.52–0.97, $P = 0.03$) and a decreased risk of cardiovascular events (RR 0.41, 95% CI 0.26–0.66, $P = 0.0002$).³¹

Fish oil may be safely recommended to aid in triglyceride reduction and to increase omega-3 dietary intake. Patients who are interested in fish oil for reduction of cardiovascular risk should be counseled that the potential benefit may be low and is affected by many factors, including concomitant statin therapy.

Garlic

Therapeutic Uses

Garlic products derived from dried or fresh bulbs of *Allium sativum* are promoted for treating hyperlipidemia, hypertension, type 2 diabetes mellitus,

as well as for increasing immune function and preventing of cancers.

Physiologic Activity

Garlic bulbs contain the odorless sulfur-containing amino acid derivative alliin (S-allyl-L-cysteine sulfoxide). When crushed, the enzyme allinase is released and converts alliin to pungent allicin, the main component of garlic's volatile oil. Allicin is used as a product quality marker but is not the only active compound; other substances such as S-allylcysteine (SAC) also exert pharmacologic effects. In animal and in vitro models, garlic has been shown to possess antiplatelet and anti-infective properties. Garlic's ability to prevent lipid oxidation may be as important to cardiovascular health as its hypolipidemic and antihypertensive activity.³² Garlic increases levels of the vasodilator hydrogen sulfide, enhances nitric oxide production, and may inhibit angiotensin-converting enzyme.³³

Dosage and Product Considerations

Differences in dosage forms may be responsible for varied outcomes in clinical trials. Patients should use only products similar to those used in clinical trials: either powdered garlic standardized to allicin content of 1%–1.6% providing 3–5 mg allicin per day or aged garlic extracts (AGE) containing at least 1.2 mg SAC should be recommended.³⁴ Enteric-coated products may help to decrease “garlic breath.”

Safety Considerations

Although well tolerated, garlic may cause GI adverse effects including nausea, reflux, vomiting, and heartburn, especially with higher dosages or in the first week of therapy. Garlic breath and body odor also may occur. Allergic reactions have been reported rarely.

Garlic should be stopped 10–14 days prior to surgical procedures to avoid excessive bleeding. Patients taking antithrombotic agents should use garlic supplements with caution because of the potential risk of bleeding, which may vary with the type of product; however, dietary amounts of garlic do not affect platelet function.^{35,36}

Garlic's effects on cytochrome (CYP) P450 isoenzymes are unclear, but enzyme

induction is possible; drug profiles should be reviewed for potentially severe interactions before garlic is initiated. (See [Table 51–2](#) for potential drug interactions.)

Summary of Clinical Evidence

A 2013 meta-analysis of 37 trials concluded that garlic reduces TC by 15 mg/dL, which may be clinically meaningful for only patients who need small reductions. Studies of 13–52 weeks in duration reported reductions up to 19.63 mg/dL; decreases in LDL levels were more modest at 7–9 mg/dL.³⁴ A subgroup analysis suggests that aged garlic extracts may have more health benefits than garlic powder products; garlic oil and raw garlic have shown little beneficial effect.³⁴ Overall, patients with TC levels higher than 200 mg/dL experienced greater reductions.

With respect to hypertension, a 2016 meta-analysis of nine trials concluded that in hypertensive patients, garlic reduces systolic blood pressure (SBP) and diastolic blood pressure (DBP) by a mean of 8.7 and 6.1 mm Hg, respectively, compared with placebo.³⁷ However, normotensive individuals had SBP and DBP reductions of 5.1 and 2.5 mm Hg, respectively.³⁷ A 2015 meta-analysis concluded that garlic effected SBP and DBP mean reductions of 9.36 and 3.82 mm Hg, respectively; the authors stated the reductions were similar to those in a meta-analysis of 354 short-term studies of prescription antihypertensive agents.^{38,39}

A 2016 randomized controlled trial evaluated blood pressure response in 88 individuals who had hypertension and were receiving 1.2 g daily of AGE for 12 weeks.⁴⁰ Responders were classified as those with reductions of more than 3% in SBP and DBP. The mean SBP reduction in all participants was 5 mm Hg ($P = 0.016$ compared with placebo); however, in the responder subgroup, the mean SBP reduction was 11.5 mm Hg, with a 6.3 mm Hg decline in DBP ($P < 0.001$). Overall, current evidence does support garlic as a suitable option for patients with mild hypertension, mild hypercholesterolemia, or both; however, long-term outcome studies are not available.

Red Yeast Rice

Monascus purpureus, a yeast that grows on fermented rice and gives Peking duck its red hue, is used in traditional Chinese medicine.

Therapeutic Uses

Red yeast rice is used to lower lipid concentrations.

Physiologic Activity

Red yeast rice contains multiple components, including several closely related compounds termed *monacolins*. Monocolin K, which is structurally identical to lovastatin, is the most important monacolin. The standard dosing for most red yeast rice products usually contains less than 5 mg daily of monacolin K. Therefore, it cannot be solely responsible for the extent of lipid-lowering effects reported in clinical trials. Additional mechanisms are probable, including increased bile acid excretion.

Dosage and Product Considerations

For hyperlipidemia, the dosage of red yeast rice is 1.2–2.4 g daily in 2 doses. In the United States, certain red yeast rice products have been declared illegal, because they contained an “unauthorized drug.”⁴¹ As a result, many manufacturers no longer ensure products contain a standardized amount of monacolin K, making selection of a high-quality, effective product more difficult.⁴¹ study of 28 supplements found that monacolin K content ranged from 0.09–5.48 mg per 1200 mg of red yeast rice.⁴²

Safety Considerations

Although red yeast rice usually is well tolerated, adverse effects such as allergic reactions, headache, and mild GI symptoms that include bloating, flatulence, and heartburn can occur. A 2019 systematic review and meta-analysis examined red yeast rice safety in trials that included 8535 patients. No increase in musculoskeletal adverse events were noted, and, compared with controls, the risks of non-musculoskeletal adverse events and serious adverse events were reduced: OR = 0.59 (95% CI 0.50–0.69) vs OR = 0.54 (95% CI 0.46–0.64), respectively.⁴³ Monitoring liver function 1–2 months after starting red yeast rice, and annually thereafter, is recommended because of reported increased levels of liver function enzymes.⁴¹ Patients with daily alcohol intake of more than 2 drinks should not use red yeast rice because of the potential risk of increased hepatotoxicity. One case report exists of erectile dysfunction that resolved after discontinuation of the red yeast rice supplement.⁴⁴ Any use of

red yeast rice is contraindicated in pregnancy.⁴⁵

The *M. purpureus* yeast also can generate citrinin, a nephrotoxin, during fermentation.⁴⁶ Only red yeast rice brands assured to be free of citrinin should be used; patients with kidney disease should not use red yeast rice.

At least three studies have found that red yeast rice can be used safely in patients unable to take statins. Rare cases of rhabdomyolysis associated with red yeast rice have been reported; these cases may be associated with products of higher monacolin K content.^{47–49} For patients with previous statin-induced myalgia, increased monitoring at the start of red yeast rice therapy is appropriate.

Summary of Clinical Evidence

Multiple studies have demonstrated that red yeast rice lowers lipid concentrations. A 2015 meta-analysis reported a mean reduction of 39.44 mg/dL in LDL compared with placebo; the authors noted that the reduction was similar to the LDL-lowering effects of statin use.⁵⁰ A 2016 systematic review of 10 trials of red yeast rice versus simvastatin examined the effects of both treatments on TC, LDL, HDL, and TG. Simvastatin and red yeast rice were found to have similar effects on all lipid measures.⁵¹ A 2019 study in 50 patients of 3 month's duration compared a monacolin K-rich red yeast rice supplement and a gamma aminobutyric acid (GABA)-rich supplement with placebo.⁵² Reductions of TC and LDL levels in only the monacolin K-rich group were significant and also were similar to reductions observed in previous trials, –44.5 mg/dL ($P < 0.001$) and –31 mg/dL ($P < 0.001$), respectively. TG reductions were greater, although not significantly, in the GABA-rich group, and no changes were seen in HDL in any group.

Whether red yeast rice possesses benefits for cardiovascular risk reduction similar to statins remains unknown.

Resveratrol

Therapeutic Uses

Resveratrol is a polyphenol derived from grapes and berries. Interest in its properties resulted from epidemiologic research that found a cardioprotective

effect associated with red wine intake. Higher dietary intake also has been associated with lower lipid levels, blood pressure, glucose, and heart rate.⁵³

Physiologic Activity

Resveratrol is an antioxidant with anti-inflammatory activity; in vitro and animal studies have demonstrated its antineoplastic effects in multiple types of cancers.⁵⁴ Effects in cardiovascular diseases include decreased SBP and DPB, as well as improved vasodilation and vascular relaxation. Multiple animal species models have shown reduction of atherosclerosis development, attenuation of myocardial injury, and reduction of cardiac remodeling ischemia or infarction. The mechanisms of these effects are multiple and include increased endothelial nitric oxide synthesis, reduced messenger RNA expression of proinflammatory molecules such as tumor necrosis factor α (TNF α), and decreased expression of vascular cell adhesion molecule 1.⁵⁴ Use of resveratrol in humans improved cardiovascular risk markers such as lipid levels, apolipoprotein A-1, TNF α , C-reactive protein, and interleukin-10 (IL-10).⁵⁵ Resveratrol also increases insulin sensitivity; animal studies have noted improvements in glucose, fructosamine, and hemoglobin A1C levels.⁵⁶

Dosage and Product Considerations

Although about 75% of a resveratrol is absorbed, bioavailability is actually <1%, because of hepatic and intestinal metabolism.⁵⁷ Trials have used dosages of 25–4000 mg daily. The optimum dosage has not been determined.

Safety Considerations

Resveratrol is well tolerated. Clinical trial subjects have reported mild GI symptoms of loose stools with increased frequency for the first month of treatment.⁵⁸ Patients on peritoneal dialysis have reported increased frequency of GI symptoms, headache, and muscle cramps. Animal data have not reported negative pregnancy outcomes; use in pregnant women is not recommended, because data for resveratrol's effects in humans are lacking.⁵⁹

Summary of Clinical Evidence

A meta-analysis of 17 trials examined resveratrol's effects on blood pressure.⁵⁸ Researchers noted heterogeneity in trial results. Overall, the mean differences

seen for SBP, mean arterial pressure, and pulse pressure were -2.468 , -1.346 , and -0.855 , respectively; these results did not reach statistical significance ($P = 0.116$, 0.07 , 0.449 , respectively). In most of the trials, DBP showed little or no change. A subgroup analysis found that patients with diabetes were more likely to experience SBP-lowering effects with resveratrol treatment (-8.8 mm Hg, 95% CI -12.5 to -5 , $P < 0.001$). The mean difference in SBP reductions in patients taking dosages of 300 mg daily or more was -2.5 mm Hg (95% CI -4.9 to -0.04 , $P < 0.047$). The authors concluded that further research into resveratrol's benefits on hypertension is warranted. The clinical data do not yet include long-term outcomes such as cardiovascular morbidity or mortality.

Central Nervous System

Butterbur

Petasites hybridus, also known as butterbur, is native to marshy areas in northern Asia, Europe, and parts of North America. It is a member of the Asteraceae/Compositae family, which includes a wide range of flower plants, such as daisies and ragweed. Many natural products discussed in this chapter belong to this family.

Therapeutic Uses

Butterbur is used to prevent migraines and treat allergic rhinitis and asthma.

Physiologic Activity

Petasin and isopetasin are isolated from butterbur's rhizomes, roots, and leaves. Extracts also contain volatile oils, tannins, flavonoids, and pyrrolizidine alkaloids (PAs). Petasin may reduce spasms in smooth muscle and vascular walls and may also inhibit leukotriene synthesis. Isopetasin decreases prostaglandin synthesis, thereby reducing inflammation. Both compounds have an affinity for cerebral blood vessels.⁶⁰

Dosage and Product Considerations

For migraine prevention, studies have used standardized extracts of butterbur containing a minimum of petasin 7.5 mg and isopetasin 7.5 mg per 50 mg

tablet or capsule. Dosages of standardized butterbur ranging from 50 to 75 mg twice daily are taken for 4–6 months and then tapered until the incidence of migraines increases. The maximum study duration has been 12–16 weeks.⁶⁰ Standardized petasin (Ze 339) 8–16 mg has been administered 3–4 times daily for allergic rhinitis.^{61,62}

Safety Considerations

Butterbur is well tolerated with minor GI symptoms most commonly reported, followed by skin changes and dizziness.⁶⁰ Butterbur extracts contain the toxic compounds PAs and their N-oxides that can cause serious hepatotoxicity and carcinogenesis. Products labeled as PA-free should be recommended.⁶³ Patients with an allergy to ragweed and related plants in the Asteraceae/Compositae family should avoid butterbur. Its use also should be avoided during pregnancy and lactation because of the potential for hepatotoxicity.

Summary of Clinical Evidence

The American Academy of Neurology and the American Headache Society considers butterbur effective for the prevention of migraine, with an evidence level of A based on two randomized controlled trials.⁶⁴ Studies including children and adolescents also have shown positive results in lower-quality studies.⁶⁵ In patients with seasonal allergic rhinitis, short-term studies of butterbur suggest efficacy similar to that of cetirizine and fexofenadine.^{61,62}

Feverfew

Tanacetum parthenium, also known as feverfew, is a member of the Asteraceae/Compositae family. The plant is native to the Balkans and is now found throughout the world.

Therapeutic Uses

Feverfew is used to prevent migraines and to treat dysmenorrhea, arthritis, and psoriasis.

Physiologic Activity

The activity of feverfew for migraine prevention involves multiple mechanisms.

Parthenolide, a sesquiterpene lactone, is the most abundant and biologically active component; it likely contributes anti-inflammatory benefits. Other active components include flavonoids, volatile oils, and additional sesquiterpene lactones. Feverfew may have effects on prostaglandin synthesis, platelet aggregation, serotonin release, histamine release, and vascular smooth muscle contraction.⁶⁶

Dosage and Product Considerations

Studies have used feverfew leaf 50–100 mg daily in divided doses or 6.25 mg carbon dioxide–standardized extract (MIG-99) of 0.2%–0.35% of parthenolide 2–3 times daily.⁶⁷ Standardization of a product to its parthenolide content has not appeared to be necessary, because the content has varied throughout studies. Feverfew must be taken continuously for migraine prophylaxis and is not effective for treatment of acute migraine attacks.

Safety Considerations

GI adverse effects may result from ingestion of feverfew. Oral ulcers can occur from chewing fresh leaves. Post-feverfew syndrome has been reported after abrupt withdrawal from chronic use, resulting in anxiety, headaches, insomnia, and muscle stiffness. Patients who are allergic to plants in the Asteraceae/Compositae family should avoid use of feverfew, as should women who are pregnant or breastfeeding.⁶⁶ Possible antiplatelet effects have been identified, so patients taking antithrombotic agents should use feverfew with caution.^{66,68}

Summary of Clinical Evidence

A Cochrane review found insufficient evidence to support feverfew for the prevention of migraines, although an update included a well-designed study of MIG-99 that showed an overall decrease of 0.6 migraines per month compared with placebo.⁶⁷ The long-term safety and efficacy have not been established, and the American Academy of Neurology and the American Headache Society consider MIG-99 probably effective for prevention of migraine, with an evidence level of B.⁶⁴ Preliminary evidence of a fixed combination of feverfew 100 mg, coQ10 100 mg, and magnesium 112.5 mg taken daily has shown benefit in migraine symptoms.⁶⁹

A Word About Cannabidiol

Cannabidiol (CBD) is a chemical compound present in *Cannabis sativa* L. (*Cannabis spp.* or *Cannabis*); it can be isolated from either marijuana or hemp. In 2018, FDA approved Epidiolex as a Schedule V prescription medication for treatment of seizures caused by Lennox-Gastaut syndrome and Dravet syndrome. CBD derived from marijuana is classified as a Schedule I controlled substance, whereas hemp derivatives are legal federally and in most states. Hemp has $\leq 0.3\%$ (on a dry weight basis) concentrations of the psychoactive compound delta-9-tetrahydrocannabinol (THC). Prior to the approval of Epidiolex, CBD was classified as an Investigational New Drug; therefore, FDA explicitly states that CBD products cannot be defined as a dietary supplement.^a However, CBD is being widely marketed as a topical natural product in community pharmacies as creams, sprays, or roll-ons, as well as in smoke and vape shops.^b Additional regulations of products for oral ingestion are forthcoming from FDA.^c Although evidence to support seizure disorders is strong, data for use in other conditions such as anxiety, schizophrenia, pain, and spasticity are limited.^{d,e} Clinical trials are lacking for topical use in humans.

Ginkgo

Ginkgo biloba is a tree and the only living member of the family Ginkgoaceae.

Therapeutic Uses

Ginkgo has been used for Alzheimer's disease (AD), vascular dementia, attention-deficit/hyperactivity disorder (ADHD), tardive dyskinesia, intermittent claudication, tinnitus, acute mountain sickness, and age-related macular degeneration.

Physiologic Activity

The standardized *G. biloba* (EGb 761) concentrated (50:1) leaf extract contains ginkgolides (A, B, C, and M) and bilobalide. These constituents may be responsible for neuroprotective properties reported with the leaf extract. Ginkgolide B is a potent platelet-activating factor antagonist. The extract also contains bioflavonoids and flavone glycosides, such as quercetin, 3-methyl quercetin, and kaempferol. The flavonoid fractions may possess antioxidant and free radical scavenger effects.⁷⁰

Dosage and Product Considerations

Recommended dosages for dementias, intermittent claudication, and ADHD range between 120 and 240 mg daily of ginkgo leaf extract in 2–3 divided doses. EGb 761 is used in many clinical trials; formulations containing 24% ginkgo flavone glycosides and 6% terpenoids are available.⁷⁰

Safety Considerations

Studies have shown ginkgo to be generally well tolerated. Mild GI adverse effects, headache, dizziness, and allergic skin reactions have been reported.⁷¹ Ginkgo should be avoided during pregnancy and lactation because of the lack of safety information. Several potential drug interactions with ginkgo are listed in [Table 51–2](#).^{71,72}

Increased bleeding risk has been associated with use of ginkgo, although the evidence has been contradictory.^{68,73} A large retrospective analysis found the risk of bleeding increased about 40% with concurrent use of ginkgo and antithrombotic agents.⁷⁴ Patients taking antithrombotic agents should use ginkgo with caution.

Summary of Clinical Evidence

When combined with medications for treatment of cognitive impairment and dementia, ginkgo may provide modest benefit. A systematic review of 10 systematic reviews, the majority of which were high quality, evaluated ginkgo's effectiveness for treatment of mild cognitive impairment and dementia (both AD and vascular). Ginkgo combined with conventional medications resulted in improvement of cognition and daily activities. Daily dosages of 240 mg or higher reported the greatest benefit. Prevention of cognitive decline also was examined, but the study lacked consistent efficacy data to support benefit.⁷⁵ Evidence is lacking for prevention of cognitive decline in healthy individuals.

Melatonin

Therapeutic Uses

Melatonin, a hormone and potent antioxidant produced by the pineal gland, is synthesized from tryptophan via a serotonin pathway. Melatonin has FDA orphan drug status for sleep disorders in blind patients. The dietary supplement form of melatonin is used primarily for insomnia, prevention of “jet lag,” and sleep issues related to shift work.

Physiologic Activity

Melatonin regulates sleep and circadian rhythms; its release is induced by

darkness and suppressed by light, especially blue light emitted by phone and computer screens. Exogenous administration stimulates sleep regulation mechanisms. Melatonin usually does not cause “sleepiness,” although some morning drowsiness can occur as a side effect; rather, it may make attempts to sleep more successful. Melatonin has regulatory effects on sexual development and ovulation, and it may have effects on bone regulation.^{76,77}

Dosage and Product Considerations

For insomnia, 0.3–5 mg is taken orally 30–60 minutes prior to bedtime. For jet lag, the dosage is 2–5 mg taken the evening (between 5:00 and 10:00 pm) of arrival at the destination and at bedtime for the following 2–5 days. The dosage for occasional insomnia is unclear; supraphysiologic concentrations are produced by a 0.3 mg dose, and higher doses may not be more effective.⁷⁸

Most melatonin supplements are synthetically produced. Melatonin extracted from bovine pineal glands should be avoided because of the added risk of bacterial contamination and bovine spongiform encephalitis (mad cow disease). Some wine varieties contain small amounts of melatonin that are naturally produced during fermentation.

Safety Considerations

Rare adverse effects include nausea and vomiting, headache, irritability, dysthymia and worsening of depressive symptoms, and morning grogginess. A 2019 meta-analysis systematic review of melatonin’s adverse effects suggests that most can be ameliorated by dosing in concordance with circadian rhythms.⁷⁹ Long-term use should be under the supervision of a primary care provider.

Although melatonin is safe to use in younger children, use in adolescents is controversial because of possible hormonal effects on sexual development; any use in children in or around the age of puberty should be discussed first with a primary care provider. Pregnant and lactating women should not use melatonin.

Melatonin has variable effects on cancer treatments; patients should discuss melatonin with their oncologists before any use.⁸⁰

Summary of Clinical Evidence

Evidence of melatonin's effectiveness for occasional or primary insomnia in generally healthy people is variable, although a meta-analysis concluded that melatonin had small but clinically significant improvements in sleep quality.⁷⁸ Beneficial responses, including improved sleep and daytime behaviors, have been demonstrated more consistently in chronic sleep disorders, as well as in children and adults who have developmental disabilities, neurologic disorders, or autism.^{81,82} Depressed patients with sleep disorders may experience additional benefits for mood, although a systematic review of melatonin as a mood disorder treatment found that improvement was not significant, as measured by the standardized mean difference (SMD) of mood scales (SMD 0.37, 95% CI -0.05 to 0.37)).⁸³ Older patients (ages 55–80 years) may respond better to melatonin regardless of their endogenous levels, and prolonged-release formulations have improved sleep quality, daytime alertness, and psychomotor performance in this population.^{84,85} In patients treated with beta-blockers, 2.5 mg of melatonin for 3 weeks improved sleep time and efficiency.⁸⁶ Because of its mild adverse effect profile, melatonin may be an option on a trial basis for many individuals, albeit they should be counseled that the benefits may be small.

A 2014 meta-analysis concluded that melatonin used for insomnia caused by shift work may increase the duration of sleep slightly, but it does not improve sleep quality or symptoms such as sleepiness during the work shift.⁸⁷

Melatonin can decrease jet lag when five or more time zones are crossed. Its effects are greater for eastward travel than westward, and individual responses vary. The amount and timing of daylight exposure after arrival can decrease benefits.⁸⁸ Melatonin may not be as effective as zolpidem for sleep improvement or daytime tiredness associated with jet lag.⁸⁹

St. John's Wort

Hypericum perforatum, also known as St. John's wort, is a perennial with more than 400 species that grow wild throughout Europe, Asia, North America, and South America. The yellow flowers and the leaves contain the highest levels of medicinally useful compounds. St. John's wort (SJW) is classified in the Clusiaceae family but also may be listed under the Hypericaceae family.

Therapeutic Uses

SJW is used to treat depression, pain, anxiety, obsessive-compulsive disorder, menopause symptoms, and premenstrual syndrome.

Physiologic Activity

Although hypericin previously was considered to have antidepressant activity, evidence now indicates that hyperforin and its related compounds are primarily responsible. Other potential biologically active constituents include flavonoids and its derivatives, as well as procyanidins tannins, volatile oils, amino acids, phenylpropanes, and xanthones. SJW may modulate serotonin, dopamine, and norepinephrine. Additional data suggest that SJW also may activate GABA and glutamate receptors, and that it may potentially inhibit monoamine oxidase inhibitor.⁹⁰

Dosage and Product Considerations

The dosage of SJW for adults with mild to moderate depression is 900–1800 mg daily of a standardized extract of 0.3% hypericin or 2%–5% hyperforin. SJW should be taken in 3 divided doses with meals. Extracts commonly used in clinical studies include LI 160, ZE 117, WS 5570, STW3, and STW3-VI. The content of hypericin and hyperforin can vary in commercial preparations, and these products may not be interchangeable. As with prescription antidepressants, the therapeutic effects of SJW are not evident for several weeks. Depression should never be self-diagnosed or self-treated. Patients should seek appropriate medical care before using SJW.

Safety Considerations

An analysis of randomized trials found that rates of adverse effects in participants taking SJW were similar to those taking a placebo. In addition, the rates for SJW were lower compared with selective serotonin reuptake inhibitors (SSRIs).⁹¹ The most commonly reported adverse effects include nausea, fatigue, and skin reactions. Photosensitivity reactions have been reported, so patients should limit their exposure to sun and apply sunscreen before exposure.⁹² SJW should be avoided in patients with bipolar disorder and schizophrenia. As with SSRIs, SJW may cause sexual dysfunction. Abrupt discontinuation after chronic use may result in withdrawal symptoms similar

to those of conventional antidepressants. Limited evidence is available to assess the safety of SJW during pregnancy and lactation.

