

20th
EDITION

Handbook of Nonprescription Drugs

An Interactive
Approach to Self-Care

Daniel L. Krinsky • Stefanie P. Ferreri • Brian A. Hemstreet
Anne L. Hume • Carol J. Rollins • Karen J. Tietze

Contributors and Copyright

Editor-in-Chief

Daniel L. Krinsky, MS, RPh

Owner and Pharmacist, EduCare4U, LLC; Co-owner and Co-founder, PGx101, LLC; Adjunct Professor, Lake Erie College of Osteopathic Medicine School of Pharmacy, Stow, Ohio

Associate Editors

Stefanie P. Ferreri, PharmD, BCACP, FAPhA

Professor and Chair, Division of Practice Advancement and Clinical Education, UNC Eshelman School of Pharmacy, University of North Carolina at Chapel Hill

Brian Hemstreet, PharmD, FCCP, BCPS

Assistant Dean for Student Affairs and Professor, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Aurora

Anne L. Hume, PharmD, FCCP, BCPS

Professor of Pharmacy, Department of Pharmacy Practice, University of Rhode Island College of Pharmacy, Kingston; Adjunct Professor of Family Medicine, Brown University/Memorial Hospital of Rhode Island, Providence; Adjunct Professor of Quantitative Health Services, University of Massachusetts Medical School, Worcester

Daniel L. Krinsky, MS, RPh

Owner and Pharmacist, EduCare4U, LLC; Co-owner and Co-founder, PGx101, LLC; Adjunct Professor, Lake Erie College of Osteopathic Medicine School of Pharmacy, Stow, Ohio

Carol J. Rollins, MS, RD, PharmD, BCNSP

Clinical Professor, Department of Pharmacy Practice and Science, The University of Arizona College of Pharmacy, Tucson

Karen J. Tietze, PharmD

Professor of Clinical Pharmacy, Department of Pharmacy Practice and Pharmacy Administration, Philadelphia College of Pharmacy, University of the Sciences, Philadelphia, Pennsylvania

Contributors

Authors

Note: Numbers in parentheses denote the chapter(s) authored or coauthored.

Donna M. Adkins, PharmD, BCGP, FASCP (43)

Professor and Chair, Department of Pharmacy Practice and Administration, William Carey University School of Pharmacy– Tradition Campus, Biloxi, Mississippi

Nicole Paolini Albanese, PharmD, CDCES, BCACP (32)

Clinical Associate Professor, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, Buffalo, New York; and PGY2 Ambulatory Care Residency Director, Buffalo Medical Group, P.C., Buffalo, New York

Maha B. Alharbi, PharmD, MSc (52)

Quality and Safety Fellow at Brigham and Women's Hospital, Boston, Massachusetts; and Department of Quality and Safety, Kuwait University Faculty of Pharmacy, Safat

Chelsea M. Baker, PharmD, BCACP (38)

Clinical Assistant Professor of Pharmacy Practice, Purdue University College of Pharmacy, West Lafayette, Indiana

Kim W. Benner, PharmD, BCPS, FASHP, FPPAG (33)

Professor of Pharmacy Practice, Samford University McWhorter School of Pharmacy, Birmingham, Alabama; and Clinical Pharmacy Specialist, Children's of Alabama, Birmingham

Tricia M. Berry, PharmD, BCPS (45)

Professor, Department of Pharmacy Practice, St. Louis College of Pharmacy, St. Louis, Missouri

Elizabeth W. Blake, PharmD, BCPS, FNAP (37)

Clinical Associate Professor and Director of Interprofessional Education, Clinical Pharmacy and Outcomes Sciences Department, University of South Carolina College of Pharmacy, Columbia

Mary M. Bridgeman, PharmD, BCPS, BCGP (23)

Clinical Associate Professor, Ernest Mario School of Pharmacy, Rutgers, The State University of New Jersey, Piscataway; and Internal Medicine Clinical Pharmacist, Robert Wood Johnson

University Hospital, New Brunswick, New Jersey

Sherrill Brown DVM, PharmD, BCPS (27)

Associate Professor, Department of Pharmacy Practice; Director of Drug Information Service, University of Montana Skaggs School of Pharmacy, Missoula

Juliana Chan, PharmD, FCCP, BCACP (17)

Clinical Associate Professor, Colleges of Pharmacy and Medicine, University of Illinois at Chicago; and Clinical Pharmacist, Illinois Department of Corrections Hepatology Telemedicine, University of Illinois Hospital & Health Sciences System, Chicago

Aleda M. H. Chen, PharmD, MS, PhD (29)

Assistant Dean and Associate Professor, Cedarville University School of Pharmacy, Cedarville, Ohio

M. Petrea Cober, PharmD, BCNSP, BCPPS, FASPEN (26)

Clinical Coordinator, Neonatal Intensive Care Unit, Akron Children's Hospital, Akron, Ohio; and Associate Professor of Pharmacy Practice, Northeast Ohio Medical University, College of Pharmacy, Rootstown

Janice C. Colwell, MS, APRN, CWOCN, FAAN (22)

Advanced Practice Nurse, Department of General Surgery, University of Chicago Medicine, Chicago, Illinois

Kimberly M. Crosby, PharmD, BCPS, BCGP, CDCES, BC-ADM (39)

Associate Professor, Department of Family Medicine, The University of Oklahoma School of Community Medicine, Tulsa

Barbara Crouch, PharmD, MSPH (21)

Executive Director, Utah Poison Control Center, and Professor (Clinical), University of Utah College of Pharmacy, Salt Lake City

Richard H. Dang, PharmD, APh, BCACP (17)

Assistant Professor of Clinical Pharmacy, University of Southern California School of Pharmacy, Los Angeles

Cathi Dennehy, PharmD, FCSHP (50)

Health Sciences Clinical Professor of Pharmacy, Department of Clinical Pharmacy, University of California–San Francisco School of Pharmacy

Holly Divine, PharmD, BCACP, BCGP, CDE, FAPhA (2)

Clinical Professor, Pharmacy Practice and Science, University of Kentucky College of Pharmacy, Lexington

Mark Donaldson BSP, ACPR, PharmD, FASHP, FACHE (32)

Associate Principal, Pharmacy Advisory Solutions, Vizient, Inc., Irving, Texas

Christine Eisenhower, PharmD, BCPS (46)

Clinical Associate Professor, University of Rhode Island College of Pharmacy, Kingston

Shareen Y. El-Ibiary, PharmD, FCCP, BCPS (10)

Professor and Chair, Department of Pharmacy Practice, Midwestern University
College of Pharmacy–Glendale Campus, Glendale, Arizona

Patricia H. Fabel, PharmD, BCPS (37)

Associate Professor, Department of Clinical Pharmacy and Outcomes Sciences,
and Executive Director, Kennedy Pharmacy Innovation Center, University of
South Carolina College of Pharmacy, Columbia

Brett Feret, PharmD (6)

Clinical Professor, University of Rhode Island College of Pharmacy, Kingston

Richard Fiscella, PharmD, MPH (28)

Clinical Professor Emeritus, Department of Pharmacy Practice, University of
Illinois at Chicago School of Pharmacy

Gretchen Garofoli, PharmD, BCACP (13)

Clinical Associate Professor, West Virginia University School of Pharmacy,
Morgantown

Sharon Gatewood, PharmD, BCACP, FAPhA (15)

Associate Professor, Virginia Commonwealth University School of Pharmacy,
Richmond

Erica Pascale Greene, PharmD (32)

Clinical Pharmacy Specialist–Ambulatory Care, Saint Vincent Hospital, Erie,
Pennsylvania

Karl M. Hess, PharmD, APh, CTH, FCPPhA, FAPhA, AFTM RCPS

(Glasg) (18)

Associate Professor of Pharmacy Practice and Director of Community
Pharmacy Practice Innovations, Chapman University School of Pharmacy,
Irvine, California

Rebekah Jackowski, PharmD, MPH (14)

Assistant Professor of Pharmacy Practice, Midwestern University College of Pharmacy–Glendale Campus, Glendale, Arizona

Anita N. Jacobson, PharmD (3)

Clinical Associate Professor, University of Rhode Island College of Pharmacy, Kingston

Michael K. Jensen MS, RPh (28)

Clinical Ophthalmic Pharmacology Specialist and Clinical Compliance Manager, Intermountain Healthcare, Salt Lake City, Utah

Pramodini B. Kale-Pradhan, PharmD, FCCP (20)

Professor (Clinical) Department of Pharmacy Practice, Eugene Applebaum College of Pharmacy and Health Science, Wayne State University, Detroit. Michigan; and Clinical Specialist– Infectious Diseases, Department of Pharmacy Services, Ascension St. John Hospital, Detroit. Michigan

Connie Kang, PharmD, BCPS, BCGP (18)

Assistant Professor of Clinical Pharmacy and Director of Interprofessional Education, University of Southern California School of Pharmacy, Los Angeles

Wendy Klein-Schwartz, PharmD, MPH, FACCT (21)

Toxicology Specialist, Maryland Poison Center, and Professor Emeritus, Department of Pharmacy Practice and Science, University of Maryland School of Pharmacy, Baltimore

Barbara A. Kochanowski, MS, PhD (1)

Senior Vice President, Regulatory & Scientific Affairs, Consumer Healthcare Products Association, Washington, DC

Daniel L. Krinsky MS, RPh, FAPhA (48)

Owner and Pharmacist, EduCare4U, LLC; Co-Owner and Co-Founder, PGx101, LLC; and Adjunct Faculty, Lake Erie College of Osteopathic Medicine (LECOM)

School of Pharmacy, Stow, Ohio

Virginia Lemay, PharmD, CDOE, CVDOE (6)

Clinical Associate Professor and PGY1 Community Residency Program Director, University of Rhode Island College of Pharmacy, Kingston; and The University of Rhode Island/Rite Aid Community Pharmacist, MTM Specialist, Certified Immunizer, and Diabetes Educator, Kingston

Nicole M. Lodise, PharmD (8)

Professor of Pharmacy Practice–Women’s Health/Tobacco Cessation, Albany College of Pharmacy and Health Sciences, and Clinical Pharmacy Specialist, Albany Medical Center, Albany, New York

Rupal Patel Mansukhani, PharmD, CTTS, FAPhA (34)

Clinical Associate Professor, Department of Pharmacy Practice and Administration, Rutgers, The State University of New Jersey Ernest Mario School of Pharmacy, Piscataway; and Clinical Pharmacist, Morristown Medical Center, Morristown, New Jersey

Beth A. Martin RPh, PhD, TTS, FAPhA (47)

Professor and Chair, University of Wisconsin School of Pharmacy, Madison

Tera McIntosh, PharmD, BCACP (2)

Clinical Assistant Professor, University of Kentucky College of Pharmacy, Lexington

Cydney E. McQueen, PharmD (51)

Clinical Associate Professor, Pharmacy Practice and Administration, University of Missouri–Kansas City School of Pharmacy

Karleen Melody, PharmD (31)

Associate Professor of Clinical Pharmacy, Department of Pharmacy Practice and Pharmacy Administration, University of the Sciences Philadelphia College of Pharmacy, Philadelphia, Pennsylvania

Sarah J. Miller, PharmD, BCNSP (27)

Professor of Clinical Pharmacy, University of Montana Skaggs School of Pharmacy, Missoula; and Clinical Pharmacy Consultant, Providence Saint Patrick Hospital, Missoula

Cortney Mospan, PharmD, BCACP, BCGP, CPP (35)

Associate Professor of Pharmacy, Wingate University School of Pharmacy, Wingate, North Carolina; and Clinical Pharmacist Practitioner, Novant Health Arboretum Family & Sports Medicine, Charlotte, North Carolina

Nardine Nakhla, PharmD (9)

Clinical Lecturer, University of Waterloo School of Pharmacy, Kitchener, Ontario, Canada

Mark Newnham, PharmD, BCPS, BCNSP (25)

Clinical Pharmacist, Lawnwood Regional Medical Center and Heart Institute, Fort Pierce, Florida

Julie L. Olenak, PharmD (7)

Assistant Dean of Student Affairs and Professor of Pharmacy Practice, Wilkes University Nesbitt School of Pharmacy, Wilkes-Barre, Pennsylvania

Katherine S. O'Neal, PharmD, MBA, BCACP, CDE, BC-ADM,

AE-C (40)

Associate Professor, University of Oklahoma College of Pharmacy, Tulsa; and Adjunct Associate Professor, University of Oklahoma College of Medicine Department of Medicine, General Internal Medicine, Tulsa

Christine Karabin O'Neil BS., PharmD. BCPS, BCGP, FCCP,

FASCP (49)

Professor of Pharmacy Practice and Assistant Dean of Curricular Development and Interprofessional Education, Duquesne University School of Pharmacy, Pittsburgh, Pennsylvania

Katherine Kelly Orr, PharmD (51)

Clinical Professor, Department of Pharmacy Practice, and Director, Doctor of Pharmacy Program, The University of Rhode Island College of Pharmacy, Kingston

Caitlyn Bloom, PharmD, BCACP, AE-C (24)

Clinical Specialty Pharmacist, Northwell Health, Manhasset, New York

Nicole C. Pezzino, PharmD, BCACP, CDCES (7)

Assistant Professor, Department of Pharmacy Practice; Director, PGY1 Community Pharmacy Residency; and Director, Community Outreach & Innovation, Wilkes University Nesbitt School of Pharmacy, Wilkes-Barre, Pennsylvania

Traci M. Poole, PharmD, BCACP, BCGP (14)

Associate Professor of Pharmacy Practice, Belmont University College of Pharmacy, Nashville, Tennessee

Erin Raney, PharmD, BCPS, BC-ADM, FCCP (10)

Professor of Pharmacy Practice, Midwestern University College of Pharmacy–Glendale Campus, Glendale, Arizona

Carol J. Rollins MS, PharmD, BCNSP, FASPEN, FASHP (23, 24)

Clinical Professor, Department of Pharmacy Practice and Science, The University of Arizona College of Pharmacy, Tucson

Martha M. Rumore, PharmD, JD, MS, LLM, FAPhA (4)

Senior Counsel, Frier Levitt, LLC, New York, New York; and Adjunct Professor of Law, Maurice A. Deane School of Law, Hofstra University, Long Island, New York

Kelly L. Scolaro, PharmD (11)

Associate Professor of Pharmacy Practice, Lake Erie College of Osteopathic Medicine (LECOM) School of Pharmacy–Bradenton Campus, Bradenton, Florida

Jeri J. Sias, PharmD, MPH (3)

Clinical Professor, The University of Texas at El Paso School of Pharmacy

Megan G. Smith, PharmD, BCACP (42)

Assistant Professor, Department of Pharmacy Practice, University of Arkansas for Medical Sciences, Little Rock

Jenelle L. Sobotka, PharmD, FAPhA, FNAP (1)

Professor and Director of Online Certificate and Master's Programs in Pharmacy Leadership, University of Cincinnati James L. Winkle College of Pharmacy, Cincinnati, Ohio

Sneha Baxi Srivastava, PharmD, BCACP, CDECS, DipACLM (44)

Associate Professor, Department of Pharmacy Practice, Rosalind Franklin University of Medicine and Science College of Pharmacy, North Chicago, Illinois

Nora Stelter, PharmD, CHWC (41)

Associate Professor of Pharmacy Practice and Coordinator of P3 IPPE, Drake University College of Pharmacy and Health Sciences, Des Moines, Iowa

Karen J. Tietze, PharmD (12)

Professor of Clinical Pharmacy, University of the Sciences Philadelphia College of Pharmacy, Philadelphia, Pennsylvania

Katherine Tromp, PharmD (5)

Associate Dean for Florida Pathways and Associate Professor, Lake Erie College of Osteopathic Medicine (LECOM) School of Pharmacy–Bradenton Campus, Bradenton, Florida

Candy Tsourounis, PharmD (50)

Professor of Clinical Pharmacy, Department of Clinical Pharmacy, University of California–San Francisco School of Pharmacy

Catherine Ulbricht, PharmD, MBA, CPPS (52)

Director of Clinical and Academic Programs, Brigham and Women's Hospital, Boston, Massachusetts; and Senior Attending Clinical Pharmacist, Massachusetts General Hospital, Boston

Lucio Volino, PharmD, CTTS (34)

Department of Pharmacy Practice and Administration, Rutgers, The State University of New Jersey, Ernest Mario School of Pharmacy, Piscataway; and Clinical Pharmacist, RWJBarnabas Health, Livingston, New Jersey

Paul C. Walker, PharmD, FASHP (16)

Clinical Professor and Assistant Dean of Experiential Education and Community Engagement, The University of Michigan College of Pharmacy, Ann Arbor

Adam C. Welch, PharmD, MBA, FAPhA (19)

Associate Professor, Department of Pharmacy Practice, Bill Gatton College of Pharmacy, East Tennessee State University, Johnson City

Tara Whetsel, PharmD, BCACP, BC-ADM (13)

Clinical Associate Professor, Department of Clinical Pharmacy, West Virginia University School of Pharmacy, Morgantown

Kristin Wiisanen, PharmD, FAPhA, FCCP (15)

Associate Director, University of Florida Health Personalized Medicine Program; Director, Graduate Program In Precision Medicine; Director, Office Of Continuing Pharmacy Education; and Clinical Professor, Department of Pharmacotherapy and Translational Research, University of Florida College of Pharmacy, Gainesville

Miranda Wilhelm, PharmD (36)

Clinical Professor, Southern Illinois University–Edwardsville School of Pharmacy, Edwardsville

Sheila Wilhelm, PharmD, FCCP, BCPS (20)

Professor (Clinical), Department of Pharmacy Practice; Patient Care Laboratory

Coordinator, Eugene Applebaum College of Pharmacy and Health Sciences,
Wayne State University, Detroit, Michigan

Julie J. Wilkinson, PharmD, MS, BCPS (5)

Professor of Pharmacy Practice, Lake Erie College of Osteopathic Medicine
(LECOM) School of Pharmacy–Bradenton Campus, Bradenton, Florida

Sharon Wilson, PharmD, BCCCP, BCPS (22)

Clinical Specialist–Surgery Critical Care, Department of Pharmacy Services,
University of Maryland Medical Center; and Clinical Associate Professor,
Resident Program Director–Critical Care Pharmacy Practice, University of
Maryland School of Pharmacy, Baltimore

Jamie L. Woodyard, PharmD, BCACP (38)

Director of Professional Program Laboratories, Clinical Assistant Professor of
Pharmacy Practice, Purdue University College of Pharmacy, West Lafayette,
Indiana

Maria C. Wopat, PharmD, BCACP, CTTS (47)

Clinical Pharmacy Specialist and PGY1 Residency Program Director, William S.
Middleton Memorial Veterans Hospital, Madison, Wisconsin

Deborah Zeitlin, PharmD (30)

Assistant Professor of Pharmacy Practice, Butler University College of
Pharmacy and Health Sciences, Indianapolis, Indiana

Reviewers

Note: Numbers in parentheses denote the chapter(s) reviewed.

Fady Abdllrasul, PharmD (14)

Assistant Professor of Pharmacy Practice, Northeast Ohio Medical University
College of Pharmacy, Rootstown

W. René Acosta, RPh, MS (12)

Associate Dean for Academic Affairs, Clinical Professor, Abbott Endowed Fellow in Pharmacy, and Provost's Teaching Fellow, Health Outcomes and Pharmacy Practice Division, The University of Texas at Austin College of Pharmacy

Erin Adams, PharmD, BCACP (42)

Associate Professor of Pharmacy Practice, Shenandoah University Bernard J. Dunn School of Pharmacy–Fairfax Campus, Fairfax, Virginia

Fatema Alrashed, PharmD, MS, BCPS (51)

Teaching Assistant, Massachusetts College of Pharmacy and Health Sciences University, Boston

Kunal Amin, BSPS, PharmD (16)

Assistant Professor of Pharmacy Practice and Director of Clinical Services, Pharmacy Innovations, Northeast Ohio Medical University, Rootstown

Jennifer Baggs, PharmD, BCPS, BCNSP (23)

Clinical Assistant Professor, Department of Pharmacy Practice and Science, The University of Arizona Health Sciences, Tucson; and Residency Program Coordinator, Clinical Pharmacist–Critical Care and Nutrition Support, Banner–University Medical Center Tucson

Karen M.S. Bastianelli, PharmD, BCACP (33)

Director, Pharmaceutical Care Learning Center, and Associate Professor, Department of Pharmacy Practice and Pharmaceutical Sciences, University of Minnesota College of Pharmacy, Duluth

Jessica Bates, PharmD, BCPS (42)

Clinical Coordinator, Pharmacy Skills Lab, The University of Kansas School of Pharmacy, Lawrence

Renee Anne Bellanger, PharmD, BCNSP (50)

Professor, Department of Pharmacy Practice, University of the Incarnate Word Joan and Rita Feik School of Pharmacy, San Antonio, Texas; and Pharmacy

Faculty, Children's Hospital of San Antonio, San Antonio, Texas

Daphne Bernard, PharmD (41)

Associate Provost, Institutional Accreditation and Assessment, and Associate Professor, Howard University College of Pharmacy, Washington, DC

Teresa J. Bigler, DHEd, PA-C, DFAAPA (30)

Assistant Professor and Program Director, Physician Assistant Department, School of Allied Health Professions, Louisiana State University Health Sciences Center, Shreveport, Louisiana

Elizabeth W. Blake, PharmD, BCPS (36)

Director, Interprofessional Education, and Clinical Associate Professor, Department of Clinical Pharmacy and Outcomes Sciences, University of South Carolina College of Pharmacy, Columbia; and Clinical Pharmacy Specialist, Primary Care, Palmetto Health Richland, Columbia

Sara Elizabeth Bliss, PharmD, BCPS (23, 24, 27)

Surgery/Nutrition Support Pharmacist, Wake Forest University Baptist Medical Center, Winston-Salem, North Carolina

KarenBeth H. Bohan, PharmD, BCPS (44)

Professor, Department of Pharmacy Practice, Binghamton University School of Pharmacy and Pharmaceutical Sciences, Binghamton, New York

Courtney Bradley, PharmD, BCACP (6)

Assistant Professor of Clinical Sciences, Applied Laboratory Coordinator, High Point University, High Point, North Carolina

Kristy L. Brittain, PharmD, BCPS, CDE (4)

Associate Professor, Department of Clinical Pharmacy and Outcomes Sciences, Medical University of South Carolina College of Pharmacy, Charleston,

Kimberly Broedel-Zaugg, RPh, MBA, PhD (1)

Professor and Chair, Pharmacy Practice, Administration, and Research,
Marshall University School of Pharmacy, Huntington, West Virginia

Wayne Erwin Buff, BS, PharmD (1)

Senior Associate Dean and Clinical Associate Professor, Department of Clinical
Pharmacy and Outcomes Sciences, University of South Carolina College of
Pharmacy, Columbia

Andrea Burns, PharmD (5)

Assistant Professor, Department of Pharmacy Practice, Midwestern University
College of Pharmacy–Glendale Campus, Glendale, Arizona

Kimberly Carter, PharmD (31)

Assistant Professor of Pharmacy Practice, Thomas Jefferson University
Jefferson College of Pharmacy, Philadelphia, Pennsylvania

Mary Chavez, PharmD (52)

Associate Dean, Professor of Pharmacy Practice, University of Texas at El Paso
School of Pharmacy, El Paso

Valerie B. Clinard, PharmD (43)

Director for Experiential Education and Associate Professor, Department of
Clinical Pharmacy, University of California at San Francisco School of Pharmacy

M. Petrea Cober, PharmD, BCNSP, BCPPS, FASPEN (6)

Clinical Coordinator, Neonatal Intensive Care Unit, Akron Children's Hospital,
Akron, Ohio; and Associate Professor of Pharmacy Practice, Northeast Ohio
Medical University College of Pharmacy, Rootstown

Lucille Cooke, RDN (26)

Clinical Dietitian, Banner University Medical Center, Tucson, Arizona

Janet Cooley, PharmD, BCACP (24)

Director, Experiential Education; Associate Director, Interprofessional

Education; and Assistant Professor, Department of Pharmacy Practice and Science, The University of Arizona College of Pharmacy, Tucson

Bernadette Cornelison, PharmD, MS, BCPS (26)

Assistant Professor, The University of Arizona College of Pharmacy, Tucson; and Pharmacist, Alvernon Family Medicine Clinic, Tucson

Deeatra Craddock, PharmD, BCACP (8)

Residency Program Director, Department of Pharmacy Practice, Texas Tech University Health Science Center Jerry H. Hodge School of Pharmacy, Lubbock

Steven J. Crosby, BSP, RPh, MA, FASCP (45)

Assistant Dean of Student Engagement and Success, and Associate Professor of Pharmacy Practice, Massachusetts College of Pharmacy and Health Sciences University, Boston

Erin Dalton, PharmD (35)

Assistant Professor, Department of Pharmacy Practice, and Director, Community-Based Pharmacy Residency Program, South University School of Pharmacy, Savannah, Georgia

Christopher J. Daly, PharmD, MBA (36)

Clinical Assistant Professor, Department of Pharmacy Practice, University at Buffalo School of Pharmacy and Pharmaceutical Sciences, Buffalo, New York

Altaf S. Darvesh, M Pharm, PhD (16)

Associate Professor, Pharmaceutical Sciences, College of Pharmacy; and Associate Professor, Psychiatry, College of Medicine; Northeast Ohio Medical University, Rootstown

Mark Anthony Della Paolera, BS, RPh, PharmD, BCPS,

BCACP (43)

Medical Science Liaison, AstraZeneca, San Francisco, California

Aimee Dietle Dawson, PharmD (46)

Assistant Professor, Department of Pharmacy Practice, Massachusetts College of Pharmacy and Health Sciences University, Boston

Lisa Dinkins, PharmD (35)

Associate Professor, IPPE, and Director, Wingate University School of Pharmacy, Wingate, North Carolina

Erin Dorval, PharmD (34)

Assistant Professor of Pharmacy Practice, Palm Beach Atlantic University Lloyd L. Gregory School of Pharmacy, West Palm Beach, Florida

Kaelen C. Dunican, PharmD, RPh (43, 45, 50)

Professor of Pharmacy Practice, Massachusetts College of Pharmacy and Health Sciences University, Boston

Margarita Echeverri, MSc, PhD (3)

Associate Professor, Division of Clinical and Administrative Sciences, Xavier University of Louisiana College of Pharmacy, New Orleans

Patricia H. Fabel, PharmD, BCPS (19)

Associate Professor, Department of Clinical Pharmacy and Outcomes Sciences, University of South Carolina College of Pharmacy, Columbia; and Executive Director, Kennedy Pharmacy Innovation Center, Columbia

Christian Fink, BS (48)

Doctor of Pharmacy Candidate, Purdue University College of Pharmacy, West Lafayette, Indiana

Alicia Forinash, PharmD, FCCP, BCPS, BCACP (10)

Professor of Pharmacy Practice and PGY2 Ambulatory Care Residency Program Director, St. Louis College of Pharmacy, St. Louis, Missouri; and Clinical Pharmacy Specialist, Maternal & Fetal Care Center, SSM Health at St. Mary's, Clayton/Richmond Heights, Missouri

Karla T. Foster, PharmD, BCPS (19)

Pharmacist, Walgreens Company, Ridgeland, Mississippi

Andrea R. Franks, PharmD, BCPS (17)

Professor and Vice Chair for Education, Department of Clinical Pharmacy, University of Tennessee Health Science Center College of Pharmacy, Knoxville; and Associate Professor, Department of Family Medicine, University of Tennessee Graduate School of Medicine, Knoxville

Randolph V. Fugit, PharmD, BCPS (13)

Internal Medicine Clinical Specialist, Denver Veterans Affairs Medical Center, Denver, Colorado; and Associate Clinical Professor, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Anschutz Medical Campus, Aurora

Margaret Goldberg, RN, MSN, CWOCN (22)

Wound Ostomy and Continence Nursing Consultant, Delray Wound Treatment Center, Boca Raton, Florida

Justin Gollon, RN, PharmD, BCPS, BCNSP (25)

Clinical Staff Pharmacist, The University of Arizona Medical Center, Tucson

William C. Gong, PharmD, FASHP, FCSHP (2)

Associate Professor, Department of Clinical Pharmacy, and Director, Residency and Fellowship Programs, University of Southern California School of Pharmacy, Los Angeles

Yasmin Grace, PharmD (16)

Associate Professor, Department of Pharmacy Practice, Palm Beach Atlantic University Lloyd L. Gregory School of Pharmacy, West Palm Beach, Florida

Erica Pascale Greene, PharmD, (32)

Clinical Pharmacy Specialist–Ambulatory Care, Saint Vincent Hospital, Erie, Pennsylvania

Ashley Hannings, PharmD, BCACP (35)

Public Service Associate, Experience Programs, and Associate IPPE Director, Ambulatory Care, University of Georgia College of Pharmacy, Athens

Anne Haring, PharmD (13)

Assistant Professor, Department of Pharmacy Practice, Palm Beach Atlantic University, Lloyd L. Gregory School of Pharmacy, West Palm Beach, Florida

Brian A. Hemstreet, PharmD, FCCP, BCPS (20)

Assistant Dean for Student Affairs, and Professor, Department of Pharmacy Practice, University of Colorado Skaggs School of Pharmacy and Pharmaceutical Sciences, Anschutz Medical Campus, Aurora

Morgan Sayler Herring, PharmD, BCPS (44)

Clinical Associate Professor, Department of Pharmacy Practice, University of Iowa College of Pharmacy, Des Moines; and Clinical Pharmacist, Iowa Lutheran Hospital Family Medicine Residency Program, Des Moines

Michelle L. Hilaire, PharmD, FCCP, CDE, BCPS, BCACP (28)

Associate Dean of Student Affairs–College of Health Sciences, Chair of the Department of Pharmacy Practice, and Clinical Professor, University of Wyoming School of Pharmacy, Laramie; and Clinical Pharmacist, Fort Collins Family Medicine Residency Program, Fort Collins, Colorado

Alexander Hoffman, PharmD, BCPS, CDE (47)

Associate Professor of Pharmacy Practice, Northeast Ohio Medical University College of Pharmacy, Rootstown; and Ambulatory Care Clinical Pharmacist, University Hospitals of Cleveland, Cleveland, Ohio

Timothy R. Hudd, BS, PharmD, RPh, AE-C (30)

Professor, Department of Pharmacy Practice, Massachusetts College of Pharmacy and Health Sciences University, Boston; Clinical Pharmacist, Lowell General Hospital – Primary Care of the Andovers, North Andover, Massachusetts; and Chair, Executive Committee, National Asthma Educator

Certification Board, Puyallup, Washington

Tannis Jurgens, BSc (Pharm), MSc, PhD (51)

Professor, Medicinal Chemistry and Natural Health Products, Dalhousie University College of Pharmacy, Halifax, Nova Scotia

Julie Kalabalik-Hoganson, PharmD, BCPS, BCCCP (7, 51)

Director and Associate Professor, Department of Pharmacy Practice, Fairleigh Dickinson University School of Pharmacy and Health Sciences, Madison, New Jersey

Pramodini B. Kale-Pradhan, PharmD, FCCP (12)

Professor (Clinical), Department of Pharmacy Practice, Eugene Applebaum College of Pharmacy and Health Sciences, Wayne State University, Detroit, Michigan; and Clinical Specialist – Infectious Diseases, Department of Pharmacy Services, Ascension St. John Hospital, Detroit, Michigan

Roaa M. Khinkar, PharmD (50)

Quality and Safety Fellow, Department of Quality and Safety, Brigham and Women's Hospital, Boston, Massachusetts

Cynthia King, PharmD, BCACP, CACP (47)

Clinical Assistant Professor, Department of Pharmacy Practice, Northeast Ohio Medical University College of Pharmacy, Rootstown; and Ambulatory Care Pharmacy Specialist, Pharmacy Residency Program Coordinator, MetroHealth Medical Center, Cleveland, Ohio

Joshua Davis Kinsey, PharmD (45)

Clinical Assistant Professor, Department of Pharmacy Practice, and Director, Community Pharmacy Residency Program, Mercer University College of Pharmacy, Atlanta, Georgia

Erika Kleppinger, PharmD, BCPS (29)

Associate Clinical Professor, Department of Pharmacy Practice, Auburn University Harrison School of Pharmacy, Auburn, Alabama

Laura E. Knockel, PharmD, BCACP (5)

Clinical Assistant Professor, Department of Pharmacy Practice and Science, Division of Applied Clinical Sciences, University of Iowa College of Pharmacy; and Ambulatory Care Clinical Pharmacist, University of Iowa Hospitals and Clinics, Iowa City, Iowa

Daniel L. Krinsky, MS, RPh, FAPhA (37)

Founder and President, EduCare4U, LLC; Co-Founder and Co-Owner, PGx101, LLC; and Adjunct Professor, Lake Erie College of Osteopathic Medicine (LECOM) School of Pharmacy, Stow, Ohio

Gregory M. Kwiatkowski, PharmD, BCPS (5)

Clinical Pharmacist, Department of Pharmacy, Spectrum Health, Grand Rapids, Michigan

Karen W. Lee, PharmD, BCPS (11)

Regional Vice President of Clinical Services, Comprehensive Pharmacy Services, Roxbury, Massachusetts

Jeannie K. Lee, PharmD, BCPS, BCGP, FASHP (52)

Assistant Dean, Student Services, and Associate Professor, Department of Pharmacy Practice and Science, The University of Arizona College of Pharmacy, Phoenix; and Clinical Associate Professor, Division of Geriatrics, Department of General Internal Medicine and Palliative Medicine, The University of Arizona College of Medicine, Phoenix; and Research Associate and Faculty, Arizona Center on Aging, Tucson

Nicholas Leon, PharmD (30)

Associate Professor of Pharmacy Practice, Thomas Jefferson University Jefferson College of Pharmacy, Philadelphia, Pennsylvania

Emily Leppien, PharmD, BCPS (32)

Clinical Assistant Professor, Department of Pharmacy Practice, Binghamton University State University of New York School of Pharmacy and

Pharmaceutical Sciences, Binghamton, New York

Phil Lewis (25)

Director, Sports Nutrition, The University of Arizona, Tucson, Arizona

Janene Marie Madras, BS Pharm, PharmD, BCPS, BCACP (32)

Director of Student Services and Professor, Department of Pharmacy Practice, Lake Erie College of Osteopathic Medicine (LECOM) School of Pharmacy–Erie Campus, Erie, Pennsylvania

Marina L. Maes, PharmD, BCPS, BCACP (9)

Assistant Professor, Pharmacy Practice, University of Wisconsin– Madison School of Pharmacy

Michele L. Matthews, PharmD, CPE, BCACP, FASHP (7)

Professor of Pharmacy Practice, Massachusetts College of Pharmacy and Health Sciences University, Boston; and Advanced Practice Pharmacist – Pain Management, Brigham and Women’s Hospital, Boston, Massachusetts

Melissa Mattison, PharmD (35)

Clinical Associate Professor of Pharmacy Practice, Community Patient Care Center, Western New England University College of Pharmacy, Springfield, Massachusetts

Abigale T. Matulewicz, PharmD (43)

Assistant Professor, Department of Pharmacotherapy and Outcomes Science, Virginia Commonwealth University School of Pharmacy, Falls Church, Virginia

Jamie Lynn McConaha, PharmD, CTTS, BCACP, CDE (40)

Associate Professor, Department of Pharmacy Practice, Duquesne University School of Pharmacy, Pittsburgh, Pennsylvania

Marsha McFalls, PharmD, MEd, RPh (41)

Assistant Professor, Division of Pharmacy Practice; Director, Educational

Technology; and Director, Distance Learning Program and Online Program, Duquesne University School of Pharmacy, Pittsburgh, Pennsylvania

Bella H. Mehta, PharmD, FAPhA (51)

Professor–Clinical, Department of Pharmacy Practice and Science, and Director, Continuing Professional Development, The Ohio State University College of Pharmacy, Columbus, Ohio

Jill E. Michels, PharmD, DABAT (21)

Director, Palmetto Poison Center, and Associate Professor, Department of Clinical Pharmacy and Outcomes Sciences, University of South Carolina College of Pharmacy, Columbia

Sarah J. Miller, PharmD, MS, BCNSP (23)

Professor, Department of Pharmacy Practice, University of Montana College of Health, Missoula

Amee D. Mistry, PharmD (34)

Associate Professor, Department of Pharmacy Practice, and Director, Postdoctoral Biopharmaceutical Industry Fellowship Program, Massachusetts College of Pharmacy and Health Sciences University, Boston

Wendy Mobley-Bukstein, PharmD, BCACP, CDE, CHWC, FAPhA (15)

Associate Professor of Pharmacy Practice, Drake University College of Pharmacy, Des Moines, Iowa

Leigh Anne Nelson, PharmD, BCPP (46)

Associate Professor, Division of Pharmacy Practice and Administration, University of Missouri–Kansas City School of Pharmacy

Kimmy Nguyen, PharmD, BCACP (44)

Assistant Professor, Department of Pharmacy Practice, Wilkes University Nesbitt School of Pharmacy, Wilkes-Barre, Pennsylvania

Monika M. Nuffer, PharmD (51, 52)

Academic and Experiential Program Coordinator, and Senior Instructor, Department of Clinical Pharmacy, Skaggs School of Pharmacy and Pharmaceutical Sciences, Anschutz Medical Center, Aurora, Colorado

Erin Nystrom, PharmD, RPh, BCNSP (23, 27)

Clinical Pharmacy Specialist, Alluma, Irving, Texas; and Assistant Professor of Pharmacy, Clinical Pharmacy Specialist – Nutrition Support, Mayo Clinic College of Medicine and Science, Rochester, Minnesota

Shanna O'Connor, PharmD (34)

Clinical Assistant Professor, Department of Pharmacy Practice, Idaho State University College of Pharmacy, Boise, Idaho

Rachel R. Ogden, PharmD, MS Med Ed, BCGP, FASCP (12)

Dean and Professor of Pharmacy Practice, Lake Erie College of Osteopathic Medicine (LECOM) School of Pharmacy–Erie Campus, Erie, Pennsylvania

Phung C. On, PharmD, BCPS (7)

Notice

Drug therapy and other treatment information are evolving constantly, because of ongoing research and clinical experience, and are often subject to interpretation. The publisher, editors, authors, and other contributors have made every effort to ensure the accuracy and completeness of the information presented in this publication. However, these parties cannot be held responsible for the continued accuracy of the information, any inadvertent errors or omissions, or the application of this information, and shall have no liability to any person or entity with regard to claims, loss, or damage caused or alleged to be caused, directly or indirectly, by the use of the information contained herein. Readers are advised that decisions regarding any treatment, including drug therapy, must be based on the independent judgment of the clinician, changing information about a treatment or drug (e.g., as reflected in the literature and manufacturer's most current product information), and changing medical practices.

The authors and other contributors have written this book in their private capacities. No official support or endorsement by any federal or state agency or pharmaceutical company is intended or inferred.

Foreword

Since 1967, the American Pharmacists Association's (APhA) *Handbook of Nonprescription Drugs: An Interactive Approach to Self-Care* has been the definitive resource for pharmacists and other health care providers as they guide patients in pursuit of high-quality self-care. This twentieth edition continues the proud tradition of providing generations of pharmacists with the comprehensive content they have come to expect from APhA.

And now more than ever, they need it.

The United States is the world's largest market for nonprescription products. According to the Consumer Healthcare Products Association, annual spending on these products is approaching \$40 billion. This number is likely to rise. Growth in self-care is fueled partly by an increase in direct-to-consumer advertising of prescription and nonprescription medications. Information obtained from television commercials, newspaper and magazine advertisements, the internet, and health-related articles also have empowered consumers to make decisions about their health care.

The 2012 National Health Interview Study reported that Americans are increasingly using natural products—also known as dietary supplements—other than vitamins and minerals for self-treatment: 17.7% of U.S. citizens older than 18 years of age and 4.9% of children between the ages of 4 and 17 years. The use of complementary alternative medicine (CAM) therapies, dietary supplements, nondrug measures, diagnostic tests, and medical devices also is changing self-care. Unlike nonprescription medications, no federal regulatory agency evaluates the safety and effectiveness of CAM therapies.

Individuals who wish to self-treat minor health disorders are faced with a staggering number of single-entity and combination nonprescription products, and they may lack adequate information to determine whether their medical disorder is amenable to self-treatment and whether the self-selected treatment is appropriate for them. An anticipated increase in the number of prescription medications that will be reclassified as nonprescription will provide new self-care possibilities.

Expanded options mean more complexity and more demand for pharmacists'

expertise.

Limited clinical evidence as to self-care products' safety and effectiveness, and the potential for serious adverse events when they are combined with prescription or nonprescription medications, puts health care providers' expertise on alternatives to traditional medications at a premium. We must be ready to provide therapeutic information and guidance to our patients. This responsibility requires pharmacists to be on the cutting edge: The twentieth edition of the *APhA Handbook of Nonprescription Drugs: An Interactive Approach to Self-Care* will help you get and stay there.

The information in this edition also is available online through the subscription-based PharmacyLibrary portal at www.pharmacylibrary.com. Here you will find the complete *Handbook* content along with many other complementary resources. Through PharmacyLibrary, APhA also is publishing additional case studies to reinforce key concepts discussed in these chapters.

I am so honored to be the chief executive officer (CEO) of the organization that created this esteemed resource for all health care educators, students, and providers engaged in self-care. This text is a jewel among APhA's excellent and up-to-date resources, and we are exceedingly proud of it.

Scott Knoer, MS, PharmD, FASHP

Executive Vice President & CEO

American Pharmacists Association

Preface

The newly revised and updated twentieth edition of the *Handbook of Nonprescription Drugs: An Interactive Approach to Self-care* is a comprehensive and authoritative textbook on self-care and nonprescription medications. Written and reviewed by experts in practice and academia, this edition of the *Handbook* continues to serve as an authoritative source for students and health care providers who guide and care for individuals undertaking self-treatment. The major goals for this edition were to

- enhance the content in all chapters from the previous edition with up-to-date information that is beneficial to all health care providers and students.
- update the objectives to complement the content in the chapters that focus on medical disorders.
- create an accompanying “Emerging Issues” chapter (available at pharmacylibrary.com/updates) that will provide information on evolving self-care topics that do not fit into any of the published chapters.

This edition remains true to the spirit of previous editions, that is, to assist health care providers and students in developing the knowledge and problem-solving skills needed to

- assess a patient’s health status, medical problems, and current practice of self-treatment, including nonprescription and prescription medications, dietary supplements, and other self-care measures.
- determine whether self-care and/or self-testing and monitoring are necessary and/or appropriate.
- recommend safe and effective self-care measures, taking into account the patient’s treatment preferences, where appropriate.
- Removal of the pregnancy risk categories for all drugs and natural products, and subsequently, the removal of the two appendices that focused on pregnancy risk information.

The following explains the reasoning for this decision:

In 2015 the Food and Drug Administration (FDA) implemented the

Pregnancy and Lactation Labeling Rule (PLLR), which replaces the former pregnancy risk letter categories (A, B, C, D, X) for prescription drugs with more descriptive content in the following fields^{1,2}:

- Pregnancy: now includes labor and delivery
- Lactation
- Females and males of reproductive potential

Although this new categorization provides clinicians with more detail for decision making, clinicians still need to apply this information on a case-by-case basis. The PLLR will be implemented in phases, with the final phase to be completed by June 29, 2018. However, this rule is not applicable to self-care and nonprescription products.

Previous editions of the *Handbook* have included pregnancy risk letter designations, where available, and oftentimes this was based on the designation for the prescription version of the medication. With the changes that have taken place and the lack of support for letter designations to identify pregnancy risk, the editors decided to remove any reference to a pregnancy risk category within chapters, and to remove both appendices. Where this information appeared previously we now include general language that supports the reader in determining, based on available literature, what is best for their particular patient in each situation. The following is the standard language in all chapters that mention medication or product use in pregnancy:

- See the Preface for a detailed explanation of the pregnancy data.
- Use in pregnancy should be limited to clinical situations in which the potential benefit justifies potential risk to the fetus

Where a pregnancy issue exists for a nonprescription product, the Drug Facts Label states that the consumer should ask a health care professional before using the product if she is pregnant or breastfeeding. FDA is aware of the limitations of the Drug Facts Label for communicating complex issues such as pregnancy labeling. They attempt to ensure nonprescription labeling is as consistent as possible with the prescription drug labels when a drug is available in both forms. However, the challenge with nonprescription products is to provide information that consumers can understand but is detailed enough to address any concerns. FDA is aware of the inconsistencies this situation has created and, at the time of this writing, was discussing options to

enhance the pregnancy content for nonprescription products.

As with the previous edition, an online version of the book resides on APhA's digital platform PharmacyLibrary (www.pharmacylibrary.com), which allows regular updating and/or revision of chapters. With this edition, purchasers of the print book will have access to the online updates and revisions at <https://pharmacylibrary.com/updates>. For the print and online versions of the book, two new comprehensive patient cases per chapter are included; these cases are based on the revised nineteenth edition case format. The online version of the book provides additional cases that are based on the abbreviated case format used in previous editions.

Self-care opportunities exist for many individuals with myriad health disorders. The discussion of these disorders in this book lends itself to the following objectives. For each patient complaint

- identify its most likely underlying cause(s).
- identify common signs and symptoms.
- determine whether the complaint is amenable to self-care, the patient requires referral, or nothing needs to be done.
- identify the FDA-approved monograph active ingredient(s) in a given nonprescription drug category or drug that would best treat the complaint.
- determine common side effects for a drug or a given category of nonprescription drugs.
- determine contraindications to the use of a given drug or category of nonprescription drugs or devices.
- distinguish indications and limitations for use of a given drug or category of nonprescription drugs or devices.
- explain nondrug measures commonly used in treatment or prevention.
- develop an appropriate care plan for a given patient who seeks self-care advice.
- formulate a list of key counseling points to educate a patient on the appropriate use of a nonprescription drug, nondrug measures, or a device.

Considerable time and effort have been invested in improving this edition. We are hopeful that each of the chapter enhancements and updates improves the quality and usability of the book, as well as provides increased clarity and convenience.

Chapter Content

All disorder-related chapters in this edition include the following features and information:

- Up-to-date information on nonprescription medications, including indications, dosages, interactions, supportive evidence for efficacy and safety, medical disorders or symptoms amenable to self-treatment, prescription-to-nonprescription reclassifications, and nonprescription drug withdrawals from the market
- Treatment algorithms that outline triage and treatment
- Controversies in self-care therapeutics
- Self-care treatment or prevention guidelines
- Product tables with examples of specific nonprescription products
- New nonprescription medications and dietary supplements, including nutrition-related dietary supplements, such as vitamins and minerals, which are discussed in the nutrition section of the book

Chapter Features

Most chapter features remain unchanged and are intended to promote an interactive approach to self-care. Students and health care providers can use these features to develop or improve problem-solving and critical thinking skills.

- Disorder-related chapters are grouped primarily according to body systems. These chapters begin with a discussion of the epidemiologic, etiologic, and pathophysiologic characteristics and the clinical manifestations of the disorder. These discussions are followed by a comprehensive discussion of self-care options. The inclusion of dietary supplements, as well as nonpharmacologic and preventive measures, completes the discussion of self-care options. Information about one preventive measure, vaccines, is incorporated in chapters in which the content is deemed synergistic.
- Case studies, treatment algorithms, comparisons of self-treatments, patient education boxes, and product selection guidelines foster an interactive therapeutic approach to learning.

- The case studies in the Handbook utilize the Pharmacists' Patient Care Process (PPCP) format which is described in detail in [Chapter 2](#). The online case studies utilize the QuEST/SCHOLAR-MAC process. These are consistent with previous editions.
 - Sections on the evaluation of patient outcomes reinforce follow-up of patients who are self-treating. This section defines the parameters for confirming successful self-treatment and those that indicate the need for medical referral.
 - Chapters include tables that list interactions (drug–drug, drug–supplement, drug–nutrient), as well as dosage and administration guidelines.
 - At the end of each chapter, authors provide a list of key points. These are intended to serve as a summary of critical information in the chapter and can be an excellent resource for educators.
 - Authors provide comparisons of agents based on clinical studies of safety and efficacy, as well as product selection guidelines based on patient factors and preferences.
 - Authors discuss the role of nonprescription therapies among the available treatment options for a specific disorder and describe other options in the event that nonprescription therapy fails or is not appropriate.
 - The book's organization and content allow students and health care providers to quickly identify the information needed to make a treatment recommendation and to counsel patients.
-

Acknowledgments

We would like to acknowledge the hundreds of individuals who contributed to the new edition of this textbook. We are grateful to each of the authors and reviewers who contributed to this comprehensive and authoritative textbook. These individuals were selected from many practice settings and health professions throughout the country. Their scholarship and clinical experience reflect a broad perspective and interdisciplinary approach to patient care. The dedication of the authors and reviewers in ensuring that the chapters were accurate, comprehensive, balanced, and relevant to practice and of the highest quality is deeply appreciated.

The editors of this edition also want to acknowledge the contributions of

previous editors, authors, reviewers, and the many health care providers, students, residents, and others who have helped make the *Handbook of Nonprescription Drugs* the premier resource for self-care content. We also want to thank the staff of the American Pharmacists Association, in particular John Fedor, Jesse Vineyard, and Janan Sarwar, for their ongoing support of our vision for the content and its incorporation into the print version and the online version available at PharmacyLibrary.com.

We would like to convey a very special thanks to Linda Young, our managing editor. Once again Ms. Young provided invaluable guidance and support to the editors, authors, and reviewers in all aspects related to the publication of this edition. She contributed to the copyediting of chapters, and managed the design, editorial, and composition stages of the book. Without her tireless efforts, experience, and attention to detail, the improvements in this edition would not have been possible.

We are confident that the combined efforts of these individuals will ensure that the *Handbook of Nonprescription Drugs: An Interactive Approach to Self-Care* continues to serve as the worldwide practice and teaching resource on self-care and nonprescription products.

Chapter 1: Self-Care and Nonprescription Pharmacotherapy

Authors: Jenelle L. Sobotka, Barbara A. Kochanowski

This chapter introduces the concept of self-care, delineates characteristics of today's self-care consumer, and examines the growing importance of self-care in modern health care systems. *Self-care*, as defined by the Global Self-Care Federation, is “[t]he practice of individuals looking after their own health using the knowledge and information available to them. It is a decisionmaking process that empowers individuals to look after their own health efficiently and conveniently, in collaboration with health and social care professionals as needed.”¹ As discussed in this chapter, the pharmacist has a key role in providing assistance, advice, and information to address self-care needs. An overview of the self-care marketplace, as well as the legislative and regulatory environment, is presented first, with a brief perspective on future changes expected for expansion of self-care and related health care technology.

Broad public education has been shown to be a key factor in advancing the consumer's role in prevention of illness and general health management; accordingly, several public education programs are reviewed in this chapter to illustrate pharmacists' role in supporting this effort. The chapter concludes by reviewing the roles of the pharmacist and student pharmacist in assisting patients with their self-care needs, while emphasizing the key elements of safety and efficacy in the management of self-care conditions.

The Expanding Definition of Self-Care

A simple definition of *self-care* is as the independent act of preventing, diagnosing, and treating one's illnesses with or without seeking professional advice. However, self-care definitions can vary according to one's perspective, with health care professionals' definition frequently differing from that of the general public. Health care providers (e.g., doctors, pharmacists, nurses) typically consider self-care to include the clinical management of self-care conditions and use of relevant self-care products available to patients without a prescription. Health care providers who wish to acknowledge the expanded role for today's pharmacists would add that self-care should include assistance

in determining whether a patient's condition is appropriate for self-care. Pharmacists are accessible to patients when most self-care decisions are made and are valuable experts in this area. A pharmacist can help the patient improve by recommending the best nonprescription product for treatment of the condition and/or identifying beneficial nonpharmacologic measures (e.g., dietary or lifestyle changes). Such measures also may be helpful to prevent further occurrences of the condition. In this context, the process becomes "pharmacist-assisted self-care." The primary focus of this book is the pharmacist's role in this process but also introduces roles that student pharmacists can assume as they develop their patient care skills for self-treatable conditions. Other health care providers (e.g., nurse practitioners, physician assistants) who also may be involved in advising patients on self-care will find significant applications of the concepts, content, and processes provided in this book.

Consumers' perspective and their definitions of self-care can differ considerably from those of health care providers. When consumers were asked to describe what self-care involves, their responses went far beyond the use of nonprescription medications.² The consumers listed healthy habits, such as diet and exercise, but they also noted other important aspects of self-care: screenings and wellness check-ups, preventive care, consultations with doctors, and their own participation in deciding how to deal with a health problem. All of these factors represent consumers' increasing interest in and expectation to be accountable for their own health and wellness. In the United States, "personal accountability" to manage and improve health is expanding the general public's definition of self-care.

The engagement of a health care provider easily differentiates pharmacist-assisted self-care from self-care. However, when does pharmacist-assisted self-care undergo transition to primary care in a more contemporary health care system? Many people who are not health care professionals turn to Wikipedia to find common definitions. Wikipedia defines *primary care* as "the day-to-day health care given by a health care provider. Typically, this provider acts as the first contact and principal point of continuing care for patients within a health care system, and coordinates other specialist care that the patient may need."³ Is the pharmacist considered a health care provider under this definition? Is the pharmacist serving as the first point of contact and a principal point of ongoing care for the patient? Many would answer "yes" to these questions, in recognition of pharmacists' evolving role in providing patient care services and

medication therapy management (MTM) in their practice settings. In addition, state and federal legislation to secure pharmacists' recognition as "health care providers" is further advancing this belief.⁴ Continued delivery of patient care services, such as immunizations and point-of-care testing, also will advance the public's recognition of pharmacists as primary care providers. In the future, these efforts will contribute to further blurring of the distinguishable differences between pharmacist-assisted self-care and primary care delivery by pharmacists.

The patient-centered care model of health care delivery is gaining popularity as part of ongoing health care reform in the United States. The Institute of Medicine defines *patient-centered care* as "providing care that is respectful of and responsive to individual patient preferences, needs, and values, and ensuring that patient values guide all clinical decisions."⁵ This definition implies that patients and their team of health care providers must have a strong partnership and make decisions together based on the patient's desires and priorities for his or her health goals. As John Gans, former chief executive officer of the American Pharmacists Association (APhA), often said, "All care is self-care!" His point was that the patient is always in charge and will make the final decision on implementing any actions to try to improve his or her health. A key area of emphasis in the patient-provider partnership is the recognition and integration of cultural beliefs, values, and traditions, because these also play an important role in a patient's personal health care decisions. (See [Chapter 3](#) for further discussion of cultural competency in health care.) Furthering advancements in patient-centered, team-based care will involve an interprofessional team of providers who honor the health care priorities of the patient.

It also is important to note that self-care involves the full spectrum of care, including prevention and wellness strategies, diagnosis and screening, and measures for treatment of or relief from symptoms. Preventive self-care involves maintaining well-being and appearance, both subjective and objective, through a healthy lifestyle. For many people, a healthy lifestyle includes controlling the diet; taking vitamins, minerals, and herbal supplements; participating in regular exercise and keeping fit; and maintaining physical appearance with use of dental, skin, and hair care products. By contrast, self-care for persons who are ill involves identifying (diagnosing) the responsible condition and then obtaining products for mitigating illness and relieving symptoms. Examples of selfcare measures in

illness are dietary options (e.g., consuming hot soup for a cold); utilization of certain medical devices for both disease assessment (e.g., home blood glucose meters, cholesterol tests) and treatment (e.g., ice packs, first aid bandages, vaporizers, nasal strips); and use of nonprescription medications (e.g., pain relievers, cold medicines). The use of self-care products typically is limited to cases involving mild illness or short-term management of more acute conditions, and most products warn users to contact a health care provider if improvement is not obtained within a short period of time. In some instances, however, self-care involves long-term management of ongoing symptoms or chronic conditions with nonprescription medications, even when such regimens are recommended by a physician. For example, acetaminophen may be used for the ongoing management of arthritis pain. [Figure 1-1](#) provides a depiction of the self-care continuum, extending from “pure self-care with individual responsibility” to “pure medical care with professional responsibility,” as described by the Self Care Forum.⁶

Globally, both the importance of self-care in the overall health care spectrum

and the role of the pharmacist are gaining additional visibility. In 2017, the International Pharmaceutical Federation (FIP) released both a reference paper and a policy statement on self-care.^{7,8} The reference paper provides a global view of the growing role of pharmacists in self-care and improvement of population health around the world. The policy statement provides recommendations to government agencies and insurers, pharmacy organizations, and pharmacists to advance the adoption of selfcare in health systems around the world. These documents serve as position statements and educational tools for promoting the growing role of pharmacists in self-care to improve global health.

The FIP reference paper refers to an earlier 2005 report from the London Department of Health that highlighted the large role that self-care plays in the total health care model (Figure 1-2).⁹ For professional care, Figure 1-2 includes primary health care as basic medical care, along with secondary and tertiary health care as more complex medical care services (e.g., specialist physicians, intensive hospitalization care). Self-care, when compared with professional care, is shown to be a much larger component in the individual patient's overall health care experience. The FIP paper also references the same London Department of Health report for promoting the importance and supporting the value of self-care behaviors for improved population health, as shown in Figure 1-3.⁹ Professional care for treatment of minor ailments, acute illness, and long-term conditions is depicted in the crescent-shaped area of the oval section on the right of the model. The patient's self-management of these same minor, acute and long-term health conditions is depicted as a larger component of the oval. To the left in the model, preventive self-care measures, important for good health and illness prevention, are depicted as a large component of self-care that does not involve professional care. Again, this model conveys visually the important concept of the very significant role of self-care within the overall health care spectrum. The lower section of the model identifies many important elements for supporting patients' self-care measures. Pharmacists would use most of these elements as tools and processes to assist their patients in implementing self-care approaches.

Most care is shared care and can involve a small or large component of self-care.

Figure 1–3 Self-care and self-care support. (Source: Adapted from [reference 9](#) with the permission of the Department of Health, UK.GOV; contains public sector information licensed under the Open Government Licence v1.0.)

The International Self-Care Foundation offers additional evidence of the broad scope of self-care, as illustrated by their seven pillars of self-care, shown in photograph 1 of the [Color Plates](#) and outlined in [Table 1–1](#).¹⁰ Clearly, self-care is significant to global health care to manage or treat active conditions and to address preventive health and wellness.

Table 1–1 Seven Pillars of Self-Care as Defined by the International Self-Care Foundation

Self-Care Component	Description
Health literacy	Includes the capacity of people to obtain, process, and understand basic health information and services needed to make appropriate health decisions
Self-awareness of physical and mental condition	Includes knowing one’s BMI, cholesterol level, and blood pressure; engaging in health screening
Physical activity	Practicing moderate intensity physical activity, such as walking

Self-Care Component	Description
	or cycling, or participating in sports at a desirable frequency
Healthy eating	Includes eating a nutritious, balanced diet with appropriate level of caloric intake
Risk avoidance or mitigation	Includes quitting tobacco use, limiting alcohol use, being vaccinated, practicing safer sex, and using sunscreen
Good hygiene	Includes washing hands regularly, brushing teeth, and washing food before consumption
Rational and responsible use of products, services, diagnostics, and medications	Includes being aware of dangers, using responsibly when necessary

key: BMI = Body mass index.

Understanding Today's Self-Care Consumer

Consumers today are motivated and empowered by their ability to use self-care to manage their health. They feel less dependent on physicians and want more control over their health care. Consumers appreciate the availability and convenience of nonprescription medications that enable them to self-treat minor illnesses or injuries, thus avoiding unnecessary inconvenience and copays for treatment from a medical provider.

A survey by the Consumer Healthcare Products Association (CHPA) asked consumers for their perspectives on the role of nonprescription medications in their self-care.¹¹ A key finding was that consumers trust nonprescription medications, when they are available, for health care management for themselves and their children. Key drivers of trust were effectiveness, adverse effects, and doctor recommendation. Consumers also prefer using a nonprescription over a prescription medication for first-line therapy and for certain ailments such as pain, cough and colds, acid reflux, and upset stomach. Additional data collected in the survey “Your Health at Hand: Perceptions of Over-the-Counter Medicine in the U.S.” support the view that both consumers

and physicians recognize the role of nonprescription medications in self-care. Key survey results include the following¹²:

- 93% of physicians believe that medications for minor ailments should be available over the counter.
- 96% of consumers believe that nonprescription medications make it easy to care for minor medical ailments.
- 87% of physicians and 89% of consumers believe that use of nonprescription medications is an important part of overall and family health care.
- 93% of adults prefer to treat minor ailments with nonprescription medications before seeking professional care.
- 88% of physicians recommend that patients address minor ailments with self-care, including the use of nonprescription medications, before seeking professional care.

Today's consumers also are much more knowledgeable about health care products and health care in general. In addition, consumers are more motivated to focus on their health and wellness. For example, consumers are making lifestyle changes, such as drinking more water, taking supplements and vitamins, and eating and exercising more responsibly. Employers, through employee wellness programs, also are offering incentives to improve health. Nearly 90% of employers now offer wellness incentives, such as financial rewards or prizes, to employees who work toward becoming healthier.¹³

The CHPA survey also showed that one in four respondents self-identified as a “family health influencer” based on being knowledgeable about nonprescription medications and playing a role in educating others in the family about their self-care options.¹⁰ These influencers report that they are knowledgeable about different nonprescription medications, they avoid going to the doctor unless they absolutely have to, and they choose a medication on the basis of the symptoms it will treat. The family health influencer is more likely to be female, and many are mothers in the family unit. In addition, the survey found that multigenerational households, Hispanic households, and households that provide care for an adult outside the home place a high value on a pharmacist's or other in-store health care provider's recommendations. Health care providers must acknowledge and partner with this family health influencer in their caregiver role for the family. Other influencers also may be involved in decision making, as depicted in [Figure 1-4](#).¹¹

Figure 1–4 Influencers of consumers’ self-treatment decisions. (Source: Reference 11.)

Internet sources of health information have become increasingly popular across all age groups and demographic populations. Web-based health information is easily and rapidly accessed in the privacy and comfort of one’s home. According to a 2013 Pew Internet and American Life Project report, 59% of U.S. adults searched for online health information in the previous year.¹⁴ Most health information seekers, 77%, begin with a major search engine, such as Google, Yahoo, or Bing, whereas another 13% use a more health-specific site such as WebMD. The report has identified approximately one third of adults (35%) as “online diagnosers” because they have gone online to diagnose their own or someone else’s medical condition.

Consumers who were most likely to search for health information online were white adult women with higher levels of education and income. Dependence on the internet for self-care information can be problematic. No single organization is accountable for the quality or accuracy of health-related information available on websites. The sheer number and diversity of internet sources increase the likelihood that patients may unknowingly view biased or outdated information. When asked if the information found online led them to think they needed the attention of a medical professional, 46% of online diagnosers answered “yes,” demonstrating the potential role for a pharmacist to provide accurate information and answer questions. All health care providers, including pharmacists, should assist their patients in identifying credible resources for health information. A number of valid internet sources are available to provide information on nonprescription drugs; these include the National Institutes of Health (www.nlm.nih.gov/medlineplus) and websites such as those for the Cleveland Clinic (www.clevelandclinicmeded.com), WebMD (www.webmd.com), the Mayo Clinic (www.mayoclinic.com), and the CHPA Educational Foundation (www.knowyourOTCs.org).

In addition to increased access to health care information, consumers need to be able to understand basic health information to make appropriate health decisions. *Health literacy* is the umbrella term that refers to “the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health

decisions.”¹⁵ Health literacy includes numeracy skills, for example, understanding laboratory values, selecting the proper dose of a medication, and reviewing medical bills. The National Assessment of Adult Literacy showed that only 12% of adults have proficient health literacy and 30% of adults have below-basic levels of health literacy.¹⁵ Health literacy affects people’s ability to navigate the health care system in a variety of areas: filling out forms, locating physicians and services, discussing their health information, and selecting a community pharmacy and pharmacist to support their engagement in self-care. Low-level literacy has been linked to poor health outcomes, such as higher rates of hospitalization and less frequent use of preventive services.¹⁵

Health care providers need to be aware that health literacy varies across the population they serve and that they may need to tailor their own language to try to match the patient’s skill level. One approach is to use “plain language”—that is, communication that patients can understand the first time they read or hear it. Key components of plain language include putting the most important points first, breaking complex concepts into chunks (small bits of information), adhering to simple wording, defining technical or medical terms, and using the active voice in which the subject performs the action. Resources for more information include Plain Language.gov (www.plainlanguage.gov) and the Centers for Disease Control and Prevention (CDC) health literacy training module (www.cdc.gov/healthliteracy/training).

The changing demographics of this country’s population also are changing the profile of the self-care consumer. The growth of the older population, whose members are heavy users of nonprescription medications, will continue to expand the self-care consumer base. The results of the 2017 National Projections by the U.S. Census Bureau found that by 2030, all baby boomers will be older than 65 years of age.¹⁶ The average life expectancy for Americans has increased, with people who attain 65 years expected to live an additional 16–22 years, depending on gender and race. The fastest growing segment of the elderly population is that consisting of persons older than 85 years. The racial and ethnic diversity of the older population also will change as the populations of Hispanic and non-White groups increase. These specific groups will have a significant impact on the future of U.S. health care policy and the health care system as their individual members deal with illness and disability and need longterm care and other resources.

The growth in minority populations in the United States will drive a need for

cultural considerations in self-care recommendations. [Chapter 3](#) provides details on cultural considerations in self-care. [Chapter 2](#) provides additional details on self-care for special populations, including geriatric patients, infants and children, and pregnant and breastfeeding patients.

In summary, today's consumer is more empowered and more likely than ever before to take charge of his or her health, often turning to nonprescription medications as first-line therapy options for a variety of conditions. In the decades ahead, the older population will continue to expand and will need information and health care resources, including pharmacists, to manage their health.

Self-Care Changes Driven by Health Care Reform and Changes in Pharmacy Practice

In addition to the consumer factors that affect self-care utilization, notable drivers for self-care utilization are arising from the reform occurring in the U.S. health care system. The passage of the Affordable Care Act (ACA) in 2010 was a key factor in stimulating health care reform. The legislation called for changes to many areas of the U.S. health care system, with a focus on increasing access and quality while decreasing costs. However, even beyond the ACA requirements, the health care market and delivery systems have been actively adopting additional changes that focus on achieving the same goals.

Reform efforts are affecting many areas of the health care system: changes in financial models to drive cost savings, tools and processes to assess and improve care quality and patient satisfaction, and new approaches to maximize health care delivery models. Creative financial models are being tested: They feature approaches such as bundled payments and value-based purchasing, as well as new organizational structures, including accountable care organizations, that bring both financial risk and shared savings opportunities to multiple stakeholders in the health care delivery model. In these new models, providers are even more involved and accountable for the financial impact of health care choices and their patients' clinical outcomes. Patients also are bearing more of the financial burden and accountability for their health care costs through increasing use of high-deductible health care plans and health savings accounts. Quality assessment processes and a focus

on indicators of positive outcomes are expanding in all areas of health care. These processes incentivize health care providers to work in closer partnerships with patients to provide health improvement recommendations that patients will adopt to achieve better health outcomes.

Reform also is changing health care delivery to more of an interprofessional team-based model, in which health professionals from multiple disciplines practice together with a patient-centered focus. This approach should improve the coordination of care for an individual patient across the health care system, while also resulting in improved communications, outcomes, and cost efficiencies in care delivery. Reform, often through legislative changes, also is driving all health care providers, including pharmacists, to expand their scope of practice and to perform at the top of their capabilities in delivering the most cost-effective care. An overall shortage of primary care providers in the United States has led to an expanding role for nurse practitioners and physician assistants in primary care, while also further increasing demand for the pharmacist's expanding role in self-care support and patient care services. Implementation of these reform efforts across the health care continuum is leading toward the common goals of improving health care quality, access, and delivery, while also helping to better manage costs.

Of considerable importance, many of these health care reform activities also can be linked to influencing changes in the selfcare arena. Because health care reform is attempting to improve access, it is driving both patient-initiated self-care and pharmacist-assisted self-care as obvious areas for expansion. The growth of urgent care clinics, some located within pharmacies, is driven by a need for better access to primary care. It will be interesting to monitor potential future practice partnerships between pharmacists and other health care providers in these settings and to assess how these partnerships affect delivery of primary care and pharmacist-assisted self-care support.

Insurance plans also are attempting to enhance the use of self-care initiatives by patients covered under their plan, including the involvement of pharmacists. Some payors have contracted with companies such as OutcomesMTM that compensate pharmacists for providing MTM services, including comprehensive medication reviews that include a detailed review of nonprescription medications, vitamins, and supplements. Pharmacists provide MTM services, document the medication-related problems and action steps taken to improve patient outcomes, and then submit a claim and receive

payment. Data from OutcomesMTM indicate a positive return on investment (ROI) of 15% in drug product costs (\$1.15 for every \$1.00 spent) and total estimated cost avoidance for other medical expenses (\$5.44 for every \$1.00 spent) through the delivery of MTM services in one health care plan.¹⁷ In other words, the insurance plan pays less in total health care costs because pharmacists' MTM interventions serve to avoid unnecessary physician office visits, emergency department visits, and hospitalizations. It is hoped that the positive ROI, improved access to care, and enhanced access to pharmacist-assisted self-care will encourage insurers to continue to expand their new payment models for pharmacists' MTM services.

The incentive for stretching their health care dollars often drives consumers to rely on self-care. More individual patients and families now have high-deductible insurance plans with potential significant out-of-pocket costs. These patients may see self-care as a less expensive option to other medical interventions. However, consultation with a pharmacist or other health care provider can determine when self-care steps are appropriate or when medical referral is necessary. Many people have an employee health savings account that is funded with pretax dollars. Again, self-care can help minimize the spending from this account, so the monies saved can be used for more serious medical issues. For example, a patient with high initial out-of-pocket costs presents to the pharmacy with a sore throat; the cause of the ailment determines the financial consequences of the visit. Either of two scenarios, based on the QuEST/SCHOLAR-MAC process¹⁸ (see [Chapter 2](#)), is possible: (1) The pharmacist determines that the patient likely has a viral condition and that nonprescription products can be used to help treat the symptoms; or (2) the pharmacist determines that the patient likely has strep throat, a bacterial infection that requires antibiotics, and refers the patient to a prescriber. In scenario 1, avoiding an unnecessary and potentially costly physician visit is very important because of the burden of initial out-of-pocket fees. In such instances, patients will find their pharmacist to be an accessible, valuable resource to help them sort through the specifics of their condition to determine whether a medical appointment is truly necessary or whether self-care is appropriate. In addition to improved access and decreased medical expenses, self-care also offers medications and devices that typically, but not always, are far less expensive than similar prescription products. Occasionally, it may be less expensive for the patient to pay the office visit and prescription copayments because an appropriate nonprescription product or device is more expensive. However, the cost in the insurance plan for this level of health

care would be substantially more and would contribute to overall higher health care delivery costs in the system. The pharmacist can play an important role in evaluating a patient's overall medication costs by comparing the cost of self-care products with that of similar prescription products, taking into consideration the patient's insurance plan copay and deductible.

In 2018, a survey of more than 5000 individuals provided information regarding the value of nonprescription medications and their contribution to cost savings and quality care in the health care system.¹⁹ Data from the survey showed the following:

- Availability of nonprescription products provides \$147 billion in annual savings relative to alternatives, primarily a clinician office visit or phone call. The savings include \$95 billion in avoided medical office visits and diagnostic testing and \$52 billion in medication cost savings through use of nonprescription treatment options rather than prescription medications (Figure 1–5).
- Each dollar spent on nonprescription medications saves approximately \$7.20 for the health care system.
- If medicines currently offered as nonprescription were available only as prescription products, approximately 27 million consumers would no longer seek those products.
- The use of nonprescription medicines provides approximately \$34 billion in potential productivity benefits annually.

Figure 1–5 Total savings with use of nonprescription medications for the U.S. health care system. Key: OTC = Over the counter. (Source: Reference 19.)

The value of self-care is particularly important for the medically underserved and uninsured populations. Without access to self-care, this population often is forced to use a hospital emergency department for immediate health care needs. The importance of self-care to the patient and payer communities—and providers' recognition of this need—will continue to force reforms in health care delivery that address the need for increasing access to health care while decreasing costs.

The role of the pharmacist also is changing in how self-care is delivered to

patients. As pharmacists' roles evolved over the past few decades, considerable change has occurred in the pharmacy profession: Pharmacists are moving from a product-dispensing role to that of patient care provider who helps patients improve their medication use and advances their health and wellness. This evolution is well stated by the Joint Commission of Pharmacy Practitioners (JCPP) vision for the profession: "Patients will achieve optimal health and medication outcomes when pharmacists are included as essential and accountable members of patient-centered healthcare teams."²⁰ JCPP represents the combined interests of national organizations of pharmacy practitioners, who collectively adopted this new vision for the profession in January 2014. To enable this vision, JCPP approved a standardized *Pharmacist's Patient Care Process* (PPCP) in May 2014. The process is discussed in considerable detail in [Chapter 2](#). (See [Color Plates](#), photograph 2.)

At the broader level, the pharmacist's role in MTM is being consistently taught to student pharmacists, as well as practicing pharmacists seeking further education, through the APhA MTM Certificate Training Program.²¹ In this program, the five core elements of the MTM service model are defined. The first core element is the medication therapy review (MTR) to gather and evaluate all of the patient's medications, including nonprescription medications, nutritional supplements, and herbal products. From this review, the pharmacist prepares the second core element, a personal medication record (PMR) to list all the patient's medications and immunization records identified during the review. The pharmacist also prepares the third core element, a medication action plan (MAP) that identifies medication-related and health-related problems, proposed actions, and results of those actions, when known. The process concludes with the last two core elements: intervention and/or referral, followed by documentation of the findings and follow-up plans for the patient's health care needs. It is clear that all five MTM core elements ([Table 1-2](#)) include aspects of self-care, nonprescription products, and lifestyle and behavior modifications to improve patients' health and quality of life.²¹ Most of the following chapters provide comprehensive cases that also demonstrate application of MTM core elements and the PPCP for patients who are candidates for either self-care or medical referral.

Table 1–2 Medication Therapy Management (MTM) Core Elements

Core Element	Components
Medication therapy review (MTR)	Collect and evaluate all of the patient's medications.
Personal medication record (PMR)	List all of the patient's medications and immunizations.
Medication action plan (MAP)	Identify medication-related and health-related problems, proposed actions, and results of those actions, when known.
Intervention and/or referral	Take action with patient or health care providers as needed.
Documentation of the findings and follow-up plans	Record notes of the intervention, recommendations, and ongoing care, as needed.

Source: Adapted from reference 21.