Interactions with SJW are well documented and clinically significant ([Table 51-2](#)). SJW is a potent inducer of CYP3A4, resulting in significantly lower concentrations of drugs metabolized through this pathway.⁹² Oral contraceptives therefore may be less effective, so patients should use a second form of birth control. The extent of induction may correlate with hyperforin dose and varies among products. SJW also may induce P-glycoprotein transport proteins, resulting in lower serum concentrations of drugs. Additional evidence suggests induction of other CYP substrates, such as CYP2C19. If taken with other serotonergic agents, SJW may increase the risk of developing serotonin syndrome.⁹²

Summary of Clinical Evidence

SJW may be as effective as many antidepressants for mild to moderate depression, with fewer adverse effects. A Cochrane review that evaluated *Hypericum* extracts for major depression included 18 placebo-controlled trials and 17 studies with an active control. SJW had a significant benefit for mild to moderate depression compared with placebo; its efficacy was similar to that of standard antidepressants, such as SSRIs or tricyclic antidepressants. The rates for adverse effects and trial discontinuation also were lower with SJW than with older antidepressants, indicating that *Hypericum* extract may be more tolerable. In addition, the results vary depending on the country of origin, with German-speaking countries showing better outcomes. Conclusions about its efficacy in treating severe depression cannot be made.⁹³ A subsequent systematic review that included 35 studies found similar results regarding efficacy. Compared with users of antidepressants, SJW users were less likely to experience adverse effects; SJW and placebo users experienced comparable effects. The majority of studies included information on adverse effects from SJW use, but few were specifically designed to assess this outcome.⁹⁴ Because of its drug interactions and the potential seriousness of depression, SJW is not an appropriate choice for many patients.

Valerian

Native to Europe and Asia, valerian grows in most parts of the world. More than 200 plant species belong to the genus *Valeriana*. The most common plant

used from the Valerianaceae family for medicinal purposes is *Valeriana officinalis*.

Therapeutic Uses

Valerian is used for alleviating insomnia and anxiety.

Physiologic Activity

The CNS activity of valerian may be related to the valepotriates and sesquiterpene constituents of the volatile oils. Other active components include alkaloids, furofuran ligans, and free amino acids, including GABA. Valeric acid and other components likely interact with GABA receptors in the brain, with the valproates and valeric acid producing sedation.⁹⁵

Dosage and Product Considerations

Most clinical trials for insomnia use valerian root extract 400–900 mg, administered 30–120 minutes before bedtime. Teas can be prepared from dried roots, although they often have an unpleasant taste and smell. Combination products containing hops or lemon balm are commonly marketed.

A Word About Kava

Kava is derived from the rhizome and roots of *Piper methysticum* and is used widely by Pacific Islanders as a social and ceremonial tranquilizing beverage; it has been used to treat mild anxiety and sleep disturbances.^a In 2002, the Center for Food Safety and Nutrition issued a warning advising consumers and professionals of the risk of severe liver injury associated with kava-containing supplements. Germany, Switzerland, Canada, Australia, and France have restricted the sale of kava products in response to case reports of liver failure associated with use.^b Several factors related to the origin of liver injury are in question. These include aqueous versus acetone or ethanol extracts, continuous high doses, inappropriate raw products, and potential contaminants. No updates to the consumer advisory have been made.^c A systematic review and meta-analysis including randomized clinical trials examined kava's efficacy in

light of potential toxicity. Data from five trials found kava slightly more efficacious for anxiety than placebo with RR of 1.5 (95% CI 1.2–2.01), with most benefit noted in younger populations and females. Adverse effects were similar to placebo; however, no trial continued beyond 8 weeks.^d Until further data that identify the cause of liver injuries are available, patients should avoid taking kava.

^a Sarris J, LaPorte E, Schweitzer I. Kava: a comprehensive review of efficacy, safety, and psychopharmacology. *Aust N Z J Psychiatry*. 2011;45(1):27–35. doi: 10.3109/00048674.2010.522554.

^b Centers for Disease Control and Prevention. Hepatic toxicity possibly associated with kava-containing products—United States, Germany, and Switzerland, 1999–2002. *MMWR Morb Mortal Wkly Rep*. 2002;51(47):1065–1067. Available at: <https://www.cdc.gov/mmwr/preview/mmwrhtml/mm5147a1.htm>. Accessed March 12, 2019.

^c Teschke R, Lebot V. Proposal for a kava quality standardization code. *Food Chem Toxicol*. 2011;49(10):2503–2516. doi: 10.1016/j.fct.2011.06.075.

^d Smith K, Leiras C. The effectiveness and safety of Kava Kava for treating anxiety symptoms: a systematic review and analysis of randomized clinical trials. *Complement Ther Clin Pract*. 2018 Nov;33:107–117. doi: 10.1016/j.ctcp.2018.09.003. Epub 2018 Sep 15.

Safety Considerations

Valerian is generally well tolerated with headache, excitability, and paradoxical insomnia occurring infrequently. Benzodiazepine-like withdrawal symptoms have been reported after discontinuation of valerian, and residual daytime sedation has been associated with higher dosages (900 mg). *Valeriana officinalis* preparations are safe despite the known in vitro cytotoxic activity of valepotriates, which generally are not found in products. Chronic administration has been linked to hepatotoxicity, although the reports included combination products and the role of valerian was unclear. Valerian can potentiate the effects of other CNS depressants, so they should not be taken concomitantly. Pregnant women should avoid the use of valerian

because of potential induction of uterine contractions.⁷¹

Summary of Clinical Evidence

A meta-analysis of 18 randomized, placebo-controlled trials evaluated the effect of valerian on insomnia. Eight trials were of high quality. Subjective improvements were reported for insomnia, although the overall effectiveness of valerian could not be assessed.⁹⁶ A study of older adults found *V. officinalis* to be inferior to temazepam and diphenhydramine.⁹⁷ Limited evidence exists to suggest valerian is efficacious.

Gastrointestinal System

Ginger

Ginger (*Zingiber officinale*) is a perennial from the Zingiberaceae family whose rhizomes and roots are used medicinally.

Therapeutic Uses

The primary use of ginger has been to relieve nausea and vomiting associated with pregnancy, motion sickness, chemotherapy, and surgery. Ginger also has been used for indigestion, colic, and arthritis.

Physiologic Activity

Ginger rhizomes possess a volatile oil that contains sesquiterpene hydrocarbons, including zingiberene and alpha curcumene, with lesser amounts of farnesene, beta sesquiphellandrene, and beta bisabolene. Ginger also contains an oleoresin with nonvolatile pungent components, including gingerol, shogaols, and zingerone. Galanolactone, a diterpenoid isolated from ginger, and 6-shogaol have anti-5-hydroxytryptamine activity in the GI tract, which possibly contributes to ginger's antiemetic activity. Ginger does not affect GI motility or increase gastric emptying. The 6-shogaol and 6-gingerol components inhibit cyclooxygenase (COX) and lipoxygenase pathways, resulting in anti-inflammatory actions and potential inhibition of platelet thromboxane.⁹⁸

Dosage and Product Considerations

Dried ginger 250 mg taken 4 times daily has been used for nausea and vomiting in pregnancy. For motion sickness, a typical dosage is 500 mg of dried powdered ginger root taken 30 minutes before travel, followed by 1–2 additional 500 mg capsules as needed every 4 hours. Daily dosages greater than 4 g should be avoided.

Safety Considerations

Mild heartburn and belching have been reported with ginger. Ginger may increase the risk of hypoglycemia.⁷¹ Ginger also may alter platelet function, although findings are mixed; ginger should be used with caution by individuals taking antithrombotic agents.^{68,72}

Randomized controlled trials have not identified significant adverse effects on pregnancy outcomes between ginger and placebo or pyridoxine.^{99,100} A Norwegian population-based cohort study found no increase in malformations, fetal death, premature birth, low birth weight, or Apgar scores below 7. About 45% of the cohort ingested ginger during the first trimester, although timing of exposure and dosing was lacking. A small, but significant, increase in vaginal bleeding was noted after week 17 (7.8% vs. 5.8%) compared with controls.¹⁰¹ In a review of clinical evidence that focused on safety, investigators concluded that ginger appeared to be safe and effective for short-term use in nausea and vomiting in pregnancy, but stressed that patients should use only high-quality products and should be monitored by a health care provider. The potential for bleeding also should be considered.¹⁰²

Summary of Clinical Evidence

Results for ginger's efficacy in the management of postoperative and chemotherapy-induced nausea and vomiting have been mixed. A meta-analysis of 10 randomized controlled trials involved more than 900 subjects who used a visual analogue scale (VAS) to rate the effectiveness of ginger in the management of postoperative nausea and vomiting. Researchers concluded that ginger was effective in decreasing severity episodes. The incidence was not significantly reduced, possibly because of under dosing.¹⁰³ A systematic review of five randomized, controlled trials, encompassing more than 800 subjects, compared ginger with metoclopramide or placebo for

treatment of chemotherapy-induced nausea and vomiting. Ginger did not control the severity or incidence of acute nausea.¹⁰⁴ Another meta-analysis of 10 studies demonstrated benefit from use of ginger in chemotherapy-induced nausea and vomiting, specifically within an acute onset subgroup.¹⁰⁵

A systematic review and meta-analysis of pregnancy-induced nausea and vomiting evaluated 12 randomized controlled clinical trials. Studies varied in size, dosage of ginger, duration of treatment, and comparative treatments (placebo, pyridoxine, dimenhydrinate, or metoclopramide). Compared with the placebo group, use of ginger in early pregnancy improved symptoms of nausea but not the overall number of vomiting episodes. Comparison of ginger with pyridoxine in two of the studies showed no differences. Daily dosages of less than 1500 mg were most effective.¹⁰⁰ A Cochrane review concluded that ginger may have a role in early pregnancy for nausea and vomiting.¹⁰⁶ The American College of Obstetricians and Gynecologists (ACOG) practice guidelines includes ginger as an option with beneficial effects rated as level evidence B, suggesting limited or inconsistent evidence, in treating nausea and vomiting in pregnancy.¹⁰⁷ Because the effectiveness of ginger for hyperemesis gravidarum is limited, ginger should not be recommended for this condition.

Milk Thistle

Silybum marianum, or milk thistle, is a member of the Asteraceae/ Compositae family.

Therapeutic Uses

Milk thistle has been used to treat liver disease, including hepatitis and cirrhosis, and diabetes. In Europe, it is used to treat poisoning by the mushroom *Amanita phalloides* (death cap). Milk thistle has been used as a liver protective agent for exposure to alcohol, acetaminophen, and carbon tetrachloride.

Physiologic Activity

Milk thistle's seeds and fruit contain several compounds, generally referred to as silymarin. Major flavonolignans include silybin, isosilybin (A & B), silydianin, and silychristin.¹⁰⁸ These biologically active compounds have antioxidant,

antifibrotic, immunostimulating, and anti-inflammatory activity, in addition to other beneficial effects such as regulation of cell permeability and inhibition of mitochondrial injury. Stimulation of polymerase I, resulting in increased ribosomal protein synthesis, stimulates liver regeneration and the formation of new hepatocytes. The antioxidant properties of silymarin may be the primary beneficial effect.

Dosage and Product Considerations

The average dosage is silymarin 140 mg taken 3 times daily or silybin (silibinin) 240 mg twice daily. Milk thistle preparations contain varying amounts of a concentrated seed extract, standardized to flavonolignans 70%–80% calculated as silymarin; approximately 70% is silybin. Multiple products of silymarin and silybin have been used in clinical studies, but they may not be available in the United States, even with identical standardization. Liver disease resulting from alcohol, acetaminophen, and other drugs or chemicals is potentially fatal, and patients should be cautioned against self-treatment with milk thistle.

Safety Considerations

Milk thistle is generally well tolerated. Pregnant women and patients with an allergy to ragweed and other members of the Asteraceae/Compositae family should avoid the use of milk thistle. The product may stimulate lactation, although evidence is limited.¹⁰⁹ Most, but not all, studies indicate that milk thistle does not inhibit several CYP isoenzymes and P-glycoprotein, thereby reducing the likelihood of drug interactions.⁷²

Summary of Clinical Evidence

Evidence to support the use of milk thistle in liver disease is limited. A Cochrane review of 18 randomized controlled studies investigated its effect on liver disease caused by alcohol or hepatitis B or C viral infection. Reductions in mortality or complications of liver disease or changes in liver histology were not identified. Liver-related mortality was significantly reduced with inclusion of all trials but not in the five high-quality trials.¹¹⁰ A meta-analysis of five randomized controlled trials that included participants with chronic hepatitis C virus found no significant benefit in reduction of levels of serum alanine aminotransferase or hepatitis C virus RNA, or changes in quality of life.¹¹¹ Milk thistle has not been compared with the new treatments for hepatitis C and

should never be used in place of antiviral therapy.

A systematic review of milk thistle administration in patients with type 2 diabetes found potential benefit in glycemic control, with a reduction of fasting glucose numbers and hemoglobin A1C. The five studies were small, totaling 270 subjects, varied in duration of treatment and amount of silymarin taken, and lacked long-term clinical outcomes to generally support use for diabetes.¹¹²

Peppermint

Mentha piperita, or peppermint, is a member of the mint family Lamiaceae. It has been cultivated for its fragrant volatile oil, which is extracted primarily from leaves of the plant.

Therapeutic Uses

Both peppermint leaf and oil have been used for treatment of irritable bowel syndrome (IBS), nonulcerative dyspepsia, colonic spasm, and tension headache.

Physiologic Activity

The activity of peppermint may be a result of its 0.5%–4% essential oil. The oil or leaf preparations should be standardized to contain not less than 44% menthol. Menthol stereoisomers also are present, including 3% *d*-neomenthol and menthone, menthofuran, eucalyptol, and limonene. The mechanism of action of peppermint involves direct relaxation of GI smooth muscle.

Dosage and Product Considerations

The usual dosage of peppermint oil enteric-coated capsules for IBS is 0.2–0.4 mL (187–374 mg) taken 3 times daily 15–30 minutes before meals. Enteric-coated preparations reduce risk of heartburn. Clinical trials have studied 8–16 mL of peppermint oil solution as an antispasmodic.¹¹³

Safety Considerations

Heartburn may be attributed to relaxation of the lower esophageal sphincter.

Patients who have severe preexisting gastroesophageal conditions should avoid use of peppermint oil. Peppermint leaf tea or topical products should be used with caution in infants and small children because of possible laryngeal and bronchial spasms from volatilized menthol. The oil also may irritate mucous membranes; theoretically enteric-coated capsules will minimize this effect. Antacids or other medications that increase stomach pH may affect dissolution of enteric-coated capsules. Data suggest that peppermint may decrease activity of CYP3A4 for drugs such as felodipine.⁷² Further, the ingestion of peppermint may decrease absorption of iron.⁷¹

Summary of Clinical Evidence

A systematic review and meta-analysis of nine studies with enteric-coated peppermint oil capsule demonstrated short-term safety and efficacy in participants with IBS. Significant differences were found in global improvement of IBS symptoms (392 participants) and abdominal pain (357 participants) compared with placebo.¹¹⁴ A higher rate of adverse events were reported in the peppermint oil groups, with heartburn as the most common symptom. A subsequent pooled meta-analysis of 12 studies found additional safety and efficacy evidence to support peppermint oil administration in IBS for pain (556 participants) and global improvement of symptoms (507 participants). Compared with placebo, the number needed to treat to detect improvement in global symptoms was 3, and 4 were needed for abdominal pain. No significant differences were noted in adverse effects.¹¹⁵

Endocrine System

Alpha-Lipoic Acid

Therapeutic Uses

Alpha-lipoic acid, or thioctic acid, is an endogenous antioxidant promoted for patients with diabetes. For diabetic peripheral neuropathy, both intravenous and oral dosage forms have been studied.

Physiologic Activity

Alpha-lipoic acid, synthesized from linoleic acid, is a cofactor for glucose

metabolism enzymes. Small amounts of the cofactor exist in plant and animal sources; the greatest amounts are attached to lysine in spinach and broccoli.¹¹⁶ Alpha-lipoic acid has hydrophilic and lipophilic properties. These properties allow it to serve as an antioxidant within both lipid membranes and aqueous environments, in constant regenerative balance with its reduced form, dihydrolipoic acid. Alpha-lipoic acid acts on glucose transporters and stimulates glucose uptake by various mechanisms, including effects on GLUT-1 and GLUT-4 receptors. In addition to improved nerve conduction and blood flow, human studies have shown improvement in insulin sensitivity and oral glucose tolerance tests.^{116,117}

Dosage and Product Considerations

With an oral bioavailability of 30%, 600 mg of alpha-lipoic acid taken 3 times daily is comparable to the 600 mg intravenous dosage used in many European trials for diabetic neuropathy.^{116,117} However, one study found patients who improved while taking 1800 mg a day orally were able to maintain benefits when the dosage was lowered to 600 mg once daily.¹¹⁸ Food decreases absorption, so alpha-lipoic acid should be taken on an empty stomach.¹¹⁹ It must not be taken within 2–3 hours of taking antacids or other mineral-containing supplements because of their chelating activity.¹¹⁹

Safety Considerations

Adverse effects are generally mild and include headache, nausea, diarrhea, and rash. Patients who wish to add alpha-lipoic acid to antidiabetic therapy should discuss its use with their health care provider. More frequent monitoring of glucose concentrations is advised during the initial weeks of therapy, because additive hypoglycemic effects may occur. Patients with thyroid conditions should avoid alpha-lipoic acid, because it can inhibit conversion of thyroxine to triiodothyronine and may displace thyroxine from serum-binding protein.

Summary of Clinical Evidence

Although not all trials have demonstrated improvements in neuropathic symptoms in patients with diabetes who take oral alpha-lipoic acid, three meta-analyses concluded that intravenous and oral supplementation is beneficial, with improvement in total symptom scores, neuropathy impairment scores, and short-term symptoms of pain and paresthesia.^{120–122} In

a rigorous 4-year study of 460 patients, alpha-lipoic acid was demonstrated to be more useful in preventing progression of neuropathy rather than being used as an acute treatment.¹²³ A study comparing oral alpha-lipoic acid with carbamazepine and pregabalin noted that the pain severity score on a VAS was significantly improved from baseline for alpha-lipoic acid and pregabalin.¹²⁴ Alpha-lipoic acid may be considered a treatment option for diabetic neuropathy.

In several neuropathy trials, reductions in glucose and hemoglobin A1C were not significant.^{120–122} Small trials over the last decade have documented clinically significant lowering of fasting blood glucose, insulin and hemoglobin A1C, primarily when alpha-lipoic acid was added to standard antidiabetic medications. A meta-analysis of these trials reported SMDs of -0.84 (95% CI -1.39 to -0.28), -0.50 (95% CI -0.88 to -0.12), and -1.17 (95% CI -2.12 to -0.20), respectively, which could be clinically significant for some patients.¹²⁵

Although a strong recommendation for glucose control cannot yet be made, alpha-lipoic acid's safety profile supports use in individual patients.

Cinnamon (Cinnamomum cassia or C. aromaticum)

Therapeutic Uses

Cinnamon, specifically *Cinnamomum cassia*, the type most commonly found in grocery spice aisles, is used to help lower blood glucose.

Physiologic Activity

Both *Cinnamomum cassia* and true cinnamon (Ceylon cinnamon; *C. verum* also known as *C. zeylanicum*) have components that affect glucose levels with differing mechanisms of action and have had similar results in preclinical studies.^{126,127} Cinnamtannin B1, a proanthocyanidin, triggers autophosphorylation of insulin receptors to increase insulin sensitivity.¹²⁷ Cinnamaldehyde increases cellular glucose uptake by stimulating glucose transporter-1 (GLUT-1) and GLUT-4 receptors.¹²⁷ Water-soluble extracts of both *C. cassia* and *C. verum* activate PPAR-alpha and PPAR-gamma in a manner similar to that of pioglitazone, and they display inhibition of amylase and sucrose.¹²⁷ Cinnamon inhibits inactivation of insulin receptors by tyrosine

phosphatase; anti-inflammatory actions occur through changes in multiple cytokines involved in the inflammatory process.¹²⁶ Whole cinnamon seems to delay gastric emptying, which could reduce postprandial glucose spikes.

Dosage and Product Considerations

Aqueous extracts may be most effective; the dosage is 0.5–1 daily of *C. cassia* extract. The dose of ground cinnamon (*C. cassia*) is 2–6 g, given in divided doses either in capsules or sprinkled in food. A half-teaspoonful is approximately 1 g.¹²⁸

Safety Considerations

Patients should not confuse cinnamon supplements with cinnamon oil; hypersensitivity reactions to the oil can occur, as well as pediatric poisoning from ingestion.¹²⁸ Attempted ingestion of dry cinnamon powder, generally by adolescents undergoing a challenge, has led to severe adverse effects.¹²⁹ Other than allergic reactions, no adverse events have been reported in trials. One case report exists of probable medication-induced hepatitis; cinnamon is known to contain coumarins (much greater amounts in *C. cassia* than in *C. verum*) that can be hepatotoxic.¹³⁰ Potentiation of hypoglycemic reactions in patients on hypoglycemic medications is theoretically possible, but not noted in clinical trials with patients on standard treatments.

Summary of Clinical Evidence

C. verum has not received the same clinical evaluations as *C. cassia*. One human clinical trial of *C. verum* demonstrated no effect on glucose or insulin levels, whereas a human laboratory study did note reductions in the postprandial glycemia AUC.^{131,132}

Clinical trials of *C. cassia* have had contradictory results for glucose control. In general, negative trials used 1–1.5 g daily, whereas studies with positive outcomes used 3–6 g daily or equivalent aqueous extract.^{133,134} A well-designed trial of 2 g daily of ground cinnamon added to standard antidiabetic medications reduced mean hemoglobin A1C from 8.22% to 7.86% after 12 weeks, a significantly greater effect than seen with placebo.¹³⁵ A 3-month trial of low doses of cinnamon aqueous extract (120 and 360 mg daily) added to sulfonylurea therapy showed significantly reduced fasting blood glucose and

hemoglobin A1C levels compared with placebo.¹³⁶ Data from the most recent meta-analysis showed that fasting blood glucose levels were significantly reduced compared with placebo, -19.26 mg/dL (95% CI -28.08 to -10.45 , $P = 0.0001$); however, hemoglobin A1C levels were not, -0.24 (95% CI -0.48 to -0.01 , $P = 0.0001$).¹³⁷ The effect size of cinnamon on fasting plasma glucose or hemoglobin A1C can be expected to be small.¹³⁴ More study is needed, but the favorable safety profile means that cinnamon is an adjunctive option in some patients, especially those attempting to control blood glucose primarily through lifestyle changes.

A Word About Chromium

Chromium is a popular ingredient in supplements for patients with diabetes. Absorption of elemental chromium depends on an individual's chromium status and the salt form; chromium from brewer's yeast and the picolinate salt are the most well absorbed.^a The Cr^{+3} ion is a component of the glucose tolerance factor protein. Chromium also is involved in multiple processes in the body that involve carbohydrate and lipid metabolism; however, the exact mechanisms remain unclear. Theories include insulin signal amplification, direct activation of insulin receptors, and influence on estrogen receptors. Chromium does have a mild adverse event profile; in clinical trials, rates were similar to placebo and reports included headache, nausea, loose stools and constipation, and flatulence.^b

Does chromium improve glucose control in patients with diabetes? The answer to that question remains controversial. The two most recent meta-analyses, published in the same year, came to opposing conclusions. The first found that in 22 trials reporting fasting plasma glucose, the mean decrease was 20.34 mg/dL (95% CI -35.46 to 5.4) and the decrease in hemoglobin A1C was -0.58 (95% CI -0.93 to -0.23).^b Lipids were less affected, with only mean triglyceride reduction by chromium picolinate found to be significant at -26.57 mg/dL (95% CI -43.4 to -9.74). The second meta-analysis used a different statistical approach and examined effect size on fasting plasma glucose in 18 trials.^c The researcher reported a nonsignificant weighted average effect size at 0.02 (95% CI -0.12 to 0.16 , $P = 0.787$). More research is warranted to determine a realistic impact of

chromium in patients with diabetes as well as an optimum dosage. Until then, chromium should be used cautiously and dosages limited to ~200 mcg daily.

^c Bailey CH. Improved meta-analytic methods show no effect on chromium supplements on fasting glucose. *Biol Trace Elem Res*. 2014;157:1–8. doi: 10.1007/s12011-013-9863-9.

A Word About Bitter Melon

The fruit of *Momordica charantia* historically has been used both as a food and a medicine for diabetes. As a food, it is often prepared with sugar to counteract the bitterness. Multiple mechanisms are involved in its actions on blood glucose, including increased cellular glucose uptake, decreased gluconeogenesis in the liver, and increased insulin secretion. A 2019 meta-analysis that included 10 trials found that bitter melon was able to significantly reduce fasting plasma glucose, postprandial glucose, and hemoglobin A1c by 12.96 mg/dL, 25.74 mg/dL, and 0.26%, respectively.^a An additional 2018 study demonstrated similar effects on glucose outcomes as well as changes in lipid measurements, some of which reached significance: decreased TC, LDL cholesterol, and LDL/HDL ratio, and increased HDL cholesterol.^b Bitter melon is well tolerated with primarily GI side effects, such as nausea, heartburn, and diarrhea.

^a Peter EL, Kasali FM, Deyno S, et al. *Momordica charantia* L. lowers elevated glycaemia in type 2 diabetes mellitus patients: systematic review and meta-analysis. *J Ethnopharmacol*. 2019;321:311–324. doi: 10.1016/

j.jep.2018.10.033.

^b Kumari S, Dash I, Behera KK. Therapeutic effect of *Momordica charantia* on blood glucose, lipid profile and oxidative stress in type 2 diabetes mellitus patients: a randomized controlled trial. *J Clin Diag Res*. 2018;12(9):BC21– BC25. doi: 10.7860/JCDR/201/36354.12036.

Immune Modulators

Echinacea

Echinacea species used in self-care include *E. purpurea*, *E. angustifolia*, and *E. pallida*. Roots, leaves, and flowers are used medicinally. Depending on the species, the above-ground parts may have more activity.

Therapeutic Uses

Echinacea is used to prevent and treat colds and other respiratory infections.

Physiologic Activity

Echinacea has many components that target the nonspecific cellular immune system, including alkylamides, chicoric acid, flavonoids, glycoproteins, and polysaccharides. Multiple mechanisms of action are involved in the effects, including increased cytokine secretion, lymphocyte activity, and phagocytosis. Direct inactivation of viruses, bacteria, and fungi has been observed.¹³⁸ Anti-inflammatory activities and decreases in mucin production are likely to be more directly responsible for decreased symptoms of upper respiratory infections.¹³⁸ Some of the immunostimulatory activity is caused by lipopolysaccharides and xanthienopyran produced by endophytic bacteria that live within the plant.¹³⁹ The activity is not present in extracts from plants grown from sterilized seed. Bacterial load may vary between plants, and the extraction processes may affect the content of these components, which may explain the varied results in clinical trials.

Dosage and Product Considerations

Products labeled “echinacea” may be chemically different plants or plant parts, making comparisons difficult. The optimum standardization and dose for echinacea are unknown. Standardized concentrates, such as Echinaforce, generally perform better in trials. Echinacea is available in single- and multiple-ingredient formulations such as teas, extracts, juices, throat sprays, capsules, and tablets; each formulation has its own dosing regimen. Many products available in the United States are less concentrated or are labeled for use at doses much lower than those used in clinical trials and may be ineffective if used as directed. For greatest efficacy, all formulations must be taken at the first sign of illness.

Safety Considerations

Allergic reactions may occur with use of echinacea. Patients with a history of asthma or atopy should avoid echinacea; a severe allergy to the *Asteraceae/Compositae* family, which includes ragweed and chrysanthemums, is also a contraindication. Adverse effects include mild GI discomfort and headache. More serious reactions are possible: after taking an echinacea root product for 5 days while ill with a flu-like syndrome, one patient developed acute cholestatic hepatitis, which resolved quickly after product discontinuation.¹⁴⁰ Echinacea should not be used by patients with severe systemic illnesses such as HIV infection or AIDS, multiple sclerosis, tuberculosis, and autoimmune disorders, and by patients taking immunosuppressants; this concern is based on case reports and theory.¹⁴¹ Echinacea exhibits some effects on P-glycoprotein transport and several intestinal and hepatic CYP450 systems; however, these effects are not likely to be significant except for drugs with a narrow therapeutic range.¹⁴² A systematic review of echinacea use during pregnancy found no differences in rates of major malformations.¹⁴³

Summary of Clinical Evidence

Individual trials for either treatment or prevention of colds or upper respiratory infections have had widely variable results, making conclusions difficult. This may be a result of disparate doses, concentrations, plant species and parts, or extraction methods used for the study products.

For prevention, a 2015 meta-analysis that examined echinacea's impact on recurrent infection risk when used continuously for 2–4 months or in repetitive 10-day treatments over 4 months concluded that treatment resulted in a relative risk (RR) of recurrent infection of 0.649 compared with placebo ($P < 0.0001$).¹⁴⁴ A 2019 meta-analysis determined a risk ratio of 0.78 (95% CI 0.68–0.88) for prevention, but investigators cautioned that the significant heterogeneity in trial results limited the usefulness of their conclusion.¹⁴⁵

For treatment, the evidence also is mixed. A 2007 meta-analysis of 14 randomized placebo-controlled studies found a significant reduction in duration of 1.4 days.¹⁴⁶ A 2019 meta-analysis of seven studies determined a nonsignificant mean difference in illness duration of –0.45 (95% CI –1.85 to 0.84), compared with placebo.¹⁴⁵ Further study will have to determine the true effect size of treatment, but current treatment trial data do indicate that best results occur when echinacea is administered at the first sign of symptoms.

Echinacea's immunostimulatory effects were tested in a well-designed pilot study in adults with respiratory disease that compared rates of influenza- and parainfluenza-like symptoms and respiratory complications. Groups were given prophylactic doses of flu vaccine, a hydroalcoholic root extract of *E. angustifolia*, or both. Rates of symptoms were decreased for echinacea-only and echinacea+vaccine groups compared with the vaccine-alone group.¹⁴⁷ Parainfluenza-like symptoms occurred in five patients in the vaccine-only group and in only one patient in each of the echinacea-only and echinacea+vaccine groups.

Elderberry

Therapeutic Uses

Juice or extracts of the *Sambucus nigra* berry are used primarily for prevention or treatment of influenza and other upper respiratory illnesses.

Physiologic Activity

Elderberries contain many vitamins (C, B2, B6, folic acid, beta-carotene, and others) and multiple flavonoids, anthocyanins, and polysaccharides. The activities of elderberry include inhibition of virus replication, increased production of anti-inflammatory and inflammatory cytokines, strong

antioxidant capacity, increased number of viral antibodies, and inhibition of hemagglutination of the influenza virus, which prevents viral entry into cells.¹⁴⁸ Extracts have inhibited growth of gram-positive and gram-negative bacteria.¹⁴⁹

Dosage and Product Considerations

Clinical trials have used at least four elderberry dosage forms including a spray-dried juice (400 mg TID, 10% anthocyanins), a syrup standardized to flavonoid content (Sambucol), encapsulated extracts, and an infusion prepared daily from dried elderberries.^{150–153} The optimum standardization and dosage form have not been determined.

Safety Considerations

Commercially available elderberry extracts are well tolerated, with few adverse effects reported.^{151,152} Insufficiently cooked or unripe berries, stems, or leaves contain cyanogenic glycosides, which are metabolized to cyanide in the GI tract; reports exist of not only nausea and vomiting but also dizziness, weakness, and stupor with ingestion of home-prepared juices and extracts.¹⁵³ (See [Table 51–2](#) for possible drug interactions.)

Summary of Clinical Evidence

The first study of elderberry extract (Sambucol) utilized 30 mL (15 mL for children) daily for 3 days in patients reporting flu symptoms during an influenza B outbreak. Fever duration was 4 days versus 6 days in the treatment and placebo groups, respectively. After 3 days, “complete cure” was noted in 46.7% of elderberry-treated patients and 16.7% of the placebo group.¹⁵⁰ The second study ($N = 60$), conducted during an influenza A epidemic, noted that elderberry-treated patients reached scores closer to “pronounced improvement” (10 on a 0–10 VAS scale) more quickly (3–4 days) than did placebo-treated patients (7–8 days).¹⁵⁴ Elderberry-treated patients also used fewer rescue medications.

A combination elderberry and echinacea hot drink product was tested against oseltamivir in a randomized, double-dummy noninferiority trial of 473 patients with clinically diagnosed influenza.¹⁵⁵ “Recovery, (symptom alleviation) was similar at 5 and 10 days. 50.2% versus 48.8%, and 90.1% versus 84.8% in the hot

drink and oseltamivir groups, respectively. A subanalysis of patients with laboratory-confirmed influenza noted noninferiority at days 5 and 10, and the hot drink group experienced significantly greater recovery at day 10 than the oseltamivir group, 95% versus 76.2%, respectively. Complication rates were 2.5% and 6.5% in the hot drink and oseltamivir groups, respectively.

In a double-blind, placebo-controlled trial, elderberry extract was investigated for effectiveness in prevention and treatment of cold symptoms in air travelers.¹⁵³ Participants ($N = 312$) took a 300 mg capsule twice daily for 2–10 days prior to traveling, then thrice daily while traveling, and for 4 days after arriving overseas. Cold occurrence rates did not differ between the groups: 17 taking placebo and 12 taking elderberry. Average cold duration was 4.75 days and 6.88 days in the elderberry and placebo groups, respectively ($P = 0.05$). Symptom severity scores were 21 and 34 in the elderberry and placebo groups, respectively ($P = 0.02$).

More research is needed before a population recommendation can be made, but in light of the mild adverse effect profile, elderberry extracts may be an appropriate option for individual patients.

Probiotics

See [Chapter 20](#) for discussion of the immune modulation effects of probiotics.

Physical and Mental Performance Enhancers

Eleuthero (Siberian Ginseng)

Eleutherococcus senticosus from the Araliaceae family is often referred to as *Acanthopanax senticosus* or Siberian ginseng. The plant is not a genus of *Panax*, as are Asian and American ginseng species. *Eleutherococcus* is found in eastern Siberia, northeastern China, Korea, and Hokkaido Island in Japan.

Therapeutic Uses

Eleuthero's traditional use is as an adaptogen for improvement of athletic performance, chronic stress, upper respiratory conditions, and immune deficiency. Other uses include treatment of herpes simplex type 2 infections,

blood pressure, prevention of atherosclerosis, and diabetes mellitus.

Physiologic Activity

The active compounds of eleuthero, derived primarily from the root and leaf, are referred to as eleutherosides (subtypes A to M). Flavonoids, hydroxycinnamates, and other constituents such as sesamin, B-sitosterol, hederasaponin B, and isofraxidin also may have biological activity. Animal studies and in vitro analysis suggest these compounds have antiplatelet, immunostimulant, and antioxidant properties.¹⁵⁶

Dosage and Product Considerations

Commercial products often are standardized to eleutheroside B and/or E content at a dosage of 300–400 mg daily. A 33% ethanolic extract 10 mL taken 3 times daily also has been used. After 2 months of daily use, patients should discontinue the product for a minimum of 2 weeks.¹⁵⁶ Eleuthero may be found as an ingredient in energy drinks because of its caffeine-like effects.

Safety Considerations

Both drowsiness and stimulant effects similar to those of caffeine, have been reported with eleuthero. Because of its variable effects on blood pressure, eleuthero should be avoided in patients with hypertension. Theoretically, patients with diabetes mellitus should be monitored for hypoglycemia.¹⁵⁶ Safety data are lacking for use during pregnancy and lactation. In patients taking digoxin, eleuthero may interfere with digoxin assays because of the structural similarities of their glycosides.⁷²

Summary of Clinical Evidence

Well-designed, randomized clinical trials documenting the safety and efficacy of eleuthero are lacking. Most evidence exists in combination with other herbals for treatment of cough and cold. Double-blind, placebo-controlled studies have evaluated eleuthero in fixed combination with *Andrographis paniculata* for upper respiratory tract infections.¹⁵⁷ Improvements have been demonstrated on most symptoms; cough improved in the study only with the use of a combination product including *Echinacea purpurea*.^{156–158}

In a small 6-month study, *Eleutherococcus* extract taken once daily demonstrated a beneficial effect on frequency, severity, and duration of herpes simplex type 2 infections.¹⁵⁹ A study of 144 participants were assigned *E. senticosus* root extract 120 mg taken daily, professional stress management training, or a combination of both. Participants suffered from chronic stress and fatigue that resulted in impaired work capacity. All treatment groups improved similarly from baseline at weeks 2 and 8 in most parameters related to performance and stress; mental fatigue and alertness were significantly better in the combination therapy group compared with the eleuthero-alone group.¹⁶⁰

Asian Ginseng (Panax ginseng)

The root and rhizome of Asian ginseng (*P. ginseng* C. A. Meyer; from the family Araliaceae) is exported primarily from Korea, China, and Japan.

Therapeutic Uses

Asian ginseng has been used to improve mental and physical stress, anemia, diabetes mellitus, fatigue, immune response, and impotence, and to prevent cancer.

Physiologic Activity

The constituents likely responsible for ginseng's adaptogen activity are triterpenoid saponins, including ginsenosides. At least 30 ginsenosides, also referred to as *panaxosides*, have been identified. Additional constituents include carbohydrates, B vitamins, and flavonoids.¹⁶¹

Dosage and Product Considerations

Ginseng extracts are standardized to 4% ginsenosides administered at 200 mg daily in divided doses. Crude powdered root has been used in dosages of 2–3 g daily. Decoctions and tea preparations also are commonly used.¹⁶¹

Safety Considerations

Adverse effects include insomnia, headache, blood pressure changes, anorexia, rash, mastalgia, and menstrual abnormalities. Large dosages can result in

gastric upset and CNS stimulation. Ginseng should be used with caution in patients with cardiovascular disease, diabetes mellitus, or acute illness. Abuse and misuse of ginseng have been described in ginseng users, and prolonged use is not recommended.¹⁶² Ginseng should not be used during pregnancy or lactation because of a lack of data and concern about its potential estrogenic effects.¹⁶³ Several potential drug interactions are listed in [Table 51–2](#).^{71,72,161}

Summary of Clinical Evidence

Five trials were included in a Cochrane review of the role of *P. ginseng* for cognition; the majority of participants were healthy with cognitive impairment or dementia. The data could not be pooled because of varied dosing regimens, outcomes, and study durations. Although ginseng improved some end points related to cognitive function, quality of life, and behavior, the overall evidence did not support its use.¹⁶⁴ A systematic review and meta-analysis of four randomized, controlled trials of ginseng taken by patients with AD in addition to standard treatments did not identify a benefit.¹⁶⁵

A systematic review and meta-analysis examined eight randomized controlled trials of ginseng in participants with type 2 diabetes mellitus or impaired glucose tolerance, including one study using American ginseng. Subjects receiving ginseng demonstrated significant improvements in fasting glucose, postprandial insulin, insulin resistance, LDL cholesterol, triglycerides, and total cholesterol values. No significant differences were found between the ginseng and control group on hemoglobin A1C, postprandial glucose, fasting insulin, or HDL cholesterol levels. Addition of ginseng to those already treated with hypoglycemic medications or insulin also showed no difference in fasting glucose levels.¹⁶⁶

For erectile dysfunction, a systematic review of seven randomized controlled trials found significant benefit with Asian ginseng, although the review noted limitations of a small sample size and trial quality.¹⁶⁷

Green Tea

Native to southeastern Asia, the tea shrub *Camellia sinensis* belongs to the family Theaceae. Tea leaves are heated immediately after harvesting, mechanically rolled and crushed, and then allowed to dry to produce green tea. Black tea is produced by allowing the leaves to wilt before they are rolled

and left in a humid environment for several hours. This process promotes fermentation and a gradual change in color to reddish-brown. Oolong, another commonly available tea, is a partially fermented tea.

Therapeutic Uses

Green tea is considered a performance enhancer because of the stimulant effect from caffeine. Green tea also has been used to prevent cardiovascular disease, cancer, and liver disorders.

Physiologic Activity

In addition to caffeine, green tea contains polyphenolic compounds including flavonols, also known as catechins, flavonoids, and phenolic acids. The most prevalent flavonols include epicatechin, epicatechin-3-gallate, epigallocatechin, and epigallocatechin-3-gallate (or EGCG). These components have antioxidant and antitumor effects.¹⁶⁸ Both catechins and caffeine may contribute to weight loss.¹⁶⁹

A Word About Weight Loss Supplements

Dietary supplements for weight loss are some of the most popular on store shelves. The ingredients change rapidly based on the latest trends or celebrity tweets; the benefits and harms of these products can differ greatly.

Garcinia cambogia

Garcinia cambogia extracts are a source of hydroxycitric acid (HCA). Both extracts or HCA acid may exert effects by delaying glucose absorption, reducing postprandial glucose levels, and decreasing appetite, although effects in human studies have been highly variable.^a Limited clinical studies of short duration or small size have had inconsistent or not clinically significant outcomes. For example, in a 12-week study, mean weight loss in the garcinia/HCA group was 1.3 pounds higher than in the placebo group, which was statistically, but not likely clinically, significant. Garcinia extracts and HCA have been associated with reports of

hepatotoxicity, hypomania, rhabdomyolysis, and other rare but serious adverse events.^{a-c} Neither product should be recommended for weight loss.

The active components in green coffee bean extract are chlorogenic acids (CGAs). Regular roasted coffee contains very little CGA. Green coffee bean extract first became wildly popular for weight loss before any substantial human research had been conducted. Since then, a few small trials have examined effects in both normoglycemic patients and patients with diabetes. Some have demonstrated greater weight loss compared with placebo, -5 kg in 3 months in normoglycemic overweight subjects and -2 kg in 2 months in patients with metabolic syndrome.^{d,e} Both CGA and green coffee bean extract seem to be well tolerated; few adverse effects have been reported in trials. More research is needed before either CGA or green coffee bean extract can be recommended for weight loss. Patients who choose to use these products should be educated about the maximum CGA intake of no more than -900 mg daily, the maximum used in clinical trials, and about the possibility of adverse effects from caffeine if they also are using coffee drink products.

Stimulants and “Fat Burners”

After ephedrine alkaloids were banned from weight-loss supplements, some manufacturers relabeled bottles as “ephedra free!” and substituted other sources of the ephedrine alkaloids (heartleaf, country mallow). Other stimulants often are used now. Guarana, yerba maté, cola nut, and other caffeine sources are common, as is bitter orange (*Citrus aurantium*), a source of synephrine. Bitter orange has been associated with case reports of cardiovascular events and ischemic colitis, although some research has found no cardiovascular effects.^{f-h} Stimulants may provide a little boost in weight loss, but their safety issues outweigh the small benefits.

Raspberry Ketone

Raspberry ketone (4-4(hydroxyphenyl)butan-2-one) is a flavoring agent with a structure similar to that of synephrine. Increased lipolysis and adiponectin secretion in fat cells, as well as other effects noted in both

tissue and in vivo studies, indicate promise for impact on body mass, but results from animal studies for weight loss have been contradictory.ⁱ No human clinical trials of raspberry ketone alone have been published. One patient experienced sinus tachycardia, insomnia, and “jitteriness” after 1 month of raspberry ketone use, and “shakiness” also has been reported.^j At this time, patients should be discouraged from using raspberry ketone alone or in combination supplements.

^j Takematsu M, Smith SW, Hoffman RS, et al. Berries that weren't that sweet after all. A case of raspberry ketone intoxication. *Clin Toxicol*. 2013;51:284.

Dosage and Product Considerations

Dosages of green tea in epidemiologic studies vary between 1 and 10 cups daily. The preferred dosage is 3–5 cups daily, or up to 1200 mL daily, including a minimum of 250 mg daily of catechins.¹⁷⁰ Green tea extract supplements are standardized to polyphenol content and retain effects similar to those of green tea while reducing exposure to caffeine.¹⁶⁸

Safety Considerations

Despite its lower caffeine content, ingestion of large quantities of green tea can cause adverse GI symptoms as well as CNS and cardiac stimulation. One 8-ounce cup of green tea contains 25–29 mg of caffeine. In comparison, an 8-ounce cup of black tea has 25–48 mg of caffeine, and an 8-ounce cup of coffee can contain 95–165 mg on average.¹⁷¹ Green tea should be avoided if other stimulating drugs are being ingested. Green tea extracts have been associated with liver toxicity,¹⁷² and serum folate levels have been reduced by green tea.⁷² As a result, green tea should be used cautiously during pregnancy and lactation because of concerns about caffeine consumption and potential concerns about folic acid. Green tea contains small amounts of vitamin K, which in large dosages may antagonize the effects of warfarin; however, catechins and caffeine also may have antiplatelet effects.⁶⁸

A Word About Kratom

Leaves of the Southeast Asian tree kratom (*Mitragyna speciosa*) historically were used for pain treatment, but current use is primarily

recreational. Two major alkaloids, mitragynine and 7-hydroxymitragynine, are mu opioid receptor partial agonists and also affect kappa and delta receptors. Kratom is psychoactive with both stimulant and opioid-like effects; heroin addicts sometimes will substitute kratom use, although it also is highly addictive.^a Illegal in a number of countries, kratom is a recreational drug option in the United States and easily obtainable in smoke and vape shops as an “herbal incense.” Although many adverse events are associated with multidrug use, reports of adverse events when kratom is used alone are growing and include increased blood pressure, impaired cognition, cardiac arrest and arrhythmias, seizures and Torsades de Pointes unresponsive to naloxone, primary hypothyroidism, liver and kidney failure, respiratory depression, coma, and death.^{b–d} More kratom-associated deaths occur when use is combined with other stimulant or depressant drugs, such as the combination of O-desmethyl and tramadol called “krypton.”^a A number of drug–drug interactions are possible, because kratom inhibits several CYP450 isoenzymes as well as P-glycoprotein transport. No published human trial studies have examined kratom use for pain or addiction treatment, although heroin addicts in Malaysia report substituting kratom.

^d Post S, Spiller HA, Chounthirath T, Smith GA. Kratom exposures reported to United States poison control centers: 2011–2017. *Clin Toxicol.* 2019;20:1–8. doi: 10.1080/15563650.2019.1569236.

Summary of Clinical Evidence

Epidemiologic data suggest that daily consumption of green tea may protect against cardiovascular and metabolic diseases. Green and black teas were evaluated for primary prevention of cardiovascular disease by the Cochrane Heart Group.¹⁷³ Seven randomized, controlled trials were included with green tea or green tea extract as intervention for at least 3 months. A significant reduction in TC and LDL-cholesterol levels was noted, as well as small reductions in mean SBP and DBP. Cardiovascular events were not reported, presumably because of the short trial durations. Another meta-analysis of nine studies evaluating green tea's effect on cardiovascular and ischemia-related diseases found that those consuming green tea had significantly less risk of developing cardiovascular disease, intracerebral hemorrhage, or cerebral infarction compared with controls. The risk of myocardial infarction and stroke was lower in those consuming 1–3 cups versus consumption of less than 1 cup per day. In addition, those consuming high amounts, more than 10 cups per day, had significantly lower LDL cholesterol levels than those drinking fewer than 3 cups per day.¹⁷⁴ A Cochrane review found that green tea products had no significant effects for weight loss and weight maintenance in obese patients.¹⁶⁹

The consumption of green tea has been studied with regard to reducing the incidence of breast, prostate, lung, bladder, ovarian, digestive, and oral cancers. A Cochrane review of 51 studies that included 1.6 million subjects found conflicting evidence that green tea consumption affects overall cancer prevention.¹⁷⁰ Although some evidence has suggested a positive effect on prostate, lung, pancreatic, and colorectal cancers, many studies were observational in nature and performed in Asia where green tea consumption is high.

Kidney, Urinary Tract, and Prostate

African Plum

African plum is derived from the bark of *Prunus africana*, a member of the Rosaceae family.

Therapeutic Uses

Pygeum (African plum tree) bark has been used to treat benign prostatic hyperplasia (BPH).

Physiologic Activity

Pygeum bark contains phytosterols; triterpenoid pentacyclic acids, including ursolic and oleanic acids; and alcohols including docosanol. Pygeum may compete with androgen precursors and inhibit prostaglandin synthesis in the prostate. It appears to exhibit anti-inflammatory properties, inhibition of 5-alpha reductase, and reduction in concentrations of prolactin and prostate cholesterol, a precursor to testosterone synthesis.¹⁷⁵

Dosage and Product Considerations

Products are standardized to contain 14% triterpenes; the average dosage is 100 200 mg daily.¹⁷⁵

Safety Considerations

Adverse effects include diarrhea, constipation, and gastric pain. Men presenting with prostate symptoms should contact their HCP before starting pygeum to rule out prostate cancer. It is unclear if pygeum decreases prostate-specific antigen (PSA) concentrations.