In the past decade, numerous publications have described the value of pharmacists' patient care services in improving health and reducing costs. In 2011, Rear Admiral Scott Giberson was the lead author of the landmark U.S. Public Health Service pharmacy report titled "Improving Patient and Health System Outcomes through Advanced Pharmacy Practice: A Report to the U.S. Surgeon General 2011."²² This 95-page, evidence-based report included results from federal pharmacists' patient care practices, particularly from the Indian Health Service and Veterans Affairs Hospital System, as well as data referenced from other studies that validated the health value provider role for pharmacists within the health care system. Additional research projects and publications also have documented the value of pharmacists' patient care services.^{23–26} Any of these papers can be used to advocate for pharmacists' expanded patient care roles and for their recognition as health care providers. More recent emphasis has been on the pharmacist's role in point-of-care testing, ranging from blood pressure, cholesterol, blood glucose, and bone density screenings to rapid influenza diagnostic tests and pharmacogenomics. In this context, the potential benefit of point-of-care testing for patients who visit the pharmacy seeking nonprescription medications for their influenza symptoms has been well described.²⁷ If the pharmacy had the ability to

conduct rapid influenza diagnostic testing, the pharmacist could determine who were candidates for self-care and who needed to be referred to a primary care provider, resulting in decreased risk of mortality from influenza. The timeliness of this assessment is critical so that antiviral medication can be prescribed and started within the 48-hour treatment window for a referral patient. If the patient did not test positive for influenza, the pharmacist could assist with cough and cold self-care recommendations, as appropriate.

Legislative and regulatory changes also are allowing the expansion of pharmacists' patient care services. In numerous states, current and new legislation is allowing pharmacists to enter collaborative practice agreements (CPAs) with prescribers.²⁸ These agreements allow prescribers (primarily physicians) to delegate numerous activities to the pharmacist, including modifying, initiating, or discontinuing patients' drug therapy and ordering laboratory tests. The National Alliance of State Pharmacists

Associations released a report, "Key Elements for CPA Legislative and Regulatory Authority," that offers guidance for further state legislation needed to support this expanding practice area.²⁹

Recently, a study to look at the role of pharmacists in expanding access to care was initiated in the state of Washington.³⁰ Care provided for 20 minor ailments by community pharmacists will be compared with the care received in physician offices, urgent care clinics, and emergency departments. Working under CPAs, pharmacists participating in this study managed patients with conditions that may require prescription therapy and, when appropriate, referred patients for medical care. In other cases, nonprescription therapy and/or nondrug management were recommended when prescription medication or medical care was not warranted. Data collection is now complete, and analysis and reporting of results from the study are in progress. Comparisons of quality of care, costs per episode, and frequency of follow-up care, along with a review of health outcomes, will be made. Although the study includes the 20 minor ailments listed in [Table 1–3](#), pharmacists in the state of Washington are also comprehensively managing, monitoring, and initiating drug therapy through CPAs for many other conditions. Changes in pharmacy design and operations also are in progress to improve the accessibility and visibility of pharmacists. For example, Walgreens is testing small, pharmacy-only stores to provide more targeted access to medicines and pharmacists.³¹ Similar attention to changes in pharmacy layout and workflow is emerging in

other community pharmacies, with the intent that improved access to the pharmacist will lead to an increase in patient interaction and pharmacist-assisted self-care. In this type of practice model, pharmacy technicians must play an enhanced support role in the areas of prescription preparation and insurance claim management to free up the pharmacist's time for patients. Pharmacy technicians have experienced growth in their training and credentialing that better prepares them to assist the pharmacist in a patient care-focused practice: The Pharmacy Technician Certification Board (PTCB) national certification examination is an example. Pharmacy technicians can screen patients to determine who needs to speak with the pharmacist, to assist patients in locating products in the pharmacy aisles, and to help with collecting data from patients, as well as with documentation and billing. Utilizing a new pharmacy layout; enhanced training; and improved teamwork to standardize, validate, promote, and expand the pharmacist's role in patient care will drive the pharmacists' availability and capability for a growing role in self-care.

Table 1-3 Minor Ailments Included in the NACDS Institute Study: Expanding Pharmacy Care—Innovative Models from the United States and Abroad

Bronchospasm, wheezing, shortness of breath from asthma or COPD	Acute otitis media	Conjunctivitis	Eye or nasal symptoms from seasonal allergies or other allergic conditions
Nausea and vomiting (not related to motion sickness)	Ear infections caused by bacteria	Migraine headaches	Anaphylactic allergic reactions
Nausea and vomiting caused by motion sickness	Lacerations and abrasions	Contraceptive pregnancy prevention	Allergic reactions from bee stings (not anaphylactic)
Herpesvirus infections (cold sores, genital herpes, shingles)	Wound infections from burns	Vaginal yeast infections	Diarrhea that occurs while traveling
Streptococcal pharyngitis	Animal bite (human, dog, or cat)	Uncomplicated urinary tract infections	Lack of fluoride for oral health

Key: COPD = Chronic obstructive pulmonary disease; NACDS = National Association of

Chain Drug Stores.

Source: Adapted from reference 30.

The Current Self-Care Marketplace

Consumers have access to and can purchase many health care products for self-medication. Three general categories of products are available for self-medication: (1) nonprescription medications, (2) dietary supplements, and (3) other products specific for complementary and integrative health therapies and approaches. [Chapter 4](#) provides details on the regulatory process for nonprescription medications. [Chapter 50](#) covers dietary supplements and natural products, and [Chapter 52](#) covers complementary and integrative medicine.

Nonprescription Medications

The nonprescription drug market represents about \$40 billion, or 60%, of the total pharmaceutical volume (units or number of packages) sold in the United States. [Figure 1–6](#) illustrates the details.³² Five product categories account for nearly 68% of sales in the nonprescription medications market: respiratory, oral care, gastrointestinal, internal analgesics, and antiperspirants ([Figure 1–7](#)). The estimated number of available U.S. Food and Drug Administration (FDA)-approved nonprescription drug products is well over 100,000, including more than 400 active ingredients that cover more than 700 therapeutic uses. The CHPA publication *Your Health at Hand Book: Guide to OTC Active Ingredients in the United States* provides an extensive list of active ingredients, therapeutic categories, and examples of trade-name products.³³

Figure 1–6 Breakdown of total U.S. pharmaceutical sales, by market classification. (Source: [Reference 32.](#)) Key: OTC = Over-the-counter; Rx = prescription.

Figure 1–7 Top-selling categories of nonprescription medications. Key: CCSF = Cough/cold/sinus/flu; OTC = over-the-counter. (Source: [Reference 32.](#))

Many nonprescription medications were once available only by prescription. A generally favorable environment for reclassification of prescription products to nonprescription status (Rx-to-OTC switch) in the United States has resulted in the availability of more than 700 nonprescription products today that were once available only by prescription. [Chapter 4](#) provides an in-depth discussion of Rx-to-OTC switches.

Dietary Supplements

A study conducted in 2018 by the Council for Responsible Nutrition found that 75% of Americans take dietary supplements, up from 65% in 2009.³⁴ Combination vitamin and mineral products remain the most popular dietary supplements, followed by singleingredient vitamin D, vitamin C, and calcium products. Herbs and botanicals, along with protein and energy supplements, also remain very popular. In the specialty supplements category, fish oil and probiotics continue to see strong sales, with probiotics estimated to reach \$2.6 billion in sales by 2020 (see [Chapter 20](#)). The overall dietary supplement market sales were \$43.2 billion in 2017, representing an all-time high.³⁵

Complementary and Integrative Health Therapies

Factors such as high out-of-pocket health care costs and restricted access to conventional health care providers lead some patients to seek care from complementary and integrative health providers. The National Center for Complementary and Integrative Health (formerly the National Center for Complementary and Alternative Medicine) reported in the 2012 National Health Interview Survey that 33.2% of U.S. adults and 11.6% of U.S. children used some form of complementary health care in 2012; similar results were reported in 2007.³⁶ The organization defines *complementary approach* as combining a non-mainstream practice with conventional medicine. Also, as in past surveys, natural products (nonvitamin and nonmineral dietary supplements) were the most commonly used complementary supplements. The mind-body approaches most commonly used by adults include yoga, chiropractic or

osteopathic manipulation, meditation, and massage therapy.³⁶

Wellness is the primary reason reported by users of natural product supplements or persons who practice yoga. Data on use of natural product supplements show that more than 85% of U.S. adults report using them for wellness, whereas more than 40% use them for treating a specific condition. More than 90% of U.S. adults who practice yoga do so for wellness, whereas more than 15% practice yoga to treat a health condition. More than two thirds of U.S. adults report feeling better from using complementary approaches.³⁶ The pharmacist is ideally situated to advise patients on appropriate choices of complementary and integrative health options. Advising patients on the best approaches requires integrating an understanding of pharmaceutical and natural product ingredients, physiology, pharmacology, potential interactions, and consumer behavior.

Legislative and Regulatory Issues Affecting Self-Care

The self-care environment is shaped by ongoing legislative and regulatory activities. Although a few unique issues are discussed here, details of the regulatory framework for nonprescription medications are provided in [Chapter 4](#).

The basic framework has been in place for decades; however, various state and federal legislative activities have an impact on access to and availability of these nonprescription medications. At the federal level, the use of flexible spending accounts that allowed consumers to use pretax dollars to purchase nonprescription medications was disallowed in 2011 as Congress sought ways to pay for the Affordable Care Act. Legislative efforts to restore this tax-incentivized opportunity are ongoing. At the state level, various legislative actions have addressed many areas relevant to nonprescription medications, including environmental impact (e.g., mandatory drug take-back programs, elimination of plastic microbeads from toothpastes and lotions), and pharmacist provider status and pharmacist prescribing authority (e.g., oral contraceptives, naloxone), which are discussed in [Chapter 4](#).

Concerns about pharmaceuticals in the environment have led individual states

to pass laws requiring manufacturer-funded take-back programs for drug disposal. Washington, California, and New York have enacted such legislation. In Illinois, Indiana, and Wisconsin, the presence of plastic microbeads in lakes led to the passage of laws that ban their use. Subsequently, a federal law that provides a harmonized timeline to ban the use of plastic microbeads in nonprescription medications and personal care products was passed in December 2015.

Educating the Public About Safe Medication Use: Collaborations

It is well known that education is an important component of any program to improve the safe and responsible use of medications. In addition, broad public education can lead to consumer empowerment, resulting in consumers' proactive management of their self-care for health and wellness. Education efforts require people, time, and money. Collaborations between a broad range of stakeholder groups, including health care professionals, government, academia, and industry, can achieve results that are difficult or impossible for one group acting alone. Such collaborations constitute an efficient way to utilize unique skill sets to develop and disseminate educational materials and messages to consumers through a variety of media. Impressive public-private partnerships have been formed to educate consumers on the safe use of nonprescription medications. Four such partnerships, described next, show that pharmacists are important stakeholders in the development and deployment of educational programming.

Be MedWise and Boy Scouts of America

A partnership between Be MedWise, a NeedyMeds (formerly National Council on Patient Information and Education [NCPPIE]) program, and the Boy Scouts of America provides Boy Scouts and Venturers ages 11–17 years with the opportunity to earn an achievement patch (see the [Color Plates](#), photograph 3) after completing four lessons on safe and responsible nonprescription medication use. The SCOUTStrong Be MedWise Award program teaches participating youths how prescription and nonprescription medications are alike and how they differ, as well as how to use nonprescription medications safely.³⁷

Up and Away

The message of the Up and Away campaign is to put medications “up and away”—that is, out of sight and reach of young children³⁸ (see the [Color Plates](#), photograph 4). Led by CDC, this innovative collaboration brings together public health agencies, private sector companies, professional organizations (including the American Pharmacists Association), consumer and patient advocates, and academic experts to develop strategies to keep children safe from unintentional medication overdoses. The developed messages are based on data and consumer research, and campaign partners work to expand the reach of these messages via social media, in-store materials, and in-office materials. Since 2011, emergency department visits for unsupervised pediatric medication exposures have dropped 3.4% each year, suggesting an incrementally positive impact of this educational effort.³⁹ Up and Away provides free educational materials on its website (www.upandaway.org/).³⁸

Know Your Dose

The Know Your Dose campaign was developed and launched in 2011 by the Acetaminophen Awareness Coalition (AAC), which consists of leading health, health care provider, and consumer organizations. The coalition’s goal is to educate consumers and patients on the importance of knowing the ingredients in their medications and following labeled directions to prevent unintentional acetaminophen overdose. Through outreach to health care providers, patients, and consumers, AAC works to ensure that acetaminophen is used only as directed or labeled. Partner organizations are diverse and include retailers, pharmacists (e.g., American Association of Colleges of Pharmacy, American Pharmacists Association), patient advocacy groups, and other health care practitioner groups. CDC, FDA, and the American Academy of Pediatrics are advisors to the coalition. The Know Your Dose campaign educates consumers and patients on how to use acetaminophen-containing medications safely. Materials are available for distribution to consumers and patients.⁴⁰ Although it can be difficult to measure the impact of educational campaigns, data from poison control centers show that since 2008, adult exposures to nonprescription acetaminophen combination products have decreased 30.4%⁴¹ (www.knowyourdose.org/).

OTC Medicine Safety Campaign

The APhA Academy of Student Pharmacists (APhA-ASP) partnered with McNeil Consumer Healthcare and Scholastic on the OTC Medicine Safety Campaign to teach the safe use and storage of nonprescription medications to 5th- and 6th-grade students and their parents or caregivers. This campaign is an opportunity for pharmacists and student pharmacists, working through APhA-ASP chapters at colleges of pharmacy, to educate participants about reading medication directions, the importance of following nonprescription label directions, proper measurement of a medication, safe storage and disposal of a medication, and the importance of consulting a parent or guardian before taking medications. Ready-made resources, including E-books, posters, and handouts designed to appeal to 5th and 6th graders, are available through the APhA-ASP website (www.pharmacist.com/apha-asp-otc-medicine-safety).⁴²

The Future of Self-Care: A Changing Marketplace and Advancements in Technology

Expansion of the Self-Care Marketplace

The self-care marketplace is expected to continue to grow, with more and improved medications and other consumer health care products available to consumers, particularly via community pharmacies. The pharmacist is playing an ever-increasing and influential provider role in assisting patients with self-care. Today, pharmacies offer vaccines and limited diagnostic testing. They also control access to medications such as pseudoephedrine to prevent abuse. In the future, pharmacists can be expected to administer more rapid diagnostic tests and to play a key role in disease identification, tracking, and management. More pharmacists will be prescribing medications such as oral contraceptives and naloxone as additional states pass legislation to improve the accessibility of these medications. The increased utilization of electronic medical record (EMR) systems is allowing more information to be shared by members of the health professional team, including pharmacists. Eventually, community pharmacists will be able to both review a patient's medical and

laboratory information and also enter important information from their self-care interventions into the patient's EMR.

For a pharmacist's self-care activities to expand, their integration into the workflow of pharmacy operations must be addressed. Workflow challenges currently exist with the delivery of patient care services such as immunizations. Any processes established to meet these challenges can be reapplied to self-care and other patient care services. A supportive financial infrastructure that allows compensation for patient care services also is crucial to sustain and build patient care practices in pharmacy. Passage of pharmacist provider status legislation mentioned earlier and new financial models of payment for pharmacists' patient care services will help address this opportunity. These changes position the pharmacist to play an ever-increasing and influential provider role in the self-care arena.

Technology

For those consumers interested in taking advantage of innovations, technology is enabling and redefining self-care in many ways, but differences among the various demographic groups must be considered. Older, less educated, and poorer Americans are much less likely to have online access.⁴³ For example, 10% of adults ages 18–29 said they do not use the internet in 2019, but that number increases to 27% among adults aged 65 and older. Yet 77% of Americans own a smartphone, and reliance on smartphones for internet access is especially common among younger adults, non-whites, and lower-income Americans.⁴⁴

In the past few years, consumer use of health monitoring technology has undergone tremendous growth. Applications available to smartphone users provide health monitoring, exercise tracking, dietary intake analysis, symptom analysis, and many more services. Wearable devices such as Fitbit and Apple Watch can provide feedback on physical fitness, quality of sleep, water intake, and even more health parameters. This collection of consumer health data can be a valuable aid in monitoring outcomes of treatment and lifestyle changes to improve health.

Nonprescription medications and dietary supplement products have also benefited from technology. Product package labels that contain QR codes (matrix barcodes) can provide much more information than that usually

printed on a standard Drug Facts label. The consumer simply uses the smartphone app to read the QR code to gain access to the additional content. One significant benefit is that these codes can hold multilingual labeling, which allows people in a region where different languages are spoken to use the same product and yet receive labeling information in their preferred language. Technology also has facilitated development of new dosage forms. For example, with application of such technology in producing chewable products, more pleasing dosage forms, such as chewable tablets and gummies, have become available. Rapid-release technology now is used in the manufacture of many nonprescription medications, such as instant-dissolve tablets or melting strips, which can make dosing for children more pleasant. Dosage form features also can offer a safety benefit, such as the flow restrictors in children's liquid acetaminophen products that provide a safeguard against accidental overdose.

The role of technology in health care will continue to expand, particularly in ways to actively engage consumers. Devices to allow point-of-care testing in the pharmacy as well as home monitoring techniques will continue to expand. For example, DNA testing for pharmacogenomic analysis to address appropriate medication use and the risk of certain diseases is becoming more widely available to the general public; this technology includes options that involve the pharmacist. For more information about the future vision of diagnostic testing by consumers, see [Chapter 48](#), and view the TED Talk video by Daniel Kraft, MD, who explores the impact and potential of rapidly developing technologies as applied to health and medicine.⁴⁵

Roles for the Pharmacist and Student Pharmacist in Self-Care Practice

As noted earlier, the role of the pharmacist has been slowly evolving from primarily dispensing medications to a health care provider role of improving medication use and health outcomes for patients. A combination of factors, including advanced education, better pharmacy layout, and favorable financial models, are supporting this practice change. With their ongoing development, student pharmacists also can be expected to play increasingly important roles in assisting patients with self-care needs. During their early professional shadowing experiences or introductory pharmacy practice experiences,

student pharmacists can observe the techniques used by the pharmacist to gather information, assess the patient, and provide recommendations. Later, during internships and advanced pharmacy practice experiences, student pharmacists can begin to engage in patient care. Under the supervision of their pharmacist preceptor, students can obtain initial basic information from the patient, help patients find products in the aisles, and later provide patient assessment and counseling. Student pharmacists can apply the specific information outlined in this section to help them develop patient care skills as they progress through their professional educational program.

Although patient counseling commonly occurs in the product aisle or at the pharmacy counter, utilization of private or semiprivate counseling areas is increasing, particularly for more extensive conversations. In the area of self-care practice, the pharmacist has the expertise to screen the patient's health information and apply professional knowledge and training to select products according to that patient's health care needs (see [Chapter 2](#) for further detail). A 2015 APhA survey of pharmacists reported on the critical role that pharmacists play in supporting patient-initiated self-care.⁴⁶ The 394 respondents reported that they provide patient counseling on self-care topics or nonprescription medications an average of 7.2 times each day. They also stated that patients were highly likely to select products consistent with their recommendations. The pharmacists identified the following areas as the most frequent counseling topics:

- Product selection for specific symptoms: 90%
- Potential drug interactions with other medications (prescription and nonprescription): 37%
- Dosing and administration information: 34%
- Signs and/or symptoms that indicate when to seek medical advice: 22%
- Side effects and safety considerations: 14%

The same pharmacists reported that patients most frequently requested assistance for the following self-care therapeutic areas:

- Cough and cold: 87%
- Seasonal and environmental allergies: 53%
- Gastrointestinal complaints: 28%
- Dermatologic conditions: 14%
- Dietary supplements: 11%
- Nicotine replacement therapy: 2%

In providing pharmacist-assisted self-care support, two key elements, efficacy and safety, are paramount considerations. First, the pharmacist must ensure that the medication selected is the most efficacious, taking into consideration the patient's unique needs and factors such as concurrent diseases, current medication use, lifestyle, daily routine, personal priorities and preferences, and desired outcome. The second key area of importance is ensuring the patient's safety by addressing many of the concerns and possible problems related to recommended treatments for the presenting complaint, to minimize the potential for harm. Possible areas of concern and higher risk for safety issues are addressed. In addition to safety and efficacy, consideration of treatment cost also should be reviewed with the patient. It also is critical to ensure patient confidentiality in addressing all self-care issues. Specific to product selection, when considering a medication's efficacy, the pharmacist must first help in identifying the best ingredient and dose for the patient based on the desired outcome. However, other factors can come into play. The dosage form of the product is an important factor to consider and must meet the needs of the patient. For example, pharmacists can work to enhance adherence and improve outcomes by selecting a coated tablet that is easier for an elderly patient to swallow or by recommending an extended-release formulation that requires fewer daily doses for a patient with a busy schedule. Cultural considerations must always be evaluated to ensure that patients' needs are met. More information on this topic can be found in [Chapter 3](#).

After helping a patient find the most efficacious medication, the pharmacist also should ascertain other ways to improve the patient's health or help manage a symptomatic condition. Recommendations could include lifestyle, dietary, and behavioral changes that will improve the patient's symptoms, contribute to optimal management for an underlying condition, or help prevent the development of other illnesses. Sometimes such recommendations become more important in ensuring the patient's wellness than the medication itself. For example, coaching patients with heartburn on dietary modifications may help prevent worsening of symptoms or progression to a more serious problem.

In addition to efficacy, medication safety is the other paramount concern of the pharmacist. Pharmacists must ensure that their patients understand all aspects of the self-care intervention, including the recommended medication dosage and special administration instructions. This step can be especially important for patients with limited health literacy. A critical counseling point is

ensuring that the patient knows the time limit for symptomatic improvement or, alternatively, if symptoms worsen, at what point to seek medical care. In the previously mentioned survey, pharmacists reported the following three top barriers to patient engagement for self-care⁴⁵:

- Patient is seeking recommendation of when medical care is indicated: 66%
- Patients are in a hurry to leave the pharmacy: 65%
- Patients erroneously consider nonprescription products to be overly safe: 64%

The pharmacist must play a key role in helping the patient understand safety parameters for self-care for a specific condition.

Pharmacists also must consider the needs of various special populations, including children and the elderly, patients who are pregnant or breastfeeding, and persons with chronic conditions. With patients who are pregnant or breastfeeding, self-care support is particularly challenging, because it is critical to balance the need for medication with the risk to their unborn child or infant. When possible, nonpharmacologic therapy should be the first option. Pharmacists are trained to assess whether a nonprescription medication is safe for use during pregnancy, yet women often make these decisions independently. The pharmacist can use FDA guidance information, textbooks that provide guidance,⁴⁷ and the primary literature to fully assess the potential risks and benefits of a patient's medication choices. Pregnant and breastfeeding patients always should be counseled about potential side effects that could occur in the child.

Elderly patients, with their reduced hepatic and renal function, decreased metabolism and muscle mass, heightened medication sensitivity, multiple disease states, and chronic medication use, constitute another group for whom special attention to benefits and risks is warranted. A study focused on this age group characterized the changes in medication and dietary supplement use from 2005–2006 to 2010–2011 in 2351 participants with mean ages of 70.9 years and 71.4 years for the two sampling periods, respectively.⁴⁸ The prevalence of prescription medication use, polypharmacy (concurrent use of five or more prescription medications), and use of dietary supplements increased whereas use of nonprescription medications declined during the 5-year span of the study. The use of interacting medications also increased over this period, highlighting the need for all health care providers to reinforce

safe use of medications in this population. Use of the Beers Criteria, along with numerous other sources, can be helpful in assessing the risks of nonprescription medication use in the senior population. ⁴⁹

Patients with chronic conditions also merit special attention before a product is recommended. For example, patients with chronic kidney disease can be at risk for further kidney damage with chronic exposure to nonsteroidal anti-inflammatory drugs.⁵⁰ Chapters in this book that cover medical conditions include sections that address management of these special populations.

Key Points

- Self-care involves the full spectrum of care, including prevention and wellness, diagnosis and screening, and treatment or relief of symptoms.
- Self-care is becoming more significant in today's health care systems because of numerous factors. Patients are becoming more accountable and focused on improving their health. Health care reform, combined with cost reduction pressures, is driving changes in health insurance and financial models as well as health care delivery that are all leading to increased use of self-care.
- Both health care providers and patients recognize the value and cost savings that self-care and nonprescription products provide to the health care delivery model.
- Consumers are utilizing the internet and other sources to increase their knowledge about self-care and available nonprescription products. The pharmacist continues to serve as a key resource to aid patients in assessing their condition and selecting appropriate self-care treatments.
- The changing demographics of the U.S. population, to include a greater number of older adults and non-Hispanic Whites and a large population with a low level of health literacy, requires health care providers to make special considerations for the self-care needs of these patients.

- The pharmacist's role is changing from prescription dispenser to patient care provider, allowing an enhanced role in assisting patients with their self-care needs. The newly established PPCP and the core elements of MTM are applicable in the pharmacist's role in assisting with management of the use of prescription and nonprescription medications.
- The estimated number of nonprescription drug products is already well over 100,000, and the self-care marketplace continues to grow. Fueling this growth is an expanding number of Rx-to-OTC switches and changes in state regulations to allow increased access to prescription products without a prescription.
- Pharmacists' education and training prepare them to play a key role in advising patients on self-care. In addition, pharmacists can provide broad public education on selfcare topics through numerous outreach programs.
- The future of self-care is predicted to continue to expand, with advances in technology, products, and devices and expansion of the role of the pharmacist.
- The pharmacist must emphasize efficacy and safety in assisting patients with their self-care needs. Special attention is needed for higher risk populations, including children, the elderly, pregnant and breastfeeding women, and persons with chronic conditions.
- Student pharmacists can build their self-care support skills as they progress through a pharmacy program—from early shadowing and introductory pharmacy practice experiences to internships and advanced pharmacy practice experiences.

Chapter 2: Pharmacists' Patient Care Process in Self-Care

Authors: Holly Divine, Tera McIntosh

Pharmacists, and student pharmacists with appropriate supervision and mentoring, can play a valuable role in ensuring that medications are used safely and effectively in patients seeking self-care for a wide range of conditions. As discussed in [Chapter 1](#), the pharmacist can assist patients with identification of the clinical problem, selection of appropriate therapy, and/or referral to other health care providers, as needed. The pharmacist's involvement in the self-care process also may avert medication safety problems, such as duplicative therapy, drug interactions, or adverse drug reactions.¹⁻³ Community pharmacists currently have an active role in counseling patients about nonprescription medications and strongly believe that making nonprescription recommendations is an important part of their everyday practice.^{4,5}

The profession of pharmacy continues to evolve, from a primary focus on medication distribution to more advanced clinical decision making. Accordingly, the use of a systematic method or process to arrive at such decisions is desirable.^{6,7} A standardized process can be expected to ensure consistency in delivery of services to patients, including self-care encounters.⁸

The pharmaceutical care model developed by Hepler and Strand in the 1990s is one of the original systematic clinical practice blueprints for pharmacists.⁹ Other methods and approaches to providing pharmaceutical care, patient assessment, and medication therapy management have been developed, expanded, and used throughout the years; however, the types and levels of pharmacist-provided services vary between these models.¹⁰⁻¹⁴ This variation resulted in individual pharmacists' needing to determine the best model to use in a given situation. In 2014, the Joint Commission of Pharmacy Practitioners (JCPP) released the Pharmacists' Patient Care Process (PPCP), a contemporary, consistent, and comprehensive process. The PPCP is applicable to all areas of pharmacy practice and is built on previous approaches to care.⁸ Although this chapter guides the pharmacist in the use of the profession's uniform process to manage a patient's self-care disorders, other health care providers would use their own discipline-specific process to resolve a patient's

self-care concern.

Pharmacists' Patient Care Process (PPCP)

JCPP adopted a vision statement in November 2013 for pharmacy practice that states “patients achieve optimal health and medication outcomes with pharmacists as essential and accountable providers within patient-centered, team-based healthcare.”¹⁵ Recognition of the need for development of a uniform patient care process was an essential step toward achieving this vision of pharmacy practice.⁸

The PPCP is the result of a unified pharmacy professions' effort, supported by 13 national pharmacy organizations. It has been incorporated into Key Element 10.8 of the Accreditation Council for Pharmacy Education Standards 2016,¹⁶ thereby ensuring that a consistent process also is taught to student pharmacists. Implementation of the process into current practice settings is occurring through strategies that include, but are not limited to, the Pharmacy Health Information Technology Collaborative; the American Society of Health-System Pharmacists Accreditation Standards for Postgraduate Year One residency programs; and other various training programs, projects, and outreach activities.⁸

The PPCP is grounded in a patient-centered care approach that “is applicable to any practice setting where pharmacists provide patient care and for any patient care service provided by pharmacists.”⁸ For example, this process is just as applicable for the pharmacist working in a community-based or clinic-based ambulatory care setting as it is for the pharmacy professional embedded in an acute care health system. Similarly, this same process should be used when pharmacists provide patient care in a self-care encounter in a community pharmacy. The differences lie with the level of intensity in each step of the process based on the service provided.⁸

The five core components of the PPCP revolve around patient-centered care and the pharmacist's continual collaboration, documentation, and communication with prescribers, other pharmacists, and other health care providers (see [Color Plates](#), photograph 2).⁸ These five components are:

1. Collect

2. Assess
3. Plan
4. Implement
5. Follow-up: Monitor and Evaluate

PPCP in Self-Care: The Five Steps

Details about each key component of the PPCP and their implementation in patient care services are available in other published resources.¹⁷ Presented here is a brief summary of the five areas of the process, with emphasis on practical application in patient–provider interactions. Examples of how to apply the PPCP steps in specific self-care encounters are provided. These examples are intended to be snapshots of the patient encounter as a whole, rather than comprehensive procedural accounts. Diverse patient-specific factors may result in an assessment or plan for a patient, disorder, or symptom that differs from the general approach described in this chapter. The disorder-specific chapters in this book provide important background information of relevance, with referenced sources for further detail as desired, to allow the health care provider to fully research the disorder before engaging in a patient encounter. When applicable, Cases 2–1 through 2–4 are cited as examples of how to use the PPCP in self-care encounters; these cases are presented at the end of the chapter.

Step 1: Collect

“The pharmacist assures the collection of the necessary subjective and objective information about the patient in order to understand the relevant medical/medication history and clinical status of the patient.”⁸

Self-care encounters in community pharmacies generally are initiated in either of two ways: (1) either the patient or caregiver approaches or contacts the pharmacist, or (2) the pharmacist observes the patient or caregiver perusing nonprescription products on the shelf and offers assistance.¹⁸ A survey of practicing pharmacists reported that patients initiate the encounter 87% of the time.¹⁹ In either situation, the pharmacist must then engage the patient by collecting essential information to begin addressing the self-care complaint.

Collection of information from the patient or caregiver can be accomplished through the patient interview (subjective data) and by review of medical and

pharmacy records and reports of laboratory test results, direct observation, and physical assessment (objective data).²⁰ Subjective data generally are supplied by the patient or caregiver and may not always be accurate or reproducible. Conversely, objective data can be measured or observed and are not influenced by personal bias or emotion.²¹

A comprehensive patient interview will include the following components of the patient's health history^{18,20}:

- Chief complaint (CC)
- History of present illness (HPI)
- Past medical history (PMH)
- Health maintenance and immunizations
- Family history (FH)
- Personal and social history (SH)
- Review of systems and physical examination (ROS and PE)
- Medication history

Most information acquired in a self-care encounter will be subjective data obtained through the patient interview. The remainder of this information consists of objective data, collected by various means and from different sources. Of note, however, even objective data may not be entirely reliable. For example, the pharmacy record may indicate that a patient is taking one or more medications, but in fact the patient may not be adherent to the prescribed regimen. Such considerations require the pharmacist to confirm data in records with the patient—a clinical skill applied smoothly and efficiently with practice. Depending on the specific clinical situation, physical assessment skills also may be employed, such as measuring blood pressure or taking a temperature. Patients who present with a dermatologic disorder will require careful inspection of the skin. Case 2–1 documents the pharmacist's physical examination of the affected area (under the “Characteristics” heading) to assess a bee sting. Physical assessment techniques that apply to specific disorders are highlighted in the text and/or tables in subsequent chapters of this book.

The amount and type of information collected for a self-care encounter will be different from those required for other patient care services that involve a greater breadth and depth of care, and such encounters likely will not require covering all areas of the health history or full physical assessment.¹⁷ For example, for a patient who inquires about nonprescription therapy for sunburn

relief, collection of the family history may not be necessary, but appropriate assessment will include the chief complaint, history of present illness, and past medical history, in addition to observation of the area of concern on the patient's skin (see [Chapter 41](#)). Alternatively, a family history of colon cancer would be important information to collect in a patient who is inquiring about self-care for an anorectal disorder (see [Chapter 17](#)). In each self-care situation, the pharmacist will need to decide which assessment factors are pertinent. This determination requires knowledge of various self-care disorders, and subsequent chapters in this book provide a pharmacy practice-focused resource on types of information to collect for specific self-care disorders.¹⁸

The PPCP explicitly identifies patient-centered factors for which data should be collected: patient lifestyle habits, preferences and beliefs, health and functional goals, and socioeconomic factors. Some chapters in this book include “Patient Factors” and “Patient Preferences” sections, which focus on the patient-centered areas for which data should be collected and addressed as a part of developing the plan for that specific disorder. Additionally, [Chapter 3](#) reviews the cultural aspects of self-care as important background information to guide health care provider assessments and addresses several key areas of the data collection step in this context, including but not limited to cultural ideals and beliefs, literacy, and health literacy.

Professionalism, interview proficiency, and interpersonal and communication skills are essential to obtaining effective subjective information.¹⁷ Conducting an efficient patient interview is a skill that develops with practice over time and involves asking appropriate questions and actively listening to the patient.¹⁸ Communication skills are the foundation of many parts of the PPCP and are discussed further on.

Step 2: Assess

“The pharmacist assesses the information collected and analyzes the clinical effects of the patient's therapy in the context of the patient's overall health goals in order to identify and prioritize problems and achieve optimal care.”⁸

The second step involves the assessment and analysis of information collected to identify and prioritize the patient's problem(s).¹⁷ This assessment step can be categorized into three areas: (1) medication assessment, (2) patient history and risk assessment, and (3) preventive care assessment.¹⁷ Similar to the

collection step, assessing the patient's information may be more focused during a self-care encounter than during a comprehensive medication review. Additionally, it may or may not involve all three of these categories of assessment.

Medication Assessment

Comprehensive medication assessment involves the analysis of each medication for appropriateness, effectiveness, safety, and adherence.⁸ Further assessment of medications includes identification and prioritization of medication-related problems²²:

- Unnecessary drug therapy
- Needs additional drug therapy
- Ineffective drug
- Dosage too low
- Adverse drug reaction
- Dosage too high
- Adherence

In a self-care encounter, the most likely medication-related problem is “needs additional drug therapy,” as patients are presenting with the intent to purchase a self-care medication to treat a disorder and may require a nonprescription medication for resolution. Other medication-related problems in self-care include but are not limited to “ineffective drug,” if a patient is using a self-care medication that is ineffective or is not producing the desired response, and “adverse drug reaction,” if the patient is attempting to provide self-care for a disorder or a symptom that is the result of use of another medication. The pharmacist's role in the medication assessment step for self-care is to use the information collected to make appropriate medication recommendations or changes to the medication care plan.¹⁷

In contrast with a comprehensive medication review, during which the pharmacist performs an assessment of all medications the patient is currently taking for appropriateness, effectiveness, safety, and adherence, a self-care encounter is more consistent with a targeted medication review. Generally, self-care encounters require quick assessments because of the generally transient nature of the interaction. Such encounters may be initiated in an aisle outside the pharmacy counter (e.g., the pharmacist observes the patient reading several product labels and offers assistance), by telephone (e.g., a

patient or caregiver calls for advice about an appropriate medication or dose), or at the point of sale (e.g., the patient selects a product and asks the pharmacist questions during its purchase), when interaction is necessarily time-limited. Time limitations do not excuse the pharmacist from key responsibilities in medication assessments, particularly for safety and efficacy. However, in self-care encounters, the PPCP assessment step can be modified to a more focused approach.

Although the self-care encounter may not include a comprehensive medication review, the pharmacist may have compelling reasons to consider all current medications before making a recommendation. For a patient experiencing musculoskeletal pain, for example, the pharmacist may consider making a recommendation for a nonsteroidal anti-inflammatory drug (NSAID). Before any such recommendation, however, it is essential to collect information from the patient's profile and interview regarding current NSAID use to assess for duplicate therapy, drug–drug interactions, or drug–disease interactions (see [Chapter 7](#)).

Another example of a more focused approach in self-care encounters is assessing the cause of the patient's presenting medical condition or symptom as a potential medication-related problem. For a patient with a chief complaint of dyspepsia, the patient's current medication profile should be reviewed to determine whether a prescribed or other medication is causing an adverse effect, such as the recent addition of an antibiotic to the drug regimen (see [Chapter 13](#)).

Patient History and Risk Assessment

The patient history and risk assessment includes health and functional status, risk factors, health data, cultural factors, health literacy, and access to medications or other aspects of care that could influence decisions on optimal medication regimens for the patient.^{8,17} With certain self-care disorders, the collection of key information about the patient's health history, such as health and functional status, could direct the pharmacist's assessment to a completely different area of focus. The pharmacist should determine whether a patient's disease state could be causing or contributing to the presenting self-care symptom or disorder. For example, if a patient has congestive heart failure (CHF) and is seeking self-care for relief of a cough, the assessment would most likely result in a medical referral, as preexisting CHF is an exclusion

for self-care (see [Chapter 12](#)). The patient may be experiencing an exacerbation of CHF that requires medical attention beyond that for self-care. Case 2–2 demonstrates how collection of information about the patient’s chronic disorder can affect the scope and focus of assessment.

Health literacy is an important consideration to ensure delivery of safe and effective patient-centered care (see [Chapter 3](#)). Health literacy is defined as “the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions.”²³ Although validated tools are available to assess health literacy, their implementation may not be feasible in each selfcare encounter.²⁴ A more practical approach is to apply health literacy universal precautions, which assumes that all patients may have difficulty comprehending health information and accessing services.²⁵ The pharmacist should communicate clearly with everyone involved in the care of the patient and confirm that the patient understands the recommendations.

Cultural factors and health beliefs must be considered in the self-care assessment (see [Chapter 3](#)). Health beliefs constitute an array of patient opinions, including ideas about what causes illness and how to treat or prevent it.²⁶ These beliefs vary in individual patients and are greatly influenced by culture. This variability in turn may influence the kind of treatment a patient prefers, such as conventional nonprescription medications or complementary and alternative products. If a patient preference is identified, the pharmacist can use this information toward development of a patient-centered self-care plan.

Preventive Care Assessment

Preventive care assessment is an important part of the comprehensive assessment of a patient in the PPCP.^{8,17} In a specific clinical encounter, the pharmacist may focus the preventive care assessment on only the presenting disorder or problem. For example, in a patient seeking relief from the pain of sunburn, the pharmacist may assess the need for future sunburn prevention and recommend a preventive care plan that includes use of a sunscreen (see [Chapter 39](#)). Other opportunities in preventive care assessment should be used when appropriate. For example, during influenza season, the pharmacist should assess influenza immunization status in each patient presenting for self-care assistance.

Exclusions for Self-Treatment

A unique component of the PPCP in self-care management is the assessment of appropriateness for self-treatment. Within the process, pharmacists should collect the pertinent information for the disorder or problem that would lead to an assessment conclusion of “inappropriate for self-treatment.” If the pharmacist determines that the patient is not a candidate for self-treatment, the medication-related problem may be that the patient “needs additional drug therapy,” but the therapy may require an assessment from another health care provider, resulting in treatment with a prescription medication. Another outcome that may result from an exclusion for self-care is that “no drug therapy problem exists.” If a patient presents with a disorder or injury that requires medical treatment or a procedure from another health care provider as opposed to medication therapy, the patient may not have a medication-related problem to resolve.²² Exclusions for self-treatment that also require referral to another health care provider may include but are not limited to the following situations:

- Symptom characteristics or other disorder factors are beyond the scope of self-treatment.
 - Example: Patient presents with the symptom of headache that has persisted for 10 days (see [Chapter 5](#)).
- Patient-specific factors preclude treatment with nonprescription medications.
 - Example: For an 8-year-old child with excessive or impacted cerumen, nonprescription pharmacologic therapy is not indicated, because the patient is younger than 12 years (see [Chapter 30](#)).
- The patient’s health status or history precludes self-treatment, even if a nonprescription medication is indicated for the disorder.
 - Example: A pregnant patient presents with musculoskeletal pain that has not been previously assessed and diagnosed by an appropriate health care provider (see [Chapter 7](#)).
- Nonprescription medications are not indicated for the disorder.
 - Example: A patient presents with “bug bites,” but the lesions are characteristic of scabies, which requires prescription therapy (see [Chapter 37](#)).

- Previous treatment with nonprescription medications was ineffective after an adequate trial.
 - Example: Heartburn symptoms persist after 2 weeks of treatment with a nonprescription proton pump inhibitor (see [Chapter 13](#)).

The pharmacist is responsible for knowing exclusions for self-treatment for presenting disorders or symptoms, and for collecting appropriate information that may result in this assessment. In most subsequent chapters, exclusions for self-treatment for one or more disorders are included in text discussion and algorithm(s). Cases 2–2 and 2–3 provide examples of patients who have exclusions for self-treatment.

Step 3: Plan

“The pharmacist develops an individualized patient-centered care plan, in collaboration with other health care professionals and the patient or caregiver that is evidence-based and cost-effective.”⁸

The self-care plan in the patient care process uses the information collected and assessed and generally will culminate in one or more of three general recommendations: (1) recommend self-care with pharmacologic, nonpharmacologic, and/or complementary/alternative products; (2) refer the patient to an appropriate health care provider for treatment; and/or (3) recommend self-care until another health care provider can be consulted. The detailed components within the plan should address four key areas: medication-related problems, goals of therapy, patient engagement, and care continuity in collaboration with other health care professionals and the patient or caregiver.⁸

Medication-Related Problems

The plan for the first key area, medication-related problems, generally results in the pharmacist’s recommending a therapeutic product, such as a nonprescription medication, to resolve the “needs additional drug therapy” problem. Pharmacists should use their knowledge of the medication properties and determine the safest and most cost-effective option while considering all of the patient-specific factors identified in the first step. These patient-specific and therapy-specific factors include but are not limited to age, gender, medication history, medical conditions, allergies, active and inactive ingredients, adverse effects, potential interactions, and efficacy. The

recommendation also should be patient-centered, taking into account, at a minimum, patient preferences for dosage forms and dosing regimens, cost, flavors, and previous medication experience. The Drug Facts label on U.S. Food and Drug Administration (FDA)-approved nonprescription medications, further described in [Chapter 4](#), includes essential information that should be reviewed with the patient as part of the self-care plan and including but not limited to warnings and directions.

Goals of Therapy

Establishing goals of therapy has been a mainstay of the original pharmaceutical care process and remains central to the self-care plan in the PPCP.^{8,27} Goals of therapy serve as endpoints to measure outcomes and include both practitioner and patient contributions. They should be realistic, observable, and measurable and should include the following three components: clinical parameters (signs and symptoms) and/or laboratory values; a desired value or observable change in the parameter; and a specific time frame in which the goal is to be met.²⁷

Clinical parameters should include evidence-based guidelines or standards, when available, such as frequency of symptoms with heartburn. In self-care encounters, the clinical parameter is likely to focus on resolution of the presenting sign or symptom, such as “alleviate the discomfort associated with fever” when an antipyretic is recommended (see [Chapter 6](#)). Alternatively, the clinical parameter may be a preventive measure. For example, in a patient who presents with vomiting and diarrhea, an oral rehydration solution may be recommended not only to restore hydration status but also to prevent progression to severe dehydration (see [Chapter 16](#)).

In setting the clinical parameter, the desired value or change in the parameter also should be addressed. The patient should understand whether the goal of therapy includes complete resolution of the presenting symptom, a reduction in symptom severity or frequency, or partial relief. For a presenting complaint of fever, this portion of the goal might be to “*completely* alleviate the symptoms of discomfort associated with fever.” The patient-centered perspective may help determine the validity of this goal. The patient may be seeking elimination of pain as opposed to pain reduction. The pharmacist can ask three questions to help establish patient-centered goals²⁷:

- “What would you like to achieve with your medications?”

- “What are your goals for this therapy?”
- “How do you feel about trying to achieve (*insert desired outcome*) with a new drug therapy?”

Finally, the time frame in which the goal is to be met is a critical element of the self-care plan. Patients should understand how quickly the goal is achieved. In the fever example, the complete goal of therapy including the time frame might be that “the patient’s discomfort associated with fever will be completely eliminated within 2 hours.” The pharmacist should establish the time frame using both disorder-specific factors, such as medication onset and duration of action and appropriate length of time for self-treatment, and patient-specific factors, such as the patient’s or caregiver’s expectations for symptom relief. Setting a time frame establishes clear expectations. Case 2–4 demonstrates the goal of therapy (see step 8d, “Expected time to onset of relief” and step 8e, “Degree of relief that can be reasonably expected”).

Patient Engagement

Engaging the patient in the planning step involves “education, empowerment, and self-management.”⁸ Because the clinical encounter is initiated by the patient with the expectation of self-treatment for the disorder, inclusion of the patient in this portion of the self-care process is essential, because it is the patient who will carry out the treatment plan on leaving the pharmacy. Every self-care encounter in which the pharmacist provides care should include educating the patient on the presenting disorder, nonpharmacologic measures, nonprescription medications, and when to seek medical attention. Subsequent disorder-specific chapters include a display box that outlines appropriate patient education for the self-care condition discussed.

The pharmacist needs to identify the medication-specific information that should be communicated to the patient by reviewing information on the Drug Facts label in addition to any other medication-related instructions for successful use and therapeutic outcomes. A key part of an effective plan is communicating the goal of therapy and empowering the patient by inclusion in patient-centered goal setting to ensure that patient expectations align with the pharmacist’s recommendation.

Education on nonpharmacologic recommendations should be included in the plan. Patients should be educated on nonpharmacologic therapy (which includes nondrug measures, lifestyle recommendations, and preventive

measures) for their disorders, along with the nonprescription medication education. When a nonpharmacologic measure is the only recommendation, patient counseling also should specify the rationale for why that was preferable to a nonprescription medication. In the case of a patient who is experiencing insomnia caused by overuse of the stimulant caffeine, the most appropriate recommendation may be to discontinue or reduce caffeine consumption, particularly in late evenings, with corresponding education on proper sleep hygiene (see [Chapter 46](#)). Furthermore, emphasizing the potential risk versus benefit of nonpharmacologic measures for certain disorders may help promote acceptance of the nondrug plan.

Care Continuity

Finally, the plan should include care continuity, which involves follow-up, referral, and transitions of care.^{8,17} The initial follow-up plan is based on the goal of therapy and advises the patient regarding what to do once the goal is met, what should occur if the goal is not met, and what steps to take if the patient's condition worsens or the patient experiences an adverse effect. It should include the specific course of action to be taken and when that action is to be taken. The course of action may be a return to the pharmacist for further assessment, selection of a different nonprescription medication therapy, or referral to another health care professional, and it is essential to explicitly identify when that action is to be performed. If the patient has multiple goals of therapy, the follow-up plan should address each goal.

To further conceptualize the parts of the follow-up plan that should be addressed by the pharmacist in a self-care encounter, a series of questions is provided for consideration. Presented next is an illustrative case of a heartburn-related encounter, in which specific follow-up actions for the patient are suggested in response to each question.

Some preliminary notes are in order: In the following case, the pharmacist does not have a complete array of information including all patient-specific factors, and the example is not intended to serve as a plan for the management of all patients with heartburn. The follow-up plan will not be the same for each patient who presents with heartburn symptoms, and the pharmacist should refer to the disorder-specific chapters for more information. The pharmacist's responsibility is to recognize the disorder and know the limitations that would lead to a specific follow-up plan, including but not

limited to FDA-approved length of therapy for use of a nonprescription medication for self-care; common adverse effects associated with a nonprescription medication; developing or worsening symptoms that would lead to an exclusion for self-care, necessitating a medical referral; and appropriate stepwise use of an alternative nonprescription medication for efficacy.

In the example case, the patient presents with suspected heartburn (see [Chapter 13](#)). The pharmacist should evaluate the following:

- When the patient should expect results. This is communicated in the goal of therapy.
 - “Your heartburn symptom(s) should be completely gone within 10 minutes after taking the antacid.”
- What the patient should do if the goal of therapy is not met. For example, complete resolution of symptoms is the goal, but the time frame identified in the goal of therapy has passed and the patient sees no or only partial improvement. Options include the following:
 - A return visit to/communication with the pharmacist
 - “If your symptoms aren’t completely gone within 10 minutes, contact the pharmacist to help you select a different medication.”
 - Selection of a different nonprescription medication
 - “If your symptoms aren’t gone within 10 minutes, discontinue the antacid and begin omeprazole 20 mg once daily.”
 - Referral to primary care provider
 - “If your symptoms aren’t gone within 10 minutes, call your primary care provider for an appointment.”
- How long the disorder should be treated by self-care before further assessment by another health care provider (i.e., referral) is warranted
 - “If heartburn symptoms return after taking omeprazole for 14 days, as we discussed, call your primary care provider for an appointment.”
- What the patient should do (what action is indicated) in the event of an

adverse drug reaction.

- “If you develop diarrhea while taking omeprazole, stop taking the drug and call your primary care provider for an appointment.”
- What the patient should do if he or she experiences a worsening of the condition during the treatment
 - “If heartburn symptoms get worse or occur more often while taking this medication, call your primary care provider for an appointment.”

The pharmacist has the responsibility of identifying exclusions for self-care in the assessment step; therefore, the plan may not include any pharmacologic or nonpharmacologic recommendations. Each condition-specific chapter in this book identifies exclusions for self-care, usually within a treatment algorithm. The plan may simply be referral to another health care provider. Little is known about how often pharmacists make a medical referral in self-care encounters; however, a study of pharmacist consultation outcomes reported that a medical referral was made in 4.3% of the encounters.¹ Cases 2–2 and 2–3 provide examples of self-care situations leading to medical referrals.

Another unique component of self-care encounters is to recommend self-care until another health care provider can be consulted. The pharmacist typically is well positioned for this role in self-care management, simply because of ready access within a community pharmacy. The initial assessment may reveal that referral to another health care provider is warranted. If the situation is not urgent, however, the pharmacist may consider recommending self-care, pharmacologic or nonpharmacologic, while simultaneously referring the patient for further evaluation and treatment. For example, for a pediatric patient with signs of moderate dehydration, patient-specific factors identified in the initial assessment may raise concerns that the parent or caregiver may not be successful in preventing further dehydration using an oral rehydration solution. The pharmacist's recommendations may then include both referral for medical evaluation and initiation of oral rehydration, to slow the progression to severe dehydration until the patient can be seen by a medical provider (see [Chapter 16](#)). The risk in making a recommendation while waiting for an appropriate health care provider consultation is that the patient or caregiver may ignore the referral and take only the self-care recommendation. This risk is one reason why the follow-up action step with the patient is so

important in self-care practice.

The pharmacist must emphasize the importance of seeking further medical evaluation and clarify to the patient that the referral is the primary recommendation. To avoid patient denial and confusion, the pharmacist should provide clear and understandable instructions. For the preceding case example on oral rehydration solutions, appropriate instructions follow:

“Contact your primary care provider today and make an appointment. Ask for an appointment today or tomorrow morning, at the latest. In the meantime, use this oral rehydration solution as directed to help alleviate some of the symptoms. This will likely not be enough to prevent serious complications, so do not delay in contacting your primary care provider today.”²⁸ Follow-up with patients requiring referral is especially important to ensure that the situation has been properly addressed. Case 2–2 requires a plan for referral because the patient has an exclusion for self-care. Recommendations for some nonpharmacologic measures to use until the patient can see a primary care provider, however, are listed as well.

Step 4: Implement

“The pharmacist implements the care plan in collaboration with other health care professionals and the patient or caregiver.”⁸

The implementation step in PPCP is execution of the developed plan. Implementing the plan for medication-related problems would include selecting the recommended nonprescription medication from the pharmacy nonprescription section and presenting it to the patient. A full implementation step for self-care would not involve merely directing the patient to the respective aisle number to obtain the product. Implementation also includes communicating the “Goals of Therapy” that were established in the plan.

In the “Patient Engagement” part of the plan, all of the pharmacologic and nonpharmacologic educational points were established, and the implementation step is the actual provision of the education to the patient or caregiver. As with the collection step of the process, effective communication skills are required, taking into account health information collected from the initial assessment. In addition to health literacy, patients with low literacy may have difficulties comprehending information on the Drug Facts label, and additional counseling time may be required to ensure that they understand

the key concepts for appropriate use. Use of various communication methods, including but not limited to the teach-back method, may confirm that the patient understands the information. The teach-back method involves explaining the information and then asking the patient to repeat key points, and also to discuss the information as it applies to the medication regimen, and actively listening to ensure that the patient has achieved understanding.²⁹ Requesting patients to repeat the treatment information provided, in a nonjudgmental way, and supplying easy-to-read, patient-centered printed instructions have been shown to improve patient understanding and proper medication use.³⁰ Essential communication components are discussed later under “Patient-Centered Care.”

For “Care Continuity,” all of the follow-up components to the plan should be communicated to the patient and/or caregiver. If one of the follow-up actions includes returning for a follow-up visit within a specified time frame, the patient should be provided with a specific day or date on which the pharmacist will be available. Community pharmacists may have various shifts and schedules, so fully implementing the follow-up plan should include factors such as the pharmacist’s availability or formalizing an appointment. Follow-up encounters other than face-to-face meetings may be arranged, when appropriate, using telephone or other communication technologies such as email.

In self-care management, implementation may involve a referral to an appropriate health care provider or facility. The pharmacist may contact the patient’s primary care provider to communicate patient-specific information obtained during the self-care encounter, to facilitate the reason for referral. For those patients who do not have a primary care provider, the pharmacist may be integral in connecting the patient to an urgent or convenient care facility until a primary care provider contact can be established. In extreme cases, the pharmacist may call 911 in a medical emergency.

Step 5: Follow-up: Monitor and Evaluate

“The pharmacist monitors and evaluates the effectiveness of the care plan and modifies the plan in collaboration with other health care professionals and the patient or caregiver as needed.”⁸

Follow-up “brings the pharmacist full circle in the ongoing monitoring of the

patient.”¹⁷ Follow-up may not be a routine occurrence with most self-care encounters. Some literature suggests that patients may be willing to have a follow-up service for selfcare encounters.² However, because of the self-limiting nature of most presenting disorders in self-care, the pharmacist may not be included or choose not to be involved in the follow-up plan. For example, if the patient’s goal of therapy and follow-up plan include full relief of symptoms within 4 hours and resolution of the disorder within 10 days, and the goal is met, no further follow-up with the pharmacist may be warranted. Similarly, in follow-up plans that include a referral to the primary care provider, if the patient’s symptoms worsen or do not resolve, the follow-up step may not occur with the pharmacist.

If, however, the follow-up plan includes a return visit to the pharmacist within an identified time frame, the pharmacist should begin the PPCP evaluation again by collecting new information and reassessing the patient’s condition. The patient’s goal of therapy should be reviewed for achievement, and an assessment for appropriateness, efficacy, safety, and adherence of any new medication-related problems related to the recommended nonprescription medication is warranted. Adherence to recommended therapy should specifically be addressed in the follow-up step to determine its contribution to the success or failure of the intended outcome.

The pharmacist’s role in a follow-up encounter with the patient after medical referral can be challenging. A patient seeking self-care may not be an established patient at the pharmacy or with the pharmacist. The person may simply be seeking a consultation for the first time as a walk-in patient. Without a strong pharmacist-patient relationship, the logistics of following up with the patient to determine the outcome of the referral are difficult. The pharmacist may not have the essential demographic information often maintained in pharmacy records for these one-time encounters. Asking the patient for a phone number for a follow-up call may be a simple solution to initiating follow-up. For an established patient, a follow-up inquiry about the outcome of the referral brings closure to the entire PPCP. Future developments in transitions of care for established patients may help close the loop in the process. With access to electronic health records, for example, community pharmacists could communicate follow-up plans and medication changes for continued care.

PPCP in Self-Care: The Core

The PPCP has patient-centered care at its core, with continual collaboration, communication, and documentation of care with other health care providers (see [Color Plates](#), photograph 2).⁸ Developing the pharmacist–patient relationship helps establish engagement and effective communication with patients and/or caregivers to ensure that the process remains patient-centered. Presented next is an overview of the importance of patient-centered care in pharmacist patient care services, followed by detailed descriptions of each of the three core areas, with an emphasis on implementing these areas in the self-care encounter.

Patient-Centered Care

Patient-centered care, according to the Institute of Medicine (IOM), is defined as “providing care that is respectful of and responsive to individual patient preferences, needs, and values, and ensuring that patient values guide all clinical decisions.”³¹ IOM describes patient-centered care in greater detail in its 2001 report *Crossing the Quality Chasm: A New Health System for the 21st Century*. Each self-care encounter affords multiple opportunities to center the process on the patient.

The pharmacist must listen to the wants and needs of the patient when collecting information. Careful consideration of all relevant patient factors is essential to arrive at an assessment and plan that is truly patient-centered. Lifestyle habits, preferences, and beliefs, as previously described in the five steps, all are important patient-centered collection areas.

Establishing goals of therapy must include the patient’s input. Understanding the patient’s expectations of the desired outcome and time frame must be carefully considered in developing the plan. Furthermore, patient-centered implementation of the plan involves using collected patient factors regarding literacy, health literacy, and physical functions such as vision or hearing status to tailor the education and counseling to the patient’s specific needs.

An additional patient-centered area for consideration is the patient’s medication experience. The patient’s medication experience is “the sum of all the events a patient has in his [or her] lifetime that involved drug therapy. This is the patient’s personal experience with medications. This lived experience

shapes his attitudes, beliefs, and preferences about drug therapy.”³² In a brief self-care encounter, the pharmacist may focus on the patient’s personal experience with nonprescription medications or specific experiences with a certain self-care disorder. For example, if a patient expresses fear about taking a particular nonprescription medication because a family member had a bad experience with that drug, the patient’s concerns about drug safety can be recognized and addressed.³²

Specific Core Components

Collaborate

Collaboration involves working together to achieve a common goal. In self-care, collaboration occurs most often with patients and/or caregivers to ensure the entire process is patient-centered and optimal outcomes are achieved. Collaboration with other health care providers is less common in self-care encounters; however, it is essential when referrals are required or if more information is needed for safe and effective self-care recommendations.

Communicate

Although communication in the PPCP involves both providers and patients, most of the communication will be with patients in self-care encounters. Good communication skills are essential in all pharmacist interactions with patients and are not unique to self-care.

Fundamental communication skills, such as active listening and demonstrating empathy, must be mastered for collecting information.^{18,33} Active listening requires concentration and a focused effort to minimize external and internal distractions. Empathetic responses are a result of listening, and it is through empathetic response that patients feel understood.³³ Other essential communication skills include asking open-ended questions, avoiding leading questions, being aware of nonverbal modes of communication such as tone of voice or facial expression, and using the teach-back method.^{18,33}

Pharmacists need to use effective communication skills when faced with challenging situations in which patient and caregiver factors, such as vision and hearing loss, language barriers, and limited literacy and health literacy, may impede communication, and should know how to address these

challenges. Pharmacists' assumptions in resolving communication challenges may not always be appropriate. For example, with patients who are deaf or hard of hearing, the interviewing pharmacist should ask about their preferred method of communication, which may be written notes, lip reading, or the use of an interpreter, and should not assume that the same communication method applies in every patient.

Maintaining patient privacy and ensuring Health Insurance Portability and Accountability Act (HIPAA) compliance in communications for self-care encounters are important considerations, especially because the encounter initiation may occur in an open area of the pharmacy where nonprescription medications are located. Additionally, many self-care disorders include sensitive issues or topics that may be difficult or embarrassing for the patient to discuss, including but not limited to anorectal disorders, vaginal and vulvovaginal disorders, and prevention of pregnancy and sexually transmitted infections. Pharmacists must ensure that the consultation occurs at the appropriate place. Choosing a private area that minimizes interruption and provides a safe place for the patient to discuss his or her condition and health concerns is ideal. Being aware of voice volume to maintain confidentiality also is important. Using the foundational skills of active listening and empathy will further contribute to developing a trusting relationship that is needed for discussion of sensitive topics.³⁴

Document

Documenting pharmacist–patient encounters is an essential part of the PPCP. Documentation demonstrates the pharmacist's contributions to patient care, ensures continuity of care, provides legal evidence for professional liability, and contributes to billing and reimbursement needs. For these important reasons, pharmacists should document self-care encounters, whenever possible.

Documentation methods in community pharmacy vary. A survey of such methods revealed that community pharmacists who currently document patient care services use both paper (54%) and computerized (42%) documentation systems; however, little is known about documentation of self-care encounters.³⁵ Some sample paper documentation forms have been included and may serve as useful tools (Figures 2–1 and 2–2).^{28,36} Additionally, pharmacy management systems, typically designed for prescription medications, may have features that provide a venue for selfcare

documentation. Improved health information technology systems that fully integrate the PPCP steps may improve self-care documentation in community-based pharmacy.³⁷ Patient data and health information documented in a self-care encounter would be considered private information and protected under HIPAA.

Efficient Use of PPCP in Self-Care

Efficiency in the PPCP is imperative in a community pharmacy. Self-care encounters are generally not compensated outside the sale of the product; thus, the pharmacist is faced with a time management decision.³⁸ Pharmacists identify lack of time as a barrier to their involvement in resolving

self-care needs in community pharmacies because of their responsibilities in medication distribution.⁵ The time pharmacists actually spend with patients or their perception of patients' time expectations for the entire selfcare interaction is in the range of 2–6 minutes.^{1,19,36,39} Patients also report an expectation that encounters are brief, indicating a willingness to spend 1–5 minutes for a nonprescription consultation.⁴⁰

Although time constraints are a reality in community practice, professional responsibilities lie with patient care, which includes all steps of the PPCP, from collecting all pertinent information to appropriately assessing the patient and completing, communicating, and implementing the plan.¹⁸ In the previous section's comprehensive overview of the PPCP, outlining each step within the process and the multiple components of each step, it was noted at each step where modifications may occur for patient care services in self-care encounters to improve efficiencies. Another way to increase efficiency in applying the PPCP in self-care is the use of algorithms or flow charts. Treatment algorithms developed for disorders discussed in this book focus on the most pertinent information to collect and assess within the patient care process for that particular disorder. The algorithms also assist with components of the planning step by identifying appropriate lengths of therapy and follow-up time frames as well as exclusion criteria.

QuEST/SCHOLAR-MAC

Tools, mechanisms, and mnemonics have been used in patient assessment in multidisciplinary health care professions for many years.^{20,41,42} Some mnemonics developed and used by pharmacists during assessments have been shown to improve assessment skills when implemented,^{43,44} whereas others have been used rather extensively yet never truly validated.

One tool designed specifically for self-care encounters, the QuEST/SCHOLAR method, was first presented by Leibowitz and Ginsburg at the 2002 Self-Care Institute of the American Pharmacists Association.⁴⁵ This method employs a simple acronym to prompt health care providers to complete key steps in the self-care problem-solving process. Although no published studies have compared QuEST/SCHOLAR with other tools or mnemonics or validated its use in patient outcomes, the easy-to-remember acronyms can be expected to expedite completion of the problemsolving process relative to more structured models that contain no such prompts. One study conducted in a school of

pharmacy concluded that utilizing QuEST in a skills-based course improved student pharmacists' ability to provide self-care counseling and elicit important patient information in a consistent manner.⁴²

Each letter in the QuEST mnemonic represents an ordered step in the problem-solving process⁴⁵:

- Quickly and accurately assess the patient (using the SCHOLAR-MAC interviewing tool described here).
- Establish that the patient is an appropriate self-care candidate.
- Suggest appropriate self-care strategies.
- Talk with the patient.

Similarly, each letter in the mnemonic SCHOLAR represents information that the health care provider should elicit from each patient or caregiver:

- Symptoms: What are the main and associated symptoms?
- Characteristics: What is the situation like? Is it changing?
- History: What has been done so far? Has this ever happened before, and, if so, what was done then? What was successful? What wasn't?
- Onset: When did it start?
- Location: Where is the problem?
- Aggravating factors: What makes it worse?
- Remitting factors: What makes it better?

The MAC component was added to the QuEST/SCHOLAR tool as a prompt for users to collect additional key medical history information:

- Medications: prescription and nonprescription as well as complementary and alternative products
- Allergies: to medications and other substances
- Conditions: coexisting health conditions

QuEST/SCHOLAR-MAC is not a new problem-solving model or a different process for patient care. It is one option to assist the pharmacist in streamlining the PPCP in self-care encounters by highlighting key areas within the process that are most relevant for self-care. Recognition of this purpose is important, because models and mnemonics may be misinterpreted as entirely new processes to apply instead of welcomed as tools to assist in learning and in making the existing process more efficient. [Figure 2–3](#) demonstrates the

relationship of the QuEST/SCHOLAR-MAC components to the PPCP steps. Additionally, Cases 2–1 and 2–3 illustrate the application of this tool in the PPCP.

FIGURE 2–3 Relationship between PPCP and QuEST/SCHOLAR-MAC patient assessment models. Key: OTC = Over-the-counter; PPCP = Pharmacists' Patient Care Process; Rx = prescription.

Special Populations and PPCP in Self-Care

Special considerations in the PPCP are warranted for certain groups of patients known to be at higher risk for medication-related problems. These populations include pediatric, geriatric, pregnant, and lactating patients, in whom medication-related problems with nonprescription products can have serious consequences, even in a self-care setting. This final section of the chapter summarizes the characteristics and physiologic and pharmacokinetic considerations for various special populations and provides general considerations for self-care encounters using the PPCP in each such patient group. Most disorder-specific chapters in this book include a “Special Populations” section under “Product Selection Guidelines.”

Pediatric Patients

Pediatric patients present unique challenges in providing selfcare recommendations. The pediatric population consists of the following subgroups: neonates (birth to 1 month), infants (1 month to 2 years), children (2–12 years), and adolescents (12–16 years).⁴⁶ Significant differences in the pharmacokinetic and pharmacodynamic profiles between the pediatric subpopulations and general adult profiles are well recognized.

Pharmacokinetic processes (e.g., absorption, distribution, metabolism and excretion) in the pediatric population vary widely because body and organ systems in this age group are in a continuous state of growth and development.⁴⁷ The body is less tolerant of changes, especially within the younger age spectrum, which includes neonates, infants, and children. Clinical data for pediatric patients are limited, resulting in insufficient drug labeling and potential challenges with medication dosing and administration.⁴⁸ With these patients, it is particularly important to carefully evaluate the basis for

self-care recommendations and to closely follow approved labeling recommendations when self-treatment is deemed appropriate. A further consideration is that the pharmacist will communicate with the parent or caregiver in most encounters, rather than directly with the patient, which may affect data collection and other aspects of the PPCP assessment in this population.

PPCP Considerations for Pediatric Patients

Specific information to consider during each step of the PPCP for pediatric patients is outlined next.

Collect

- Verify the patient's age.
 - Several nonprescription medications have exclusions for use based on age. For example, ibuprofen is not indicated in children younger than 6 months (see [Chapter 6](#)).
 - Age is an important predictor of general exclusions for self-care regardless of nonprescription product indication and labeling. For example, infants younger than 3 months who present with fever are not candidates for self-care management and should receive a medical referral (see [Chapter 6](#)).
 - Age also can help guide dosage form selection. In general, younger children (<6–7 years) may have difficulty swallowing solid oral dosage forms. However, this patient-specific factor varies by age and should be reviewed and assessed individually.⁴⁹
- Obtain the patient's weight.
 - Nonprescription medications may be dosed according to weight for infants and children. For example, acetaminophen is dosed at 10–15 mg/kg every 4–6 hours (see [Chapter 5](#)).
- Consider caregiver factors.
 - Collecting information that leads to an appropriate assessment of the literacy and/or health literacy of the parent or caregiver is important when that person will be implementing self-care measures for the pediatric patient.
- Consider potential child care or school scheduling.

- Collecting information on whether the child attends daycare or school or is involved in extracurricular activities may help guide product selection based on dosing frequency or ease of administration.

Assess

- Determine exclusions for self-treatment.
 - Pediatric patients are more likely to have exclusions for self-treatment for various reasons. Examples are circumstances for which nonprescription medications are not available for the child's age group or in which the disorder is not self-treatable because of age considerations. For example, girls younger than 12 years who present seeking treatment for vulvovaginal candidiasis should be referred to a pediatrician or other specialist. Referral is required because of the rarity of this condition in children, which may be indicative of a more serious disorder (see [Chapter 8](#)).
- Evaluate for potential adverse drug effects.
 - Some nonprescription medications have the potential to cause unique adverse effects in children that would not occur in adults. For example, some antihistamines may cause paradoxical effects or excitation in children (see [Chapter 11](#)). With this possibility in mind, the pharmacist may recommend giving the antihistamine earlier in the day to gauge response and monitor for a potential adverse reaction, or administering the first dose on a weekend to avoid negative effects on school performance.

Plan and Implement

- Consider nonpharmacologic therapy.
 - Recommendations for nonpharmacologic measures for selfcare may be more common for pediatric patients than for the general adult population because of labeling restrictions of nonprescription medications, safety issues, and/or unknown factors regarding the use of certain products in this age group. For example, FDA recommends that cough and cold products not be used in children younger than 2 years of age, requiring nonpharmacologic measures as the primary recommendation for

treating colds in younger pediatric patients⁵⁰ (see [Chapter 11](#)). Pharmacists should assess the need for nonpharmacologic interventions and educate the parent or caregiver when nonpharmacologic recommendations are made. Parents with older children or those who may have used cough and cold products before the FDA recommendations were made available may not be aware of the changes or understand the rationale. Research confirms that parents may be unaware of the FDA changes,⁵¹ may continue to use products despite awareness of the changes,⁵² and/or lack confidence in the FDA recommendations.⁵³ The pharmacist has an important role in educating parents and/or caregivers, for whom additional time may be needed for effective counseling.

- Provide specific patient education and counseling.
 - FDA and the Consumer Healthcare Products Association have extensive resources for parents and caregivers on selection, dosing, and administration of nonprescription medications to children.^{54,55} The pharmacist's familiarity with these resources may be beneficial in patient-specific communications and also with general educational opportunities within the pharmacy.
- Describe and demonstrate appropriate dosing and administration of medications.
 - Liquid formulations require accurate measuring to ensure appropriate doses are administered, and their use has historically been a source of medication errors and unintentional medication overdoses.⁵⁶ FDA released guidelines in May 2011 for liquid nonprescription medication products that include a requirement for packaging to include a product-specific dispensing device, such as a dropper, cup, oral liquid syringe, or calibrated spoon.⁵⁷ Parents and caregivers should be instructed to use only the device included with that particular product, and only for one patient/child. No standard was available before release of the guidelines, and almost all pediatric nonprescription liquid medications contained highly variable and inconsistent dosing directions and measuring devices.⁵⁸ [Table 2-1](#) summarizes the key points of the guidance document.
 - The American Academy of Pediatrics (AAP) published

recommendations in April 2015 that called for exclusive metric-based dosing (i.e., mL) to avoid dosing errors associated with common kitchen spoons (i.e., teaspoons, tablespoons). They include a call for manufacturers to eliminate labeling, instructions, and dosing devices that contain units other than metric units. To date, however, FDA has not made any changes based on these recommendations.⁵⁶ AAP encourages advanced counseling strategies (e.g., teach-back, drawings/pictures, dose demonstration, show-back) to further reduce dosing errors.⁵⁶ The pharmacist is uniquely qualified for this role in self-care support with use of oral liquid nonprescription medications for pediatric patients.

- Age-appropriate tips for oral liquid medication administration are provided in [Table 2-2](#).
- Consider engaging the child.
 - Depending on age, the pharmacist may wish to include the child in the implementation step by allowing handling of the administration device, demonstrating its use, describing the medicine's flavor or taste, explaining how the medicine makes people feel better, encouraging the child's participation through reminders to the parent/caregiver about dosing ("Time for my medicine!"), and emphasizing that medicine should be taken only when given by the parent/caregiver. To effectively involve the child, the pharmacist should get down on a physical level that allows speaking directly to the child.

Table 2-1 FDA Key Recommendations on Dosage Delivery Devices for Orally Ingested Nonprescription Liquid Drug Products

- A dosing device should be included with all oral liquid nonprescription products.
- The device should be calibrated to the dose recommended in the product directions (e.g., teaspoon, tablespoon, milliliter).
- The device should be used only with the product with which it is packaged.
- The markings should remain visible even when the liquid is in the device.

Key: FDA = U.S. Food and Drug Administration.

Source: Reference 57.

Table 2–2 Selected Administration Guidelines for Oral Medications

Infants

- Use a calibrated dropper or oral syringe.
- If a medicine dropper is used, the medication should be squirted into the side of the cheek and not straight back into the throat so that the infant does not choke.
- Do not place the child's medication in the formula, because the baby might not like the taste of the formula and might refuse to take this formula in the future.
- Support the infant's head while holding the infant in the lap.
- Give small amounts of medication at a time to prevent choking.
- Crush non-enteric-coated or non-sustained-release tablets into a powder and sprinkle them on small amounts of food, if infant has been introduced to solid foods.
- Provide physical comfort while administering medications to help calm the infant.

Toddlers

- Allow the toddler to choose a position in which to take the medication.
- If necessary, disguise the taste of the medication with a small volume of flavored drink or small amounts of food. A rinse with a flavored drink or water will help remove an unpleasant aftertaste.
- If the medication is not palatable, ask the pharmacist whether the pharmacy offers a flavoring service and can add flavoring to the child's medication. Refrigeration also may help.
- Make sure that the medication is not referred to as candy.
- Use simple commands in the toddler's jargon to obtain cooperation.
- Allow the toddler to choose which medication (if multiple) to take first.
- Provide verbal and tactile responses to promote cooperative taking of medication.
- Allow the toddler to become familiar with the oral dosing device.

Preschool Children

- If possible, place a tablet or capsule near the back of the child's tongue, then provide water or a flavored liquid to aid the swallowing of the medication.
- If the child's teeth are loose, do not use chewable tablets.
- Use a follow-up rinse with a flavored drink to help minimize any unpleasant medication aftertaste.
- Allow the child to help make decisions about dosage formulation, place of administration,

which medication to take first, and type of flavored drink to use.

Follow-up: Monitor and Evaluate

- Pharmacists should ensure that the parent or caregiver has a clear follow-up plan that specifies a specific time frame and appropriate action step. Because of pediatric patients’ smaller body mass and decreased physiologic tolerance to change, parents or caregivers may be directed to schedule a follow-up visit with another health care provider as soon as possible to avoid potential adverse events.

Geriatric Patients

The U.S. geriatric, or older adult, population, defined as that consisting of people 65 years of age and older, is growing rapidly, and its members are heavy consumers of both prescription and nonprescription medications, as discussed in [Chapter 1](#).^{59,60} Pharmacists can expect a large number of self-care requests and encounters for patients in this age group. Understanding the unique characteristics and needs of older adults is critical to achieving appropriate patient-centered care.

The aging process includes certain physiologic changes and decline in the function of many organ systems.⁶¹ A number of these changes and characteristics can affect pharmacokinetic and pharmacodynamic profiles of medications. Absorption, distribution, metabolism, and excretion, the four primary facets of *pharmacokinetics*, or how the body processes a drug, can be altered in older adults. The general age-related pharmacokinetic changes are well described in the literature and are summarized in [Table 2–3](#).^{59,62}

Table 2–3 General Age-Related Pharmacokinetic Changes in Older Adults	
Pharmacokinetics	Physiologic Change(s)
Absorption	Increased GI secretions and motility; decreased surface area and blood flow; increased pH
Distribution	Decreased total body water and muscle mass; increased body fat
Metabolism	Decreased hepatic blood flow and enzyme activity

Pharmacokinetics	Physiologic Change(s)
Elimination	Decreased renal function

Key: GI = Gastrointestinal.

Source: References 59 and 62.

The overall effect of changes to absorption, distribution, metabolism, and excretion varies, making it difficult to accurately predict the pharmacokinetic profile of a specific drug in older adults. Patients in this age group experience these changes to a variable degree or may not experience them at all. Without the ability to assess the individual patient's specific body functionality, the pharmacist may often assume that the older adult has age-related changes in function and then adjust medication and dosage recommendations accordingly. For example, if an older adult presents seeking advice for a nonprescription calcium supplement for bone health, the pharmacist may consider a recommendation for a calcium citrate product because it relies less on gastric pH for absorption (see [Chapter 23](#)). Another example of applying knowledge of age-related pharmacokinetic changes to recommendations for nonprescription medications is that of an older adult who requests assistance in selecting an analgesic. Additional caution is warranted in advising older patients regarding use of NSAIDs because of gastrointestinal changes, cardiovascular issues, and renal function concerns associated with aging (see [Chapter 5](#)).

In addition to the pharmacokinetic changes seen in older adults, the following facts and statistics should be considered in the PPCP:

- Polypharmacy (concurrent use of 5 or more medications) and high risk of adverse drug events
 - More than 1 in 3 older adults take 5 or more prescription medications concurrently.^{63,64}
 - One in 6 older adults are at risk for major drug-drug interactions.⁶³
- Multiple chronic disorders

- Almost 3 in 4 people 65 years of age and older have multiple chronic disorders.⁶⁵
- Alterations in senses⁶⁶
 - One in 6 older adults have impaired vision.
 - One in 4 older adults have impaired hearing.
- Cognition and memory changes
 - Although aging and memory loss are not synonymous, 1 in 10 people 65 years of age and older have Alzheimer disease.⁶⁷
- Misperceptions that deficits or symptoms are part of the aging process instead of a characteristic of a disease or disorder can contribute to underreporting of such problems.⁶⁸
- *Dysphagia* (difficulty swallowing) affects 15% of the older adult population.⁶⁹
- Sensitivity to anticholinergic medications^{70,71}
 - Salivation, lacrimation, urinary output, and gastrointestinal motility are decreased and can cause nutrition problems, blurred vision, urinary retention, and constipation.
 - Cardiovascular system and body temperature regulation are altered.
 - Falls, delirium, and cognitive impairment can occur.
- The role of informal caregivers who provide assistance or participate in making treatment decisions

PPCP Considerations for Geriatric Patients

Specific information to consider during each step of the PPCP for geriatric patients is outlined next.

Collect

- Recognize that the collection step may take additional time in older adults because of the amount and complexity of information needed to make an appropriate assessment.
- Gather more detailed information to perform a comprehensive review of medical conditions and medication history to avoid potential

medication-related problems.

- Consult the pharmacy's prescription medication profile, when available, to identify potential medication-related problems from multiple medications.
 - Ask about known renal and hepatic disease or impairment.
 - Inquire about chronic health problems or disorders that may affect nonprescription medication recommendations or present exclusions for self-care, such as hypertension, diabetes, lung diseases, or Alzheimer disease.
- Observe or ask about sensory impairments (especially in vision and hearing) and memory deficits or signs of cognitive decline.
 - Involve family members or caregivers, when available, if memory impairment or cognitive decline is evident.
 - Include more in-depth questions regarding symptoms that could be unrecognized or falsely attributed to age.
 - Ask about any swallowing difficulties.
 - Inquire about physical limitations that may affect medication use, such as ability to open a medication container or apply topical agents to specific areas.

Assess

- Evaluate for potential duplicate therapy related to polypharmacy.
 - Pharmacists should specifically consider nonprescription medications available with a prescription such as proton pump inhibitors, histamine type 2 receptor antagonists, antihistamines, and analgesics to avoid duplicate therapy.
- Evaluate for potential adverse drug effects.
 - Polypharmacy increases the likelihood of adverse effects⁷²; therefore, current medications should be considered as a potential cause of any new symptom in the older adults until proven otherwise.
 - Several nonprescription medications are listed in the American Geriatrics Society Updated Beers Criteria of Potentially Inappropriate Medication Use in Older Adults.⁷³ This resource contains evidence-based information about safe medication use by older patients, including nonprescription medications

associated with high risk of adverse effects in this population. For example, based on these criteria, diphenhydramine may not be an appropriate recommendation in older adults for the treatment of insomnia and is likely to confer more risk than benefit⁷³ (see [Chapter 46](#)).

- Evaluate whether the normal adult dose is too high.
 - Dosage adjustments may be necessary for nonprescription medications in persons who have renal and/or hepatic impairment, just as with prescription medications. Because nonprescription medications are labeled to allow the patient to safely determine the appropriate drug and dosage without the advice of a health care provider, the Drug Facts label may simply state that patients should avoid taking this medication without medical supervision if they have kidney or liver disease. Labels will not provide the dosage adjustments for specific levels of renal or hepatic dysfunction. The pharmacist's self-care assessment should determine the appropriateness of nonprescription therapy for a patient with impaired renal or hepatic function.

Plan and Implement

- Consider concomitant medical conditions and other medications during product selection.
 - Older adults are more likely to have multiple medical conditions; therefore, product selection based on chronic disease status is warranted in this population. In general, it is best to avoid elixirs and sugar-sweetened liquids in patients with diabetes and to avoid liquids with excessive alcohol content in all older patients.
- Evaluate for nonadherence to medication regimens.
 - Consider the complexity of the patient's current medication regimen. Pharmacists should select products that complement or match timing for dosing with this regimen, when possible.
 - Consider adherence-assistive devices, such as medication reminder boxes, or involve caregivers when appropriate.
- Determine appropriate dosing and administration of medications.
 - Alternative dosage forms or administration methods may be

needed for patients with dysphagia. Determining appropriate dosage forms is a complex process and requires that the pharmacist collaborate with the patient or caregiver and the patient's prescribers. Considerations in making this determination may include, but are not limited to, whether the medication can be crushed, chewed, or thickened, depending on the severity of dysphagia.

- Provide specific patient education and counseling.
 - A patient who is hard of hearing may require the pharmacist to speak slowly in a slightly raised voice, but to avoid yelling, and to consider moving the encounter to an area of reduced noise. Another technique includes, but is not limited to, provision of written instructions if the patient prefers this method of communication.
 - A patient with low vision will need clear, audible instructions regarding product use. Another technique includes, but is not limited, to provision of large-print instructions.
 - Patients with physical challenges such as decreased dexterity associated with arthritis may require selection of a medication without child-resistant closures, and counseling should specifically emphasize the need to keep the product out of the reach of children and pets.
 - Given the high risk of polypharmacy in older adults, it is important to explain all active ingredients in the recommended product, to avoid duplicate therapy.

Follow-up

- As with pediatric patients, certain characteristics of older adults may be relative indications for referral to another health care provider sooner rather than later, to avoid adverse events. This is particularly true for frail older adults whose nutritional status and lower weight may contribute to higher risk for serious consequences if the disorder suddenly worsens or nonprescription therapy is ineffective. Patients who have multiple chronic diseases or limited social support or those with impairments in cognitive function also may require more intensive follow-up strategies.

Pregnant Patients

Drug therapy may be necessary to treat medical conditions or to manage common disorders associated with pregnancy. Many medications cross the placenta to some extent, with associated inherent risk, because a mother who ingests a medication may expose her unborn infant as well. Considerations to ease the mother's discomfort and to limit effects of nonprescription medications on the developing fetus are crucial. Patients should never presume that a nonprescription product is safe to use during pregnancy, and pharmacists should be able to provide well-informed guidance to determine when self-care is appropriate and when referral is needed.

PPCP Considerations for Pregnant Patients

Specific information to consider during select steps of the PPCP for the pregnant patient is outlined next.

Collect

- The pharmacist should ask all female patients of childbearing age who present with common symptoms of early pregnancy, such as nausea and vomiting, if they are pregnant or could be pregnant. Visual observation is not reliable, especially at early stages of pregnancy.
- If pregnancy is confirmed, identify the likely stage of pregnancy. For some medications, packaging includes specific information regarding safety based on the trimester of pregnancy. For example, the Drug Facts label for ibuprofen specifically warns against use in the last 3 months of pregnancy because of risks to the fetus.⁷⁴

Assess

- Evaluate the safety of medication use during pregnancy.
 - The Drug Facts label for specific nonprescription medications may advise the pregnant patient to consult a health care professional before use. The pharmacist should assess the patient's symptoms and determine whether selftreatment is appropriate with a safe product and/or if referral to another health care provider is needed.
 - FDA recently issued a final rule regarding revised pregnancy and

lactation risk categories. Pharmacists should be aware that this new rule applies only to prescription products. The Preface of this book provides a detailed explanation of the pregnancy and lactation data. The new data may include information for some nonprescription medications that also are available as prescription drugs.

- Determine whether the patient's pregnancy status is an exclusion for self-treatment even if a nonprescription product is considered safe for use in pregnancy.
 - For example, calcium carbonate generally is considered the antacid of choice for the pregnant patient; however, heartburn occurring in a patient without formal evaluation and diagnosis by an appropriate health care provider during pregnancy is an exclusion for self-treatment (see [Chapter 13](#)).

Plan and Implement

- Consider nonpharmacologic therapy options in pregnant patients.
 - To minimize medication exposure, the pharmacist may initially recommend nonpharmacologic self-care measures for pregnant patients. For example, in the pregnant patient who presents with allergic rhinitis symptoms, initial nonpharmacologic recommendations may include avoiding triggers, using saline nasal sprays or rinses, or placement of nasal dilating strips to open nasal passages. Even if a safe nonprescription medication for allergic rhinitis is available, pregnant patients may still be referred to another health care provider to confirm that the nonprescription product is safe for use (see [Chapter 11](#)).
- Discourage the use of homeopathic and herbal remedies in pregnancy because safety and effectiveness typically have not been established.
- Evaluate for nonadherence to medication regimens.
 - Because nausea and vomiting are common in early pregnancy, the pharmacist can provide education to minimize their effects on medication adherence. Advising the patient to eat small meals and frequent snacks and crackers may alleviate or minimize nausea and vomiting. Additionally, the patient can be advised to avoid foods, smells, or situations that are likely to cause vomiting.

(see [Chapter 19](#)). When possible, a nonprescription medication schedule should be established to avoid times when nausea and vomiting typically are present or more severe.

Follow-up

- Pharmacists should ensure that the pregnant patient has a clear follow-up plan that includes a specific time frame and appropriate action steps. In general, when the goal of therapy is not met in the intended time frame, a conservative approach includes referral to another health care provider as soon as possible to avoid adverse events.

Lactating Women

Similar to considerations in the pregnant patient, the nursing mother's use of medication while breastfeeding has potential for adverse effects on the infant. This potential for infant exposure is affected by the medication-specific properties and concentrations in the mother's blood, the timing of medication administration, and the medication safety profile in the infant.⁷⁵ The medication's effect on milk supply, as with some decongestants, also should be considered.⁷⁶ The benefit to the mother must again be weighed against the risks to the infant.

PPCP Considerations for Lactating Women

Specific information to consider during select steps of the PPCP for the lactating woman is outlined next.

Collect

- The pharmacist should ask female patients, particularly those who present with an infant or young child, about breastfeeding status. Assumptions or judgments are not appropriate, and professional communication is essential to collect the appropriate information to make the best assessment.

Assess

- Evaluate the safety of medication use during lactation.
 - The Drug Facts label for specific nonprescription medications

may advise the lactating patient to consult a health care professional before use. The pharmacist should assess the patient's symptoms and determine whether selftreatment is appropriate with a safe product and/or if referral to another health care provider is needed.

- FDA recently issued a final rule regarding revised pregnancy and lactation risk categories. Pharmacists should be aware that this new rule applies only to prescription products. The Preface of this book provides a detailed explanation of the pregnancy and lactation data. The new data may include information for some nonprescription medications that also are available by prescription. For example, ranitidine is available as both a prescription and a nonprescription medication, so the detailed pregnancy risk information may be not be consistent for both versions.
 - If pharmacists are unable to ascertain the safety of a medication in breastfeeding, the patient should be referred to her regular health care provider, a lactation consultant, or the child's pediatrician. Pharmacists should encourage the patient to consult with another health care provider before discontinuing breastfeeding to take a nonprescription medication.
 - Consult additional, reliable resources.
- LactMed is a free database, available online and through an application, that is peer reviewed, recommended by AAP, and maintained by the National Library of Medicine.⁷⁷ The database contains information on maternal and infant drug levels, effects on lactation and in breastfed infants, and alternative drugs to consider.^{75,78}

Plan and Implement

- Consider nonpharmacologic therapy options.⁷⁹
- Choose medications with the shortest half-life.⁷⁹

Discourage the use of homeopathic and herbal remedies during lactation, because safety and effectiveness typically have not been established.⁷⁵

Follow-up

Pharmacists should ensure that recommendations made to women who are

lactating include a clear follow-up plan with a specific time frame and appropriate action step. When therapeutic goals are not met in the intended timeframe, quick referral to another health care provider is advisable to avoid adverse events.

Case 2-1

A 35-year-old woman who is a regular patient of yours was just stung by a bee on her way to your pharmacy to pick up a prescription. She wants to know what she should do to stop the burning.	
Information to Obtain from the Patient	What the Patient Told You
Quickly and accurately assess the patient:	
Ask about the current problem (SCHOLAR).	
<u>Symptoms</u>	
What are the main and associated symptoms?	"Pain from a bee sting on my right hand."
<u>Characteristics</u>	
What is the situation like? Is it changing?	"Burning, itching, and redness." [Pharmacist notices mild, localized erythema with no signs or symptoms of systemic anaphylaxis.]
<u>History</u>	
What has been done so far? Has this ever happened before, and if so, what was done then? What was successful, and what wasn't?	"Nothing, because it just happened." "This is the first bee sting I've ever experienced."
<u>Onset</u>	
When did it start?	"Five minutes ago as I was walking from my car to the

	pharmacy.”
<u>L</u> ocation	
Where is the problem?	“The palm of my right hand.”
<u>A</u> ggravating factors	
What makes it worse?	“When I touch the bee sting area.”
<u>R</u> emitting factors	
What makes it better? Ask about other <u>M</u>edications, <u>A</u>llergies, and <u>C</u>onditions (MAC): Within reason, get as much detail as possible to assist in the decision-making process.	“I haven’t tried anything yet.” • “I take levothyroxine 50 mcg every day.” • “I’m not allergic to any medications.” • “This is the first time I’ve ever had a bee sting.”
The “E.S.T.” pieces of QuEST: Establish, Select, and Talk	Your Assessment, Recommendation, and Counseling
<u>E</u>stablish that the patient is an appropriate self-care candidate: • Any severe symptoms? • Any symptoms that persist or return repeatedly? • Is the patient self-treating to avoid medical care? <u>S</u>uggest appropriate self-care strategies.	• Symptoms are mild and localized to the right hand. Because this was her first bee sting, the risk of hypersensitivity is low. • She is not exhibiting any signs of an anaphylactic reaction, such as hives, swelling, dizziness, weakness, or difficulty breathing. • <i>Nondrug</i>: Remove the stinger by scraping with a credit card immediately; then apply an ice pack or cold compress. • <i>Medication</i>: Apply local anesthetic, such as benzocaine 20% aerosol spray, to affected area 3–4 times daily for up to 7 days to reduce itching and burning.
<u>T</u> alk with the patient about	Key Counseling Points:

• Medication action, administration, and adverse effects • What to expect from the treatment • Appropriate follow-up	• “I think you can do a few things to help this situation. Benzocaine is a topical anesthetic that will help relieve itching and irritation associated with the bee sting. Spray the affected area 3–4 times daily for up to 7 days. If the site becomes more irritated or redness increases, stop using the spray.” • “The benzocaine should provide immediate relief. The symptoms should resolve over time and should not last longer than 1 week.” • “If you experience any hives, excessive swelling, dizziness, vomiting, or difficulty breathing, seek medical attention immediately. If you feel your condition is getting worse or your symptoms have not resolved by 1 week, seek medical attention.” • “Keep the area clean by washing regularly with soap and water; do this before each application of benzocaine.”

Case 2–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of difficulty sleeping. He describes difficulty falling asleep about 2–3 nights a week and has early awakening with inability to fall back to sleep 5–7 days a week. “I just don’t sleep very well anymore, and I wonder if there’s something I can take that will help.” Symptoms started approximately 1 month ago.
b. Description of any factors	He sometimes, but not always, has “better sleep” if he sleeps

Relevant Evaluation Criteria	Scenario/Model Outcome
that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	upright in a recliner chair instead of the bed.
c. Description of the patient's efforts to relieve the symptoms	He tried melatonin 3 mg daily before bedtime last week for 3–4 nights with no relief.
d. Patient's identity	James Markum
e. Patient's age, gender, height, and weight	81 years, male, 5 ft 9 in., 170 lb
f. Patient's occupation	Retired railroad worker
g. Patient's dietary habits	Normal balanced diet. He drinks 3 cups of caffeinated coffee daily; no alcohol.
h. Patient's sleep habits	Averages 5–6 hours per night. Naps 1–2 times per day in morning and/or afternoon.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Gastroesophageal reflux disease</i> : omeprazole 20 mg daily; <i>hypertension</i> : hydrochlorothiazide 25 mg daily, lisinopril 20 mg daily; <i>depression</i> : sertraline 100 mg daily; <i>Alzheimer dementia</i> : donepezil 5 mg daily
j. Allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	None
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Insomnia, possibly secondary to current medical conditions
3. Identify exclusions for	Age ≥65 years, chronic insomnia (>3 weeks), sleep disturbances

Relevant Evaluation Criteria	Scenario/Model Outcome
self-treatment.	possibly secondary to medical disorders
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to his regular health care provider. (2) Recommend self-care with lifestyle modifications for good sleep hygiene and diphenhydramine. (3) Recommend self-care until the patient can see his primary care provider.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult his primary care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"I recommend you see your primary care provider for treatment of your sleep problems."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This is the best option for you since you have had the sleep problems for several weeks and your situation may be related to your current medical conditions. Also, the nonprescription medications typically used to treat sleep problems are not the best option for you. You may require prescription medications or adjustments of your current medications by your primary care provider."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey	Criterion does not apply in this case.

Relevant Evaluation Criteria	Scenario/Model Outcome
accurate information to the patient or caregiver.	
Solicit follow-up questions from the patient or caregiver.	"Are there any drugs I can take to help until I get an appointment with my physician?"
Answer the patient's or caregiver's questions.	"No—you tried the melatonin and it didn't work. There are no other nonprescription medications that are safe and effective for your sleep problems. I recommend contacting your primary care provider for an appointment. If you are unable to see your provider immediately, you can try to improve your sleep by avoiding or reducing caffeine, avoiding daytime naps, and participating in something relaxing before bedtime, such as reading."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Markum in 1-2 days to ensure that he has sought medical care for insomnia.

Key: NKA = No known allergies; PCP = primary care provider.

Case 2–3

The mother of a 3-month-old boy calls the pharmacy requesting advice for her son's gastrointestinal illness: He has had several watery stools since yesterday.

Information to Obtain from the Patient	What the Parent Told You
<u>Quickly</u> and accurately assess the patient:	

Ask about the current problem (SCHOLAR).	
<u>S</u> ymptoms	
What are the main and associated symptoms?	"My son has had watery diarrhea since yesterday."
<u>C</u> haracteristics	"The stool is very thin and has no consistency at all. He's breastfed, and he has stopped eating the last few hours. He seems more tired and has not had a wet diaper for several hours."
What is the situation like? Is it changing?	
<u>H</u> istory	
What has been done so far? Has this ever happened before, and if so, what was done then? What was successful; what wasn't?	"I haven't given him anything to stop the diarrhea."
<u>O</u> nset	
When did it start?	"About 24 hours ago."
<u>L</u> ocation	
Where is the problem?	"Just diarrhea. No vomiting."
Aggravating factors	
What makes it worse?	"Nothing."
<u>R</u> emitting factors	
What makes it better?	"Nothing."
Ask about other <u>M</u> edications, <u>A</u> llergies, and <u>C</u> onditions (MAC): Within reason, get as much detail as possible to assist in the decision-making process.	• "My son takes D-Vi-Sol Vitamin D drops daily." • "He's not allergic to anything that I know of." • "He is otherwise very healthy. This is the first time he has been sick."

The “E.S.T.” pieces of QuEST: Establish, Select, and Talk	Your Assessment, Recommendation, and Counseling
Establish that the patient is an appropriate self-care candidate. - Any severe symptoms? - Any symptoms that persist or return repeatedly? - Is the patient self-treating to avoid medical care? Suggest appropriate self-care strategies.	The child’s symptoms are considered severe because he is younger than 6 months and has diarrhea with signs of moderate to severe dehydration. He is not a candidate for a self-care management approach. “There aren’t appropriate nonprescription treatments to help your son, because he is so young. You should call your pediatrician immediately. Your son may need fluids that could be given only in an emergency department.”
Talk with the patient about - Medication action, administration, and adverse effects - What to expect from the treatment - Appropriate follow-up	Key Counseling Points: “Because your child is so young and has diarrhea, you should contact your son’s pediatrician immediately to ensure that he gets the fluids and help he needs to prevent becoming dehydrated.”

Case 2–4

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of a burning sensation in her stomach and throat that often is accompanied by feelings of fullness and “acid in my throat.” The

Relevant Evaluation Criteria	Scenario/Model Outcome
	burning occurs after a heavy meal no more than once weekly. Symptoms began about 1 month ago and last 2–4 hours after a meal.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms occur after eating lunch out with coworkers or after potlucks at work and last for 2–4 hours after the meal.
c. Description of the patient's efforts to relieve the symptoms	Eating a few peppermint candies did not help with symptoms. She tried Tums (calcium carbonate 500 mg) once without full symptomatic relief.
d. Patient's identity	Maria Flores
e. Patient's age, gender, height, and weight	43 years, female, 5 ft 4 in., 175 lb
f. Patient's occupation	Office assistant
g. Patient's dietary habits	Normal balanced diet. She drinks 4 or 5 cups of caffeinated coffee daily; 3 or 4 alcoholic beverages once per week.
h. Patient's sleep habits	Averages 7–9 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	No concurrent medical conditions; multivitamin daily
j. Allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Weight gain of 10 lb in the past 3 months
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Infrequent postprandial burning sensation is consistent with uncomplicated heartburn. Patient denies pregnancy.
3. Identify exclusions for self-treatment.	None

Relevant Evaluation Criteria	Scenario/Model Outcome
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required and share this information with the patient or caregiver.	Options include (1) Refer the patient to her regular health care provider. (2) Recommend self-care with lifestyle modifications and nonprescription acid-reducing medication. (3) Recommend self-care until the patient can see her primary care provider.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	A nonprescription acid-reducing medication along with lifestyle modifications should be effective.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"There are a number of things you can do on your own to decrease your symptoms. In addition, I recommend that you use the acid-reducer famotidine 20 mg for additional relief."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This medication is a reasonable first option for treating your symptoms before consulting your primary care provider. Because the heartburn is predictable with large meals, primarily after lunch, using the famotidine on an as-needed basis should be sufficient."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	"Swallow one tablet 10–60 minutes before eating food or drinking beverages that typically cause heartburn."
b. Maximum number of days the	"You can use this for up to 14 days in a row, if

Relevant Evaluation Criteria	Scenario/Model Outcome
therapy should be employed	needed. If you think you need it beyond that time, call your primary care provider for an appointment. From what you said, I can't imagine you'll need this medication more than once a week, if that."
c. Product administration procedures	"Be sure to take this medication with a full glass of water."
d. Expected time to onset of relief	"You should feel better a few hours after you take this medication. Often the relief happens sooner."
e. Degree of relief that can be reasonably expected	"You should expect at least some relief; often patients get complete relief with a single dose."
f. Most common adverse effects	"Some of the more common adverse effects are headache, diarrhea, dizziness, and constipation, but these don't happen too often and are rarely serious."
g. Adverse effects that warrant medical intervention should they occur	"If you experience any unusual bleeding or bruising, be sure to call your primary care provider and stop using this medicine."
h. Patient options in the event that condition worsens or persists	"If this situation worsens, please consult your primary care provider."
i. Product storage requirements	"Store this medicine in a cool dry place out of the reach of children."
j. Specific nondrug measures	"Other things that can help you include eating smaller, more frequent meals and avoiding or eating less of foods and drinks that cause your symptoms."
Solicit follow-up questions from the patient or caregiver.	"May I take the medication after I start the meal if I have forgotten to take it beforehand?"
Answer the patient's or caregiver's questions.	"Yes, but the medication may not be as effective in preventing heartburn symptoms."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	To evaluate efficacy of the treatment, advise Mrs. Flores to call the pharmacy to report her response after using the medication as needed for heartburn prevention.

Key: NKA = No known allergies.

Key Points for PPCP in Self-Care

- Pharmacists play an active role in assisting patients with selfcare by using the five key PPCP components: collect, assess, plan, implement, and follow-up: monitor and evaluate.
- The PPCP is the same process for self-care encounters as it is with any other pharmacist-provided patient care service and in any practice setting. The process is adaptable, depending on the breadth and depth of care needed.
- Collecting essential information for the specific presenting medical condition will lead to an appropriate assessment and may identify unique considerations in self-care, such as exclusions for self-treatment.
- The plan should include the self-care recommendation, including nonpharmacologic therapies, and the goal of therapy to identify anticipated outcomes of the recommendation and the time frame in which the outcome is expected.
- Follow-up in self-care encounters should include specific guidance on what action to take for efficacy or safety considerations. Such guidance may include resolution of the self-care disorder with no further action needed, a return to the pharmacist for additional assessment, selection of an alternative nonprescription medication, or medical referral.
- The PPCP in self-care has patient-centered care at its core, with continual collaboration, communication, and documentation of care with other health care providers.

- Efficiency in the PPCP is imperative in a community pharmacy. Tools such as QuEST/SCHOLAR-MAC and the algorithms for specific disorders in this book serve as resources to streamline the process and assist in quick and accurate application of the process in this practice setting.
- Special populations, which include pediatric patients, older adults (geriatric patients), pregnant women, and lactating patients, are at increased risk for serious adverse events if not appropriately assessed.
- Using the PPCP in self-care encounters for special populations may take additional time because of the amount and complexity of information needed for an appropriate assessment.

Chapter 3: Exploring Cultural Aspects of Self-Care

Authors: Anita N. Jacobson, Jeri J. Sias

Cultural background, identity, and characteristics are well recognized to influence patients' specific health care beliefs and behaviors.^{1,2} This chapter explores cultural aspects of self-care to guide health care providers in diverse practice settings, and often of various cultural and ethnic backgrounds themselves, to better understand patient health decisions and to develop individualized approaches to patient education. Formulation of a successful and appropriate self-care plan for a given health issue is best achieved by incorporating the patient's health beliefs and behaviors as a key component of the plan. If cultural and diversity issues are not identified and considered early in the clinical encounter, the health care provider may find challenges with assessing medical problems and educating patients effectively, and patients may have difficulty accepting and implementing self-care recommendations.¹⁻³

In clinical pharmacy practice, recognition of cultural context in patients' self-care decisions related to overall health requires familiarity with basic concepts in this aspect of service. Accordingly, this chapter begins by defining important cultural and diversity terms and then reviews theoretical frameworks for cross-cultural care. Next, demographic shifts in the composition of the U.S. population are outlined to illustrate the relevance of serving diverse populations, along with socioeconomic considerations, in the delivery of self-care health services. Examples of cultural behaviors found in various populations across the United States also are presented, with a focus on differences in cultural approaches to seeking care, particularly self-care. In this context, a valuable resource developed by the Joint Commission of Pharmacy Practitioners is the Pharmacists' Patient Care Process, which can be applied to optimize clinical interactions with marginalized populations and to assist health care providers in developing more inclusive and culturally sensitive treatment plans. This sequential process serves as the framework for the clinical cases presented throughout the book⁴

Definitions

Culture can be understood as an “integrated pattern of human behavior that includes thoughts, communications, languages, practices, beliefs, values, customs, courtesies, rituals, manners of interacting, roles, relationships and expected behaviors of a racial, ethnic, religious, or social group; the ability to transmit the above to succeeding generations; and is dynamic in nature.”⁵ Culture can influence all aspects of human behavior. Of particular importance is the role of culture in health-seeking and health maintenance behaviors and how these health beliefs and practices are passed from generation to generation.

A more succinct definition of culture is the sum total of socially inherited characteristics of a human group. This set of characteristics derives from assumptions learned from family and society about the nature of the physical, social, and spiritual world, as well as the goals of life and acceptable ways by which they can be achieved.² Culture—as a learned set of values, beliefs, and meanings—guides patient decisions, attitudes, and actions.

In this chapter, the term *Western medicine* (also viewed as *allopathic* or *conventional medicine*) refers to therapies based on science and regulated by the U.S. Food and Drug Administration (FDA), including prescription and nonprescription products. The term *complementary and alternative medicine* (CAM) encompasses Eastern and traditional medicine approaches. Of note, *complementary* often refers to therapy used in concert with Western medicine, and *alternative* often designates therapy used in the place of conventional medicine.⁶ Examples are magnet therapy, acupuncture, dietary supplements, mind–body techniques, homeopathy, and massage therapy. The concept of CAM is introduced in this chapter to promote awareness among health care providers of the potential use of such modalities in various patient populations. (See [Chapters 50](#) and [51](#) for an in-depth discussion of CAM.) *Integrative medicine* recognizes evidence-based approaches using a balance of conventional therapies with CAM. (See [Chapter 52](#) for a discussion of complementary and integrative medicine [CIM].) These concepts of Western medicine, CAM, and CIM can help to shape how health care providers understand self-care behaviors across a range of patient populations.⁶

Literature suggests that health care providers who can navigate among cultures and languages can integrate awareness, knowledge, skills, and commitment that lead to development of cultural respect, sensitivity, humility, and competence.^{3,7,8} By conveying *cultural respect*, providers optimize the

value of the clinical interaction by being “respectful of and responsive to the health beliefs, practices and cultural and linguistic needs of diverse patients.”⁷ Providers who are *culturally sensitive* consistently model attitudes and behaviors that reflect patients’ views of respect and acceptance of diversity.⁸ These providers may partner with patients to include their needs, values, and preferences in treatment plans.⁸ Patients are empowered to be in control of their health and health care decisions.⁸ *Cultural humility* refers to the “ability to maintain an interpersonal stance that is other-oriented (or open to the other) in relation to aspects of cultural identity that are most important to the [person].”⁹

Although several definitions exist, *cultural competence* is perhaps best described as the ability to provide “effective, equitable, understandable, and respectful quality care and services” that honor and respond to a diversity of cultural health attitudes, beliefs, practices, and language preferences while accounting for health literacy and other interpersonal communication styles and behaviors.^{3,5} When providers are able to communicate information appropriate to populations with unique language, literacy, and abilities in an effective and easy to understand way, they are employing *linguistic competency* skills.¹⁰ To support culturally and linguistically competent practices, organizational leadership should be able to plan, implement, and evaluate supportive policies, programs, and interventions to ensure delivery of high-quality health care services.⁵

Rationale for Exploring Cultural Aspects of Self-Care

Demographic Changes in the U.S. Population

The U.S. government classifies people into five races: (1) African American or black, (2) American Indian or Alaska Native, (3) Asian, (4) Native Hawaiian or Other Pacific Islanders, and (5) white ([Table 3–1](#)).¹¹ Although agreement on a uniform way of referring to race (beyond the human race!) is lacking, in this chapter, these five categories—alone or in combination—are used. In addition to race, people may identify themselves in terms of ethnicity, such as “Hispanic or Latino” or “not Hispanic or Latino”; accordingly race and Hispanic origin are considered two separate categories. For example, a person may self-classify as

non-Hispanic white, Hispanic white, non-Hispanic black, or Hispanic black. Historically the term *minority* refers to populations of people who do not self-identify as non-Hispanic white. To collect data, government agencies rely on respondents to the U.S. Census and other surveys and questionnaires to self-report or self-identify their race and ethnicity, with the opportunity to choose two or more races. The issue of defining race and ethnic background is increasingly complex. Research studies and epidemiology reports also compare persons from diverse races and ethnicities as a way to elucidate the basis for health disparities and to identify opportunities for improving care.

TABLE 3–1 U.S. Census Classification of Race and Ethnicity Based on Origin

Race^a (self-identified)	Population Origins
African American or Black	Any of the black racial groups stemming from Africa
American Indian or Alaska Native	Indigenous peoples of North and South America (including Central America) who also affiliate with a tribe or are attached to a community
Asian	Any of the original peoples of the Far East, Southeast Asia, or the Indian subcontinent including, for example, Cambodia, China, India, Japan, Korea, Malaysia, Pakistan, the Philippine Islands, Thailand, and Vietnam
Native Hawaiian or Other Pacific Islander	Peoples with origins in Hawaii, Guam, Samoa, or other Pacific Islands
White	Original populations stemming from Europe, the Middle East, or North Africa
Ethnicity (self-identified)	Population Origins
Hispanic or Latino	Cuban, Mexican, Puerto Rican, or South or Central American or other Spanish culture or origin regardless of race
Non-Hispanic or non-Latino	Non-Hispanic/non-Latino culture or origin

^a In the U.S. Census, race constitutes a “social definition” that is based on “racial and national origin or sociocultural groups.” Because race is self-identified in the Census, it does not require a link to a “biologic, anthropologic, or genetic” origin. Also, federal standards mandate that race and Hispanic origin (ethnicity) are separate and distinct concepts.

Source: [Reference 11](#).

The heterogeneity of the race and ethnicity classification options as defined by the U.S. government is important to recognize. For example, the groups included under Asian (e.g., Southeast Asia, East Asia, and South Asia) and Pacific Islanders exhibit great variability. This distinction also is true for the Hispanic classification, which includes four diverse groups: Mexican Americans, Puerto Ricans, Cubans, and others (e.g., Central Americans, South Americans, Spaniards). While classified as white in the 2010 U.S. Census data, populations whose ancestors come from countries such as Lebanon, Egypt, Syria, Palestine, and Morocco are a growing group self-identifying as Arab Americans, at an estimated 0.5% of U.S. residents.¹²

The reported number of minorities has resulted in a shift in the composition of the U.S. population ([Table 3–2](#)).^{13–15} In perspective, one of every three U.S. residents identifies as a minority, that is, a person who is from a non-white race. By 2044, more than one half of the U.S. population is expected to identify with a racial and ethnic group other than white.¹³ Currently, persons who identify as Hispanic constitute the largest minority population, followed by blacks and Asians. The most rapidly growing populations consist of persons who identify as being of (1) two or more races, (2) Asian, or (3) Hispanic background.

TABLE 3–2 Population Characteristics in the United States (2000, 2010–2018)

Characteristic	Total Population^a 2000	Total Population^a 2018	Total Population Projected 2050
Total population ^b	281.4 million	327.2 million	439.01 million

Characteristic	Total Population^a 2000	Total Population^a 2018	Total Population Projected 2050
		% of Total Population	
Race (self-identified)			
African American or Black	12.3	13.4	13.0
Asian	3.6	5.8	7.8
American Indian and Alaska Native	0.9	1.3	1.2
Native Hawaiian and Other Pacific Islanders	0.1	0.2	0.3
White (non-Hispanic or Latino)	69.1	60.7	46.3
Two or more races	2.4	2.7	3.7
Ethnicity: Hispanic or Latino (any race)	12.5	18.1	30.2
Age 65 years and older	12.4	15.6	19.1
Education, less than 12th grade ^c	19.6	12.7	n/a
Language other than English spoken at home (up to and including the age of 5 years)	17.9	21.3(2013-2017)	n/a

^a Total is greater than 100% because of some cross-classification in Census data.

^b Based on race alone or in combination with one or more other races.

^c Less than 9th grade; 9th–12th grade, no diploma (in persons 25 years of age and older).

Key: n/a = Not applicable.

Other changes in the landscape of health care delivery include the emergence or predominance of other groups of minorities or underserved populations. Trends in migration patterns have created unevenly distributed racial and ethnic subpopulations across the United States.¹⁵

With the increase in the number of adults 65 years of age and older, this age group now makes up 14.9% of the population ([Table 3–2](#)).¹⁵ Approximately one half of older adults 75–85 years of age use nonprescription medications.¹⁶ Populations composed of persons identifying as American Indian and Alaska Native have demonstrated the highest rates of self-reported CAM use (>50%), followed by white (43.1%) and Asian (39.9%).¹⁷ These changes have created diversity in ethnic consumer markets that may be more pronounced in certain regions of the United States. In a 2012 survey conducted by the U.S. Department of Health and Human Services, the use of complementary health approaches including, but not limited to, dietary supplements, deep breathing exercises, and yoga was reported by 37.9% of non-Hispanic whites, 37.3% of non-Hispanic other races, 22% of Hispanics, and 19.3% of non-Hispanic blacks.¹⁸

Beyond changes in race, ethnicity, and age characteristics, the U.S. population is becoming more diverse in terms of gender identity, gender expression, sexual orientation, socioeconomic status, physical abilities, veteran status, and religious affiliation. An estimated 4.5% of Americans in 2017 identified as lesbian, gay, bisexual, and/or transgender (LGBT).¹⁹ In 2014, 27.2% of Americans reported having a disability, with 17.6% of the disabilities classified as severe.²⁰ According to the U.S. Census, in 2017, 12.3% of Americans, or an estimated 1 in 8 persons, reported living below the poverty level, and more than 18.9 million identified as veterans.¹⁵

The religious landscape in the United States also is changing. Between 2007 and 2014, U.S. population groups who identify themselves as Christian have decreased from 78.4% to 70.6%, and an increasing percentage of people in this country do not affiliate with any religion (22.8% in 2014, versus 16.1% in 2007). Nearly 6% of the U.S. population in 2014 is aligned with non-Christian faiths compared with 5% in 2007.²¹ These national demographic changes across race classifications, socioeconomic status, religion, and other traits have increased the importance of health care provider education and training in diversity, cultural sensitivity, and provision of culturally appropriate services. To explore demographic, social, and economic characteristics in any given community in the United States, providers can type the relevant address or zip code for the

population they serve using the U.S. Census resource American Factfinder (<http://factfinder.census.gov>).

Health Disparities

Although the health status of some racial and ethnic groups has improved, health disparities persist among different populations.^{22,23} In many cases, health disparities cannot be explained solely on the basis of information about characteristics of racial and ethnic groups. *Health disparities* or inequities occur when differences or gaps exist in health determinants (e.g., clean air, safe communities), health access (e.g., insurance, transportation), and/or health outcomes (e.g., heart disease, diabetes) among particular populations or groups (e.g., based on race classification, socioeconomic status, disability, or other cultural identities) that have experienced marginalization.^{24,25} These differences often are connected to socioeconomic, political, and/or environmental challenges.

Individuals from some minority groups do not equally experience long life spans, good health, and access to appropriate health care services. For example, low rates of cancer screening and treatment among minority groups are attributed to cultural and linguistic barriers, as well as limited access to health services.²⁵ In the period 2013–2015, medically diagnosed diabetes prevalence rates were higher among American Indian/Alaskan Natives, non-Hispanic blacks and Hispanics, and persons with less than a high school education than among non-Hispanic whites and persons with higher education levels.²⁶ Other health disparities among different races and ethnicities continue to be identified ([Table 3–3](#)), many of which have a link to self-care.

TABLE 3–3 Examples of Health Disparities Among Racial and Ethnic Groups in the United States

Condition	Rate	Potential Self-Care Link
Obesity prevalence (2015–2016)	Hispanics (47%)	Approaches to health and wellness, request for diet or weight loss supplements
	Non-Hispanic blacks (46.8%)	
	Non-Hispanic	

Condition	Rate	Potential Self-Care Link
	whites (37.9%)	
	Non-Hispanic Asians (12.7%)	
HIV incidence, new diagnoses (2017)	Gay and bisexual men (66%)	Acceptance of “safer sex” prevention and practices
	Black/African American (43%)	
	Hispanic/Latino (26%)	
	White (26%)	
	Asian (2%)	
	Multiple races (2%)	
	American Indian/ Alaska Native (1%)	
	Native Hawaiian/ Other Pacific Islander (<1%)	
Heart disease age-adjusted rate of death/100,000, males (2016)	Non-Hispanic black (265.0)	Willingness to use low-dose aspirin for secondary prevention, use of home blood pressure monitoring
	Non-Hispanic white (213.9)	
	American Indian/ Alaska Native (147.7)	
	Hispanic (144.6)	
	Asian/Pacific Islander (106.6)	

Key: HIV, human immunodeficiency virus (infection).

Among the complex factors explaining health disparities across population groups are race classification, socioeconomic status, literacy, health practices, and social determinants of health that may be harmful or helpful. Some of the negative determinants that contribute to health disparities include psychosocial stressors, lack of resources, environmental exposures, discrimination, unfavorable sociopolitical policies, and limits on access to health care.²² These factors will influence future patterns of disease, disability, and health care utilization unless they are addressed with appropriate remediation. For example, in 2014–2016, when compared with the non-Hispanic white population, blacks, Hispanics, Asians, and American Indians/Alaska Natives experienced worse access to care.²³ In 2016, 20.9% of people with a disability lived below the poverty line, compared with 13.1% of people without disabilities.²⁷

In an effort to create a healthier society and develop strategies to decrease the gap in health care, the U.S. government has guided public health policy over 3 decades through the Healthy People initiative.²⁴ By setting health care priorities and measurable objectives, Healthy People programs create a foundation for the health care agenda for each decade (with the most recent transition from Healthy People 2020 to Healthy People 2030). The newest Healthy People 2030 overarching goals are as follows:

- 1) attain healthy, thriving lives and well-being, free of preventable disease, disability, injury and premature death,*
- 2) eliminate health disparities, achieve health equity, and attain health literacy to improve the health and well-being*

of all, 3) create social, physical, and economic environments that promote attaining full potential for health and well-being for all, 4) promote healthy development, healthy behaviors and well-being across all life stages, 5) engage leadership, key constituents, and the public across multiple sectors to take action and design policies that improve the health and well-being of all.^{20,28}

Several specific Healthy People 2020 objectives reported for the past decade are linked to self-care strategies such as selfmonitoring blood glucose in diabetes, taking measures to prevent sunburn, and making attempts to quit smoking.²⁴ With such objectives, the Healthy People initiative serves as a road map to better health and can be used by different populations, communities, professional organizations, and other groups to improve overall health.

Culturally Appropriate Health Care and Workforce Diversity

One of the factors identified by government agencies and health care groups contributing to health disparities is the lack of awareness of cultural issues and health disparities among health care providers that may be attributed to inadequate formal education on cultural issues in academic health-related training programs.²⁹ To ensure effective delivery of culturally and linguistically appropriate health care in cross-cultural and diverse settings, an understanding of basic diversity and cultural issues related to health and illness, health disparities among different groups, and communication strategies for working with culturally diverse patients is essential.³⁰

Although cultural competence and diversity education are required as part of accreditation in health professional training, lack of workforce diversity still exists in the health care arena.³⁰ This reality highlights the need for providers of all backgrounds and identities to recognize the influences of culture in health care and for health sciences curricula to incorporate content on cultural humility, respect, and competence. The current racial and ethnic group composition of health care providers in the United States does not reflect the composition of the general population. For example, only 4.4% and 7.3% of the first professional-degree pharmacy graduates in 2016 were Hispanic and black or African American, respectively. In the period 2015–2016, 19% of pharmacy

school applications were from underrepresented minority groups.³¹ The pharmacy student and graduate cohorts do not proportionately represent the U.S. population that they will serve. Across health professions, diversification of the health care workforce is needed, both for providing access to health care education and for improving representation of the multitude of populations found in the United States.³⁰

In 2000, the Office of Minority Health, of the U.S. Department of Health and Human Services, developed the National Standards for Culturally and Linguistically Appropriate Services (CLAS) in Health and Health Care.³² These standards, updated in 2013, are based on an in-depth review of the literature, regulations, laws, and standards currently used by federal and state agencies. The CLAS standards provide guidance for individuals and organizations to implement services that are culturally and linguistically appropriate to “advance health equity, improve quality, and eliminate health care disparities.” The 15 standards are divided into four main sections that address (1) the principal standard (used in this chapter’s definition for cultural competence); (2) governance, leadership, and workforce; (3) communication and language assistance; and (4) engagement, continuous improvement, and accountability.

Concepts of Working Across Cultures

Stereotyping and Generalization

Unique persons with slightly different characteristics or beliefs may belong to the same cultural group. However, individual differences within cultural groups also must be considered. In this context, the rational error of *stereotyping* is associated with serious risks to the quality of health care delivered. By contrast, the process of developing a *generalization* may provide a starting point for considering cultural influences in patient self-care. Providers should be cautious, however. When overapplied, generalizations can still lead to potentially misleading or otherwise adverse consequences.

Stereotyping may be viewed as an assumption (often negative) about behaviors or characteristics exhibited by a group of people.¹ Generalization, or predicting that a member of a specific group will often behave in the same manner for that group, may be based on documented or self-described behaviors or characteristics found in subpopulations or cultures. As examples,

stereotyping would be that all minority groups use CAM, and generalization would be that a high rate of CAM use is common in many cultural and ethnic minorities, so it is important to inquire about CAM use.

During each clinical encounter, the patient should be treated as an individual with unique beliefs and values. The provider should avoid stereotyping and be self-aware of making generalizations about groups of people. Rather than relying on such assumptions, asking patients open-ended questions will most effectively assess potential mitigating cultural factors including food selection, sexual practices, caregiver responsibilities, living situation, activity level, and alcohol, tobacco, or illicit substance use. A knowledge base that includes a general idea of behaviors and characteristics of groups of people can help expand awareness of potential health beliefs and behaviors. Familiarity with “typical” health-related practices and lifestyles that may influence disease state prevalence or acceptance of self-care treatment for commonly encountered groups can positively shape patient encounters, treatment plans, and recommendations. Knowing or inquiring about cultural communication preferences, such as salutation, preferred language, eye contact, spatial distance, and physical touch, also is important to facilitating interactions with persons of various populations.

Acculturation

Variations in behaviors among members of a group become more important when people belonging to a specific cultural group migrate to and live in places that have a different, but dominant, culture. *Acculturation* is a process whereby members of a specific cultural group adopt the beliefs and behaviors of a dominant group, but they may still value and practice their own traditional beliefs and behaviors when in the presence of their original group members.² Acculturation can occur when individuals and/or families find themselves adjusting to a different culture, community, or geographical region, or to an entirely new country.

One model identifies four levels of acculturation based on the degree to which people who resettle retain a home culture and/or adapt to a new host culture.³³ People who are able to function well in both their home culture and their host culture can *integrate* cultures; such persons often are able to navigate back and forth between cultures. Persons who adopt the new host culture but let go of their original home culture are said to *assimilate*; they

function well in the host culture but may retain little knowledge of or familiarity with the cultural heritage or language of their forebears. Some people may live between cultures and feel *separated* because they do not fit into either the new host culture or the home culture. Other persons who have moved to a new country, region, or even neighborhood, but who hold onto their home culture and/or language and never fully adopt the new host culture or language, may feel *marginalized*. For example, if a health care provider has been raised in an urban environment on the West Coast (home) and moves to rural Appalachia (host), it may take years for the person to gain a sense of fitting in or even an understanding of community norms. During the acculturation process, people who are influenced by the host culture may behave differently from the norms of their home culture.

Although acculturation is often directed at a new group adopting habits and language patterns of the dominant host group, the outcomes of acculturation can be reciprocal. The dominant host group may in turn adopt patterns typical of the new group. The adoption of ethnic or regional idiomatic expression and the enjoyment of different foods, music, festivities, and dress that represents a particular group are examples of reciprocal acculturation practices. Another example is that of a health care provider who self-identifies as a black male without a religious affiliation (home) relocates to work in a community pharmacy serving a predominantly Islamic community (host). To connect with patients, this provider makes an effort to participate in activities sponsored by the mosque and begins to adopt dietary and behavioral nuances characteristic of the host community culture.

When individuals lose or modify their cultural identity to acquire a new identity that differs from their original cultural group (*assimilation*), the new behaviors and adaptations may cause internal conflicts among members of the original group. For example, conflicts can arise when younger members of a cultural group (e.g., second- or third-generation immigrants) do not follow traditions of the older generation and start to exhibit behaviors and beliefs more consistent with the host culture. In some instances, the children of immigrants may not speak their parents' native language. Culture and acculturation can influence personal beliefs and attitudes toward health, illness, and treatment, as well as decisions regarding health and self-care issues. When providers do not understand a patient's culture, beliefs, and behaviors, the effective delivery of patient-centered care and, consequently, the achievement of optimal health outcomes may be impeded. Incongruent

beliefs and expectations between the provider and the patient may lead to misunderstandings, confusion, and, ultimately, refusal of treatment and undesirable therapeutic outcomes.

Models of Cultural Competence

Developing cultural competence is a continuous and dynamic process that should be consciously undertaken to ensure that health care is delivered in an effective manner among diverse populations of patients and providers. Three common models describe cultural competence as a process versus an achievement and can be used by providers who support patients as they seek self-care therapy options (Table 3–4).^{34–36}

TABLE 3–4 Cultural Competence Models and Applied Examples for Self-Care		
Model	Attributes	Applied Example in Self-Care
Cultural Competence Continuum (Terry Cross) ³⁴	Cultural Destructiveness <i>Beginning of the continuum and most negative stage</i> • Attitudes and policies support bigotry, racism, discrimination, and exploitation harmful to cultures and patients. • Behavior can be intentional or unintentional. In the Tuskegee study, the U.S. Public Health Service withheld syphilis treatment from African American men.	A health care provider judges patients who demonstrate religious symbols on tattoos, clothing, or jewelry. Staff members often perpetuate the attitude by making judgmental remarks about appropriate attire.
	Cultural Incapacity • Organizations or providers do not have any programs or services to respond to needs of patients from other cultures. • Ethnocentrism often exists in which a dominant culture makes assumptions about	A pharmacy may not carry candles requested by several patients in service area. This lack of response signals failure to recognize the cultural importance of a common, inexpensive, noninvasive adjunct self-care modality (prayer and candles).

Model	Attributes	Applied Example in Self-Care
	other cultures.	
	Cultural Blindness • Organizations or individuals try to remain unbiased. • Assumption is that culture or race makes no difference, that everyone should be treated “equally.” • Organizations have programs in place but do not tailor them to address cultural needs of different groups.	A provider insists on shaking hands and hugging all patients in an effort to fit in and show empathy.
	Cultural Precompetence <i>Skewed toward positive end of continuum</i> • Health care organizations or individuals recognize that cultural differences exist. • Organizations may reach out to cultures by hiring diverse workforce, interpreters, or translators for written materials. • Organizations limit their efforts to several initiatives and may become frustrated with lack of progress.	Providers might be quick to point to an herbal product line available in their pharmacy targeted for a specific cultural group and assume that this action suffices to care for different cultures.
	Cultural Competence • Acceptance and respect for differences among cultural groups is ongoing. • Providers and organizations continually increase their cultural competence knowledge and skills. • Models are implemented to deliver culturally appropriate	Organizations include annual staff training of personnel to better understand the self-care needs of patients from different cultural groups.

Model	Attributes	Applied Example in Self-Care
	care with a true commitment to improve outcomes of patients from diverse cultures. • Providers strive to assess personal cultural biases and beliefs. • Concerted efforts are made to meet and work with people of diverse backgrounds in the community. • Assessments to improve care for different cultures are ongoing.	
	Cultural Proficiency <i>Highest level in the continuum</i> • Organizations and providers have a true commitment to culturally competent practices by engaging in research, evaluating new approaches to care, publishing and disseminating findings, advocating for improvements, and conducting trainings. • Work to achieve cultural proficiency is continual, and the positive impact and the transformation of understanding and engaging different cultures are valued.	Ongoing training for staff and students on community health beliefs and values is provided, with opportunities for community members to assist in training sessions on commonly used self-care modalities, religious beliefs, preferred foods, and other cultural elements.
Cultural Competence Model (Purnell³⁵)	Unconsciously Incompetent Providers do not realize what they do not know about other cultures or the influence of culture across person, family, and community.	A provider encourages influenza vaccine for an individual, not recognizing that the family home is multigenerational and everyone could be vaccinated.
	Consciously Incompetent Providers recognize that they have	A provider realizes that there may be different values about contraception in a

Model	Attributes	Applied Example in Self-Care
	challenges working with persons from diverse backgrounds.	Nigerian culture and takes time to research information about the beliefs.
	Consciously Competent Providers are aware of their effort to work effectively within or across different cultures.	A provider trains the entire staff on cultural touchstones for a new refugee population resettled in the community. Key cultural leaders are invited to help role play and address potential cultural beliefs and practices.
	Unconsciously Competent Providers are more easily able to navigate within a different culture or across new cultures; their approach may seem effortless.	A provider who has worked with Mexican American patients with diabetes over time is able to identify various cultural barriers to self-management.
ASKED Model (Campinha-Bacote ³⁶)	Cultural Awareness Providers explore their own culture and profession through a process of understanding personal biases and assumptions about different cultures.	Providers acknowledge cultural differences in home remedies and self-care treatments commonly used to alleviate cold symptoms, such as chicken soup and hot tea with lemon.
	Cultural Skill Providers have the ability to collect, assess, evaluate, and adapt cultural information from diverse patients to improve care.	In obtaining information about religion and culture in the social history, a provider recognizes that a woman who identifies as Islamic may prefer to have a female provider discuss medication for a yeast infection.
	Cultural Knowledge Process of gaining more information about diverse cultures, values, beliefs, and practices	Providers learn about common herbs and alternative therapies used in the Vietnamese American Buddhist population living in the neighborhood surrounding the pharmacy or clinic.
	Cultural Encounters Providers may have the opportunity to work with one or more patients and families in diverse cultures to enrich their awareness, knowledge, and skills.	Daily clinical practice may include interactions with multiple patients who are Hispanic, so that over time, the importance of family in making decisions about diet and diabetes management becomes evident.
	Cultural Desire Providers are sincerely motivated to grow in their capacity and skill to navigate across cultures.	In addition to working with patients from the large Catholic parish nearby, a Hindu provider volunteers at the parish community and outreach events.

Key: CAM = Complementary and alternative medicine.

Source: [References 34–36](#).

The Cultural Competence Continuum model developed by Terry Cross explores six stages of cultural competence from cultural destructiveness to cultural proficiency.³⁴ As providers and educators gain more experience and develop their skills and knowledge, they may move toward cultural proficiency.³⁴

The Purnell model, which is based in several disciplinary theories (e.g., organizational, family development, religion, political science), describes the interrelationship of several cultural domains such as heritage, family roles, workforce issues, and high-risk behaviors ([Figure 3–1](#)).³⁵ In this model, providers go through a zigzag developmental process, moving from “unconscious incompetence,” wherein they may not realize that they lack knowledge and skills to work in diverse cultures, toward “unconscious competence,” wherein they have a positive attitude and a more developed foundation of knowledge and skills to adapt care in an efficient manner.

Figure 3–1 The Purnell Model for Cultural Competence. (Source: Reprinted with permission from [reference 34](#).)

The model developed by Campinha-Bacote has five primary constructs in the cultural competence process. The first four of these constructs are cultural awareness, cultural knowledge, cultural skills, and cultural encounters.³⁶ Overlapping these constructs is *cultural desire*—a concept that providers are caring and want to gain knowledge and skills to navigate across cultures. In this model, providers also adopt an attitude of *cultural humility*, recognizing that their own culture is not to be construed as the “right” one (ethnocentrism) and striving to maintain a state of lifelong learning about all cultures. Health care providers can use any of these models as a framework for working with patients from diverse cultures and backgrounds and for developing cultural sensitivity.

Barriers to Self-Care

Differences in patients' language and health literacy (educational), access, capacity, and motivation to take care of themselves (personal), and/or perceived health status and confidence to take care of themselves (sociocultural) pose barriers that can apply to self-care. For example, patients' perceptions of the severity of their health condition may influence whether they pursue care. Providers should be able to recognize the various barrier influences that can affect patients' self-care behaviors.

In some instances, the provider may miss small differences in the interpretation of language, gesture, or eye contact. Such omissions can lead to misunderstandings between people of different cultures and the providers they encounter. A provider's lack of cultural sensitivity and linguistic competence may impede the delivery of appropriate care.

Fear and Mistrust of Health Care Providers

Patients' mistrust of health care systems, providers, and information may create barriers to self-care management, including reduced rates of preventive and follow-up care. Patients may feel that providers do not consider their concerns, with the result that their expectations were not met. Some health disparities for minority populations, as historically found in African Americans, American Indians, and other groups, have been associated with discriminatory treatment and systemic racism. Many negative institutionalized health care policies and social aspects of provider–patient relationships remain as barriers to effective care. “Racism is insidious, cumulative, and chronic”; its effects can be felt by patients, providers, and all people in health care organizations. Ongoing mistrust and patients' perceptions, whether real or apparent, can adversely affect patient satisfaction and health outcomes.³⁷

Persons from diverse races and ethnic minority groups also may differ in their perceptions about research and research participation. For example, in some African American and other communities, mistrust of research is firmly entrenched as a result of the Tuskegee study conducted by the U.S. Public Health Service (USPHS) for 40 years, between 1932 and 1972.³⁸ In that study, African American men with (n = 399) and without (n = 201) syphilis were enrolled without informed consent for “free” medical examinations and meals

while researchers monitored the physiologic effects of the disease. Even when penicillin was discovered as a treatment for syphilis, subjects were not informed of the treatment option, nor were they offered the antibiotic. Because of the unethical decisions of the Tuskegee study, many African Americans who are not recent immigrants are unwilling today to participate in clinical trials and other aspects of the medical system. Fear persists that unfair treatment and further abuses will occur.³⁷

Other diverse populations, including women, also have often been underrepresented in clinical research trials. The National Institutes of Health (NIH) National Institute on Minority Health and Health Disparities has a mission to lead scientific research to improve minority health and eliminate health disparities.³⁹ NIH and FDA mandates for inclusion of diverse cultures and minorities in research studies have succeeded in encouraging accountability in research design through stronger commitment to community-based approaches, emphasis on institutional review board approval, and increased federal research funding.^{37,40}

American Indians also have survived a past that includes government policies and wars that damaged their peoples and culture. However, since the Indian Health Service was implemented, American Indian communities are now more protected and have been better positioned to sustain their cultural traditions through family and clan relationships, kinships with homelands, religious ceremonies, and ancient rituals.³⁷

The long and troubled history of American Indians and African Americans with public health services provided by the USPHS or through the Indian Health Service has led these communities to often mistrust providers and health systems. This mistrust perception may be based on multiple aspects, such as⁴¹

- Feelings of prejudice against their ethnic group
- Fear that their best interests are not considered and that they are treated differently from other patients
- Apprehension that their concerns and problems are not heard
- Concern that their traditional medical practices and/or beliefs will not be affirmed and will be called primitive
- Lack of confidence in the health care provider's skills to diagnose and recommend treatments

Other populations also may have perceptions of mistrust derived from sources

in their past history outside the United States.⁴² Individuals and families who have had to seek refugee status may have experienced political oppression or government policies that fostered suspicion or unfair practices. Fears may be centered on deportation for persons who entered the country undocumented, or skepticism may derive from previous experiences using different health care systems or resulting in denial of treatment because of language barriers.

Persons who identify as LGBTQ (Q = Questioning or Queer) also may experience distrust of the health care system and disparities in care, including lower overall health status and higher rates of substance use disorders and mental health illnesses.⁴³ LGBTQ patients face potential stigma and lack of understanding of their particular self-care health needs, as well as exclusive health system practices, including barriers to health insurance or visitation restrictions. Providers may be unsure of appropriate language and preferred names/pronouns (e.g., ze, zie, he, she, they) to use with patients. To provide inclusive care, it is recommended that health care organizations allow all patients to specify their preferred name/pronouns, gender identity, sexual orientation and relationship status on registration forms and other relevant documents and to avoid language that makes assumptions (e.g., using patient names instead of Mr./Mrs./Miss/Ms., asking about a spouse or partner instead of assuming the patient has a husband or wife).⁴⁴ Although LGBTQ individuals experience higher rates of sexually transmitted infections (STIs) and human immunodeficiency virus (HIV) infection than their heterosexual counterparts, health care provider education and medical literature for LGBTQ communities that focus only on STIs and/or HIV infection without inclusion of other health care needs promote perpetuation of stereotypes and biases.⁴⁵

Reducing mistrust of the health care system requires repeated positive encounters over time. Some key practices that health care providers can adopt to foster trusting relationships include one-on-one outreach and frequent personal involvement with the population served. Volunteering and partnering with community leaders, such as clergy, spiritual leaders, or special population advocacy groups, can help to form networks and establish program approval at the earliest stage of the health care planning process.⁴¹

Training of community health workers, or of other lay community health advocates, can be an effective strategy for garnering trust in the community, especially when time and resources are limited. Such community liaisons can help to diffuse health messages, integrate culturally and linguistically diverse

prevention programs, provide information about new health technologies, and provide health screenings in the language and the context best understood by the group under focus. Health care providers should embrace cultural sensitivity training to identify their own potential biases and stereotypes and to gain knowledge to better address patients' feelings of mistrust, improve communication, and create trustful relationships.

Language Barriers

The inability to speak or read English makes it difficult for many patients to communicate with their health care provider or to read instructions on prescription and nonprescription labels that are only in English. Limited English proficiency (LEP) creates a significant barrier to seeking self-care or the advice of a provider when services are only delivered in English. Because of LEP, patients may rely on information from television or magazines written in their language of origin or on the recommendations of family members, relatives, or community leaders. Although many community pharmacies have telephone-based interpreter services available, patients who are making self-care decisions in the aisle of the pharmacy may not be aware of this service and may not request assistance from the provider, who could subsequently offer information via telephonic interpretation.

According to Title VI of the Civil Rights Act, when organizations receive federal funding, they are responsible for taking measures to provide “meaningful access” for services at no charge to persons with LEP. These measures are based on four primary factors related to frequency of contact and importance of contact: the number or proportion of LEP persons in the eligible service population, frequency with which LEP patients come into contact with the program, importance of the service provided by the program, and resources available to the recipient.⁴⁶ The federal interagency LEP website includes mapping tools to gather information about English language proficiency demographics reported at county and state levels. Barriers to care arise when organizations and/or providers (1) do not have available interpreter services; (2) do not know how to work with interpreters; (3) are charging patients for interpretation services; (4) request that patients bring family members or friends as interpreters; and (5) supply signs, forms, and brochures in English only.

Literacy and Health Literacy

Studies have documented a relationship between poor reading skills and poor health.⁴⁷ People who cannot read often hide their limited literacy skills because of shame, embarrassment, low self-esteem, and fear. Without specific attention to this issue, health care providers may overlook this potential source of misinformation concerning self-care products and nonadherence to prescription drugs.

To detect literacy problems, the provider should be sensitive to cues that indicate difficulty with reading. For example, patients may not want to look at the prescription label or patient education material when asked to read information. People who read poorly may never join a group education session. Instead, such patients may prefer one-on-one consultations with their health care providers.

Health literacy, or “the degree to which individuals have the capacity to obtain, process, and understand basic health information and services needed to make appropriate health decisions,” also is an important skill for self-management and decision making about nonprescription products.⁴⁷ A person may have a high level of reading literacy but not be able to apply a combination of functional skills, such as reading, calculating basic math, and drawing conclusions, to make an informed decision about his or her health.⁴⁷

In different cultures, styles of communication and belief systems can affect health literacy.⁴⁷ Low-level health literacy is more common in minority groups and may be linked to general literacy levels and/or language. Overall low-level health literacy makes it difficult for providers to rely on using existing nonprescription labels, drug information pamphlets, or prescription labels produced by the pharmacy computer systems to give to patients. Through verbal communication with the patient, an interpreter, or an adult family member, providers must ensure that the patient understands the instructions and/or prescription label directions. The prerequisite requirements of the Durham–Humphrey (1951) and Kefauver–Harris (1962) amendments to the Federal Food, Drug, and Cosmetic Act, which the FDA uses in evaluating New Drug Applications for proposed nonprescription drugs, demonstrate the need for improved health literacy.⁴⁸ The criteria for nonprescription drug approval include evidence that (1) patients can recognize and diagnose themselves for the condition specified in the proposed indication, (2) patients can read the

product label and extract the key information necessary to use the drug properly, (3) the drug is effective when used as recommended, and (4) the drug is safe when used as instructed. The consumer must be able to read and understand the information on the label to know the proper dosage, recognize warnings and contraindications, and determine whether contraindications apply.

FDA labeling requirements implemented in 2002 were intended to make it easier for patients to read and understand nonprescription drug labels.⁴⁹ The standard product label for nonprescription drugs, titled “Drug Facts,” has specific sections for active ingredients, uses, warnings, indications for when to use the product, directions, and inactive ingredients (see [Chapters 1](#) and [4](#)). Manufacturers are required to use large print, simple language, and an easy-to-read format on the labels to help patients with product selection and dosage instruction. In addition to these requirements, pharmacists should be alert to the educational needs of all patients, particularly those with poor reading skills or low-level health literacy, buying nonprescription products.

Providers can ensure that patients understand aspects of their condition and their responsibility for self-care by integrating the following tips. First, the provider should never take for granted that the patient can fully comprehend all instructions, whether written or spoken. Patient counseling also should take into consideration the potential for shame related to lack of understanding, so it is especially important to treat the patient with respect. Patient education specialists suggest using the teach-back method to ensure clarity and comprehension of the message. This method involves using phrases such as “Tell me in your own words how you are going to take this medicine.” Gaps in the patient’s interpretation will provide additional opportunities to explain the process again or to correct gaps or misunderstandings using different methods to deliver the message. Education should be followed with presentation of materials such as pictures or demonstration products, and perhaps with follow-up phone calls.

Of note, this approach also may improve adherence to treatment and clinical outcomes.

Sociocultural Framework for Self-Care

Practices

Self-care behaviors have not been well described among different population groups. Factors that influence self-care behaviors can include the patient's understanding of their health in the cultural context of health and attitudes toward taking responsibility for one's own health and illness. Religious beliefs, family and social context, cultural expectations, education and training, and personal experiences affect self-care behaviors. These interpretations are within the foundations of an ethnomedical model of care.^{50,51}

According to Kleinman, the patient's understanding of a disease is based on a "consensus of beliefs, information, and expectations pertaining to the illness that are shared with a social network."^{50,51} This understanding helps the patient interpret healing and sickness. Normative beliefs are generated by social interaction and personal experiences, which may differ completely from a scientific research approach to evidence-based medicine and the use of technology to diagnose and treat patients, which are within the biomedical model of care.^{50,51} For example, some cultures may view hypertension as caused by tension, stress, or worry and may not understand that the disease is the chronic elevation of arterial blood pressure.

Providers who do not consider their patients' beliefs and expectations may encounter resistance to their professional advice. Expecting patients to respond to health care advice solely on the basis of biomedical principles may evoke considerable frustration for both patient and provider. Each patient may have different social support needs and concerns related to making decisions about self-care behaviors and medication use. Providers should recognize the significance of extended family and friends often seen in minority populations' self-care behaviors. For example, a mother with diabetes may be neither able nor willing to modify her dietary intake of certain traditional foods so as not to impose these restrictions on the whole family. Such patients are willing to sacrifice their own health to maintain comfort and convenience for the rest of the family.

Normative beliefs based on the group's experiences also may assist the individual patient in making decisions whether to seek care from the health system or to use CAM. Self-care practices of many cultural groups involve use of home remedies, herbs, massage therapy, acupuncture, or other treatments

that are passed from generation to generation. Communicating within the framework of the patient's culture helps break down barriers while also facilitating trust and understanding between the patient and the health care provider. Through this knowledge, the provider can lead a patient away from harmful practices and provide safe, culturally appropriate alternatives. Subsequently, the provider can develop interventions, even biomedical ones, within the context of the patient's belief system. If traditional self-care practices are not harmful or even are found to be beneficial to the patient, the provider may be able to incorporate them into a monitored and integrated treatment plan.

For example, a patient who is being monitored and treated through Western medicine might also use a folk or traditional healer. Some common healing methods include prayers, massage, and aromatherapy. Because these practices may be harmless and potentially additive to Western medicine, the provider may accept and even encourage their use as found in CAM. It is important to maintain open and consistent communication with the patient, traditional healers, and other health care providers regarding new information on CAM.

Patients and/or their family members are responsible for the day-to-day management of their illness. Consequently, better methods are needed to determine the patient's health-seeking behaviors, informational needs, preferences, and expectations about treatment management approaches. Providers are encouraged to develop a framework for understanding how patients interpret their experiences. Such a framework, according to Kleinman,^{50,51} extends beyond discrete medical episodes of "controlling the biological malfunctioning of disease" to include the psychosocial dynamics of family-based care, healer-patient transactions, spiritualism, shamanic cures, and other important holistic approaches based on the patient's world view. Using this approach can reduce the adverse impact of miscommunication, misinformed decisions, and harmful health behaviors.

General Description of Beliefs in Different Population Groups

Some common themes have emerged in the literature related to chronic illness and self-care behaviors in older adults from African American, American Indian, Asian American, and Latino backgrounds. These self-care behaviors

may be more common among minority groups whose identities are rooted in their home culture and who may feel less identity with Western culture and values.⁵² The following six concepts highlight how self-care practices may be connected to various cultural ideals or beliefs:

1. *Concepts of independence and interdependence.* In Western medicine, independence, self-determination, and autonomy may be linked to increased self-care. Among black persons, particularly women, values of self-reliance and independence are consistent with self-care. Among older American Indians and Hispanics, family needs may supersede the importance of individual health. Messages of self-care in these populations may need to focus on helping the overall family structure. Among older Asian Americans, a mixed phenomenon may occur because of a higher emphasis on self-discipline consistent with self-care, but family needs may also be valued over those of an individual.
2. *Acceptance of intergenerational households.* European American households are less likely than those of other races and ethnic groups to include older family members. When households have several generations living together, different dynamics of social and family support for self-care may exist.
3. *Gender roles within the family structure.* Across cultures, women often are given the role of “health manager” in the family, even if the basic culture of the household is patriarchal. In intact family units, women may have a greater role in influencing self-care practices of the family. When an older married man is widowed, however, he may have a decreased ability to achieve effective self-care, which may be noted especially among black and Hispanic men.
4. *Family traditions related to CAM use.* In general, older adults and immigrants from African, American Indian, Asian, and Latin cultures more often use indigenous or non-Western treatments as part of self-care compared with whites. However, the degree to which these traditions are being passed on to subsequent generations is unclear, and many alternative health practices, including the use of dietary supplements, vitamins, meditation and/or yoga, also are commonly utilized by white people.
5. *Role of friends.* Friends, godparents, and “fictive kin” (very close friends in family-like relationships) can be relied on for support as much as family. For example, in some African American communities, women rely strongly on each other to help provide child care. Hispanics,

American Indians, and Asian Americans also have strong extended friendships that are closely connected to the family.

6. *Religious and spiritual beliefs of different cultures.* The role of God and spiritual healing may influence how persons from a cultural group use and/or accept self-care practices. In some American Indian cultures, physical health is not as important as spiritual or emotional health. In some African American communities, churches have a central role that is sometimes of a familial nature.

Differences in health beliefs and behaviors, as well as the relationship of biological and societal influences, are documented in the literature.²Table 3–5 lists some of the characteristics shared by people of diverse populations in the United States.^{2,53} These characterizations are generalizations. Again, not every member of an ethnic or cultural group may conform to these attitudes and beliefs.

TABLE 3–5 Examples of Cultural Behaviors Among Selected Populations^a

Group (heritage)	General Characteristics
Hispanic	• May actively involve family in health care • May use <i>curanderos</i> and <i>curanderas</i> (traditional healers) • May use home remedies, mostly teas or herbal remedies • May use religious medals for good luck • May believe that health is a matter of “luck” or “fate” • May have an attitude toward recovery that is pessimistic (“fatalism”) • May believe that illnesses are classified as hot and cold, with treatment chosen depending on the classification of the disease
Asian	• May stress the importance of family • May seek balance between forces to define health (<i>yin</i> and <i>yang</i>) • May believe that illnesses are caused by an imbalance of cold and hot forces • May use Eastern medicine, herbal products, Ayurvedic practices (India), or other CAM modalities • May not trust Western medicine
Black (not recent immigrant)	• May stress importance of biological and fictive family • May use home remedies and folk medicine

Group (heritage)	General Characteristics
	• May distrust the health care system because of previous unfavorable experiences • May stress the importance of religion in achieving cure
American Indian	• May use sweat lodges as a means of cure • May use herbal medicine including natural roots • May use prayer for cure of illnesses • May believe that health is a harmony with “Mother Earth” • May use healers (medicine man or woman, shaman)
White	• May have non-nuclear family structures and non-traditional family roles as a result of cohabitation, divorce, and remarriage • May report more pain than people of other races • May have suboptimal health habits including overconsumption of food, often of poor nutritional quality • May have defined (formal) religious practices and a belief in one God and life after death

^a The described behaviors have been observed in these racial and ethnic groups and serve solely as a guide and do not constitute a stereotype.

The previous examples are presented to help raise provider awareness of aspects of health behavior they may encounter. Awareness of these issues may help providers to deliver more effective care with increased cultural sensitivity.

Religious beliefs also are important in patients’ acceptance of the diagnosis and self-care treatment advocated by the health care system. A set of beliefs, attitudes, and expectations of illness and treatment based on religion may

cause friction with the health care system and the health care team. For example, a person whose religious background is Jewish, Islamic, or Hindu may have restrictions on the use of certain nonprescription products ([Table 3–6](#)). Consumption of omega-3 fatty acids and other animal-based or gelatin-containing products may or may not comply with strict religious guidelines (kosher or halal) regarding consumption of animal-based products.

Note: This table does not provide a comprehensive list of resources used by various religions or cultural groups. Rather, it is a guide to explore various beliefs and practices. Individual practices and beliefs may vary.