Summary of Clinical Evidence

Pygeum has improved urinary flow, void volumes, residual volumes, nocturia, daytime frequency of urination, and subjective symptom assessments of BPH. Larger studies that include standardized dosages, active comparisons, and adequate durations are needed to fully assess its efficacy.¹⁷⁶

Cranberry

Cranberry (*Vaccinium macrocarpon*) is an evergreen bush native to North America and belongs to the family Ericaceae.

Therapeutic Uses

Cranberry has been used to prevent and treat urinary tract infections (UTIs).

Physiologic Activity

Cranberry contains proanthocyanidins; epicatechin is the primary proanthocyanidin found in cranberry extracts. Evidence suggests that cranberry blocks bacteria, *Escherichia coli*, in particular, from adhering to bladder, kidneys, and urethra. Fructose found in cranberry juice also may alter bacterial adhesion.¹⁷⁷

Dosage and Product Considerations

Many studies have used unsweetened cranberry juice. Cranberry juice cocktail is about 30% pure cranberry juice and contains sugar; it is unknown if this product will demonstrate the same effects. Efficacy may be based on the proanthocyanidin content. For prevention of UTI, the dosage of cranberry juice is 300–900 mL daily. Encapsulated cranberry formulations at a dosage of about 400 mg twice daily may be preferred to avoid the sugar content of juices.

Safety Considerations

Evidence suggests that regular use of cranberry concentrate tablets might increase risk of kidney stones. Patients may experience diarrhea with large doses (>3 L daily) of cranberry juice.⁷¹ Theoretically, cranberry juice may alter excretion of weakly alkaline drugs or neutralize effects of antacids. Case reports have suggested cranberry may cause bleeding in patients taking antithrombotic agents; pharmacokinetic and pharmacodynamic evidence has not supported this finding.^{72,178}

Summary of Clinical Evidence

A Cochrane review of 24 studies, with 13 included in a meta-analysis, concluded preventive use of cranberry products does not significantly reduce the overall risk of UTIs; nor is risk reduced in subgroups of women or children with recurrent UTIs, older adults, pregnant women, cancer patients, and catheterized patients. The long-term use of cranberry, specifically juice, is not well tolerated, potentially resulting in high dropout rates in studies.¹⁷⁹ An

additional consideration with negative studies is whether the tablet or capsule products contained adequate proanthocyanidins to be effective; ongoing studies are evaluating this relationship.¹⁸⁰ A subsequent systematic review and meta-analysis of UTIs in healthy women with recurrent infections found an overall 26% reduction in risk.¹⁸¹ Results from randomized, controlled studies published since the Cochrane review have been mixed as to cranberry's usefulness in preventing high-risk patients from UTIs in long-term care settings.^{182,183} Use of cranberry instead of antibiotics to prevent UTIs may be beneficial in reducing antibiotic resistance. Evidence to support cranberry products for the treatment of a current UTI is lacking; instead patients should be referred to their health care provider for diagnosis and treatment.¹⁸⁴

Dehydroepiandrosterone

Therapeutic Uses

Dehydroepiandrosterone (DHEA) is a steroid prehormone secreted by the adrenal cortex that declines with advancing age. Transformation to androgens and estrogens occurs in peripheral tissues and is regulated both systemically and locally.¹⁸⁵ DHEA dietary supplements are marketed to treat sexual dysfunction or improve sexual performance, to combat physical and mental symptoms of aging, and to enhance athletic performance or increase muscle mass.

Physiologic Activity

In general, exogenous use of DHEA in women increases testosterone concentrations to a higher level than those of estrogen, whereas the reverse is true in men. The extent to which androgen and estrogen transformation occurs depends largely on a patient's baseline concentrations of the hormones. In women, route of administration and menopausal status affect transformation; more androgens than estrogens are formed in postmenopausal women.¹⁸⁶ DHEA also has effects on nuclear receptors, stimulating osteoblastogenesis and inhibiting IL-6, which are involved in bone catabolism.¹⁸⁷

Dosage and Product Considerations

For most uses, the DHEA dosage is 25–100 mg once daily. Because of greater

risk of serious adverse effects with dosages higher than 25 mg, patients should use larger dosages only under the supervision of healthcare provider.¹⁸⁸

Although most DHEA products are synthetic, animal-extracted products exist but should be avoided because of contamination risks. Wild yam products are falsely promoted as DHEA or hormone precursors, because wild yam contains diosgenin. This hormone was once used by pharmaceutical manufacturers to produce estrogens and androgens, but the necessary chemical reactions do not occur in vivo. Some wild yam plants do contain very small amounts of naturally occurring DHEA, further complicating the patient education process for this hormone.

Safety Considerations

Adverse effects are sex hormone–related. Women may experience hirsutism, voice deepening that is generally irreversible, increased acne severity, and menstrual changes, whereas men may experience gynecomastia, reduced sperm count, and testicular changes. If hormone-associated adverse effects appear, DHEA use should be discontinued. Other adverse effects include increases in liver function enzymes, possible decreases in HDL cholesterol, as well as prostate growth, headache, nasal congestion, and insomnia.¹⁸⁹ At least four reports of mania requiring hospitalization exist; DHEA is contraindicated in bipolar disorder and should be avoided in any mood disorder.¹⁸⁸ DHEA should be avoided by patients who have a history of hormone-sensitive cancer, are taking hormonal or hormone-blocking medications, or are pregnant or lactating.

Summary of Clinical Evidence

Low DHEA levels have been associated with a greater risk of erectile dysfunction. The evidence for effectiveness of DHEA supplementation for ED is contradictory. In two trials, improvement was noted when ED was due to hypertension or unknown causes, but not when it was caused by diabetes mellitus or a neurologic condition.¹⁹⁰

A 2017 meta-analysis included 38 studies that investigated DHEA's effects on sexual function using a variety of measurements, such as the Female Sexual Function Index, International Index of Erectile Function, and Derogatis Interview Sexual Functioning Inventory.¹⁹¹ Conclusions of the analysis were

that oral DHEA supplementation does not improve sexual function in healthy men or premenopausal women, but peri- or postmenopausal women may experience improved sexual function that includes decreased dyspareunia and increased lubrication, arousal, frequency, and ability to orgasm. Although dosages of 50–100 mg/day were used, as little as 10 mg daily was found to be effective, with patients experiencing improvement similar to that found with hormone therapy treatment.¹⁹²

In addition to sexual effects, low DHEA levels may be associated with decreased bone mineral density (BMD), higher fasting glucose levels, ischemic heart disease, and all-cause mortality in older men and women.¹⁸⁵ A pooled analysis of four trials concluded that DHEA treatment increased spine BMD in women but not in men.¹⁹³ Increases from baseline averaged –1% at 1 year, with some patients experiencing increases up to 1.8% at 2 years.¹⁹³ Body composition and strength were improved more in women than men, and greater improvement was seen when treatment was combined with exercise. Some participants had improved skin health, such as increased epidermal thickness and sebum production and decreased tearing. Topical use also may benefit aging skin.¹⁹⁴

Saw Palmetto

Saw palmetto (*Serenoa repens*), a dwarf palm tree from the Arecaceae family, is native to the southeast coastal region of the United States.

Therapeutic Uses

Saw palmetto has been used to treat BPH.

Physiologic Activity

The lipophilic extracts from the ripened fruit contain fatty acids and glycerides, plant sterols and sitosterol derivatives. Saw palmetto inhibits 5-alpha-reductase and cytosolic androgen receptor binding; it also has local antiestrogenic and anti-inflammatory effects on the prostate and bladder. It does not reduce PSA concentrations.¹⁷⁵

Dosage and Product Considerations

The usual dosage is 160 mg twice daily or 320 mg once daily. Saw palmetto products should contain 80%–95% standardized fatty acids.

Safety Considerations

In comparative studies, saw palmetto was better tolerated than finasteride and tamsulosin. Mild GI complaints, along with fatigue and headache, were the most commonly reported symptoms.¹⁹⁵ Significant bleeding has been reported with saw palmetto, so its use in individuals taking antithrombotic agents should be avoided.⁷¹ Patients taking androgenic drugs also should avoid its use. Men with prostate symptoms should contact their provider to rule out prostate cancer before starting saw palmetto. Saw palmetto is occasionally used in multi-ingredient products intended for women. Because of the inhibition of 5-alpha-reductase, it is absolutely contraindicated in pregnancy and also should not be used in lactation.

Summary of Clinical Evidence

In a Cochrane review of 32 randomized controlled trials ranging from 4 to 72 weeks and involving more than 5000 men, saw palmetto was not effective for treating urinary symptoms, increasing peak urine flow, or reducing prostate size.¹⁹⁶ The meta-analysis included two high-quality trials of 582 men; data analysis based on the American Urological Association Symptom Score Index demonstrated no difference in lower urinary tract symptoms for those taking saw palmetto compared with placebo. A 72-week study at 2–3 times the usual dose of 320 mg daily found insignificant differences in lower urinary tract symptoms, including nocturnal symptoms. Three high-quality trials assessing peak urine flow in 667 men also found no change compared with placebo. No difference was noted in prostate size after a 12-month trial. Overall, the evidence does not support use of saw palmetto for BPH symptoms. Preliminary data for the effects of a combination product containing saw palmetto, lycopene, and selenium appear to be noninferior to tadalafil's effect on lower urinary tract symptoms.¹⁹⁷ Higher-quality studies are needed to further assess saw palmetto's benefit.

Musculoskeletal System

Glucosamine and Chondroitin

Therapeutic Uses

Glucosamine and chondroitin commonly are used together in supplements for osteoarthritis (OA) and joint health.

Physiologic Activity

Both glucosamine, an endogenous monosaccharide precursor to glycoaminoglycans, and chondroitin sulfate, a glycoaminoglycan, serve as “building materials” for cartilage production, but each has additional mechanisms of action. Glucosamine stimulates chondrocytes to produce cartilage and synoviocytes to produce synovial fluid and hyaluronic acid, inhibits matrix metalloproteinase, and modulates activities of inflammatory cytokines.¹⁹⁸ Cell studies have demonstrated that glucosamine also stimulates osteoblast proliferation, although it remains to be seen if the effect is significant in vivo.¹⁹⁹

Chondroitin sulfate inhibits leukocyte elastase, an enzyme involved in cartilage degradation, and bone resorption by osteoclasts; stimulates chondrocytes; reduces inflammation via inhibition of the translocation of nuclear factor kappa (involved in activating B cells); and donates sulfur, essential for the sulfur bonds used in cartilage synthesis.²⁰⁰

An in vivo pharmacoproteomics study determined that glucosamine and chondroitin used together have additional synergistic benefits on cartilage metabolism.²⁰¹ A meta-analysis of clinical studies has concluded that long-term use of both glucosamine sulfate and chondroitin can slow progression of cartilage degradation in knee OA.²⁰²

Dosage and Product Considerations

The dosage for OA is 1500 mg of glucosamine and 1200 mg of chondroitin sulfate daily taken either once or in divided doses. For larger individuals, the dosage is 2000/1600 mg; surpassing this dosage provides no additional

benefit. If glucosamine monotherapy is desired, only the sulfate salt should be used; evidence does not support use of glucosamine hydrochloride monotherapy.^{203,204} The daily dosages for glucosamine sulfate, glucosamine hydrochloride, or chondroitin monotherapy are the same when used in combination therapy. Products should be taken with food if nausea or GI upset occurs.

Neither glucosamine sulfate, chondroitin sulfate, nor their combined use will provide pain relief as quickly as ibuprofen or acetaminophen, so concurrent analgesics should be continued as needed. Effects may not be experienced for 6–8 weeks, with full benefits not evident for 4–6 months. If no benefits are noted after 6 months of therapy, it should be discontinued.

Both glucosamine sulfate and chondroitin sulfate are available in prescription-grade forms in Europe; these products have demonstrated much greater success in clinical trials, and chondroitin is considered a symptomatic slow-acting drug in OA (SYSADOA).²⁰⁰ Although these products are recommended, U.S. patients usually have to purchase them on the internet. Widely available dietary supplement products are of lower quality; expectations of the degree of effectiveness with treatment should be correspondingly lower. Patients using dietary supplement glucosamine and/or chondroitin should be counselled to purchase only products that display the USP Verified seal or were tested by a similar laboratory, or that were used in successful clinical trials.

Safety Considerations

Adverse effects for both components include mild GI upset, nausea, diarrhea, and constipation, which can often be alleviated by taking divided doses with meals. Drowsiness, headache, and skin reactions have been reported infrequently with glucosamine, whereas allergic reactions, edema, and hair loss have been reported with chondroitin sulfate. Chondroitin often is produced from bovine or porcine trachea, so there is a slight microbial contamination risk. Because trachea contains little neural tissue, risk of bovine spongiform encephalitis is minimal. Some newer sources of chondroitin do include fish or shark cartilage, so patients with severe shellfish allergies should ensure products are mammalian sourced.²⁰⁵

Glucosamine is manufactured from shellfish chitin or produced synthetically.

Some products claim to be allergen-free, because processing removes allergenic material. Two studies tested this claim using shellfish-derived products and found no reactions in individuals with documented shellfish allergies.²⁰⁶ Because source materials may not remain consistent even for a particular manufacturer, patients with severe shellfish allergies should avoid use of glucosamine and instead use bovine or porcine chondroitin monotherapy.

Pregnant or lactating women should avoid both glucosamine and chondroitin, because safety data are lacking. There are no known drug interactions for either supplement.

Summary of Clinical Evidence

Glucosamine sulfate, glucosamine hydrochloride, and chondroitin sulfate have been examined separately, with varying results for all three supplements. OA treatment guidelines from the European Society for Clinical and Economic Aspects of Osteoporosis and Osteoarthritis include pharmaceutical grade crystalline glucosamine sulfate as first-line therapy for knee OA.²⁰⁷ Other organizations, such as the European League Against Rheumatism and the American College of Rheumatology, do not distinguish activities of the supplements and consider their benefits as not clinically significant.²⁰⁸ A 2018 meta-analysis of multiple long-term treatments for knee OA included six trials of glucosamine sulfate; investigators determined that its use was associated with decreased pain in both the initial analysis and after studies with a high risk of bias were excluded, with an SMD of -0.29 (95% CI -0.49 to -0.10).²⁰⁹ For comparison, the SMD for celecoxib was -0.18 . A determination of effectiveness using surface under the cumulative ranking (SUCRA) curve methodology ranked glucosamine as most likely to be effective, with a SUCRA mean of 0.92 (95% CI 0.59 – 1.00). Hyaluronic acid plus triamcinolone ranked second at 0.88 and celecoxib third at 0.79 . A second 2018 meta-analysis included 18 trials.²¹⁰ Analysis of VAS pain scores for glucosamine determined a small effect size of -0.19 (95% CI -0.36 to -0.03) and a nonsignificant effect size of -0.04 (95% CI -0.13 to 0.06) on Western Ontario and McMaster Arthritis Index (WOMAC) scores. The Japanese Knee Osteoarthritis Measurement indicated a more favorable impact on quality of life, with an effect size of -0.73 (95% CI -1.13 to -0.32).

Benefits of glucosamine sulfate treatment may extend beyond symptom

reduction; patients who participated in two 3-year studies of a pharmaceutical grade crystalline glucosamine sulfate product and were followed for 5 years experienced a 57% reduction in the number of patients needing knee joint replacement, compared with placebo.²⁰⁷

Chondroitin monotherapy has been shown to decrease degradation rates of knee cartilage.²¹¹ A 2018 trial of 6 months duration in 604 patients compared pharmaceutical grade chondroitin with celecoxib and placebo.²¹² The pain reduction scores on a 100 mm VAS were -42.6 mm, -39.5 mm, and -33 mm in the chondroitin ($P = 0.001$), celecoxib ($P = 0.009$), and placebo groups, respectively. A 2019 meta-analysis including 18 trials in knee OA compared the SMD of pain with Lequesne index scores.²¹³ The overall effect size for pain was -0.18 (95% CI -0.25 to -0.12) but increased to -0.25 (95% CI -0.34 to -0.16) for trials using pharmaceutical grade chondroitin. Chondroitin had a greater impact on functionality; the effect size determined by the Lequesne index was -0.28 (95% CI -0.39 to -0.18) for all trials, and -0.33 (95% CI -0.47 to -0.20) for those using pharmaceutical grade chondroitin. The European League Against Rheumatism recommends chondroitin to reduce pain and to increase function in hand OA.²¹⁴

The greatest benefits may be achieved with combination of either salt of glucosamine with chondroitin. One trial of 606 patients with knee OA of moderate to severe pain compared glucosamine hydrochloride/chondroitin sulfate, 500/400 mg taken 3 times daily, with celecoxib 200 mg daily for 6 months.²¹⁵ The WOMAC scores for pain, stiffness, and function were decreased similarly at 6 months in the glucosamine hydrochloride/chondroitin and celecoxib groups, respectively: 51.1% versus 50.2%, 46.9% versus 49.2%, and 45.5% versus 46.4%. The patient or physician global assessments were similar in the groups. In the first month, rescue medications were used more often by the glucosamine hydrochloride/chondroitin group. After that period, use of rescue medications was similar between the groups.

The question of whether glucosamine sulfate/chondroitin sulfate is more efficacious than glucosamine hydrochloride/chondroitin sulfate was addressed in an open label noninferiority trial in 909 participants with mild to moderate OA. The interventions were glucosamine sulfate/chondroitin sulfate given once daily (Artrolive 1500/1200 mg sachet) or 3 times daily (Artrolive 500/400 mg capsules) compared with glucosamine hydrochloride/chondroitin sulfate (Cosamin DS 500/400 mg capsules) given 3 times daily for 16 weeks.²¹⁶ At study

end, all treatment groups had achieved significant reductions from baseline in the pain VAS ($P = 0.001$), Lequesne Index scores ($P = 0.001$), and patient and physician global assessment VAS (both $P < 0.05$), with no differences noted between groups.

Current research supports that chondroitin sulfate combined with either salt of glucosamine, chondroitin sulfate monotherapy, and crystalline glucosamine sulfate monotherapy, but not glucosamine hydrochloride monotherapy, should be considered options for treatment of patients with mild to moderate OA symptoms.

Methylsulfonylmethane

Therapeutic Uses

Methylsulfonylmethane (MSM) occurs naturally in foods and is a major metabolite of dimethylsulfoxide (DMSO), an industrial solvent. Arthritic workers began using DMSO topically, and MSM was developed in an attempt to avoid DMSO's toxicity and unpleasant side effects.²¹⁷

Physiologic Activity

Intestinal bacteria break down MSM to release sulfur, which is then incorporated into amino acids such as cysteine. Sulfur is essential for cartilage bonding; animal studies have found lower levels of sulfur in arthritic cartilage. Preclinical studies have demonstrated anti-inflammatory effects such as reduced production of IL-6 and TNF α , decreased COX-2 expression, and inhibition of nuclear factor kappaB.²¹⁸

Dosage and Product Considerations

OA dosages used in clinical trials have varied from 1500 to 3000 mg daily in 1 dose or divided doses.²¹⁹ A patient choosing to use MSM should not exceed 3000 mg daily. MSM can be destroyed by water or excessive heat during manufacture or storage, so purchasing from a reliable manufacturer and storing the product properly are essential. It is common to see smaller doses of MSM in combination products for OA; these products may not offer benefit, but they are not known to present a hazard.

Safety Considerations

Adverse effects include headache, pruritus, nausea, and diarrhea. Use in pregnancy and lactation should be avoided because of a lack of safety information. No drug interactions are known.

Summary of Clinical Evidence

A placebo-controlled pilot trial of 50 patients with knee OA noted greater improvement with MSM.²¹⁹ More recently, MSM 1.125 g given 3 times daily was compared with placebo for 12 weeks in a trial of 40 patients with knee OA.²²⁰ Reductions in WOMAC pain, stiffness, and function scores, and Aggregated Locomotor Function (ALF) scores were significantly better than placebo at 12 weeks ($P = 0.05, 0.01, 0.01$, and 0.00 , respectively), although pain VAS scores were similar. The data analyses accounted for differences between study groups at baseline in body mass index and ALF scores, which were higher in the MSM group.

MSM is used most often in combination with other supplements. One 12-week trial in 118 participants compared MSM with glucosamine sulfate, placebo, and the combination of MSM and glucosamine; significant improvement in pain and functioning was reported by all groups but placebo. Improvement was greater in the combination group than with MSM or glucosamine alone.²¹⁹ A trial in 147 patients compared glucosamine sulfate/chondroitin sulfate (1500/1200 mg daily) with glucosamine sulfate/chondroitin sulfate/MSM (1500/1200/500 mg daily) and with placebo for 12 weeks.²²¹ At the end of the study, improvements in the WOMAC scores differed significantly between groups ($P = 0.03$) at week 12, whereas only the glucosamine sulfate/chondroitin sulfate/MSM group showed significant improvement from baseline (decrease from 34.16 to 22.04, $P = 0.01$). Improvements in the VAS for pain followed a similar pattern. However, the evidence is insufficient to recommend MSM alone or in combination with other therapies.

S-adenosyl-L-Methionine (SAME)

Therapeutic Uses

S-Adenosyl-L-methionine (SAME) is an endogenous substance formed from L-methionine and ATP. SAME is marketed for OA and depression.

Physiologic Activity

SAMe is produced primarily in the liver. Liver disease and low levels of vitamin B₁₂ or folate may decrease SAMe concentrations.²²² For OA, SAMe stimulates chondrocytes to produce proteoglycans, reduces cartilage degradation enzymes such as matrix metalloproteinase-3 in serum and synovial fluid, and has anti-inflammatory effects such as decreased TNF α and IL-1 β .^{222,223}

SAMe donates methyl groups to neurotransmitters and catecholamines and thereby increases brain neurotransmitter levels, including those of norepinephrine, dopamine, and serotonin, which may contribute to antidepressant effects.

Dosage and Product Considerations

Most OA trials used dosages of 400–800 mg daily in divided doses, whereas dosages for depression are 1200–1600 mg daily.²²⁴

Safety Considerations

Adverse effects include nausea, diarrhea, and heartburn. Less frequently, dry mouth, headache, dizziness, nervousness, insomnia, cognitive impairment, and a switch to mania in patients with bipolar disorder have been reported.²²⁴

SAMe also is associated with hypomania or severe mania in subjects who have no personal or family history of mania or bipolar disorder; a report of mixed mania with suicidal ideation occurred within 2 weeks of its use.^{224,225} These CNS effects may be dose related, because mania and hypomania have been reported with the higher dosages used for depression but not with the lower dosages used in OA trials. Patients who use SAMe for OA should take the lowest dosage that provides relief but no more than 800 mg daily.

Use in pregnancy or lactation should be avoided. Potential drug interactions are listed in [Table 51–2](#).

Summary of Clinical Evidence

Many early OA trials with positive results were of short duration and poor design, and they used injectable dosage forms or combinations of intravenous and oral therapies.²²⁶ When oral SAMe was compared with NSAIDs or a COX-2

inhibitor, equivalent results in restoration of functionality and decreased pain were seen, although with slower onset.²²⁷ A more rigorously designed trial compared SAME (1200 mg daily) with nabumetone.²²⁸ Pain measured on a 40-mm VAS showed a significant decrease to a similar extent in the SAME (–13 mm) and nabumetone (–15.7 mm) groups at 8 weeks. The WOMAC index also decreased similarly in the SAME and nabumetone groups (–6.9 mm and –9.3 mm, respectively; $P = 0.459$). However, the changes occurred more slowly in the SAME group. A meta-analysis concluded that SAME's clinical effects may be small.²²⁶ Because of the limited evidence and the severity of possible adverse effects, use of SAME should not be recommended.

Turmeric/Curcumin

The names *curcumin* and *turmeric* often are used interchangeably, especially for the spice used in cooking, but curcumin is the primary curcuminoid present in the turmeric plant (*Curcuma longa*).²²⁹

Therapeutic Uses

Turmeric extracts and curcumin are used primarily for arthritis and inflammatory conditions.

Physiologic Activity

Curcumin has anti-inflammatory activity via inhibition of arachidonic acid metabolism, lipooxygenase, COX, TNF α , and interleukins.²²⁹ It also decreases expression of matrix metalloproteinase-3.²³⁰ In a study of patients with knee OA, turmeric extract 90 mg daily decreased COX2 secretion into synovial fluid similarly to diclofenac 75 mg daily.²³¹ Curcumin extracts have antihyperlipidemic, antitumor, antibacterial, antioxidant, and antidiabetic effects. Its body distribution is fairly low but increases when ingested with oils; researchers have developed a nanoparticle formulation with increased bioavailability.²²⁹

Dosage and Product Considerations

An optimum dosage has not been determined. Clinical trials demonstrating benefit have used 1000–1500 mg daily in divided doses.