Key: n/a = Not applicable.

People from different cultures may choose to treat illnesses using different rituals and religious items that are outside the realm of Western medicine. For example, patients who identify as Hispanic may use home remedies or other artifacts recommended by spiritual healers, sometimes called *curanderos*. These healers may use a combination of herbal remedies and religious rituals. When providers are nonjudgmental, they can better understand how and when the patient plans to use drug therapy or another, alternative treatment. Knowing this information can help in determining what previous treatments the patient used or is going to use or whether the potential for major interactions exists between the nonprescription product and the patient's alternative treatment.

Risks of Self-Medication and Suboptimal Responses to Nonprescription Drug Therapy

Limited data are available specifically on the use of nonprescription products among patients of diverse cultural backgrounds, ability levels, religions, and lifestyles. The improper use of nonprescription products places vulnerable populations at an increased risk for adverse drug reactions, drug–drug interactions, and toxic effects from long-term exposure. Therefore, the potential for misuse of drugs that are available for self-treatment may outweigh the benefit–risk ratio in some patients. Increased use of nonprescription products by diverse populations may create another self-care challenge.

Low-income patients are often vulnerable to the harmful effects of overuse of nonprescription products for several reasons. First, patients who are chronically ill and have inadequate health insurance may restrict use of prescription drugs when their costs increase. Many uninsured patients use

nonprescription products as alternatives to prescription drugs simply because of cost. These same patients may seek medical care only for the most urgent symptoms, delaying routine visits to their primary care provider's office. Pharmacists who educate patients on the use of nonprescription products can help prevent delays in seeking medical care. Conditions such as hypertension and hyperlipidemia often are not recognized because of lack of symptoms. Nonprescription products may be used by patients to treat minor symptoms associated with these conditions, such as headache or chest discomfort. The key problem with a suboptimal response to a nonprescription medication is that a more serious condition may not be diagnosed until the patient experiences a complication.

Communication With Culturally Diverse Groups

Collecting and Assessing Patient Information

When interacting with patients from different cultures, providers should use specialized communication skills to gather information about a specific patient's cultural and spiritual health-related beliefs and practices. These communication skills include (1) openness to alternative viewpoints and approaches; (2) routine use of inclusive language (e.g., inquiring about a spouse or partner versus husband or wife, asking about sex or gender identity versus assuming male or female) in gathering demographic information; (3) selfawareness of one's own prejudices and biases; (4) engagement to identify the patient's beliefs, expectations, and barriers to treatment; (5) understanding of how the patient's beliefs and attitudes may influence the treatment plan; and (6) negotiating treatment that is acceptable to both the patient and the provider. Trust is essential to gaining awareness of the issues involved in the interaction, and appropriate language and nonverbal signals and behaviors are crucial to effective communication.⁴¹

One classic model for individual and institutional crosscultural development is *LEARN*, a mnemonic that may be used in clinical encounters.⁵⁴ The steps in the LEARN model are as follows:

- Listen with sympathy and understanding to the patient's perception of

the problem.

- Explain your perceptions of the problem.
- Acknowledge and discuss the differences and similarities.
- Recommend treatment.
- Negotiate a treatment plan that is mutually agreed upon.

In the first step of listening, providers can further assess patients' understanding of their illness by applying another tool, the 4 Cs, as adapted from Kleinman's Patient Explanatory Model (PEM).¹ The 4 Cs frame the following questions for the patient and/or family members, to elicit additional valuable information:

1. "What do you call the problem?" (perception)
2. "What do you think caused the problem?" (beliefs regarding source of illness)
3. "How do you cope with the problem?" (use of CAM or other treatments)
4. "What concerns do you have about the problem or treatment?" (understanding of fears; may also address adherence)

Table 3–7 presents examples of how to use the LEARN model in clinical practice. Other techniques and models have been suggested to improve communication and care in cross-cultural settings (**Table 3–8**).

TABLE 3–8 Using the LEARN Model: Examples

Listen with sympathy to the patient’s perception: A woman from the African country of Somalia is reluctant to give her mother medication for pain. When asked about this reluctance, she explains that she would prefer to help relieve her mother’s pain through massage.^a

Explain your perceptions of the problem: A pharmacist encounters a patient from Iraq who is experiencing upper respiratory sneezing and coughing and requests an antibiotic. The pharmacist,

who is aware of the wide availability of such drugs without a prescription in Iraq's health care system, explains the differences in pharmacy practice between the two countries and emphasizes the concern among today's health care providers about overprescribing antibiotics, which do not work for viral infections and increase the growth of antibiotic-resistant bacteria. The pharmacist recommends appropriate nonprescription symptomatic therapy, suggests that the patient see a primary care provider, and helps to find an appropriate provider.^b

Acknowledge, Recommend, and Negotiate: A patient from Cambodia complains that her 7-year-old child has had a "fever" for several days. The health care provider has read that the word for "fever" in the Cambodian language may not necessarily mean an elevated temperature. Rather, the term may refer to just not feeling well. The provider clarifies with the mother that the child actually has had a common cold and no elevated temperature.^c Together, they find an appropriate nonprescription therapy to treat the symptoms. The mother agrees with the plan.

Using Language Assistance and Support

In many instances, a barrier to effective communication may be the patient's inability to speak English. Several websites (Table 3–9) provide tips for providers to work with health care interpreters and with patients who have limited English proficiency, and CLAS standards 5–8 outline a blueprint for organizations in providing communication and language assistance.³

Interpreter services provide a means of addressing a language barrier, but this approach has limitations when only untrained interpreters are available.¹ Problems may arise when family members are used as interpreters because the intimate nature of information conveyed may place participants in an uncomfortable position. An additional issue emerges when a younger family member, sometimes a child, is asked to interpret for older family members, such as parents or grandparents, in a clinical encounter. Putting a child in a position of responsibility is not acceptable and can lead to family conflicts by altering the hierarchy within the family. It also places an undue psychological burden on the child. Accordingly, this situation should be avoided.³

Using family members or untrained personnel to interpret may lead to receiving or transmitting inaccurate information. The health care provider may miss relevant and critical information, or information may be misinterpreted by the interpreter and/or patient. These problems can be avoided with use of only personnel who are trained in medical language interpretation, collaborate frequently with providers, and are familiar with the patient's cultural background. Of note, in some cultures, shared health care decision making with other family members, spiritual leaders, and/or cultural leaders is highly valued, and inclusion of these persons may be beneficial to aiding patient comfort with health care recommendations.¹

Developing a Self-Care Plan

Self-care activities include a range of individual health behaviors such as

health maintenance, use of preventive services, symptom evaluation, self-treatment, interaction with health care providers, and seeking advice through lay and alternative care networks. In general, providers should encourage patients' and their families' participation in self-care behaviors to promote patient empowerment. Unfortunately, some health care providers do not encourage self-care behaviors because they are not aware of appropriately targeted techniques, strategies, and support systems that patients can use.

When assisting patients in their self-care behaviors and self-medication, providers can help to initiate dialogue to support informed decision making. Providers also can participate in health screening programs to identify health risks in the community and can lead health awareness campaigns.

The self-care plan should include the cultural values, behaviors, and beliefs expressed by the patient. The provider must then use this information to develop self-care recommendations and patient education strategies. Communication with other health care providers about the patient's cultural beliefs and preferences is essential. A collaborative approach helps to ensure that all providers are aware of the patient's preferences. For example, when developing a plan of care for the treatment of a self-limiting illness that requires nonprescription drug therapy, providers can synthesize their knowledge and skills by expanding on "negotiating a treatment plan" from the LEARN model. When negotiating a plan, providers can evaluate the following issues:

- Communication styles and needs (e.g., interpreter, family support)
- Patient beliefs and perceptions (as revealed from the PEM and 4Cs) and relevant restrictions related to religion, cultural beliefs, insurance, work environment, socioeconomic position, immigration status, and so on
- Previous treatments (prescription, nonprescription, and CAM modalities) and acceptance of these therapies
- Use of tools to help patient understand and apply recommendation (e.g., medication calendar, pictograms, dosing reminders, pill boxes)
- Appropriate follow-up support (e.g., adverse event, worsening of condition, need to see a provider)

Ensuring Cultural Competence in Health Care

Organizational Commitment

Even the most culturally sensitive, respectful, and competent health care providers will find it difficult to optimize care for patients without organizational commitment, support, and training to work across diverse cultures. CLAS standards provide guiding principles for organizations.³

Organizations that support more culturally competent services should have established policies and infrastructure (e.g., guiding values and principles, recruitment of diverse providers and staff, policies for using interpreters) to support culturally and linguistically authentic, high-quality health care.⁴⁴

Furthermore, such organizations demonstrate a capacity to systematically include feedback from consumers and communities they serve as well as to participate in ongoing self-assessment. Both providers and health system leaders should have a commitment to change, hold a genuine conviction of the significance of the task, and conduct periodic in-depth self-assessments of the beliefs and attitudes of personnel and the institution itself.

Organizational leadership can conduct cultural and linguistic competence self-assessments of the sponsoring institution and the quality of care being provided ([Table 3–9](#)). For example, leaders could form a committee to conduct a baseline self-assessment among department managers, staff members, patients, and community agencies to gain perceptions of the mission, hiring policies, access to interpreters, and community outreach as components of the self-assessment. This process could be evaluated by the committee with recommendations for action. Ongoing organizational support for cultural sensitivity and competency training within the workforce provides a path for continuous improvement. As of 2015, three states had CLAS training legislation (in development or enacted), 11 had state-sponsored implementation activities, and 21 states had both legislation and implementation activities to provide cultural sensitivity training to part or all of the health care workforce.⁵⁵ Other broad resources listed in [Table 3–9](#) may be helpful for learning more about how to improve cultural sensitivity.

Organizations can also evaluate how they serve persons with diverse health literacy skills. The Agency for Healthcare Research and Quality (AHRQ) maintains a website exploring health literacy issues in a pharmacy setting ([Table 3–9](#)).⁵⁶ The AHRQ Pharmacy Health Literacy Assessment tool guides an examination of the physical pharmacy layout, assessment of pharmacy staff, and eliciting feedback from patient focus groups. Recommended educational

materials should be at a sixth-grade reading level or below and use a variety of media to convey a health message.⁵⁷ Creation of a culturally inclusive pharmacy environment can assist with communication and welcome diverse patient groups. Example strategies are increased diversity of persons in photographs used for advertising or education (e.g., with respect to age, race, ethnicity, ability level, or gender expression) and provision of bilingual materials and signage, display of universal symbols, and availability of private counseling areas, and communication aids (interpreter services, special phone, and braille). Pharmacy computer databases should record specific cultural needs and behaviors of the patient. These platforms should include information such as religion, language, preferred pronoun and preferred name, gender identity, special needs or accommodations, and health literacy level.

Cases 3–1 and 3–2 illustrate important aspects of culturally sensitive care in the area of self-care. These cases present examples of issues that may commonly be encountered in community practice.

Case 3–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
Integrate the Patient Explanatory Model (PEM) with the 4Cs ¹ : • What do you call the problem? • What do you think caused the problem? • How do you cope with the problem? • What concerns do	

Relevant Evaluation Criteria	Scenario/Model Outcome
you have about the problem or treatment?	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient comes to the pharmacy asking for help in locating gluten-free selenium supplements. She states that she was advised by her sister in Mexico that selenium could help with "fogginess and feeling tired all the time." She reports that she has noticed markedly increased fatigue and forgetfulness for about 3 months. On further questioning she also reports constipation, weight gain, and dry skin.
PEM: What do you call the problem? (or What do you think you have?)	"I think I have a lot of fatigue."
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She states that she notes that she often feels cold. She keeps a light sweater with her.
PEM: What do you think has caused the problem?	"I think that I must be low in nutrients. It has been hard to eat well after I retired."
c. Description of the patient's efforts to relieve the symptoms	She has tried homemade bone broth with minimal relief.
d. Patient's identity	Claudia Castañeda de Orta
e. Patient's age, gender,	64 years, female, Hispanic, 5 ft 6 in., 168 lb

Relevant Evaluation Criteria	Scenario/Model Outcome
race/ethnicity, height, and weight	
f. Patient's occupation	Retired
g. Patient's dietary habits	Patient adheres to a gluten-free diet.
h. Patient's sleep habits	She sleeps an average of 7 hours per night but also has been napping in the afternoon lately owing to increased fatigue.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Osteoarthritis:</i> Glucosamine and chondroitin, turmeric
	<i>Seasonal allergies:</i> Butterbur
	<i>Hypertension:</i> Losartan 10 mg daily; grapeseed and hawthorn extract
	<i>Gluten intolerance</i> (not diagnosed with celiac disease or allergy)
j. Allergies	Seasonal (spring and fall)
k. History of other adverse reactions to medications	None
l. Other (describe) -----	Patient prefers use of "natural products" to medication whenever possible. She does have a primary care physician, whom she sees every year for her annual physical examination. She will consider use of Western medicine for "serious illnesses."
PEM: How do you cope with the problem?	
PEM: What concerns do you have about the problem or treatment?	Patient wants to enjoy retirement and her grandchildren. With the loss of energy, she feels very frustrated.
Assess	

Relevant Evaluation Criteria	Scenario/Model Outcome
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Patient is suffering from fatigue, forgetfulness, dry skin, constipation, cold intolerance, and weight gain, most likely indicative of hypothyroidism.
3. Identify exclusions for self-treatment.	Serious condition with potential for severe sequelae if it goes untreated
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend self-care with drug, nondrug, and/or complementary therapies. (2) Refer the patient to a primary care provider for treatment. (3) Recommend self-care until a primary care provider can be consulted. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mrs. Castañeda should consult her primary care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver using the LEARN model. ⁵⁴	Apply the LEARN model:
<i>Listen to the patient.</i>	Listen: As described earlier, the health care provider has noted the patient's preference for natural medicine.

Relevant Evaluation Criteria	Scenario/Model Outcome
<i>Explain your rationale.</i>	Explain: “Mrs. Castañeda, I am concerned about your well-being. While you have been using the selenium, it sounds like you have not been feeling better. In fact, it seems that you feel worse.”
<i>Acknowledge the patient's feelings and experience.</i>	Acknowledge: “I recognize how important it is for you to use natural products. I also want to be sure that we are not missing any serious problems. I also hear that you want to have quality time with your grandchildren and enjoy retirement.”
<i>Recommend a course of action.</i>	Recommend: “It seems that your situation is severe and may lead to serious complications such as depression or heart problems if you don’t take care of it. You really need to consult your primary care provider to check some lab values and explore a prescription treatment.”
<i>Negotiate a plan.</i>	Negotiate: “I see that you are taking Losartan, which was prescribed by your primary care provider. I would like to confirm your commitment to seeing your regular provider as quickly as possible. Would you be able to call your provider today?”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	Treatment with natural products is not recommended until you have been evaluated and diagnosed by your primary care provider.
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	n/a
Solicit follow-up questions from the	“Are there any natural thyroid supplements that I could use instead of prescription medications?”

Relevant Evaluation Criteria	Scenario/Model Outcome
patient or caregiver.	
Answer the patient's or caregiver's questions.	"You may notice supplements available on the shelf that claim to support thyroid health. However, none of these supplements are approved to treat an actual thyroid disorder. Your primary care provider can run blood tests to see how your thyroid is working and then recommend the best treatment for you based on those results. If you wish to also take a natural supplement, after you have seen your primary care provider for treatment, please come back and we can help you choose one that won't interact with your thyroid medication."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mrs. Castañeda in 1-2 days to ensure that she made an appointment and sought medical care.

Key: n/a = Not applicable.

Case 3-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
Integrate the Patient Explanatory Model (PEM) with the 4Cs ¹ : 1. What do you call the problem?	

Relevant Evaluation Criteria	Scenario/Model Outcome
2. What do you think caused the problem? 3. How do you cope with the problem? 4. What concerns do you have about the problem or treatment?	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A mother comes into the pharmacy looking for an over-the-counter senna extract (Castoria) to treat colic in her breastfeeding infant. She was advised by her grandmother that this natural remedy can help with fussiness and abdominal tension by helping to increase the frequency of bowel movements. She reports that for the last few days her baby cries for 1-2 hours a night starting at 6 pm, "like clockwork." She appears distressed and tired and expresses that she may "just need to stop breastfeeding."
PEM: What do you call the problem? (or What do you think is wrong?)	The mother thinks the baby is colicky.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms are worse in the evening and after nursing. Sometimes the symptoms lessen in severity after the infant passes gas or has a bowel movement.
PEM: What do you think has caused the problem?	The mother states that she feels she is a "terrible mother" and doesn't know how to take care of her baby.

Relevant Evaluation Criteria	Scenario/Model Outcome
c. Description of the patient's efforts to relieve the symptoms	She has tried drinking catnip tea to pass to the infant in her breast milk without noticeable improvement.
PEM: How do you cope with the problem?	The mother states, "I've been drinking herbal tea."
d. Patient's identity	Eden Fenton and infant son Jamal Fenton
e. Patient's age, gender, race/ethnicity, height, and weight	<i>Mother:</i> 32 years, female, African American
	<i>Infant:</i> 6 weeks, male, African American
f. Patient's occupation	Ms. Fenton works in the restaurant industry.
g. Patient's dietary habits	She has no dietary restrictions.
h. Patient's sleep habits	She has had difficulty establishing a sleep schedule since Jamal was born. She reports no more than 4-5 hours of sleep in a 24-hour period for past 6 weeks.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Mother:</i> Gestational diabetes, controlled with diet; no current medications
	<i>Infant:</i> No known medical conditions
j. Allergies	<i>Mother, infant:</i> None known
k. History of other adverse reactions to medications	<i>Mother, infant:</i> None
l. Other (describe) -----	Ms. Fenton is planning to return to work in 2 weeks and feels "desperate" to control the colic before that date. She wants to use childcare services in the evenings during her shift without being worried that her baby is crying the whole time.
PEM: What concerns do	

Relevant Evaluation Criteria	Scenario/Model Outcome
you have about the problem or treatment?	
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Infant is suffering from symptoms of colic, including predictable bouts of crying without apparent cause occurring in the evening.
3. Identify exclusions for self-treatment.	Excessive, inconsolable crying for more than 3 hours per day may be an indication of a condition that is causing pain or discomfort.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend self-care with drug, nondrug, and/or complementary therapies. (2) Refer Ms. Fenton to a pediatric care provider for treatment for her baby's symptoms. (3) Recommend self-care until the health care provider can be consulted. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Discourage use of senna and recommend alternative self-care strategies until a pediatric specialist can be consulted to rule out underlying causes of colic (such as reflux).
6. Describe the recommended therapeutic approach to the patient or caregiver using the LEARN model. ⁵⁴	Apply the LEARN model:

Relevant Evaluation Criteria	Scenario/Model Outcome
<i>Listen to the patient.</i>	Listen: The health care provider has noted the patient's stated preference for senna as a natural medicine.
<i>Explain your rationale.</i>	Explain: "Ms. Fenton, senna is a laxative that can be harmful to children under the age of 2 years. Sometimes colic can be a sign of a painful condition, and it would be best to ask your pediatrician to check Jamal to see if a medical problem is causing the crying."
<i>Acknowledge the patient's feelings and experience.</i>	Acknowledge: "I realize how frustrated and even exhausted you must feel."
<i>Recommend a course of action.</i>	Recommend: "In the meantime, I would recommend soothing strategies for Jamal including pacifiers, car rides, walks in a stroller, rocking him in your arms, swaddling, warm baths, soothing sounds, and belly or back rubs. Also, while breastfeeding, consider taking foods out of your diet that may cause problems such as irritation or allergies for your baby. These food items can include nuts, milk products, cabbage, spicy foods, and wheat."
<i>Negotiate a plan.</i>	Negotiate: "Do you have a friend from work, your grandmother, or another family member who might be willing you to help you a couple of nights while you try these changes?"
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"These non-medication options are best, because use of laxatives may lead to severe dehydration and other serious health risks in infants and young children."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Soothing and feeding strategies to improve colic may be time-intensive, and it is important to also take care of yourself by taking breaks, talking with people about your feelings, asking for help with meals and housework, exercising, and getting as much sleep as possible."

Relevant Evaluation Criteria	Scenario/Model Outcome
Solicit follow-up questions from the patient or caregiver.	“Would it be better for me to switch to formula and stop breastfeeding?”
Answer the patient’s or caregiver’s questions.	“There is strong evidence that breastfeeding is best for infants, so it is encouraged for at least 12 months whenever possible. Strategies to help reduce colic in breastfed infants include limiting cow’s milk in your diet, ensuring that the baby feeds long enough to empty one breast (to get the richer ‘hindmilk’), and ‘burping’ the baby regularly. Also, it might be helpful to consider joining a mom’s group or La Leche League for additional support.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Ms. Fenton in 1 week to ensure that she made an appointment with the pediatrician.

Key: n/a = Not applicable.

Key Points for Multicultural Aspects of Self-Care

- Cultural and diversity issues may affect patients’ attitudes and behaviors toward health and illness, as well as their acceptance of and adherence to self-care treatment plans.
- Demographic shifts in the U.S. population from age, race, and language to religion, disability status, and other cultural group changes affect the approach and delivery of care to patients.
- Minority populations—including patients from diverse races and ethnic groups, women, people with disabilities, persons who identify with the LGBTQ community, and older adults—have

experienced a range of health disparities. A disproportionately high number of minority-population patients continue to experience increased burden of disease, lower access to care, and higher rates of complications compared with those in other populations.

- Mistrust and fear of the U.S. health care system and providers can prevent some minority-population patients from seeking care. Clinical interactions that are culturally and linguistically sensitive, respectful, and competent can positively affect the quality of care for patients in diverse populations.
- Health care providers should assess and evaluate their own values and beliefs about cultures while acquiring knowledge and skills to deliver effective care for patients from diverse cultures and backgrounds.
- When collecting information from patients, providers should integrate PEM processes to gain understanding of patients' perspectives on causes, treatment, and concerns specific to their illness and overall health status.
- When making a therapy recommendation, providers can apply the LEARN model to listen, explain, acknowledge, recommend, and negotiate a more culturally appropriate self-care plan.
- Providers who can work across diverse cultural groups can support patients in making self-care decisions.

Chapter 4: Legal and Regulatory Issues in Self-Care Pharmacy Practice

Authors: Martha M. Rumore

This chapter examines the legal and regulatory aspects of the manufacturing, distribution, labeling, and marketing of nonprescription drug products in the United States. Theories of civil liability, negligence, and breach of warranty also are discussed.

A working understanding of legal and regulatory issues for nonprescription, homeopathic, and dietary supplement products is necessary for today's pharmacist, whose pivotal role in patient counseling on the selection and use of these products continues to expand. Staying ahead of the dynamic and frequently changing myriad of legal and regulatory issues in self-care pharmacy practice is essential for effective communication across the continuum from patients to elected representatives. With appropriate consideration of corresponding legal liability, this practice area constitutes a natural and broad-based opportunity for engaging patients in the clinical process, facilitating communication, and documenting professional services provided. Nonprescription and prescription drugs are regulated differently, but both are held to the same standards for safety and efficacy. Nonprescription medications are actively and stringently regulated by the U.S. Food and Drug Administration (FDA) and the Federal Trade Commission (FTC). For pharmacists and other health care providers, familiarity with these regulations is essential for framing the most helpful responses to patients' questions and concerns about the self-care products they use.

Reflecting formal usage in pharmacy practice, the term *nonprescription* replaces *over-the-counter* (OTC) throughout this book. However, historically and in many publications, as well as in common parlance, these designations are used interchangeably.

History of Self-Care

Self-care has evolved over many decades, from the era of patent medicine, with often expansive promises of benefit including cure as well as purely

fraudulent claims of efficacy, to the current availability of both standard and novel nonprescription therapeutic agents with proven health benefits and cost savings for self-reliant consumers.

In 1906, the Pure Food and Drugs Act¹ prohibited adulteration and misbranding. As a result, many patent medicines (ineffective cure-alls also referred to as nostrums and/or snake oils) were forced off the market. This was followed in 1914 by the Harrison Narcotic Act,² which required prescription-only status for opium and other narcotics. However, this law exempted patent medicine manufacturers if their products contained less than threshold amounts of opium and proved difficult to enforce. In 1938, the Food, Drug & Cosmetic Act (FDCA)³ mandated safety of foods, drugs, and cosmetics, with further standards established in 1951 with the Durham-Humphrey Amendment.⁴

Before enactment of the Durham-Humphrey Amendment, the manufacturer determined whether a product would be a prescription or nonprescription drug. Confusion ensued, with some manufacturers of a particular product marketing the drug as a nonprescription medication and other manufacturers of the same drug specifying prescription-only status. There was no FDA listing of prescription medications, and the manufacturer's interpretation of the FDA regulations of prescription versus nonprescription status was often arbitrary. If FDA disagreed with a product status determination, its sole recourse for remedy was to sue the manufacturer for misbranding.⁵ Many nonprescription products were marketed without approved New Drug Applications (NDAs) and were considered "grandfathered" drugs.

In 1937, ingestion of a preparation of sulfanilamide using diethylene glycol as a solvent resulted in the deaths of more than 100 people from kidney failure. At that time, the toxicity of diethylene glycol was unknown. The product was sold over the counter. The event prompted the passage of the 1938 FDCA. However, even the tragedy related to the nonprescription sale of sulfanilamide (as "Elixir of Sulfanilamide") in 1937 did not clarify when a medication should be available without a prescription, and the confusion continued until 1951 with passage of the Durham-Humphrey Amendment. This amendment provided the statutory basis for two classes of drugs in the United States: prescription and nonprescription. The FDCA required that in the absence of a medical need to restrict distribution, nonprescription availability is the default status for FDA-regulated products.

The next legislation that affected nonprescription drugs was the Kefauver-Harris Drug Amendments of 1962, which required proven efficacy for marketed products, including nonprescription drugs.⁶ To address this requirement, the focus was on a review of prescription drugs through a Drug Efficacy Study Implementation (DESI) program. Subsequently, in 1972, FDA instituted the “OTC Review” process, described later in the chapter (see “The Nonprescription Drug Review Process”).

In 1991, FDA created the Division of Nonprescription Drug Products within the Office of Drug Evaluation in the Center for Drug Evaluation and Research (CDER). FDA has issued more than 25 guidance documents for nonprescription medications. Although not legally enforceable, these directives describe FDA’s current opinion on a topic and should be viewed as recommendations. A listing of guidance documents pertaining to nonprescription drugs, with brief content summaries, is presented in [Table 4–1](#).

Table 4–1 FDA Guidance Documents	
Document	Description
Maximal Usage Trials for Topically Applied Active Ingredients Being Considered for Inclusion in an Over-the-Counter Monograph: Study Elements and Considerations (2019)	Document describes need for maximal usage trials to support an FDA determination that a topically applied product for OTC use is GRASE.
Self-Monitoring Blood Glucose Test Systems for Over-the-Counter Use (Draft) (2018)	Document describes performance studies required for validation of sterility and disinfection tests for FDA approval to enhance infection control with these devices.
Innovative Approaches for Nonprescription Drug Products (Draft) (2018)	Document presents two additional approaches for FDA approval of additional conditions for OTC products when the Drug Facts label alone is not sufficient for this purpose.
Policy Regarding Quantitative Labeling of Dietary Supplements Containing Live Microbials (Draft) (2018)	Document explains that FDA will use enforcement discretion for probiotics labeled in colony-forming units rather than weight.
Enforcement Policy- OTC Sunscreen Drug Products	Document explains FDA’s enforcement approach and certain products and claims (e.g. prevents skin cancer) for which it will no

Document	Description
Marketed Without an Approved Application (2018)	longer exercise enforcement discretion.
Drug Products Labeled as Homeopathic (Draft) (2017)	Document refers to FDA's enforcement priorities for homeopathic drugs, none of which have undergone FDA approval or OTC Review.
Gluten in Drug Products and Associated Labeling Recommendations (Draft) (2017)	Document includes voluntary gluten labeling statement for oral OTC drug products (including those applied inside the mouth or near the lips) and its placement outside the Drug Facts label.
Child-Resistant Packaging Statements in Drug Product Labeling (Draft) (2017)	Document provides labeling recommendations regarding child-resistant packaging statements.
Recommended Statement for Over-the-Counter Aspirin-Containing Drug Products Labeled With Cardiovascular Related Imagery (2017)	Document discusses that FDA will not take enforcement action against aspirin manufacturers who include imagery (e.g., heart image, electrocardiography graphic) if the label includes a statement advising patients to consult with their health care provider before using the product for cardiac indications.
Recommended Warnings for Over-the-Counter Acetaminophen Containing Drug Products and Labeling Statements Regarding Serious Skin Reactions (2017)	Document provides recommendations for label warnings about serious skin reactions on acetaminophen products.
Nonprescription Sunscreen Drug Products-Format and Content of Data Submissions (2016)	Document provides further details regarding processes FDA will use to determine if a sunscreen is GRASE.
Nonprescription Sunscreen Drug Products-Safety and Effectiveness Data (2016)	Document details the quality/manufacturing and clinical/nonclinical and postmarketing safety data needed to establish that a sunscreen is GRASE.
Self-Monitoring Blood Glucose Test Systems for Over-the-Counter Use (2016)	Document provides guidance for 510(k) submissions for blood glucose test systems for home use by lay persons.
Sunscreen Innovation Act: Withdrawal of a 586A Request or Pending Request & 586C(c) Advisory Committee Process	Two guidances regarding processes FDA will use to determine if a sunscreen is GRASE and should be added to the OTC sunscreen drug monograph.

Document	Description
(2016)	
Organ-Specific Warnings: Internal Analgesic, Antipyretic, and Antirheumatic (IAAA) Drug Products for Over-the-Counter Human Use—Labeling for Products That Contain Acetaminophen (2015)	Document covers alternative allowable language for acceptable liver warnings for products in view of the fact that some IAAA products have maximum daily doses of acetaminophen of <4 g.
Over-the-Counter Pediatric Oral Liquid Drug Products Containing Acetaminophen (2015)	Document covers standardization of concentration to 160 mg/5 mL in view of dosing errors from multiple concentrations. The package must include a dosage delivery device. Dosing directions should be provided in milliliter units only.
Nonprescription Sunscreen Products—Content and Format of Data Submissions to Support a GRASE Determination Under the Sunscreen Innovation Act (SIA) (2015)	Document covers format and content of information needed for 586A requests.
Self-selection Studies for Nonprescription Drug Products (2013)	Document provides recommendations for conducting studies to assess the ability of consumers to apply drug labeling information to their personal health situation to make correct nonprescription purchases.
Labeling and Effectiveness Testing: Sunscreen Products for OTC Human Use (2012)	Document provides information to assist industry to comply with labeling and testing requirements for ultraviolet A and B radiation protection for nonprescription sunscreen products.
Labeling for Bronchodilators: Cough, Cold, Allergy, Bronchodilator, and Asthmatic Drug Products for OTC Human Use (2012)	Document provides information to help industry comply with additional warnings on bronchodilator products (i.e., Asthma Alert and revised indications, warnings, and directions).
Toll-free Number Labeling and Related Requirements for Over-the-Counter and Prescription Drugs Marketed With Approved Applications (2012)	Document provides requirements for toll-free number for ADR reporting (not for medical advice) for products approved pursuant to a monograph process and contact for those approved pursuant to an approved application.

Document	Description
Time and Extent Applications for OTC Drug Products (2011)	Document explains what information is required for submission of a TEA to show that the product has been used “to a material extent” and “for a material time.”
Topical Acne Drug Products for OTC Use—Revision of Labeling and Classification of Benzoyl Peroxide	Document covers addition of benzoyl peroxide as a GRASE active ingredient for nonprescription acne products with new warnings, directions, and labeling requirements.
Label Comprehension Studies for Nonprescription Drug Products (2010)	Document covers recommendations on conducting label comprehension studies.
Organ-Specific Warnings: Internal Analgesic, Antipyretic and Antirheumatic Drug Products (2010)	Document covers labeling requirements for warnings regarding potential liver injury and stomach bleeding.
Postmarketing Adverse Event Reporting for Nonprescription Human Drug Products Marketed Without an Approved Application (2009)	Document covers minimum elements and format for ADR reports and how and where to submit reports.
Labeling of Nonprescription Human Drug Products Marketed Without an Approved Application: Questions and Answers (2009)	Document explains the standardized labeling content and format for products not marketed pursuant to an NDA or ANDA in a Q&A format.
Labeling OTC Human Drug Products—Small Entity Compliance Guide (2009)	Document explains the standardized labeling content and format.
Labeling OTC Human Drug Products—Questions and Answers (2009)	Document clarifies, in Q&A format, the standardized labeling content and format.
Labeling OTC Human Products Updating Labeling in RLDs and ANDAs (2002)	Document assists manufacturers of nonprescription drugs marketed via an ANDA or those holding RLDs to comply with the standardized labeling content and format.
Guidance for Over-the-Counter Human Chorionic Gonadotropin (hCG) 510(k)s (2000)	Document covers pregnancy test kit 510(k) medical device approval and patient labeling requirements.

Document	Description
Labeling of OTC Human Drug Products Using a Column Format (2000)	Document describes how more than one Drug Facts box can be used for each side of a package to allow for the use of columns.
Enforcement Policy on Marketing OTC Combination Products (1984)	Document covers policy regarding marketing of combinations of ingredients.
General Guidelines on OTC Drug Combination Products (1978)	Document describes rules for combinations permitted for marketing. Within each monograph, combinations are detailed: Category I ^b ingredients from <i>different</i> therapeutic categories may be combined to treat different symptoms concurrently in certain circumstances. Category I ingredients from the <i>same</i> therapeutic category should not be combined if they have the same mechanism of action.
Upgrading Category III ^a Antiperspirants to Category I (1978)	Document details the studies required to bring Category III antiperspirant ingredients into Category I.

^a Category III drugs are considered to have insufficient evidence to prove safety and/or effectiveness.

^b Category I drugs are considered to be GRASE.

Key: ADR = Adverse drug reaction; ANDA = Abbreviated New Drug Application; FDA = U.S. Food and Drug Administration; GRASE = generally recognized as safe and effective; OTC = over-the-counter; Q&A = question-and-answer; RLD = reference-listed drug; TEA = Time and Extent Application.

The Food and Drug Modernization Act of 1997⁷ expanded FDA's authority over nonprescription drugs in establishing inactive ingredient labeling requirements. This act preempted states from establishing state-specific labeling requirements when federal requirements exist. In the United States, nonprescription drug manufacturers and distributors are represented by the Consumer Healthcare Products Association (CHPA) (formerly the Proprietary Association and, subsequently, the Nonprescription Drug Manufacturers Association).

Over the past 20 years, legislative and regulatory changes pertaining to nonprescription drugs have been implemented, including standardized labeling with the *Drug Facts* format, additional final monographs (as discussed later under “The Nonprescription Drug Review Process”), prescription-to-nonprescription switches for drugs never marketed before, and a mechanism for drugs marketed in foreign countries to be considered for the OTC Review process. In 2014, the Sunscreen Innovation Act (SIA) provided an alternative process for the review of safety and effectiveness of nonprescription sunscreen active ingredients, a category considered as drugs by FDA.⁸ Most recently, FDA has sought input from stakeholders and the public to improve the regulatory processes for nonprescription drugs.

Nonprescription Drugs: Approval and Regulatory Processes

Definition of Nonprescription Status

Nonprescription medications, by definition, may be used without medical supervision. A drug can be marketed as a nonprescription product if it can be used by a consumer guided by the product label such that the consumer can self-diagnose, self-treat, and self-manage the condition requiring attention and if no health care provider is needed for the safe and effective use of the product.⁹ The drug also must have a low potential for abuse and misuse, and the benefits of nonprescription availability must outweigh the risks.⁹ A state may not allow a prescription drug to be sold as other than prescribed, but a state may restrict a drug with nonprescription status under federal law to prescription status.¹⁰ In *Whitehall Labs v. Wilbar*,¹¹ the court upheld a Pennsylvania law requiring a prescription for Primatene tablets, which was a nonprescription drug by federal rules, finding the Pennsylvania law to be consistent with tenets of consumer protection. Similarly, in *Northwest Corp. v. Oregon Board of Pharmacy*,¹² the court upheld the state’s decision to establish prescription status for ephedrine.

Some nonprescription medications also are available as prescription drugs. In such cases, a determination has been made that the medication is safe for nonprescription use in certain dosages or dosage forms, or for specific indications but not for others. Examples are ibuprofen, for which the 200 mg

dose is nonprescription for pain but higher dosages and strengths are prescription-only for such conditions as arthritis; meclizine, which is a prescription drug for vertigo but a nonprescription medication for nausea with motion sickness; and nicotine products, which have nonprescription status in gum, lozenge, and patch formulations but prescription-only status for inhaled and nasal products.

The FDCA prohibits the simultaneous marketing of the same active ingredient in both a prescription drug product and a nonprescription drug product unless a “meaningful difference” exists between the two that makes the prescription product safe only under the supervision of a healthcare practitioner.¹³ Recently, FDA withdrew the Abbreviated New Drug Applications (ANDAs) for PEG3350 laxative products that were prescription versions of the nonprescription drug, determining there was no “meaningful difference” between the products. The ANDA holders sought review of FDA’s decision by the D.C. District Court, claiming that the duration of therapy differs.¹⁴ The court concluded that there was no “meaningful difference” between the prescription version’s recommended use for 2 weeks or less and the nonprescription version’s recommended use for no longer than 7 days.

The Nonprescription Drug Review Process

On May 11, 1972, FDA announced a review of nonprescription products marketed between 1938 and 1962 that were not covered under an NDA. Rather than review the more than 300,000 products,¹⁵ FDA divided them into categories according to intended therapeutic effect and active ingredients. It then assigned 17 different panels of experts to review each category (e.g., internal analgesics) and each of the more than 700 listed ingredients for safety and effectiveness. Ingredients were assigned to one of three categories: Category I, generally recognized as safe and effective (GRASE); Category II, not GRASE; or Category III, insufficient evidence to prove safety and/or effectiveness (i.e., further information is needed to show safety and efficacy and classify as Category I or II). The panels also considered the first prescription-to-nonprescription (also referred to as “Rx-to-OTC”) switches, such as those for diphenhydramine and hydrocortisone. Panel deliberations were published in the *Federal Register*, with a comment period followed by a proposed rule and, finally, formal monographs, also published in the *Federal Register*, detailing the dosages and labeling requirements for each ingredient.

Manufacturers of products containing ingredients in Category II were required to either reformulate or remove those products from the market. However, banned products could continue to be sold until the inventory was depleted from the pharmacy or wholesaler stock. In some cases, consumers were actually harmed by banned products (e.g., with quinine-induced renal failure) that continued to be sold.¹⁶

For those ingredients placed in Category III, manufacturers were given more than 15 years to conduct necessary studies or to reformulate their products with Category I ingredients. Other manufacturers simply removed the products from the market promptly, primarily because of the prohibitive costs of studies in view of the product sale history. Some regulators thought that the 15-year grace period was too long, and in *Cutler v. Kennedy*, several consumers sued to have Category III ingredients removed from the market.¹⁷ To take advantage of Category III classification without fear of regulatory action, a manufacturer must provide timely notification of, and initiate, testing.¹⁸ In *Cutler v. Kennedy*, the court held that the OTC Review required removal of Category III ingredients after the final monograph was published, to prevent exposure to unsafe or ineffective drugs. Consequently, many products were removed from the market, and others were reformulated. Some products were moved from one category to another on the basis of research data regarding safety and efficacy.

After more than 40 years, the OTC Review process continues to be applied for new ingredients, amendments to monographs, unfinished monographs, and switches. (Of note, at present, several monographs have not yet been finalized and are in “tentative final” or stayed status.) This public rule-making process is documented by publication in the *Federal Register*, with a corresponding comment period, for each of the three phases: (1) Advance Notice of Proposed Rulemaking, (2) Tentative Final Monograph, and (3) Final Monograph. These monographs in final form are then codified in the Code of Federal Regulations (CFR), where they can be found in 21 CFR parts 331–358.

Pathways to Nonprescription Status

Two mechanisms exist for licensing and commercial marketing of nonprescription drug products: NDA and the drug monograph. Today, if a manufacturer follows the monograph process, it need not obtain FDA approval for the product. Monographs are tantamount to “recipe books” that specify the

active ingredients, dosages, and formulations, as well as the labeling and conditions whereby nonprescription drug ingredients are GRASE-compliant. For products that fall outside the monograph specifications, the manufacturer will need either to pursue an NDA,¹⁹ petition to amend the monograph, or modify the product to comply with the monograph specifications.

New agents that are not included in an OTC Review monograph must be regarded as new drugs. For new sunscreen agents, for example, FDA had taken the position that these are constituted of new ingredients requiring an NDA. Under the 2014 SIA, an alternate process known as a 586A request for review of sunscreens was established. In 2015, FDA published four draft guidance documents regarding scientific testing required for determination of GRASE status for a sunscreen and the timelines for FDA review.^{20–23} Examples of nonprescription medications that have required NDAs for a switch from prescription-to-nonprescription status are oxybutynin, ibuprofen, budesonide, and fluticasone nasal spray.

Various types of NDAs can be submitted for marketing of a nonprescription drug:

- Prescription-to-nonprescription switches effected using an NDA or NDA supplement (e.g., omeprazole, nicotine gum, orlistat)
- “Direct-to-nonprescription” (acetaminophen, nicotine lozenge)
- NDA deviation (for new nonprescription products that differ only slightly from monograph products) (rarely used)²⁴
- ANDA used for switching a generic drug to nonprescription status (e.g., loratadine).

A product containing an ingredient new to the nonprescription marketplace is regulated under the NDA process under section 505(b)(1) of the FDCA, such as for a prescription-to-nonprescription switch NDA. An NDA can be used to request approval of a nonprescription drug product that deviates from monograph specifications. The product can be marketed only with the exact formulation and labeling approved by FDA. To make a change, the manufacturer must submit an NDA supplement. Nonprescription products also can be approved by means of a 505(b)(2) application, in which data from previous safety and efficacy testing not conducted by or for the applicant may be used, or using an ANDA under section 505(j) of the FDCA.²⁵ These applications are confidential, but a fee is required. Nonprescription products approved through the NDA route receive a period of exclusivity whereby no

other versions can appear on the market. A comparison of the NDA and monograph routes for nonprescription drug approval is detailed in [Table 4–2](#).

Table 4–2 Comparison of New Drug Application (NDA) and Drug Monograph Regulatory Approval Pathways	
NDA	Monograph
Premarket approval	No premarket approval
Confidential	Public
Drug product-specific	Applies to all products with the ingredient
Potential for marketing exclusivity	No exclusivity
Application filing fees	No filing fees
GMPs apply	GMPs apply
Clinical development required	No clinical development required

Key: GMPs = Good manufacturing practices.

Two mechanisms are available for amending a drug monograph: a Citizen Petition²⁶ and a Time and Extent Application (TEA).²⁷ A Citizen Petition can be used to request an amendment or repeal of conditions covered in a monograph at any stage. However, the Citizen Petition is limited to pre-1975 marketing conditions—that is, active ingredient, dosage form, or indication. For petitions, the product cannot be marketed until FDA approves the petition.

A TEA can be used to request that applicable drug products be considered for inclusion in the OTC Review monograph system.²⁷ A TEA is submitted for drug products that can meet the statutory standard of marketing to a “material extent” and “for a material time.” This scenario is defined to encompass the following: drug products initially marketed under an NDA in the United States after 1972; drug products without any U.S. marketing experience; or those not GRASE (i.e., not meeting monograph specifications) in the original OTC Review but for which additional data are now available. The conditions must have been marketed for nonprescription purchase and for at least 5 continuous

years in the same country in sufficient quantity. Several sunscreen ingredients, such as amiloxate and bisoctrizole, have used the TEA process to reach the U.S. market.

Consumer behavior studies and label comprehension studies are often used to assess whether consumers can appropriately use the product on a nonprescription basis. Because no learned intermediary (i.e., the prescriber) is involved, as for prescription products, such data often are needed to support a switch from prescription to nonprescription status.

It also is mandatory for nonprescription drug manufacturers to register their establishments and list their drug products with FDA.²⁸ Additionally, FDA may require in vivo or in vitro finished-formulation testing (e.g., dissolution tests for enteric-coated and sustained-release products).

Prescription-to-Nonprescription Switch

Since the mid-1970s, FDA has switched more than 100 ingredients, dosages, or indications from prescription to nonprescription status ([Table 4–3](#)). Switch decisions are made by FDA with the advice of advisory councils. Consumers can benefit from prescription-to-nonprescription switches because they broaden access to important medications. In addition, the nonprescription versions usually are cost-effective for consumers and third-party insurers. A survey found that consumers save up to \$750 million a year as a result of using nonprescription cough and cold medications that once were available only by prescription. The same study demonstrated that physician visits for the common cold dropped by 110,000 a year between 1976 and 1989, suggesting that access to nonprescription products contributed to a reduction in office visits.²⁹

Table 4–3 Select Prescription-to-Nonprescription Switches^{a,b}

Purpose/Class of Drug	Drug Name^c	Year of Switch
Allergic rhinitis	Xyzal Allergy 24HR Tablets (levocetirizine)	2017
	Children’s Xyzal Allergy 24HR Oral Solution (levocetirizine)	
	Rhinocort Allergy Spray (budesonide)	2015

Purpose/Class of Drug	Drug Name^c	Year of Switch
	Flonase Allergy Relief (fluticasone propionate)	2014
	Nasacort Allergy 24 HR (triamcinolone) (nasal spray)	2013
	Nasalcrom (cromolyn sodium)	1996
Analgesic/antipyretic	Motrin Migraine Pain, Advil Migraine Liqui-gels (ibuprofen)	2000
	Excedrin Migraine (aspirin/caffeine/acetaminophen)	1998
	Children's Motrin	1995
	Aleve (naproxen)	1994
	Advil, Nuprin (ibuprofen)	1984
Analgesic/decongestant	Advil Congestion Relief (ibuprofen/phenylephrine)	2010
	Children's Advil Cold (ibuprofen/pseudoephedrine)	2002
	Aleve Cold & Sinus (naproxen/pseudoephedrine)	1999
	Advil Cold & Sinus (ibuprofen/pseudoephedrine)	1989
Anthelmintic	Pyrantel pamoate	1986
Anticandidal	Monistat 3 (miconazole nitrate 4%)	1998
	Vagistat-1 (tioconazole)	1997
	Gyne-Lotrimin 3 (clotrimazole)	1996
	Monistat 3 (miconazole nitrate 2%)	1996
	Femstat 3 (butoconazole nitrate)	1995
	Monistat 7 (miconazole nitrate)	1991
	Gyne-Lotrimin, Mycelex-7 (clotrimazole)	1990
Antidiarrheal	Imodium Advanced	1997
	Imodium A-D (loperamide)	1988
Antihistamine	Allegra (fexofenadine HCl)	2011

Purpose/Class of Drug	Drug Name^c	Year of Switch
	Children's Zyrtec Allergy and Children's Zyrtec Hives Relief (cetirizine), syrup and chewable tablets	2007
	Claritin tablets, reditabs, and syrup (loratadine)	2002
	Tavist-1 (clemastine fumarate)	1992
	Doxylamine	1987
	Diphenhydramine HCl	1985
	Drixoral (dexbrompheniramine maleate)	1982
	Tripolidine	1982
	Chlorpheniramine maleate	1976
Antihistamine eye drop	Zaditor	2006
	Alaway	2006
Antihistamine and decongestant or antitussive	Allegra D (fexofenadine/pseudoephedrine)	2011
	Zyrtec D (cetirizine/pseudoephedrine)	2007
	Claritin-D 24 Hour	2002
	Drixoral Plus (dexbrompheniramine maleate/chlophedianol HCl)	1987
	Actifed (pseudoephedrine/triprolidine)	1985
Acid reducer/PPI	Nexium 24HR (esomeprazole magnesium)	2014
	Prevacid 24HR (lansoprazole)	2009
	Prilosec OTC (omeprazole)	2003
	Pepcid Complete (famotidine/calcium carbonate/magnesium hydroxide)	2000
	Zantac 75 (ranitidine)	1995
	Pepcid AC (famotidine)	1995

Purpose/Class of Drug	Drug Name^c	Year of Switch
Anorectal vasoconstrictor	Ephedrine sulfate	1980
	Epinephrine hydrochloride	1980
	Phenylephrine hydrochloride	1980
Antiemetic	Diphenhydramine HCl	1987
Antidandruff	Nizoral (ketoconazole)	1997
Antihistamine	Pataday Once Daily Relief (olopatadine HCl, 0.2%)	2020
	Pataday Twice Daily Relief (olopatadine HCl, 0.1%)	2020
Antimicrobial	E-Z Scrub (povidone/iodine sponge)	1987
Antipyretic	Hydrocortisone (>0.5%–1%)	1991
	Hydrocortisone	1979
Cold sores	Abreva (docosanol)	2000
Decongestant	Afrinol Repetabs (pseudoephedrine, timed-release)	1982
	Oxymetazoline	1976
	Pseudoephedrine	1976
	Xylometazoline	1976
Dental rinse	Acidulated phosphate fluoride	1980
	Sodium fluoride; stannous fluoride	1980
Emergency contraception	Plan B One Step (levonorgestrel)	2009
	Plan B (levonorgestrel)	2006
Expectorant/ decongestant	Mucinex D ER Tablet	2004
	Mucinex DM ER Tablet	2004
	Mucinex ER Tablet (guaifenesin)	2002
Hair regrowth	Rogaine Extra Strength (minoxidil)	1997

Purpose/Class of Drug	Drug Name^c	Year of Switch
	Rogaine (minoxidil)	1996
Laxative	MiraLax (polyethylene glycol)	2006
Ocular vasoconstrictor/ decongestant	Lumify (brimonidine tartrate)	2017
	Zaditor (ketoprofen)	2006
	Naphcon A, Opcon A, Ocuhist (pheniramine/naphazoline)	1994
	Vasocon A (antazoline phosphate/naphazoline)	1994
	Ocuclear (oxymetazoline HCl)	1986
Oral anesthetic	Dyclonine HCl (solution, suspension, lozenge)	1982
Overactive bladder	Oxytrol for Women (oxybutynin)	2013
Pediculicide	Nix (permethrin)	1990
Poison ivy protection	Ivy Block (bentoquaram)	1996
Sleep aid	Advil PM (ibuprofen/diphenhydramine)	2005
	Diphenhydramine (HCl and monocitrate)	1982
	Doxylamine succinate	1978
Smoking cessation	Commit (lozenge)	2002
	Nicotrol TD	2002
	Nicorette (gum)	1996
	Nicotrol, Nicoderm CQ (patch)	1996
Sunscreen	Anthelios SX (Ecamsule/avobenzone/octocrylene)	2006
Topical analgesic	Voltaren (diclofenac sodium gel)	2020
Topical antifungal	Lamisil Derm Gel	2006
	Lotrimin Ultra (butenafine HCl)	2001
	Lamisil AT (terbinafine HCl)	1999

Purpose/Class of Drug	Drug Name ^c	Year of Switch
	Lotrimin AF (clotrimazole)	1989
	Miconazole	1982
Weight loss aid	Alli (orlistat)	2007

^a Complete listing can be found at <http://www.chpa.org/Switch.aspx>.

^b There were no switches from January 1, 2018 through April 1, 2019.

^c When a brand name is listed, the switch was effected using the NDA process. Key: NDA = New drug application; PPI = proton pump inhibitor.

Among the first products to be switched to nonprescription status was ibuprofen for the treatment of pain in 1984. In a few cases, a drug that was available as a nonprescription product was returned to prescription status, an example being metaproterenol sulfate. FDA itself initiated the switch for metaproterenol—a decision that was met with great opposition from physicians and pharmacists.³⁰ Of note, however, FDA considered that selfdiagnosis and self-treatment of asthma with nonprescription metaproterenol may delay physician visits in patients with asthma. Furthermore, a nonprescription product must not require routine medical examinations or laboratory testing, and it was for this reason metaproterenol was returned to prescription status. However, exceptions exist for grandfathered drugs—that is, those available before the FDCA of 1938. This is the reason why Asthmanefrin (racedrine) is available over the counter for temporary relief of mild respiratory symptoms of bronchial asthma. An additional requirement for nonprescription status is that the condition must be one that a patient can self-diagnose, thus keeping products like acyclovir for genital herpes or statins for hypercholesterolemia from being switched to nonprescription status.³¹ Additional issues for acyclovir pertained to increasing resistance to the drug. Similarly, histamine type 2 receptor (H₂) blockers cannot be labeled for use with ulcers, because the patient's symptoms may mask the presence of gastric cancer.³²

Products may be switched from prescription to nonprescription status by any of three routes:

1. Submitting a supplemental NDA (applies to a particular product)
2. Petitioning the FDA (may be filed by interested parties such as manufacturers, health insurance companies, associations, or pharmacy benefit managers)
3. Amending the drug monograph (applies to all products with the ingredient)

The supplemental NDA route is the most commonly used for prescription-to-nonprescription switches, because unlike with the other two routes, the proceedings are confidential and allow for 3 years of marketing exclusivity. The exclusivity is an incentive for status switching of medications for which patents are about to expire, with ensuing generic competition. The supplemental NDA route is used if the manufacturer is planning to switch the prescription drug without a change in the previously approved dosage form or route. However, if the manufacturer intends to convert some but not all of the indications to nonprescription status, an NDA must be filed. If the manufacturer intends to market a new product whose active substance, indication, or dosage form has never been nonprescription, either an original NDA (505)(b)(1) or 505(b)(2) is required. After a drug goes off patent, anyone can file a 505(b)(2) NDA to switch the drug to nonprescription status. Additional efficacy studies may be required in these situations or when the nonprescription population differs from the population used to support the original NDA (e.g., with ibuprofen, for which the nonprescription indications include pain, fever, and dysmenorrhea but the prescription indications are osteoarthritis and rheumatoid arthritis). Label comprehension studies also may be required. However, comparative studies with other agents are not required.

The second switch mechanism is to file a formal request with FDA. This occurs by a Citizen Petition, which must be accompanied by data demonstrating safety and efficacy. In one instance, a managed care organization successfully petitioned FDA to switch several nonsedating antihistamines to nonprescription status in an effort to save money in plan beneficiary reimbursement. Most insurance plans do not cover nonprescription medications.³³ Additionally, Medicaid and Medicare programs often do not pay for nonprescription products. In the case of the nonsedating antihistamines, the manufacturers objected to any switch to nonprescription status, because

they stood to lose revenue if the agents became nonprescription drugs. Profitability of a drug when sold by prescription versus over the counter has a profound effect on whether or not nonprescription status will be sought.

The third switch mechanism is to amend the monograph. A process exists to request amendment or repeal of conditions covered by nonprescription drug monographs. Companies may need to file a complete (not supplemental) NDA to request approval of a nonprescription drug that deviates in any respect from a monograph description. In some instances, FDA itself has decided to allow self-use, as with hydrocortisone and diphenhydramine. The respective monographs were then amended to add these drugs.

In some cases (e.g., ibuprofen, naproxen), a partial switch for nonprescription status occurs whereby some doses become nonprescription whereas others remain prescription. In other instances, two different preparations of a product at the same dose may be marketed as both prescription and nonprescription drugs (e.g., cimetidine 200 mg tablets, loperamide 2 mg capsules). In such cases, the prescription and nonprescription versions may not resemble each other in appearance. Additionally, the indications may differ between the nonprescription and prescription versions (e.g., proton pump inhibitors are nonprescription drugs for heartburn but are prescription-only medications for peptic ulcer disease).

Safe Use of Nonprescription Drugs

Adulteration and Misbranding

A nonprescription drug is *adulterated* if it contains a substance that may make the product harmful to consumers under customary conditions for use; if it contains any filthy, putrid, or decomposed substance; if its container is composed of a harmful substance; or if it is manufactured or held under unsanitary conditions. All nonprescription drug manufacturing must adhere to *good manufacturing practices* (GMPs). Failure to follow GMP requirements may result in adulteration of a nonprescription drug preparation.³⁴

A nonprescription medication is considered *misbranded* if its labeling is false or misleading, if it does not bear the required labeling information, or if the container is made or filled in a deceptive manner. *Labeling* refers to all labels

and other printed, written, or graphic matter on or accompanying a product.

FDA is authorized to inspect nonprescription drug manufacturing facilities, in a capacity similar to its enforcement powers regarding prescription drugs.³⁵ It can then use administrative enforcement tools such as issuing warning letters or requesting a product recall, or it may seek judicial enforcement by means of a civil injunction, criminal penalties, or product seizure. FDA can request but not mandate a recall of nonprescription drug products.³⁶ However, if a manufacturer fails to recall a product pursuant to such a request, FDA may apply other enforcement options such as injunction, seizure, or criminal prosecution.³⁷ Once a manufacturer agrees to recall a product, FDA conducts a health hazard evaluation (HHE), classifies the recall, as described next, and notifies the manufacturer of the classification.³⁶

Three recall categories have been defined. For a Class I recall, a reasonable probability exists that the use of, or exposure to, a violative product will cause serious adverse health consequences or death. For a Class II recall, use of, or exposure to, a violative product may cause temporary or medically reversible adverse health consequences, or the probability of serious adverse health consequences is remote. For a Class III recall, use of, or exposure to, a violative product is not likely to cause adverse health consequences. Additionally, a recall can extend to the manufacturer, wholesale, retail, or consumer level. Depending on the class or level of recall, the manufacturer's notification can be to direct accounts, such as wholesalers, or to pharmacies, or to the general public by way of the FDA website or media coverage. For recalls at the consumer level, the patient may return the nonprescription product to the place of purchase for a refund. Pharmacists can advise patients about the recall and recommend alternative products to replace the recalled product. Additionally, in the event of a recall, manufacturers provide a toll-free number for consumers to obtain additional information. FDA has a recall audit program to ensure that the recall has been effective.^{36,37} For example, in 2011 FDA mandated changes to dosing instructions for many pediatric (infants and children) acetaminophen products. Immediately upon this 2011 labeling change, acetaminophen products actually in commerce became ineligible for sale. They were subject to a recall owing to their nonmonograph status.

Adverse Drug Reaction Reporting

In 2004, a dietary supplement ephedra (i.e., ma huang) was linked to stroke,

arrhythmias, and death. The product was banned from the U.S. market. Of importance, the incident prompted the mandatory reporting of serious adverse events for dietary supplements and nonprescription drugs.³⁸ The 2006 Dietary Supplement and Nonprescription Drug Consumer Protection Act mandated reporting of serious adverse drug reactions (ADRs) by dietary supplement and nonprescription drug manufacturers.³⁹ Before this act, ADR reporting was required only for nonprescription drugs marketed pursuant to an NDA or ANDA. Manufacturers should notify FDA of all serious ADRs (Table 4-4) by submitting an Individual Case Safety Report (ICSR) on FDA form 3500A, together with a copy of the medication label, via either mail or telephone-transmitted facsimile (fax), within 15 business days of receipt. The ADR also may be reported online using the MedWatch reporting form. Consumers may report adverse reactions from nonprescription products using the MedWatch online form or by mail or fax using FDA form 3500B.

Table 4-4 Defining Criteria for Serious Adverse Events

- Death
- Life-threatening
- Hospitalization (initial or prolonged)
- Disability or permanent damage
- Congenital anomaly/birth defect
- Required intervention to prevent permanent impairment or damage (including device placement)
- Other serious important medical events (e.g., allergic bronchospasm requiring treatment in an emergency department; seizure that does not result in hospitalization)

For nonprescription products approved under an NDA or ANDA, the requirements are the same as for prescription products approved under these applications—that is, 15-day, periodic, and annual reports of both serious and nonserious ADRs. All ADR reports must be retained by the manufacturer for a 6-year period. For prescription products, labeling warnings often are included in the prescribing information to inform prescribers even when a causal relationship has not been definitively established; however, only clearly documented, clinically significant, and important warnings are required for nonprescription products.³⁹

The Dietary Supplement and Nonprescription Drug Consumer Protection Act

also requires that a manufacturer of nonprescription products marketed under a monograph review process must place “responsible person” contact information (i.e., domestic address or phone number) on its labels for consumer reporting of ADRs. The responsible person is defined as the manufacturer, packer, or distributor whose name appears on the label. For nonprescription products marketed pursuant to an NDA or ANDA, a toll-free number is required. If the company does not have a tollfree number, the label may include FDA’s toll-free MedWatch telephone number. However, enforcement of this provision has been problematic. Additionally, consumers may report adverse events to FDA at www.safetyreporting.hhs.gov.

ADRs have led to various FDA actions including requiring additional warnings, MedWatch Safety Alerts (e.g., for methemoglobinemia resulting from benzocaine sprays, gels, or liquids applied topically or to gums), category reclassification (e.g., from I to II), request for a recall, or market removal (e.g., of phenylpropanolamine).⁴⁰ Two recent FDA Safety Alerts were prompted by ADRs reported for nonprescription medical devices and dietary supplements that resulted in patient deaths. FDA warned that biotin, especially at dosages in hair and nail supplements, may interfere with laboratory testing. One patient taking high levels of biotin died when a cardiac troponin assay gave falsely low test results.⁴¹ In 2019, FDA warned against use of previously owned test strips (e.g., for glucose or international normalized ratio) or those not authorized for sale in the United States. These products are often sold online.⁴²

Labeling

FDA regulates nonprescription drug labeling. FDA reviews nonprescription drug labels for products marketed under an NDA. Nonprescription products must be labeled with adequate directions for patient use, with accommodation for persons with low-level reading comprehension, without the need for medical consultation. The labeling must be “likely to be read” and “likely to be understood” by the “ordinary individual.” All labels must be in English. However, manufacturers may include a toll-free number for Spanish-speaking consumers to call with inquiries.

Since 1999, the content and format requirements for nonprescription drug labeling have been standardized and specific.⁴³ FDA has even provided guidance on font size for the label, which must be in 6-point type or larger.⁴⁴ The label must appear on the outside container or wrapper, or may be the

immediate container label if packaging does not include an outside container or wrapper, and begins with a Drug Facts panel. It must further include active ingredient(s), purpose(s), use(s), warning(s), directions, other information, inactive ingredients, and frequently asked questions (if relevant).⁴⁵ Inactive ingredients must be listed in alphabetical order and appear on the outside container. Flavors and fragrances may be listed as “flavors” and “fragrances,” respectively.⁴⁵ Trade secret ingredients may be listed as “and other ingredients.” Incidental ingredients present at insignificant levels need not be identified, unless the omission would constitute a failure to reveal a material fact.⁴⁵ (See [Figures 4-1, 4-2, and 4-3.](#))

Figure 4-1 Drug facts labeling outline. (Source: [Reference 44.](#))

Figure 4-2 Drug facts labeling sample 1. (Source: [Reference 44.](#))

Figure 4-3 Drug facts labeling sample 2. (Source: [Reference 44.](#))

Drug Facts warnings may include but are not limited to the following specific phrases and topics: “for external/rectal/vaginal use only”; Reye syndrome warning; allergic reaction warning; flammability warning; choking warning; alcohol warning; sore throat warning; dosage warning; “do not use” warning; “ask a doctor if you have”; “ask a doctor or pharmacist before you use”; “stop use and ask a doctor if”; pregnancy/breastfeeding warning; “keep out of reach of children”; and “contains phenylalanine.” Drug Facts rules detail how to group warnings and how to bullet-list them. In addition, other rules specify what information should appear on the *principal display panel*, which is defined as “that part of the label that is most likely to be displayed, presented, shown, or examined under normal and customary conditions of display for retail sale.”⁴⁶

The labeling permitted for each nonprescription ingredient is detailed in the

monograph. Minor changes are permitted, provided that the content is truthful and the language not misleading. Additionally, repackagers of nonprescription products must comply with the same labeling requirements as those for manufacturers. FDA takes action if label claims are false or misleading. Jurisdiction extends to all labels and labeling in any media, including websites and social media.⁴⁷ NDA ingredients are not found in the monograph, because only the NDA filer is eligible to market these products. Therefore, no rationale exists for providing information for other manufacturers, because they must still go through the ANDA process once the patents expire.

Manufacturers of nonprescription products must warn of foreseeable risks. A voluntary “Flag the Label” program has been adopted by nonprescription drug manufacturers to alert consumers of changes in currently marketed products or labels. *Significant changes* are defined as (1) expansion or limitation of the claims, (2) modification of the dosage level, (3) change in active ingredients or directions for use, (4) new warnings or contraindications, and (5) any other significant new information. The “flag” should be carried on the label for at least 6 months after such a change is made.

An example is product *line extensions*, that is, new products with altered features such as flavors, ingredients, or dosage forms. Line extensions for which product names share the same root name with a suffix or other modifier are prone to patient confusion and errors. FDA reviews and approves proposed trade names for nonprescription products that are approved under the NDA or ANDA process. When products are switched from prescription to nonprescription status, the product may keep its name or use a new name. For partial switches, such as when only one strength formulation is switched to nonprescription status, a new name is usually selected for the nonprescription version. Another example of a change requiring a “Flag the Label” warning is a change in active ingredients. Such was the case when kaolin and pectin were replaced by bismuth subsalicylate in the antidiarrheal Kaopectate.

Some monographs (e.g., for antacid, antiflatulent, topical antifungal, antiemetic, and cough and cold products) contain professional labeling for health care professionals not included in the nonprescription drug labeling for consumers. The professional labeling is located in the nonprescription monograph. For example, the professional labeling in the monograph for nonprescription antiflatulence products contains additional indications for

postoperative gas pain or use in endoscopic examination.⁴⁸

Packaging

Most oral, nasal, otic, ophthalmic, rectal, and vaginal nonprescription medications must be tamper-resistant as required under the Federal Anti-Tampering Act and implementing regulations.^{49,50}

- *Tamper-resistant* refers to a feature of the product packaging that is created to resist access to the product.
- *Tamper-evident* packaging is characterized by features that make previous unauthorized access to the product easily detectable by the prospective consumer. Exceptions include dermatologics, dentifrices, and insulin.
- Tamper-resistant packaging is defined as “an indicator or barrier to entry which if breached or missing can reasonably be expected to provide visible evidence to consumers that product tampering has occurred.”⁴⁹

This requirement was in response to the 1982 case of tampering with and adulteration of Extra Strength Tylenol capsules, resulting in several deaths in Chicago. A tamper-resistant warning statement must be placed on the package and be clearly visible to alert consumers. The statement also must advise consumers not to purchase the product if the tamper-evident features are breached or missing.

Nonprescription products must bear an expiration date, which is determined by appropriate stability testing. However, a nonprescription product is exempt from this requirement if its label does not specify any dosage limitations and if the medicine is stable for at least 3 years.

Under the Poison Prevention Packaging Act (PPPA),⁵¹ child-resistant packaging is required for some nonprescription products commonly available in the home, such as aspirin, acetaminophen, ibuprofen, and methyl salicylates, and for any product switched from prescription to nonprescription status.⁵² The complete list of products that require child-resistant packaging may be found at 16 CFR §1700.14. The Consumer Product Safety Commission (CPSC) has authority for enforcement of the PPPA. Manufacturers have the option of offering one size of a product with a non-child-resistant closure. The

label for this product must specify “this package for households without young children.” However, if that size happens to be the most popular size (e.g., bottles of 100 tablets), the manufacturer also must market that size in child-resistant packaging.

For nonprescription drugs approved via an application (e.g. NDA, ANDA), FDA reviews data related to container closure systems. However, FDA does not approve or review individual products under the monograph system and therefore does not review data related to container closure systems. Even though no process has been defined for ensuring that such nonprescription products meet CPSC standards for child-resistant packaging, manufacturers that have data to demonstrate this safety feature may include a child-resistant packaging statement (e.g. “child-resistant package” or “this package is child-resistant”) on the labeling.

Advertising

FTC regulates advertising of nonprescription drugs, devices, and dietary supplements and prohibits false advertisements, which are defined as those that are misleading in a material respect.⁵³ There is no “fair balance” requirement for benefits versus warnings or contraindications. Advertisements must be supported by the level of data in the manufacturer’s files that the ad wording communicates. For example, if the advertisement states that “pharmacists and doctors recommend” the product, then tests, recommendations, and/or studies must substantiate this statement. A “reasonable basis” standard is applied, meaning that a manufacturer must have objective evidence to support a claim before running an advertisement.^{54,55} In *Warner Lambert Co v. FTC*, the claims for Listerine in the prevention, cure, and symptomatic alleviation of the common cold were found not to be substantiated, and the company was required not only to stop the advertisement but to run corrective advertisements.⁵⁶ In addition to corrective advertising, in other cases FTC has required a manufacturer to conduct at least two clinical trials to substantiate advertising claims.⁵⁵

The National Advertising Division of the Council of the Better Business Bureaus investigates complaints from consumers, competitors, or other parties regarding the truth and accuracy of nonprescription drug advertisements and may escalate the matter to the attention of FTC. Additionally, a manufacturer may file private lawsuits against competitors for false claims in advertising,

packaging, and labeling through Section 43(a) of the Lanham Act.⁵⁷

FDA has indirect authority over advertising of nonprescription drugs. Advertising claims not included in OTC Review monographs may be subject to agency regulatory action under the misbranding provisions of the FDCA.⁵⁸ Additionally, FTC is empowered to issue cease-and-desist orders against false, deceptive, or misleading advertisements of nonprescription drugs. FDA and FTC often act in tandem in reviewing nonprescription drug promotion and have issued joint warning letters to companies that their advertising violates both the FDCA and the FTC Act.

Third Class of Drugs

A little over a decade after passage of the Durham-Humphrey Amendment, various organizations began to advocate for an additional or third class of medications. This intermediate class of drugs would be available without a prescription, but a pharmacist would be required to be involved with the sale. **Table 4–5** shows drug classification in 10 countries. As can be seen, the two-tier system of prescription and nonprescription status in the United States is unique. In fact, the United States and South Africa are the only two countries without such a third class of drugs.

Table 4–5 Drug Classification in 10 Countries			
Country	Prescription	Pharmacist/Pharmacy Class	Nonprescription
United States	x		x
Australia	x	x	x
Canada	x	x	x
Denmark	x	x	x
France	x	x	
Italy	x	x	
Germany	x	x	x
United Kingdom	x	x	x

Country	Prescription	Pharmacist/Pharmacy Class	Nonprescription
Sweden	x	x	x
Switzerland	x	x	x
Netherlands	x	x	

The availability of an intermediate or third class of drugs in the United States, as elsewhere, could be expected to be of considerable benefit in terms of both quality and costs of health care. As a relatively recent example, after the introduction of statins, an important drug class in combating modern diseases, a switch from prescription to nonprescription status would have been not only appropriate but also highly effective in optimizing health care outcomes. With pharmacists involved in the monitoring and education of patients, it is probable that costs, whether economic or health-related (e.g., associated with ADRs), would have been curtailed if these agents had been more readily available as an option for early intervention. An intermediate class of drugs also could be used for those nonprescription products with a potential for abuse or those requiring closer monitoring by a pharmacist.

What is the expected role of pharmacists in this scenario? A major consideration is that a tracking system to capture ADRs would be required. Previous concerns have been the time burden such tracking would place on pharmacists and the likelihood of increased costs. The benefits would be obvious, however, when the medication has a potential for abuse or requires closer monitoring or is a first-in-class agent for a new indication.

Pharmacy associations, the National Consumer League, and other consumer groups favor a third or transition class of drugs. By contrast, CHPA, retail industries, senior citizen groups (for whom former prescription drugs typically would no longer be covered by insurance), and medical groups oppose a third class of drugs. FDA has traditionally opposed a third class of drugs, but in 2012 the agency declared an intent and held a public meeting to clarify parameters for novel switches to nonprescription status. This initiative was termed *Nonprescription Drug Safe Use Regulatory Expansion* (NSURE). Under NSURE, FDA would, for certain common diseases, allow prescription drug products to be available on a nonprescription basis through the use of newer technologies

(e.g., smartphone applications, point-of-care kiosks) or other conditions for safe use (such as pharmacist interventions).⁵⁹ Under NSURE, certain monitoring mechanisms for prescription-to-nonprescription-switch drugs would be allowed, with the proviso of “conditions of safe use.” To date, the criteria have not been established, and the conceptional framework is still in development. However, NSURE has the future potential to increase filings for switches of prescription products that traditionally have been outside the realm of traditional switch candidates, such as first-in-class agents for new indications. Of importance, as a “condition for use,” pharmacist interventions under NSURE would undergo definitive expansion with respect to consultation in recommending nonprescription medications.⁶⁰

FDA has emphasized that NSURE was not intended to create a so-called third class of drugs but rather would operate within the existing two classes. Thus, in accordance with the two-tier system in the United States, medications can either be prescription-only or sold in the local convenience store, with no middle ground.⁵⁹ Aside from the economic interests of the opposers, FDA has been reluctant to establish a third drug class, citing reasons that the current two-class system works and that evidence that a third class would improve public health is insufficient for action.⁶¹ These arguments fall short, however, because as discussed further on, strong evidence indicates that a de facto third class of drugs has a tremendous impact on improving public health.

Since 2006, emergency contraception products for women have been nonprescription. Additionally, several attempts have been made to allow nonprescription sales of oral contraceptives. Studies have shown that women in the United States are very interested in access to oral contraceptives without a prescription, that women can accurately identify contraindications to use of oral contraceptives with simple checklists, and that nonprescription contraception would increase use, with consequent reductions in unintended pregnancy rates.⁶² Thus far, however, every attempt to change the status of oral contraceptives to nonprescription has been met with strong opposition from “pro-life” groups.⁶³ Because an OTC Review monograph for oral contraceptives is lacking, a manufacturer would have to demonstrate product safety and consumers’ understanding of the labeling. Health insurers are required under the Affordable Care Act⁶⁴ to cover the costs of prescriptions for contraceptives. If contraceptives are moved to nonprescription status, insurers would be less likely to pay for them. Removal of this coverage is a disincentive for a change to nonprescription status. Currently, oral contraceptives are

available from pharmacists in several states (e.g., Tennessee, Washington) and Washington, DC, under collaborative practice agreements with licensed prescribers and in other states (e.g., Oregon, California) through direct pharmacist prescribing.^{65,66} However, oral contraceptives remain as prescription products in these scenarios, with pharmacists given additional authority to initiate access to these products via protocol or to prescribe them directly. Although California has no age restrictions, in Oregon female patients younger than 18 years of age must have a previous prescription from a physician or pharmacist. Several states are considering similar legislation. Alternatively, oral contraceptives could be a candidate for an intermediate or third class of drugs.

In 2007, FDA signaled a possible change in its opposition in calling a meeting to obtain comments about creation of a “behind-the-counter” class of drugs.⁶⁷ Unfortunately, the Government Accountability Office (GAO) report issued from that meeting concluded that the experiences in other countries provided little insight into the likely effect of a behind-the-counter class in the United States.⁶⁸ As recently as 2012, FDA announced it was considering creation of a class of nonprescription drugs that could be made available to patients “under conditions for safe use,” which may potentially include pharmacist intervention.⁶⁹ Hearings were held, with the same groups in opposition to the concept. However, no progress has been made moving forward on the concept since then.

De Facto Third Class of Drugs

Certain prescription-status products are already supplied to patients without a prescription, but consumer access to them is restricted: They are available only “behind the counter”—that is, only by expressly asking a pharmacist for them, thereby creating a de facto third class of drugs. This group includes a small number of exempt narcotic combination products placed in Schedule V (e.g., codeine, available without a prescription in several states such as Oklahoma and Washington),⁷⁰ pseudoephedrine (see [Chapter 11](#)), NPH and recombinant (R) U-100 insulin, syringes and needles, and naloxone. Federal requirements for Schedule V medications sold without a prescription are found in [Table 4–6](#).

Another example of voluntary restricted access is that for dextromethorphan, a cough suppressant. Although dextromethorphan is not a Schedule V medication, it is an opioid derivative with psychoactive properties, with the

potential for abuse. Accordingly, drug manufacturers and retailers have imposed state-specific voluntary age restrictions on its purchase, making the drug far less available to teens looking for a hallucinogenic “high.”⁷¹

Table 4–6 Federal Requirements for Schedule V Medications

Feature	Specific Requirement(s)
Schedule V definition	• Codeine preparations: limited to 200 mg/100 mL or 100 g • Dihydrocodeine, ethylmorphine, opium preparations: limited to 100 mg/100 mL or 100 g • Diphenoxylate: limited to 25 mg/25 mcg atropine sulfate • Diphenoxin: limited to 0.5 mg/25 mcg atropine sulfate
Age and personal identification requirement	• Purchaser must be 18 years of age. • Identification is required when pharmacist does not know purchaser.
Seller requirement	• Dispensed only by pharmacist or intern
Medication limitations	• Not more than 240 mL (8 ounces) of any such controlled substance containing opium • Not more than 120 mL (4 ounces) of any other such controlled substance • Not more than 48 dosage units of any such controlled substance containing opium • Not more than 24 dosage units of any other such controlled substance may be dispensed at retail to the same purchaser in any 48-hour period.
Documentation requirement	• Bound record book containing: ◦ Purchaser’s name and address ◦ Name and quantity of medication ◦ Date ◦ Name or initials of dispensing pharmacist
Stricter law prevails	• No state or local law requires a prescription to dispense.

Additionally, in an increasing number of states, pharmacists have been given prescriptive authority to dispense a limited number of prescription-only products without a medical prescription. The first state to allow this provider role was Florida, where pharmacists can prescribe medications listed on a formulary that consists of fluoride- or lindane-containing products, some topical anti-infectives, antihistamines and decongestants, and products recommended by an FDA advisory panel for transfer to nonprescription status but pending FDA action.^{72,73} Currently, six states—Montana, New Mexico, North Carolina, North Dakota, Oregon, and California—give pharmacists midlevel practitioner status, allowing them to initiate and modify drug therapy pursuant to a collaborative practice agreement with a physician.⁷⁴ In 2013 and 2016, laws in California and Oregon, respectively, took effect that allow pharmacists to prescribe oral contraceptives to women 18 years and older.⁷⁵ In California, the professional scope of practice for pharmacists was expanded to include the following⁷⁶:

- Prescribing nicotine replacement therapy, which normally requires a prescription
- Prescribing medications for travel health purposes (e.g., scopolamine patches)
- Mandating tests to monitor and maintain drug therapy for patients with comorbid conditions such as diabetes, hypertension, and hyperlipidemia

Other states are considering similar legislation.

Pharmacists, who constitute the most accessible health professional interface between the community and the health care system,⁷⁷ are ideally positioned to provide overdose education and to expand access to naloxone. Most states have laws that permit, under certain circumstances, any ordinary person to obtain naloxone without a prescription at a pharmacy.^{78,79} However, not all pharmacies carry it. Limited availability of this lifesaving drug, coupled with increased demand, drug shortages, and limited competition among naloxone manufacturers and resultant price increases, has resulted in direct action by FDA to make naloxone available over the counter. In January 2019, FDA took the unprecedented step of proactively creating model labeling via Drug Facts label templates and conducted patient comprehension studies to support OTC naloxone nasal spray and injectable products.⁸⁰

Abuse of Nonprescription Medications

A list of nonprescription medications that have been abused, along with legislative and regulatory initiatives to curb such abuse, is presented in [Table 4–7](#). In protecting the public from abuse of nonprescription medications, pharmacists have a key role to play.

Table 4–7 Anti-Abuse Measures for Various Nonprescription Medications^a

Medication	Effect(s)/Use	Legislative/Regulatory Action
Dextromethorphan	Dissociative effects; altered mental status; intoxication	Many products reformulated to omit ingredient; in some states, behind-the-counter sale only (e.g., New York, Utah)
Pseudoephedrine (also applied to ephedrine, but sale limits differ)	Precursor used in manufacture of methamphetamine	Combat Methamphetamine Epidemic Act of 2005 (logbook of sales; limits daily purchase amounts to 3.5 g, with 30-day limit of 9 g and mail order 30-day limit 7.5 g) Schedule V in some states (Illinois, Iowa, Kansas), Schedule III in others (Oregon, Mississippi) ^b
Class V Controlled Substances (e.g., cough syrups)	Opioid abuse	See Table 4–5
Laxatives	Anorexia; electrolyte imbalances; gastrointestinal complications	
Loperamide ^c	Cardiotoxicity; ventricular arrhythmias; QT and QRS prolongation	None
Nonprescription antihistamines; dimenhydrinate	Intoxication; stimulant effects including euphoria and hallucinations	None

Key: DEA = Drug Enforcement Agency.

From Cosmetic to Drug: Crossing the Line

FDA's authority over cosmetics is less comprehensive than its authority over other FDA-regulated products. Laws that pertain to cosmetics are the FDCA, specifically, the adulteration and misbranding provisions⁸¹; the Poison Prevention Packaging Act; and the Fair Packaging and Labeling Act.⁸² There are no requirements for manufacturer registration, premarket notification, ingredient safety testing, product listing, monographs, GMPs, or ADR reporting.⁸³ Cosmetic manufacturers may voluntarily decide to register with FDA and report ingredients in their products. FDA does not have authority to require a manufacturer to recall a cosmetic product from the marketplace.⁸⁴ Regulation is under the FDA Center for Food Safety & Applied Nutrition, specifically, the Division of Colors and Cosmetics.

In an early opinion, FDA stated that some cosmetics are also nonprescription drugs. Such products must meet the regulatory requirements (including labeling and packaging) for both cosmetics and drugs. Additionally, many legal precedents are in place for products that have crossed the line from cosmetic to drug—so-called cosmeceuticals.⁸⁵ Early cases involved wrinkle removal products for which the product claims included strong therapeutic implications.^{86,87} Other cases involve cosmetic product claims that establish the product as intended to treat or prevent disease or otherwise affect the

structure or functions of the human body. Often it is not the ingredient used in the product but rather the labeling claims content that determines whether the product is considered a cosmetic or a drug. Examples are claims that products will restore hair growth, reduce cellulite, treat varicose veins, or regenerate cells. The mere presence of ingredients in low or inactive levels, that is, below those specified in an OTC Review monograph, also does not make a cosmetic a drug. Examples of cosmetic products that also may be drugs are listed in [Table 4–8](#).

Table 4–8 Cosmetics That Also May Be Drugs

- Topical antimicrobial products (e.g., soaps containing antimicrobials)
- Skin protectants
- Sunscreen products
- Antiperspirant products
- Skin-bleaching products
- Nail hardeners
- Teeth whiteners with bleach
- Indoor and oral tanning preparations
- Hormone creams
- Eye wrinkle creams
- Wrinkle eradicators or antiaging creams

If a cosmetic is also a drug, the active ingredients must be listed first, followed by other ingredients, except flavors and fragrances, in descending order of predominance, on the product package. The “principal display panel” on the label must include the net quantity, name and place of the manufacturer, the declaration of ingredients, and any warning statements. Specific content that determines when a cosmetic should be classified as a drug includes (1) claims to cure, mitigate, treat, or prevent a disease; (2) claims to effect major changes in the structure of the body, or in a major bodily function; and (3) presence of a compendium-listed ingredient intended to serve medicinal purposes.⁸⁸

Compounding Nonprescription Drugs

At one time, nonprescription products were routinely compounded as needed. Although explicit guidelines on compounding nonprescription medications

are lacking, and the pharmacy compounding provisions of the Food and Drug Modernization Act of 1997 do not directly address nonprescription drugs, pharmacists should rely on guidance established for compounding prescription medications. Pharmacists should not compound any medication for nonprescription use that is intended to be used pursuant to a prescription or one that has not been approved for nonprescription use. Additionally, as with prescription medications, pharmacists should not compound large quantities of nonprescription medications that are essentially copies of commercially available nonprescription drugs.⁸⁹ A summary of regulatory requirements for nonprescription drugs is presented in [Table 4–9](#).

Table 4–9 Summary of Nonprescription Drug Regulations	
Feature	Component(s)
Labeling	• Drug Facts format • Regulated by FDA • Inactive ingredients in alphabetical order
ADR reporting	• Required for both OTC Review monograph- and NDA-approved nonprescription drugs
Manufacturing	• GMPs
Advertising	• Regulated by FTC
Packaging	• Tamper-resistant • Child-resistant
Marketing	• By NDA • By monograph route

Key: ADR = Adverse drug reaction; FDA = U.S. Food and Drug Administration; FTC = Federal Trade Commission; GMPs = good manufacturing practices; NDA = New Drug

Application.

Nonprescription Homeopathic Drugs

Homeopathy is a system of alternative medicine based on the practice of treating symptoms of a disease with substances that produce symptoms of the disease in healthy subjects (i.e., on the basis of the principle “like cures like”). Nonprescription homeopathic preparations are regulated by FDA as drugs⁹⁰ and must have a therapeutic indication for a self-limiting, self-diagnosable condition. FDA has not reviewed any products labeled as homeopathic under the OTC Review process for drugs, because these agents are categorized as a separate entity and FDA has deferred consideration of them.⁹¹ Homeopathic products and ingredients do not go through any FDA approval process, nor are they subject to any nonprescription monograph approval. They are governed by the Homeopathic Pharmacopoeia of the United States (HPUS) and its supplements, which are produced by the Homeopathic Pharmacopoeia Convention of the United States.⁹² The same criteria under the FDCA for a determination of nonprescription or prescription status apply to homeopathic products. The regulatory framework for marketing is found in FDA’s Compliance Policy Guide (CPG), specifically, CPG 7132.15.

Labeling of homeopathic products includes the word “homeopathic” but also includes a “Drug Facts” box, which could result in confusion that the products are FDA approved. However, the ingredients are listed in terms of dilution (e.g., 1X, 6X, 2C)—a clear difference from conventional product labeling. The dosing is covered in [Chapter 52](#), along with efficacy concerns. These products must comply with display panel requirements but are exempt from expiration dating. Advertising of these products is regulated by FTC. Homeopathic drugs were not included in either the DESI or the Nonprescription Drug Review and have never been required to show safety or efficacy before marketing. However, nonprescription homeopathic drugs cannot be marketed for conditions that require a prescription. Manufacturers must register with FDA, list their products, and adhere to GMPs.⁹³

More recently, FDA is taking a closer look at homeopathic products. In 2015, a

public hearing was held evaluating FDA's regulatory framework, including labeling, safety and enforcement policies, and mechanisms and means of improving such policies going forward. The homeopathic industry has grown, safety issues have emerged, and many cases of poison exposure related to homeopathic products are reported annually by the American Association of Poison Control Centers.⁹⁴ In a 2017 draft guidance, FDA indicated an intent to reexamine its enforcement policies and apply a risk-based approach focusing on products with reported safety issues, products intended for prevention or treatment of life-threatening conditions, products for vulnerable populations, and products deemed adulterated under the FDCA.⁹⁵

Dietary Supplements

Although often offered alongside nonprescription drug products on pharmacy shelves, dietary supplements are regulated by FDA's Center for Food Safety and Applied Nutrition as foods, not drugs. Although dietary supplement claims and nonprescription drug claims have different evidence standards, they may be perceived by the consumer as indistinguishable. Dietary supplements belong to a separate category that is not tightly regulated.

More than 200 million Americans take dietary supplements, and botanical dietary supplements are used by 17.9% of U.S. adults.⁹⁶ Dietary supplements are regulated under the Dietary Supplement Health and Education Act (DSHEA) of 1994.⁹⁷ Under the DSHEA, dietary supplements are defined to include "vitamins, minerals, herb or other botanical, amino acid, a substance which increases the dietary intake of it, or a concentrate, metabolite, constituent, extract, or combination of any ingredient described above."⁹⁸

Dietary supplements are not approved by FDA but are subject to the adulteration and misbranding provisions of the FDCA and should be manufactured in accordance with GMPs. GMPs are nonbinding on manufacturers, however, and herbal product manufacturers in particular have largely ignored them because of considerable variation in the ingredients for herbal preparations.⁹⁹ A petition must be filed to market new dietary ingredients (i.e., those not already marketed before 1994), thus requiring premarket notification but not an evaluation for efficacy or safety. Enforcement of this provision has been problematic, however, with only approximately 170 notices from 1994 to 2012 despite the introduction of

thousands of new supplements to the marketplace.⁹³ FDA enforcement activities such as warning letters have recently increased against dietary supplement manufacturers making medical claims. In 2019, FDA took action against 17 companies selling supplement products claiming to treat Alzheimer disease.¹⁰⁰ Also in 2019, FDA issued 12 warning letters to companies marketing dietary supplements containing DMHA (also known as 1,5-dimethylhexylamine), used for sports performance and weight loss, and phenibut (also known as β -phenyl- γ -aminobutyric acid), used as a sleep aid.¹⁰¹

Recently, FDA has mounted new efforts to strengthen regulation of dietary supplements including new 75-day premarket notification requirements for new dietary ingredient (NDI) notification and implementation of a dietary supplement ingredient advisory list.¹⁰² The list is intended to quickly alert the public when FDA identifies ingredients that do not appear to be lawfully marketed in dietary supplements. Under the DSHEA, labels must bear the term “dietary supplement,” and each ingredient must have the quantity stated. For a proprietary blend, however, the quantities of each ingredient are not stated; only a net contents for the blend is included. Inactive ingredients must be listed in descending order of predominance. The labeling must contain a *Supplement Facts* panel identifying the dietary ingredient(s) contained in the product. When no daily recommended dose has been established, the dietary supplement may be marketed without this information. Such products also may be marketed in any combination of supplement ingredients (e.g., calcium plus magnesium).¹⁰³ Although FDA requires that manufacturers verify that every supplement they produce is safe and accurately labeled, the system essentially operates on the honor code. Under DSHEA, a dietary supplement deemed unsafe may continue to be marketed until the courts rule in FDA’s favor.¹⁰⁴

Advertising claims in all media are regulated by FTC. However, FDA is responsible for claims on product labeling. [Chapter 50](#) provides information about proper labeling of dietary supplement products.

Dietary supplement manufacturers are subject to GMPs and FDA inspection. Nevertheless, these products often have been found to be tainted with active pharmaceutical ingredients or adulterated with other ingredients, or fail to contain the purported active ingredient, or may be sold at toxic doses.¹⁰⁵ The DSHEA requires the government to bear the burden of proof to show that a dietary supplement is either adulterated or misbranded, and each case must

be tried de novo. Categories of dietary supplements that often have been found to be tainted include male enhancement supplements,¹⁰⁶ herbal products, and weight loss products. FDA's Medication Health Fraud website (<https://www.fda.gov/consumers/protecting-yourself/health-fraud-scams>) is a useful resource for information regarding tainted products sold as dietary supplements. Additionally, to improve regulation of dietary supplements, FDA has created an Office of Dietary Supplements Programs. One FDA initiative is unit-of-measure label changes from international units (IU) to metric units of measure (mcg or mg) for nonprescription vitamins A, D, and E. Also required is the listing of the absolute amounts of vitamins and minerals in metric units in addition to the percent daily value (%DV) on the label.¹⁰⁷ The Institute for Safe Medication Practices (ISMP), a nonprofit organization dedicated to development of such practices, notes that most health care practitioners remain unaware of the change, making safe transition to metric-only labeling difficult and confusing.¹⁰⁸ Chapter 50 provides a more in-depth look at dietary supplements.

Direct-to-Consumer Diagnostic Devices

Unlike nonprescription drugs, the in vitro direct-to-consumer tests marketed today are considered devices that may or may not be reviewed by FDA's Center for Devices and Radiological Health. For example, carrier screening tests, ancestry tests, and low-risk general wellness tests do not require FDA premarket review, whereas cancer predisposition tests, pharmacogenetics tests, and generic health risk tests generally require FDA clearance. Direct-to-consumer tests may be approved via a Premarket Approval (PMA) application or via the 510(k) route, or not at all, depending upon the risk classification.¹⁰⁹ A company with 510(k) clearance for a prescription device will need to submit a new 510(k) form to market the product for nonprescription use. Data will be required to show that consumers can use the device and interpret the results without the assistance of a health care professional.¹¹⁰ FDA has created a database of nonprescription in vitro device tests it regulates.¹¹¹ Point-of-care testing can be self-initiated, as when the patient is responding to symptoms, or prescriber-initiated, as when a sample is taken in the home environment or clinic and returned to be assayed in a laboratory.

A majority of direct-to-consumer tests sold today are genetic test kits (e.g., 23andMe). Others measure levels of drugs of abuse or toxins in urine, or levels

and types of bacteria. Considerable consumer interest in kits for human immunodeficiency virus (HIV) testing and for cholesterol screening and monitoring continues to grow. All point-of-care laboratory testing in pharmacies is subject to regulation by the Centers for Medicare & Medicaid Services as part of the Clinical Laboratory Improvement Amendments (CLIA) program. However, most point-of-care tests conducted in community pharmacies or at health screenings are considered CLIA waived. To obtain a CLIA waiver, the pharmacy must first obtain a CLIA certificate and then apply for laboratory status at the state level, usually through the state health department.¹⁰⁰ Each state has its own CLIA program and may impose additional requirements or restrictions. Pharmacies with CLIA waivers are still subject to inspection to ensure compliance and also must comply with standards set forth in Occupational Safety and Health Administration (OSHA) universal precautions to reduce risk of exposure to blood-borne pathogens.

Currently, approximately 18% of community pharmacies have a CLIA waiver and can perform CLIA-waived tests such as determination of the international normalized ratio (INR), blood glucose, glycosylated hemoglobin (HbA_{1c}), and lipid profile.¹¹² With the upsurge in pharmacy-based disease state management programs and health screening-related collaborative practice agreements, the number of pharmacies with CLIA waiver status is likely to increase in the future.

Nonprescription Product Liability

Most legal cases involving nonprescription drugs are product liability cases, brought against manufacturers, not pharmacies or pharmacists. Although not as common as claims against prescription drugs, incidents involving nonprescription drugs have been the subject of civil litigation. Claims are brought for breach of the Implied Warranty of Fitness¹¹³ and for breach of the Implied Warranty of Merchantability.¹¹⁴ Recovery under these legal theories is generally limited to issues related to sale of a product, rather than performance of a service in which a defective product may be involved only incidentally. When the service being performed is a professional service, such as with a pharmacist recommendation for a defective nonprescription product, the courts exhibit a reluctance to impose strict liability without fault. However, the pharmacist may still be liable for negligence and/or intentional misconduct as appropriate to the facts of the case.¹¹⁵ In litigation in which a

pharmacist sold the patient camphorated oil instead of castor oil, with subsequent harm to the patient, the court held the pharmacist negligent.¹¹⁶

For the nonprescription drug plaintiff, the first evidentiary hurdle is proof of purchase, which can result in a summary judgment on this threshold issue. The injured party will need to furnish a receipt or other evidence of proof of purchase. Causation is another issue, in that a purchased nonprescription product may sit in the medicine cabinet for months before actual use. It is difficult to prove, with mere plaintiff testimony, proximity in time between use of the product and injury. However, unlike the case with prescription drugs, in which the learned intermediary (the prescriber) is a defense for manufacturers, for nonprescription drug products, manufacturer warnings must go directly to the consumer. In *Yugler v. Pharmacia & Upjohn Co.*, the court denied application of the learned intermediary doctrine, even when the provider had initially prescribed prescription Motrin and the patient obtained refills over the counter.¹¹⁷

Liability for Advice on Nonprescription Drugs

Pharmacists can be sued for malpractice and negligence for inaccurate advice (with liability requiring affirmative misrepresentations) regarding nonprescription drugs that harm the patient. A recommendation for use of a nonprescription product not in accordance with the labeling may increase the risk for liability if the patient is harmed. Additionally, in a case in which a pharmacist recommended a nonprescription product in place of the prescribed one, and the patient was harmed, the court denied the pharmacy's motion for summary judgment that the patient was "contributory negligent" in ignoring the label directions.¹¹⁸

A recent high-profile case centering on pharmacists' advice for nonprescription products is *Whiting v. Rite Aid Pharmacy*,¹¹⁹ wherein the patient's estate sued the pharmacist for a recommendation that the patient could safely take phenylpropanolamine and Sudafed. The plaintiff contended that she informed the pharmacist of the patient's prostate problems. The pharmacist denied that the conversation ever occurred. The plaintiff asserted that the use of the drug exacerbated the patient's prostate condition, resulting in the need for several surgeries and, ultimately, his death several years later from an unrelated illness. The pharmacy contended that learned intermediary doctrine protects the pharmacist from such liability and that the pharmacist's

duty of care does not require giving adequate advice about nonprescription drugs. Falling under the learned intermediary doctrine is a defense of tort lawsuits stating that the duty to warn of the dangers of a nonprescription product is that of the manufacturer. The court ruled that the learned intermediary doctrine applies only to prescription drugs. Additionally, however, the court was clear with respect to the duty of care for pharmacists¹¹⁹:

Pharmacists in Utah clearly have duties regarding nonprescription drugs. If a pharmacist answers a customer's question and offers advice about nonprescription drugs, the pharmacist must advise and act in a non-negligent manner consistent with a reasonably prudent pharmacist's response to a customer's question about the safety of a nonprescription drug.

Ingredients in nonprescription drug products change often, and pharmacists should be certain of a product's ingredients and contraindications before recommending it. The Drug Facts labeling of the product should form a basis for any patient consultation and advice on nonprescription drug products. Counseling for patient education should be routinely and briefly documented.¹²⁰ As nonprescription marketing of medications becomes more prevalent in the United States, litigation against manufacturers of nonprescription drug products will similarly increase.

Liability Associated With Nonprescription Drugs

Strict liability could apply to pharmacists for failure to effect timely removal of a recalled or expired product from the shelves when a patient is harmed. The courts have generally ruled that no liability accrues to the pharmacist for defective medications sold in prepackaged containers. However, if a pharmacy repackages the drug with its own label, it may be held liable.¹²¹ The label of the repackaged drug should contain the same amount of information as on the original label.¹⁰ In *Patrick v. Carrier Stevens Co.*,¹²² the plaintiff prevailed when he purchased a flea repellant warranted by the pharmacist as safe for his pet even if ingested, but which then subsequently harmed his other animals.

Manufacturers are subject to strict liability for harm caused by a "product in a defective condition unreasonably dangerous to the user or consumer."¹²³ Class action lawsuits for defective nonprescription products continue to be initiated, especially when the company delayed in warning consumers of ADRs. Notable

examples of adverse events involving nonprescription drugs leading to class action lawsuits are severe, potentially fatal hypersensitivity allergic reactions from nonprescription acne products; bone fractures and hypomagnesemia from proton pump inhibitors; and Stevens-Johnson syndrome and toxic epidermal necrolysis from ibuprofen.¹²⁴⁻¹²⁶

The Future: Innovative Approaches for Nonprescription Drug Products

Innovation under the OTC Monograph system is slow, cumbersome, and difficult, in that changing a monograph requires utilization of the rule-making process (Advance Notice of Proposed Rulemaking, Tentative Final Monograph or Final Monograph). FDA recognizes that at times both the OTC Monograph and the NDA processes are cumbersome, and in an effort to reduce health care costs, the agency has taken several steps toward making more medications available without a prescription, including those for some chronic conditions. In 2018, FDA issued a guidance document that detailed two innovative approaches to demonstrate safety and efficacy for products when the Drug Facts labeling (DFL) alone is not sufficient to ensure that the product can be used in a nonprescription setting.¹²⁷ The innovative approaches involve (1) the development of labeling in addition to the DFL and (2) the implementation of additional requirements so that consumers appropriately self-select and use the product.

On March 27, 2020, the U.S. Congress passed the Coronavirus Aid, Relief and Economic Security Act (CARES Act).¹²⁸ This statute includes landmark legislation to reform the nonprescription drug review monograph system by granting FDA transformative new authorities to modernize the nonprescription drug development and review process. Under this act, new processes to update existing monographs replace the multilayered rule-making process that posed inherent difficulties in updating product labels with new safety information and had caused a backlog of nonprescription drug monographs.

In addition to an increase in FDA staff and funding, the statute includes the following provisions:

- Establishment of a centralized database of information and labeling requirements
- Establishment of timelines for FDA reviews together with user fees for nonprescription drug manufacturers and those utilizing the administrative review process
- Creation of an administrative review process (via administrative orders) that replaces the monograph system
- Categorization of currently marketed nonprescription drugs that are GRASE (previously referred to as *Category I*) as either those that can be marketed over the counter or as new drugs that require submission of an NDA
- Creation of an 18-month exclusivity period for new nonprescription drugs
- Authorization for FDA to issue administrative orders on its own initiative when a nonprescription product poses an imminent hazard to public health
- Sunsetting of the Sunscreen Innovation Act¹²⁹ and its alternative processes for review of this class of products
- Exclusion of homeopathic drugs from the nonprescription drug review process

The new process was intended to facilitate the review of new ingredients and to clarify the legal and regulatory status of tentative final monograph products. Drugs that were classified as Category III or Category I in an Advance Notice of Proposed Rulemaking will be permitted to remain on the market without approved NDAs until and unless FDA issues a final order that they are not GRASE. Category II drugs must be removed from the market within 180 days of passage of the act. New drugs (those not considered GRASE) and nonprescription drugs that are not in the other mentioned categories are subject to the NDA requirement. Administrative orders have replaced the notice-and-comment rulemaking process and can be of three types: (1) FDA-initiated, (2) expedited (e.g., imminent hazard), and (3) industry-initiated (i.e., based on submissions by sponsors seeking approval of new active ingredients or other changes such as new dosage forms). Minor changes for drugs can be implemented without Administrative Orders and in some cases by conducting studies and submitting data.¹³⁰

These changes reflect many years of work aimed at nonprescription drug reform. On the negative side, some products will be removed from the market

or will be subject to enforcement action. On the positive side, the new regulatory framework is easier and faster to use, and it is expected to result in the marketing of innovative nonprescription products with new ingredients, dosage forms (e.g., dissolvable films), and combination drugs.

Key Points

- Over the past 100-plus years, regulatory transition of nonprescription medications from patent medicines to scientifically based therapies have occurred.
- Nonprescription medications are vital to appropriate selfcare and one of the least costly components of the U.S. health care system.
- Regulation of nonprescription medications is important to protect the public but should not place limits on achieving an optimal level of personal health.
- Existing overregulation of nonprescription medications prevents patients from gaining control over their health care, increases patient costs, and requires unnecessary use of health care resources to obtain some prescriptions.
- The past few decades have seen a large number of prescription-to-nonprescription switches, and today's consumers are taking greater responsibility for their own health care.
- An essential element of collaborative clinical practice for health care professionals is a full understanding of the regulatory and legal aspects of how nonprescription products are manufactured, labeled, and marketed.

Chapter 5: Headache

Authors: Julie J. Wilkinson, Katherine Tromp

Headache is an important cause of pain and disability worldwide. The prevalence of migraine headache is 1.04 billion; for tension-type headache, the rate is 1.89 billion.¹ Tension headache is much more common, but migraine is more severe. Migraine is the second leading cause of disability globally.¹ Worldwide, 50% of the population has suffered from headache within the previous year, and among persons afflicted with headache, 30% had migraine.² Headaches caused by sinus congestion and those resulting from the overuse of analgesics also are common.

Headaches generally are classified as primary or secondary. *Primary* headaches (approximately 90% of headaches) are not associated with an underlying illness. Examples are episodic and chronic tension-type headaches, migraine headache with and without aura (sensory disturbances), and cluster headaches. *Secondary* headaches are symptomatic of an underlying condition, such as head trauma, stroke, substance abuse or withdrawal, bacterial and viral diseases, and disorders of craniofacial structures. Medication overuse headaches are considered a complication of the underlying headache disorder and are related to a withdrawal effect of medications.³ Cluster headaches and secondary headaches are not discussed in this chapter because they are not amenable to self-care management.

Tension-type headaches, also called stress headaches, can be episodic or chronic. *Chronic* headaches occur 15 or more days per month for at least 3 months, whereas episodic tension-type headaches occur less than 15 days per month.³ *Episodic* tension-type headaches are further classified as frequent episodic if at least 10 episodes of headache occur on 1–14 days per month.³ The usual onset of tension-type headache is during the teenage years; women are affected more commonly than men, in a ratio of 3:2.² Tension-type headache is generally less severe than migraine, but it may occur more frequently, leading to substantial disability.⁴

Two primary types of migraine headache are recognized: with and without aura. Migraine of either type is characterized by the presence of at least two of the following criteria: moderate to severe head pain, unilateral pain, pulsating quality of pain, and aggravation of pain by routine physical activity. In addition,

the episode must be accompanied by either nausea/vomiting or photophobia/phonophobia.⁵ Migraine with aura further includes neurologic signs and symptoms that precede or coincide with onset of the head pain and subsequently resolve fully. The neurologic manifestations may be visual, sensory, speech, language, or motor. Aura should be considered in patients with or without a headache if they have at least one neurologic sign or symptom that develops slowly during a period of at least 5 minutes, lasts for 5–60 minutes, and resolves fully. Both types of migraine may also include a prodrome or postdrome of symptoms and signs such as hyperactivity, hypoactivity, depression, food cravings, yawning, fatigue, and neck pain or stiffness. A *prodrome* refers to one or more such signs and symptoms occurring before clinical onset of the migraine; a *postdrome* is one or more manifestations emerging after the migraine episode.³

The prevalence and impact of migraine and severe headache of other etiology in the United States have been evaluated in several national surveys.⁶ Researchers found that nearly 1 of every 6 Americans reported suffering from severe headache within a 3-month period (15.3% overall [95% CI 14.75–15.85]). The prevalence was twice as high in females as in males (20.7% versus 9.7%). Among ethnic groups, the rate was highest in American Indian or Alaska Natives at 18.4% and lowest in Asians at 11.3%. The estimated rates for whites, blacks, and Hispanics were 16.6%, 15.4%, and 14.5%, respectively. This condition is more common in younger adults without other health conditions. Headache is the fifth most common reason for emergency department visits, accounting for 3% of all such visits.⁶

Patients with a preexisting headache disorder who experience headache on 15 or more days per month and who regularly use headache medications for longer than 3 months may be suffering from medication overuse headaches. This problem is clinically important: Estimated frequency of medication overuse ranges from 11% to 63%.⁷ The available research methods are limited in their ability to clarify the effect of the medication overuse as a factor distinct from underlying headache severity.⁷

Sinus headache is frequently reported in patients with acute sinusitis. These patients also experience other sinus symptoms such as facial tenderness and pain, nasal congestion, and nasal discharge. Although rhinosinusitis leads to pain, it does not usually manifest as frontal head pain. If the patient is experiencing head pain while congested, it also may be caused by migraine or

tension-type headache.⁸

The economic impact of headache is substantial. Researchers have estimated the burden of the disease using the measure of years of life lived with disability (YLDs). Migraine was found to have caused 45 million YLDs and tension-type caused 7 million YLDs worldwide in 2016.¹ Most studies looking at the economic burden of headache have focused on migraine headache. Annual direct medical costs of migraine average \$13,045 per patient.⁹ The combination of direct costs for medical services and indirect costs from lost productivity and wages adds up to more than \$14 billion annually for U.S. employers.⁹

This chapter focuses on the most common types of headaches that are amenable to self-treatment: tension-type, diagnosed migraine, and sinus headaches. Medication overuse headache also is discussed, in keeping with the pharmacist's role in preventing this type of headache through counseling; however, this type of headache requires a medical referral if it occurs. Nonprescription analgesics are useful for treating headache, either in monotherapy regimens or as adjuncts to nonpharmacologic or prescription therapy. An important category of these medications is the class of nonsteroidal anti-inflammatory drugs (NSAIDs), which include aspirin and other salicylates as well as ibuprofen and naproxen. Many headache sufferers self-treat with nonprescription remedies, rather than seeking medical attention. As much as two thirds of nonprescription analgesic use may be for headache.¹⁰ Researchers found that 24% of patients chronically overused medication and that only 14.5% had ever been advised by a health care provider to limit their intake of acute headache remedies.¹⁰ Careful evaluation, counseling, and referral for prescription-only treatments have great potential to improve quality of life for many affected persons.

Pathophysiology of Headache

Tension-type headaches often arise in response to stress, anxiety, depression, emotional conflicts, or other stimuli. Myofascial tissues in the pericranial area contain nociceptors that play a role in the pathophysiology of tension-type headaches.¹¹ The episodic tension-type headache subtype is thought to result in pain sensed by the peripheral nervous system, whereas the chronic subtype is thought to result from stimuli to the central nervous system.³ A genetic component is likely in predisposition (or resistance) to development of tension-

type headaches. Furthermore, tension-type and migraine headaches appear to share pathophysiologic features, making them more similar than distinct.¹²

Migraine headache is a neurobiologic disorder. According to current evidence-based theory, migraine-associated pathophysiologic changes originate in the central nervous system, rather than primarily in the vascular system. Pain pathways are stimulated and messenger molecules are involved, including nitric oxide, serotonin, and calcitonin gene-related peptide. The trigeminovascular system also plays a role.³ Stress, fatigue, irregular sleep patterns, fasting or missing a meal, vasoactive substances in food, caffeine, alcohol, changes in female hormones, changes in barometric pressure and altitude, bright lights, odor, neck pain, exercise, and smoking all may trigger migraine.⁵ Medications (e.g., reserpine, nitrates, oral contraceptives, postmenopausal hormones) also have been identified as triggers. The pathophysiology of migraine with aura involves neuronal depolarization that spreads slowly across the cerebral cortex during the aura phase.¹³ Magnesium deficiency may contribute to this state.¹⁴ During the headache phase, stimulation (by an axon reflex) of trigeminal sensory fibers in the large cerebral and dural vessels causes neuropeptide release with concomitant neurogenic inflammation, vasodilation, and activation of platelets and mast cells.¹³

As mentioned previously, changes in female hormone levels may cause migraines. Migraines related to the menstrual cycle occur in less than 10% of women and generally are not associated with aura.³ Attacks during menstruation may have a longer duration and feature more severe nausea. With menstrual migraine, pathophysiologic changes are mediated by estrogen withdrawal.¹⁵ *Medication overuse headache* results from excessive use of analgesics, which may cause a change from episodic headaches to chronic headaches. This type of headache is distinct from that occurring as an adverse effect of certain medications such as nitrates and phosphodiesterase type-5 inhibitors. Some patients who suffer from migraine or tension-type headaches receive limited relief from analgesics and over time may increase their use of one or more such drugs, which can lead to development of medication overuse headaches. These headaches usually are associated with frequent medication use (more than twice weekly) for 3 months or longer. Onset of the headache occurs within hours of stopping the agent, and readministration of the agent provides relief. Medication overuse headache should be suspected if the frequency of headaches is 15 days per month or greater in patients taking analgesics including acetaminophen, aspirin, ibuprofen, naproxen, or

prescription NSAIDs for a duration of 3 months. Headache frequency of 10 days per month after taking triptans, opioids, ergots, or combination analgesics for 3 months should be evaluated.¹⁶ Caffeine, butalbital, and ergotamine also may cause medication overuse headache. *Sinus headache* occurs when infection or blockage of the paranasal sinuses causes inflammation or distention of the sensitive sinus walls (see [Chapter 11](#)). Sinus congestion may be caused by viral or bacterial infection, or by allergic rhinitis. Pathophysiologic mechanisms at work during migraine headache can result in prominent sinus congestion, leading to confusion about which problem is the cause and which is the effect.

Clinical Presentation of Headache

Headaches can be differentiated by their signs and symptoms; the major defining characteristics are listed in [Table 5–1](#). It is important to distinguish primary from secondary headaches because a headache can indicate a life-threatening condition. Exclusions to self-care, shown in [Figure 5–1](#), are important because of the seriousness of certain disorders that manifest with headache. The severity of pain associated with tension-type headaches is highly variable. Some headaches are so mild they do not require treatment, whereas others are sufficiently severe to be disabling. Episodic tension-type headaches may last a few hours, but duration up to several days has been described. Chronic tension-type headaches often are more severe and frequently last for several days. The pain initially feels like pressure or tightening on both sides of the head and subsequently may spread to feel like a band around the head.^{2,3}

Table 5–1 Characteristics of Tension-Type, Migraine, and Sinus Headaches			
Feature	Tension-Type Headache	Migraine Headache	Sinus Headache
Location	Bilateral	Usually unilateral	Face, forehead, or periorbital area
Nature	Diffuse ache, tightening, pressing, constricting	Throbbing, pulsating	Pressure behind eyes or face, dull and bilateral pain
Intensity	Mild–moderate	Moderate–severe	Mild–severe

Feature	Tension-Type Headache	Migraine Headache	Sinus Headache
Onset	Gradual	Sudden	Simultaneous with sinus symptoms
Duration	30 minutes to 7 days	4–72 hours	Days (resolves with sinus symptoms)
Aggravating factors	Stress, anxiety	Physical activity, light, sound	Nasal congestion
Non-headache symptoms	Scalp tenderness, neck pain and muscle tension	Nausea, vomiting, aura	Nasal congestion nasal discharge

Source: References 3 and 16.

Migraine headaches are classified as migraine with or without aura. *Aura* manifests as a series of neurologic signs and symptoms: ocular perceptions of shimmering or flashing areas or blind spots, visual and auditory hallucinations, muscle weakness that usually is one-sided, and difficulty speaking (occurring rarely). These symptoms may last up to 30 minutes, and the throbbing headache pain that follows may last from several hours to 3 days. Of note, however, aura is not always followed by a migraine headache. Migraines without aura begin immediately with throbbing headache pain. Both forms of migraine often are associated with nausea, vomiting, photophobia, phonophobia, sinus symptoms, tinnitus, light-headedness, vertigo, and irritability and are aggravated by routine physical activity.⁵ Premonitory (prodrome) signs and symptoms in migraine can be neuropsychiatric (e.g., anxiety, irritability, yawning, emotional distress, insomnia), sensory (e.g., phonophobia, photophobia, focusing difficulties, speech difficulties), digestive (e.g., food craving, nausea, vomiting, diarrhea, constipation), or general (e.g., asthenia, fatigue, fluid retention, urinary frequency). Premonitory signs and symptoms can be a feature of migraine headaches with and those without aura.

Medication overuse headache occurs as a rebound phenomenon after repeated and excessive use of the implicated drug in a patient with an

episodic headache disorder. Continued overuse causes headache symptomatology to shift from the baseline headache type to a nearly continuous headache, particularly noticeable on awakening. Additional symptoms may include difficulty concentrating, lethargy, irritability, and nausea.

Sinus headache usually is localized to facial areas over the sinuses and is difficult to differentiate from migraine without aura. The pain of a sinus headache typically is described as dull and pressure-like. Stooping or blowing the nose often intensifies the pain, but the headache is not accompanied by nausea, vomiting, or visual disturbances. Persistent sinus pain and/or discharge suggests possible infection and warrants referral for medical evaluation.

Figure 5–1 Self-care for headache. Key: CABG = Coronary artery bypass graft; CHF = congestive heart failure; GI = gastrointestinal; HBP = high blood pressure; HIV = human immunodeficiency virus; NSAID = nonsteroidal anti-inflammatory drug.

Treatment of Headache

Treatment Goals

The goals of treating headache are (1) to reduce the severity and alleviate acute pain, (2) to restore normal functioning, (3) to prevent relapse, and (4) to minimize adverse effects. For chronic headache, an additional goal is to reduce the frequency of headaches.

General Treatment Approach

Most patients with episodic headaches obtain an adequate response to self-treatment with nonpharmacologic interventions, nonprescription medications, or both. However, some patients with episodic headaches and most with chronic headaches are candidates for prescription treatments.

Episodic tension-type headaches often respond well to nonprescription analgesics, including acetaminophen and NSAIDs such as salicylates, especially when taken at the onset of the headache.¹⁶ If nonprescription analgesics are used to treat chronic headache, frequency of use should be limited to less than 3 days per week or 14 days per month, to prevent medication overuse headache.¹⁷ Patients with chronic tension-type headaches may benefit from physical therapy and relaxation exercises in addition to nonprescription or prescription medications. [Figure 5–1](#) outlines selfcare for headaches and lists exclusions for self-treatment.^{5,11,17–19}

A medical diagnosis of migraine is required before self-treatment can be recommended. First-line pharmaceutical agents for relief of migraine headache include triptans, NSAIDs, and combinations of a triptan with acetaminophen or an NSAID.¹⁶ Taking an NSAID, such as a salicylate, at the onset of symptoms can abort mild or moderate migraine headache. Analgesics work best in the early stages of a migraine. Patients with migraine who can predict the occurrence of the headache (e.g., during menstruation) should take an analgesic before occurrence of the event known to trigger the headache, as well as throughout the duration of the event. For patients with coexisting tension and migraine headaches, treatment of the initiating headache type can abort the mixed headache. Antiemetic treatment also is indicated.¹⁶ Prophylactic therapy for migraine includes various regimens of beta blockers, tricyclic antidepressants, calcium channel blockers, divalproex, topiramate, or gabapentin.⁵

When medication overuse headache is suspected, use of the offending agent(s) should be stopped immediately for a period of at least 1 month. Discontinuation of the medication should be done with medical supervision because prescription therapies may be needed to combat the increased headaches that temporarily ensue during the days to weeks of the withdrawal period. Additionally, medication may be needed to treat the baseline headache disorder that caused the initial overuse of the headache medications.¹⁶

Sinus headaches respond well to oral and nasal decongestants (e.g., pseudoephedrine, oxymetazoline), which reduce congestion by causing vasoconstriction in the nasal passages (see [Chapter 11](#)). Concomitant use of decongestants and nonprescription analgesics can relieve sinus headache pain. Chronic congestion and sinus infections may be a sign of structural abnormalities and indicate the need for an appropriate medical referral.

Nonpharmacologic Therapy

Patient education is an important component of self-care management of headache. Information about the underlying diagnosis, safe medication use, and lifestyle modification should be included to optimize the self-treatment regimen. Keeping a headache diary for a minimum of 8 weeks to record frequency, duration, related symptoms, precipitating factors, medications used for relief, and menstruation schedule may improve diagnostic accuracy and medication management.¹⁶ Acupuncture studies have yielded some evidence supporting a role for this modality in reducing the frequency and intensity of headache. Manual therapy offered by osteopathic physicians, chiropractors, and massage therapists has been shown to result in short-term improvement in persons with headache.²⁰ Adjunctive therapy for tension-type headache includes stress management and physical therapy.⁵

General treatment measures for migraine include maintaining a regular schedule for sleeping, eating, and exercise; stress management; biofeedback; and cognitive therapy. Some patients obtain relief from the pain of acute migraine attacks by resting in a quiet dark room and applying ice or cold packs combined with pressure to the forehead or temple areas. Nutritional strategies are intended to prevent migraine and are based on (1) dietary restriction of foods that contain trigger substances, (2) avoidance of hunger and low blood glucose (a trigger of migraine), and (3) magnesium supplementation.^{14,21} Advocates of nutritional therapy recommend avoiding known food allergens and foods with vasoactive substances, such as nitrites (found in cured meats), tyramine (found in red wine and aged cheese), phenylalanine (found in the artificial sweetener aspartame), monosodium glutamate (often found in Asian food), caffeine, and theobromines (found in chocolate).²¹

Pharmacologic Therapy

Available nonprescription analgesics for the management of headache include

acetaminophen and NSAIDs such as ibuprofen and naproxen and especially salicylates (aspirin and magnesium salicylate). Selection of an analgesic should be based on a careful review of the patient's medical and medication histories. Medical management of nausea accompanying migraine headache also may be indicated to improve symptomatic relief and to facilitate medication delivery by the oral route.

Acetaminophen

Acetaminophen is an effective analgesic and antipyretic. According to long-standing hypothesis, acetaminophen produces analgesia through central inhibition of prostaglandin synthesis. A broader view, however, is that its mechanism of action may be more complex, involving aspects that are not yet fully understood. Other suggested mechanisms, for example, include descending serotonergic pathway activation and endocannabinoid reuptake inhibition.²²

Acetaminophen is absorbed rapidly from the gastrointestinal (GI) tract and extensively metabolized in the liver to inactive glucuronic and sulfuric acid conjugates. Acetaminophen also is metabolized by the cytochrome P450 enzyme system to a hepatotoxic intermediate metabolite that is detoxified by glutathione. When given by suppository, acetaminophen has a rectal bioavailability of approximately 50%–60% of that achieved with oral administration. Onset of analgesic activity of acetaminophen occurs approximately 30 minutes after oral administration. Duration of activity is approximately 4 hours and is increased to 6–8 hours with an extended-release formulation.

U.S. Food and Drug Administration (FDA)-approved uses for nonprescription acetaminophen include reducing fever and relieving mild to moderate pain. It is effective in relieving mild to moderate pain of nonvisceral origin (i.e., pain that is not organ-related). Randomized, double-blind studies have documented the effectiveness of acetaminophen 1000 mg over placebo in patients with migraine and tension-type headache.²³

Recommended child and adult dosages of acetaminophen are provided in [Tables 5–2](#) and [5–3](#).²⁴ [Table 5–4](#) lists selected trade-name products.

Acetaminophen is available for administration in various oral and rectal dosage forms.

Table 5–2 FDA-Approved Dosages for Nonprescription Analgesics in Children Younger Than 12 Years

Dosage Basics	Ibuprofen (mg)	Acetaminophen (mg)	
Weight-based dosing	5–10 mg/kg	10–15 mg/kg	
Dosing schedule	Every 6–8 hours as needed	Every 4–6 hours as needed	
Maximum daily dose	300 mg per dose up to 4 doses, or 40 mg/kg/day; not to exceed 1200 mg total daily dose	480 mg per dose up to 5 doses, or 75 mg/kg/day; not to exceed 2400 mg total daily dose	
Age Group	Weight (lb)		
6–11 months	12–17	50	80 mg ^a
12–23 months	18–23	75	120 mg ^a
2–3 years	24–35	100	160
4–5 years	36–47	150	240
6–8 years	48–59	200	320
9–10 years	60–71	250	400
11 years	72–95	300	480

^a Labeling recommends referral to primary care provider before use.

Key: FDA = U.S. Food and Drug Administration.

Table 5–3 Recommended Dosages of Nonprescription Analgesics for Adults and Children 12 Years and Older

Agent	Dosage Forms	Usual Adult Dosage (maximum daily dosage)
Acetaminophen	Immediate-release, extended-release, effervescent, dispersible, and chewable tablets; capsules; liquid; suppositories; powder packet	325–1000 mg every 4–6 hours as needed for immediate-release products (3000 mg, <i>or</i> 4000 mg ^a) 650–1300 mg every 8 hours as needed for extended-release products (3000 mg, <i>or</i> 4000 mg ^a)
Ibuprofen	Immediate-release and chewable tablets; capsules; suspension	200–400 mg every 4–6 hours as needed (1200 mg)
Naproxen sodium	Immediate-release and delayed-release tablets, capsules	220 mg every 8–12 hours as needed (660 mg) <i>For initial dose: 2 tablets within the first hour</i>
Aspirin	Immediate-release, buffered, enteric-coated, film-coated, effervescent, and chewable tablets; suppositories	325–1000 mg every 4–6 hours as needed (4000 mg)
Magnesium salicylate	Tablets	1160 mg every 6 hours as needed (4640 mg)

^a Maximum daily dose of regular-strength (325 mg) products: 3250 mg, *or* 4000 mg with supervision of HCP; extra-strength (500 mg) products: 3000 mg, *or* 4000 mg with supervision of HCP; extended-release (650 mg) products: 3900 mg.

Key: FDA = U.S. Food and Drug Administration; HCP = health care provider.

Acetaminophen oral capsules contain tasteless granules that can be added to a spoon containing a small amount of cold beverage (hot beverages result in a bitter taste) or soft food. Capsule contents should not be combined with larger quantities of liquid because a significant proportion of the granules may adhere to the container surface.

Acetaminophen is potentially hepatotoxic in doses exceeding 4 g daily, especially with chronic use. Patients should be cautioned against exceeding the dose limit. More conservative dosing (i.e., ≤ 2 g daily) or complete avoidance may be warranted in patients at increased risk for acetaminophen-induced hepatotoxicity, specifically those with diagnosed liver disease, concurrent use of other potentially hepatotoxic drugs, poor nutritional intake, or consumption of three or more alcoholic drinks per day.²⁵ One alcoholic drink is defined as 12 ounces of beer, 5 ounces of wine, or 1.5 ounces of 80 proof liquor.

FDA requires manufacturers to include a boxed warning on acetaminophen

products that addresses its potential to cause hepatotoxicity. The basic language of the warning is as follows:

Liver warning: This product contains acetaminophen. Severe liver damage may occur if

- an adult takes more than 4000 mg of acetaminophen in 24 hours
- a child takes more than 5 doses in 24 hours, which is the maximum daily amount
- the product is taken with other drugs containing acetaminophen
- an adult has three or more alcoholic drinks every day while using this product

The warning varies depending on whether the product is labeled for use in children and/or adults. In order to decrease acetaminophen-induced hepatic injury, FDA limited the acetaminophen content of prescription-only combination opioid analgesics to 325 mg per dosage unit.^{26,27} FDA also has recommended that manufacturers of nonprescription products lower the maximum daily dose from 4000 mg to 3250 mg per day and to limit pediatric oral dosage forms to a single strength of 160 mg.^{28,29} McNeil followed this recommendation by listing a maximum daily dose of 3250 mg for regular-release products and 3000 mg for extra-strength products (dosing interval of every 6 hours as opposed to every 4–6 hours). However, 650-mg extended-release products have a maximum daily dose listed as 3900 mg. Errors in dosing occur with the 650-mg extended-release formulation because patients do not understand that they need to wait 8 hours between doses.²⁶

Acetaminophen poisoning is a major reason for contacting poison control centers and constitutes the leading cause of acute liver failure in the United States.³⁰ Unintended chronic overdose accounts for approximately one half of the cases of acetaminophen-induced acute liver failure. Researchers have documented that significant knowledge gaps lead to incorrect dosing.³¹ Contributing factors include repeated dosing in excess of package labeling, use of more than one product containing acetaminophen, and concurrent alcohol ingestion. It is estimated that in 30% of emergency department visits for acetaminophen poisoning, the overdose was unintentional.³¹

Acetaminophen toxicity evolves in four stages. Stage I includes signs and symptoms of nausea, vomiting, drowsiness, confusion, and abdominal pain, but such early manifestations may be absent or delayed, belying the potential

severity of the exposure. Stage II is characterized by emergence of the first symptoms of hepatotoxicity and begins 24–48 hours after acute ingestion of acetaminophen. Stage II signs and symptoms include increased aspartate aminotransferase (AST) and alanine aminotransferase (ALT), increased bilirubin with jaundice, prolonged prothrombin time, and obtundation. Stage III develops after 3 or 4 days and progresses to liver failure in the absence of treatment. Signs and symptoms at this stage may include metabolic acidosis, encephalopathy, cerebral edema, and renal failure. GI symptoms may also be present during this stage. Stage IV begins 4 days after ingestion and can last for several weeks. During this stage, in a majority of cases, hepatic damage is reversible over a period of weeks or months, but more severe cases may require liver transplantation or result in fatal hepatic necrosis.³²

Because of the potential seriousness of acetaminophen overdose, all cases should be referred to a poison control center or hospital emergency department. Supportive care is provided, along with activated charcoal to reduce acetaminophen absorption in patients who present for treatment within 1 hour after ingestion. When acetaminophen serum levels, with consideration of time since ingestion, exceed those known to cause hepatic injury, prompt administration of acetylcysteine is warranted to supplement glutathione, which is essential for deactivation of a toxic intermediate metabolite of acetaminophen. Acetylcysteine's effectiveness decreases if it is administered more than 8 hours after acute ingestion. Asymptomatic elevations in ALT have been reported in otherwise healthy persons taking acetaminophen 4 g daily. In a prospective study, 39% of patients experienced ALT elevations to greater than three times the upper limit of normal. These elevations generally appeared in the first week of use, with some resolution occurring despite continued dosing. The clinical significance of this observation is uncertain.³³

Patients with glucose-6-phosphate dehydrogenase deficiency, a hereditary disease that causes premature breakdown of red blood cells, are at increased risk for adverse reactions to acetaminophen. It is unclear whether regular doses of acetaminophen will cause toxicity in patients with such deficiency; however, case reports of hemolysis in patients with glucose-6-phosphate dehydrogenase deficiency who took an excessive amount of acetaminophen have been recorded.³⁴ In patients with hypersensitivity to acetaminophen, the drug is contraindicated for future use.

Rare but serious cutaneous adverse reactions (SCARs) have been found to be associated with use of acetaminophen as well as other analgesics including NSAIDs. Skin reactions may occur in either new or current users of the drug and have the potential to progress to a life-threatening rash, as in Stevens-Johnson syndrome and toxic epidermal necrolysis. Although these events are very rare, it is important to be aware of the possibility and to refer patients as appropriate for further evaluation.³⁵ FDA recommends that the following language appear in the Warnings section of the Drug Facts Label for all single-ingredient and combination-ingredient acetaminophen products:

Allergy alert: Acetaminophen may cause severe skin reactions. Symptoms may include

- skin reddening
- blisters
- rash

If a skin rash occurs, stop use and seek medical help right away.³⁵

Clinically important drug interactions for acetaminophen are listed in [Table 5–5](#). In patients taking warfarin, acetaminophen is considered the analgesic of choice; however, it has been associated with increases in the international normalized ratio (INR). Regular acetaminophen use should be discouraged in patients on warfarin. Patients who require higher scheduled doses (e.g., those with osteoarthritis) should have their INR monitored and warfarin dose adjusted as acetaminophen doses are titrated.

Table 5–5 Clinically Important Drug-Drug Interactions With Nonprescription Analgesic Agents

Analgesic/ Antipyretic	Interactive Drug	Potential Interaction	Management/Preventive Measure(s)
Acetaminophen	Alcohol	Increased risk of hepatotoxicity	Avoid concurrent use if possible; minimize alcohol intake when using acetaminophen.
Acetaminophen	Warfarin	Increased risk of bleeding (elevations in INR)	Limit acetaminophen to occasional use; monitor INR for several weeks when acetaminophen 2–4 g daily is added or discontinued in patients on warfarin.

Analgesic/ Antipyretic	Interactive Drug	Potential Interaction	Management/Preventive Measure(s)
Aspirin	Valproic acid	Displacement from protein-binding sites and inhibition of valproic acid metabolism	Avoid concurrent use; use naproxen instead of aspirin (no interaction).
Aspirin	NSAIDs, including COX-2 inhibitors	Increased risk of gastroduodenal ulcers and bleeding	Avoid concurrent use if possible.
Salicylates	Live influenza virus vaccine	Risk of Reye syndrome in children and adolescents	Avoid concurrent administration in children younger than 18 years.
Ibuprofen	Aspirin	Decreased antiplatelet effect of aspirin	Aspirin should be taken at least 60 minutes before or 8 hours after ibuprofen. Use acetaminophen (or other analgesic) instead of ibuprofen.
Ibuprofen	Phenytoin	Displacement from protein-binding sites	Monitor free phenytoin levels; adjust dose as indicated.
Salicylates and other NSAIDs	Bisphosphonates	Increased risk of GI or esophageal ulceration	Use caution with concomitant use.
NSAIDs	Digoxin	Renal clearance of digoxin inhibited	Monitor digoxin levels; adjust dose as indicated.
Salicylates and other NSAIDs	Agents with antiplatelet properties (SSRIs, NSAIDs, P2Y12 inhibitors)	Increased risk of bleeding	Monitor therapy
Salicylates and other NSAIDs	Antihypertensive agents, beta blockers, ACE inhibitors, vasodilators, diuretics	Antihypertensive effect inhibited; possible hyperkalemia with potassium-sparing diuretics and ACE inhibitors	Monitor blood pressure, cardiac function, and potassium levels.
Salicylates and other NSAIDs	Anticoagulants	Increased risk of bleeding, especially GI	Avoid concurrent use, if possible.

Analgesic/ Antipyretic	Interactive Drug	Potential Interaction	Management/Preventive Measure(s)
Salicylates and other NSAIDs	Alcohol	Increased risk of GI bleeding	Avoid concurrent use, if possible; minimize alcohol intake when using salicylates and NSAIDs.
Salicylates and other NSAIDs	Methotrexate	Decreased methotrexate clearance	Avoid salicylates and NSAIDs with high-dose methotrexate therapy; monitor levels with concurrent treatment.
Salicylates (moderate-high doses)	Sulfonylureas	Increased risk of hypoglycemia	Avoid concurrent use, if possible; monitor blood glucose levels when changing salicylate dose.

Key: ACE = Angiotensin-converting enzyme; COX = cyclooxygenase; GI = gastrointestinal; INR = international normalized ratio;

NSAIDs = nonsteroidal anti-inflammatory drugs; SSRIs = selective serotonin reuptake inhibitors.

Source: [Reference 24](#).

Nonsalicylate Nonsteroidal Anti-inflammatory Drugs

NSAIDs relieve pain through central and peripheral inhibition of cyclooxygenase (COX) with consequent inhibition of prostaglandin synthesis.

All nonprescription NSAIDs are rapidly absorbed from the GI tract, with consistently high degree of bioavailability. They are extensively metabolized, mainly by glucuronidation, to inactive compounds in the liver. Elimination occurs primarily through the kidneys. Time to onset of activity for naproxen sodium and ibuprofen is approximately 30 minutes. Duration of activity is up to 12 hours for naproxen sodium and 6–8 hours for ibuprofen. FDA-approved uses for nonprescription NSAIDs include reducing fever and relieving minor pain associated with headache, the common cold, toothache, muscle ache, backache, arthritis, and menstrual cramps. NSAIDs have analgesic, antipyretic, and anti-inflammatory activity, and they are useful in managing mild to moderate pain of nonvisceral origin. Ibuprofen and naproxen sodium and became available for nonprescription use in 1984 and 1994, respectively, and

both are propionic acid derivatives. Although FDA has approved ketoprofen for nonprescription use, no commercially available nonprescription analgesics currently contain this agent.

Recommended child and adult dosages of nonprescription NSAIDs are provided in [Tables 5–2](#) and [5–3](#). [Table 5–6](#) lists selected trade-name products. Ibuprofen is available as a liquid for pediatric use and comes in two different strengths (50 mg/1.25 mL and 100 mg/5 mL). This dual option may contribute to the potential for dosing errors. A dose–effect relationship has been demonstrated for ibuprofen analgesia in the range of 100–400 mg.

Table 5–6 Selected Single-Entity Nonprescription Nonsalicylate Nonsteroidal Anti-inflammatory Drugs	
Trade Name	Primary Ingredient
Ibuprofen Products: Pediatric Formulations	
Children’s Advil Suspension	Ibuprofen 100 mg/5 mL
Children’s Motrin Suspension	Ibuprofen 100 mg/5 mL
Motrin Infants’ Drops Suspension	Ibuprofen 50 mg/1.25 mL
Junior Strength Advil Chewable Tablet	Ibuprofen 100 mg
Ibuprofen Products: Adult Formulations	
Advil tablet/capsule	Ibuprofen 200 mg
Motrin IB Ibuprofen tablet	Ibuprofen 200 mg
Advil Migraine capsule	Ibuprofen 200 mg
Naproxen Products	
Aleve tablet/capsule	Naproxen sodium 220 mg
Mediproxen tablet	Naproxen sodium 220 mg
All Day Relief tablet	Naproxen sodium 220 mg

The most frequent adverse effects of NSAIDs involve the GI tract and include

dyspepsia, heartburn, nausea, anorexia, and epigastric pain. NSAIDs may be taken with food, milk, or antacids if upset stomach occurs. Tablets should be taken with a full glass of water, suspensions should be shaken thoroughly, and enteric-coated or sustained-release preparations should never be crushed or chewed. Other adverse effects include dizziness, fatigue, headache, and nervousness. Rashes or pruritus (itching), photosensitivity, and fluid retention or edema may occur in some patients; at normal doses, however, these effects usually are rare.

GI ulceration, perforation, and bleeding are serious potential complications of NSAID use. Risk factors include age older than 60 years, previous ulcer disease, concurrent use of anticoagulants (including aspirin), higher dose or longer duration of treatment, and consumption of three or more alcoholic drinks per day. Product labeling for NSAIDs includes warnings about stomach bleeding with adult doses (see the box “A Word About NSAIDs and Stomach Bleeding”).³⁶ Labeling for prescription products that contain ibuprofen and naproxen includes the following warning:

NSAIDs cause an increased risk of serious gastrointestinal adverse events including bleeding, ulceration, and perforation of the stomach or intestines, which can be fatal. These events can occur at any time during use and without warning symptoms. Elderly patients are at greater risk for serious gastrointestinal events.

NSAID use is associated with increased risk for myocardial infarction (MI), heart failure, hypertension, and stroke. While not completely understood, the pathophysiologic mechanism for increased cardiovascular risk includes increased thromboxane A₂ activity and suppressed vascular prostacyclin synthesis, resulting in vasoconstriction and platelet aggregation. The cardiovascular risk associated with nonselective NSAIDs appears to depend on dose and duration; people with underlying risk factors such as hypertension, heart failure, and diabetes are at greater risk. Limited data suggest that the risk may not be the same for all nonselective NSAIDs.³⁷

The American Heart Association recommends that patients with cardiovascular disease or those at high risk for cardiac events (e.g., hyperlipidemia, hypertension, diabetes, other macrovascular disease) avoid NSAIDs. Patients at low cardiac risk should nevertheless exercise caution with use of NSAIDs by taking the minimum dose for the shortest duration needed to control symptoms. Clinical evidence has shown that the use of NSAIDs in

patients with a history of MI is associated with an increased risk of future cardiovascular events, extending indefinitely.³⁸ Labeling for prescription products that contain ibuprofen and naproxen includes the following warning²⁴:

NSAIDs may cause an increased risk of serious cardiovascular thrombotic events, myocardial infarction, and stroke, which can be fatal. This risk may increase with duration of use. Patients with cardiovascular disease or risk factors for cardiovascular disease may be at greater risk.

Ibuprofen and naproxen tablets are contraindicated for treatment of perioperative pain in the setting of coronary artery bypass graft (CABG) surgery. NSAIDs may decrease renal blood flow and glomerular filtration rate through inhibition of renal prostaglandin synthesis. Consequently, blood urea nitrogen and serum creatinine levels can increase, often with concomitant sodium and water retention. Advanced age, hypertension, diabetes, atherosclerotic cardiovascular disease, and use of diuretics appear to increase the risk of renal toxicity with ibuprofen use. Congestive heart failure may be exacerbated by the use of NSAIDs because of sodium and water retention, increased systemic vascular resistance, and impaired response to diuretics.³⁹ Therefore, patients with a history of impaired renal function, congestive heart failure, or diseases that compromise renal hemodynamics should not self-treat with NSAIDs.

Clinically important drug–drug interactions of NSAIDs are listed in [Table 5–5](#). Ibuprofen increases bleeding time by reversibly inhibiting platelet aggregation. Patients on aspirin for cardiovascular prophylaxis should take it at least 1 hour before or 8 hours after ibuprofen to avoid a pharmacodynamic interaction that inhibits the antiplatelet effect of aspirin. Ibuprofen should not be recommended for self-treatment in patients who concurrently are taking anticoagulants, because its antiplatelet activity could increase GI bleeding. Owing to concerns regarding decreased cardiovascular protection and increased bleeding risk, great caution is warranted in combining aspirin and ibuprofen.

Patients who ingest three or more alcoholic drinks per day should be cautioned about the increased risk of adverse GI events, including stomach bleeding. They also should be referred to a primary care provider for monitoring of their NSAID use.

NSAID overdoses usually are associated with minimal signs and symptoms of toxicity and are rarely fatal. GI manifestations are common and include nausea, vomiting, abdominal pain, and diarrhea. The most serious effects of large NSAID overdoses include renal failure, neurologic toxicity, and acid–base changes. Examples of specific neurologic symptoms are drowsiness, changes in vision, headache, and confusion. Convulsions have been reported in children who have taken an overdose of ibuprofen. Case reports of GI bleeding also exist.⁴⁰

A Word About NSAIDs and Stomach Bleeding

The following label wording is required for the FDA warning concerning stomach bleeding for nonprescription products that contain NSAIDs in adult doses:

Stomach bleeding warning: This product contains an NSAID, which may cause severe stomach bleeding. The chance is higher if you

- have had stomach ulcers or bleeding problems
- take a blood-thinning (anticoagulant) or steroid drug
- take other drugs containing prescription or nonprescription NSAIDs (aspirin, ibuprofen, naproxen, or others)
- take more or for a longer time than directed
- are age 60 or older
- have three or more alcoholic drinks every day while using this product

Ask a doctor before use if the stomach bleeding warning applies to you:

- You have a history of stomach problems, such as heartburn.
- You have high blood pressure, heart disease, liver cirrhosis, or kidney disease.
- You are taking a diuretic.

Stop use and ask a doctor if

- You experience any of the following signs of stomach bleeding:
 - feel faint

- vomit blood
- have bloody or black stools
- have stomach pain that does not get better

Key: FDA = U.S. Food and Drug Administration; NSAID = nonsteroidal anti-inflammatory drug.

Source: [Reference 36](#).

Salicylates

Salicylates inhibit prostaglandin synthesis from arachidonic acid by inhibiting both isoforms of the COX enzyme (COX-1 and COX-2). The resulting decrease in prostaglandins reduces the sensitivity of pain receptors to the initiation of pain impulses at sites of inflammation and trauma. Although some evidence suggests that aspirin also produces analgesia through a central mechanism, its site of action is primarily peripheral.

Salicylates are absorbed by means of passive diffusion of the nonionized drug in the stomach and small intestine. Factors affecting absorption include dosage form, gastric pH, gastric emptying time, dissolution rate, and the presence of antacids or food. Absorption from immediate-release aspirin products is complete. Rectal absorption of a salicylate suppository is slow and unreliable, as well as proportional to rectal retention time.

Once absorbed, aspirin is hydrolyzed in the plasma to salicylic acid in 1–2 hours. Salicylic acid is widely distributed to all tissues and fluids in the body, including central nervous system tissue, breast milk, and fetal tissue. Protein binding is concentration-dependent. At concentrations lower than 100 mg/mL, approximately 90% of salicylic acid is bound to albumin, whereas at concentrations greater than 400 mg/mL, approximately 75% is bound. Salicylic acid is largely eliminated through the kidney. Urine pH determines the amount of unchanged drug that is eliminated, with urinary concentrations increasing substantially in more alkaline urine (pH ~8).

Dosage form alterations include enteric coating, buffering, and sustained release. These formulations were developed to change the rate of absorption

and/or to reduce the potential for GI toxicity. Enteric-coated aspirin is absorbed only from the small intestine; its absorption is markedly slowed by food, which is attributed to prolonged gastric emptying time. Hypochlorhydria from acid-suppressing agents (especially proton pump inhibitors) may result in dissolution of enteric-coated products in the stomach, negating any potential benefit in preventing local gastric irritation. For patients requiring rapid pain relief, enteric-coated aspirin is inappropriate because of the delay in absorption and time to onset of analgesic effect.

Buffered aspirin products are available in both tablet and effervescent forms. Although buffered products are absorbed more rapidly than nonbuffered products, time to onset of effect is not improved appreciably. Common buffers include aluminum hydroxide; magnesium carbonate, hydroxide, or oxide; calcium carbonate; and sodium bicarbonate (in effervescent formulations). Some effervescent aspirin solutions contain large amounts of sodium and must be avoided by patients who require restricted sodium intake (such as those with hypertension, heart failure, or renal failure). Sustained-release aspirin is formulated to prolong duration of action by slowing dissolution and absorption. Other salicylates approved for nonprescription use are magnesium salicylate and sodium salicylate. Currently, sodium salicylate is not available in a commercial product; however, magnesium salicylate is available as a tablet.

FDA-approved uses for salicylates include treatment of symptoms for osteoarthritis, rheumatoid arthritis, and other rheumatologic diseases, as well as temporary relief of minor aches and pains associated with backache or muscle aches. Salicylates also are effective in treating mild to moderate pain from musculoskeletal conditions and fever.

Because of its inhibitory effects on platelet function, aspirin is also used for prevention of thromboembolic events (e.g., MI, stroke) in high-risk patients. Unlike with the NSAIDs previously discussed, this inhibitory effect is irreversible for aspirin. Thus, the inhibition continues for the duration of the platelet's life. With NSAIDs, the duration of inhibition depends on factors such as dose, serum level, and half-life. Aspirin's use for prophylaxis against MI and other forms of ischemic cardiovascular disease must be guided by a primary care provider. In March 2019, the American College of Chest Physicians and the American Heart Association issued a Guideline on the Primary Prevention of Cardiovascular Disease.⁴¹ The guideline provides evidence-based recommendations for decreasing the risk of developing atherosclerotic

cardiovascular disease (ASCVD). Adults aged 40–75 years should be screened to determine their estimated 10-year risk of developing ASCVD. Online risk assessment tools are available to quantify this risk (http://tools.acc.org/ldl/ascvd_risk_estimator/index.html#!/calculate/estimator/).⁴²

The use of aspirin for ASCVD prevention is discussed in the guideline. On the basis of recent findings, the guidelines state that aspirin use for primary prevention is not recommended for most patients. For some patients at high risk for development of ASCVD coupled with a low risk for bleeding, the use of low-dose aspirin (75–100 mg orally daily) may be recommended. Patients older than age 70 are at increased risk for bleeding and should not routinely receive aspirin for primary prevention, nor should patients of any age identified as being at increased risk for bleeding.

The decision to use low-dose aspirin for primary prevention must consider risk factors for developing a cardiac event and risk factors for bleeding. The guideline includes a list of factors that may favor the use of aspirin including family history of early MI; inability to achieve goals for lipids, blood pressure, or glucose; or significant elevation of coronary artery calcium score. The guideline also includes a list of factors that may signify a greater risk of bleeding from aspirin, including a history of GI bleeding or peptic ulcer disease, bleeding at other sites, age older than 70 years, thrombocytopenia, coagulopathy, chronic kidney disease, use of medications that increase the risk of bleeding such as NSAIDs, steroids, direct oral anticoagulants, and warfarin. As noted by the guideline authors, these lists are not exhaustive, however, and a careful patient-specific analysis of the potential risks and benefits must include consideration of the patient’s understanding of the decision.⁴¹ Recommended child and adult dosages of nonprescription salicylates are provided in [Tables 5–2](#) and [5–3](#). [Table 5–7](#) provides selected salicylate products. Aspirin dosages of 4–6 g daily usually are needed to produce anti-inflammatory effects. The maximum analgesic dosage for self-medication with aspirin is 4 g daily; therefore, anti-inflammatory activity often will not occur unless the drug is used at the high end of the acceptable dosage range.

Table 5–7 Selected Adult Formulations of Nonprescription Single-Entity Salicylate Products

Trade Name	Primary Ingredient
Bayer Low-Dose Aspirin tablet	Aspirin 81 mg

Trade Name	Primary Ingredient
St. Joseph Chewable Aspirin 81 mg tablet	Aspirin 81 mg
Ecotrin Enteric-Coated tablet	Aspirin 325 mg
Bayer Aspirin Delayed Release tablet	Aspirin 325 mg
Bayer Plus Extra Strength tablet	Aspirin 500 mg
DeWitts Pain Reliever tablet	Magnesium salicylate 325 mg
Extra Strength Doan's tablet	Magnesium salicylate tetrahydrate 580 mg
Percogesic Maximum Strength Backache Relief Coated caplet/tablet	Magnesium salicylate tetrahydrate 580 mg

Aspirin is known to commonly cause dyspepsia, which may be minimized by taking it with food. In addition, aspirin is associated with development of gastritis and ulceration of the upper GI tract. It produces GI mucosal damage by compromising the protective mucous and bicarbonate layers of the gastric mucosa, thereby permitting back-diffusion of acid, with consequent cellular damage and vascular erosion. Two distinct mechanisms are involved: (1) a local irritant effect resulting from contact of the medication with the gastric mucosa and (2) a systemic effect from prostaglandin inhibition. Lack of upper abdominal pain or discomfort is not a reliable indicator for the absence of GI damage associated with use of NSAIDs.^{43,44}

The use of aspirin has been shown to increase the risk for serious upper GI events two- to fourfold.⁴³ Patients with risk factors for upper GI bleeding should avoid self-treatment with aspirin. Recognized risk factors are (1) history of stomach bleeding or ulcers; (2) age older than 60 years; (3) concomitant use of NSAIDs, anticoagulants, antiplatelet agents, or systemic corticosteroids; (4) infection with *Helicobacter pylori*; (5) consumption of three or more alcoholic drinks per day; and (6) use for longer than directed.^{36,45} Use of aspirin products with enteric coating may reduce the impact of local gastric irritation. However, presence of enteric coating or buffering does not decrease the risk of serious GI toxicity because it is caused by a systemic effect of reduced production of prostaglandins that are important in maintaining the protective lining of the

GI tract.

Serious aspirin intolerance is uncommon and consists of two types: *cutaneous* (manifesting as urticaria and angioedema) and *respiratory* (manifesting as bronchospasm, laryngospasm, and rhinorrhea). The mechanism is not immunologically mediated. Risk factors for serious aspirin intolerance include chronic urticaria for the cutaneous type and asthma with nasal polyps for the respiratory type. Ten percent of people diagnosed with asthma have aspirin sensitivity.⁴⁶ The degree of intolerance is variable, ranging from minor to severe. Patients with aspirin intolerance generally are advised to avoid NSAIDs. However, the nonacetylated salicylates (magnesium salicylate) and acetaminophen are considered safe.⁴⁶

Nonprescription salicylates interact with several other important drugs and drug classes. Clinically important drug interactions of salicylates are listed in [Table 5–5](#). When monitoring therapy in patients who are taking high-dose salicylates, health care providers should review current drug interaction references for newly identified interactions.

Aspirin ingestion may produce a positive result on fecal occult blood testing, so its use should be discontinued at least 3 days before testing. Similarly, aspirin should be discontinued 2–7 days before surgery and should not be used to relieve pain after tonsillectomy, dental extraction, or other surgical procedures, except under the close supervision of a primary care provider. Aspirin can potentiate bleeding from capillary-rich sites such as the GI tract, tonsillar beds, and tooth sockets.