Safety Considerations

The most common side effects are GI discomfort and nausea. Human studies show good tolerance with dosages as high as 12,000 mg daily.²²⁹ Curcumin inhibits platelet aggregation, so patients on antithrombotic agents should use curcumin cautiously.

Summary of Clinical Evidence

A noninferiority trial ($n = 367$) compared 1500 mg of turmeric extract daily to 1200 mg of ibuprofen daily for 4 weeks.²³² The WOMAC total, pain, stiffness, and function scores were all similar between the turmeric and ibuprofen groups; 64.3% and 63.8% of turmeric and ibuprofen patients, respectively, rated themselves as “improved” on the global assessment. Adverse events were similar except for less abdominal pain/distention in the turmeric group, (10.8% vs. 18.1%, $P = 0.046$). Similar results were observed in a study comparing 500 mg curcumin 3 times daily to 50 mg daily of diclofenac in 139 patients.²³³ All scores on the Knee Injury and Osteoarthritis Outcome Score improved similarly; pain subscores decreased from 53.29 to 35.48 and 53.15 to 37.23 in the curcumin and diclofenac groups, respectively. Adverse events were mild, occurring in 13% of the curcumin group and 38% of the diclofenac group. Curcumin-treated patients experienced significantly less flatulence ($P < 0.01$) than patients taking diclofenac and a greater decrease in weight, 1.01 kg vs. 0.12 kg ($P < 0.01$).

A polysaccharide-rich turmeric extract was examined in an OA trial in 120 patients.²³⁴ Patients were randomized to receive 500 mg turmeric extract, 750 mg glucosamine sulfate, curcumin extract/glucosamine sulfate, or placebo, each twice daily for 42 days. The VAS pain scores were reduced significantly from baseline in all groups, with the greatest change in the turmeric group, decreasing from 66.5 to 19.48 ($P < 0.01$). WOMAC scores also were improved in the turmeric group, decreasing from 54.97 to 17.14 ($P < 0.01$). Pain and WOMAC score reductions for glucosamine also were significantly better than baseline, but less so than those for turmeric. Combination treatment was less effective than either treatment alone, so no synergistic or additive effect was demonstrated.

The evidence for curcumin/turmeric is supportive, especially in light of its favorable safety record. It may be an appropriate option for some patients with

mild osteoarthritis symptoms.

Skin Conditions

Aloe Vera

Aloe vera or *Aloe barbadensis*, commonly called “aloe vera,” is a succulent perennial, endemic to desert regions. Found in the leaf mucilage is a viscous, clear gel that has been historically used since ancient Egyptian times for dermatologic conditions. It is a member of the Liliaceae family, and is also known as the “desert lily.”²³⁵

Therapeutic Uses

Aloe vera gel has been used topically for wound healing, including cuts, scrapes, and minor burns. Oral aloe products had been approved as a nonprescription stimulant laxative ingredient, but this dosage form was removed in 2002 from the nonprescription drug monographs because of a lack of safety and efficacy data.²³⁶

Physiological Activity

Aloe vera gel is derived from the mucilage of the plant and contains immunostimulating polysaccharides, called glucomannan, which contribute to collagen production, stimulate fibroblast growth factor, and improve transversal connections promoting skin healing. It also is rich in vitamins E, C, amino acids, and other antioxidants. Aloe vera may have anti-inflammatory and antimicrobial effects.²³⁵ The outer skin of the plant, the latex, contains anthraquinone glycosides, including aloin, aloe-emodin, and barbaloin, which are responsible for laxative actions. Whole leaf extract contains both mucilage and latex.²³⁷

Dosage and Product Concerns

Aloe vera gel is applied topically 2–3 times per day for the treatment of minor cuts, scrapes, and burns. Aloe vera is a component in many beauty and nonprescription products as an inactive ingredient. The International Aloe Science Council will certify products on the basis of labeling, aloe content, aloe

source, and quality standards defined by the council. It sets criteria of less than 10 ppm of aloin for oral products and 50 ppm for topical formulations.²³⁸

Safety Considerations

Topical aloe vera generally is well tolerated, with occasional adverse effects of rashes and skin irritations, especially if the person has an allergy to members of the Liliaceae family, such as lilies, garlic, or onions. Oral administration may cause laxative effects, GI upset, hypoglycemia, or hypokalemia related to the presence of anthraquinones. Case reports of hepatotoxicity have been attributed to oral aloe use.²³⁷ Drug interactions have been reported with hypoglycemic, antiretroviral, and antithrombotic agents.⁷¹ The consumption of oral aloe should be avoided, because safety data are lacking.

Summary of Clinical Evidence

A Cochrane systematic review of randomized, controlled studies evaluated seven trials involving 347 subjects using aloe or aloe-derived products, either as topical gels or wound dressing, for wound healing. Five trials included participants with burns, hemorrhoidectomy, and skin biopsies. In a comparison of aloe with silver sulfadiazine, no difference in the duration of burn healing was noted. Healing time was significantly decreased after hemorrhoidectomy in the aloe group (RR 16.33 days [95% CI 3.46–77.15]). No difference in the completion of healing of skin biopsy sites was found. Two trials evaluating time to healing in chronic wounds found no difference or significant delay.²³⁹

An analysis of four trials comprising 371 subjects identified benefits in healing of first- and second-degree burns. Studies were combined and data analyzed using weighted mean differences (WMDs) on healing time. The WMD on the healing time was significantly decreased by 8.79 days in the aloe vera group versus the control group. Using active comparison control subjects, aloe demonstrated benefit over silver sulfadiazine and petrolatum (Vaseline) gauze. The trials were small and of variable quality.²⁴⁰

Overall, topical aloe vera is well tolerated, but evidence to support its efficacy in acute wound healing is mixed. It may be a useful adjunct to treatment in selected patients who are appropriate candidates for self-care.

Tea Tree Oil

Tea tree oil (TTO) is derived from leaves of the tree *Melaleuca alternifolia*, a member of the family Myrtaceae. The tea tree is not related to the plant used to make black and green teas.

Therapeutic Uses

TTO has been used as a topical anti-infective agent for conditions affecting skin and mucosa.

Physiologic Activity

TTO's major active component is terpinen-4-ol, which has displayed broad-spectrum antimicrobial activity against bacteria, fungus, viruses, and protozoa. Terpinen-4-ol also has demonstrated anti-inflammatory properties in decreasing TNF, IL-1, IL-8, IL-10, and prostaglandin E2. TTO constituents such as alpha-terpinene, alpha-terpinolene, and gamma-terpinene may have antioxidant properties.²⁴¹

Dosage and Product Concerns

The oil is applied topically once or twice daily in concentrations of 0.4%–100%, depending on the condition and area of treatment. For acne, a 5% concentration is applied daily. For athlete's foot, TTO solution 25%–50% is applied twice daily for 4 weeks. For fungal toenail infections, TTO 100% has been used twice daily for 6 months.

Safety Considerations

Skin irritation may occur upon topical application, especially at higher concentrations. Contact dermatitis, various skin reactions, and prepubertal male gynecomastia have been reported. Although the oil can be used safely on oral mucosa, it should not be swallowed, because its ingestion may be toxic.²⁴¹

Summary of Clinical Evidence

TTO may be effective for athlete's foot and other fungal infections of the skin,

hair (dandruff), and nails.²⁴²⁻²⁴⁴ For onychomycosis, TTO was compared with clotrimazole 1% solution; after 6 months both had similar culture and clinical resolutions.²⁴⁴ Evidence supporting TTO use for fungal conditions is older and has not been compared with current treatment options; it may be an option for individuals who are not tolerating current therapies for the treatment of athlete's foot or onychomycosis.

TTO often is an ingredient included in commercial acne products. Although evidence to support efficacy is positive, it is limited. In the treatment of mild to moderate acne, daily application of TTO gel 5% for 45 days significantly reduced the total acne lesion count and acne severity index compared with placebo.²⁴⁵ A recent open-label, phase II pilot study found TTO gel (200 mg/g) also significantly improved lesion count over 12 weeks and was well tolerated.²⁴⁶

Women's Health

Black Cohosh

Black cohosh is made from the dried rhizome and roots of *Cimicifuga racemosa*, formerly *Actaea racemosa*. It is a member of the Ranunculaceae (buttercup) family.

Therapeutic Uses

Black cohosh has been used to treat the symptoms of premenstrual syndrome, dysmenorrhea, menopause, and rheumatoid arthritis.

Physiologic Activity

The active components of black cohosh rhizomes are triterpene glycosides, including acetin, cimicifugoside, and 27-deoxyacetin. Isoflavones such as formononetin often are present, but they may be absent from commercial products. Other constituents include isoferulic and salicylic acids, tannins, resin, starch, and sugars.²⁴⁷ Black cohosh extract also may modulate serotonin.²⁴⁸ Black cohosh probably does not exhibit estrogenic activity and has no effect on vaginal epithelium, endometrium, or hormone concentrations.²⁴⁹

Dosage and Product Considerations

Black cohosh, as a standardized extract, is usually taken as 40 mg daily in 1–2 doses. One proprietary preparation is Remifemin. The extract is standardized to 1 mg of triterpene glycosides, calculated as 27-deoxyactein, per 20-mg extract tablet.²⁵⁰

Safety Considerations

Adverse effects are mild and include GI complaints, headache, rash, and weight gain. Hepatitis, seizures, and cardiovascular disease have been reported in patients taking combination products that contain black cohosh, although a causal relationship has not been established.²⁵¹ Case reports of acute hepatitis while taking black cohosh have been reported; the USP Botanical Dietary Supplements and Herbal Medicines Expert Committee recommended that a cautionary statement regarding potential hepatotoxicity be placed on product labels.²⁵⁰ Further evaluations have suggested lack of product quality may have contributed, with the wrong plant being used. The use of black cohosh for longer than 6 months is not recommended because of the lack of long-term safety studies.²⁵² Data on drug interactions with black cohosh are limited, with the exception of possible additive effects with tamoxifen.²⁵¹ Unprocessed black cohosh plants contain small amounts of salicylic acid, but its presence in commercial products is unknown. Data on concurrent use with estrogens or progestins are not available. The use of black cohosh should be avoided during pregnancy and lactation because of its potential hormonal effects.²⁵⁰

Summary of Clinical Evidence

Several clinical trials that have evaluated black cohosh alone and in combination products for menopausal symptoms reported mixed results. A systematic review of black cohosh included 16 randomized controlled trials with 2027 perimenopausal or postmenopausal women.²⁵³ Efficacy was compared against placebo, hormone therapy, red clover, and fluoxetine. Analysis found the median dose of 40 mg daily of black cohosh for a 23-week average. For hot flashes and menopausal scores, no significant difference was noted between black cohosh and placebo, whereas hormone therapy significantly reduced these outcomes. Other data provided inconclusive results as to the efficacy of black cohosh.²⁵³

Multi-ingredient product comparisons with placebo, hormonal therapy, and fluoxetine lack standardized dosing and have poor methodologic quality or small differences compared with placebo, making it difficult to establish efficacy. Benefits from other constituents in multi-ingredient products and from SJW may contribute to improvement in symptoms. Combining black cohosh with SJW has demonstrated an improvement in climacteric symptoms.²⁵⁴ The ACOG practice guideline for managing menopausal symptoms stated insufficient evidence exists to support use of natural products.²⁵⁵

The safety and efficacy of black cohosh in women who have had breast cancer remain controversial. A systematic review in women with a history of breast cancer found inconclusive evidence to support safety and efficacy, although the product did not exert estrogenic effects.²⁵⁶ A second systematic review of women with or without greater risk of breast cancer found the use of black cohosh did not increase risk of developing cancer.²⁵⁷ The long-term effects on cardiovascular disease, osteoporosis, and breast cancer are unknown.

Chasteberrys

Chaste tree (*Vitex agnus-castus*), commonly referred to as “vitex,” is a member of the Verbenaceae family. The dried ripe fruits, or berries, and the leaves are the medicinally useful parts of the plant.

Therapeutic Uses

Chasteberry has been used to treat symptoms of premenstrual syndrome (PMS), premenstrual dysphoric disorder (PMDD), dysmenorrhea, mastalgia, and menopausal symptoms.

Physiologic Activity

The fruits contain essential oils, diterpenes, iridoid glycosides, and flavonoids. Effects on menstrual regulation are likely caused by the dopaminergic compounds diterpenes, which are responsible for suppressing prolactin release by binding to the dopamine-2 receptor. Chasteberry may have weak estrogenic activity.²⁵⁸

Dosage and Product Considerations

Clinical trials have used 20–40 mg of the extract daily. The standardization of chasteberry has not been well established. It is available alone or in combination products.

Safety Considerations

GI complaints occur occasionally with use of chasteberry. Other symptoms include dry mouth, headache, rashes, itching, acne, menstrual disorders, and agitation. Chasteberry should be avoided during pregnancy because of insufficient data to support safe use and the possibility of lactation suppression. Theoretically, chasteberry may interact with medications that impact dopamine, as well as hormone replacement therapies and oral contraceptives.²⁵⁹

Summary of Clinical Evidence

Evidence for chasteberry, in combination with other herbal medicines, for menopausal symptoms is mixed. A randomized, double-blind, placebo-controlled parallel trial studied combination SJW (*H. perforatum*) and chasteberry administered twice daily over 16 weeks in 100 perimenopausal and postmenopausal women. Symptoms regarding the primary end point of hot flashes did not differ between the groups.²⁶⁰ Phyto-Female Complex, standardized extracts of black cohosh, dong quai, milk thistle, red clover, American ginseng, and chasteberry, has been studied in 50 premenopausal and postmenopausal women in a randomized, placebo-controlled trial. Improvements in hot flashes, night sweats, and sleep quality were reported, with no changes on vaginal ultrasonography, or with levels of estradiol, follicle-stimulating hormone, liver enzymes, or thyroid-stimulating hormone.²⁶¹

Chasteberry extract may be effective in PMS, PMDD, and latent hyperprolactinemia. A systematic review of seven trials of PMS found chasteberry to be more effective than placebo, pyridoxine, or magnesium. In two trials on PMDD that compared fluoxetine and chasteberry, data were conflicting, with one study showing chasteberry as effective. Chasteberry was more effective than placebo in one trial, and as effective as bromocriptine in another, for the treatment of hyperprolactinemia and associated clinical markers.²⁶² Methodologic quality has been limited by small study sizes, as well

as variability in chasteberry preparations, diagnostic criteria, and treatment measures.

Evening Primrose Oil

Evening primrose (*Oenothera biennis*) is a member of the primrose family Onagraceae and is used for its high content of essential fatty acids. The seed oils of black currant (*Ribes nigrum*) and borage (*Borago officinalis*) also are used for similar purposes.

Therapeutic Uses

Evening primrose oil (EPO) has been used for mastalgia, PMS, menopause, preeclampsia, diabetic neuropathy, chronic fatigue syndrome, and atopic dermatitis.

Physiologic Activity

The oil from evening primrose seeds consists of omega-6 essential fatty acids, primarily 65%–75% linoleic acid and 7%–10% gamma linolenic acid. These components are thought to be responsible for anti-inflammatory activity.^{263,264} The seed oil contains smaller amounts of palmitic, oleic, and stearic acids, as well as campesterol and beta sitosterol.²⁶⁴

Dosage and Product Considerations

In clinical trials, daily dosages of EPO 2–4 g have been used as a liquid or a capsule. A standardized product, Efamol, a 1 g capsule, contains 0.62 g linoleic acid, 0.05 g gamma linolenic acid, and 0.062 g oleic acid.²⁶³

Safety Considerations

Adverse effects include headache, nausea, diarrhea, and occasional abdominal pain. EPO products may possess antiplatelet effects and should be used with caution in patients taking antithrombotic agents. Seizures have been reported in people taking EPO, so individuals taking anticonvulsants should avoid its use.^{71,72} Use of EPO for cervical ripening during labor may be associated with adverse pregnancy outcomes including prolonged rupture of membranes and vacuum extraction.²⁶⁴ Use for cervical ripening is further unsupported by a

recent randomized controlled trial that also found EPO had no impact on duration of pregnancy or labor when administered at 40 weeks of gestation.²⁶⁵

Summary of Clinical Evidence

Few studies exist for the benefit of EPO on mastalgia. A randomized pilot placebo-controlled study found improvement in cyclic mastalgia with EPO 3 g, taken alone or in combination with vitamin E 1200 IU over 6 months.²⁶⁶ A large double-blind, randomized, placebo-controlled trial that compared a branded British product containing gamma linolenic acid with or without antioxidant vitamins found no significant changes in reported pain in patients with moderate to severe mastalgia. A large placebo effect was noted, with 40% of subjects reporting improvement without therapy.²⁶⁷ Another trial of 90 participants over a 2-month period compared EPO, flaxseed, and vitamin E effects on breast pain, finding only flaxseed to have a significant improvement from baseline.²⁶⁸

A Cochrane review of 19 studies using oral EPO and borage oil concluded neither was effective for the treatment of atopic eczema. Studies of EPO found no improvement in global eczema symptoms recorded by a VAS.²⁶⁹ A small randomized, placebo-controlled study conducted more recently in participants from Korea with mild atopic eczema found significant benefit in Eczema Severity Index Scores with EPO.²⁷⁰

Fenugreek

Fenugreek (*Trigonella foenum-graecum*) has a long history of use as a spice and a medicine in India, China, and Northern Africa. Both leaves and seeds may have medicinal properties.²⁷¹

Therapeutic Uses

Fenugreek has been used for diabetes mellitus, hyperlipidemia, GI conditions, and stimulation of breast milk production.

Physiologic Activity

An active constituent of fenugreek, 4-hydroxyisoleucine, may contribute to the hypoglycemic effects by stimulating glucose-induced insulin release and

reducing insulin resistance.²⁷¹ Saponins converted to sapogenins in the GI tract may decrease cholesterol levels through activation of biliary cholesterol secretion. Fenugreek seeds are high in fiber and possibly delay glucose absorption or binding of cholesterol.²⁷² Lactation effects may result from increased sweat production that impacts the milk duct or from phytoestrogens and diosgenin found in fenugreek.²⁷³

Dosage and Product Considerations

Dosages have varied, with fenugreek seed powder capsules 2.5 g twice daily or seed powder 25 g daily in 2 divided doses used in studies. Defatted seeds also have been used at 100 g daily in 2 equally divided doses. Fenugreek also can be administered in a tea.²⁷² For increasing milk supply, 2–3 capsules (580–610 mg per capsule) can be administered 3–4 times daily.²⁷³ Alternatively, seeds may be soaked in water and strained, and then the water is consumed.

Safety Considerations

Fenugreek is generally safe when used in meal preparation. When fenugreek is consumed, urine, sweat, and breast milk have been noted to smell like maple syrup, which is caused by sotolone excretion. This effect also occurs in breastfeeding infants, which has led to mistaken cases of maple syrup urine disease. Patients with an allergy to chickpeas should avoid fenugreek because of possible cross-reactivity; inhalation of the powder has resulted in bronchospasm. Fenugreek consumption in higher amounts than found in food should be avoided during pregnancy because of potential oxytocic and uterine stimulant effects. Hypoglycemia or hypokalemia may result from use. The high-fiber content can bind with oral medications and decrease absorption.²⁷² Fenugreek may impact platelet aggregation, potentially increasing risk of bleeding in patients taking antithrombotic agents.⁶⁸

Summary of Clinical Evidence

Although fenugreek is promoted to stimulate production of breast milk, evidence is limited.²⁷³ A systematic review and network meta-analysis evaluated five small studies with various comparators, including placebo, control, and other galactagogues (palm dates, *Coleus ambonicus*). Paired comparisons in four studies showed a slight, but significant, increase in milk production against placebo or control, but not when compared with other

galactogogues.²⁷⁴ Small studies of varying quality and dosages have noted potential benefit of glycemic control and dyslipidemia in patients with prediabetes and diabetes mellitus. Pooled results of 10 studies demonstrated clinically significant benefits in fasting blood glucose, 2-hour postprandial blood glucose, hemoglobin A1C, and total cholesterol, but not in triglycerides, LDL cholesterol, and HDL cholesterol. Limitations exist in methodology, sample size, duration, and dosage, and the formulation of fenugreek used.²⁷⁵

Phytoestrogens

Phytoestrogens are found in many different plants; supplements have been derived primarily from soy (*Glycine max*) and red clover (*Trifolium pratense*).

Therapeutic Uses

Phytoestrogens have been used mainly for symptoms associated with menopause and related bone health. Soy also is consumed for its potential benefits in prevention of cardiovascular disease and cancer.

Physiologic Activity

Soy-based phytoestrogens are composed of isoflavones, such as genistein, daidzein, and glycitein. Red clover-based products have greater content of the isoflavones biochanin A and formononetin.²⁷⁶ These compounds' effects include estrogenic, antiestrogenic, antioxidant, and anticancer activity.

Dosage and Product Considerations

A recommended dosage of phytoestrogen has not been established, but the majority of clinical trials include 50–100 mg daily of isoflavones.²⁴⁸ Phytoestrogen products contain varying amounts and types of isoflavones. Products derived from soy and red clover sources may have different effects; red clover isoflavones may have greater bioavailability.²⁴⁸ The benefits from soy are primarily from dietary sources, not from supplements.

Safety Considerations

Phytoestrogen products derived from soy or red clover are well tolerated. GI complaints and allergic reactions may occur. The long-term safety of

phytoestrogens is not established, especially with respect to the risk of estrogen-dependent cancers and thromboembolic disease. The safety of phytoestrogen supplements in women with hormone-sensitive cancers is unknown, and their use should be avoided.⁷¹

Summary of Clinical Evidence

Purported benefits of phytoestrogens, especially soy-based products, are derived from population-based observational studies of dietary patterns. The lifetime risk of any disease is unlikely to be related solely to the presence or absence of one dietary component such as isoflavones. The phytoestrogen content in foods, especially of the biologically active isoflavones, varies significantly, even in soy foods.

The most common use of phytoestrogens is to manage menopausal symptoms. A large meta-analysis and systematic review of 63 randomized, controlled studies and more than 6000 women evaluated the effectiveness of plant-based agents. Pooled mean differences showed that scores for daily hot flash frequency and vaginal dryness improved significantly in the phytoestrogen groups, although night sweats did not.²⁷⁷

The effect of phytoestrogens on BMD may be beneficial in women experiencing menopause, but mixed findings have been reported. A systematic review of 23 randomized, double-blind, controlled trials evaluated extracts of red clover, soy isoflavone, genistein (singularly or combined with daidzen), and dietary soy intake on BMD. Impact on bone health varied with duration of intake, as well as dosage and isoflavone content.²⁷⁸

FDA recently challenged the health claim that daily ingestion of soy protein as part of a diet low in saturated fat and cholesterol may reduce the risk of coronary heart disease. In the proposed revocation, it cites current evidence does not support this previous designation and extended an open comment period as part of its review.²⁷⁹

Epidemiologic research has indicated consumption of soy products has a role in decreasing breast cancer risk although concerns exist that estrogenic activity will increase recurrence. The potential effect likely will depend on the specific isoflavone, timing of exposure, and genetic factors, and whether estrogen receptors are positive or negative for cancer. Dietary consumption of soy similar to that in Asian populations does not appear to increase cancer

recurrence, nor does it cause interactions with tamoxifen or anastrozole.²⁸⁰ Another review concluded overall safety is promising, because endometrial, uterine, and breast cancer risk do not appear to be increased. Dietary soy intake may even be associated with a decrease in endometrial or uterine cancers; however, it should be used with caution at the present time.²⁸¹ A systematic review and a meta-analysis suggest that consumption of soy food, genistein, daidzein, and unfermented soy food may significantly reduce prostate cancer risk.²⁸²

A Word About Piperine

Piperine is the main alkaloid in black pepper (*Piper nigrum*). It demonstrates nonspecific inhibition of CYP450 enzymes and strongly inhibits P-glycoprotein, leading to increased absorption and increases in many drug concentrations.^a Piperine also inhibits bacterial efflux pumps, which could increase the effectiveness of antibiotic therapy.^b Dietary supplement manufacturers are including *Piper nigrum* extracts, piperine, or BioPerine, a patented extract, in many dietary supplements to increase absorption or to prolong effects. Patients taking these products also must consider the impact on any prescription medications. Increases in drug concentrations could be seen with many oral drugs; phenytoin concentrations were doubled in one study, whereas the area under curve of nevirapine increased by 170%.^{a,c}

Assessment of Natural Product Use: A Case-

Based Approach

As stated in [Chapter 50](#), the health care provider should determine the patient's reasons for purchasing a natural product. The appropriateness of supplement use must be determined, especially for a child, a pregnant woman, or an older adult. If a medical condition is being treated and use of a supplement is appropriate, the patient should be encouraged to involve the health care provider in its use. Information about possible allergies to plant materials, current drug therapy, and comorbid conditions will identify possible contraindications. If self-treatment is appropriate, the provider should review the length of therapy and recommended dosages with the patient. Cases 51–1 and 51–2 provide examples of assessment of patients who are considering use of a natural product.