Because of its effect on hemostasis, aspirin is contraindicated in patients with hypoprothrombinemia, vitamin K deficiency, hemophilia, history of any bleeding disorder, or history of peptic ulcer disease. In patients with compromised renal function, renal excretion of magnesium may be decreased, allowing accumulation of toxic levels with regimens including magnesium salicylate. The maximum 24-hour dose of magnesium salicylate delivers 400 mg of magnesium.

All salicylates should be avoided in patients with a history of gout or hyperuricemia because of dose-related effects on renal uric acid handling. In such patients, taking low-dose aspirin for 2 consecutive days is associated with increased risk for onset or reemergence of gout. Serum urate monitoring should be considered in patients with gout who are receiving aspirin

therapy.⁴⁷

Reye syndrome is an acute illness occurring almost exclusively in children and teenagers.⁴⁸ The cause is unknown, but the use of salicylates to treat viral illnesses has been associated with the syndrome. Onset usually follows a viral infection with influenza (type A or B) or varicella (chickenpox). *Reye syndrome* is characterized by progressive neurologic damage, fatty liver with encephalopathy, and hypoglycemia. Neurologic manifestations may start with lethargy and progress to delirium, confusion, and seizures. The mortality rate may be as high as 50%.

The American Academy of Pediatrics, FDA, the Centers for Disease Control and Prevention, and the Surgeon General have issued warnings that aspirin and other salicylates (including bismuth subsalicylate and nonaspirin salicylates) should be avoided in children and teenagers who have influenza or chickenpox. The following statement is included in the Electronic Code of Federal Regulations⁴⁸ and is required on labeling for nonprescription aspirin and aspirin-containing products:

Reye's syndrome: Children and teenagers who have or are recovering from chickenpox or flu-like symptoms should not use this product. When using this product, if changes in behavior with nausea and vomiting occur, consult a doctor because these symptoms could be an early sign of Reye's syndrome, a rare but serious illness.

Although a simple viral upper respiratory infection does not contraindicate aspirin use, differentiation of its symptoms from those of influenza and chickenpox can be difficult. Many health care providers recommend a conservative approach of avoiding aspirin whenever influenza-like symptoms are present. Use of aspirin as a pediatric antipyretic and reports of *Reye syndrome* have all but ceased in the United States.

All nonprescription analgesic and antipyretic products for adult use bear a warning regarding alcohol use. Use of aspirin with alcohol intake increases the risk of adverse GI events, including stomach bleeding. Patients who consume three or more alcoholic drinks daily should be counseled about the associated risks and referred to their primary care provider before they use aspirin.

Mild salicylate intoxication (*salicylism*) occurs with chronic toxic blood levels, generally achieved in adults who take 90–100 mg/kg per day of a salicylate for

at least 2 days. Symptoms and signs of salicylate toxicity include headache, dizziness, tinnitus, difficulty hearing, dimness of vision, mental confusion, lassitude, drowsiness, sweating, thirst, hyperventilation, nausea, vomiting, and occasional diarrhea. These clinical abnormalities all can be reversed by lowering the plasma concentration to a therapeutic range. Tinnitus, typically an early manifestation, should not be used as a sole indicator of salicylate toxicity.

Acute salicylate intoxication is categorized as mild (associated with ingestion of <150 mg/kg), moderate (with ingestion of $150\text{--}300$ mg/kg), or severe (with ingestion of >300 mg/kg). Clinical manifestations depend on the plasma drug concentration and may include lethargy, nausea, vomiting, dehydration, tinnitus, hemorrhage, tachypnea and pulmonary edema, convulsions, and coma. Acid-base disturbances are prominent and range from respiratory alkalosis to metabolic acidosis. Initially, salicylate affects the respiratory center in the medulla, producing hyperventilation and respiratory alkalosis. In severely intoxicated adults and in most salicylate-poisoned children younger than 5 years, respiratory alkalosis progresses rapidly to metabolic acidosis. Children are more likely than adults to exhibit high fever in salicylate poisoning. Hypoglycemia resulting from increased glucose utilization may be especially serious in children. Bleeding may occur from the GI tract or mucosal surfaces, and petechiae are a prominent feature at autopsy in fatal cases.

Emergency management of acute salicylate intoxication is directed at preventing absorption of salicylate from the GI tract and providing supportive care. Activated charcoal should be used at home only if recommended by poison control center or emergency medical services personnel. In a hospital emergency department setting, GI tract decontamination with gastric lavage or activated charcoal may be undertaken. Enhancing renal elimination can be accomplished through alkalinization of the urine. Dosing recommendations for the use of activated charcoal are included in [Chapter 21](#).

Combination Products

Many nonprescription analgesics are available in combination products ([Table 5–8](#)).

Table 5–8 Selected Nonprescription Combination Analgesic Products

Trade Name	Primary Ingredient(s)
Acetaminophen-Containing Products	
Excedrin Tension Headache caplet	Acetaminophen 500 mg; caffeine 65 mg
Excedrin PM Headache caplet	Acetaminophen 250 mg; aspirin 250 mg; diphenhydramine 38 mg
Goody's Headache Relief Shot Liquid	Acetaminophen 1000 mg; caffeine 65 mg
Percogesic Original Strength tablet	Acetaminophen 325 mg; diphenhydramine 12.5 mg
Percogesic Extra Strength tablet	Acetaminophen 500 mg; diphenhydramine 12.5 mg
Sudafed PE Pressure + Pain caplet	Acetaminophen 325 mg; phenylephrine 5 mg
Tylenol PM caplet	Acetaminophen 500 mg; diphenhydramine 25 mg
Tylenol Sinus + Headache caplet	Acetaminophen 325 mg; phenylephrine 5 mg
Tylenol Sinus Severe caplet	Acetaminophen 325 mg; phenylephrine 5 mg; guaifenesin 200 mg
Nonsalicylate NSAID-Containing Products	
Advil Cold & Sinus tablet (behind the counter)	Ibuprofen 200 mg; pseudoephedrine 30 mg
Advil Allergy and Congestion Relief coated tablet	Ibuprofen 200 mg; phenylephrine 10 mg; chlorpheniramine maleate 4 mg
Advil Sinus Congestion and Pain tablet	Ibuprofen 200 mg; phenylephrine 10 mg
Aleve-D Sinus & Headache caplet (behind the counter)	Naproxen sodium 220 mg; pseudoephedrine 120 mg
Motrin PM caplet	Ibuprofen 200 mg; diphenhydramine 38 mg
Sudafed 12 Hour Pressure + Pain Extended Release tablet (behind the counter)	Naproxen sodium 220 mg; pseudoephedrine 120 mg
Aspirin-Containing Products	

Trade Name	Primary Ingredient(s)
Anacin Regular Strength tablet	Aspirin 400 mg; caffeine 32 mg
Bayer Cafiaspirina caplet	Aspirin 500 mg; caffeine 40 mg
Excedrin Migraine caplet	Aspirin 250 mg; acetaminophen 250 mg; caffeine 65 mg
Goody's Cool Orange Powder	Aspirin 500 mg; acetaminophen 325 mg; caffeine 65 mg
Goody's Extra Strength Headache Powder	Aspirin 520 mg; acetaminophen 260 mg; caffeine 32.5 mg

Key: NSAID = Nonsteroidal anti-inflammatory drug.

Caffeine is used as an adjunct to analgesics for tension-type and migraine headaches. It also may have its own analgesic properties, and curbing or ceasing caffeine consumption is known to cause withdrawal headache when it is taken regularly. Clinical trials have suggested that combining caffeine with analgesics may result in better efficacy.⁴⁹ Of note, however, caffeine itself may be a trigger for migraines, and withdrawal of caffeine, as stated, may result in headache. Combination dosage formulations containing a decongestant and either acetaminophen or an NSAID also are available. Use of such combinations appears to be logical in sinus headaches or other indications for which both analgesia and decongestion are needed.

Combinations of NSAIDs such as aspirin and/or acetaminophen may achieve goals of pain relief with lower doses of the individual agents; however, insufficient evidence is available to support the safety and effectiveness of this practice. Dosing limits for combination products should be closely monitored.

Pharmacotherapeutic Comparison

Aspirin Versus Nonacetylated Salicylates

Although definitive clinical data are lacking, aspirin and non-acetylated salicylates are believed to be of equal anti-inflammatory potency; however,

aspirin is thought to be a superior analgesic and antipyretic. With all analgesics, individual patients may respond better to one agent than to another.

Aspirin Versus Acetaminophen

Numerous controlled studies have demonstrated the equivalent analgesic efficacy of aspirin and acetaminophen on a milligram-for-milligram basis; however, statistical methods used to compare effectiveness among different studies show that acetaminophen may not be as effective in some types of pain in which an inflammatory component predominates.⁵⁰ A recent systematic review found a lack of evidence for effectiveness of acetaminophen for osteoarthritis.⁵¹

Aspirin Versus Nonsalicylate NSAID

Ibuprofen has been shown to be at least as effective as aspirin in treating various types of pain, including dental extraction pain, dysmenorrhea, and episiotomy pain. Because aspirin must be dosed at levels near the self-care maximum to achieve anti-inflammatory effects, nonsalicylate NSAIDs may be preferred for self-treatment of inflammatory disorders such as rheumatoid arthritis or acute muscle injury.⁵⁰ Nonsalicylate NSAIDs have a safety advantage of lower toxicity in overdose.

NSAID Versus Acetaminophen

For episodic tension-type headache, acetaminophen 1000 mg appears to provide relief equivalent to that achieved with naproxen 375 mg.⁵² For moderate to severe dental or sore throat pain in children, single doses of acetaminophen 7–15 mg/kg produced pain relief similar to that with ibuprofen 4–10 mg/kg. Ibuprofen was a more effective antipyretic, and both drugs were well tolerated.⁵³ A review of evidence comparing ibuprofen with acetaminophen for headache treatment in children and adults found that only two trials had shown a modest advantage for ibuprofen, and the researchers concluded that the two agents should be considered equally effective.⁵⁴ Acetaminophen does not have anti-inflammatory properties, which limits its effectiveness in inflammatory conditions, including dysmenorrhea and osteoarthritis.⁵⁰ NSAIDs are less toxic than acetaminophen in the case of an overdose.

Naproxen Versus Ibuprofen

Naproxen sodium 220 mg and ibuprofen 200 mg appear to have similar efficacy. The time to onset of activity also is similar for these two NSAIDs. Duration of action of naproxen is longer than that of ibuprofen, with a dosing schedule of every 8–12 hours versus ibuprofen's dosing schedule of every 4–6 hours. Individual patients may report a better response to one NSAID than to another, for reasons that are unclear.

Product Selection Guidelines

Special Population Considerations

Age is an important consideration in the selection of an appropriate nonprescription medication for self-treatment for headache.

Parents of children younger than 8 years should consult a pediatrician before giving their children nonprescription medications. After appropriate evaluation, children 2 years and older may use acetaminophen or ibuprofen. Children 12 years and older may use naproxen. To decrease the risk of Reye syndrome, parents should not use aspirin or aspirin-containing products in children and teenagers unless directed to do so by a primary care provider.

Older patients are at increased risk for many adverse effects of salicylates and NSAIDs. Comorbid conditions, impaired renal function, and concurrent use of other medications contribute to the increased risk. These patients are more vulnerable to serious GI toxicity and the hypertensive and renal effects of salicylates and NSAIDs. Acetaminophen may be the safest alternative in the geriatric population.

Many safety considerations have been raised regarding the use of these medications in patients who are pregnant or breastfeeding; however, no such considerations apply for males and females of reproductive potential in general. (See the Preface for a detailed explanation of the pregnancy data.) Acetaminophen crosses the placenta but is considered safe for use during pregnancy. Acetaminophen appears in breast milk, producing a milk-to-maternal plasma ratio of 0.5:1. A maternal dose of 1 g correlates with an estimated maximum infant dose that is 1.85% of the maternal dose. The only adverse effect reported in infants exposed to acetaminophen through breast milk is a rarely occurring maculopapular rash, which subsides upon drug

discontinuation. Acetaminophen use is considered compatible with breastfeeding.⁵⁵

No evidence exists that NSAIDs are teratogenic in either humans or animals. Use of these agents is contraindicated during the third trimester of pregnancy, however, because all potent prostaglandin synthesis inhibitors can cause delayed parturition, prolonged labor, and increased postpartum bleeding. These agents also can have adverse fetal cardiovascular effects (e.g., premature closure of the ductus arteriosus) when used in pregnancy (particularly in late pregnancy). Reproductive animal studies have not shown evidence of harm to the fetus; however, adequate studies to verify safety have not been conducted in humans. Use in pregnancy should be limited to clinical situations in which the potential benefit justifies potential risk to the fetus.^{55,56}

Ibuprofen is considered the safest analgesic for use by nursing mothers. This designation is based on the low concentration of ibuprofen in breast milk and the lack of reported ill effects with use of ibuprofen in infants. The concentration of ibuprofen found in breast milk has been found to be less than 1% of the recommended infant dose.²⁴ Nursing mothers should not use naproxen, however. The naproxen anion has been measured in human milk, where it accumulates at a level of 1% of the maximum plasma concentration for naproxen. Prostaglandin-inhibiting drugs have the potential to cause harm in neonates; therefore, this level of exposure in milk has led to the labeling statement to avoid use during lactation.⁵⁶

Aspirin should be avoided during pregnancy, especially during the last trimester, and during breastfeeding. Its ingestion during pregnancy may be associated with maternal adverse effects such as anemia, antepartum or postpartum hemorrhage, and prolonged gestation and labor. Regular aspirin ingestion during pregnancy may increase the risk for complicated deliveries, including unplanned cesarean section, breech delivery, and forceps delivery. Definitive data supporting these concerns, however, are lacking.

Aspirin readily crosses the placenta and can be found in higher serum concentrations in the neonate than in the mother. Salicylate elimination is slow in neonates because of the liver's immaturity and underdeveloped capacity to form glycine and glucuronic acid conjugates and because of reduced urinary excretion resulting from low glomerular filtration rates.

Fetal effects from in utero aspirin exposure include intrauterine growth

retardation, congenital salicylate intoxication, decreased albumin-binding capacity, and increased perinatal mortality. In utero death results, in part, from antepartum hemorrhage or premature closure of the ductus arteriosus. In utero aspirin exposure within 1 week of delivery can result in neonatal hemorrhagic episodes and/or pruritic rash. Reported neonatal bleeding complications include petechiae, hematuria, cephalhematoma, subconjunctival hemorrhage, and increased bleeding after circumcision.⁵⁵ An increased incidence of intracranial hemorrhage in premature or low-birth-weight infants associated with maternal aspirin use near the time of birth also has been reported.⁵⁵ An association between maternal aspirin ingestion and oral clefting and congenital heart disease has been noted. The relationship between maternal aspirin ingestion and congenital malformation remains unresolved, however, and studies have failed to confirm a relationship between maternal ingestion of aspirin and increased risk of fetal malformation.

Aspirin and other salicylates are excreted into breast milk in low concentrations. After single-dose oral salicylate ingestion, peak milk levels occur at approximately 3 hours, producing a milk-to-maternal plasma ratio of 3:8. Although no adverse effects on platelet function in nursing infants exposed to aspirin via breast milk have been reported, these agents still must be considered to carry a risk for such effects.⁵⁵

For patients with renal impairment, caution is indicated with use of salicylates and other NSAIDs. Clinically important alterations in renal blood flow that result in acute reduction in renal function can result from even short courses of salicylates. Referral for medical evaluation for assistance in selecting an analgesic is appropriate.

For patients with hepatic impairment, caution is warranted with use of acetaminophen. Presence of active liver disease is a risk factor for hepatic injury from this drug. Patients with hepatic impairment of any degree should use the smallest dose for the shortest duration possible. Prolonged use of this drug at high doses should be avoided.

Patient Factors

Nonprescription analgesics are available in a number of dosage forms. During patient assessment, the health care provider should determine which dosage form will provide an optimal clinical outcome. If rapid response is desired, then immediate-release oral dosage forms are preferred over coated or extended-

release forms. For patients experiencing migraine headache with severe nausea, rectal dosage forms may be needed. Liquid dosage forms often are used in children or adult patients who have difficulty swallowing tablets or capsules. Information regarding the FDA requirements for dispensing devices included in liquid nonprescription products is located in [Chapter 11](#), under “Special Populations.”

Use of ibuprofen in the pediatric population is complicated by the availability of two liquid formulations of different strengths. Unintended over- or underdosing can occur when parents switch between the concentrated drops (50 mg/1.25 mL) and the suspension (100 mg/5 mL). In addition, rapidly growing infants quickly outgrow previous dose requirements. Therefore, recalculation of the pediatric dose according to present age and body weight is recommended at the time of each treatment course.

Patients whose lifestyle encompasses significant alcohol ingestion (three or more drinks per day) should avoid self-treatment with nonprescription analgesics.

Patients with intolerance to aspirin also may experience cross-reactions with other chemicals or drugs. Up to 15% of aspirin-intolerant patients may exhibit signs of cross-reaction when exposed to tartrazine (a dye designated by the FDA-administered Food, Drug, and Cosmetic Act as FD&C Yellow 5), which can be found in many drugs and foods. Among persons documented to have the respiratory type of aspirin sensitivity, rates of cross-reaction between aspirin and acetaminophen, ibuprofen, and naproxen are 7%, 98%, and 100%, respectively. High cross-reaction rates also are reported with some prescription NSAIDs. The proposed mechanism of cross-sensitivity between aspirin and other NSAIDs involves shunting arachidonic metabolism down the lipoxygenase pathway (consequent to inhibition of the COX-1 enzyme pathway), resulting in accumulation of leukotrienes, which can cause bronchospasm and anaphylaxis. Acetaminophen and nonacetylated salicylates are weak inhibitors of COX-1 at moderate doses. Patients with a history of aspirin intolerance should therefore be advised to avoid all aspirin- and other NSAID-containing products, and to use acetaminophen or a nonacetylated salicylate, with the caveat that acetaminophen does not offer anti-inflammatory properties.

Patient Preferences

Consideration of dosing frequency in product selection may lead to improved outcomes for individual patients. Naproxen can be taken 2 or 3 times daily, which may improve patient adherence to the medication regimen. By contrast, immediate-release products of acetaminophen, ibuprofen, and salicylates may require dosing as frequently as every 4 hours. Acetaminophen 650 mg in extended-release form is given every 8 hours.

Complementary Therapies

Butterbur, feverfew, riboflavin, and coenzyme Q10 are commonly used for the prevention of migraine headaches and are discussed in depth in [Chapter 51](#). These natural products have limited efficacy for the treatment of other types of headaches. Essential oil remedies include application of peppermint oil to the forehead and temples for treatment of tension headache and inhalation of aromatized lavender oil to relieve migraine. Recent and well-designed trials to further clarify the efficacy and safety of essential oils are lacking. Magnesium and omega-3 polyunsaturated fatty acid supplementation for headache prevention also has been considered.²⁰

Acupuncture has been used to prevent migraine and tension-type headache. Evaluation of acupuncture is complicated by difficulties in blinding of study participants and investigators and by differences in identifying acupuncture points. Overall, results have been variable, but several randomized, placebo-controlled trials found acupuncture to be effective in reducing frequency and severity of headache.⁵⁶ Methods focusing on stress relief and relaxation techniques such as massage, yoga, and biofeedback therapy may be useful for the prevention and treatment of headache.²⁰ Some of these methods are discussed in more depth in [Chapter 52](#).

Assessment of Headache: A Case-Based Approach

Before self-treatment of headache can be recommended, the health care provider must assess the patient's headache complaint to determine type, severity, location, frequency, intensity over time, and age at onset. The next

step is to obtain a medical and psychosocial history. All current medications should be inventoried, and all past and present headache treatments should be reviewed, with emphasis on determining which treatments, if any, were successful or preferred.

Secondary headaches, other than minor sinus headache, are excluded from self-treatment. Headache associated with seizures, confusion, drowsiness, or cognitive impairment may be a clinical indicator of brain tumor, ischemic stroke, subdural hematoma, or subarachnoid hemorrhage. Headache accompanied by nausea, vomiting, fever, and stiff neck may indicate brain abscess or meningitis. Headache with night sweats, aching joints, fever, weight loss, and visual symptoms (e.g., blurring) in patients with rheumatoid arthritis may indicate cranial arteritis. Headache associated with localized facial pain, muscle tenderness, and limited motion of the jaw may indicate temporomandibular joint disorder.

Cases 5–1 and 5–2 illustrate assessment of two different patients with headache.

Patient Counseling for Headache

To optimize outcomes from therapy, the health care provider should instruct patients to take an appropriate dose of analgesic early in the course of the headache. The use of nonprescription analgesics to preempt or abort migraine headaches should also be explained to patients with migraines whose headaches are predictable. Patients for whom headache is a relatively common occurrence should be encouraged to keep a log of their headache episodes to document triggers, frequency, intensity, duration of episodes, and response to treatment. This record may also be helpful in identifying factors that can improve headache prevention and treatment. Patients should be advised that continuing or escalating pain can be a sign of a more serious problem and that such pain warrants prompt medical attention. Appropriate drug and nondrug measures for treating headaches should be explained in appropriate detail. Frequent use of nonprescription analgesics is not advisable because of the risk for medication overuse headache. The health care provider should convey the message that nonprescription analgesics are potent medications with accompanying potential adverse effects, interactions, and precautions and warnings. The box “Patient Education for Headache” lists

specific information for patient counseling.

Evaluation of Patient Outcomes for Headache

Appropriate follow-up evaluation will depend on headache frequency and severity, as well as patient factors. Headache pain relief should begin within 30 minutes and peak at 2 hours after administration of an over-the-counter analgesic. Patients should seek medical attention if headaches persist longer than 3 days or worsen despite self-treatment. For patients with episodic headaches, a trial of 6–12 weeks may be needed to assess efficacy of treatment. For chronic headache, follow-up evaluation after 4–6 weeks should be adequate to assess treatment efficacy. Patients with migraine headaches who do not obtain adequate relief with self-treatment should be referred for medical evaluation, because effective prescription therapies are available to substantially limit pain and disability.

Case 5–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient describes a dull ache in her forehead. She said it started a few hours ago and is interfering with her ability to concentrate on studying for an upcoming exam. It seems to feel worse when she tries to think and study for the exam. Headaches are generally uncommon for her but seem to increase in frequency during final exams.
b. Description of any factors that seem to	Closing her eyes and resting seem to help relieve the pain.

Relevant Evaluation Criteria	Scenario/Model Outcome
precipitate, exacerbate, and/or relieve the patient's symptom(s)	
c. Description of the patient's efforts to relieve the symptoms	Other than closing her eyes, the patient has not tried anything else to relieve pain.
d. Patient's identity	Cynthia Marshall
e. Patient's age, gender, height, and weight	20 years, female, 5 ft 3 in., 130 lb
f. Patient's occupation	Student
g. Patient's dietary habits	Breakfast bar for breakfast, salad from the school cafeteria for lunch, and dinner varies daily depending on schedule. She does not consume alcohol and has a single cup of coffee most mornings.
h. Patient's sleep habits	Reports sleeping 6-7 hours nightly.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Multivitamin
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary	Ms. Marshall is experiencing a dull ache in her forehead consistent with a tension-type headache. This is likely a response to the stress of school.

Relevant Evaluation Criteria	Scenario/Model Outcome
problem(s).	
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Marshall to an appropriate HCP. (2) Recommend self-care with a nonprescription analgesic and nondrug measures. (3) Recommend self-care until Ms. Marshall can see an appropriate HCP. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. Marshall should use a nonprescription analgesic and nondrug measures to treat her problem.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Acetaminophen, ibuprofen, and naproxen are all appropriate options. Correct dosing for the selected medication is essential, with careful attention to not take more than the recommended daily amount. Additional stress relief measures should be used when needed."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Tension-type headache can be effectively treated with nonprescription medications. Because stress is a likely trigger for the headache, it is important to focus on stress-relieving activities as well. If the medication chosen does not relieve the pain or if the pain worsens, you should see a health care provider."
Implement	

Relevant Evaluation Criteria	Scenario/Model Outcome
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	The specific administration of the medication is determined by the specific analgesic chosen. Most pain relievers will start working within about 30 minutes, and pain relief duration will depend on the analgesic used. The pain should be gone or noticeably diminished by the analgesic. Adverse effects will depend on the product chosen. All medications should be kept in a cool, dry place and out of reach of children. A headache diary will help keep track of headache frequency and help identify possible triggers.
Solicit follow-up questions from the patient or caregiver.	“Is it possible to not have these headaches while I’m in school?”
Answer the patient’s or caregiver’s questions.	“Various methods to reduce stress may help decrease the frequency of the headaches. Stress reduction measures will include appropriate study strategies and adequate sleep.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Follow-up with the patient should occur in 4–6 weeks. Owing to the episodic nature of this headache, 6 weeks may be necessary to fully evaluate the treatment.

Key: HCP = Health care provider; n/a = not applicable.

Case 5–2

Collect	
1. Gather essential information about the patient’s symptoms and medical history,	

Relevant Evaluation Criteria	Scenario/Model Outcome
including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient approaches the pharmacy wearing her sunglasses. She says that she is experiencing throbbing pain on one side of her head. She is feeling a bit nauseous as well and says the pain started about 30 minutes ago.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She said that light makes the pain worse, which is why she is wearing sunglasses. She also said that she is sensitive to sound. The only relief seems to come from resting in a dark, quiet room.
c. Description of the patient's efforts to relieve the symptoms	She has tried going to a dark and quiet location, but the pain continued. She also tried a cold towel on her face, but the pain still continued.
d. Patient's identity	Betsy Ogaku
e. Patient's age, gender, height, and weight	34 years, female, 5 ft 6 in., 150 lb
f. Patient's occupation	Real estate agent
g. Patient's dietary habits	Egg white wrap for breakfast, salad with grilled chicken for lunch, and a well-rounded dinner each evening.
h. Patient's sleep habits	About 7 hours each evening
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Citalopram 20 mg once daily for depression Levothyroxine 137 mcg for hypothyroidism Tums as needed for occasional heartburn No dietary supplements
j. Allergies	Penicillin
k. History of other adverse reactions to medications	None
l. Other (describe) _____	n/a
Assess	

Relevant Evaluation Criteria	Scenario/Model Outcome
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Mrs. Ogaku is suffering from unilateral, throbbing pain associated with sensitivity sound and light. She additionally is experiencing nausea. These symptoms are caused by migraine.
3. Identify exclusions for self-treatment.	Symptoms consistent with migraine, but no formal diagnosis of migraine headache.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mrs. Ogaku to an appropriate HCP. (2) Recommend self-care with a nonprescription analgesic and nondrug measures. (3) Recommend self-care until Mrs. Ogaku can see an appropriate HCP. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mrs. Ogaku should see a health care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should see your primary care provider for treatment."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best because you are experiencing a migraine headache. Self-treatment with over-the-counter medications is not recommended for a migraine until you have been evaluated and diagnosed by your primary care provider."
Implement	
8. When recommending self-care with	"Work with your primary care provider to

Relevant Evaluation Criteria	Scenario/Model Outcome
nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	determine the cause of this migraine. Try to implement lifestyle changes to prevent a future occurrence.”
Solicit follow-up questions from the patient or caregiver.	“Does this mean that I will continue to have this problem in the future?”
Answer the patient’s or caregiver’s questions.	“The frequency of migraine headache varies for each affected person. A thorough understanding of the cause of your migraine will help you try to prevent another in the future.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact the patient the following day to ensure that she made an appointment with a primary care provider.

Key: HCP = Health care provider.

Patient Education for Headache

The objectives of self-treatment are (1) to relieve headache pain, (2) to prevent headaches when possible, and (3) to prevent medication overuse headaches by avoiding chronic use of nonprescription analgesics. Carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Tension-Type Headaches

- Nonprescription pain relievers (analgesics) are usually effective in relieving tension-type headaches. However, consult your primary care provider before using such medications for chronic tension-

type headaches that occur 15 days per month or more often over a 3-month period.

- If nonprescription pain relievers are used for chronic headaches, keep records of how often they are used, and share this information with your primary care provider.

Migraine Headache

- Avoid substances (food, caffeine, alcohol, medications) or situations (stress, fatigue, oversleeping, fasting, missing meals) that you know can trigger a migraine.
- Use the following nutritional strategies to prevent migraine:
 - Avoid foods or food additives known to trigger migraines, including red wine, aged cheese, aspartame, monosodium glutamate, coffee, tea, cola beverages, and chocolate.
 - Avoid foods to which you are allergic.
 - Eat regularly to avoid hunger and low blood sugar.
- If onset of migraines is predictable (e.g., occurrence of headache during menstruation), take aspirin, ibuprofen, or naproxen to prevent the headache. Start taking the analgesic 2 days before you expect the headache and continue regular use during the time the headache might start.
- Try to stop a migraine by taking an NSAID such as aspirin or acetaminophen at the onset of headache pain.
- If desired, rest in a quiet, dark room and use an ice bag or cold pack applied with pressure to the forehead or temples to reduce the pain associated with acute migraine attacks.

Sinus Headache

- Consider using a combination of a decongestant and a nonprescription analgesic to relieve the pain of sinus headache.

Precautions for Nonprescription Analgesics

- If you are pregnant or breastfeeding, consult your primary care provider before taking any nonprescription medications.

- If you have a medical condition or are taking prescription medications, obtain medical advice before taking any of these medications. Nonprescription analgesics are known to interact with several medications.
- Do not take nonprescription analgesics more often than 3 days per week unless a health care provider has recommended prolonged use.
- Do not take these medications if you consume three or more alcoholic beverages daily.
- Do not exceed recommended dosages.
- Products containing aspartame and/or phenylalanine (usually chewable tablets) should not be given to persons with phenylketonuria.

Salicylates (Aspirin and Magnesium Salicylate) and Other NSAIDs (Ibuprofen and Naproxen)

- Do not take salicylates or nonsalicylate NSAIDs during the last 3 months of pregnancy unless a primary care provider is supervising such use. Unsupervised use of this medication could harm the unborn child or cause complications during delivery.
- Do not give aspirin or products that contain aspirin to children and teenagers who have or are recovering from chickenpox or influenza-like symptoms. To avoid the risk of Reye syndrome, a rare but potentially fatal condition, use acetaminophen for pain relief.
- Do not take aspirin or other NSAIDs if you are allergic to aspirin or have asthma and nasal polyps. Take acetaminophen instead.
- Do not take aspirin or other NSAIDs if you have stomach problems or ulcers, liver disease, kidney disease, or heart failure.
- Do not take NSAIDs if you have or are at high risk for heart disease or stroke unless the use is supervised by a health care provider.
- Do not take aspirin if you have gout, diabetes mellitus, or arthritis unless the use is supervised by a health care provider.
- Do not take salicylates or other NSAIDs if you are taking anticoagulants.
- Do not take magnesium salicylate if you have kidney disease.
- Do not give naproxen to a child younger than 12 years.

When to Seek Medical Attention

- Stop taking salicylates or other NSAIDs and seek medical attention if any of the following signs and symptoms are noted:
 - Headache, dizziness, ringing in the ears, difficulty in hearing, dimness of vision, mental confusion, lassitude, drowsiness, sweating, thirst, hyperventilation, nausea, vomiting, or occasional diarrhea. These signs and symptoms indicate mild salicylate toxicity.
 - Dizziness, nausea and mild stomach pain, constipation, ringing in the ears, or swelling in the feet or legs. These signs and symptoms are common adverse effects of salicylates and other NSAIDs.
 - Rash or hives, or red, peeling skin; swelling in the face or around the eyes; wheezing or trouble breathing; bloody or cloudy urine; unexplained bruising and bleeding; or signs of stomach bleeding such as bloody or black tarry stools, severe stomach pain, or bloody vomit (see the box “A Word About NSAIDs and Stomach Bleeding”). These signs and symptoms warrant immediate medical attention.

Acetaminophen

- To avoid possible damage to the liver, do not take more than 4 g of acetaminophen a day (total dose from all nonprescription and prescription single-ingredient or combination products containing acetaminophen).
- Do not drink alcohol while taking this medication.
- Follow dosage instructions for acetaminophen carefully if you have glucose-6-phosphate dehydrogenase deficiency.

When to Seek Medical Attention

- Stop taking acetaminophen and seek medical attention if you develop nausea, vomiting, drowsiness, confusion, or abdominal pain.

Key: NSAID = Nonsteroidal anti-inflammatory drug.

Key Points for Headache

- Most tension-type, migraine, and sinus headaches are amenable to treatment with nonprescription medications.
- Patients with signs and symptoms suggestive of secondary headaches (except for minor sinus headache) or of undiagnosed migraine headaches should be referred for medical evaluation.
- Many patients with frequent headaches may experience improvement after identifying and modifying environmental, behavioral, nutritional, or other triggers for their headaches.
- The choice of nonprescription analgesic depends on patient preferences, presence of precautionary or contraindicating conditions, concomitant medications, cost, and other factors.
- Pharmacists have been identified as key sources of information on nonprescription analgesics to reduce risk for acetaminophen-induced hepatotoxicity and NSAID-induced GI bleeding, cardiovascular events, and nephrotoxicity.
- Use of nonprescription analgesics for headache should be limited to 3 days per week to prevent medication overuse headache.

Chapter 6: Fever

Authors: Virginia Lemay, Brett Feret

Fever is a common reason for visits to pediatricians' offices, with the National Ambulatory Medical Care Survey estimating that 6% of all ambulatory visits to pediatricians are related to fever.¹ Fever also is the leading cause of visits to an emergency department for both male and female patients younger than 15 years.² In 2012, patients with the primary complaint of fever made approximately 10.9 million medical office visits, with a slight preponderance of men.³ Fever is more commonly reported in children than in adults: The rate of reported fevers is 10 per 100 children younger than 5 years, versus 0.5 per 100 adults. Nonetheless, occurrence rates do not seem to differ significantly with respect to gender, race, or geographic area of residence in the United States.⁴

In most cases, fever is self-limited and nonthreatening in presentation; however, fever can cause a great deal of discomfort and occasionally may indicate a serious underlying pathologic condition (e.g., acute infectious process) for which prompt medical evaluation is indicated. The principal reason for treating fever is to alleviate discomfort, but the underlying cause should be identified and appropriate management instituted.

Fever must be distinguished from hyperthermia and hyperpyrexia. Fever is caused by a regulated rise in body temperature, maintained by the hypothalamus, in response to a pyrogen. *Fever* is defined by a body temperature higher than the normal core (oral) temperature of 100°F (37.8°C). It thus signals an increase in the body's thermoregulatory set point.

Hyperthermia, by contrast, represents a malfunctioning of the normal thermoregulatory process at the hypothalamic level caused by excessive heat exposure or production.⁵ Because of their different mechanisms, treatment of fever versus hyperthermia also varies.

Hyperpyrexia is defined by a body temperature greater than 106°F (41.1°C; oral) that typically is associated with mental and physical signs and symptoms. Hyperpyrexia may develop with either fever or hyperthermia.

Pathophysiology of Fever

Core body temperature is controlled by the hypothalamus and regulated by a feedback system involving information transmitted between the thermoregulatory center in the anterior hypothalamus and the thermosensitive neurons in the skin and central nervous system (CNS). Physiologic (e.g., sweating, vasodilation) and behavioral mechanisms regulate body temperature within the normal range. Although skin temperature may fluctuate greatly in response to environmental conditions, the core temperature is maintained within a narrow range.⁶

Normal thermoregulation prevents wide fluctuations in body temperature, with the average oral temperature usually maintained between 97.5°F and 98.9°F (36.4°C and 37.2°C, respectively). Temperature maintained in this range is considered to be the “set point” at which physiologic or behavioral mechanisms are not activated. For practical purposes, the commonly accepted core body temperature is usually 98.6°F (37.0°C; oral).

Pyrogens, either exogenous or endogenous, are fever-producing substances that activate the body's host defenses, resulting in an increase in the set point. Exogenous pyrogens (e.g., those of microbial origin or plant toxins) do not independently increase the hypothalamic temperature set point. These substances stimulate the release of endogenous pyrogens (e.g., immune cytokines), thereby increasing the core temperature. Endogenous pyrogens are products released in response to or from damaged tissue, such as interleukins, interferons, and tumor necrosis factor.^{6–8}

Prostaglandins of the E₂ series (PGE₂) are produced in response to circulating pyrogens and elevate the thermoregulatory set point in the hypothalamus. Within hours, body temperature reaches the new set point, and fever occurs. During the period of upward temperature readjustment, the patient experiences chills, caused by peripheral vasoconstriction and muscle rigidity, to maintain homeostasis.⁶

An increase in body temperature may be idiopathic or the result of a variety of mechanisms, including those associated with infectious and other pathologic processes, systemic response to certain drugs, and vigorous activity.

Most febrile episodes are caused by microbial infections (i.e., due to viruses, bacteria, fungi, yeasts, or protozoa). No basis has been found for differentiating viral from bacterial infections according to the magnitude of the fever or temperature reduction with antipyretic drug therapy. Fever often is less

pronounced in older patients; consequently, infection may not be recognized easily, or early, in this age group if fever is the primary assessment criterion.⁹

Noninfectious pathologic causes of increases in temperature include malignancies, tissue damage (e.g., myocardial infarction, surgery), antigen–antibody reactions, dehydration, heat stroke, CNS inflammation, and metabolic disorders such as hyperthyroidism or gout. Many of these processes may cause hyperthermia, rather than fever, because they interfere with the hypothalamic regulation of temperature.

Drug fever is simply defined as a febrile response to the administration of a medication. Its incidence in ambulatory settings is unknown but among hospitalized patients is approximately 10%¹⁰ (Table 6–1). With drug-induced fever, temperatures usually range from 98.9°F (37.2°C; oral) to as high as 109°F (42.8°C; oral). Drug fever should be suspected in patients without an obvious source of fever; however, this condition often goes unrecognized because of inconsistent signs and symptoms. Failure to discontinue the offending drug may result in substantial morbidity and death.^{11,12}

Table 6–1 Selected Medications That Induce Hyperthermia

Anti-infectives	Antineoplastics	Cardiovascular	CNS Agents	Other Agents
Aminoglycosides	Bleomycin	Epinephrine	Amphetamines	Allopurinol
Amphotericin B	Chlorambucil	Hydralazine	Barbiturates	Atropine
Cephalosporins	Cytarabine	Methyldopa	Benztropine	Azathioprine
Clindamycin	Daunorubicin	Nifedipine	Carbamazepine	Cimetidine
Chloramphenicol	Hydroxyurea	Procainamide	Haloperidol	Corticosteroids
Imipenem	L-Asparaginase	Quinidine	Lithium	Folate
Isoniazid	6-Mercaptopurine	Streptokinase	MAOIs	Inhaled anesthetics
Linezolid	Procarbazine		Nomifensine	Interferon
Macrolides	Streptozocin		Phenytoin	Iodides
Mebendazole			Phenothiazines	Metoclopramide

Anti-infectives	Antineoplastics	Cardiovascular	CNS Agents	Other Agents
Nitrofurantoin			SNRIs	Propylthiouracil
Para-aminosalicylic acid			SSRIs	Prostaglandin E ₂
Penicillins			Sumatriptan	Salicylates
Rifampin			Thioridazine	Tolmetin
Streptomycin			Trifluoperazine	
Sulfonamides			TCA's	
Tetracyclines			Topiramate	
Vancomycin			Zonisamide	

Key: CNS = Central nervous system; MAOIs = monoamine oxidase inhibitors; SNRIs = serotonin-norepinephrine reuptake inhibitors; SSRIs = selective serotonin reuptake inhibitors; TCAs = tricyclic antidepressants.

Source: References 5, 10, and 12.

Drug fever may be differentiated from other potentially causative disorders by establishing a temporal relationship between the fever and the administration of a medication, as well as by observing a temperature elevation despite clinical improvement with respect to the underlying disorder.

The management of drug fever involves discontinuing all medications temporarily, if feasible, in addition to the suspected medication whenever possible. If the hyperthermia is drug-induced, the patient's temperature generally will decrease within 24–72 hours after the offending agent is withdrawn. After the patient's safety has been secured and the offending medication has been identified and discontinued, each medication may be restarted, one at a time, with careful monitoring for fever recurrence.¹²

Clinical Presentation of Fever

Because clinical manifestations of fever are nonspecific and do not occur in all patients, the specific cause of a fever may be difficult to determine. The most important indicator of fever is an elevated body temperature; therefore, accurate temperature measurement is paramount. Fever is symptomatic of a larger underlying process, whether an infection, an abnormality of metabolism, or a drug-induced syndrome.

Once the presence of fever is established, investigation into the underlying cause is essential. Signs and symptoms that typically accompany fever and cause a great deal of discomfort include headache, diaphoresis, generalized malaise, chills, tachycardia, arthralgia, myalgia, irritability, and anorexia. Most children will tolerate a fever well, so if they continue to be alert, play normally, and stay hydrated, the fever is not a reason for great concern. However, high body temperature dulls intellectual function and causes disorientation and delirium, especially in persons with preexisting dementia, cerebral arteriosclerosis, or alcoholism.

Detection of Fever

The most accurate method of assessing for fever is to use a thermometer properly to measure body temperature. The patient's age and level of physical and emotional stress, the environmental temperature, the time of day, and the anatomic site at which the temperature is measured are important considerations in that each factor can affect the temperature reading obtained.

Core temperature is estimated using various types of thermometers at the rectal, axillary, oral, temporal, or tympanic site. Rectal temperature has long been considered the gold standard measurement; however, its utility has been challenged.¹³ Many patients and caregivers prefer other methods of temperature measurement because of comfort and ease of use. Body temperature should be measured with the same thermometer at the same site over the course of an illness, because the readings from different thermometers or sites may vary ([Table 6–2](#)). Discrepancy among the various sites of temperature measurement is normal and should not be ascribed to

improper measurement technique. On average, a rectal temperature greater than 100.4°F (38.0°C), an oral temperature greater than 99.5°F (37.5°C), an axillary temperature greater than 99°F (37.2°C), a tympanic temperature greater than 100.4°F (38.0°C), or a temporal measurement higher than 100.1°F (37.8°C) is considered elevated.^{14,15} The observed variation in temperatures at the different sites is in accord with a simple concept of temperature measurement familiar to the general public: Add 1 degree to an oral temperature to get a rectal or tympanic equivalent, and subtract 1 degree from an oral temperature for an axillary measurement. Normal body temperature may differ by 1.8°F–2.5°F (1.0°C–1.4°C) from these general criteria. Diurnal rhythms cause body temperature to vary during the day, with higher temperatures typically seen in the late afternoon to early evening.

Table 6–2 Body Temperature Range Based on Anatomic Site/Method of Measurement

Site/Method of Measurement	Normal Range^a	Fever^a
Rectal	97.9°F–100.4°F (36.6°C–38.0°C)	>100.4°F (38.0°C)
Oral	95.9°F–99.5°F (35.5°C–37.5°C)	>99.5°F (37.5°C)
Axillary	94.5°F–99°F (34.7°C–37.2°C)	>99°F (37.2°C)
Tympanic	96.3°F–100.4°F (35.7°C–38.0°C)	>100.4°F (38.0°C)
Temporal	97.9°F–100.1°F (36.6°C–37.8°C)	<i>0–2 months of age:</i> >100.7°F (38.1°C)
		<i>3–47 months of age:</i> >100.3°F (37.9°C)
		<i>>4 years of age:</i> >100.1°F (37.8°C)

^a Conversion formulas: Celsius = 5/9(°F – 32); Fahrenheit = (9/5 × °C) + 32.

Source: References 14 and 15.

Because the U.S. Food and Drug Administration (FDA) regulates thermometers as medical devices, all approved types of thermometers are accurate and reliable, if used appropriately. Today's providers should not recommend mercury-in-glass thermometers for use because of environmental concerns about mercury. Federal and state authorities have lobbied for a ban on mercury thermometers, and 13 states have passed laws that prohibit the manufacture, sale, and distribution of mercury-containing thermometers. In addition, the National Institute of Standards and Technology in conjunction with the Environmental Protection Agency will no longer provide any calibration services for mercury-containing thermometers.^{16,17}

Electronic probe thermometers are available for oral, rectal, and axillary temperature measurements. The probes have an electronic transducer that provides a temperature reading in approximately 10–60 seconds. The oral electronic probes are mostly available as either a pen or a pacifier. The pacifier-shaped electronic thermometer is for oral use only and is recommended for infants who are unable to hold a probe under the tongue. The length of time the pacifier needs to stay in the child's mouth varies depending on the manufacturer but can range from 3 to 8 minutes.^{15,18} The pen-shaped probe may be used in oral, rectal, and axillary sites. Because of their electronic digital temperature displays, electronic thermometers provide quick readings, eliminate the possibility of injury from glass breakage, and are easier to read than traditional glass thermometers. The use of disposable probe covers with electronic thermometers also reduces the need for disinfection between uses. Disinfection protocols are still indicated, however, if the thermometer is being used for multiple patients. A thermometer that is used rectally should never be used subsequently for oral measurement.

Infrared thermometers are available for tympanic artery and temporal artery temperature measurements. These thermometers use infrared technology to detect heat from the arterial blood supply. They must be placed directly over the course of the relevant blood vessel, whether near the temporal artery or the tympanic membrane. Infrared thermometers give a temperature reading in less than 5 seconds and are considered very accurate if used properly. The major problem with infrared thermometers is that the device may not always be placed appropriately, or it may have a dirty lens and consequently may give inaccurate readings. Infrared thermometers are relatively expensive and require batteries, but many families with young children prefer them because of their convenience and noninvasive nature. Newer technology also includes

no-touch infrared thermometers, which offer the advantage of not having to wake a sleeping child to take a temperature.^{15,19}

Color-change thermometers are easy to use, but they are not sufficiently accurate or reliable. With these thermometers, an adhesive strip containing heat-sensitive material changes color in response to different temperature gradients. The strip may be placed anywhere on the skin, preferably the forehead, which shows less variation in temperature compared with other parts of the body. Although this method may detect changes in skin temperature, it does not reliably detect changes in core temperature.

Patient-related factors may preclude the use of a particular type of thermometer. Although a variety of routes for temperature measurement are practicable, rectal temperature measurement historically has been the standard, because the site is not influenced by ambient temperatures, and because this route is appropriate for use in patients of various ages.¹⁴ Oral, tympanic, axillary, and temporal routes are all satisfactory for temperature measurement if the proper procedure is followed.

Table 6–3 describes the proper methods of taking *rectal* temperatures in children and adults. Although the rectal route gives the closest estimate of stable core temperature, its intrusive nature can be very frightening and possibly psychologically harmful to older children. In children younger than 3 months, however, rectal temperature measurement is the preferred method for assessing fever and should be recommended if caregivers are confident they can safely use this technique.¹⁵ Risks associated with taking a rectal temperature include retention of the thermometer, rectal or intestinal perforation, and peritonitis. Rectal temperature measurement is also very time-consuming, and the patient should never be left unattended while the rectal thermometer remains in place; a positional change may cause the thermometer to be expelled or broken. Rectal temperature measurement is relatively contraindicated in patients who are neutropenic, have had recent rectal surgery or injury, or have a pathologic process involving the rectum (e.g., obstructive hemorrhoids, diarrhea). In addition, rectal temperature measurement is slow to detect rapid changes in body temperature because of the large muscle mass and poor blood flow in the surrounding anatomic area.^{14,15,20}

Table 6–3 Guidelines for Rectal Temperature Measurement Using Electronic Thermometers

1. Cover the tip of thermometer with a probe cover.
2. Turn on the thermometer and wait until the device signals that it is ready for use.
3. Apply a water-soluble lubricant or petroleum jelly to tip of thermometer to allow for easy passage through the anal sphincter and to reduce risk of trauma.
4. For infants or young children, place child face down over your lap or face up with legs bent to the chest, separate the buttocks with the thumb and forefinger of one hand, and insert the thermometer gently in the direction of the child's umbilicus with the other hand. For infants, insert the thermometer to the length of the tip only. For young children, insert it no more than 1 inch into the rectum.
5. For adults, have the patient lie on one side with the legs flexed to an approximately 45-degree angle from the abdomen. Insert the tip 0.5–2 inches into the rectum by holding the thermometer 0.5–2 inches away from the tip and inserting it until the finger touches the anus. Have the patient take a deep breath during this process to facilitate proper positioning of the thermometer.
6. Hold the thermometer in place until it beeps and a temperature is displayed.
7. Remove the thermometer and record the displayed temperature.
8. Dispose of probe cover and clean thermometer with an antiseptic such as alcohol or a povidone/iodine solution by wiping away from the stem toward tip. Rinse with cool water.
9. Wipe away any remaining lubricant from the anus.

Table 6–4 summarizes the proper methods of *oral* temperature measurement with electronic thermometers.¹⁵ Of note, use of oral measurement techniques is not acceptable in patients who are mouth-breathing or hyperventilating; have recently had oral surgery; are not fully alert; or are uncooperative, lethargic, or confused. Oral digital probe thermometers may not be appropriate for use in most children younger than 3 years of age owing to the difficulty of maintaining a tight seal around the thermometer and keeping the thermometer under the tongue. Accordingly, in these younger children, use of a pacifier thermometer may be recommended. Pacifier thermometers provide reliable temperature readings compared with rectal measurements; however, in children younger than 3 months, pacifier thermometers are less accurate.^{21,22}

Table 6–4 Guidelines for Oral Temperature Measurement Using Electronic Thermometers

Digital Probe

1. Wait 20–30 minutes after drinking or eating.
2. Place a clean disposable probe cover over tip of thermometer.
3. Turn on the thermometer and wait until it is ready for use.
4. Place tip of thermometer under tongue.
5. Close mouth and breathe through nose.
6. Hold thermometer in place until it beeps and temperature has been recorded (usually after 5–30 seconds).
7. Remove the thermometer from mouth and record the displayed temperature.
8. Remove and dispose of probe cover.

Digital Pacifier Thermometer

1. Wait 20–30 minutes after drinking or eating.
2. Inspect the pacifier for any tears or cracks. Do not use if worn.
3. Press the button to turn on thermometer.
4. Place the pacifier in the child's mouth.
5. Have the child hold pacifier in mouth without moving, if possible, for time specified on packaging of thermometer (2–6 minutes).
6. Remove thermometer after the beep and record displayed temperature.

Source: References 15 and 18.

Table 6–5 describes the proper method of using *tympanic* thermometers, which varies slightly with the age of the patient.¹⁵ Tympanic thermometers have digital readouts, and many can be set to provide either a rectal or an oral temperature equivalent. The tympanic membrane is close to the hypothalamus, and the blood supply to both anatomic areas is at the same temperature, providing an accurate reading of the core body temperature. The thermometer must be positioned in the ear canal properly to ensure that the measured infrared radiation is from the tympanic membrane and not from the ear canal or adjacent areas. In clinical trials, accuracy of tympanic thermometers is lower, with more variable readings, than that for thermometers using rectal and oral routes.^{23,24} Variations in measured tympanic temperatures have been attributed to cerumen impaction, inflammation in the ear canal (e.g., otitis media), age of the patient (and corresponding size of the ear canal), and inappropriate technique.¹⁵ Use of tympanic thermometers is not recommended in infants younger than 6

months, in whom the ear canal is not fully developed, leading to inappropriate technique and inaccurate readings. Although not as reliable as the rectal method in children, if used correctly, tympanic thermometry has been found to be more accurate than axillary or oral thermometry in estimating core temperature.²⁰

Table 6–5 Guidelines for Tympanic Temperature Measurement

1. Place a clean disposable lens cover over ear probe or clean probe per manufacturer directions.
2. Turn on thermometer and wait until it is ready for use.
3. For children *6 months to 1 year*, pull ear straight backward to straighten ear canal. Place ear probe into canal, aiming the tip of the probe toward the patient's eye on that side.
4. For patients *older than 1 year*, pull ear backward and then upward to straighten ear canal. Place the ear probe into canal, aiming the tip of probe toward the patient's eye.
5. Press the button for temperature measurement (which usually appears after only 1–5 seconds).
6. Read and record temperature.
7. Discard lens cover.

Source: Reference 15.

Temporal touch thermometers are placed on the side of the forehead directly over the temporal artery and moved across the forehead (**Table 6–6**). The temporal artery is directly supplied by the hypothalamus and is near the surface of the skin at the side of the head, permitting surface measurement using infrared technology. The temporal thermometer is capable of providing a reading in a few seconds. The rapid, noninvasive nature of this method makes temporal touch a preferred route of temperature measurement for most patients, and the temporal thermometer is significantly more sensitive than the tympanic thermometer for detecting fever in infants.²⁵ Of note, however, temporal temperature measurement still has not shown superiority or greater reliability over the rectal method.²¹ Temporal temperatures may differ from rectal temperatures by $\pm 2.3^{\circ}\text{F}$ (1.3°C).^{22,23} The presence of hair near the temporal area may confound the temperature reading, so hair must be pushed away before a reading is obtained.

Table 6–6 Guidelines for Temporal Artery Temperature Measurement

1. Allow thermometer to acclimatize to the environment for about 30 minutes if the thermometer was moved from a hot room to a cold room or vice versa.
2. Remove protective cap and clean probe per manufacturer directions.
3. Place probe on one side of forehead midway between hairline and eyebrows.
4. Depress button and hold while scanning for the temporal artery temperature.
5. Lightly sweep thermometer across forehead to the hairline on the opposite side of the head. Ensure that probe remains in contact with skin at all times, and hold button down until scanning is completed.
6. If sweat is visible on the forehead, sweep the thermometer as normal, but nestle the thermometer on the neck directly behind the ear lobe before releasing the button.
7. Lift thermometer, release the button, and document the recorded temperature.

Source: References 15 and 19.

No-touch infrared thermometers do not require contact of the device with the body for measurement. Temperature is measured by aiming the thermometer at the center of the patient's forehead. Certain models may also allow use of alternative sites such as the navel and neck, although readings at these sites are less accurate.¹⁵ Although no-touch infrared thermometers are convenient and less invasive, a study of children 1 month to 4 years of age treated in the emergency department found no-touch infrared thermometers to be less accurate and reliable than rectal measurement.²⁶

Axillary temperature measurement is frequently used by caregivers and in ambulatory settings, because it is relatively noninvasive. However, axillary measurement performed with digital thermometers (**Table 6–7**) is not as reliable for detecting fever compared with the oral and rectal methods.^{27,28} Reported large variations in temperatures taken by the axillary method are attributable to inappropriate placement of the thermometer, movement of the arm during measurement leading to a poor seal around the thermometer, and insufficient duration of the measurement period. Axillary temperature should not be taken directly after vigorous activity or bathing because both can affect body temperature temporarily without altering the thermoregulatory set point at the hypothalamus. If a fever is detected with the axillary method, a confirmation reading using another method is recommended.

Table 6–7 Guidelines for Axillary Temperature Measurement Using Electronic Thermometer

1. Place a clean disposable probe cover over tip of thermometer or clean probe per manufacturer directions.
2. Turn on thermometer and wait until it is ready for use.
3. Place tip of thermometer in armpit. Ensure that armpit is clean and dry. Thermometer must be touching skin, not clothing.
4. If taking a child's temperature, hold the child close, if necessary, to secure the thermometer within the armpit.
5. Read and record temperature when thermometer beeps.

Source: Reference 15.

Complications of Fever

The presence of fever is of great concern among caregivers, although in most cases fever typically is self-limiting and serious complications are rare. In one study, 73% of caregivers were “very concerned” about the potential complications of fever, and 88% were “very concerned” when a child’s fever was not reduced by antipyretics. There is less concern about complications of fever now than 20 years ago; however, interviewed caregivers still perceived seizures (32%), brain damage (15%), and death (16%) as the main complications of fever.²⁹ Overall, the major risks associated with fever are rare but may include acute complications such as seizures, dehydration, and change in mental status.

Febrile seizure is defined as a seizure accompanied by fever in infants or children who do not have an intracranial infection, a metabolic disturbance, or an otherwise defined cause.³⁰ Febrile seizures occur in 2%–5% of all children from the ages of 6 months to 5 years, with peak occurrence in the age range of 18–24 months. Risk factors for a first febrile seizure include daycare attendance, developmental delay, a family history of febrile seizure, and a neonatal hospital stay longer than 30 days. The severity of the fever and the rate of temperature increase also appear to be critical determinants in the precipitation of a first febrile seizure.³¹ The most common seizures associated with fever are simple febrile seizures, which are characterized by nonfocal movements, generally less than 15 minutes in duration, with only one episode in a 24-hour period.

Significant neurologic sequelae (e.g., impaired intellectual development, epilepsy) are unlikely after a single pediatric febrile seizure. The risk of recurrence is increased in children who have had multiple febrile seizures, are younger than 1 year at the time of their first seizure, and have a family history of epilepsy. Antipyretics generally are recommended to make the child more comfortable, although they do not reduce the risk of recurrent febrile seizures.^{30,32,33} Prophylaxis against simple febrile seizures with antiepileptic or antipyretic drugs is not recommended by the American Academy of Pediatrics.³⁰

Serious detrimental effects (e.g., dehydration, delirium, seizures, coma, irreversible neurologic or muscle damage) occur more often in patients with hyperpyrexia (temperatures >106.0°F [41.1°C; oral]), which is usually associated with hyperthermia and not fever. Because of the homeostatic mechanisms of the hypothalamus, a core temperature exceeding 106.0°F (41.1°C; oral) in a febrile person is rare. Even body temperature elevations of lesser magnitude, however, may be life-threatening in patients with heart disease or pulmonary dysfunction. Increased risk of complications is recognized in infants and patients with brain tumors or hemorrhage, CNS infections, preexisting neurologic damage, and a decreased ability to dissipate heat in concert with lower tolerance of elevated body temperature. Older patients are at a higher risk for fever-related complications because of their decreased thirst perception and ability to perspire.^{6,34}

Treatment of Fever

Overall treatment of fever should focus on the primary cause, rather than on the temperature reading itself. No correlation exists between the magnitude and pattern of temperature elevation (i.e., persistent, intermittent, recurrent, prolonged) and the principal etiologic disorder or severity of the disease. Consequently, determining the cause of the fever on the sole basis of the temperature reading is difficult.

The decision to treat fever is based on a patient-specific risk-benefit ratio and the desire to improve comfort.³⁵ Fever is not associated with many harmful effects unless the temperature exceeds 106.0°F (41.1°C; oral); most fevers are of short duration and may actually have beneficial effects on host defense mechanisms (e.g., antigen recognition, T-helper lymphocyte function,

leukocyte motility). Certain microbes are thermolabile, and their growth may be impaired by higher-than-normal temperatures. Accordingly, overtreatment of fever for viral and bacterial infections may be detrimental.³⁵ Other arguments against treatment include the generally benign and self-limited course of fever, the delayed identification of the diagnosis, and the untoward effects of antipyretic medications.³⁶

Treatment Goals

The major goal of self-treatment is to alleviate the discomfort of fever, rather than treating to achieve a specific temperature.^{35,37}

General Treatment Approach

Treatment of fever using antipyretics (see [Chapter 5](#), Tables 5–2 and 5–3) is most often indicated for patients with elevated temperatures who have an underlying medical problem such as heart or lung disease or have discomfort.³⁸ Fever may be treated with antipyretic agents as well as nonpharmacologic measures.

Self-care measures, including antipyretics, are appropriate initial therapy, unless the patient has exclusions for self-treatment ([Figure 6–1](#)).^{35,37,39} In all cases, self-care measures should be started while medical evaluation is being sought.

Nonpharmacologic Therapy

Nonpharmacologic therapy consists mainly of adequate fluid intake to prevent dehydration. Sponging or baths have limited utility in the management of fever. Body sponging with tepid water may facilitate heat dissipation, in that only a small temperature gradient between the body and the sponging medium is necessary to achieve an effective antipyretic response. However, sponging is not routinely recommended for patients with a temperature less than 104.0°F (40°C; oral); sponging is usually uncomfortable and often induces shivering, which could raise body temperature further. Bathing with ice water or sponging with hydroalcoholic solutions (e.g., isopropyl or ethyl alcohol) is uncomfortable, dangerous, and not recommended owing to risk of cutaneous absorption. Unlike with acetaminophen and nonsteroidal anti-inflammatory drugs (NSAIDs), sponging does not reduce the hypothalamic set point;

therefore, implementation of this measure, if utilized, should be delayed until 1 hour after an oral antipyretic dose, to permit appropriate reduction of the hypothalamic set point and promote a more sustained temperature-lowering response.⁴⁰

Other nonpharmacologic interventions, regardless of the temperature reading, include wearing lightweight clothing, removing blankets, maintaining a comfortable room temperature of approximately 68.0°F (20.0°C), and drinking sufficient fluid to replenish insensible losses. Because a fever will cause a child to lose fluids more rapidly, sufficient fluid intake is recommended to avoid dehydration. Fluid intake in fever should be increased by at least 30–60 mL (1–2 ounces) of fluids per hour in children and by at least 60–120 mL (3–4 ounces) of fluids per hour in adults, unless fluids are contraindicated. Sports drinks, fruit juice, water, balanced electrolyte replacement products, or ice pops may be offered. Milk should also be offered to children who are still on formula or breastfeeding. Caution should be exercised in recommending fruit juice and sports drinks to patients with diarrhea; drinks with high sugar loads may worsen concurrent diarrhea.³⁸

Pharmacologic Therapy

Antipyretics inhibit PGE₂ synthesis, which decreases the feedback between the thermoregulatory neurons and the hypothalamus, thereby reducing the hypothalamic set point during fever. All antipyretics decrease the production of PGE₂ by inhibiting the cyclooxygenase (COX) enzyme. NSAIDs including aspirin inhibit the COX enzyme in both the peripheral nervous system and CNS, whereas acetaminophen mainly inhibits the COX enzyme in the CNS.⁴¹ Chapter 5 provides an in-depth discussion of the pharmacokinetics, dosing, adverse effect profile, interactions, contraindications, and precautions for nonprescription antipyretic agents.

Acetaminophen typically effects a maximum temperature reduction at 2 hours at usual recommended dosing of 10–15 mg/kg every 4–6 hours, with a maximum of 5 doses daily (see Chapter 5, Tables 5–2 and 5–3). Approximately 80% of children will experience a reduction in their fever with this regimen.³⁵ Adult dosing ranges from 325 mg to 1000 mg every 4–6 hours, up to a maximum of 4000 mg daily. Some providers have recommended loading doses of acetaminophen for the reduction of fever at 30 mg/kg per dose, after a small study found a faster (one-half hour) and more significant (0.9°F [0.5°C])

decrease than that achieved with a traditional dose.⁴² This practice is not recommended, however, because of the lack of any follow-up evidence of benefit, as well as the small size and limitations of the study.

Acetaminophen also is available in rectal suppository form. Although a suppository may be an advantage for parents and caregivers who have problems giving their children oral medications, or for children who are vomiting or are having a febrile seizure, absorption with this dosage form is erratic, and studies on its antipyretic activity have yielded conflicting findings.⁴³

Ibuprofen is the most common NSAID used as an antipyretic; maximum temperature reduction typically is achieved at 2 hours at the recommended dosing of 5–10 mg/kg per dose every 6–8 hours, with a maximum of 4 doses per day (see [Chapter 5](#), Tables 5–2 and 5–3). Of note, ibuprofen is approved for the reduction of fever only in patients older than 6 months, and patients and caregivers should recognize the two different pediatric concentrations of ibuprofen available (100 mg/5 mL and 50 mg/1.25 mL). Adult dosing ranges from 200 to 400 mg every 4–6 hours, up to a maximum of 1200 mg daily.

Although NSAIDs and acetaminophen are safe and effective when taken at low doses for short-duration therapy, they should not be used for more than 3 days to treat fever without medical referral for further evaluation to determine the underlying cause. Common medication errors associated with use of nonprescription antipyretics include overdosing or duplicating therapy, attributed to using multiple products with similar ingredients, and inappropriate dosing for pediatric patients, attributed to mathematical errors in calculating a weight-based dose. A study of dosing by parents demonstrated that 51% of pediatric patients received an inaccurate dose of medication (62% for acetaminophen and 26% for ibuprofen).⁴⁴ Because of these alarming statistics, an important function for pharmacist health care providers is to demonstrate to patients and caregivers proper dosing and measurement of the medications with the measuring device provided. In addition, patients should be educated on the appropriate dosing interval and the avoidance of combining antipyretics with cold and cough products containing either acetaminophen or ibuprofen. Furthermore, owing to safety concerns, FDA issued a guidance statement to companies that manufacture, market, or distribute nonprescription liquid medications regarding the dispensing devices that accompany the drug products. Specifically, FDA

recommends that dosage delivery devices such as cups and syringes be included with all nonprescription liquid medications, marked with clear and appropriate calibrated units, and used only with the accompanying medication.⁴⁵

Pharmacotherapeutic Comparison

Both ibuprofen and acetaminophen are more effective than placebo in reducing fever, with both showing reductions of approximately 1 or 2 degrees within 30 minutes to 1 hour. Clinical trials comparing the antipyretic effects of ibuprofen and acetaminophen in recommended dosages have produced variable results, making conclusions on superiority of one or the other agent difficult. A review of the findings in 14 clinical trials comparing ibuprofen and acetaminophen in febrile children found that ibuprofen was slightly more effective than acetaminophen in reducing fever after a single dose; furthermore, ibuprofen was found to be more effective after 6 hours, thus showing a longer duration of action.⁴⁶ The same review found that multiple-dose studies failed to show any statistically significant clinical difference. The risk of serious adverse effects did not differ between the medications. The investigators concluded that the efficacy and safety of acetaminophen and of ibuprofen are similar at recommended dosages, with slightly more benefit for ibuprofen in time to onset of effect and duration of action and fever reduction; however, more conclusive findings are needed. A meta-analysis of data for both children and adults also concluded that ibuprofen was more efficacious than acetaminophen in the reduction of fever in both adults and children and that both were equally safe.⁴⁷ Although ibuprofen has been studied most frequently, other NSAIDs (e.g., naproxen, aspirin) may also be appropriate as antipyretics in adults.

Alternating different antipyretics in the same regimen has become a widespread practice. A survey of 256 caregivers showed that 67% alternated acetaminophen and ibuprofen, and 81% stated that their primary care provider or pediatrician advised them to do so. Although alternating the antipyretics was recommended, only 61% of caregivers received any type of written instructions on how to dose the medications, and the dosing intervals varied, ranging from 2 to 6 hours.⁴⁸ Despite those practices and clinical trials showing lower temperatures at 4 or more hours with combination therapy, the American Academy of Pediatrics does not recommend alternating antipyretics because of the risk of overdose, medication errors resulting from the

complexity of the regimens, and an increased rate of adverse effects.^{35,44} In addition, only one study actually showed less stress and time missed from day care with alternating therapy.⁴⁹ HCPs should be prepared to provide counseling on the practical application of alternating antipyretics if the patient or caregiver has been instructed to use this regimen by a primary care provider. For example, caregivers should be encouraged to write down the generic name, dose, and time of administration for each medication, to minimize the likelihood of duplicate dosing and adverse effects.

The use of antipyretics immediately after vaccine administration is a widespread practice meant to reduce anticipated discomfort and fever. Two open-label randomized trials found that the administration of acetaminophen was effective in reducing febrile episodes, but it also significantly reduced the antibody response to several vaccines, although all levels achieved were still considered protective.⁵⁰ The clinical significance of these antibody reductions is still unknown; nevertheless, the Advisory Committee on Immunization Practices (ACIP) discourages the use of antipyretics before or at the time of vaccination.⁵¹ Symptomatic postvaccination reactions may still be treated with antipyretics until additional data indicate otherwise.

Product Selection Guidelines

Age is an important consideration in the utilization and/or selection of an antipyretic, particularly for neonates. Parents and caregivers of children younger than 3 months of age should immediately seek medical evaluation for rectal temperatures or their equivalent of 100.4°F (38.0°C) or higher. Children older than 3 months with a rectal temperature or equivalent of 104.0°F (40.0°C) or higher should also be referred. Ibuprofen should be used only in children older than 6 months; because of the risk of Reye's syndrome, children and teenagers who have or are recovering from chicken-pox or influenza-like symptoms should not use aspirin or aspirin-containing products.⁵² (See [Chapter 5](#) for a complete discussion of these products.) Special populations of patients, such as pregnant women and older adults, may require additional consideration in assessing fever and referring their care. Specifically, as previously stated, fever may be blunted in older patients, thereby predisposing them to a greater risk of complications if a more serious underlying disorder goes unrecognized. In addition, pregnant women or patients with uncontrolled high blood pressure, heart failure, renal failure, or an allergy to aspirin should avoid use of NSAIDs, including aspirin-containing products. A

detailed description of additional criteria for the appropriate use of antipyretic agents in special populations is available in [Chapter 5](#).

The choice of an antipyretic depends on the patient, since both are safe and effective. Both acetaminophen and ibuprofen are available in a variety of dosage forms and flavors for both children and adults, including tablets, chewable tablets, suspensions, and even suppositories. Selection of a dosage form can be left to patient preference. Consideration of palatability and the taste of the different ibuprofen and acetaminophen suspensions may improve outcomes and adherence to antipyretic regimens in children. (See [Chapter 11](#) under “Special Populations,” for FDA requirements for dispensing devices included in liquid nonprescription products.) The more favorable dosing frequency for ibuprofen of once every 6–8 hours, versus that for acetaminophen of once every 4–6 hours, may also improve adherence and can be considered in product selection, especially in children who have difficulty taking medicine.

Complementary Therapies

Currently, insufficient evidence exists to recommend any dietary supplement or other complementary therapy to treat fever.

Algorithm: Fever

Figure 6–1 Self-care for fever. Key: CNS = Central nervous system; CV = cardiovascular; D/C = discontinue; HIV = human immunodeficiency virus.

Assessment of Fever: A Case-Based Approach

The first step in assessing a patient with fever-related symptoms is to obtain an objective temperature measurement to confirm the presence of fever and rule out any subjective sense of increased body temperature or an inaccurate thermometer reading. If fever is present, assessment of its severity, the seriousness of the underlying cause, and other associated symptoms is indicated. Children who are capable of providing and understanding

information should be included in any dialogue concerning their care.

Cases 6–1 and 6–2 are examples of the assessment of two different patients presenting with fever.

Case 6–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A worried mother reports that her son Colin came home today after school complaining of not feeling well. She noticed Colin seemed more tired than usual and did not have much of an appetite. She states that before today, Colin was feeling healthy and well. Colin's mother also noticed that his forehead felt warm. When she took Colin's temperature with a tympanic thermometer, it was 102.4°F.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Colin's mom cannot identify anything that makes his symptoms worse or provides relief.
c. Description of the patient's/caregiver's efforts to relieve the symptoms	Neither Colin nor his mother had tried anything to treat his fever up to this point.
d. Patient's identity	Colin Betts
e. Patient's age, gender, height, and weight	12 years, male, 5 ft 1 in., 95 lb
f. Patient's occupation	Colin attends sixth grade.
g. Patient's dietary habits	Normal diet, but he has decreased appetite today.

Relevant Evaluation Criteria	Scenario/Model Outcome
h. Patient's sleep habits	Normal sleep patterns, but he is more tired today.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Seasonal allergies Loratadine 10 mg by mouth once every morning
j. Allergies	NKDA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Colin also complains of a dull headache that just started this morning. You retake his temperature in the pharmacy using an oral thermometer, which reads 102.1°F.
Assess	
2. Differentiate the patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Colin is experiencing symptoms associated with a fever. When asked, he denies noticing any additional signs or symptoms, suggestive of a more serious illness, that would warrant immediate medical attention.
3. Identify exclusions for self-treatment (Figure 6-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a primary care provider is required, and share this information with the patient/caregiver	Options include (1) Refer Colin for immediate medical attention. (2) Monitor his symptoms and fever, and recommend nondrug measures only. (3) Recommend a medication alone or in combination with nondrug measures. (4) Take no action.
Plan	

Relevant Evaluation Criteria	Scenario/Model Outcome
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient/caregiver preferences.	Colin has a fever and is experiencing some discomfort. He has no exclusions for self-care at this time (Figure 6-1), so treatment with either acetaminophen or ibuprofen is appropriate. Drug therapy should be used in conjunction with nondrug measures. He should not receive any aspirin-containing medications.
6. Describe the recommended therapeutic approach to the patient/caregiver.	See Table 5-2 in Chapter 5 for recommended doses of acetaminophen or ibuprofen. "If fever persists for longer than 72 hours with or without treatment, Colin should be seen by a primary care provider"
7. Explain to patient/caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Colin has a fever that is causing some discomfort, so minimizing the fever with an antipyretic medication, either acetaminophen or ibuprofen, should help. His pediatrician should be contacted if his fever gets worse or persists for longer than 72 hours or if he complains of other symptoms, such as a stiff neck, severe headache or sore throat, or severe ear pain, or if an unexplained rash or repeated vomiting or diarrhea develops."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient/caregiver.	
a. Appropriate dose and frequency of administration	"You can give Colin regular strength acetaminophen tablets (325 mg per tablet). Give 2 tablets every 4-6 hours while symptoms last. Do not exceed 5 doses per 24 hours."
b. Maximum number of days the therapy should be employed	"Do not give Colin the medication for more than 3 days."
c. Product administration procedures	"If Colin cannot swallow tablets, chewable tablets and liquid are available options. Colin should swallow the tablet completely, followed by drinking a full glass of water."

Relevant Evaluation Criteria	Scenario/Model Outcome
d. Expected time to onset of relief	"A reduction in temperature with some relief of discomfort usually occurs within 1/2 to 1 hour. Maximum reduction is usually seen within 2 hours."
e. Degree of relief that can be reasonably expected	"A 1- or 2-degree reduction in temperature is expected, but complete resolution of symptoms may or may not be achieved, depending on the underlying cause of the fever."
f. Most common adverse effects	"Adverse effects are rare, but gastrointestinal effects such as upset stomach or rash are possible. Colin can take the medication with food if an upset stomach occurs."
g. Adverse effects that warrant medical intervention, should they occur	"Contact your primary care provider if signs of an allergic reaction, such as a rash or trouble breathing, occur after a dose is given."
h. Patient's options in the event that condition worsens or persists	"Contact your primary care provider if the fever persists or symptoms worsen beyond 72 hours."
i. Product storage requirements	"Keep medication in a tightly secured container away from any extreme temperatures and out of reach of children."
j. Specific nondrug measures	"Maintain room temperature at 68°F. Encourage adequate fluid intake and have him dress in lightweight clothing."
Solicit follow-up questions from patient/caregiver.	"I read on my favorite 'Mommy Blog' that I can check Colin for fever by feeling his forehead with my palm, which is a lot easier than using that ear thermometer! Is that ok?"
Answer patient's/caregiver's questions.	"You should not use your hand to measure his temperature. This practice is called tactile temperature measurement, and it will not give an accurate representation of his temperature, since your sense of the warmth of his skin may be affected by your own body temperature. If he does not like the ear thermometer, we have many other options, which I am happy to show you how to use."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Colin's mother in 1-2 days to see if Colin's fever is

Relevant Evaluation Criteria	Scenario/Model Outcome
	responding.

Key: NKDA = No known drug allergies.

Case 6–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Mrs. Martinez approaches the pharmacy counter looking for a medication to treat her child's fever. She says her daughter, Ryann, woke up this morning with a red rash on her tummy, arms, and legs and has not been eating. When taking Ryann's temperature orally for the past 5 days, she had temperature readings of 101.4°F, 101.6°F, 102.1°F, 101.7°F, and 101.5°F. Mrs. Martinez does not want to "bother" Ryann's pediatrician since the medical office is "always so busy."
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Ryann's mother states lukewarm baths seem to temporarily soothe Ryann; however, this has not helped to bring down Ryann's temperature.
c. Description of the patient's/caregiver's efforts to relieve the symptoms	Mrs. Martinez has given Ryann 10 mL (2 teaspoonsful) of Children's Advil liquid (100 mg/5 mL) every 6 hours.

Relevant Evaluation Criteria	Scenario/Model Outcome
d. Patient's identity	Ryann Martinez
e. Patient's age, gender, height, and weight	5 years, female, 42 in., 40 lb
f. Patient's occupation	n/a
g. Patient's dietary habits	Ryann eats 3 meals a day with 2 or 3 snacks in between.
h. Patient's sleep habits	Usually sleeps at least 8–9 hours every night, but during the last few nights, she has been getting only 4–5 hours of sleep and takes 30-minute naps during the day.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Advair Diskus 100/50 mcg 1 inhalation twice a day and ProAir HFA 2 puffs every 4 to 6 hours as needed for mild persistent asthma
j. Allergies	NKDA
k. History of other adverse reactions to medications	None reported
l. Other (describe)	n/a
Assess	
2. Differentiate the patient's signs and symptoms, and correctly identify the patient's primary problem(s).	Ryann has a fever that is concerning because of its duration despite treatment; the recent appearance of a skin rash also is concerning.
3. Identify exclusions for self-treatment (Figure 6-1).	Fever lasting for more than 72 hours and skin rash
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a primary care	Options include (1) Refer Ryann to her pediatrician. (2) Refer Ryann to a hospital emergency department for immediate medical attention.

Relevant Evaluation Criteria	Scenario/Model Outcome
provider is required, and share this information with the patient/caregiver.	(3) Monitor her symptoms and fever, and recommend nondrug measures only. (4) Recommend a medication alone or in combination with nondrug measures. (5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient/caregiver preferences.	Ryann has exclusions for self-care: (1) persistent fever lasting more than 72 hours and (2) appearance of a skin rash. Ryann's mother should contact her pediatrician immediately to rule out any serious conditions.
6. Describe the recommended therapeutic approach to the patient/caregiver.	"No medication is recommended at this time. Immediate medical referral is indicated."
7. Explain to the patient/caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Ryann has a fever that has persisted longer than 72 hours even after treatment with appropriate medication, and a skin rash that appeared today."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient/caregiver.	
a. Appropriate dose and	None recommended

Relevant Evaluation Criteria	Scenario/Model Outcome
frequency of administration	
b. Patient's options in the event that condition worsens or persists	"If fever worsens or continues without improvement, you should take Ryann to a hospital emergency department after speaking with the pediatrician."
c. Specific nondrug measures	"Maintain a room temperature of 68.0°F, and dress her in lightweight clothing."
Solicit follow-up questions from patient/caregiver.	"Can I try giving Ryann ibuprofen (Advil) liquid and acetaminophen (Tylenol) liquid at alternating times until I can get her to her pediatrician?"
Answer patient's/caregiver's questions.	"Alternating between acetaminophen and ibuprofen has not been proven to help children feel better faster, and it may increase risk of adverse effects. I am concerned Ryann may require additional treatment that is not available over the counter. Please call your pediatrician immediately."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mrs. Martinez in 1-2 days to ensure that she sought medical care for Ryann.

Key: n/a = Not applicable; NKDA = no known drug allergies.

Patient Counseling for Fever

Although fever is a common presenting symptom, it often is misunderstood and poorly treated. Studies suggest that fever may be incorrectly considered a disease associated with detrimental consequences, is frequently treated inappropriately, and is evaluated improperly.⁵³ Many parents and caregivers have "fever phobia," characterized by heightened anxiety regarding effects of fever and in consequent inappropriate treatment.²⁹

Pharmacists as health care providers are well poised to improve clinical outcomes by educating patients and caregivers about fever and by teaching self-assessment skills (e.g., the proper methods for measuring body temperature using the variety of thermometers available, as well as interpretation of the results). If patients and caregivers are still using mercury-in-glass thermometers, they should be urged to dispose of these devices according to local environmental standards. Patient counseling also should include an explanation of the appropriate nonpharmacologic and pharmacologic treatments for fever and should identify indications for seeking further medical care. Discussions of pharmacologic treatments should highlight methods for safe use of antipyretics and nonpharmacologic therapy. The box “Patient

Education for Fever” provides specific information to include in patient counseling.

Evaluation of Patient Outcomes for Fever

The primary monitoring parameters for febrile patients are temperature and discomfort. In one study, 32% of caregivers stated that they would check a febrile patient’s temperature at least every hour.²⁹ Overaggressive monitoring may result from “fever phobia.” Because fever may actually be of physiologic benefit, the ultimate goal of antipyretic therapy is not to normalize temperature but rather to improve overall comfort and well-being.³⁵ The presence of any associated signs and symptoms (e.g., headache, diaphoresis, generalized malaise, chills, tachycardia, arthralgia, myalgia, irritability, anorexia) should also be monitored daily. Although most patients demonstrate a reduction in temperature after each individual dose of an antipyretic, pharmacologic therapy for fever may take up to 1 day to result in core temperature decrease. If clinical improvement is not obtained or if symptoms worsen over the course of 3 days of self-treatment, regardless of a drop in temperature, a primary care provider should be consulted by either phone or appointment for further evaluation.³⁹ Timeliness of patient follow-up assessment with appropriate medical care is important in identifying a non-self-limiting underlying cause.

Patient Education for Fever

The primary objectives of treating fever are (1) to relieve the discomfort of fever and (2) to prevent complications associated with fever. For most patients, carefully following product instructions and the self-care measures listed here will help to ensure optimal therapeutic outcomes.

Temperature Measurement

- Do not rely on skin contact to detect fever. Take a temperature reading with an appropriate thermometer.
- For children up to 3 months of age, the rectal method of temperature measurement is preferred ([Table 6–3](#)). Use of a tympanic thermometer is not recommended in children younger than 6 months because of the specific size and shape of the infant's ear canal.
- For children ages 6 months to 3 years, the rectal, oral, tympanic, or temporal method may be used if proper technique is followed ([Tables 6–3 through 6–6](#)).
- For patients older than 3 years, the oral, tympanic, or temporal method is appropriate ([Tables 6–4 through 6–6](#)).

Nondrug Measures

- Do not use isopropyl or ethyl alcohol for body sponging. Alcohol poisoning can result from skin absorption or inhalation of aerosols from topically applied alcohol solutions.
- For all levels of fever, wear lightweight clothing, remove blankets, and maintain room temperature at 68°F.
- Unless advised otherwise, drink or provide sufficient fluids to replenish body fluid losses. For children, increase fluid intake by at least 1–2 ounces per hour; for adults, increase intake by at least 2–4 ounces per hour. Sports drinks, fruit juice, a balanced electrolyte formulation, and water all are acceptable.

Nonprescription Medications

- Nonprescription analgesics and antipyretics, specifically acetaminophen and ibuprofen (see [Chapter 5](#), Tables 5–2 and 5–3, for dosages), help in alleviating discomfort associated with fever and reducing the temperature, respectively.
- Nonprescription analgesics and antipyretics typically take 30 minutes to 1 hour to begin to decrease discomfort and lower body temperature.
- Monitor level of discomfort and body temperature using the same thermometer at the same body site 2 or 3 times per day during a febrile illness.
- Use single-entity nonprescription analgesics and antipyretics at low doses for up to 3 days for treatment of fever (see [Chapter 5](#), Tables 5–2 and 5–3 for dosages), in the absence of any exclusions for self-care ([Figure 6–1](#)).
- Avoid alternating antipyretics because of the complexity of the dosing regimens, increased risk of medication errors, and adverse effects.
- Dosing of either ibuprofen or acetaminophen in children should be based on body weight, not age.
- To avoid incorrect dosing, use the measuring device that was provided with the product, such as a syringe, dosing spoon, or medicine cup, for administering liquid medication.
- Patients who are pregnant or have uncontrolled high blood pressure, congestive heart failure, renal failure, or an allergy to aspirin should avoid use of nonsteroidal anti-inflammatory drugs (ibuprofen and naproxen sodium) or aspirin-containing products.
- To avoid the possible risk of Reye’s syndrome, do not use aspirin or aspirin-containing products for fever in children and teenagers who have or are recovering from chickenpox or an influenza-like illness.

When to Seek Medical Attention

- Seek medical attention if fever or discomfort persists or worsens after 3 days of drug treatment.

Key Points for Fever

- Fever is self-limiting and rarely poses severe consequences unless the core temperature is greater than 106.0°F (41.1°C; oral).
- The main treatment goals for fever are to alleviate the associated discomfort and to eliminate the underlying cause.
- Fever should be confirmed only by means of a thermometer, which is an FDA-regulated medical device.
- Patients should be educated on the proper measurement techniques for the selected thermometry method.
- Patients should be referred for further evaluation if the rectal temperature or its equivalent is greater than 104.0°F (40.0°C), they have a history of febrile seizures, they have comorbid conditions compromising their health, or they are younger than 3 months of age with a rectal temperature exceeding 100.4°F (38.0°C) or its equivalent.
- Sponge baths using topical isopropyl or ethyl alcohol to reduce fever should be discouraged.
- Acetaminophen and ibuprofen are both safe and efficacious nonprescription medications that may be used as antipyretics in both adults and children.
- Referral for further medical evaluation is appropriate to detect an underlying cause if self-treatment for 3 days does not successfully reduce fever in a patient older than 2 years and for at least 24 hours in a child younger than 2 years of age.
- Health care providers should counsel patients on the proper use of nonprescription antipyretic agents (including appropriate use of measuring devices), to limit medication errors and adverse effects. For patients for whom concomitant use of alternate antipyretic therapies has been recommended, counseling should emphasize the importance of recording the generic name of each

drug given, the dose, and the time of administration, to avoid any adverse effects.

Chapter 7: Musculoskeletal Injuries and Disorders

Authors: Julie L. Olenak, Nicole C. Pezzino

Pain is one of the most common reasons for visits to health care providers, including today's pharmacists. Because pain is a common symptom of disease or injury, affected patients often seek medical attention, although many seek to relieve the pain by self-treating with nonprescription analgesics. In a large number of cases, the pain that prompts efforts at self-treatment arises from the musculoskeletal system. Musculoskeletal pain may be felt in the affected tissue itself or referred from another anatomic source (e.g., hip pain referred from its primary source in the low back).¹

Musculoskeletal pain arises from the muscles, bones, joints, and connective tissue. The development of musculoskeletal pain can be acute, such as with sports injuries (e.g., tendonitis, sprains, strains), or it can stem from exacerbation of a pathologic condition (e.g., osteoarthritis). *Acute* pain is typically defined as pain lasting less than 4 weeks. Subacute pain is that experienced in the period after acute pain, lasting up to 3 months. Pain lasting at least 3 months is considered *chronic* pain, which may arise from degenerative joint disease, osteoarthritis, or chronic tendonitis (e.g., carpal tunnel syndrome).¹

The rate of use of nonprescription systemic and topical analgesics remains high, with more than \$4171 million and \$858 million spent, respectively, per year in the United States on such remedies.² The health care provider's assessment should include appropriate questions to identify the type of pain for which the patient is seeking treatment, to elucidate the nature of the pain complaints. In addition, reasonable recommendations should be presented for either self-treatment or further evaluation.

Musculoskeletal complaints result in a significant number of lost workdays, work limitations, loss of employment, and increased utilization of the health care system. These complaints are believed to be the greatest contributors to the economic burden of chronic pain. The total annual cost of persistent chronic pain for adults in the United States is estimated to be \$560 billion. Approximately 20% of adults report chronic pain.³

Pathophysiology of Musculoskeletal Injuries and Disorders

The musculoskeletal system includes the muscles, tendons, ligaments, cartilage, and bones. Muscles are attached to bones by tendons, and ligaments connect bone to bone. Tendons and ligaments normally have limited ability to stretch and twist. Because of their high tensile strength, tendons and ligaments rarely rupture unless subjected to intense forces. However, they may become damaged when the articulation (joint) is hyperextended or with overuse.

Synovial bursae are fluid-filled sacs located between joint spaces to provide lubrication and cushioning. Cartilage functions as protective pads between bones in joints and in the vertebral column.¹

Skeletal, or striated, muscle is composed of cells (myocytes) in which two constituents (actin and myosin) are primarily responsible for contraction. Muscle contraction also involves several electrolytes within the muscle tissue, including calcium and potassium. Pain receptors are located in skeletal muscle and the overlying fascia, and those receptors can be stimulated as a result of overuse or injury to the muscle or surrounding structures.¹

Somatic pain occurs when pain impulses are transmitted from peripheral nociceptors to the central nervous system (CNS) by nerve fibers. Common sites of origin are muscles, fascia, and bones. Somatic pain is most commonly myofascial (e.g., with muscle strain) or musculoskeletal (e.g., with arthritis).¹

Mechanoreceptors and chemoreceptors mediate muscle pain. These nerve endings are heterogeneous in nature: Only a single chemical can stimulate some endings, whereas a variety of chemical, mechanical, and thermal triggers can stimulate others.¹

Erythema (redness), edema, and hyperalgesia (an exaggerated pain response to minor amounts of noxious stimuli) at the affected site characterize the inflammatory response. The inflammatory response develops through participation of multiple mediators, including histamine, bradykinin, serotonin, leukotrienes, and prostaglandin E.¹

Overexertion or *repeated unaccustomed eccentric muscle contraction* is associated with delayed-onset (8 hours or more) muscle soreness, which can last for days, usually peaking at 24–48 hours. This pain reflects muscle damage that presumably was initiated by force generated in the muscle fibers; pathophysiologic components are thought to include inflammation, acidosis, muscle spasms, and/or microlesions. Prolonged tonic contraction produced by exercise, tension, or poor posture and by improper body mechanics can also produce muscle pain. Overexertion injury is common among people who do not exercise regularly but then begin an exercise regimen at a level of high intensity.

Myalgia, or *muscle pain*, can result from systemic infections (e.g., influenza), chronic disorders (e.g., fibromyalgia, polymyalgia rheumatica), and medication effects (e.g., with some cholesterol-lowering agents such as hydroxymethylglutaryl-coenzyme A [HMG-CoA] reductase inhibitors). Abuse of alcohol may precipitate acute alcoholic myopathy. Bone and muscle pain also may be related to vitamin D deficiency, as in osteomalacia. In these conditions, the pain typically is widespread or bilateral in distribution and is not specifically associated with a recent injury.¹

Strains are a result of an injury to a muscle or a tendon. A strain can be caused by an acute injury, or with prolonged overuse, the pathoanatomic changes can result in a chronic condition. The movements that cause a strain involve twisting or pulling. Tendons can become strained when their stretch capacity is exceeded (e.g., hyperextension injury involving an arm or a leg). The strain injury is caused by eccentric contraction of the muscle fibers while the muscle itself is lengthening. A tear of the muscle or tendon also can occur.⁴

Tendonitis is the inflammation of a tendon, which results from acute injury or from chronic repetitive movements (overuse) of a body part. An example of an overuse injury is carpal tunnel syndrome, a condition characterized by tingling or numbness that initially appears in the thumb, index or middle fingers of the hand caused by repetitive use of the hand and wrist. Tendon sheaths become inflamed, with consequent constriction of the median nerve as it passes through a narrow channel between the wrist bones. Tendonitis can also commonly occur in the Achilles tendon, which connects the calf muscle to the heel.¹

Common terms that describe sports-related tendonitis from overuse include tennis elbow, golfer's elbow, swimmer's shoulder, and jumper's knee. In sports-

related overuse injuries, potential contributing factors for tendonitis include older age, poor technique, improper conditioning, exercise of prolonged intensity or duration, and poorly designed equipment for specific activities (e.g., inadequately cushioned athletic shoes).¹

Finally, certain medications (e.g., fluoroquinolone antimicrobials) are associated with the development of tendonitis or tendon rupture. For these medications, the U.S. Food and Drug Administration (FDA) requires the drug label to carry a boxed warning highlighting the risk of such injury.⁵

Bursitis is a common cause of localized pain, tenderness, and swelling in the affected joint, which are worsened by any movement of adjacent structures. Bursitis generally results from an acute injury to the joint or overrepetitive joint action. When pain is accompanied by a local puncture (as from intra-articular injection), a near-by source of infection, or severe inflammation, an infectious cause should be ruled out before self-treatment can be recommended.

Sprains are the most common problem with ligaments. Sprains are graded as follows: Grade I sprains result from excessive stretching, grade II sprains result from a partial tear, and grade III sprains involve a complete tear of the tissue. Grade II and grade III sprains typically are associated with moderate to severe pain, loss of function of the affected limb, and an inability to bear weight. Tears and ruptures are more common in ligaments than in tendons.⁶ Sprains commonly occur during physical activity. It is estimated that 25,000 ankle sprains occur daily.⁷

Low back pain is one of the most common reasons for which patients see their primary care provider. The National Institute of Arthritis and Musculoskeletal and Skin Disease reports that 25% of people report at least 1 day of back pain in a 3-month period.⁸

Main risk factors for the development of low back pain include sedentary lifestyle (particularly one disrupted by bursts of activity), poor posture, wearing improper shoes, excessive body weight, poor-quality mattress and faulty sleeping posture, and improper technique for lifting heavy objects. Most patients recover within a few days to a few weeks, even without treatment; pain that persists for more than 3 months is classified as chronic low back pain.⁹ Other causes of low back pain include congenital anomalies, osteoarthritis, vertebral fractures and compressions, spinal tuberculosis, and referred pain from diseased kidneys, pancreas, liver, or prostate.¹

Osteoarthritis is characterized by a gradual softening and destruction of the cartilage between bones. Over time, cartilage and bone are destroyed in the joint spaces and then regenerate, with consequent rearrangement of the synovial architecture. Often referred to as “degenerative joint disease,” osteoarthritis is caused by genetic, metabolic, and environmental factors. Heavy physical activity, repetitive movement, and lifting of heavy weights may aggravate this condition, whereas routine moderate exercise (i.e., walking, strengthening, neuromuscular training, aquatic, tai chi) does not and is generally beneficial.^{10,11} Approximately 54 million people older than 18 years of age in the United States have a diagnosis of various types of arthritis; by 2040, that number is expected to increase to 78 million.¹²

Clinical Presentation of Musculoskeletal Injuries and Disorders

Table 7–1 lists many of the presenting signs and symptoms of musculoskeletal disorders and other differentiating factors. Pain is a common symptom among all of these disorders.

Table 7–1 Comparison of Musculoskeletal Disorders					
Myalgia	Tendonitis	Bursitis	Sprain	Strain	Osteoarthritis
Location Muscles of the body	Tendon locations around joint areas	Inflammation of the bursae within joints; common locations include knee, shoulder, big toe	Stretching or tearing of a ligament within a joint	Hyperextension of a joint that results in overstretching or tearing the muscle or tendon	Weight-bearing joints, knees, hips, low back, hands
Signs Possible swelling (rare)	Warmth, swelling, erythema	Warmth, edema, erythema, and possible crepitus	Swelling, bruising	Swelling, bruising	Noninflammatory joints, narrowing of joint space, restructuring of bone and cartilage (resulting in joint deformities), possible joint

Myalgia	Tendonitis	Bursitis	Sprain	Strain	Osteoarthritis
					swelling
Symptoms Dull, constant ache (sharp pain relatively rare); weakness and fatigue of muscles also common	Mild-severe pain generally occurring after use; loss of range of motion	Constant pain that worsens with movement or application of external pressure over the joint	Initial severe pain followed by pain, particularly with joint use; tenderness; reduction in joint stability and function	Initial severe pain with continued pain upon movement and at rest; muscle weakness; loss of some function	Dull joint pain relieved by rest; joint stiffness <20-30 minutes; localized symptoms to joint; crepitus
Onset Varies depending on cause (e.g., trauma = acute, but drug-induced = insidious)	Often gradual, but can develop suddenly	Acute with injury; recurs with precipitant use of joint	Acute with injury	Acute with injury	Insidious development over years
Modifying Factors Elimination of cause; use of stretching, rest, heat, topical analgesics, systemic analgesics	Elimination of cause; use of stretching, rest, ice, topical analgesics, systemic analgesics	Joint rest; immobilization; topical analgesics; systemic analgesics	RICE; stretching; use of protective wraps (e.g., ankle tape, knee brace, cane); topical analgesics; systemic analgesics	RICE; stretching; use of protective wraps; topical analgesics; systemic analgesics	Continuous exercise (light-moderate activity); weight loss, heat, analgesic medication; topical pain relievers

Key: RICE = Rest, *ice*, compression, elevation ([Table 7-2](#)).

Source: References 1,4, and 11

In addition to the pain induced by a sprain, impairment of joint function of variable degree will be present. If an apparent sprain is associated with noticeably limited joint function, the injury is most likely to be a grade II or grade III sprain, necessitating proper workup to rule out a fracture or tear. If the affected joint is visibly deformed, emergency medical assistance is warranted.⁴

Patients with carpal tunnel syndrome often describe a diminished ability to feel heat or cold; a sense that the affected hand is swollen, despite the absence of visible change; a weakness in the hand that may affect performance of fine motor movements (e.g., buttoning a shirt); and a tendency to drop things. Symptoms persist during sleep and even when the hand is not being used, a characteristic that can be used to distinguish this disorder from others.

The pain of osteoarthritis does not correlate directly with the degree of joint damage. Pain is often referred, and proximal muscles can be involved if a person with osteoarthritis guards the affected joint by changing the gait to reduce discomfort. Low back pain can also be neuropathic in nature, involving the sciatic nerve, with sharp referred pain in one or both legs. Low back pain can often limit the patient's ability to bend, move, sit, or walk.^{1,8}

Complications of untreated pain-inducing injuries include further tissue damage and (in advanced arthritis) bone and cartilage remodeling. Pain is associated with significant limitations, including a reduction in ability to perform activities of daily living (ADLs), disability, loss of work time, and physical impairments (e.g., insomnia).

Treatment of Musculoskeletal Injuries and Disorders

Acute pain is the body's alarm system; it signals injury by trauma, disease, muscle spasms, or inflammation. Chronic pain, conversely, may or may not be indicative of injury and requires assessment by a primary care provider before treatment is initiated.

Treatment Goals

Treatment of the patient with musculoskeletal complaints encompasses many different goals, the most important of which are (1) decreasing the subjective intensity (severity) of pain; (2) decreasing the duration of pain, when possible; (3) restoring function of the affected area; (4) preventing reinjury and disability (i.e., improving capacity for ADLs); and (5) preventing acute pain from becoming chronic persistent pain.

General Treatment Approach

Patients with musculoskeletal injuries present with common symptoms (especially pain and swelling of the affected area) and generally can use similar self-treatment approaches. Nonpharmacologic therapy consisting of rest, ice, compression, and elevation (RICE), with or without nonprescription oral analgesics and/or topical analgesics, during the first 1–3 days after injury is helpful.⁴ The health care provider should carefully screen the patient for warning signs and symptoms that preclude self-treatment to ensure that the patient receives appropriate care. The algorithm in [Figure 7–1](#) presents a stepwise approach to self-management of pain for patients who have none of the listed exclusions for self-care.

Management of acute back pain can include the use of nonprescription oral or topical analgesics and nonpharmacologic treatments, including the use of heat.¹³ Patients with subacute or chronic low back pain require medical evaluation before they initiate self-treatment, in view of the prolonged duration of symptoms.

Pain associated with osteoarthritis is approved for self-treatment after an initial medical diagnosis. The general treatment approach includes appropriate lifestyle changes (incorporating weight loss, educational, behavioral, psychosocial, and physical interventions) and use of an oral or topical analgesic (e.g., topical NSAID), which may be a nonprescription medication.¹⁰

Nonpharmacologic Therapy

Injury from playing sports or exercising can be prevented by warming up and stretching muscles before physical activity, ensuring proper hydration, and wearing appropriate footwear. For muscle cramps, stretching and massaging

the affected area followed by immediate rest will loosen the muscle. Appropriate hydration is important, and plain water, sports drinks, or enhanced waters with electrolytes may be used based on patient preference.

RICE therapy promotes healing and helps reduce swelling and inflammation associated with muscle and joint injuries (Table 7–2). Ice should not be applied for more than 15–20 minutes because excessive icing causes considerable vasoconstriction and reduces vascular clearance of inflammatory mediators from the damaged area. Thermal therapies also can be recommended for patients with osteoarthritis experiencing pain and/or swelling.¹⁰ Both cold and heat, at temperatures outside the skin’s threshold for tolerance, can be damaging and can result in blistering or burning; with both types of therapies, therefore, direct application of the medium to the skin is contraindicated.

Table 7–2 Guidelines for RICE Therapy

- *Rest:* Rest the injured area and continue until pain is reduced (generally 1 or 2 days). Slings, splints, or crutches can be used if necessary.
- *Ice:* As soon as possible, apply ice to the injured area in 15- to 20-minute increments, at least 3 or 4 times a day. Continue the ice pack therapy until swelling subsides (usually 1–3 days, depending on the severity of injury).
- *Compression:* Apply compression to the injured area with an elastic support or an elasticized bandage, as follows:
 - Choose the appropriate-size bandage for the injured body part. If preferred, a product specifically designed for the injured body part can be purchased.
 - If ice is also being applied to the injured area, soak the bandage in water to aid the transfer of cold.
 - Wrap the injured area by overlapping the previous layer of bandage by approximately one-third to one-half its width.
 - Wrap the point most distal from the injury (e.g., if the ankle is injured, begin wrapping just above the toes).
 - Decrease the tightness of the bandage as you continue to wrap. If the bandage feels tight or uncomfortable, or if circulation is impaired, remove the compression bandage and rewrap it. Cold toes or swollen fingers indicate that the bandage is too tight.
 - After removal, wash the used bandage in lukewarm, soapy water; do not scrub it. Rinse the bandage thoroughly and allow to air dry on a flat surface.
 - Roll up the bandage to prevent wrinkles, and store it in a cool, dry place. Do not iron the bandage to remove wrinkles.
- *Elevation:* Elevate the limb or body part with the injured area at or above the level of the heart, to decrease swelling and relieve pain.

Key: RICE = Rest, ice, compression, elevation. Source: Reference 4.

Heat therapy is an alternative for patients in whom pain of a noninflammatory nature develops and may relieve with stiffness. It has been studied in the treatment of acute low back pain with favorable effects.¹³ In addition, some osteoarthritis guidelines recommend heat as an adjunct nonpharmacologic therapy.^{14–16} The American College of Rheumatology (ACR) and Arthritis Foundation (AF) osteoarthritis guidelines conditionally recommend thermotherapy; the recommendation is based on the short-term benefits of thermotherapy and the difficulty in assessing therapeutic benefit from the literature because of the variety of methods used to deliver heat.¹⁰ Although its mechanism of action is not fully understood, heat may alleviate pain by increasing blood flow, reducing muscle spasm, and relieving stiffness. Heat should be applied for 15–20 minutes, 3 or 4 times a day. Heat should not be applied to inflamed areas because it can intensify vasodilation and exacerbate vascular leakage.

Heat can be applied to the affected area in the form of a warm wet compress, heating pad, or hot water bottle. Ease of use favors newer, heat-generating adhesive and wrap products (e.g., ThermaCare, Precise, various generic brands), which can be worn on the affected area up to 8 hours (up to 12 hours for some products). The products come in various shapes to accommodate different anatomic areas, including back, hip, neck, knee, wrist and hand, shoulder, elbow, and lower abdomen.

The adhesive products should be applied on dry skin that is free of lotion. In a few exceptions, certain products carry unique directions for use (e.g., ThermaCare menstrual product, BodiHeat), such as placing the adhesive side on the undergarment or clothing.

Heating devices should not be used on areas of broken skin or areas with decreased sensation, a practice that can lead to a skin burn. Specifically, ThermaCare heat-generating products should not be placed on the back of the knee or inside the bend of the arm.¹⁷

Although not generally associated with many adverse effects, heat-generating

patches can cause skin irritation or even burns. Patients should be advised to remove the patch immediately if they experience any pain or discomfort, itching, or burning. Heat wraps should be worn over a towel or layer of clothing in patients older than 55 years; heat wraps should not be used during sleep.¹⁷

Limited scientific information is available regarding contrast therapy (alternating heat and ice) to aid in sports injury recovery. Anecdotally, some patients report relief. One study evaluated heat and contrast therapy in the subacute stage of ankle sprain injuries. In the immediate period after applying thermotherapy, heat reduced pain better than contrast therapy. After three days of continuous use, contrast therapy was found to reduce swelling. Insufficient scientific evidence is available in the literature to justify recommendation of this practice; however, the patient may consider use of contrast therapy if it brings relief.⁶

Transcutaneous electrical nerve stimulation (TENS) therapy is used widely by various practitioners (e.g., physicians, physical therapists, chiropractors) in the treatment of pain. FDA has approved TENS therapy for nonprescription use. The TENS device is a class II medical device for the relief of pain associated with sore, aching muscles; joint pain; or chronic intractable pain.¹⁸ Pain relief is thought to come from two mechanisms: alteration of pain transmission and an increase in the production of natural endorphins. A TENS device typically is used for an interval of 15–30 minutes up to 3 times daily. The electrode pads can be placed on various areas of the body for pain relief (e.g., back, legs, ankles, arms, shoulders), but placement is product-dependent. Because of safety concerns, patients should avoid placing the electrodes on the throat, chest, head, or over the carotid arteries. The electrodes also should not be placed on open wounds, rashes, inflamed skin, cancerous lesions, or areas of skin with altered sensation, or over areas treated with topical analgesics. Patients with internal or attached medical devices (e.g., pacemakers, defibrillators, electrocardiographic monitors, respirators), pregnant women, and pediatric populations should avoid using nonprescription TENS devices.^{19,20} The directions for proper and safe use of these devices are product-specific, so a review of the directions with the patient is indicated. The 2019 ACR/AF guidelines strongly recommend against the use of TENS in osteoarthritis of the knee and hip.¹⁰

Historically, some patients prefer to use magnesium sulfate (Epsom salt) solution applied to areas of minor sprains and bruises, for a nonpharmacologic

treatment for relief of discomfort. However, scientific evidence to support claims of effectiveness in the general population is lacking. For this self-treatment modality, the magnesium sulfate is dissolved in warm water for soaking the affected part in a bath or for application on wet bandages for an average of 20 minutes.

Heat, massage, acupuncture, and spinal manipulation are nonpharmacologic therapies recommended to treat acute or subacute low back pain. Patients with chronic low back pain should consider nonpharmacologic measures as first-line treatment. Recommendations include exercise; multidisciplinary rehabilitation; acupuncture; psychological therapies (e.g., mindfulness-based stress reduction, progressive relaxation, cognitive behavioral therapy, electromyography biofeedback, operant therapy); tai chi; yoga; motor control exercise (i.e., focus on strengthening the muscles that support the spine and improving coordination); low-level laser treatments using noninvasive infrared beams as light therapy; and spinal manipulation by a licensed provider (e.g. chiropractor, physical therapist).⁹

Pharmacologic Therapy

Systemic Analgesics

Acetaminophen, aspirin, and non-aspirin nonsteroidal antiinflammatory drugs (NSAIDs), such as ibuprofen, naproxen, and magnesium salicylate tetrahydrate, are commonly used nonprescription analgesics; they are often used in the initial treatment of musculoskeletal injuries. Systemic analgesic therapy for selfcare should be limited to 10 days,²¹ and patients should seek appropriate medical care if the condition continues beyond this period or worsens during the course of treatment. (See [Chapter 5](#) for dosages, safety, and properties of nonprescription systemic analgesics.)

The impact of systemic NSAIDs on muscle recovery after an acute injury has been debated and was evaluated in a recent study. A number of mechanisms have been hypothesized, including the possibility of delayed muscle healing secondary to impaired protein synthesis and cell regeneration. A systematic review and meta-analysis reported that use of NSAIDs, for 14 days or less, after an acute muscle injury conferred a small to moderate benefit in reducing soreness and lowering blood creatine kinase levels. A beneficial effect on strength was observed as well. The study authors noted on data analysis that

NSAIDs seemed to work better with lower body than with upper body injuries and recommended additional research on this topic.²²

For the treatment of osteoarthritis of the hip and knee, acetaminophen has been recommended historically by some organizations for first-line therapy, despite data suggesting that NSAIDs provide slightly better pain relief.²³ A meta-analysis demonstrated a significant effect of NSAIDs and acetaminophen for reducing pain and improving function. However, naproxen was found to be most likely to improve pain control and function in patients with osteoarthritis of the knee.²⁴ In reference to systemic agents, the 2019 ACR/AF guidelines strongly recommend oral NSAIDs and conditionally recommend acetaminophen for patients with knee, hip, and/or hand osteoarthritis.¹⁰ The Osteoarthritis Research Society International (OARSI) 2019 guidelines did not recommend acetaminophen as oral therapy for any type of osteoarthritis.¹⁵

Chronic use of NSAIDs leads to more severe and prevalent adverse effects (e.g., nephropathy, gastrointestinal ulcerations and bleeding, increased risk for cardiac events). According to the OARSI guidelines, a proton pump inhibitor should be considered for gastrointestinal protection if the patient is high risk or if a systemic nonselective NSAID will be used chronically for the management of osteoarthritis.¹⁵ (See [Chapter 13](#) for further information on risks of long-term use of proton pump inhibitors.) The ACR/AF guidelines strongly recommend oral NSAIDs for knee, hip, and hand osteoarthritis. In addition, they also strongly recommend topical NSAIDs for knee arthritis and conditionally recommend them for hand arthritis. The updated guidelines recommend that, when practical, topical NSAIDs be considered prior to the use of systemic NSAIDs to reduce systemic exposure in all age groups.¹⁰

A randomized clinical trial compared the effect of opioid versus nonopioid medications on pain-related function and pain intensity over 12 months. The trial utilized acetaminophen and prescription doses of NSAIDs as first-line therapeutic options; however, the nonopioid group did have access to tramadol, which could be a potential confounder in this study. Over the course of the study, pain intensity was statistically lower in the nonopioid group. There was no difference between the opioid and nonopioid treatment groups in improvement of pain-related function.²⁵

The American College of Physicians (ACP) published guidelines regarding the management of acute, subacute, and chronic back pain.⁹ Among nonprescription medications recommended by a health care provider for the

treatment of acute back pain, acetaminophen is no longer considered a first-line agent. A patient with chronic low back pain should consider nonpharmacologic measures as first-line treatment. In studies including a large randomized, placebo-controlled trial, acetaminophen was no different than placebo in addressing acute low back pain intensity and function.¹³ If the patient has no contraindications to use of NSAIDs, an agent of this group should be recommended over acetaminophen and is considered first-line pharmacologic therapy. Moderate-quality evidence showed that NSAIDs provided some reduction in pain intensity, and low-quality evidence showed some improvement in function. If adequate pain relief is not achieved with the NSAID, the patient should be referred to his or her primary care provider, who may recommend prescription medications.^{9,13}

Topical Products

Topical analgesics may have local analgesic, anesthetic, antipruritic, and/or counterirritant effects. Nonprescription topical analgesics are approved specifically for the topical treatment of minor to moderate aches and pains of muscles and joints (e.g., simple backache, arthritis pain, strains, bruises, sprains).²⁶ In February 2020, FDA reclassified diclofenac gel 1%, a topical NSAID, as a nonprescription drug through the Rx-to-OTC switch process. This agent is approved for relief of joint pain from osteoarthritis in the hand, wrist, elbow, foot, ankle, and knee.^{27,28} A topical anesthetic, lidocaine, is available as a nonprescription medication marketed for nerve pain. Topical nonprescription agents are recommended as adjuncts to pharmacologic and nonpharmacologic therapy of musculoskeletal injuries and disorders. [Table 7–3](#) lists examples of commercially available products.

Table 7–3 Selected Nonprescription External Analgesic Products	
Trade Name	Primary Ingredient(s)
Menthol-Containing Products	
Aspercreme Heat Pain Relieving Gel	Menthol 10%
Bengay Ultra Strength Pain Relieving Patch	Menthol 5%
Icy Hot No Mess Applicator	Menthol 16%
Mineral Ice	Menthol 2%

Trade Name	Primary Ingredient(s)
Camphor-Containing Products	
JointFlex Arthritis Pain Relieving Cream	Camphor 3.2%
Capsaicin-Containing Products	
Capzasin Arthritis Pain Relief No-Mess Applicator	Capsaicin 0.15%
Capzasin-HP Arthritis Pain Relief Cream	Capsaicin 0.1%
Zostrix Maximum Strength Cream	Capsaicin 0.1%
Histamine Dihydrochloride-Containing Products	
Australian Dream Pain Relieving Arthritis Cream	Histamine dihydrochloride 0.025%
Trolamine Salicylate-Containing Products	
Aspercreme Cream	Trolamine salicylate 10%
Sportscreme Deep Penetrating Pain Relieving Rub Cream	Trolamine salicylate 10%
Lidocaine-Containing Products	
Aspercreme With Lidocaine Maximum Strength	Lidocaine hydrochloride 4%
Lidocare Patch	Lidocaine 4%
Diclofenac-Containing Product	
Voltaren Arthritis Pain Gel	Diclofenac sodium 1%
Combination Products	
Arthritis Hot Cream	Methyl salicylate 15%; menthol 10%
Bengay Ultra Strength Pain Relieving Cream	Methyl salicylate 30%; menthol 10%; camphor 4%
Flexall Plus	Menthol 16%; methyl salicylate 10%; camphor 3.1%
Precise Pain Relieving Cream	Methyl salicylate 30%; menthol 10%
Icy Hot Advanced Relief Cream	Camphor 11%; menthol 16%

Trade Name	Primary Ingredient(s)
Icy Hot Lidocaine Cream	Lidocaine HCl 4%; menthol 1%
Mentholatum Ointment	Camphor 9%; natural menthol 1.3%
Salonpas Pain Relief Patch	Methyl salicylate 10%; menthol 3%
Salonpas DEEP Relieving Gel	Camphor 3.1%; menthol 10%; methyl salicylate 15%
Salonpas Lidocaine Pain Relieving Gel-Patch	Lidocaine 4%
Sloan's Liniment	Turpentine oil 47%; capsaicin 0.025%
Tiger Balm Ultra Strength Pain Relieving Ointment	Camphor 11%; menthol 11%

Topical NSAIDs

In February 2020, topical diclofenac sodium 1% (Voltaren) was reclassified as a nonprescription drug for the temporary relief of arthritis pain in the hand, wrist, elbow, foot, ankle, or knee in adults older than 18 years.²⁸ This agent is applied on the skin directly at the targeted site to provide relief from joint pain. Topical NSAIDs share the same mechanism of action for inhibiting prostaglandins, to reduce pain and inflammation, but they are applied locally to the targeted joint that is experiencing pain from arthritis. When diclofenac is applied according to the prescription package insert recommendations (e.g., 4 g applied 4 times per day to one knee), the amount of the agent that is absorbed systemically is 6%, or 17 times lower than the systemic exposure from oral diclofenac.²⁹ The treatment dosage should be the lowest effective dosage for the shortest duration that is consistent with individual patient treatment goals. Although systemic absorption is significantly lower, some absorption does occur. Widespread application on the body or application of the product over broken skin increases its absorption. The health care provider should educate the patient on using the dosing card to measure the proper dose of diclofenac.

Topical diclofenac is contraindicated in patients who are hypersensitive to diclofenac; who have a history of asthma, urticaria, or other allergic-type reactions with use of aspirin or other NSAIDs; and who have undergone coronary artery bypass surgery.²⁹ All NSAIDs, except aspirin, are known to increase the risk of cardiovascular complications (i.e., heart attack, heart failure,

stroke). Patients on low-dose aspirin therapy for cardiovascular or stroke prevention should consult their health care provider. Additional warnings for gastrointestinal complications and renal and liver toxicity also are indicated, because diclofenac belongs to the NSAID drug class.²⁹ A common side effect includes skin irritation that is usually mild.^{29,30} If a serious skin reaction occurs, patients should discontinue use and contact their health care provider.²⁹ Topical diclofenac may take up to 7 days to work, and patients should stop using the product after 21 days. Patients who do not experience improvement in pain after 7 days should contact their health care provider.²⁷

A 2016 Cochrane review concluded that topical diclofenac is effective in reducing pain for osteoarthritis, but that no evidence is available to support its use in other chronic pain conditions. The review also stated that topical diclofenac provided good pain relief but for only 10% more patients than those using a topical placebo.³⁰ The FDA news release also highlighted that topical diclofenac has not been shown to be effective for strains, sprains, bruises, or sports injuries.²⁷

Counterirritants

Topical counterirritants are applied to the skin to relieve pain. Counterirritation is the paradoxical pain-relieving effect achieved by producing a less severe pain to counter a more intense one. The pain relief results more from nerve stimulation than from suppression of the sensation.^{26,31} When applied to the skin at pain sites, counterirritants produce a mild, local inflammatory reaction, which provides symptomatic relief at the site underlying the skin surface being treated. These induced sensations distract from the deep-seated pain in muscles, joints, and tendons. Pain is only as intense as it is perceived to be, and the perception of other sensations caused by the counterirritant or its application (e.g., massage, warmth, redness) causes the sufferer to disregard the sensation of pain.³¹ On the basis of their topical effects, counterirritants are classified into four groups: rubefacients, those that produce a cooling sensation, those that cause vasodilation, and those that incite irritation without rubefaction ([Table 7–4](#)).

Table 7-4 Classification and Dosage Guidelines for Nonprescription Counterirritant External Analgesics

Group	Ingredient(s)	Concentration (%)	Mechanism of Action	Frequency and Duration of Use
A	Allyl isothiocyanate	0.5-5.0	Rubefacients (increase blood flow)	For all counterirritants: Apply no more than 3-4 times/day, as needed, for up to 7 days
	Ammonia water	1.0-2.5		
	Methyl salicylate	10-60		
	Turpentine oil	6-50		
B	Camphor	3-11	Produce cooling sensation	As in group A
	Menthol	1.25-16.0		
C	Histamine dihydrochloride	0.025-0.1	Cause vasodilation	As in group A
	Methyl nicotinate	0.25-1.0		
D	Capsicum	0.025-0.25	Incite irritation without rubefaction; are as potent as group A ingredients	<i>For acute pain:</i> As in group A
	Capsicum oleoresin	0.025-0.25		<i>For chronic pain:</i> Apply 3-4 times/day for duration of pain (often long-term use with medical supervision).
	Capsaicin	0.025-0.25		

^a Dosages approved for adults and for children 2 years and older.

Source: Reference 26.

All regulations and labeling for topical counterirritants are based on the detailed previous proposed rulemaking documents published in the *Federal Register* in 1979 and 1983.^{26,32} FDA has recognized the ingredients in [Table 7–4](#) Category I (generally recognized as safe and effective ([GRASE]) counterirritants for use in adults and in children 2 years of age and older.³² Of note, for many topical nonprescription analgesic products, the lower age limit is older than 2 years.

Labels for most counterirritants indicate that the product is to be used for “the temporary relief of minor to moderate aches and sprains of muscles and joints.” In addition, the labeling recommended by most of the FDA review panels includes claims for “simple backache, arthritis pain, strains, bruises, and sprains.”³² FDA previously issued a Drug Safety Communication about serious burns caused by nonprescription topical counterirritants. Most of the second- and third-degree burn cases were associated with use of topical counterirritant products with higher concentrations of menthol as the single ingredient or with a combination product containing greater than 3% menthol and 10% methyl salicylate. In many of the case reports, the reactions occurred with only one application, and the resulting injury developed within 24 hours. Additionally, some case reports described burns from products containing capsaicin.³³ FDA recommendations for safe use of nonprescription topical analgesic products are presented in [Table 7–5](#). A feeling of warmth or coolness is normal with topical counterirritant use, but patients should seek medical attention if burning pain or blistering occurs.³³

Table 7–5 FDA Recommendations for Application of Nonprescription Topical Analgesic Products

- If pain, swelling, or blistering of the skin occurs after application of a topical analgesic, the patient should immediately discontinue use of the product and seek medical attention.
- Do not bandage the area tightly where the product has been applied.
- Do not use any heat where the product has been applied.
- Do not apply to wounded, damaged, broken, or irritated skin.
- Do not allow these medications to come in contact with the eyes, inside the nose or mouth, or with the genitals.

Key: FDA = U.S. Food and Drug Administration.

Source: Reference 33.

Table 7–4 provides dosing information for the various counterirritants.

Described next are the commonly used counterirritants currently available in the United States.

METHYL SALICYLATE. Methyl salicylate occurs naturally as wintergreen oil or sweet birch oil; gaultheria oil, teaberry oil, and mountain tea are other names for the compound. Methyl salicylate is usually combined with other ingredients (e.g., menthol and/or camphor).

As a rubefacient, methyl salicylate causes vasodilation of cutaneous vasculature, thereby producing reactive hyperemia. This increase in blood pooling and/or flow is hypothesized to be accompanied by an increase in localized skin temperature, which in turn may exert a counterirritant effect. Because of its rubefacient action, methyl salicylate is responsible for the “hot” action in many topical counterirritant products.³¹

In addition to the mechanisms described previously, topically applied methyl salicylate products inhibit both central and peripheral prostaglandin synthesis. Studies on the rate and extent of percutaneous absorption of various commercially available methyl salicylate preparations show direct tissue penetration rather than redistribution by the systemic blood supply, indicating a localized effect of the topical product.³¹

Localized reactions (e.g., skin irritation, rash) and systemic reactions (e.g., salicylate toxicity) may occur with the use of methyl salicylate. Strong irritation may cause local reactions such as erythema, blistering, neurotoxicity, or thermal hyperalgesia. In addition, heat exposure and exercise after applying methyl salicylate have been associated with a threefold increase in systemic absorption of salicylate, which can lead to increases in adverse systemic reactions.³⁴ **Table 7–5** reviews appropriate precautions to take with use of topical analgesics. Because percutaneous absorption of salicylate can occur,

methyl salicylate should be avoided in children and used with caution in individuals who are sensitive to aspirin. Concomitant use of salicylate-containing topical analgesics and maintenance warfarin therapy has been implicated in prolonging prothrombin time.³¹ Chapter 5 describes other potential drug interactions related to systemically absorbed salicylates.

The 2017 report of the American Association of Poison Control Centers documents 5875 methyl salicylate exposures, 4118 of which are in children 6 years of age and younger. In this age group, just a teaspoon of wintergreen oil can cause death.³⁵ Although an FDA survey found that oral ingestion of methyl salicylate in ointment form caused no deaths and that few cases were associated with severe symptoms, regulations require the use of child-resistant containers for liquid preparations containing concentrations greater than 5%.²⁶

CAMPHOR. Although camphor occurs naturally and is obtained from the camphor tree, approximately three fourths of the camphor used medicinally is prepared synthetically.

In concentrations of 0.1%–3.0%, camphor depresses cutaneous receptors and is used as a topical analgesic, anesthetic, and antipruritic. In concentrations exceeding 3%, particularly when combined with other counterirritant ingredients, camphor stimulates the nerve endings in the skin, thereby inducing relief of pain and discomfort by masking moderate to severe deeper visceral pain, with a milder pain arising from the skin at the level of innervation. When applied vigorously, it produces a rubefacient reaction.

Concentrations higher than those recommended are not more effective and can cause more serious adverse reactions if the preparation is accidentally ingested.³² CNS effects, manifested primarily as tonic-clonic seizures, constitute the major form of toxicity and begin to emerge as early as 10 minutes after ingestion. High doses of camphor can cause nausea, vomiting, colic, headache, dizziness, delirium, convulsion, coma, and death.³⁶ Although nonprescription camphor-containing preparations cannot exceed concentrations of 11%, camphor toxicity continues to occur.³⁶ The American Association of Poison Control Centers documented 9975 camphor exposures, with 8252 of the cases in children 6 years of age and younger.³⁵ Parents should be aware of this potential danger, and patient counseling should emphasize use of modalities that do not contain camphor.

MENTHOL. Menthol is either prepared synthetically or extracted from

peppermint oil (which contains a 30%–50% concentration of menthol). Menthol may be used safely in small quantities as a flavoring agent and has found wide acceptance in candy, chewing gum, cigarettes, cough drops, toothpaste, nasal sprays, and liqueurs. It is also used as a permeability enhancer to increase absorption of other topically administered medications.³⁷

At concentrations less than 1%, menthol depresses cutaneous receptor response (i.e., acts as an anesthetic); at concentrations greater than 1.25%, menthol stimulates cutaneous receptor response (i.e., acts as a counterirritant).³⁷

Studies have led to the identification of heat- and cold-sensitive receptors within sensory neurons called transient receptor potential (TRP) cation channels. Topically applied menthol activates the TRPM8 menthol receptor, triggering the sensation of cold.³⁷ The resultant cold sensation travels along pathways similar to the somatic pain sensations from the affected muscle or joint, which distracts from the sensation of pain. The initial feeling of coolness is soon followed by a sensation of warmth.

Menthol is contraindicated in patients with hypersensitivity or sensitization to the agent (e.g., urticaria, erythema, other cutaneous lesions).³⁷ Treatment should be discontinued if the patient experiences irritation, rash, burning, stinging, swelling, or infection.

METHYL NICOTINATE. Although nicotinic acid is inactive topically, methyl nicotinate readily penetrates the cutaneous barrier. Vasodilation and elevation of skin temperature result from very low concentrations, with higher penetration rates reported for hydrophilic media (i.e., gels). One study showed that indomethacin, ibuprofen, and aspirin significantly depress the skin's vascular response to methyl nicotinate. Because these three drugs suppress prostaglandin biosynthesis, the vasodilator response to methyl nicotinate is thought to be mediated, at least in part, by prostaglandin biosynthesis.³⁸

Generalized vascular dilation can occur when methyl nicotinate passes through the skin into the circulatory system. Consequently, persons who apply methyl nicotinate over large areas may experience a drop in blood pressure, a decrease in pulse rate, and syncope secondary to the generalized vascular dilation.³⁸

CAPSICUM PREPARATIONS. Capsicum preparations—capsaicin and capsicum

oleoresin—are derived from the fruit of various species of pepper plants (in the nightshade family). Capsaicin is the major constituent of hot (chili) peppers. Capsicum oleoresin refers to a concentrated extract, containing capsaicin, which is composed of oil and resin.

When applied to normal skin, capsaicin elicits a transient feeling of warmth through stimulation of the TRPV1 receptor. The mechanism of action is thought to be directly related to capsaicin's effects on the depletion of substance P. This substance is found in slow-conducting, unmyelinated type C neurons that innervate the dermis and epidermis. It is released in the skin in response to endogenous (e.g., stress) and exogenous (e.g., trauma, injury) factors. It appears that pruritic stimuli along with pain impulses are conveyed to central processing centers by type C fibers in the skin, for which capsaicin has selective activity. Local application of capsaicin to the peripheral axon appears to deplete substance P from sensory neurons. The depletion occurs both peripherally and centrally, presumably as the result of impulse initiation. When substance P is released, burning pain occurs, but this effect abates with repeated applications. The diminishing sensation experienced with repeated applications can lead to adherence-related failures; health care providers should educate patients about such effects and the importance of continuing therapy.³⁹

Capsaicin has additional indications beyond those of other counterirritants. Capsaicin is used to reduce the pain—but not the inflammation—of rheumatoid arthritis and osteoarthritis; it is also used in the management of a wide variety of other pain disorders (e.g., postherpetic neuralgia, diabetic neuropathy, back pain).

The optimal dose of capsaicin varies among patients. The efficacy of capsaicin decreases (and local discomfort increases) when capsaicin is applied less often than directed, because the drug's duration of action is 4–6 hours. Pain relief is usually noted within 14 days after therapy has begun, but relief will occasionally be delayed by as much as 4–6 weeks in cases of chronic pain.³⁹

Once topical nonprescription capsaicin has begun to relieve pain, its use must continue regularly 3 or 4 times a day, as directed. If capsaicin treatment is stopped and the pain returns, applications can be resumed. Capsaicin may produce a sensation of burning or stinging pain. As a result of tachyphylaxis, however, this local effect diminishes in intensity with repeated applications, typically within a few days but sometimes after as long as 1–2 weeks.^{39,40} To

reduce the likelihood of capsaicin contact with topically sensitive areas (e.g., mucous membranes), patients should be instructed to use a glove for application and to wash their hands after use.³⁹ If the hands are the site of application, the patient should wait 30 minutes after application and then wash the hands. During use, capsaicin should not come in contact with the eyes or other sensitive areas of the body, because it will cause a burning sensation.³⁹ Capsaicin is available in a roll-on applicator or patch formulation, which may be preferred by some patients for its ease of application. Patients using such formulations should still be instructed to wash their hands after handling the product.

Use in patients with hypersensitivity to capsaicin is contraindicated. The agent should be discontinued temporarily if skin breaks down (i.e., appears weeping and red, with development of small ulcers), and the agent should not be applied to wounds or damaged skin.

In addition to skin reactions, capsaicin has also been associated with a cough, “runny nose,” or sneezing if particles are inhaled.³⁵ Overdose with use of capsaicin has not been reported, but more serious and intense adverse effects are reported with higher concentrations.³⁹

Capsaicin also is available in a prescription patch formulation (Qutenza 8%) approved for the treatment of postherpetic neuralgia.⁴¹

ADDITIONAL COUNTERIRRITANTS. Allyl isothiocyanate, ammonia water, turpentine oil, and histamine dihydrochloride are also classified as Category I counterirritants by FDA, but few counterirritant preparations contain those ingredients. Most products that incorporate them also contain other topical analgesics, making any beneficial actions or adverse effects of the products indistinguishable from those of other ingredients. In addition, very little evidence supports the efficacy of such compounds. Allyl isothiocyanate, ammonia water, and turpentine oil are rubefacients, so they should be expected to have effects similar to those of methyl salicylate. However, histamine dihydrochloride causes vasodilation, by mechanisms similar to those for methyl nicotinate.

PHARMACOTHERAPEUTIC EFFICACY AND RECOMMENDATIONS FOR COUNTERIRRITANTS. Literature regarding the efficacy of counterirritants is conflicting, and current studies are lacking. However, Cochrane reviews evaluating the use of counterirritants in specific conditions and guidelines for

osteoarthritis provide some guidance.

One such review reports that topical rubefacients (those specifically containing salicylates) are not supported by enough evidence to be recommended for use in acute or chronic pain. The reviewers noted that studies in assessing acute pain were highly variable in design and limited in number, with small trial sizes and very-low-quality evidence; however, the data showed a 50% pain reduction in 64% of the patients treated after 1 week (number needed to treat: 3) and a 50% pain reduction in 45% of the patients treated after 2 weeks (number needed to treat: 6).⁴²

In the Strategies for Prescribing Analgesics Comparative Effectiveness (SPACE) randomized clinical trial, step-up therapy included topical analgesics, capsaicin, or lidocaine as part of the protocol. Of interest, the nonopioid group reported significantly less pain intensity, and drop-out rates were significantly less.²⁵

One study evaluated the use of a nonprescription combination methyl salicylate and menthol patch for the treatment of mild to moderate muscle strain; the results showed that pain relief was approximately 40% better in subjects using the 8-hour patch than in the placebo group.⁴³ These patch formulations (Salonpas Pain Relief Patch and Salonpas Arthritis Pain Patch) are the only nonprescription analgesic patches to receive FDA approval for a New Drug Application.

Conflicting recommendations have been noted regarding capsaicin. Another Cochrane review focused on reevaluating low-concentration (<1%) capsaicin products for the treatment of chronic neuropathic pain. In this report, insufficient evidence was available to allow a conclusion about low-dose capsaicin in treating neuropathic pain, but such preparations were deemed unlikely to have any “meaningful effect.”⁴⁰ A 2014 Cochrane review concluded that there was moderate evidence for use of capsaicin to reduce low back pain.⁴⁴

The Osteoarthritis Research Society International (OARSI) guidelines recommend against capsaicin for managing osteoarthritis.¹⁵ The ACR/AF guidelines for the management of osteoarthritis conditionally recommend topical capsaicin as an option for symptom management in the knee. Those guidelines, however, also conditionally recommend against the use of capsaicin in the management of osteoarthritis of the hand. No

recommendations regarding nonprescription topical analgesics in the management of osteoarthritis of the hip are included because the depth of the joint beneath the surface makes it unlikely for the agents to have an effect.¹⁰

Other Topical Analgesics

Trolamine Salicylate

Trolamine salicylate is a Category III (nonGRASE) ingredient (insufficient data are available to establish safety and efficacy). Despite this designation, several nonprescription products contain trolamine salicylate as the primary ingredient ([Table 7-3](#)).

It has been suggested that trolamine salicylate (triethanolamine salicylate) is absorbed through the skin, resulting in synovial fluid salicylate concentrations below those of oral aspirin. The recommended topical dosage of trolamine salicylate for adults and for children 2 years of age and older is a 10%–15% concentration applied to the affected area not more than 3 or 4 times a day, as needed. No recent studies have been published regarding the efficacy of topical trolamine salicylate.

Trolamine salicylate is still available as a nonprescription agent and may be most useful to those patients who do not favor the localized irritation or the scent of Category I counterirritants.

Trolamine salicylate has the same considerations for drug interactions and contraindications as those of other salicylates (see [Chapter 5](#)). During use, the agent should not contact the eyes or mucous membranes.

Topical Anesthetics

Lidocaine has widely been available as a nonprescription medication in primarily skin preparations to relieve pain and itching. It is also used for anorectal pain, as a local or injected topical anesthetic, and the prescription patch is approved for postherpetic neuralgia.⁴⁵ In the management of injuries, its primary role is in neuropathic pain owing to its mechanism of action. This mechanism of action includes inhibiting the conduction of nerve impulses. As with other topical analgesics, the FDA-approved time frame is 7 days of use. Patients allergic to lidocaine or other amide local anesthetics should avoid this group of agents. Lidocaine is classified by FDA as Category I, as an external

analgesic, and is approved in concentrations of 0.5%–4% for nonprescription products. It can be used every 6–8 hours as needed, not to exceed 3 applications in 24 hours. The product should be applied to intact skin.^{26,32} If a localized reaction such as a rash, itching, or skin irritation occurs, the product should be removed and the area should be cleansed.

Combination Products

Four separate chemical and/or pharmacologic groups of counterirritants provide four qualitatively different types of irritation.³² Many marketed preparations aim for at least two such effects when greater potency is desired, provided that each active ingredient is from a different group.

Combining counterirritants with skin protectants is not appropriate: the protectants oppose and may nullify counterirritant effects.

Preparation labels must list the active ingredients, including their concentrations, and must identify them by their officially recognized, established names. In addition, manufacturers voluntarily list ingredients on the label. Many manufacturers of combination products list only some of the active ingredients under the “active” heading, and they list many of the other pharmacologically viable products in the inactive ingredients section (e.g., BenGay Vanishing Scent Gel lists camphor and Aspercreme Heat Pain Relieving Gel lists capsaicin under inactive ingredients). Although the concentrations of inactive ingredients are not listed, they are generally below therapeutically determined amounts and are added for reasons other than pain-relieving effects.²⁶

Product Selection Guidelines

Special Populations

No significant variability in response has been noted for patients of different ages or racial backgrounds.

The minimum age of patients on product labeling, as specified by the manufacturer, varies. Such age limits warrant attention in choosing an appropriate topical preparation. According to the tentative final monograph published in the *Federal Register* in 1983, use of external analgesics, as labeled within the confines of the statement, is to be avoided in children younger than

2 years.³² However, most available products elect to label the minimum age as older than 12 years, and some products (particularly capsaicin and diclofenac products) specify 18 years and older. In making recommendations, health care providers should follow labeling instructions for specific products. These products should be used cautiously or avoided entirely in populations in which patients cannot effectively communicate adverse effects they are experiencing after application of a topical analgesic. Of particular concern is use of such products in young children.

Musculoskeletal complaints are common in pregnancy, but complications may occur; therefore, patients should be evaluated by their primary care provider.⁴⁶ Limited information is available regarding use of nonprescription topical analgesics in pregnancy. (See the Preface for a detailed explanation of the pregnancy data.) The prescription capsaicin package insert for Qutenza states that no well-controlled human studies for the patch formulation have been conducted in pregnant women but that animal studies did not reveal teratogenicity. In addition, although controlled studies in nursing mothers are lacking, capsaicin is known to be excreted in breast milk. According to the prescription insert, the exposure to the child can be reduced by avoiding breastfeeding on the day of treatment.⁴¹ Topical lidocaine, at prescription strength, is suggested to be compatible with use during pregnancy and based on limited human data, probably compatible with breastfeeding.⁴⁷ Use of this drug in pregnancy has not been well studied in humans, but animal studies have not shown harm in doses 6.6 times the human dose.⁴⁸ Camphor, menthol, methyl salicylate, trolamine salicylate, and methyl nicotinate were not previously categorized. On the basis of limited data suggesting low risk for adverse effects in this setting, topical camphor is suggested to be compatible with use during pregnancy, and although human data are lacking, it is listed as probably compatible with breastfeeding.⁴⁹

Definitive recommendations are not available because of the limited—or, in some cases, complete lack of—data that are available on topical analgesic use in pregnancy and lactation. Consideration should be given to the systemic absorption of topical salicylates, particularly in the third trimester. This precaution also applies to topical NSAIDs. Information regarding use of salicylates and NSAIDs in pregnancy can be found in [Chapter 5](#). No information on effects on female and male reproductive potential in general is available for the topical analgesics discussed in this chapter.

Patient Factors

The choice of treatment for acute pain syndromes and chronic conditions such as osteoarthritis is patient dependent. In addition to nonpharmacologic treatment, oral drug therapy is often employed. In such decisions, important considerations include the patient's history (identifying any exclusions for self-treatment), other medications the patient is taking, and any known allergies to medications. Topical analgesics are used as an adjunct or substitute to oral drug therapy. If a counterirritant is selected, an agent with Category I GRASE ingredients should be recommended. Product concentrations are variable; in general, the lowest effective dose should be recommended for the shortest duration needed.

Patient Preferences

Factors that affect product selection include dosage form, ease of use, cost, and even odor of the preparation. Both oral and topical dosage forms are available; topical dosage forms available include solutions, liniments, gels, lotions, ointments, creams, and patches. Oleaginous preparations (ointments and oil-based liniments) have increased absorption compared with solutions, gels, lotions, and creams; however, their use is limited owing to an unpleasant "greasy" feel. The use of patches is becoming more popular because of their simple application and long duration of action. With the exception of patches and solutions, topical products should be rubbed into the skin.

Complementary Therapies

The most common dietary supplement used for osteoarthritis contains glucosamine and chondroitin.⁵⁰ Published data regarding these supplements are conflicting because of variability in population size, trial duration, preparations used (e.g., prescription products that are available only in other countries), and outcomes measured (i.e., quality of life, pain indices, and radiologic changes). Initial results from the 6-month Glucosamine/Chondroitin Arthritis Intervention Trial (GAIT) demonstrated no benefit with mild pain but showed a statistically significant reduction with moderate to severe pain. However, only 22% of patients enrolled in the study were categorized as having moderate to severe pain; accordingly, the GAIT investigators concluded that further studies are needed because of the small population size.⁵⁰ A 2-year follow-up evaluation in patients from the GAIT study showed no clinical

difference in reduction of pain and function and joint space width in comparison with placebo.^{51,52}

Reflecting the popularity of these supplements, additional studies continue to contribute to the body of literature. An observational study examined the structural effect of glucosamine and chondroitin sulfate on cartilage in patients with moderate osteoarthritis of the knee who had proven meniscal damage at baseline. The study outcome was assessed at 6 years. In this specific population, use of the supplement for 2 or more years reduced the amount of cartilage lost. The protective effect on cartilage was not associated with symptomatic improvement.⁵³

In the Multicentre Osteoarthritis interVEntional trial with Sysadua (MOVES) trial, investigators concluded that a combination of glucosamine hydrochloride and chondroitin sulfate, as a European prescription product, was similar in efficacy to celecoxib in reducing pain over a 6-month period in patients with severe painful knee osteoarthritis.⁵⁴ For patients with symptomatic knee degenerative joint disease, one study demonstrated that glucosamine plus chondroitin sulfate was no better than placebo in reducing pain or improving function over 6 months.⁵⁵ A 2015 Cochrane review of data on chondroitin, while acknowledging that it mostly included low-quality trials, found that this supplement reduced pain by 10% at 6 months in comparison with placebo for persons with osteoarthritis.⁵⁶ A 2018 systematic review and meta-analysis of glucosamine sulfate reviewed 47 randomized, controlled trials ranging in duration from 1 to 4 years. Although the authors admitted to uncertainty for all estimates compared with placebo, they ultimately reported symptomatic improvement in chronic pain with slow-acting glucosamine sulfate for patients with osteoarthritis. Of note, however, the evidence for this pain improvement emerged after manipulation of the analyzed data using the mean difference on a scale from 0 to 100 and excluding trials with high bias risk.⁵⁷

The effectiveness of and recommendations for glucosamine are controversial. The ACR/AF guidelines recommend strongly against the use of glucosamine in patients with knee, hip, and/or hand osteoarthritis; however, chondroitin sulfate (in combination products with glucosamine) is conditionally recommended in patients with hand osteoarthritis.¹⁰ The AAOS guidelines do not recommend the use of glucosamine and chondroitin for patients with symptomatic knee osteoarthritis.¹⁶ European guidelines support the use of glucosamine and chondroitin but note that this recommendation is based on

the availability of a prescription product.⁵⁸ Use of these products and other complementary therapies is discussed in greater detail in [Chapter 51](#).

Algorithm: Musculoskeletal Injuries and Disorders

Figure 7–1 Self-care for musculoskeletal injuries and disorders. Key: ADR = Adverse drug reaction; FDA = U.S. Food and Drug Administration; OTC = over-the-counter; PCP = primary care provider; RICE = *rest, ice, compression, elevation*. (Source: Adapted from Self-care of self-limited pain. In: Albrant DH, ed. *The American Pharmaceutical Association Drug Treatment Protocols*. 2nd ed. Washington, DC: American Pharmaceutical Association; 2001:424–425.)

Assessment of Musculoskeletal Injuries and Disorders: A Case-Based Approach

With all musculoskeletal injuries and disorders, the health care provider's initial assessment should include an inventory of all patient medications, especially pain medications, and should note the patient's satisfaction with or preference for past treatments. In addition, the clinical interview should ascertain those aspects of the patient's medical history that relate directly to the origin or treatment of pain.

Before any attempt is made to treat a pain complaint, it is essential to qualify and quantify the pain. Inquiry about the cause, duration, location, and severity of pain, as well as factors that relieve and exacerbate the pain, will help in completing a thorough assessment of this symptom. [Chapter 2](#) outlines effective strategies for obtaining information from patients about specific complaints. Using a pain scale helps to quantify the intensity of the pain. With the numerical pain scale, the patient ranks the present pain on a scale of 0–10, with 0 being no pain and 10 being the worst imaginable pain level. Typically, mild pain is defined as a score of 1–3, moderate pain as 4–6, and severe pain as

7–10 on the numerical pain scale.¹ Initially, pain scores establish a baseline for pain before treatment. In addition, a high pain score can be used to identify patients who would be better served by an appropriate medical evaluation. Pain scores also serve as a metric for assessing therapeutic outcomes. Other scales are available for pain rating in children (e.g., Wong-Baker FACES Pain Scale), adolescents, people who do not speak English, and other special populations.

A chronic painful condition presents a different set of challenges. An observant health care provider should intervene with a patient who regularly purchases nonprescription analgesics. If additional interviewing indicates an inadequately treated pain problem, further workup and referral to a primary care provider are appropriate. Information should be offered regarding the risks of inadequate treatment as well as the overuse of medications.

Cases 7–1 and 7–2 are examples of the assessment of two different patients with a musculoskeletal injury or disorder.

Case 7–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (e.g., nature, onset, duration, severity, associated symptoms)	Patient presents with finger and hand pain. She reports that she jammed her finger into the floor during her volleyball game today. The finger is discolored and crooked. She rates the pain as an 8 on a scale of 0–10.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She reports that any attempt to move her finger results in more discomfort.
c. Description of the patient's efforts to relieve the symptom(s)	The patient has been icing the hand, with minimal relief.

Relevant Evaluation Criteria	Scenario/Model Outcome
d. Patient's identity	Amanda George
e. Patient's age, gender, height, and weight	15 years, female, 5 ft 1 in., 110 lb
f. Patient's occupation	High school student
g. Patient's dietary habits	She is a vegetarian.
h. Patient's sleep habits	She sleeps 7 hours each night. On weekends, sleeps 10 hours a night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	History of asthma and allergic rhinitis Loratadine 10 mg once daily, albuterol 1 or 2 inhalations as needed, budesonide 180 mcg inhale twice daily
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other patient preferences	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Patient is experiencing severe pain in her finger and hand, which may be severely sprained, have a tendon tear, or be dislocated or broken, based on physical presentation.
3. Identify exclusions for self-treatment (Figure 7-1).	The patient has exclusions for self-care. The pain is severe (score greater than 6 on pain scale) and the finger appears dislocated or broken, so an emergency medical referral would be recommended.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Implement an emergency medical referral for further assessment and treatment. (2) Recommend self-care with an oral NSAID. (3) Recommend self-care until patient can see a

Relevant Evaluation Criteria	Scenario/Model Outcome
	PCP. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient should consult a PCP for further evaluation. Nondrug measures such as ice may continue to be used.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"It would be best to seek emergency medical care because of the severity of the pain and the discoloration in the finger. You may continue to ice the area in 15- to 20-minute increments. Between applications, take the ice off for at least 15-20 minutes. Although this is not providing much pain relief, it is likely helping to keep the swelling down."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"It is best to seek medical care, because additional tests such as an x-ray may be needed to determine if the finger is broken or dislocated."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	The patient's mother asks: "Can I just buy a finger splint for my daughter?"
Answer the patient's or caregiver's questions.	"No, you should take her for a medical evaluation so that the injury can be assessed."
Follow-up: Monitor and Evaluate	

Relevant Evaluation Criteria	Scenario/Model Outcome
9. Assess patient outcome.	Maintain scheduled contact with the patient or her mother, by email or phone, to monitor for a reduction in her reported pain level using a pain scale.

Key: n/a = Not applicable; NSAID = nonsteroidal anti-inflammatory drug; PCP = primary care provider.

Case 7-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (e.g., nature, onset, duration, severity, associated symptoms)	Patient presents with a complaint of low back pain that started as a dull ache approximately 3 days ago. She rates her pain now as a 4 on a scale of 0-10.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She reported sleeping on a couch over the past week while on vacation. The achiness began when she woke up 3 days ago. She reports the discomfort is located in her lower back and she describes the pain as a dull ache. She states it is tolerable but annoying, especially when she needs to work all day.
c. Description of the patient's efforts to relieve the symptom(s)	She started taking 1000 mg acetaminophen 3 times daily for 2 days; she denied obtaining improvement or relief.
d. Patient's identity	Lynda Byrd
e. Patient's age, gender, height, and weight	22 years, female, 5 ft 2 in., 160 lb

Relevant Evaluation Criteria	Scenario/Model Outcome
f. Patient's occupation	Grocery store clerk
g. Patient's dietary habits	She prefers quick, easy meals (frozen meals, drive-through food or other grab-and-go options).
h. Patient's sleep habits She sleeps approximately 8–10 hours each night.	
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	She has a history of allergies and takes cetirizine 10 mg one tablet at bedtime. She uses NuvaRing (etonogestrel/ethinyl estradiol vaginal ring) as prescribed. She takes a Flintstones gummy multivitamin once daily.
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) _____	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Patient is experiencing acute low back pain, which is most likely from improper sleeping posture.
3. Identify exclusions for self-treatment (Figure 7-1).	Patient does not have any exclusions for self-care. If her pain were more severe (score greater than 6 on pain scale) or had lasted longer than 10 days, a medical referral would be recommended.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer patient to PCP for further assessment and treatment. (2) Continue acetaminophen. (3) Recommend an alternative agent (NSAID such as ibuprofen or naproxen).

Relevant Evaluation Criteria	Scenario/Model Outcome
	(4) Recommend nondrug measures (heat). (5) Recommend a topical analgesic, either a single or a combination product. (6) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend nondrug measures, including heat since this is an acute back stiffness due to poor posture. Encourage proper sleep posture if possible. The patient is a candidate for self-care, so recommend an oral analgesic. The patient does not have any contraindications to an oral NSAID regimen, which is first-line therapy.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"A medication in the NSAID class can be used to help relieve your low back pain, and we can select either naproxen or ibuprofen to take by mouth."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Since acetaminophen is not providing adequate relief and NSAIDs have better evidence for low back pain relief, either naproxen or ibuprofen by mouth can be tried as an alternative treatment to relieve the pain."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	"Take naproxen 220 mg by mouth every 8 to 12 hours if needed for pain. Do not exceed 3 doses (660 mg) in a 24-hour period."
b. Maximum number of days the therapy should be employed	"This medication can be used for self-treatment for up to 10 days."

Relevant Evaluation Criteria	Scenario/Model Outcome
c. Product administration procedures	"Take 1 tablet every 8 to 12 hours if needed for pain. For the first dose, you may take 2 tablets within the first hour. Do not exceed 2 tablets in any 8- to 12-hour period. Do not exceed 3 tablets in a 24-hour period. Take with food to minimize stomach upset."
d. Expected time to onset of relief	"You should expect to get some relief from the pain within 60 minutes after taking your first dose."
e. Degree of relief that can be reasonably expected	"The medicine will help reduce the pain, but it may not completely eliminate it."
f. Most common adverse effects	"Most common side effect is some stomach upset, which can be minimized by taking this with food."

Key: NSAID = Nonsteroidal anti-inflammatory drug; PCP = primary care provider.

Patient Counseling for Musculoskeletal Injuries and Disorders

Consultation with the patient should include an explanation of the expected benefit of any recommended medication, the appropriate dose and drug administration schedule, application directions, potential adverse reactions, potential drug–drug or drug–disease interactions, and self-monitoring techniques for assessing response to therapy. Printed materials reinforce verbal information. Many such pamphlets or single-page handouts are available from national professional societies (e.g., www.arthritis.org). These materials offer advice on exercise, diet, and sleep habits, as well as outlining the advantages and disadvantages of pharmacologic therapy.