Case 51–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Information Gathering	
1. Gather essential information about the patient's symptoms and medical history, including	A patient asks you for instructions on how to use melatonin for jet lag. She is going on a work trip to Croatia next week.
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	"I get horrible jet lag when I fly that far! I just can't sleep the first few days, and I really need to function better to do my job."
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient tries to maintain good sleep habits even while traveling. She uses a sleep mask but has found ear plugs too irritating for long-term use.
c. description of the patient's efforts to relieve the symptoms	She has tried antihistamines in the past and found they left her extremely groggy.
d. patient's identity	Rachel Klebser
e. age, gender, height, and weight	36 years old female, 5 ft 5 in., 136 lb
f. patient's occupation	Location scout for fashion photography magazine

Relevant Evaluation Criteria	Scenario/Model Outcome
g. patient's dietary habits	Tries to follow a Mediterranean-style diet most of the time.
h. patient's sleep habits	Usually gets 6–8 hours of sleep per night; rarely has a sleepless night.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Endometriosis: symptoms controlled with continuous-use oral contraceptive. Takes generic multivitamin and mineral, 1 tablet daily.
j. allergies	NKDA; no known food or plant allergies
k. history of other adverse reactions to medications	None
l. other (describe) _____	Patient brings to the pharmacy counter a combination multi-herbal and melatonin product that contains 0.3 mg of melatonin.
Assessment and Triage	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Patient wishes to minimize effects of air travel.
3. Identify exclusions for self-treatment.	The patient has chosen a product with an inappropriate dosage of an active ingredient and extra herbal ingredients not assessed for efficacy.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend an adequate dosage of melatonin with appropriate education on usage. (2) Recommend that the patient try a different nonprescription sleep aid. (3) Refer patient to health care provider for a prescription hypnotic. (4) Take no action.

Relevant Evaluation Criteria	Scenario/Model Outcome
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Suggest melatonin 5 mg supplement, preferably a brand that is DSVP certified or tested through another third-party laboratory.
6. Describe the recommended therapeutic approach to the patient or caregiver.	After arriving at the travel destination, take melatonin 5 mg between 5 and 10 pm. Ideally, it would be taken 30–60 minutes before attempting to sleep. Continue taking 1 tablet about 30 minutes before bedtime for the next 2–5 days.
	Continue good sleep practices such as a warm bath or shower before bed and use of a sleep mask. Consider taking your personal pillow with you. Because you cannot tolerate earplugs, you could try a portable white-noise machine to mask noises.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	The dose of melatonin in the product she has chosen is not high enough to prevent jet lag. The multi-herbal combination has not been studied to show if it has any effect in treating jetlag and if it can increase the risk of adverse effects.
Patient Education	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Explain that melatonin works by helping to “reset” the body's natural clock, the circadian rhythm, and probably will not cause a feeling of “sleepiness.” Side effects are uncommon but include headache and nausea. Morning drowsiness is a possibility.
Solicit follow-up questions from the patient or caregiver.	“What if this still doesn't help me get to sleep?”
Answer the patient's or caregiver's questions.	If the melatonin and additional sleep hygiene suggestions do not sufficiently help you sleep on this trip, try halving the dose of antihistamine you used previously and taking it earlier in the evening. These measures should help reduce morning grogginess. After you return, we can discuss some other options for future trips, such as use of

Relevant Evaluation Criteria	Scenario/Model Outcome
	valerian.
Evaluation of Patient Outcome	
9. Assess patient outcome.	Patient's sleep difficulties during the first days of her trip are not likely to be resolved completely, but they should be reduced to a tolerable level.

Key: DSVP = Dietary Supplement Verification Program.

Case 51-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Information Gathering	
1. Gather essential information about the patient's symptoms and medical history, including	
a. description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is inquiring, "Does this really work?" He is holding a bottle of St. John's Wort and pointing to the statement "supports emotional health."
b. description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient says he has been feeling "down" and "hopeless" for a few months now. He describes having low energy, and he does not want to get out of bed in the morning. Upon questioning, he tells you he does not feel suicidal.
c. description of the patient's efforts to relieve the symptoms	He has not spoken to anyone about his feelings; he is embarrassed to go see his family doctor to "talk about these things."
d. patient's identity	Samuel Jackson
e. age, gender, height, and weight	50 years old, male, 5 ft 10 in., 185 lb

Relevant Evaluation Criteria	Scenario/Model Outcome
f. patient's occupation	Welder at a large manufacturing plant
g. patient's dietary habits	Occasionally eats fast food for lunch or dinner.
h. patient's sleep habits	Not sleeping well, 4–5 hours per night; frequently wakes up.
i. concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	High blood pressure and dyslipidemia treated with lisinopril 20 mg and atorvastatin 10 mg, respectively.
j. allergies	NKDA
k. history of other adverse reactions to medications	No adverse reactions to medications
l. other (describe) _____	n/a
Assessment and Triage	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	The described symptoms indicate he may be suffering from depression.
3. Identify exclusions for self-treatment.	Symptoms of depression should not be self-treated, so he should be referred for evaluation, diagnosis, and treatment.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer patient to an appropriate health care provider or mental health professional. (2) Recommend self-care with a nonprescription/dietary supplement product. (3) Recommend self-care until patient can see an appropriate health care provider. (4) Take no action.

Relevant Evaluation Criteria	Scenario/Model Outcome
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	No alternative treatment may be recommended.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a health care provider or mental health professional to discuss your symptoms and be evaluated."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best, because you should be evaluated, treated, and monitored to help you feel better. "
Patient Education	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Patient is not a candidate for self-treatment.
Solicit follow-up questions from the patient or caregiver.	"Why can't I take this in the meantime?"
Answer the patient's or caregiver's questions.	"Symptoms such as yours should not be self-treated. Additionally, SJW may interact with atorvastatin."
Evaluation of Patient Outcome	
9. Assess patient outcome.	Contact the patient in a day or two to ensure that he made an appointment and sought medical care.

Key: n/a = Not applicable; NKDA = no known drug allergies; SJW = St. John's wort.

Chapter 52: Common Complementary and Integrative Medicine Health Systems

Authors: Catherine Ulbricht, Maha B. Alharbi

The term *complementary and integrative medicine* (CIM) refers to a broad domain of healing practices that include diverse health systems, modalities, and practices, and their accompanying theories and beliefs.¹⁻³ CIM includes many modalities beyond simply the use of dietary supplements.

Complementary medicine refers to use of a non-mainstream approach together with conventional medicine. *Integrative medicine* is defined as integrating nontraditional approaches into conventional medicine.² Other terms used to describe CIM include *folkloric, holistic, irregular, nonconventional, non-Western, traditional, unorthodox, and unproven medicine*. Common CIM therapies and health systems include homeopathy, naturopathy, traditional Chinese medicine, acupuncture, chiropractic care, Ayurveda, and massage. This chapter presents a brief overview of common types of CIM other than natural products, which are discussed in [Chapter 51](#).

Overview of Common CIM Health Systems

Major Categories

In the United States, the National Center for Complementary and Integrative Health (NCCIH) classifies CIM therapies into three broad categories.² These include natural products, mind–body practices, and other complementary health approaches. Natural products include herbal medicines, or botanicals; nonbotanicals; minerals; vitamins; and other products such as probiotics. The mind–body practices are diverse and feature procedures or techniques that are taught or conducted by a trained practitioner or teacher. Examples of mind–body medicine include chiropractic manipulation, acupuncture, guided imagery, hypnotherapy, *qi gong*, *tai chi*, yoga, and massage therapy, among many others. The third category is especially broad; it includes traditional healers, energy therapies such as Reiki, and whole medical systems such as Ayurveda, Traditional Chinese Medicine (TCM), homeopathy, functional medicine, and naturopathy.² The NCCIH website (<https://nccih.nih.gov>)

contains extensive information on many forms of CIM.

Healing systems encompass complete sets of theories and practices. A system focuses on a philosophy or lifestyle, such as the power of nature or the presence of energy in the body. Some CIM therapies have been integrated into conventional medicine. Many prescription drugs originally came from natural products such as paclitaxel from the bark of the yew tree, yohimbine from yohimbe bark, and oseltamivir from Chinese star anise. Other examples include etoposide and teniposide derived from *Podophyllum peltatum*, and vincristine and vinblastine derived from *Catharanthus roseus*.⁴

Potential Risks and Benefits

CIM often is considered a form of preventive medicine and is used widely to maintain health and reduce disease risk.² The attraction of CIM includes the potential to treat diseases for which conventional therapies have been ineffective. CIM also may provide an increased sense of patient empowerment and participation. A widespread belief about CIM is that it represents safe and natural therapeutic approaches. Cancer patients have cited the media as influencing their decisions to try these therapies. In addition, some patients use CIM techniques, such as meditation and prayer, to cope with chronic or untreatable illnesses.³

Although some CIM therapies are supported by basic science and clinical evidence, others have not undergone rigorous testing. For example, natural products potentially may cause adverse effects or have clinically significant interactions with prescription and nonprescription drugs, foods, or other supplements. Therefore, CIM therapies should be used under the guidance of a health care provider and not in place of proven conventional therapies.

Research Perspective

In 1992, the U.S. Congress established the Office of Alternative Medicine within the National Institutes of Health (NIH) and provided a budget of \$2 million for rigorous evaluation of CIM practices. In 1998, with the creation of NCCIH, Congress elevated the status of the Office of Alternative Medicine to an NIH center with a budget of \$50 million for fiscal year 1999. The federal appropriations for NCCIH reached \$146.5 million for fiscal year 2019. The mission of NCCIH is to “define, through rigorous scientific investigation, the

usefulness and safety of complementary and integrative health interventions and their roles in improving health and health care.”⁵

In October 1998, the National Cancer Institute (NCI) established the Office of Cancer Complementary and Alternative Medicine (OCCAM), which is housed in the Division of Cancer Treatment and Diagnosis. OCCAM’s mandate is to coordinate and enhance the activities of NCI and to increase the amount of high-quality cancer research and information on the use of CIM. According to OCCAM, in fiscal year 2010, NCI supported \$105,341,737 in CIM-related research. This represents more than 382 projects in the form of grants, cooperative agreements, supplements, or contracts. Other NIH institutes also contribute funds to CIM research, with estimates of almost \$25 billion for all institutes and centers combined.¹

Despite this investment, evidence of the safety and efficacy of CIM may be difficult to obtain. This challenge may be partly related to the fact that many CIM studies are reported in foreign languages and in journals that are not peer reviewed. To conduct evidence-based assessments on CIM, authors of systematic reviews and meta-analyses often broaden literature searches to include languages other than English. Several databases may be searched in addition to PubMed, Embase, Cochrane Library, and MEDLINE. Researchers also may use guides and validated scales, such as the Jadad scale, which has been used to rate the quality of the available studies concerning CIM therapies.⁶

Another issue in evaluating CIM research is the lack of standardization. Many individual therapies involve multiple techniques or dosages, making comparisons difficult. Some types of CIM, such as Ayurveda, do not require providers to be licensed or formally trained, which may contribute to the variable research results.

Experimental design is the most problematic issue in CIM research. The metaphysical aspects of some CIM therapies, such as the harmony between the body and the universe in Ayurveda, are difficult to test with scientific methods.⁷ Integral elements of clinical research, such as placebo control and double blinding, are difficult to conduct in many CIM studies. For example, the participatory nature of meditation prevents blinding of the subject to the active treatment.⁸ Double blinding is a central problem with modalities such as acupuncture, because this therapy cannot be easily delivered by a provider blinded to the intervention. However, this problem can be solved by having a

blinded examiner collect and evaluate outcomes. The Jadad score is sometimes modified for application to acupuncture studies because of the difficulty in blinding the acupuncturist.⁹ In such cases, modified Jadad scoring may include awarding one point if the trial is single blinded or if outcomes are assessed by a blinded investigator rather than the acupuncturist.

To meet the challenge of developing a placebo-controlled study for CIM therapies such as acupuncture, researchers have developed sham treatments to approximate subject blinding. For acupuncture, sham treatment typically involves placement of needles at non-active sites or at a specific distance, usually about 1 inch, from the active sites in the study, whereas depth and stimulation remain the same. Other sham acupuncture techniques involve treatment at actual acupuncture points but without needle penetration. Critics of this approach argue that even pressure at acupuncture points may elicit effects. Although some studies have demonstrated that sham procedures achieved blinding of subjects, methods used to create sham acupuncture vary widely. Sham acupuncture often is not regarded as a true placebo, because the patient is subjected to physical stimulation, and studies have shown that this technique also elicits effects.¹⁰

Working With CIM Providers

Ideally, conventional and CIM providers should work collaboratively for the benefit of the patient. Pharmacists and other health care providers should have an objective attitude toward CIM providers, especially given that some interventions are now provided in conventional medical centers. An example of an integrative approach is a clinic that includes both conventional and CIM providers. Conventional providers may refer patients to CIM practitioners to meet the high demand.

Individuals who use CIM may lack a clear understanding about the therapies. A survey among users of homeopathy in England showed that around 10% of users were confused about what constitutes a homeopathic product.¹¹ Patients should feel comfortable discussing potential CIM therapies with their conventional health care providers, and an increasing number of these providers now integrate certain evidence-based CIM techniques into their practices. Unfortunately, many health care providers lack the resources, knowledge, and training to respond to patients' CIM inquiries. In the following sections, some of the most common complementary and integrative health

systems will be reviewed.

Homeopathy

Homeopathy is a distinct system of medicine with its own pharmacopeia and principles of practice. The term *homeopathy* comes from the two Greek words *homoios* (similar) and *pathos* (suffering or disease). Dr. Samuel Hahnemann developed homeopathy in the early 1800s and coined the term *allopathy* as a synonym for conventional medicine. Homeopathy is based on the principle of “like cures like” or the “law of similars.” This principle maintains that if a substance produces the symptoms of an illness in large doses, that same substance can cure it in very small doses. The more dilute a homeopathic medicine is, the greater its potency. The efficacy of homeopathic medicines is believed to depend not only on the dilution factor but also on vigorous shaking, or *succussion*, which is performed with each dilution.

The homeopathic principle of “like cures like” is often compared with *vaccination*, which involves administration of antigenic material to induce immunity to infectious agents. However, this comparison is not entirely accurate. Vaccines typically contain measurable levels of attenuated or killed pathogens (or their purified antigens) and are used for prophylaxis. In contrast, homeopathic preparations are often so dilute that they contain statistically negligible amounts of the purported active ingredients. In addition, homeopathic remedies generally are used to treat an existing illness rather than for prophylaxis. One exception is *Oscillococcinum*, a homeopathic preparation derived from duck heart and liver, which is used both to prevent and to treat influenza, although evidence of its efficacy is lacking.¹²

Although homeopathic medicines generally are intended to be ingested, they are not classified as dietary supplements. The Food and Drug Administration (FDA) regulates homeopathic medicines under sections 201(g) and 201(j) of the Federal Food, Drug, and Cosmetic Act (FDCA) as drugs recognized in the official *United States Pharmacopeia* (USP), *Homoeopathic Pharmacopoeia of the United States* (HPUS), or *National Formulary* (NF). For homeopathic drugs, the premarket approval process is distinct from the approval process for conventional drugs. Homeopathic drugs are approved with the publication of a monograph by the Homeopathic Pharmacopoeia Convention of the United States (HPCUS) in HPUS. For a homeopathic drug to be included in HPUS, it

must be manufactured according to approved methods of preparation and determined by HPCUS to be safe and effective. The safety and the efficacy of a homeopathic drug are determined by procedures called “provings” (or “research procedures” in the HPUS), which determine the dosages necessary to induce symptoms in healthy individuals. Evidence from homeopathic provings is subject to verification by foundations for the clinical practice of homeopathy; however, according to FDA, “compliance with requirements of the HPUS, USP, or NF does not establish that it has been shown by appropriate means to be safe, effective, and not misbranded for its intended use.”¹³

As with conventional drugs, homeopathic remedies may be sold without a prescription if they are intended to treat self-limiting conditions such as headaches and colds. Most homeopathic remedies are available without a prescription, with only about 5% requiring prescriptions from medical care providers. Homeopathic medicines commonly are found in integrative pharmacies that stock dietary supplements and complementary remedies along with standard drugs. Chain pharmacies and health food markets also may carry homeopathic medicines, including pediatric and veterinary formulations.¹³

Homeopathic product sales steadily increased by 16% between 2008 and 2013, with Americans spending \$6.4 billion on these products in 2012.¹⁴ Despite the widespread use of homeopathic products, particularly in children, surveys have demonstrated that confusion exists about what constitutes a homeopathic product, suggesting better patient education is needed.¹¹

Practice

Medicines used in homeopathy are derived from many substances, including botanical, mineral, pharmaceutical, and zoological sources. These substances are serially diluted and succussed (or *trituated*), which is thought to increase the strength or potency of the medication. This process is called “attenuation” or “potentization.” After each attenuation step, the preparation is given a higher number, so a substance that was attenuated 4 times would be designated as 4X, 4C, or LM4 depending on the dilution factor.¹⁵ The decimal (1:10 dilutions) and centesimal (1:100 dilutions) scales of attenuation are used to make X and C potencies, respectively (Figure 52–1). The letter M means 1000C, not the use of 1:1000 dilutions in the attenuation process. A 1:50,000 dilution is represented by the potency LM, which is derived by combining Roman

numerals L and M for 50 and 1000, respectively (although the actual Roman numeral LM means 1000 minus 50, or 950). The method for preparing LM potencies is illustrated in [Figure 52–2](#). Although many homeopathic medicines are derived from highly toxic materials such as aconite and arnica, the final preparations often are so dilute that they are well below toxic dosages.

Training

More than 30 schools in North America offer training in homeopathy. The Accreditation Commission for Homeopathic Education in North America (ACHENA, formerly Council on Homeopathy Education [CHE]) continually develops professional standards for homeopathic education. Currently, the site lists four accredited homeopathic schools and three schools that are seeking accreditation. The Council for Homeopathic Certification offers a Certificate in Classical Homeopathy (CCH) and provides listings of certified homeopathic practitioners on their website for use by health care providers to identify qualified homeopaths.

Certification with CCH is not recognized by any state as a license to practice homeopathy. Arizona, Connecticut, and Nevada require that homeopaths also be licensed allopathic or osteopathic health care providers. Health freedom acts in some states, such as State of California Senate Bill 577, protect the rights of professionals without medical licenses to practice homeopathy and other modalities that the state deems harmless. Most other states lack specific

regulatory language for homeopathy; therefore, homeopathy falls under the statutes regulating the practice of medicine.

Theory and Evidence

Because homeopathic preparations contain little-to-no active ingredient, critics argue that any demonstrated efficacy is simply a placebo effect. Proponents of homeopathy state that trials have demonstrated effectiveness in either infants or animals, and that these subjects are unlikely to have preconceived expectations that may influence their perceptions. Overall, the effectiveness of homeopathy has not been demonstrated consistently in randomized controlled trials. A 2010 analysis of six reviews in the Cochrane Database of Systematic Reviews concluded that the evidence suggests the effects of homeopathic therapies are similar to those of placebo.¹⁶ A 2014 systematic review and meta-analysis of placebo-controlled randomized controlled trials of individualized homeopathic therapies concluded that the overall quality of the scientific evidence that support homeopathic therapies as being distinguishable from placebo effect are low or unclear, preventing firm conclusions.¹⁷ Citing the contradictory results of clinical trials and the overall lack of evidence determined by systematic reviews and meta-analyses, NCCIH has stated that homeopathy has not been proven definitively to treat any clinical condition. Similarly, the American Medical Association and the American Academy of Pediatrics have neither accepted nor rejected homeopathy in the treatment of any medical condition.¹⁶

Safety

For most homeopathic medicines, the risk of toxicity is low because of the extremely dilute nature of the homeopathic remedies. Studies have suggested that adverse effects are less frequent in patients receiving homeopathic treatments than in those receiving conventional care.¹⁸ The popular cold remedy Zicam has been labeled homeopathic, but some formulations contain significant levels of zinc. The nasal spray formulation containing zinc gluconate is known to cause irreversible damage to human nasal tissue.¹⁹ According to FDA, more than 100 reports of loss of sense of smell have been associated with the use of this product, and this dosage form has since been withdrawn from the U.S. market. Homeopathic remedies are regulated as drugs under the FDCA. FDA currently requires that nonprescription homeopathy drugs and non-homeopathic drugs have similar efficacy and

safety claims, in both advertising and labeling of the products.²⁰ FDA enforcement policies for homeopathic drugs are described in the agency's compliance policy guide *Conditions Under Which Homeopathic Drugs May be Marketed* (CPG 7132.15).²¹ According to a National Health and Medical Research Council study, patients who use only homeopathic products may put their health at risk if they reject, exclude, or delay treatments that have scientifically proven safety and efficacy.¹⁴

Naturopathy

The term *naturopathy* was coined in the late 1890s by German priest Sebastian Kneipp, who practiced herbal medicine and water therapies. Dr. Benedict Lust, who studied under Kneipp, purportedly purchased the rights to naturopathic medicine from another of Kneipp's students. In 1902, Dr. Lust opened the American School of Naturopathy in New York City. Because he was instrumental in promoting this field of medicine, Dr. Lust is generally credited as the founder of naturopathy.

Traditional naturopathy is a philosophy of life and an approach to living that encourages lifestyles and therapies as close to nature as possible. A system of naturopathic therapy employs natural forces such as light, heat, air, water, and massage. Naturopathy focuses primarily on building health rather than on treating disease. The practice of naturopathic medicine emerges from six underlying principles of healing that distinguish the profession from other medical approaches. These principles are based on observation of the nature of health and disease, and they are reexamined continually in light of scientific analysis. The first principle, "The Healing Power of Nature," is that the body has the inherent ability to maintain and restore health. The second principle "Identify and Treat the Causes" implies that the naturopathic health care provider's aim is to identify and treat the cause, rather than the symptoms, of a disease. The third principle is "First Do No Harm." This principle emphasizes the use of less-toxic natural therapies. The fourth principle "Doctor as Teacher" means that the naturopath educates and encourages patients to take responsibility for their own health. The fifth principle is "Treat the Whole Person": the health care provider treats the whole person, taking into account the physical, spiritual, mental, and social aspects of the individual. The final principle "Prevention" requires the naturopath to assess risk factors and hereditary susceptibility to disease and to make appropriate interventions to

prevent further harm or risk to patients.²²

Practice

In most cases of disease or wellness, nutritional counseling and support are major components of naturopathic treatments. Naturopathic health care providers use dietetics, fasting, and nutritional supplementation in practice. Botanical medicine and homeopathy also may be used.

Naturopathic medicine has its own methods of therapeutic manipulation of the muscles, bones, and spine. Naturopaths use ultrasound, acupuncture, *diathermy* (electrically induced heat), exercise, massage, water, heat, cold, air, and gentle electrical pulses. They also may provide natural childbirth care. They offer prenatal and postnatal care using modern diagnostic techniques. In some states, naturopaths may perform minor outpatient surgeries, such as repair of superficial wounds or removal of foreign bodies or cysts.

Because naturopaths believe that mental attitudes and emotional states may influence or cause physical illnesses, they may incorporate counseling, nutritional balancing, stress management, hypnotherapy, biofeedback, and other therapies to help patients heal on the psychological level.

Naturopaths may prescribe substances that are deemed appropriate by the Naturopathic Formulary Advisory Peer Committee. Listed substances depend on state law and vary among states. Some state-specific regulations, such as the Naturopathic Physician Practice Act Rule of Utah,²³ allow naturopaths to prescribe only medicines listed in the *Naturopathic Physician Formulary*.

Training and Licensure

In North America, six schools offer training for the Doctor of Naturopathic Medicine (ND) degree. These include Bastyr University (San Diego, California, and Seattle, Washington); Boucher Institute of Naturopathic Medicine (Vancouver, British Columbia, Canada); the Canadian College of Naturopathic Medicine (Toronto, Ontario, Canada); National University of Natural Medicine (Portland, Oregon); National University of Health Sciences (Chicago, Illinois); and Southwest College of Naturopathic Medicine (Phoenix, Arizona).

Similar to allopathic medical schools, admission into a naturopathic training

program requires 4 years of undergraduate study that includes premedical coursework. The ND degree consists of 4 years of postgraduate training, which includes about 4500 hours of academic and clinical training. Academic training includes courses such as anatomy, biochemistry, microbiology, and pathology. Clinical training encompasses various alternative modalities, including herbal therapy and homeopathy, in addition to mainstream clinical training such as that in cardiology and nutrition. Naturopathic health care providers are educated in modern methods of diagnostic testing and imaging, including radiology, ultrasound, and other imaging techniques. Some naturopaths may participate in residency programs, including integrative programs that train NDs in conventional medical settings.²⁴

In addition to a standard medical curriculum, a naturopath must study holistic therapies that have a strong emphasis on preventing disease and optimizing wellness. NDs are required to complete training in clinical nutrition, acupuncture, homeopathic medicine, botanical medicine, psychology, and counseling. Before they can practice, naturopathic health care providers must pass board examinations set by the North American Board of Naturopathic Examiners, and most states require NDs to complete continuing education hours to renew their licenses.²⁵

The licensing of naturopathic health care providers varies among states. According to the Association of Accredited Naturopathic Medical Colleges (<https://aanmc.org/careers/licensure>) and the Council on Naturopathic Medical Education (<http://www.cnme.org/faq.html>), the practice of naturopathic medicine is allowed in 17 states (Alaska, Arizona, California, Colorado, Connecticut, Hawaii, Idaho, Kansas, Maine, Minnesota, Montana, New Hampshire, North Dakota, Oregon, Utah, Vermont, Washington) and four provinces (British Columbia, Manitoba, Ontario, Saskatchewan).

Because of naturopathy's popularity, more health care providers trained in conventional medicine or other CIM fields are incorporating naturopathic treatments into their practices. health care providers who hold degrees in osteopathy, chiropractic, acupuncture, dentistry, and veterinary medicine may seek additional training in naturopathy; they sometimes use terms such as *holistic*, *natural*, or *integrative* to promote their practices.

Theory and Evidence

The individual methods used in naturopathic medicine vary in their effectiveness. A proper diet may help prevent heart disease, but this measure is recommended in conventional and naturopathic medicine. However, other forms of naturopathic treatment may not be more effective than conventional medicine. For example, acupuncture may help to reduce pain in some instances, but it is not widely recommended for use in place of standard analgesics for extreme pain or in surgery. On the other hand, some naturopathic treatments may be more effective than conventional therapies. For example, a combination naturopathic treatment consisting of nutrition counseling, relaxation techniques, and vitamin and herbal supplementation was more effective than a standardized psychotherapy intervention for anxiety.²⁶

Safety

The safety of naturopathic remedies depends on the treatment and the condition. Naturopathic methods generally are considered safer alternatives for some conventional drugs or treatments. The safety of other approaches such as fasting or other dietary restrictions depends on the individual. As with all CIM therapies, naturopathic treatments should not be used in place of proven conventional therapies for serious medical conditions.

Traditional Chinese Medicine

Chinese medicine is a broad term encompassing many different modalities and traditions of healing, including herbal medicine and acupuncture.⁴ These therapies share a common root in Chinese philosophy, including Taoism, Confucianism, and Buddhism, and may date back more than 5000 years.

In the 1940s and 1950s, the Chinese government undertook an effort to coalesce diverse forms of Chinese medicine into a unified system to be officially defined as traditional Chinese medicine (TCM). The intent was to integrate traditional providers into an organized health system and to provide care for a large population by using familiar and inexpensive methods.

CM is considered to be a complementary or alternative medicine in most of the Western world; however, in several Asian countries, including China, the term for TCM literally means “central medicine.” TCM and Western medicine frequently are used side by side in modern China. As a result, compared with Western countries, China is relatively advanced in using alternative medicine. The most prominent focus of TCM is the treatment of major illnesses, including cancer and heart disease. According to the World Health Organization, TCM is fully integrated into the Chinese health system and is practiced in 95% of Chinese hospitals.²⁷

Technique

TCM emphasizes herbal medicine. In the United States, herbs usually are given as pills, extracts, capsules, tinctures, or powders, but TCM practitioners usually prepare herbal medicines as decoctions.²⁸ More than 2000 different types of herbs are used in Chinese medicine, with 400 used frequently and 50 considered “fundamental” herbs.²⁹ Some Chinese herbs have received attention in Western medicine for treating serious disorders. For example, the *Monascus purpureus* fungus, found in red yeast rice, is a natural source of lovastatin.³⁰ Artemisinin is an antimalarial drug that was isolated from *Artemisia annua* or sweet wormwood L. by Youyou Tu, who was awarded the Nobel Prize in 2015. In addition to its antimalarial activity against *Plasmodium falciparum*, artemisinin has shown potent anticancer activity in vitro.³¹ Bevirimat, derived from the Chinese herb *Syzygium claviflorum*, is being investigated in clinical trials in human immunodeficiency virus (HIV).³⁰

TCM incorporates not only herbs but also minerals, metals, and animal products into therapeutic preparations. The use of animal products has become more infrequent in recent years, in part because of restrictions on certain species, particularly endangered species.

Acupuncture also is considered a form of TCM, although it is regarded as more of a supportive treatment to herbal therapy. Many varieties of acupuncture exist both in Chinese and Western medicine. Classic acupuncture, also known as five-element acupuncture, uses a different needling technique and relies on acupuncture without the use of herbs. Needles used in Japanese acupuncture are smaller than those of other forms of acupuncture. Medical acupuncture refers to an acupuncture therapy that uses knowledge of pathology, anatomy, and physiology but omits certain components of TCM.⁹ Auricular acupuncture

treats the entire body through acupuncture points in the ears only, and electroacupuncture uses electrical currents attached to acupuncture needles. As with many forms of TCM, acupuncture may require multiple treatments and long-term follow-up for symptom improvement and health maintenance.

Cupping and moxibustion are commonly used to complement acupuncture, but these techniques also may be used independently in TCM. They share the principle of using heat to stimulate circulation to break up congestion or stagnation of blood and *chi* (or *qi*), which is the life force central to health and well-being in TCM. Cupping has some relation to the massage technique *tuina*, which uses rapid skin pinching at points on the back to break up congestion and stimulate circulation. Cupping also may be used over acupuncture points or other areas of the body. Popular in the United States, moxibustion involves the burning of dried moxa (mugwort), either on or near the skin, and sometimes in conjunction with cupping or acupuncture on specific points.³²

TCM providers may use other modalities such as meditation and martial arts. *Tai chi chuan* (or *tai chi*) is a meditative form of martial arts that incorporates the theories of *yin* and *yang* from both Taoism and Confucianism. *Tai chi* is practiced to improve balance, coordination, and relaxation, and overall well-being. TCM also may incorporate *feng shui*, which is the art of arranging furniture and objects to increase health and prosperity.

Training

The Accreditation Commission of Acupuncture and Oriental Medicine (ACAOM) accredits professional acupuncture programs and is recognized by the U.S. Department of Education. According to the ACAOM, acupuncture and Oriental medicine is a 3- or 4-year master's degree program, offered by over 70 accredited or candidate colleges in the United States.³³

The National Certification Commission for Acupuncture and Oriental Medicine (NCCAOM) offers four independent certification programs, including Acupuncture, Chinese Herbology, Oriental Medicine, and Asian Bodywork Therapy.³⁴ Acupuncturists who pass national examinations administered by NCCAOM are entitled to identify themselves as board certified in their discipline and as diplomates of the NCCAOM. Licenses to practice acupuncture are granted by individual states. Although requirements vary, many states require acupuncturists to pass the NCCAOM examinations and obtain

continuing education.³⁴

Theory and Evidence

Taoism, Confucianism, and Buddhism provided the basis for the development of Chinese medical theory. According to these philosophies, nature and the laws that govern the ongoing, harmonious flow of life energy through the natural world also govern the body and health. The person is viewed as an ecosystem that is embedded in the larger ecosystem of nature and is therefore subject to the same laws. The life force called *chi* (*qi*) circulates through the body and enlivens it. Health is a function of a balanced, harmonious flow of *chi*, and illness results when there is a blockage or an imbalance in the flow of *chi*. *Yin* and *yang* are opposite and complementary qualities of life energy (*chi*). *Yin* is regarded as the feminine principle and *yang*, the masculine principle. The human being has a system of pathways called “meridians,” sometimes referred to as “channels,” through which *chi* flows. Meridians correspond with specific organs or organ systems (organ networks). Health is believed to be an ongoing process of maintaining balance and harmony of the circulation of *chi* through all the organs and systems of the body. In TCM theory, the body has five organ networks, each corresponding with a particular element.³⁵

Despite the popularity of TCM in the West, its effectiveness remains debatable. Scientific evidence supports the use of acupuncture for several indications including osteoarthritis and various types of pain and nausea. The American Cancer Society states “clinical studies have found that acupuncture may help treat nausea caused by chemotherapy drugs and surgical anesthesia.”³⁶

Moxibustion, which is traditionally used to turn breech babies, has been used with some success, although systematic reviews and meta-analyses have yielded insufficient evidence to support its efficacy.³² In general, few well-designed trials of TCM herbal formulas have been conducted, highlighting the need to improve the methodological quality of TCM research. A 2013 study evaluated systematic reviews of TCM techniques used for a variety of conditions. Forty-one of 70 systematic reviews were unable to conclude if a technique worked for the condition under investigation because of a lack of good-quality evidence.³⁵ Of the 41 systematic reviews, 19 analyzed studies of acupuncture and 22 evaluated studies of Chinese herbal medicine. Potential benefits were proposed in the other 29 systematic reviews; however, researchers were unable to confirm these benefits because of the limited

number or poor quality of the studies.³⁵

Safety

Chinese herbs have been associated with adverse effects. In April 2004, FDA banned the sale of products containing ephedra or ma huang (*Ephedra sinica*) in response to more than 18,000 adverse event reports.³⁷ The U.S. Poison Control Centers have reported that ephedra-related poisonings declined from 10,326 in 2002 to 180 in 2013, and the number of adverse events resulting in major effects or death declined by 98%.³⁷ Some Chinese herbal products have contained toxins or heavy metals.³⁶ In addition, prescription drugs, such as corticosteroids, have been included in the preparations but not listed as ingredients.³⁸ Patients should purchase Chinese herbs from trustworthy sources and should be aware that Chinese herbs can interact with foods, drugs, and other herbs.

Few complications have been reported from using acupuncture. Use of nonsterile needles and improper delivery of treatment are contributing factors to adverse events associated with acupuncture. Potential serious adverse events include infections, injury to the central nervous system, and punctured organs. FDA regulates acupuncture needles and requires that they be sterile, nontoxic, and labeled for single use by a qualified practitioner.³⁹ Because of theoretical and reported adverse effects, acupuncture should be avoided or used cautiously in individuals with heart disease, seizures, infections, bleeding disorders, or neurologic disorders, or among individuals using antithrombotic drugs. Acupuncture should not be performed on areas that have received radiation therapy and for conditions of unknown medical origin. Caution is advised for its use during pregnancy. Frail older adults or otherwise medically complex patients should use acupuncture with caution. Electroacupuncture should be avoided in patients with severe heart disease or cancer and in patients with pacemakers.³⁹

Cupping commonly leaves a temporary bruising of the skin. Moxibustion also may leave a temporary discoloration on the skin, which may be washed off or will disappear on its own. Historically, some traditional providers of moxibustion have intentionally employed more aggressive use of the technique to an extent that might leave minor scarring, but this aggressive form of practice is not used regularly in the West.

Chiropractic Care

Chiropractic focuses on the relationship between spinal structure and body function mediated by the nervous system. It originated in 1895 with D. D. Palmer, a popular hands-on healer in Davenport, Iowa. The term *chiropractic* combines the Greek words *cheir* (hand) and *praxis* (practice). Palmer's original philosophy described the approach as connecting "man the spiritual" to "man the physical" by eliminating interference to the flow of "Innate Intelligence" through each individual. This innate intelligence, an almost metaphysical phenomenon, was thought to flow through the nervous system.⁴⁰ The utilization rate of chiropractic services has increased in the United States. Some studies have shown that women, patients with chronic pain, and patients with back pain are more likely to seek chiropractic care. Common chiropractic services include spinal manipulation and soft-tissue therapy.

Important distinctions exist between the profession of chiropractic, chiropractic care, and spinal manipulation. A chiropractor delivers chiropractic care that involves a full range of treatments delivered in one or more therapeutic encounters. These treatments include procedures and techniques of assessment and a tailored mix of therapeutic interventions to improve a patient's health status. The term *spinal manipulation* or *spinal adjustment* does not operationally define the profession or chiropractic care, although it is a well-known procedure. Chiropractic care also includes other procedures, such as exercise, dietary advice, ergonomic and lifestyle advice, supplement use, all forms of physical therapy and rehabilitation intervention, and referral to other providers as needed.⁴⁰

Techniques

Patients usually lie face down on a Cox table, which is similar to a massage table with an open space in which to place the face. Depending on the technique used, chiropractic visits may last 15 minutes to 1 hour or more. Chiropractors may see patients up to 3 times a week initially and then less frequently over time. Patients can be diagnosed by different procedures including X-ray, computed tomography, magnetic resonance imaging, electrical current, and ultrasound therapy. Thermography also may be used, followed by treatment with ice packs and heat packs.

More than 100 chiropractic and spinal manipulative adjusting techniques may be employed. Spinal manipulative therapy uses many techniques to apply force to an area of the spine joint. Massage or mobilization of soft tissue is used in techniques such as myofascial trigger point therapy, cross-friction massage, active release therapy, muscle stripping, Rolfing, or other forms of structural integration. Mechanical traction or the use of external resistance on the spine also may be used. The cracking sound typically has been associated with cavitation in the spinal zygapophyseal (the neural arch between the joint processes) joints. The cracking or popping of a joint has not been proven to be essential to a clinically effective manipulation.⁴¹

Training

According to the U.S. Department of Labor, an estimated 33,360 chiropractors were practicing in 2017.⁴² The Council on Chiropractic Education (CCE) accredits programs and institutions offering the Doctor of Chiropractic degree, which currently includes 16 schools in the United States (CCEUS) and two in Canada (CCEC).⁴³ According to the Federation of Chiropractic Licensing Boards, all 50 states have formal statutes that recognize and regulate the practice of chiropractic.

The Doctor of Chiropractic degree requires the completion of didactic coursework and clinical training totaling a minimum of 4200 instructional hours. Clinical training with actual patients typically lasts a minimum of 1 year. Specialty training is available through residency programs, which may require an additional 2–3 years of clinical training. Before they are allowed to practice, doctors of chiropractic must pass national board examinations and become licensed. Chiropractors generally do not prescribe drugs, but those who also are licensed naturopaths or other health care professionals may prescribe remedies according to their respective state regulations.⁴⁴

Theory and Evidence

Designing clinical trials to evaluate the efficacy of chiropractic is difficult, primarily because of the issues in developing an appropriate control. Other major issues include a potentially strong placebo effect and the high rate of spontaneous recovery. In addition, patients often seek chiropractic treatment for conditions with poorly understood pathologies, such as fibromyalgia; available evidence is insufficient to support the use of chiropractic for this

condition.⁴⁵ For low back pain, sufficient evidence from both blinded and nonblinded trials supports the use of spinal manipulation, although the benefits are modest and of uncertain clinical significance.⁴⁶ Chiropractic has been used to treat asthma, colic, ear infection, headache, whiplash, and hypertension, although evidence of its effectiveness is insufficient.

Safety

The safety of chiropractic is controversial. Some systematic reviews show that spinal manipulation is associated with mild to moderate adverse effects. The most common serious adverse effects with spinal manipulation are vertebral artery dissection and stroke (VADS).⁴⁷ Published cases in 2010 review revealed 26 deaths associated with chiropractic spinal manipulation, and more fatalities may be unpublished.⁴⁸ Few studies have shown proper research of chiropractic spinal manipulation and its association with VADS, myelopathy, vertebral disc extrusion, and epidural hematoma.⁴⁸ Patients with VADS may be more likely to seek chiropractic treatment because of the disorder's initial symptoms, which suggests a potential sampling bias. A 2009 systematic review showed that adverse events occurred with a frequency of 33%–60.9%, but serious adverse events were rare, with as few as 1.46 serious adverse events and 2.68 deaths for every 10 million manipulations. Although this study did not support a strong causal relationship between chiropractic manipulation and the adverse events, the authors stated further high-quality studies are needed to assess its safety.⁴⁹

Patients with osteoporosis or any type of acute arthritis should either avoid chiropractic adjustment or use it cautiously because of the risk of fracture. Caution also is warranted in patients with bleeding disorders, migraines, and tumors or metastases to the spine. Patients with symptoms of vertebrobasilar vascular insufficiency, aneurysms, arteritis, or unstable spondylolisthesis should avoid chiropractic care. Patients receiving anticoagulant therapy also should be advised to avoid chiropractic care.

A final consideration is that chiropractors traditionally have been believed to discourage the use of routine vaccinations, although available data have suggested otherwise. Using data from the 2007 National Health Interview Survey, 12,164 adults were identified as individuals who were at high risk for developing influenza. The likelihood of receiving influenza vaccine was similar among individuals who used chiropractic care and those who did not.⁵⁰

Ayurveda

Ayurveda originated in India more than 5000 years ago and is probably the world's oldest system of natural medicine.⁵¹ When translated, *Ayurveda* means science of life, which stems from the spiritual teachings known as the Vedas. Ayurveda may be the original basis for Chinese medicine and is an integrated system of specific theories and techniques that employ diet, herbs, exercise, meditation, yoga, and massage or bodywork. The goal of Ayurveda is to achieve optimal health on physical, psychological, and spiritual levels.

In India, Ayurveda involves the eight principal branches of medicine: pediatrics, gynecology, obstetrics, ophthalmology, geriatrics, otolaryngology, general medicine, and surgery. In Western countries, the practice of Ayurveda is less focused on its spiritual roots than on its use as a form of CIM. Ayurveda relies on the individual's willingness to participate in lifestyle and behavior changes.

Technique

Ayurveda teaches that vital energy (*prana*) is the basis of all life and healing.⁵¹ As *prana* circulates throughout the human body, it is governed by the five elements of earth, air, fire, water, and ether. The five elements combine with one another into pairs called *doshas* that include *vata* (ether and air), *pitta* (fire and water), and *kapha* (earth and water). Health is thought to be a state of balance and harmony among the five elements, and illness occurs when there is an imbalance or lack of harmony among them.

The regulation of diet as a form of therapy is a central idea in Ayurveda. An individual's temperament and mental and spiritual development can be influenced by the quality and quantity of food consumed. An important principle in Ayurveda is that "there is nothing in the world that is not a medicine or food." Foods and herbs are described in terms of their energetic qualities rather than chemical properties. Sweet foods (called *madhura*) provide nourishment and coolness and also aid in increasing body weight. Sour foods (called *amla*) provide warmth and aid weight gain. Salty foods (*lavana*) provide warmth, stimulate the senses, and aid weight gain. In contrast, bitter foods (*katu*) provide coolness and help weight loss. Pungent foods (*tikta*) also aid weight loss but provide warmth and stimulation. Numerous herbs and spices, including turmeric and cumin, are used in

Ayurveda.⁵¹

Ayurveda holds that each 24-hour cycle is divided into 4-hour segments governed by the *doshas*. These time periods are believed to correspond with nature. Ayurvedic providers guide patients to plan their activities to be in harmony with these natural principles of timing.⁵¹

A provider usually interviews the patient about his or her medical history. The provider then palpates the patient's wrist to determine subtle qualities of the pulse. Providers also may evaluate the appearance of the tongue, face, lips, nails, or eyes. Laboratory tests of blood, urine, and stools may be used to help with the diagnosis. The initial consultation usually is the longest, lasting from 45 to 90 minutes or longer. Follow-up consultations may be spaced by several weeks or months to monitor the individual's progress. Follow-up usually will entail brief office visits that involve a diagnostic review and an adjustment of the regimen.

Training

In India, 240 institutions offer graduate level degrees in Ayurvedic medicine; the standard length of training is at least 5 years. Despite the abundance of institutions, the standard of Ayurvedic education in India is poorly structured and largely unregulated, which has resulted in a global negative perception of the practice.⁵²

According to NCCIH, no national standard for Ayurvedic training or certification exists in the United States. Ayurveda is practiced in Western medicine by health care providers who are licensed in a variety of disciplines.⁵¹ Allopathic and osteopathic health care providers, naturopaths, acupuncturists, primary care providers, massage therapists, and chiropractors may practice Ayurveda. Health counselors, educators, or consultants also may incorporate Ayurveda into their practices without specific licensing. In Western countries, two major approaches to training and practice exist. The first is offered by diverse teachers and providers, many of whom are either from India or were trained there. The second consists of devotees of Maharishi Mahesh Yogi, the Indian spiritual teacher who introduced Transcendental Meditation (TM) to the West. In 1980, this group coined the term *Maharishi Ayur-Ved*, a practice that incorporates TM as part of an Ayurvedic approach.

Theory and Evidence

Some of the more metaphysical aspects of Ayurveda, such as harmony between the body and the universe, are difficult to assess with modern scientific methods.⁷ Several herbal formulations have been studied in Western-style clinical trials, but current evidence is inadequate to recommend Ayurveda for any indication.

Safety

Many different Ayurvedic herbs exist, and they are frequently taken in combination with other herbs and/or minerals. Safety and toxicity will vary depending on the herb and its preparation. In general, Ayurvedic herbal medicines should be used cautiously, because their potencies may not be tested or standardized. Therapeutic levels of sildenafil have been detected in Ayurvedic herbal preparations used for aphrodisiac purposes.⁵³ Patients should purchase Ayurvedic herbs from trustworthy sources and should be aware that Ayurvedic herbs can interact with other herbs, foods, and drugs. For example, ginger, which is commonly used in Ayurveda, may increase the risk of bleeding when used with antithrombotic drugs.

Heavy metal contamination continues to be a concern in Ayurvedic medicines. In addition to herbs, Ayurvedic formulas known as *rasa shastra* also may contain metals such as arsenic, mercury, and zinc. Providers claim that these medicines are safe when properly prepared and administered. However, toxicity with these products have been documented in case reports. According to the U.S. Centers for Disease Control and Prevention, 12 cases of lead poisoning in five states were associated with Ayurvedic medicines from 2000 to 2003.⁵⁴ Consequently, patients are advised to use Ayurvedic herbs cautiously. Products that have USP seals of quality approval have been tested and should not contain unacceptable levels of harmful metals. Product testing information also is available from sites such as [ConsumerLab.com](https://www.ConsumerLab.com) (see [Chapter 50](#)).

Massage

Soft tissue manipulation has been practiced for thousands of years in diverse

cultures. Chinese use of massage dates to 1600 BC, and as early as 400 BC, Hippocrates referred to the importance of primary care providers being experienced with “rubbing.”

Massage spread throughout Europe during the Renaissance and was introduced in the United States in the 1850s. By the early 1930s, massage became a less prominent part of Western medicine. Renewed interest in therapeutic massage emerged in the 1970s, particularly among athletes to promote well-being, relaxation, analgesia, stress relief, healing of musculoskeletal injuries, sleep enhancement, and quality of life. Massage is one of the most common forms of CIM therapy used in the United States.

A common goal of massage therapy is to help the body heal itself. Touch is fundamental to massage therapy and is used by therapists to locate painful or tense areas, to determine how much pressure to apply, and to establish a therapeutic relationship with patients.

Technique

Different therapeutic techniques can be classified as massage therapy. Most involve the application of fixed or moving pressure or the manipulation of the patients’ muscles and connective tissues. Providers may use their hands or other areas such as forearms, elbows, or feet. Lubricants may be used to aid the smoothness of massage strokes. Examples of massage therapy include Swedish massage, sports massage, deep tissue massage, and trigger point massage.

Training

Training requirements for massage therapy vary in the United States, but they generally involve 500–1000 hours for certification by the National Certification Board for Therapeutic Massage and Bodywork. More than 1000 massage training programs exist, and some have received accreditation by the Commission on Massage Therapy Accreditation, which is recognized by the U.S. Department of Education. Upon fulfilling the necessary requirements, massage therapists receive the designation of Nationally Certified in Therapeutic Massage and Bodywork. A national examination is available from the National Certification Board for Therapeutic Massage and Bodywork. Most states require massage therapists to be certified before practicing.

Theory and Evidence

Research on massage therapy is limited, and available studies frequently used a variety of techniques and trial designs. Although studies have identified potential benefits in some conditions, most studies are of lower quality because of the low number of participants or poor design. In people with knee osteoarthritis, short-term massage has shown statistically and clinically significant improvement in symptoms.⁵⁵ Massage remains popular for improving relaxation, mood, and overall well-being, particularly in palliative care.

Safety

Adverse effects have been reported with massage. For example, fractures, discomfort, bruising, swelling of massaged tissues, and liver hematoma have been reported. Vigorous massage should be avoided in patients with bleeding disorders, peripheral vascular disease, or thrombocytopenia, or in those receiving antithrombotic therapy. According to preliminary data, blood pressure may increase in healthy patients following vigorous massage (e.g., trigger point therapy, which focuses on painful muscle knots). However, in patients with hypertension, massage may lower blood pressure. Areas that should not be massaged include those with osteoporotic and other fractures, open or healing skin wounds, skin infections, and blood clots, and those that have undergone surgery. Massage and other touch-based therapies should be used cautiously in patients with a history of physical abuse. Women who are pregnant should consult their obstetrician before beginning massage therapy. Allergies or skin irritation can occur with the oils used in massages, such as olive and mineral oil.

Conclusion

Patients increasingly seek care from CIM providers and health systems. Although some historical and scientific evidence supports the effectiveness of some approaches, it is difficult to make general statements on the safety and efficacy of CIM. Because important components of clinical trials such as placebo controls and blinding are difficult to achieve for some forms of CIM therapy, evidence of effectiveness is limited. Because the use of CIM continues

to increase, both patients and conventional health care providers should be informed about the potential risks and benefits of CIM techniques. [Table 52–1](#) lists common evidence-based uses of CIM health systems. Cases 52–1 and 52–2 provide examples of disorders that are amenable to CIM therapies.

TABLE 52–1 Common Health Issues with Evidence of Benefit from CIM	
Condition	CIM Treatment
Osteoarthritis	Acupuncture
Chronic pain, fibromyalgia, postoperative pain	Acupuncture
Nausea	Acupressure
Low back pain	Chiropractic
Quality of life in cancer patients	Massage
Anxiety and stress	Therapeutic touch

Key: CIM = Complementary and integrative medicine. Source: Reference 4.

More patients are using the internet as a source of health information before they consult a health care provider. As health information has become more available, patients have increased their responsibility for health decisions and should be encouraged to inform their health care provider whether they are using any CIM approaches. Similarly, all Western health care providers, including pharmacists, must be knowledgeable about CIM health systems and the evidence that supports or refutes their use.

Case 52–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	

1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient comes to the pharmacy seeking advice to help relieve her constant stress. She works as a sales associate in a large department store. She noticed that her stress and anxiety levels increase when she has to deal with her supervisors. The patient states that her job has been very stressful after a change in administration.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient mentions working additional hours to cover her financial responsibilities. She has been under intense pressure the past few months after her husband lost his job. Her sleep has been affected by her stress; she mentions sleeping only 3-4 hours a night. She also mentions that her stress is relieved when she takes their dog on a walk.
c. Description of the patient's efforts to relieve the symptoms	Patient states that she has tried taking diphenhydramine without relief.
d. Patient's identity	Allison Johns
e. Patient's age, gender, height, and weight	47 years old, female, 5 ft 5 in., 180 lb
f. Patient's occupation	Sales associate
g. Patient's dietary habits	Mostly fast food or frozen foods; she does not have the time to do much cooking lately. Drinks 5-6 cups of coffee a day.
h. Patient's sleep habits	She feels stressed and has difficulty sleeping at night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension: treated with lisinopril 10 mg tablet daily
	Occasionally takes melatonin 3 mg tablet at night when she has difficulty sleeping.
j. Allergies	None
k. History of other adverse	None

reactions to medications	
I. Other (describe) _____	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Stress, insomnia
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to her HCP or to an integrative medicine provider, such as a certified yoga instructor. (2) Advise the patient to consider yoga practices to reduce stress: for example, specific breathing techniques, meditation, and different physical postures. (3) Recommend sleep hygiene practices, including limiting alcohol and caffeine consumption, and establishing a consistent sleep-wake pattern. (4) Recommend self-care until the patient can see an appropriate provider.(5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend yoga with a certified trainer and sleep hygiene best practices. Suggest meditation and relaxation therapy
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Practicing yoga may help to relieve your stress symptoms. Proper sleep hygiene should help your insomnia and stress. Avoid stimulants such as caffeine, and limit alcohol intake. Regular exercise can alleviate stress and promote good sleep. In addition, many programs for meditation are available."

7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“A naturopath or certified yoga trainer may be able to help you manage the stress as well as improve your sleep through diet and lifestyle changes. Previously you used walking your dog as a stress reliever and occasionally took melatonin. These measures have shown some benefit, but you are still looking for more options. Yoga may help to reduce some of your stress-related symptoms and help regulate your sleep.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	“Yoga practices may require training, but they will likely help with your stress and other concerns. The good sleep hygiene practices may help with your symptoms and just require consistent application to see an effect.”
Solicit follow-up questions from the patient or caregiver.	“How long will it take to see the effect?”
Answer the patient’s or caregiver’s questions.	“Responses are variable, so it is important to be consistent in practicing the yoga techniques you learn and in following the sleep hygiene practices.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Call the patient in a week to evaluate the outcome.

Key: HCP = Health care provider; n/a = not applicable.

Case 52–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	

1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient presents to the pharmacy to buy acetaminophen for pain associated with his osteoarthritis. He recently was diagnosed with mild osteoarthritis and has been controlling his pain somewhat with acetaminophen. The patient mentions searching for other nondrug options that can help ease his pain. He worries that as his disease progresses, he will need to take more medications and wants to ask you about available nondrug treatment options.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient has noticed increased stiffness and pain, especially in the morning.
c. Description of the patient's efforts to relieve the symptoms	He is taking acetaminophen with some relief.
d. Patient's identity	Steve Harts
e. Patient's age, gender, height, and weight	68 years old, male, 5 ft 6 in., 220 lb
f. Patient's occupation	Accountant; currently working part time until he retires next year.
g. Patient's dietary habits	He loves preparing home cooked meals for himself and his family. He says that he enjoys eating steak at least twice a week, but he tries to vary his diet the rest of the week.
h. Patient's sleep habits	Sleeps 8–9 hours a night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Hypertension on valsartan 80 mg/day;
	hyperlipidemia on rosuvastatin 10 mg/day

j. Allergies	Takes ACE inhibitors for cough.
k. History of other adverse reactions to medications	None
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Pain and stiffness
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to his HCP. (2) Suggest that he consider yoga practices, tai chi, or massage to control his pain and stiffness. (3) Recommend self-management programs. (4) Refer the patient to a physical therapist to determine the appropriate exercises for him. (5) Suggest using patellar taping or thermal agents after consulting with his HCP.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult an HCP.
6. Describe the recommended therapeutic	"You should consult your regular health care provider for possible referral to a yoga, acupuncture, tai chi, or massage

approach to the patient or caregiver.	practitioner. Tai chi or acupuncture may be good options. Also consider referral to a physical therapist.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“This option should help you to slow down the progression of the disease and to avoid the need for surgery.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Provide an evidence-based patient education handout on yoga, acupuncture, and physical therapy for the patient to examine.
Solicit follow-up questions from the patient or caregiver.	“How can I prevent this condition from getting worse?”
Answer the patient’s or caregiver’s questions.	“Keep a log of activities that exacerbate your condition, and try to avoid them. Explore different integrative therapies to find the one that works best for you. Try patellar taping or thermal agents first. These measures will help you avoid medication-associated adverse events.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact the patient within a few days to ensure that he has sought care.

Key: ACE = Angiotensin-converting enzyme; HCP = health care provider; n/a = not applicable.

Key Points for CIM Health Systems

- The term *complementary and integrative medicine* (CIM) is a broad group of healing philosophies, diagnostic approaches, and therapeutic interventions that, in general, are not considered part of the conventional Western health system. Common CIM approaches include homeopathy, naturopathy, TCM and acupuncture, chiropractic care, Ayurveda, and massage.
- Homeopathy is based on the principle of “like cures like,” which states that if a substance produces the symptoms of an illness in large doses, that same substance can cure it in very minute dosages. The efficacy of homeopathy has not been determined for any clinical condition, although the risk of toxicity is low.
- Naturopathy employs natural forces such as light, heat, air, and water through nutrition, botanical medicine, psychotherapy, acupuncture, homeopathy, massage, and spinal manipulation; this therapy focuses on building health rather than on treating disease. Naturopathy is based on six principles: (1) the healing power of nature, (2) identifying and treating the cause, (3) doing no harm, (4) treating the whole person, (5) the conventional primary care provider as teacher, and (6) preventing disease.
- TCM includes herbal medicines as well as techniques such as acupuncture, exercise, massage, moxibustion, and cupping. TCM focuses on the life force (*chi*), which is thought to circulate through the body through meridians (channels) that connect all major organs. *Chi* consists of *yin* and *yang*, which are opposite and complementary qualities. Illness is believed to result when these forces are unbalanced. An acupuncturist inserts sterilized needles into channels of energy to try to restore balance to the patient’s *chi*.
- Chiropractic focuses on the relationship between spinal structure and body function mediated by the nervous system. Spinal manipulation is a well-known procedure, but chiropractic care also includes other procedures, including all forms of physical therapy and rehabilitation intervention. Spinal manipulation may be helpful for back pain.
- Ayurveda is an integrated system employing diet, herbs, exercise,

meditation, yoga, and massage or bodywork. Ayurveda teaches that vital energy (*prana*) is the basis of all life and healing. As *prana* circulates throughout the body, it is governed by the five elements of earth, air, fire, water, and ether. The five elements combine with one another into pairs called *doshas*, which include *vata* (ether and air), *pitta* (fire and water), and *kapha* (earth and water).

- Touch is fundamental to massage therapy and is used by massage therapists to locate painful or tense areas, to determine how much pressure to apply, and to establish a therapeutic relationship with patients.

Pharmacists' Patient Care Process

Pharmacists use a patient-centered approach in collaboration with other providers on the health care team to optimize patient health and medication outcomes.

Using principles of evidence-based practice, pharmacists:

Collect

The pharmacist assures the collection of the necessary subjective and objective information about the patient in order to understand the relevant medical/medication history and clinical status of the patient.

Assess

The pharmacist assesses the information collected and analyzes the clinical effects of the patient's therapy in the context of the patient's overall health goals in order to identify and prioritize problems and achieve optimal care.

Plan

The pharmacist develops an individualized patient-centered care plan, in collaboration with other health care professionals and the patient or caregiver that is evidence-based and cost-effective.

Implement

The pharmacist implements the care plan in collaboration with other health care professionals and the patient or caregiver.

Follow-up: Monitor and Evaluate

The pharmacist monitors and evaluates the effectiveness of the care plan and modifies the plan in collaboration with other health care professionals and the patient or caregiver as needed.

5A, B, and C Pinworm infection, the most common worm infestation in the United States, is caused by ingestion of pinworm eggs from fecally contaminated hands, food, clothing, or bedding. A, The adult pinworm is a small (1-cm long), white, thread-like worm with a pin-shaped, pointed tail. B, The mature female stores approximately 11,000 eggs in her body, which she deposits in the perianal region of the host, usually at night. Reinfection occurs when the hatched larvae return to the large intestine or when eggs are transferred from the anus to the mouth and swallowed. C, Commercial pinworm detection kits use a sticky paddle, instead of tape, to affix the adult pinworm to a slide, which is then examined microscopically (see Chapter 18). 6A–B There are three major types of ostomies: ileostomy, colostomy, or urinary diversion. **A**, In an ileostomy, a portion of the ileum is brought through the abdominal wall. **B**, The two most common types of continent ileostomies are the ileoanal reservoir and the Kock continent ileostomy. The ileoanal reservoir is created by stripping diseased mucosa from the rectum, creating an internal pouch from the ileum, and pulling the distal end of the pouch through the rectum and attaching it. In the Kock continent ileostomy, an internal pouch is created from the ileum and an intussusception of the bowel is used to create a “nipple.”

6C–F Colostomies are located on the ascending, transverse, or descending/sigmoid colon. **C**, Ascending colostomies are uncommon. The ascending colon is retained, but the rest of the large bowel is removed or bypassed. The stoma is usually on the right side of the abdomen. The transverse colon is the site of most temporary colostomies. A loop of the transverse colon is lifted through the abdominal incision, and a rod or bridge is placed under the loop to give it support. **D**, Loop colostomies have one large opening, but two tracts. The proximal tract discharges fecal material; the distal tract secretes small amounts of mucus. **E**, In a double-barrel transverse colostomy, the bowel is completely divided by bringing both the proximal end and the distal end through the abdominal wall and suturing them to the skin. **F**, Descending and sigmoid colostomies are fairly common and generally are on the left side of the abdomen.

6G–I Urinary diversion surgery diverts the urinary stream through an opening in the abdominal wall. G, In the ileal conduit, the most common type of urinary diversion, ileal and colon conduits are created after removal of the bladder by implanting the ureters into an isolated loop of bowel, the distal end of which is brought to the surface of the abdomen. H, Mucous shreds will be present if the bowel is used to create the diversion. I, In a ureterostomy, one or both ureters are detached from the bladder and brought to the outside of the abdominal wall, where a stoma is created. This procedure is used less frequently because the ureters tend to narrow unless they have been dilated permanently by previous disease (see Chapter 22). (Copyrighted photographs 2B, D, and G courtesy of Hollister Incorporated, Libertyville, Illinois. Copyrighted photographs 2A, C, E, F, H, and I courtesy of Joan Lerner Selekof, BSN, CWOCN, University of Maryland Medical Center, Baltimore, Maryland.)

All rights reserved. Any use is subject to the Terms of Use.

9 Dental fluorosis (mottled enamel) can develop during the time of tooth formation in children who receive higher than optimal intake of fluoride. Discoloration of the teeth varies, depending on the level of fluoride in the water, and ranges from white flecks or spots to brownish stains, small pits, or deep irregular pits that are dark brown in color (see Chapter 31).

8—Gingivitis, chronic

10 Chronic gingivitis, an asymptomatic inflammation of the gingivae (gums) at the necks of the teeth, is an early stage of periodontitis and is usually caused by poor oral hygiene. The gingivae are erythematous (red) and may have areas that appear swollen and glossy. In addition, mild bleeding may occur during toothbrushing (see Chapter 31).

9—Periodontitis, chronic

All rights reserved. Any use is subject to the Terms of Use.

11 Chronic periodontitis (pyorrhea), an inflammation of the tissues surrounding the teeth, including the gingivae, periodontal ligaments, alveolar bone, and the cementum (bony material covering the root of a tooth), is caused by plaque accumulation resulting from poor oral hygiene. The gingivae may be erythematous and swollen, and may recede from the necks of the teeth. The condition is not painful and usually is accompanied by halitosis, loosening of the teeth, and mild bleeding during toothbrushing (see Chapter 31).

10—Candidiasis, oral

Copyright © 2006. American Pharmacists Association. All rights reserved. Any use is subject to the TERMS OF USE
<<http://www.otchandbook.com/terms.htm>>

Copyright©American Pharmacists Association PharmacyLibrary.
All rights reserved. Any use is subject to the Terms of Use.

12 Candidiasis (candidosis, moniliasis, thrush), an infection caused by overgrowth of *Candida albicans*, tends to occur in people with debilitating or chronic systemic disease or those on long-term antibiotic therapy. Candidiasis commonly manifests as a whitish-gray to yellowish, soft, slightly elevated pseudomembrane-like plaque on the oral mucosa; the plaque is often described as having a milk curd appearance. If the membrane is stripped away, a raw bleeding surface remains. A dull, burning pain is often present (see Chapters 31 and 32).

12—Recurrent aphthous ulcers

Copyright © 2006. American Pharmacists Association. All rights reserved. Any use is subject to the TERMS OF USE
<<http://www.otchandbook.com/terms.htm>>

Copyright©American Pharmacists Association PharmacyLibrary.
All rights reserved. Any use is subject to the Terms of Use.

13 Recurrent aphthous ulcers (canker sores) are recurrent, painful, single, or multiple ulcerations of bacterial origin. The central ulceration is sharply demarcated, often has a gray to grayish-yellow surface of necrotic debris, and is surrounded by an erythematous margin (see Chapter 32).

Color Plate-7

11—Aspirin burn of oral cavity

14 Aspirin burn results from the topical use of aspirin to relieve toothache. An aspirin tablet is placed against the tooth, where it is held in place by pressure from the buccal (cheek) mucosa. The mucosa becomes necrotic and is characterized by a white slough that rubs away, revealing a painful ulceration (see Chapter 32).

15 Herpes simplex lesions of the mouth and the eye usually start as a small cluster of vesicles (tiny blisters) that subsequently heal over with a serosanguineous (blood-tinged) crust. Local stinging, burning, and pain often herald the onset of lesions. Eye involvement should always be referred to an ophthalmologist (see Chapter 32).

16A, B, and C Atopic dermatitis (eczema) is an inflammatory condition that occurs **(A)** on the extensor surface of the elbows and knees during the first year of life and then **(B)** involves predominantly the flexors. **C**, The hands,

feet, and face are often involved as well. The dermatitis is characterized by erythema, scale, increased skin surface markings, and crusting; secondary infection is common (see Chapter 33).

17 Seborrheic dermatitis is a red scaling condition of the scalp, midface, and upper midchest of adults. This dermatitis is marked by characteristic greasy, yellowish scaling and is associated with erythema (see Chapter 34).

Color Plate-8

18A, B, and C Psoriasis is a scaling condition in which erythematous plaques (red raised areas) are covered by a thick adherent scale. The borders of the lesions are well developed and vary from guttate (very small drop-shaped plaques) to much larger plaques: **(A)** guttate, **(B)** medium-size plaques, **(C)** large plaques (see Chapter 34).

19A, B, and C Poison ivy, oak, and sumac account for the majority of plant-induced allergic contact dermatitis. **A**, In the United States, poison ivy is the most common of the three plants. It usually grows as a scrambling shrub or a climbing hairy vine that often grows up poles, trees, and building walls. Its leaves are usually large, broad, and spoon-shaped. **B**, Two species of poison oak are indigenous to the United States; both possess leaves with unlobed edges that look similar to those of oak trees. Eastern poison oak (*Toxicodendron toxicarium*) commonly displays three leaflets, whereas Western poison oak (*Toxicodendron diversilobum*) has between 3 and 11 leaflets per stem. Poison oak usually grows as a shrub capable of reaching heights of 131 feet (40 meters). **C**, Poison sumac (*Toxicodendron vernix*) grows in remote areas of the eastern one third of the United States in peat bogs and swampy areas. It grows as a shrub or small tree and attains a height of about 9.8 feet (3 meters). Its pinnate leaves have smooth edges that come to a tip and may be almost 16 inches (40 cm) in length. The leaves are odd numbered, ranging between 7 and 13 leaflets (see Chapter 35). (Photographs courtesy of George Yatskievych, PhD, Missouri Botanical Garden, St. Louis, © 2000.)

Color Plate-9

20A, B, and C **Poison ivy** dermatitis is often associated with **(A)** fluid-filled vesicles (blisters) or bullae, depending on a person's sensitivity. **B**, Streaks of vesicles that correspond to the points of urushiol contact from the damaged plant are highly suggestive of poison ivy exposure. **C**, Oozing and weeping of the vesicular fluid occur for several days, until the affected area develops crusts and begins to dry. Similar reactions can also be caused by poison oak and poison sumac (see Chapter 35). (Photographs courtesy of Christopher Huerter, MD, Creighton University Medical Center, Omaha, Nebraska, © 2002.)

21 **Diaper dermatitis** presents as erythema of the groin (crease area around the genitals) and is common in infants. The case shown here was caused by a contact allergen. Contact irritants, such as urine and feces, and secondary bacterial and yeast infections may also cause problems in this area (see Chapter 36). (Photograph reprinted with permission from emedicine.com, Inc., © 2003.)

22 **Miliaria rubra (heat rash)** is an obstruction of sweat glands. Superficial involvement results in only tiny vesicles (blisters) appearing on the skin surface (miliaria crystallina). When deeper inflammation is present, the surrounding erythema is characteristic of miliaria rubra (see Chapter 36). (Photograph reprinted with permission from emedicine.com, Inc., © 2003.)

Color Plate-10

23 **Scabies** is caused by a small mite that burrows under the superficial skin layers. Small linear blisters that cause intense itching can be seen between the finger webs, on the inner wrists, in the axilla, around the areola (nipple) of the breast, and on the genitalia (see Chapter 37). (Photograph reprinted with permission from emedicine.com, Inc., © 2003.)

24 Ticks can attach to human skin and burrow into superficial skin layers. With careful examination, the back of the organism is usually visible on the skin surface. Ticks are vectors of several systemic diseases (see Chapter 37).

25A and B Pediculus humanus capitis is a louse infestation of the scalp. **A**, Examination of the scalp hair in this infestation shows tiny nits (eggs) attached to the hair shaft. **B**, The organism shown is only occasionally seen (see Chapter 37).

26 Comedonic acne (noninflammatory) occurs when follicles become plugged with sebum, forming a comedone on the surface. The black color is caused by oxidation of lipid and melanin, not dirt as is commonly believed (see Chapter 38).

27 Pustular acne (inflammatory) presents as inflamed papules that are formed when superficial hair follicles become plugged and rupture at a deeper level. Superficial inflammation results in pustules; deep lesions cause large cysts to form with possible resultant scarring (see Chapter 38).

Color Plate-11

28 Sunburn presents as an erythema that occurs after excessive sun exposure; severe burns can result in large blister formation. Proper sunscreen application can provide photoprotection for susceptible patients (see Chapters 39 and 41).

29 Drug-induced photosensitivity is a reaction that occurs on sun-exposed surfaces of the head, neck, and dorsum (back) of the hands. The erythema does not occur on photoprotected areas, such as under the nose and chin, behind the ears, and between the fingers (see Chapter 39).

30 Cosmetic-induced photosensitivity can be caused by ingredients in certain topical colognes and perfumes. This reaction produces a local

erythema that leaves characteristic postinflammatory pigmentation (see Chapter 39).

31 Tinea pedis infection of the toes characteristically starts between the fourth and fifth web space and spreads proximally. Scaling can progress to maceration with resultant small fissures (see Chapter 42).

32 Tinea capitis, a fungal infection of the scalp, is marked by scale on the scalp with local breaking or loss of hair; erythema (redness) is usually not observed (see Chapter 42).

Color Plate-12

33 Common warts are viral-induced lesions that present as localized rough accumulations of keratin (hyperkeratosis) containing many tiny furrows. If the wart's surface is pared, small bleeding points can be seen (see Chapter 43).

34 Plantar warts, caused by a viral infection, are often found on the plantar surface of the foot and present with hard, localized accumulations of keratin. The punctate bleeding points seen when the lesions are pared distinguish plantar warts from calluses (see Chapter 43). (Photograph reprinted with permission from emedicine.com, Inc., © 2003.)

35 Calluses are thickened scales that often form on joints and weight-bearing areas. A callus on the plantar surface of the foot is shown here (see Chapter 44).

Updates

Content Update for “Preface”

- Removal of the pregnancy risk categories for all drugs and natural products, and subsequently, the removal of the two appendices that focused on pregnancy risk information.

The following explains the reasoning for this decision:

In 2015 the Food and Drug Administration (FDA) implemented the Pregnancy and Lactation Labeling Rule (PLLR), which replaces the former pregnancy risk letter categories (A, B, C, D, X) for prescription drugs with more descriptive content in the following fields^{1,2}:

- Pregnancy: now includes labor and delivery
- Lactation
- Females and males of reproductive potential

Although this new categorization provides clinicians with more detail for decision making, clinicians still need to apply this information on a case-by-case basis. The PLLR will be implemented in phases, with the final phase to be completed by June 29, 2018. However, this rule is not applicable to self-care and nonprescription products.

Previous editions of the *Handbook* have included pregnancy risk letter designations, where available, and oftentimes this was based on the designation for the prescription version of the medication. With the changes that have taken place and the lack of support for letter designations to identify pregnancy risk, the editors decided to remove any reference to a pregnancy risk category within chapters, and to remove both appendices. Where this information appeared previously we now include general language that supports the reader in determining, based on available literature, what is best for their particular patient in each situation. The following is the standard language in all chapters that mention medication or product use in pregnancy:

- See the Preface for a detailed explanation of the pregnancy data.

- Use in pregnancy should be limited to clinical situations in which the potential benefit justifies potential risk to the fetus

Where a pregnancy issue exists for a nonprescription product, the Drug Facts Label states that the consumer should ask a health care professional before using the product if she is pregnant or breastfeeding. FDA is aware of the limitations of the Drug Facts Label for communicating complex issues such as pregnancy labeling. They attempt to ensure nonprescription labeling is as consistent as possible with the prescription drug labels when a drug is available in both forms. However, the challenge with nonprescription products is to provide information that consumers can understand but is detailed enough to address any concerns. FDA is aware of the inconsistencies this situation has created and, at the time of this writing, was discussing options to enhance the pregnancy content for nonprescription products.