In acute pain management, early administration of nonprescription analgesics is warranted to prevent escalating pain, with downward tapering of the analgesic doses as pain severity allows. Patients should be assessed for the appropriateness of nonprescription oral analgesic regimens ([Chapter 5](#)).

Patients should be instructed to notify their primary care provider if the pain worsens in quality or severity, or if new acute pain develops. Other sudden, uncharacteristic pain may be a sign of new tissue damage.

The box “Patient Education for Musculoskeletal Injuries and Disorders” lists specific information about oral and topical analgesics, as well as preventive and nondrug measures, to include in patient counseling.

Patient Education for Musculoskeletal Injuries and Disorders

The objectives of self-treatment are (1) to reduce the severity of pain; (2) to reduce the duration of pain, when possible; (3) to restore function to the affected area; (4) to prevent re-injury and disability; and (5) to prevent acute pain from becoming chronic persistent pain. Certain nondrug measures and nonprescription topical analgesics can relieve pain from a sudden and recent muscle, tendon, or ligament injury; an overuse injury (e.g., tendonitis, bursitis, repetitive stress injury); low back pain; or arthritis. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Preventive Measures

- To prevent muscle or joint strains and sprains, do warm-up and stretching exercises before playing sports or exercising, and wrap injured muscle or joint with protective bandage or tape.
- To prevent repetitive strain, exercise the muscles that are vulnerable to the injury, and use ergonomic controls to adjust posture, stresses, motions, and other damaging physical factors.
- To prevent tendonitis and cramps, do warm-up and stretching exercises before physical activity, drink sufficient fluids, and do not exercise to the point of exhaustion. To help prevent nocturnal leg cramps, raise the foot of the bed. For Achilles tendonitis, wearing better-fitting shoes with heel lifts may help alleviate the symptoms.
- To prevent or reduce the occurrence of low back pain, do exercises

to strengthen the muscles of the low back and abdomen, and use assistive devices (e.g., cane or walker) if needed.

- To prevent or reduce the occurrence of osteoarthritis, avoid a sedentary lifestyle; keep joints active; lose weight, if overweight; and use assistive devices if needed.

Nondrug Measures

- For pain related to muscle or joint injuries, begin treatment with RICE therapy ([Table 7–2](#)).
- For periodic muscle cramps, stretch and massage the affected area immediately; then rest or reduce activity of the muscle to allow it to loosen.
- For stiffness, apply heat to the affected area in the form of a warm wet compress, a heating pad, single-use patch, or a hot water bottle.
- For osteoarthritis, try a combination of nondrug measures, including physical, psychosocial, and mind–body approaches to manage pain.

Nonprescription Medications

- For mild to moderate muscle pain, take a nonprescription oral analgesic for no longer than 10 days²¹ (see [Chapter 5](#) for a listing of nonprescription analgesics), and/or use a topical analgesic for no longer than 7 days³² ([Table 7–4](#) provides recommended dosages of counterirritants).
- Topical NSAIDs should be considered a first-line option for osteoarthritis. If pain relief does not occur with 7 days of use, you should see your health care provider. These medications should not be used longer than 21 days without consulting a health care provider.²⁷
- Do not use topical analgesics if your skin is abraded, sunburned, or otherwise damaged.
- When using counterirritants, especially capsaicin, wash your hands after application and before touching your eyes and mucous membranes, or before handling contact lenses.

- Gently rub a thin layer of topical products into affected muscles or joints until you cannot see the product. Thick application does not make the product work better.
- Do not put a tight bandage or dressing over an area treated with a counterirritant. Do not use heat or warming devices with counterirritants.
- Do not treat a child 2 years of age or younger with counterirritants unless a primary care provider supervises the use. Follow age limits on product labeling.
- If you have asthma and experience worsening of symptoms of wheezing and shortness of breath while you are using a mentholated formulation or an NSAID, stop using it.
- If you are receiving anticoagulation therapy (especially warfarin), do not use products containing salicylates (i.e., methyl salicylate and trolamine salicylate) or topical NSAIDs for a prolonged time without monitoring.
- If a counterirritant or topical analgesic product causes excessive redness and blistering or hives and vomiting, stop using it.

When to Seek Medical Attention

- A feeling of warmth or coolness is normal; however, if burning pain or blistering occurs, seek medical attention.
- If you experience nausea, vomiting, colic, and other unusual symptoms while using a product containing camphor, seek medical care immediately.
- If the pain has been present for more than 10 days or has worsened, consult your primary care provider.²¹
- If the symptoms persist after more than 7 days of treatment with a topical product, or if the pain is constant and can be felt in any position, consult your primary care provider.³²

Key: NSAID = Nonsteroidal anti-inflammatory drug; RICE = rest, *ice*, compression, elevation.

Evaluation of Patient Outcomes for Musculoskeletal Injuries and Disorders

The primary indicator of treatment effectiveness is the patient's perception of pain relief. If the patient reports that the pain is still present or has worsened after 7 days of using topical nonprescription analgesics³² or after 21 days of using a topical nonprescription NSAID,²⁷ referral for further evaluation is indicated. In many instances, the lack of a return visit to the health care center indicates a successful treatment regimen (a follow-up call to the patient in a few days will determine whether the complaint has resolved). However, a patient who returns with signs of continued swelling, pain, or inflammation should be referred for medical evaluation.

Key Points for Musculoskeletal Injuries and Disorders

- Among patients presenting with pain secondary to an injury or a disorder of the musculoskeletal system, self-treatment should be limited to those with mild to moderate pain and no exclusions for self-treatment ([Figure 7-1](#)).
- Self-treatment for acute musculoskeletal injuries should include nondrug therapy, such as RICE. Heat therapy also may provide benefit after symptoms of inflammation have abated.
- Systemic analgesics are valid first-line agents to treat a majority of musculoskeletal injuries and disorders. Acetaminophen is appropriate in noninflammatory diseases, whereas NSAIDs are preferred if inflammation is present. Adverse effects and drug interactions should be considered before therapy is chosen (see [Chapter 5](#)).
- Patient counseling should include the discussion points listed in [Table 7-5](#) to avoid chemical burns with topical nonprescription analgesics.

- Health care providers should monitor the outcome of self-treatment regimens and advise patients who self-treat their acute musculoskeletal injury with a nonprescription topical analgesic or NSAID to seek medical attention if they do not obtain symptomatic improvement after 7 days. Regardless of the selected treatment, patients who experience pain for longer than 10 days, with the exception of osteoarthritis-induced pain, also should be referred. Patients who have used a nonprescription NSAID for more than 21 days should consult their health care provider.

Chapter 8: Vaginal and Vulvovaginal Disorders

Authors: Nicole M. Lodise

Vaginal infections are common among women, with bacterial vaginosis (BV), vulvovaginal candidiasis (VVC), and trichomoniasis occurring most frequently. Many factors affect the risk of vaginal infections such as changes in the normal flora, vaginal pH, douching, and the number of sex partners. VVC is the primary vaginal infection that can be appropriately self-treated. The availability of nonprescription vaginal pH selftesting devices can reduce the risk of inappropriate treatment with nonprescription products as vaginal pH does not increase in VVC, unlike the elevation that occurs with bacterial vaginosis and trichomoniasis. Nonprescription imidazoles include clotrimazole, miconazole, and tioconazole, which are available as vaginal creams, suppositories, and tablets. The drugs are the first-line options to treat uncomplicated VVC and few differences exist between products. The selection of one product over another is based on patient preference rather than product specifics. The use of complementary therapies such as lactobacillus products may decrease the recurrence of VVC. In addition to VVC, this chapter also reviews atrophic vaginitis and douching. Atrophic vaginitis is an inflammation of the vagina potentially leading to painful intercourse, also known as dyspareunia. Multiple nonprescription vaginal lubricants are available and may be beneficial in reducing the symptoms associated with atrophic vaginitis. Douching is the use of products to mechanically irrigate the vagina and clear away mucus. A common reason for douching is to cleanse the vagina, however, douching may lead to adverse health outcomes including disruption of the normal vaginal flora and pH. More seriously, the practice has been associated with an increased risk of pelvic inflammatory disease. Women should be advised about the possible adverse health effects of douching and that this practice is unnecessary as the vagina is a self-cleansing organ.

Vaginal symptoms are among the most common health concerns of women, either of reproductive age or older. Vaginal symptoms may be experienced by all women, whether sexually active or abstinent, homosexual or heterosexual, and premenopausal or postmenopausal.¹ Approximately 65% of women experiencing vaginal symptoms will have one of three common vaginal infections: bacterial vaginosis (BV), vulvovaginal candidiasis (VVC), and

trichomoniasis.¹ Infections also may be mixed, with more than one causative organism.

In general, vaginal infections are perceived as minor health problems for which patients may consider self-treatment. Women also may self-treat for vaginal signs and symptoms of noninfectious origin, such as vaginal dryness, atrophic vaginitis, and allergic or chemical dermatologic reactions.^{1,2} BV and trichomoniasis, however, have been linked to significant health problems, such as pelvic inflammatory disease (PID), preterm birth, and facilitation of transmission of human immunodeficiency virus (HIV).^{2,3} In view of the frequency of these vaginal infections and the current availability of nonprescription vaginal antifungal products, health care providers need to manage these infections carefully and provide appropriate patient education regarding VVC. It is essential to ensure that patients are making informed self-care decisions by providing them the necessary information and tools to know when and how to self-treat.

The vagina is an elastic fibromuscular tube that extends 8–10 cm from the vulva to the uterus. The upper end of the vagina is closed except for the *cervical os*, the opening to the cervix or neck of the uterus. Anatomically, the vagina lies between the urinary bladder and the rectum. At the lower (vulvar) end of the vagina are the Bartholin glands, which produce secretions in response to sexual stimulation. At puberty, with the influence of estrogen, the vaginal lining changes to stratified squamous epithelium, which contains glycogen. *Lactobacillus* bacteria convert glycogen to lactic acid, which creates an acidic pH of 4–4.5. This acidic pH and the production of hydrogen peroxide by these bacteria in some patients help protect the vagina from infection with other bacteria. With menopause, changes in vaginal flora, especially *Lactobacillus* species, may occur as a consequence of reduced estrogen, as well as increases in vaginal pH, potentially leading to vaginal atrophy.⁴

The mature vagina is colonized by many organisms. *Lactobacillus* species predominate, accounting for more than 95% of the vaginal flora.⁵ Additional bacterial organisms, including *Mobiluncus*, *Gardnerella vaginalis*, *Prevotella*, and *Bacteroides*, are present in small quantities, with *Candida albicans* isolated in the absence of active infection in approximately 20% of women.²

The vaginal ecosystem is affected by the number and types of endogenous organisms, vaginal pH, and glycogen concentration. Hormonal fluctuations during the menstrual cycle, in addition to other factors such as drug therapy,

douching, and number of sex partners, also can influence the vaginal ecosystem.

The healthy vagina is cleansed daily through production of secretions that lubricate the vaginal tract. The normal vaginal discharge of these secretions, termed *leukorrhea*, is odorless, clear or white, and viscous or sticky.⁶ This physiologic leukorrhea should not be associated with irritation, itching, or burning. An increase in vaginal secretions is normal during ovulation, during pregnancy, after menses, and with sexual excitement or emotional flares. Alterations in vaginal secretions also may occur in response to vaginal irritants such as feminine hygiene deodorant products and vaginal douches, as well as presence of barrier contraceptive products or tampons.

Differentiation of Common Vaginal Infections

The clinical manifestations of different vaginal infections may be similar, making diagnosis challenging; the characteristic signs or symptoms that often help differentiate such infections also may be absent ([Table 8–1](#)). Accurately distinguishing VVC from BV and trichomoniasis is important because of the availability of nonprescription vaginal antifungal therapy for VVC.

Table 8–1 Differentiation of Common Vaginal Infections		
Classic Signs and Symptoms ^{1,15}	Differentiating Findings ^{1,3,11,14,15}	Etiology and Epidemiology ^{1,3,13,16}
Bacterial Vaginosis (vaginal pH >4.5)		
Thin (watery), white or gray, sometimes foamy discharge; unpleasant “fishy” odor that increases after sexual intercourse or menses; increased vaginal pH (e.g., with menses)	Vaginal irritation and dysuria are less frequent with BV than with VVC or trichomoniasis. A foul odor is strongly associated with BV; absence of odor rules out BV.	Polymicrobial infection resulting from imbalance in normal vaginal flora, with increases in <i>Gardnerella vaginalis</i> , anaerobes (<i>Mobiluncus</i> and <i>Prevotella</i>), and <i>Mycoplasma hominis</i> and decreases in <i>Lactobacillus</i> species Risk factors: multiple or new sexual partner, use of an IUD, douching, sexual practices, tobacco use, and prior pregnancy Responsible for 30% of vaginal symptoms Predominantly affects sexually active

Classic Signs and Symptoms ^{1,15}	Differentiating Findings ^{1,3,11,14,15}	Etiology and Epidemiology ^{1,3,13,16}
		women but can arise spontaneously regardless of sexual activity
Trichomoniasis (vaginal pH >4.5)		
Frothy, malodorous, yellow-green (or discolored) discharge; pruritus; possible vaginal irritation; dysuria No symptoms initially in ~50% of affected women with approximately 30% developing symptoms in 6 months Most men asymptomatic; serve as reservoirs of the infection	Vaginal pruritus (itching) and possible irritation may occur. Frothy, yellow-green, malodorous discharge more likely to be associated with trichomoniasis	STI caused by <i>Trichomonas vaginalis</i> Risk factors: multiple sex partners, new sexual partner, nonuse of barrier contraceptives, and presence of other STIs Responsible for 15%–20% of vaginal infections
Vulvovaginal Candidiasis (no change in vaginal pH)		
Thick, white (“cottage cheese”) discharge without odor; dysuria; normal pH (see text for detailed information; also referred to as “yeast infection”)	Vaginal itching, irritation, erythema, and absence of malodor increase likelihood of VVC; thick, “cheesy” discharge is strongly predictive of VVC.	Organisms: <i>Candida albicans</i> , <i>Candida glabrata</i> , <i>Candida tropicalis</i> , <i>Candida parapsilosis</i> , and <i>Candida krusei</i> Risk factors: pregnancy, use of medications such as antibiotics and immunosuppressive agents No identifiable cause for most infections Responsible for 20%–25% of vaginal infections

Key: BV = Bacterial vaginosis; IUD = intrauterine device; OC = oral contraceptive; STI = sexually transmitted infection; VVC = vulvovaginal candidiasis.

Given the availability of nonprescription vaginal antifungal products, patients may prefer to self-treat for presumed VVC; this approach, however, may potentially lead to improper therapy.⁷ Women should be encouraged to consult an appropriate health care provider, who can identify optimal measures for self-care.

Many women and health care providers may have trouble identifying VVC on the basis of signs and symptoms alone.^{8,9} The feature most likely to differentiate a *Candida* vaginal infection from BV and trichomoniasis is absence of an offensive odor of the vaginal discharge.⁸

Noninfectious conditions such as irritation or pruritus caused by allergic reactions secondary to douching or exposure to feminine hygiene products, latex, spermicides, or soaps also may add to the confusion of diagnosing vaginal infections.⁸

Inappropriate use of vaginal antifungal products carries several risks, including unnecessary drug use and a delay in effective treatment for an underlying condition. Product labels advise patients to seek help for persistent symptoms. If these guidelines are followed, the delay in treatment from misdiagnosis will likely present few serious consequences.

One method to assist patients in appropriate self-care management is the use of vaginal pH self-testing devices to identify elevations in pH, indicating a need for medical evaluation. One study compared the results obtained by a patient's use of a pH self-testing device with their providers' vaginal pH testing to ensure ease and accuracy of use of the device by the patient. Nearly 85% of the patients obtained pH results similar to those obtained by the providers. This outcome supports the use of such tools as an important screening device to assist in self-diagnosis or to encourage further medical evaluation.¹⁰ The use of vaginal pH self-testing devices also may offer benefit in reducing inappropriate self-treatment with antifungal products.

Table 8–1 lists the classic signs and symptoms of the three most common vaginal infections and describes differentiating factors helpful in diagnosis.^{1,3,8,11–16}

Vulvovaginal Candidiasis

VVC is also referred to as a *yeast infection* or *moniliasis*. This condition is one of the most common vaginal infections, with nearly 75% of women reporting at least one VVC infection over their lifetimes.² Recurrent infections occur in less than 5% of women.³ Approximately 20% of women may be colonized with *C. albicans* without experiencing vaginal symptoms.^{2,17,18}

Pathophysiology of Vulvovaginal Candidiasis

Candida fungi are the causative organisms of VVC, with approximately 80%–92% of cases caused by *C. albicans*.³ The incidence of non-*C. albicans* infections has increased in the past 2 decades. *Candida glabrata*, *Candida tropicalis*, and *Saccharomyces cerevisiae* now account for approximately 10% of fungal vaginal infections.^{3,6} This increase may be a result of the widespread use of nonprescription antifungals, short courses of topical imidazole therapy, and long-term suppressive therapy with imidazole antifungals.³

No single causative factor has been identified for most episodes of VVC. Pregnancy, high-dose combined oral contraceptives, and estrogen therapy may affect vaginal pH and the vaginal susceptibility to *Candida* vaginal infections. During the reproductive years, the vaginal epithelium cells are thick and continually provide the lactobacilli, of the primary flora, with glycogen to produce lactic acid.^{19,20} Women with diabetes are at increased risk for *Candida* vaginal infections, particularly if their glycemic control is poor. Antibiotics also may increase the risk of these infections. Between 25% and 70% of women in studies reported acquiring *Candida* vaginal infections during or just after treatment with antibiotics such as tetracycline, ampicillin/amoxicillin, and cephalosporins.²¹ The proposed mechanism is a decrease in normal vaginal flora, especially lactobacilli, allowing an overgrowth of *Candida* organisms. However, neither an increase in vaginal *Candida* organisms nor a decrease in lactobacilli occurs in all women who take these antibiotics. In addition, patients who have received an organ transplant, have HIV infection, or are taking systemic corticosteroid, antineoplastic, or immunosuppressant drugs also may be at increased risk for developing *Candida* vaginal infections.

An increased frequency of VVC may be associated with the onset of regular sexual activity. However, neither the number of sexual partners nor the frequency of sexual intercourse is related to occurrence of VVC episodes.³ Evidence has suggested an increased risk of VVC associated with receptive oral sex.¹ In addition, use of an intrauterine or vaginal sponge contraceptive increases the risk for VVC.³

A consistent association between tight-fitting, nonabsorbent clothing or pantyhose and the development of VVC has not been demonstrated. Clothing of this type, however, may increase risk by creating a warm and moist

environment. Dietary factors such as regular consumption of yogurt may be beneficial in decreasing the symptoms of VVC, but further research is needed.²²

Treatment for *Candida* vaginal infections does not typically include treatment of the male partner, nor has such treatment been shown to prevent recurrence of *Candida* vaginal infections in women. In women who have recurrent infections or when male partners have balanitis, the men may be treated with a topical imidazole.¹¹ If treatment is necessary, topical imidazoles may be applied to the affected area twice a day for 2–4 weeks.

Clinical Presentation of Vulvovaginal Candidiasis

The characteristic signs and symptoms of VVC are listed in [Table 8–1](#). *Candida* vaginal infections typically do not alter vaginal pH, so a pH greater than 4.5 may indicate a bacterial or trichomonal vaginal infection.¹⁹ Use of vaginal pH self-testing devices can assist patients in distinguishing *Candida* vaginal infections that can be self-treated from infections that require medical evaluation and prescription drug therapy. The user-friendly kits use a color test to determine vaginal pH. Limitations with some products include the fact that testing cannot occur until 72 hours after the use of any vaginal preparation, such as a contraceptive spermicide or an antifungal product, and 48 hours after sexual intercourse or douching. In addition, the product cannot be used until 5 days after a menstrual period.

Algorithm: Vulvovaginal Candidiasis

Figure 8–1 Self-care for vulvovaginal candidiasis. Key: BV = bacterial vaginosis; CAM = Complementary and alternative medicine; HIV = human immunodeficiency virus; VVC = vulvovaginal candidiasis. (Source: [References 1, 3, 11, 13, and 14.](#))

Treatment of Vulvovaginal Candidiasis

The treatment of VVC is determined by the severity of symptoms and the frequency of episodes. VVC can be categorized as uncomplicated or complicated, with recurrent VVC considered a complicated infection.² Recurrent or complicated infections are reported in approximately 5% of women; they may be related to host factors such as an inability of normal flora to prevent *Candida* colonization or the presence of potentially resistant organisms.²³

Treatment Goals

The goals of therapy for vaginal fungal infections are relief of symptoms, eradication of the infection, and reestablishment of normal vaginal flora. A single course of drug therapy is effective in achieving these goals for most women. Some women will experience persistent or recurrent infections and will require prolonged therapy or higher dosages of medication.

General Treatment Approach

Self-treatment for VVC with nonprescription antifungal therapy is appropriate for women with uncomplicated disease, infrequent episodes, and mild to moderate symptoms. Women with more severe symptoms, predisposing illnesses or medications, or recurrent infections should be referred to their primary care provider for assessment and treatment.

Recurrent VVC is defined by the occurrence of least four documented infections in a 1-year period.³ Patients should be evaluated for the possibility of a mixed infection or a strain other than *C. albicans*. In addition, frequent or recurrent episodes of VVC may be an early sign of HIV infection or diabetes. The U.S. Food and Drug Administration (FDA) requires labels of nonprescription drug products to include a warning similar to the following²⁴:

Frequent vaginal infections or recurring infections that do not clear up easily with proper treatment require medical evaluation. Possible causes of the infection include pregnancy or a serious underlying medical disorder, such as diabetes or a weakened immune system including exposure to HIV, the virus that causes acquired immunodeficiency syndrome.

Preventive measures are not a standard part of therapy for *Candida* vaginal

infections. Women with frequent infections or those unresponsive to usual treatments may try dietary changes and other nondrug measures, such as avoidance of nonabsorbent clothing. A 3- to 4-month trial of these approaches is sufficient to determine whether they are useful for individual patients.¹ [Figure 8–1](#) outlines the approach to treating a patient with vaginal symptoms.

Nonpharmacologic Therapy

Consumption of yogurt-containing live cultures may potentially decrease VVC episodes, particularly for women who experience recurrent infections.^{1,22}

Discontinuing a drug known to increase susceptibility to *Candida* vaginal infections may potentially be effective in decreasing their incidence. Low-dose oral contraceptives are unlikely to contribute to the occurrence of VVC, but discontinuation of these agents may be tried to determine whether the frequency of infection is altered. Another form of contraception should be recommended and initiated before discontinuation of the oral contraceptive. Patients taking antibiotics or immunosuppressant drugs should consult their primary care provider about these medications.

Pharmacologic Therapy

Vaginal Antifungals

A nonprescription FDA-approved imidazole regimen is the recommended initial therapy for uncomplicated VVC and relief of external vulvar itching and irritation associated with the infection. Approved nonprescription drugs include clotrimazole, miconazole, and tioconazole, which are available as vaginal creams, suppositories, and tablets. [Tables 8–2](#) and [8–3](#) provide proper dosing and administration guidelines, respectively.

Table 8–2 Selected Nonprescription Vaginal Antifungal Products and Their Dosages		
Trade Name	Primary Ingredient	Dosage
Clotrimazole Products		
Gyne-Lotrimin 7	Clotrimazole	Insert cream into vagina daily for 7 days; apply to vulva twice

Trade Name	Primary Ingredient	Dosage
Cream	1%	daily as needed for itching.
Mycelex-7 Cream		
Mycelex-7 Combination Pack	<i>Tablet:</i> clotrimazole 100 mg <i>Cream:</i> clotrimazole 1% ^b	Insert tablet into vagina daily for 7 days; apply cream to vulva twice daily as needed to relieve itching for up to 7 days.
Gyne-Lotrimin 3 Cream	Clotrimazole 2%	Insert cream into vagina daily for 3 days; apply to vulva twice daily for itching.
Miconazole Nitrate Products		
Monistat 1 Combination Pack Day or Night	<i>Cream:</i> miconazole nitrate 2% ^b <i>Suppository:</i> miconazole nitrate 1200 mg	Apply cream to vulva twice daily as needed to relieve itching for up to 7 days; insert suppository into vagina daily (morning or at bedtime) for 1 day.
Monistat 3 Combination Pack ^a Vagistat 3 Combination Pack ^a	<i>Cream:</i> miconazole nitrate 2% ^b <i>Suppository:</i> miconazole nitrate 200 mg	Apply cream to vulva twice daily as needed for itching up to 7 days; insert suppository into vagina daily for 3 days.
Monistat 3 Cream ^a	Miconazole nitrate 4%	Insert cream into vagina daily for 3 days; apply to vulva twice daily as needed for itching.
Monistat 7 Suppository	Miconazole nitrate 100 mg	Insert suppository into vagina daily for 7 days at bedtime.
Monistat 7 Cream	Miconazole nitrate 2%	Insert cream into vagina daily for 7 days; apply to vulva twice daily as needed for itching.
Monistat 7 Combination Pack	<i>Cream:</i> miconazole nitrate 2% ^b <i>Suppository:</i>	Apply cream to vulva twice daily as needed for itching up to 7 days; insert suppository into vagina daily for 7 days.

Trade Name	Primary Ingredient	Dosage
	miconazole nitrate 100 mg	
Tioconazole Products		
Vagistat-1 Ointment 1-Day	Tioconazole 6.5%	Insert ointment into vagina daily for 1 day.
Monistat-1 Day		

^a Prefilled applicators are available for this product.

^b Use for more than 7 days is not recommended. If no symptom relief occurs, patients should see their primary care provider.

Table 8–3 Guidelines for Applying Vaginal Antifungal Products

1. Start treatment at any time of day or prior to going to bed. Lying down will reduce leakage of the product from the vagina.
2. Wash the entire vaginal area with mild soap and water, and dry completely before applying the product.
3. *Vaginal cream:* (If prefilled applicators are being used, skip to step 4.) Unscrew the cap; place the cap upside down on the end of the tube. Push down firmly until the seal is broken. Attach the applicator to the tube by turning the applicator clockwise. Squeeze the tube from the bottom to force the cream into the applicator. Squeeze until the inside piece of the applicator is pushed out as far as possible and the applicator is completely filled with cream. Remove the applicator from the tube. *Vaginal tablets or suppositories:* Remove the wrapper and place the product into the end of the applicator barrel.
4. While standing with feet slightly apart and knees bent, as shown in drawing A, or while lying on your back with knees bent, as shown in drawing B, gently insert the applicator into the vagina as far as it will go comfortably.
5. Push in the inside piece of the applicator, and place the cream as far back in the vagina as possible. To deposit vaginal tablets or suppositories, insert the applicator into the vagina and press the plunger until it stops.
6. Remove the applicator from the vagina.

7. After use, recap the tube (if using cream). Then clean the reusable applicator by pulling the two pieces apart and washing them with soap and warm water. Throw away disposable applicators after 1 use. 8. If desired, wear a sanitary pad to absorb leakage of the vaginal antifungal. Do not use a tampon to absorb leakage, as this will absorb the medication and reduce its efficacy. 9. Continue using the product for the length of time specified in the product instructions. Use the product every day without skipping any days, even during menstrual flow.	

The major effect of antifungals is alteration of fungal cell membrane permeability. These drugs inhibit cytochrome P450 (CYP) enzymes in the cell membrane, thereby decreasing synthesis of the fungal sterol ergosterol. The reduced membrane content of ergosterol is accompanied by an increase in lanosterol-like methylated sterols. These sterols cause structural damage to fungal membranes, resulting in the loss of normal membrane function.

Systemic absorption of clotrimazole is approximately 3%–10%, with negligible absorption for miconazole and tioconazole.^{25–28} Adverse effects from topical imidazoles include vulvovaginal burning, itching, and irritation in 3%–7% of patients.^{25–27} These adverse effects are more likely to occur with the initial application of the vaginal preparation and are similar to symptoms of the vaginal infection. This vaginal irritation may be dose-related, so selecting a product formulation with a longer course and lower strength may help. Abdominal cramps (3%), penile irritation, and allergic reactions (3%–7%) are uncommon, and headache may occur in up to 9% of women.¹

Drug interactions are unlikely because absorption of the antifungals is limited. However, a documented interaction between miconazole vaginal suppositories and warfarin indicates that their concomitant use might pose an increased bleeding risk, because both medications are metabolized by CYP2C9.²⁸ Therefore, pharmacists should contact the patient's primary care provider about possible dosage reductions of warfarin during concurrent therapy, to avoid an increase in the international normalized ratio (INR). The product information advises women using warfarin in combination with these products that bleeding or bruising may occur. Aside from an allergy to imidazoles, contraindications do not exist with the use of topical imidazoles.

Pharmacotherapeutic Comparison

Studies have shown the imidazoles to be equally efficacious, with effectiveness rates of about 80%–90%.^{3,11} A comparison of miconazole single-dose and 7-day treatments has shown similar overall cure rates, with significantly faster rates of symptom relief by day 3 in the single-dose group than in the 7-day treatment group.²⁹ Nonprescription antifungals are available as 7-day regimens of clotrimazole and miconazole; 3-day regimens of clotrimazole and miconazole; and single-dose regimens of clotrimazole, miconazole, and tioconazole. Reviews assessing VVC treatments continue to show similar efficacy among the nonprescription imidazole products.^{14,30}

Several other nonprescription vaginal preparations, such as Vagisil cream, containing benzocaine and resorcinol, also are available. These agents may provide relief of pruritus (itching), but the underlying cause is not addressed. Health care providers should counsel patients on the possible risk of methemoglobinemia associated with benzocaine-containing products.³¹ The use of these agents is therefore rarely, if ever, appropriate, especially in view of the benefits of the imidazole antifungals, including superior efficacy, improved patient adherence, less frequent local reactions, reduced rate of associated adverse effects, and shorter treatment durations. Rarely, products containing benzocaine and resorcinol and medicated douches may be reserved for vaginal and vulvar irritation and itching; they should be used for a limited time only and on the advice of a primary care provider ([Table 8–4](#)).

Table 8–4 Selected Nonprescription Drug Products for Vaginal Itching and Irritation

Trade Name	Primary Ingredient(s)
Pramoxine Products^a	
Vagisil Anti-Itch Original Formula	Benzocaine 5%; resorcinol 2%
Vagisil Maximum Strength	Benzocaine 20%; resorcinol 3%
Hydrocortisone Products^b	
Cortizone-10 Feminine Relief	Hydrocortisone 1%
Povidone/Iodine Products	
Summer's Eve Medicated	Povidone/iodine 0.3% (in disposable bottles)

Trade Name	Primary Ingredient(s)
Douche	
Homeopathic Products	
Yeast-Gard Suppository ^c	<i>Pulsatilla</i> (27×); <i>Candida albicans</i> (27×) <i>Candida parapsilosis</i> (27×)
Yeast-Gard Gel Treatment ^d	<i>Pulsatilla</i> (27×); <i>Candida albicans</i> (27×) <i>Candida parapsilosis</i> (27×)
Other Products	
Summer's Eve Feminine Powder ^e	
Vagisil Feminine Powder ^e	Cornstarch; aloe; mineral oil (in Summer's Eve)

^a Apply benzocaine products externally.

^b Apply hydrocortisone products externally; avoid prolonged use; may use concomitantly with antifungal products.

^c Use 1 Yeast-Gard suppository daily for 7 days.

^d Use 1 Yeast-Gard gel treatment daily as needed.

^e Apply feminine powders externally to absorb moisture.

Product Selection Guidelines

Special Populations

Self-treatment for VVC is not appropriate for patients younger than 12 years of age. This condition is rare in premenarchal girls. Vaginal symptoms in this age group warrant a medical referral to determine the cause. Infections in prepubertal children may indicate potential sexual abuse.³²

Self-care in pregnancy is not appropriate. However, when treatment of VVC is indicated, treatment may consist of the 7-day options of clotrimazole, miconazole, or tioconazole.¹¹ When possible, treatment should be withheld during the first trimester.³² The patient's primary care provider should evaluate for complications, such as hyperglycemia, and assess for other organisms,

because BV and trichomoniasis have the potential for adverse pregnancy outcomes. No special considerations are necessary to treat breastfeeding, older, or immunocompetent women presenting with a VVC infection.¹¹

Patient Factors and Preferences

Selection of cream, tablet, or suppository formulations can be left to the patient, because some women may prefer the convenience of prefilled applicators. Women who have previously experienced VVC may prefer shorter courses of therapy such as single-dose or 3-day options, whereas those who have not had a prior infection opt for more prolonged therapy.¹ Once VVC is confirmed, the decision regarding which product to select should be based on patient preference or other patient-specific factors.³³ If vulvar symptoms are significant, a cream preparation or the combination of a cream with vaginal suppositories or tablets is preferred. Morning or bedtime dosing is available to provide flexibility for patients.

Complementary Therapies

Alternative approaches to treating VVC may include the use of *Lactobacillus* preparations and products such as tea tree oil or boric acid. With *Lactobacillus* products, the rationale for their use is to reestablish normal vaginal flora and inhibit overgrowth of *Candida* organisms. Available data on the effectiveness of this approach, although limited, show benefit for prevention. One study showed a reduction in VVC recurrence with a regimen of *Lactobacillus fermentum* and *Lactobacillus acidophilus* vaginal tablets on alternating days for 10 days followed by 1 vaginal tablet per week for 10 weeks.³⁴ Daily consumption of yogurt with live cultures also may be of some benefit in decreasing VVC symptoms.²² Nonprescription probiotic feminine supplements may be used to reestablish *Lactobacillus*. RepHresh Pro-B probiotic feminine supplement is an easy-to-use product (at a cost of approximately \$25–\$30 for a 30-day supply). Patients take 1 capsule by mouth daily. (See [Chapter 20](#), Table 20–2, for information about probiotics.)

A sodium bicarbonate sitz bath may afford prompt, temporary relief of vulvar irritation associated with a *Candida* vaginal infection before antifungal agents can provide noticeable benefit.³⁵ With resistant VVC infections, tea tree oil may be beneficial owing to its dual antibacterial and antifungal properties.³⁶ A 200-mg vaginal suppository containing tea tree oil may be used once daily for

6 consecutive nights. Allergic dermatitis may occur with this treatment, however. (Further information on tea tree oil is presented in [Chapter 51](#).)

Gentian violet is a topical option used for resistant *Candida* vaginal infections.³⁷ A tampon may be soaked in gentian violet and inserted into the vagina for several hours or overnight. Often a single application is adequate, but tampons saturated with gentian violet can be used once or twice a day for up to 5 consecutive days.

To manage non-*C. albicans* infections, which may be resistant to imidazole antifungals, boric acid may be an effective option. A boric acid 600-mg capsule may be inserted vaginally once daily for 14 days.^{3,11} Short-term cure rates with boric acid demonstrate efficacy, with approximate cure rates of 70% when used in women whose infection did not respond to vaginal antifungals.^{9,11,38} Boric acid capsules may be compounded in community pharmacies. Patient counseling should stress that the capsule is not to be ingested. Pregnant women should not use boric acid.

Assessment of Vulvovaginal Candidiasis: A Case-Based Approach

Many episodes of VVC are uncomplicated and can be effectively treated with topical imidazole agents.³ In particular, the best candidates for self-treatment are otherwise healthy women who experience episodes that are sporadic and uncomplicated and those patients who predictably experience VVC after a course of antibiotic therapy.²¹

Determining the appropriateness of self-care and the likelihood of a *Candida* vaginal infection are important initial steps in advising the patient about the management of vaginal symptoms with nonprescription drug therapy.

Health care providers may advise patients when it is appropriate to self-treat for vaginal symptoms that are consistent with VVC, and when medical evaluation, including pelvic examination and laboratory examination of vaginal secretions, is indicated. Self-treatment is most appropriate when the clinical scenario meets the following four criteria¹¹:

1. Vaginal symptoms are infrequent (i.e., no more than 3 vaginal infections

- per year and no vaginal infection within the past 2 months).
2. A medical practitioner diagnosed at least 1 previous episode of VVC.
 3. Symptoms are mild to moderate and consistent with the characteristic signs and symptoms of VVC, particularly in the absence of a foul odor to the discharge.
 4. If measured, vaginal pH is 4.5 or lower.

Case 8–1 provides an example of the assessment of a patient presenting with a vaginal infection.

Patient Counseling for Vulvovaginal Candidiasis

Counseling of patients who are considering self-treatment with vaginal antifungals should emphasize limiting this approach to management of mild to moderate classic symptoms, infrequent vaginal symptoms, and predictable antibiotic-associated VVC. Patients with possible recurrent infections or with predisposing illnesses are not candidates for self-care; they should be advised to see their primary care provider and may require treatment with prescription options. Therefore, a medical evaluation should be obtained if symptoms persist beyond 1 week after treatment or if they recur within 2 months. Also, if vaginal symptoms occur more than 3 times in a 12-month interval, further evaluation is needed. Women taking warfarin should be referred to their primary care provider.

Patients should be informed that a single-dose to 7-day course of a nonprescription vaginal antifungal product will kill the yeast organisms that caused the infection. Label instructions should be reviewed in appropriate detail. Use of the product only once a day for the specified length of time should be stressed. The patient should be advised that symptomatic relief will likely begin within 2 or 3 days but that it may take a week for complete resolution of symptoms. The patient also should be provided with a list of signs and symptoms indicating the need for medical evaluation. The box “Patient Education for Vulvovaginal Candidiasis” lists specific information for patient counseling.

Case 8–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient reports experiencing vaginal pruritus (itching) with discharge for the past 4 days.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient does not report any relevant factors.
c. Description of the patient's efforts to relieve the symptoms	Patient reports that she has not tried anything yet.
d. Patient's identity	Bonnie Stickly
e. Patient's age, gender, height, and weight	34 years, female, 5 ft 5 in., 130 lb
f. Patient's occupation	Chef
g. Patient's dietary habits	Reports eating 3 regular meals/day, with 1 or 2 snacks in between.
h. Patient's sleep habits	Reports sleeping about 7–8 hours each night.
i. Concurrent medical conditions, prescription and nonprescription	Seasonique 1 tablet daily; loratadine 10 mg as needed for seasonal allergies.

Relevant Evaluation Criteria	Scenario/Model Outcome
medications, and dietary supplements	
j. Allergies/other adverse reactions to medications	Sulfa (rash)
k. History of other adverse reactions to medications	None
l. Other (describe)	Per her medical history, Mrs. Stickly has been diagnosed with previous VVC infections, with her most recent infection 4 years ago. She indicates her current discharge is white and she does not notice an odor. She states the symptoms remind her of previous VVC infections.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 8–1).	Mrs. Stickly has itching and white discharge without an odor, findings consistent with a <i>Candida</i> vaginal infection.
3. Identify exclusions for self-treatment (Figure 8–1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mrs. Stickly for medical evaluation. (2) Recommend self-treatment with an OTC vaginal antifungal product to Mrs. Stickly. (3) Take no action.
Plan	
5. Select an optimal	Mrs. Stickly has symptoms associated with an uncomplicated VVC

Relevant Evaluation Criteria	Scenario/Model Outcome
therapeutic alternative to address the patient's problem, taking into account patient preferences.	infection. She has had a previous VVC infection and reports no chronic medical problems. She is a candidate for self-treatment. (See Figure 8-1 .)
6. Describe the recommended therapeutic approach to the patient or caregiver.	"There are several nonprescription vaginal antifungal products available. Given the bothersome vulvar itching, a combination product with a suppository and a cream may be preferred to assist in relieving your symptoms." (See the box "Patient Education for Vulvovaginal Candidiasis" for instructions on proper use.)
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This treatment is appropriate because you have symptoms common with vulvovaginal candidiasis infections, your symptoms are mild to moderate, and you have no contraindications or exclusions to self-treatment. It is recommended that you see your primary care provider if your symptoms do not subside within 3 days or are not gone within 1 week; if the vaginal discharge changes (especially if it becomes malodorous or changes presentation from white to yellow); or if your symptoms return within the next 2 months."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	"Insert the clotrimazole cream vaginally once daily for 3 days; apply externally to the vulva as needed to relieve itching for up to 7 days."
b. Maximum number of days the therapy should be employed	"Insert the cream for 3 days."
c. Product administration	See Table 8-3 .

Relevant Evaluation Criteria	Scenario/Model Outcome
procedures	
d. Expected time to onset of relief	"Relief should occur within the first 3 days; often initial relief occurs within hours of the first application."
e. Degree of relief that can be reasonably expected	"All symptoms typically resolve within 1 week after beginning treatment."
f. Most common adverse effects	"Vulvovaginal burning and itching are the most common adverse effects."
g. Adverse effects that warrant medical intervention should they occur	"Significant stinging, burning, or itching that persists beyond the first 48 hours of treatment should be medically evaluated."
h. Patient options in the event that condition worsens or persists	"See your primary care provider if symptoms do not lessen in 3 days or they worsen."
i. Product storage requirements	"The product should be stored in a cool area; storage in the bathroom or bedside is appropriate for ease of use."
j. Specific nondrug measures	None
Solicit follow-up questions from patient or caregiver.	(1) "Are any of the nonprescription vaginal antifungal products more effective than another?"
	(2) "Can probiotics also treat this infection?"
Answer patient's or caregiver's questions.	(1) "No, all of the products and regimens are equally effective in treating this infection."
	(2) "Probiotics may be helpful with prevention of infections and may decrease VVC recurrences. The OTC imidazoles are preferred for treatment."
Follow-up: Monitor and Evaluate	

Relevant Evaluation Criteria	Scenario/Model Outcome
9. Assess patient response.	Ask the patient to contact you regarding her treatment outcome. Alternatively, you could call her in a week to evaluate her response to the treatment.
	You called Mrs. Stickly 1 week later, and she reported that her symptoms had resolved.

Key: OTC = Over-the-counter; VVC = vulvovaginal candidiasis.

Evaluation of Patient Outcomes for Vulvovaginal Candidiasis

Symptoms of VVC should lessen within 2 or 3 days of initiation of therapy and resolve within 1 week. The length of treatment, particularly for single-dose and 3-day treatments, does not directly correspond with the time to resolution of symptoms.

The health care provider should advise the patient to call if symptoms persist. With any selected regimen, the importance of adherence must be emphasized. Persistent or new symptoms that are not consistent with VVC constitute a reason for advising the patient to seek a medical referral.

Atrophic Vaginitis

Atrophic vaginitis is inflammation of the vagina related to atrophy of the vaginal mucosa secondary to decreased estrogen levels.

Although up to 45% of postmenopausal women may experience symptomatic atrophic vaginitis, only a small percentage may seek treatment.⁴ *Dyspareunia*, or painful intercourse, is a symptom sometimes related to inadequate vaginal lubrication or atrophic vaginitis.

Pathophysiology of Atrophic Vaginitis

During menopause, the postpartum period, and breastfeeding, the vaginal epithelium becomes thin, and vaginal lubrication declines because of a decrease in estrogen levels. Women may experience atrophic vaginitis and dyspareunia during these intervals.⁴ Atrophic vaginitis also may occur among women with decreased ovarian estrogen production, such as that caused by radiation therapy or chemotherapy. Women taking gonadotropin-releasing hormone (GnRH) agonists, antiestrogenic drugs, and aromatase inhibitors also may experience atrophic vaginitis.⁴

Patient Education for Vulvovaginal Candidiasis

The goals of self-treatment are to cure the vaginal fungal infection and to reestablish normal vaginal flora. Carefully following the product instructions and the self-care measures will help ensure optimal therapeutic outcomes.

Nondrug Measures

- If significant irritation of the vulva is present, take a sodium bicarbonate sitz bath to provide relief and allow the antifungal medication time to become effective.
 - Add 1 teaspoon sodium bicarbonate to 1 pint of water.
 - Add 2–4 tablespoons of the solution to 2 inches of bath water.
 - Sit in the sitz bath or bathtub for 15 minutes as needed for symptom control.
- For recurrent infections, try eating yogurt (1 cup per day of live-culture yogurt) and decreasing dietary sugar and refined carbohydrates.

Nonprescription Medications

- Insert the antifungal product into the vagina once a day, preferably at bedtime to minimize leakage from the vagina. Use a sanitary pad or panty liner to avoid staining of underwear.
- **Table 8–3** provides instructions on administering vaginal antifungals. Significant relief of symptoms should occur within 24–48 hours, and relief is often apparent within hours after the first dose. However, the length of treatment (particularly for single-dose to 3-day treatments) does not directly correspond with the time to resolution of symptoms.
- Continue the therapy for the recommended length of time, even if symptoms have resolved. Stopping treatment early is a common reason for recurrence of vaginal symptoms and, possibly, colonization with difficult-to-treat organisms.
- Vaginal antifungals can be used during a menstrual period. If desired, wait and treat the infection after menses ends. Do not interrupt a course of therapy if menses begins.
- Do not use tampons or douche while using a vaginal antifungal and for 3 days after use.
- Although adverse effects are uncommon, the first dose of the antifungal may cause some vaginal burning and irritation, and a few women (about 1 in 10) experience a headache.
- Refrain from sexual intercourse during treatment with the vaginal antifungal. Vaginal lubricants and vaginal spermicides should not be used at the same time as the vaginal antifungal. Vaginal antifungals can damage latex condoms and diaphragms and may result in unreliable contraceptive effects. Do not use these contraceptives during therapy or for 3 days after therapy, because the antifungal medication remains in the vagina for several days.

When to Seek Medical Attention

- Do not use vaginal antifungals if
 - You have not been medically diagnosed with VVC at least once.
 - You are younger than 12 years of age.
 - You are pregnant.
 - You have diabetes; are positive for human immunodeficiency

virus (HIV) or have acquired immunodeficiency syndrome (AIDS); or have impaired immune function, including that due to certain medications with effects on the immune system.

- You are using warfarin.

When to Seek Medical Attention

- Seek medical attention if symptoms do not lessen within 3 days or symptoms persist beyond 7 days.
- Seek medical attention if vaginal symptoms worsen or change, especially if the vaginal secretions begin to smell bad or become frothy or discolored, or if other symptoms (e.g., abdominal tenderness) occur. These events may indicate that the *Candida* (yeast) organisms are resistant to the nonprescription therapy or that another type of vaginal infection is present.

Clinical Presentation of Atrophic Vaginitis

Atrophic vaginitis is associated with a decrease in vaginal lubrication.⁴ Other manifestations include vaginal irritation, dryness, burning, itching, and dyspareunia. A thin, watery (occasionally bloody), or yellow malodorous vaginal discharge or “spotting” also may be present.^{3,4,6} Sexual activity may result in vaginal bleeding or spotting. A new episode of postmenopausal vaginal bleeding warrants medical referral to rule out endometrial cancer.

Treatment of Atrophic Vaginitis

Self-treatment for atrophic vaginitis is limited to alleviating the primary symptom, vaginal dryness, with lubricant products. To alleviate vaginal dryness in women experiencing moderate to severe symptoms, estrogen therapy may be required. Women who are breastfeeding or have recently given birth often experience a temporary decline in estrogen levels. Vaginal lubricants may be

needed only until estrogen levels return to normal.

Treatment Goals

The goals of therapy are to reduce or eliminate the symptoms of vaginal dryness, burning, and itching, and to eliminate dyspareunia if vaginal dryness is the cause of painful sexual intercourse, by providing lubrication to vaginal tissue.

General Treatment Approach

Vaginal dryness may often be treated with a variety of lubricants such as those listed in [Table 8–5](#). Self-treatment is appropriate when the symptoms are mild to moderate and confined to the vaginal area and when no bleeding is present. Women with severe vaginal dryness, dyspareunia, or bleeding should be referred for medical evaluation.

Table 8–5 Selected Nonprescription Vaginal Lubricants	
Trade Name	Primary Ingredient(s)
Astroglide; K-Y Personal Lubricant Liquid ^a	Glycerin; propylene glycol; hydroxyethylcellulose
K-Y Liquibeads	Glycerin; dimethicone; dimethiconol; gelatin
K-Y Warming Liquid Personal Lubricant	Propylene glycol; hydroxypropylcellulose; tocopherol; PEG 8
Replens Gel Silky Smooth Personal Lubricant	Glycerin; mineral oil

^a Fragrance-free formulation.

Key: PEG = Polyethylene glycol.

[Figure 8–2](#) outlines the approach to treating vaginal dryness associated with atrophic vaginitis.

Nonpharmacologic Therapy

Vaginal Lubricants

Multiple water-soluble products, including Astroglide, K-Y Jelly, and Replens, are available for vaginal lubrication. Personal lubricant products temporarily moisten vaginal tissues. These products provide short-term improvement of symptoms such as burning and itching. Personal lubricants also can provide vaginal lubrication to facilitate sexual intercourse.⁴

Petroleum jelly should not be used because it is difficult to remove from the vagina. Only water-soluble lubricants should be used with a latex condom or diaphragm, because other products may damage the latex and impair the efficacy of these contraceptive devices. Water-soluble lubricant gels can be applied both externally and internally. Initially, the patient should be instructed to use a liberal quantity of lubricant (≤ 2 teaspoons) and then to tailor the quantity and frequency of use to her specific needs. If the patient is self-treating for dyspareunia, the lubricant should be applied to both the vaginal opening and the penis. If the use of lubricants does not produce adequate benefit or is esthetically unappealing to the patient, she should be referred for medical evaluation.

Algorithm: Atrophic Vaginitis

Figure 8–2 Self-care for atrophic vaginitis. (Source: [Reference 4.](#))

Assessment of Atrophic Vaginitis: A Case-Based Approach

When discussing a complaint of vaginal dryness during the patient assessment, the health care provider should obtain a description of signs and symptoms, including any association with sexual intercourse and their severity. This assessment also should ascertain whether the woman has recently given birth, is lactating, or is perimenopausal or postmenopausal. In addition, the use of any vaginal or feminine hygiene products that may cause or worsen vaginal

irritation and dyspareunia should be identified.

Case 8–2 provides an example of the assessment of a patient presenting with atrophic vaginitis.

Patient Counseling for Atrophic Vaginitis

The health care provider should stress the short-term nature of the tissue changes leading to atrophic vaginitis in women who are breastfeeding or who have recently given birth. Women who are perimenopausal or postmenopausal should be advised that long-term treatment with vaginal lubricants may be necessary. In either case, the health care provider should explain the proper use of lubricants for treatment of vaginal dryness or dyspareunia. The box “Patient Education for Atrophic Vaginitis” lists specific information to provide in patient counseling.

Case 8–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is experiencing vaginal irritation, dryness and dyspareunia. She reports experiencing these symptoms for several weeks.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms are worse during intercourse.

Relevant Evaluation Criteria	Scenario/Model Outcome
c. Description of the patient's efforts to relieve the symptoms	Patient reports that she has tried OTC lubricants sometimes during intercourse but still has symptoms.
d. Patient's identity	Kerry Korr
e. Patient's age, gender, height, and weight	50 years, female, 5 ft 4 in., 139 lb
f. Patient's occupation	Jewelry store owner
g. Patient's dietary habits	Reports eating 3 meals per day, with 2 snacks/day as needed.
h. Patient's sleep habits	Reports sleeping 7–8 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Daily multivitamin
j. Allergies/other adverse reactions to medications	NKDA
k. History of other adverse reactions to medications	None
l. Other (describe) -----	Ms. Korr is postmenopausal and experiencing vaginal irritation, dryness, and dyspareunia not relieved by OTC lubricants. Per her medical history, she has tried such lubricants sometimes during intercourse and has no prior use of estrogen therapy. She reports a history of a hysterectomy 1 year ago.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Ms. Korr is postmenopausal. She has vaginal irritation, dryness and dyspareunia but no symptoms indicative of other vaginal infections. These symptoms are consistent with atrophic vaginitis.
3. Identify exclusions for self-treatment (Figure 8-2).	She has vaginal irritation, dryness, and dyspareunia as her primary symptoms. She has tried OTC lubricants during

Relevant Evaluation Criteria	Scenario/Model Outcome
	intercourse with minimal relief.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required and share this information with the patient or caregiver.	Options include (1) Educate Ms. Korr on using the OTC lubricants more frequently. She may use the lubricants daily, as well as during intercourse. (2) Refer Ms. Korr to her primary care provider for possible vaginal estrogen therapy. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because Ms. Korr has dyspareunia as one of her symptoms and has tried OTC lubricants during intercourse with minimal relief, she is not a candidate for self-care. The recommended option for this patient is to see her primary care provider to further assess her dyspareunia and vaginal irritation and dryness. Her primary care provider may explore the use of vaginal estrogen therapy to relieve the patient's symptoms.
6. Describe the recommended therapeutic approach to the patient or caregiver.	See the box "Patient Education for Atrophic Vaginitis."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"With your vaginal dryness and dyspareunia symptoms, I recommend that you follow up with your primary care provider to consider the use of a vaginal estrogen product. They are generally more effective than lubricants and moisturizers for atrophic vaginitis, such as the product you have been trying. However, you may still use your nonprescription lubricant to assist you with some symptom relief until you see your primary care provider."
Implement	
8. When recommending self-care with nonprescription	Criterion does not apply in this case.

Relevant Evaluation Criteria	Scenario/Model Outcome
medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
Solicit follow-up questions from patient or caregiver.	(1) "I was using my lubricant sometimes with intercourse. How often may I use this nonprescription lubricant?"
	(2) "Will I have to take oral estrogen?"
Answer patient's or caregiver's questions.	(1) "A liberal quantity (2 teaspoons) of nonprescription lubricants may be used as frequently as needed. You may try daily and during intercourse to see if it relieves your symptoms before seeing your primary care provider."
	(2) "Oral estrogen therapy usually is not needed for the treatment of atrophic vaginitis. Typically, the use of vaginal estrogen products (creams, tablets or vaginal rings) will offer relief of symptoms."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact the patient in 1-2 days to follow up and confirm she has made an appointment for further evaluation and medical care.

Key: NKDA = No known drug allergy; OTC = over-the-counter.

Patient Education for Atrophic Vaginitis

The objective of self-treatment with vaginal lubricants is to relieve vaginal dryness and pain during sexual intercourse related to atrophic vaginitis. Carefully following product instructions and the self-care measures listed

here will help to ensure optimal therapeutic outcomes.

- Apply the vaginal lubricant as frequently as needed for relief of vaginal dryness, irritation, burning, or itching, or for inadequate vaginal lubrication.
- Begin treatment for atrophic symptoms with a liberal quantity of lubricant (2 teaspoons); tailor subsequent doses to the quantity and frequency of use needed to provide relief.
- If using lubricants at the time of sexual intercourse, apply the lubricant to the vagina, particularly at the vaginal opening, and to the penis.
- Some leakage of product will occur. If desired, use a sanitary napkin or panty liner to avoid staining of underwear.
- Relief of symptoms may be apparent within hours after the first dose. Regular application of a lubricant can reverse atrophic symptoms to some extent.
- If no improvement is noticeable within a week, or if symptoms worsen or there is any vaginal bleeding, see your primary care provider.

Evaluation of Patient Outcomes for Atrophic Vaginitis

Symptoms of atrophic vaginitis typically lessen within a week of initiation of treatment. The health care provider should advise the patient to call to discuss treatment effectiveness if concerns arise, and to call after 1 week of treatment to report progress in symptom resolution. Persistence of symptoms or the presence of bleeding necessitates medical evaluation.

Vaginal Douching

Prevalence of Douching

The Centers for Disease Control and Prevention reports that 18.8% of U.S. women practice douching.³⁹

A common reason stated for douching is to achieve good vaginal hygiene.^{40,41} Because vaginal douches mechanically irrigate the vagina, clearing away mucus and other accumulated debris, these products may be considered for use as cosmetic cleansing agents. Douching products may vary by ingredients, such as water/vinegar (acetic acid) or povidone/iodine products.

Potential Adverse Effects of Douching

Douching may lead to adverse health outcomes. Douching has been associated with an increased risk for PID, ectopic pregnancy, vaginal infections such as BV, and preterm delivery.^{40,41} Additional problems may include irritation or sensitization from douche ingredients and disruption of the normal vaginal flora and vaginal pH. Allergic reactions may occur with intravaginal povidone/iodine, because systemic absorption is possible. Products containing this combination agent should not be used by women who are allergic to iodine. [Table 8–4](#) lists examples of douche products that contain povidone/iodine.

Use of Douching Equipment

Two types of syringes are available for douching purposes: douche bags and bulb douche syringes. The douche bag, or fountain syringe or folding feminine syringe, holds 1–2 quarts of fluid and comes with tubing and a shutoff valve. Two types of tips are supplied: one for enema use (the shorter rectal nozzle) and a longer one for douching. The two tips are not interchangeable; vaginal infections may occur if a single tip is used for both douching and enemas.

Bulb douche syringes are available as both disposable and nondisposable products. The nondisposable units hold 8–16 ounces of fluid, whereas the disposable units contain 3–9 ounces. The flow rate is regulated by the amount

of hand pressure exerted when the bulb is squeezed. Gentle pressure is recommended, because excess pressure may force fluid through the cervix, causing uterine inflammation. Instructions on proper use of the device are presented in [Table 8–6](#).

Table 8–6 Administration Guidelines for Douches

Bulb Douche Syringe Method

- Choose a comfortable douching position. Two positions are recommended: (1) sitting on the toilet or (2) standing in the shower. Whichever position is chosen, remember that douching is easier when the user is relaxed.
- Gently insert the nozzle about 3 inches into the vagina. Avoid closing the lips of the vagina.
- Squeeze bottle gently, letting solution cleanse the vagina and then flow freely from the body.
- After douching, throw away bottle and nozzle, if they are disposable.

Douche Bag Method

- Fill the douche bag with the prescribed solution or with a warm water and vinegar solution.
- Lie back in the tub with knees bent. Place the douche bag about 1 foot above the height of hips. Do not place or hang the bag any higher because such height will cause the pressure of fluid entering the vagina to be too high.
- Insert the nozzle several inches into the vagina. Aim the nozzle up and back toward the small of the back. While holding the labia closed around the nozzle, release the clamp slowly to allow fluid to enter the vagina. Rotate the tip and allow fluid to enter the vagina until the vagina feels full. Stop the flow of fluid; then hold the fluid in the vagina for about 30–60 seconds. Release and allow the fluid to flow out; repeat until the douche bag is empty.
- Wash the nozzle with mild soap and water.

Patient Counseling for Douching

In the patient assessment, the health care provider should ascertain the woman's reasons for douching. The possible adverse consequences of douching should be clearly identified, with emphasis that this practice is not necessary for internal cleanliness because the vagina is self-cleansing. Douching for routine hygienic purposes should be discouraged, and douching is contraindicated during pregnancy. Douching should be delayed at least 6–8 hours after sexual intercourse if a vaginal spermicide was used as a contraceptive agent.

An alternative cleansing method for vaginal and perineal areas should be

suggested, such as using the fingers to gently wash the outer vaginal area and the vulvar, perineal, and anal regions with lukewarm water and mild soap. If a woman is douching to prevent or treat symptoms of a vaginal infection, such as an abnormal vaginal discharge, she should be counseled about more effective therapy or referred for medical evaluation, as appropriate.

Patients for whom douches have been prescribed or those who insist on douching for other reasons should be instructed on how to use these products safely and effectively. The box “Patient Education for Douching” lists specific information to provide in patient counseling.

Patient Education for Douching

Women should be informed that douching is not necessary for cleansing of the vagina. An alternative cleansing method for vaginal and perineal areas should be suggested, such as using the fingers to gently wash the outer vaginal area and the vulvar, perineal, and anal regions with lukewarm water and mild soap. Improper methods of douching or too-frequent douching can cause vaginal irritation. Douching also can increase the risk for adverse outcomes such as pelvic inflammatory disease. Strictly following the product instructions and the self-care measures listed here will help avoid these problems.

- Keep all douche equipment clean.
- Use lukewarm water to dilute products.
- Follow the appropriate instructions in [Table 8–6](#) for the method of douching being used.
- Never instill the douche solution with forceful pressure.
- Do not use these products for birth control.
- Do not douche until at least 6–8 hours after intercourse during which a diaphragm, cervical cap, or contraceptive jelly, cream, or foam was used.
- Do not douche for at least 3 days after the last dose of vaginal antifungal medication.
- Do not douche for 48 hours before any gynecologic examination.
- Do not douche during pregnancy unless under the supervision of a

primary care provider.

- Use douches only as directed and as recommended by a primary care provider.
- Do not douche more often than twice a week, except on the advice of a primary care provider.
- If vaginal dryness or irritation occurs, discontinue use of the douche.

Key Points for Vaginal and Vulvovaginal Disorders

- Vaginal symptoms often are nonspecific, and it may be difficult to distinguish among symptoms of the three common vaginal infections. The feature most likely to differentiate a *Candida* vaginal infection from BV and trichomoniasis is absence of an offensive odor of the vaginal secretions. Measurement of vaginal pH (pH >4.5 rules out a *Candida* infection) also may help to identify *Candida* infection and to reduce inappropriate use of nonprescription vaginal antifungals.
- *Candida* vaginal infections typically are caused by *C. albicans*, but non-*C. albicans* vaginal infections have increased in frequency. The latter may be more resistant to nonprescription vaginal antifungals.
- Self-treatment for a *Candida* vaginal infection is most appropriate when the patient's symptoms are mild to moderate, when she does not have predisposing illnesses or is taking predisposing medications, when she has had one previously diagnosed infection, and when her symptoms are not recurrent. Recurrent infections are defined as more than three infections occurring within a 12-month period and symptoms recurring within 2 months of previous vaginal symptoms.

- The nonprescription vaginal antifungals are equally effective. Selection of length of regimen or time of day for administration may be determined by patient preference. A medical referral is advised for women taking warfarin. Patients should be informed that symptoms typically lessen within 2 or 3 days after initiation of the nonprescription vaginal antifungals and resolve within a week. The length of the treatment regimen does not directly correspond with resolution of symptoms.
- Use of a sodium bicarbonate sitz bath may provide relief of pruritus (itching) and irritation before the onset of definitive benefit from the antifungal.
- Daily consumption of yogurt with live cultures may benefit some patients in preventing recurrent VVC infections.
- Atrophic vaginitis may occur after menopause, after giving birth, during breastfeeding, or as a result of antiestrogenic medications. Vaginal dryness and dyspareunia may be relieved with use of topical personal lubricant products. If symptoms persist, medical evaluation is needed.
- Atrophic vaginitis may cause vaginal bleeding. Any patient who reports postmenopausal bleeding should be referred to an appropriate health care provider to rule out endometrial cancer.
- Douching is not recommended for vaginal cleansing, because douching can have adverse consequences. Douching is contraindicated during pregnancy. Douching should be postponed until at least 6–8 hours after sexual intercourse if a vaginal spermicide was used for contraception.

Chapter 9: Disorders Related to Menstruation

Authors: Nardine Nakhla

The menstrual cycle is a regular physiologic event for women that begins in adolescence and usually continues through late middle age. Women are able to self-treat for two common menstrual disorders: primary dysmenorrhea and premenstrual syndrome (PMS). Many women use nonprescription products and seek advice from health care providers on how best to manage symptoms of these disorders, including abdominal pain and cramping, irritability, and fluid retention.¹ An understanding of the menstrual cycle will help both patients and health care providers make informed and appropriate decisions about selfcare. Familiarity with common menstrual symptoms and disorders, as well as the risks for toxic shock syndrome, also will support optimal self-care management.

Menstruation results from the monthly cycling of female reproductive hormones. A *single menstrual cycle* is the time between the onset of one period of menstrual flow (menstruation or menses) and the onset of the next. The average age at *menarche* (the initial menstrual cycle) in U.S. women is 12 years, although normal menarche may occur as early as age 11 or as late as age 14.5.¹ The onset of menstruation is influenced by factors such as race, genetics, nutritional status, and body mass. Menarcheal age has important health implications, as early menarche has been linked to breast and endometrial cancer and late menarche is associated with osteoporosis and increased fracture risk.²

The median menstrual cycle length is 28 days, with a range of 25–34 days for adult women; adolescents show more variability, with long cycle lengths and bleeding irregularities in the first 5 years after menarche until regular ovulatory cycles are established with hormonal maturation.³ The menstrual period lasts 3–7 days, with most blood loss occurring during days 1 and 2.^{1,3} The major components of menstrual fluid are blood and endometrial cellular debris; the average blood loss per cycle is 30 mL, with a range of 10–84 mL.³ A loss of more than 80 mL per cycle or bleeding lasting longer than 7 days is considered abnormal and has classically been defined as *menorrhagia*. Excessive and/or prolonged uterine bleeding requires thorough investigation, as it has been

associated with severe anemia and significant impairments in daily functioning.

The menstrual cycle ([Figure 9-1](#)) results from the combined hormonal activity of the hypothalamus, pituitary gland, and ovaries; this is known as the hypothalamic-pituitary-ovarian (HPO) axis. The hypothalamus plays the key role in regulating the menstrual cycle by producing gonadotropin-releasing hormone (GnRH). Low levels of both estradiol and progesterone, present at the end of the previous menstrual cycle, stimulate the hypothalamus to release GnRH, which stimulates pituitary gonadotroph cells to synthesize and secrete luteinizing hormone (LH) and follicle-stimulating hormone (FSH).

Two principal reproductive events occur during each menstrual cycle: the maturation and release of an ovum (egg) from the ovaries and the preparation of the endometrial lining of the uterus for the implantation of a fertilized ovum. The events of the menstrual cycle can be described in phases that reflect changes in either the ovary (follicular/ovulatory and luteal phases) or the uterine endometrium (menstrual/proliferative and secretory phases). The follicular/ovulatory phase coincides with the menstrual/proliferative phase, and the luteal phase coincides with the secretory phase.

Cycle day 1 is the first day of menstrual flow and the beginning of the follicular and menstrual/proliferative phases. The follicular phase lasts an average of 14 days, ranging in length from several days to several weeks, and ends with ovulation. During the follicular phase, FSH stimulates the maturation of a group of ovarian follicles. These maturing follicles secrete estradiol promoting growth of the uterine endometrium.

By approximately day 8 of the menstrual cycle, a single ovarian follicle usually becomes dominant, and the remaining follicles will undergo atresia. Anti-Müllerian hormone (AMH) plays a role in the selection of this dominant follicle, which typically results in the release or ovulation of only one mature egg. The ovulatory phase of the cycle is about 3 days in length. During this phase, the pituitary gland secretes high levels of LH for a 48-hour period, which is known as the LH surge. The LH surge catalyzes the final steps in the maturation of the ovum and stimulates production of prostaglandins and proteolytic enzymes necessary for ovulation. Estradiol levels decrease during the LH surge, sometimes resulting in midcycle endometrial bleeding. Ovulation typically occurs 12 hours after the LH surge. Ovulation releases 5–10 mL of follicular fluid, which contains the oocyte mass and prostaglandins; this event may be associated with abdominal pain (*mittelschmerz*, German for “middle pain”) for some women.

The *luteal phase* is the time between ovulation and the beginning of menstrual blood flow. After the follicle ruptures, it is referred to as the corpus luteum. The luteal phase is typically consistent in length (about 14 ± 2 days) in

all women and reflects the 10- to 12-day functional period of the corpus luteum. The corpus luteum secretes progesterone, estradiol, and androgens. The increased levels of estrogen and progesterone alter the uterine endometrial lining. Glands mature, proliferate, and become secretory as the uterus prepares for the implantation of a fertilized egg. Progesterone and estrogen levels increase in the middle of the luteal phase, but LH and FSH levels decline in response to the increased hormone levels. If pregnancy occurs, human chorionic gonadotropin released by the developing placenta supports the function of the corpus luteum until the placenta develops enough to begin secreting estrogen and progesterone. If pregnancy does not occur, the corpus luteum ceases to function. Estrogen and progesterone levels then decline, causing the endometrial lining of the uterus to become edematous and necrotic. The decrease in progesterone also leads to prostaglandin synthesis. Following prostaglandin-initiated vasoconstriction and uterine contractions, sloughing of the outer two endometrial layers occurs. The decline in estrogen and progesterone results in an increase in GnRH and in the renewed production of LH and FSH, which begins a new menstrual cycle.

Dysmenorrhea

Dysmenorrhea, defined as painful menstruation, is the most common gynecologic problem among adolescents and young adult women. The prevalence of dysmenorrhea is highest in adolescence, with up to 93% of girls being affected.^{4,5} Dysmenorrhea is divided into primary and secondary disorders by etiology. *Primary dysmenorrhea* is associated with cramp-like lower abdominal pain at the time of menstruation in the absence of pelvic disease. Primary dysmenorrhea usually develops within 6–12 months after menarche, generally affecting women during their teens and early 20s.⁶ Primary dysmenorrhea occurs only during ovulatory cycles. Its prevalence increases between early and older adolescence as the regularity of ovulation increases and decreases after age 24.^{4,6,7}

Approximately 10% of women with dysmenorrhea have secondary dysmenorrhea.⁸ As opposed to primary dysmenorrhea, which is menstrual pain without underlying disease, *secondary dysmenorrhea* is typically associated with pelvic pathology. *Endometriosis* is the most common cause of secondary dysmenorrhea and involves growth of cells similar to endometrial cells in locations outside the uterus. *Adenomyosis*, which is growth of

endometrial tissue into the *myometrium*—the muscular wall of the uterus—is another common cause of secondary dysmenorrhea.⁹ An *ectopic pregnancy*, a potentially life-threatening condition in which a fertilized egg implants outside of the uterus, may manifest with signs and symptoms mimicking severe dysmenorrhea and requires emergent referral. Because of the risk of serious complications, ectopic pregnancy should be considered in all women of childbearing age with vaginal bleeding and/or abdominal pain, especially if the history includes amenorrhea for longer than 4 weeks and/or pregnancy status is unknown.

Secondary dysmenorrhea should also be suspected if symptoms first appear 2 years or more after menarche, if pelvic pain occurs at times other than during menses, or if the patient has irregular menstrual cycles or a history of pelvic inflammatory disease (PID), dyspareunia, or infertility.^{4,5,10} In these situations, referral to a primary care provider is required to identify the underlying cause of dysmenorrhea, so that treatment can be targeted appropriately.

Dysmenorrhea is the leading cause of school absenteeism and lost working hours among adolescent girls and young women. About 26% of adolescent girls report dysmenorrhea-related school absenteeism, which increases to 50% among those who report severe pain.¹⁰ In addition, adolescents with severe menstrual pain reported that the pain interferes with function in other aspects of daily life, such as social activities, sports, work, and relationships with friends and family.^{4,10} Similarly, an estimated 600 million work hours are lost annually because of dysmenorrhea.⁷

The decreased prevalence and severity of dysmenorrhea in women in their mid-20s and older may be partially attributed to a higher rate of pregnancy in this age group, as well as more frequent use of OCs, an effective therapy for primary dysmenorrhea. With use of OC regimens, the thickness of the endometrium decreases, resulting in lower prostaglandin production. Prostaglandins are thought to induce ischemia and hypoxia, resulting in dysrhythmic uterine contractions and decreased blood flow (see “Pathophysiology of Primary Dysmenorrhea” for more detail), so reduced prostaglandin synthesis with use of OCs may decrease the symptoms of dysmenorrhea.¹¹ During the last trimester of pregnancy, uterine adrenergic nerves virtually disappear, and only a portion of the nerves regenerate after childbirth. For many women, this phenomenon results in a decreased prevalence of primary dysmenorrhea following childbirth.¹²

Factors other than young age (under 30) and nulliparity can increase the risk for or severity of primary dysmenorrhea.⁸ These include early menarche (before age 12); heavy menstrual flow; tobacco smoking; a body mass index of less than 20 kg/m²; premenstrual symptoms; history of sexual assault; and stress, anxiety, and depression.^{5,13} Low intake of fruits and vegetables, fish, milk, and other dairy products also may increase the risk of dysmenorrhea: A recent systematic review suggested that increased consumption of these foods may be associated with reduced menstrual pain.¹⁴ Obesity is linked to early menarche and can predispose the patient to primary dysmenorrhea.⁷ In addition, factors such as stress and attempting to lose weight can make dysmenorrhea pain more troublesome.¹²

Pathophysiology of Primary Dysmenorrhea

The cause of primary dysmenorrhea is not fully understood. However, prostaglandins and leukotrienes contribute substantially to the occurrence and severity of dysmenorrhea.^{4,5,7} Abnormal levels of nitric oxide and vasopressin also may be involved.^{5,7} Ovulation increases serum progesterone, which leads to increases in arachidonic acid. During menstruation, arachidonic acid is converted to prostaglandins and leukotrienes, which are then released from lysing endometrial cells in an ovulatory cycle. Prostaglandin levels are 2–4 times greater in women with dysmenorrhea than in women without dysmenorrhea; the severity of dysmenorrhea is proportional to the endometrial concentration of the prostaglandin F₂α (PGF₂α).⁶ *Leukotrienes*, inflammatory mediators known to cause vasoconstriction and uterine contractions, are elevated in women with dysmenorrhea. Leukotrienes may contribute significantly to dysmenorrhea in women who do not respond to NSAIDs.⁷ Conversely, nitric oxide, a substance that promotes uterine quiescence during pregnancy and stops uterine contractility when given during premature labor, may reduce dysmenorrhea pain.⁷ In fact, transdermal nitroglycerin patches, which increase nitric oxide levels, have been shown to decrease dysmenorrhea-related pain. Circulating levels of *vasopressin* (a substance that can produce dysrhythmic uterine contractions) are higher in women with dysmenorrhea than in asymptomatic individuals; however, the role of vasopressin in the etiology of primary dysmenorrhea remains controversial.^{4,5}

Prostaglandins stimulate uterine contractions. Normal contractions and

vasoconstriction help expel menstrual fluids and control bleeding as the endometrium sloughs. However, the increased levels of prostaglandins and leukotrienes typical with dysmenorrhea can lead to strong uterine contractions similar to those experienced during labor and excessive vasoconstriction, resulting in uterine ischemia and pain. In women without dysmenorrhea, uterine contractions are rhythmic, and contraction pressure reaches 120 mm Hg. In contrast, women with dysmenorrhea have more frequent contractions, with pressures up to 180 mm Hg that contribute to ischemia and tissue hypoxia and, thus, pain.

Clinical Presentation of Primary Dysmenorrhea

The pain with primary dysmenorrhea is cyclic in nature and is directly related to the onset of menstruation, usually subsiding within 2 or 3 days ([Table 9–1](#)). Pain is typically experienced as a continuous dull ache, with spasmodic cramping in the lower midabdominal or suprapubic region that may radiate to the lower back and upper thighs. The uterine contractions can force prostaglandins and leukotrienes into the systemic circulation, causing additional symptoms such as nausea, vomiting, fatigue, dizziness, bloating, diarrhea, and headache.⁴ In a large study in adolescents, the most common menstrual symptoms reported were fatigue (78%), cramping (71%), and headaches (64%).¹⁰ Other symptoms included lower back pain (58%) and nausea (37%).¹⁰ Clinical presentation can be adequate for the diagnosis of primary dysmenorrhea, if the pain is mild to moderate in intensity and responds to NSAID therapy.⁴

Table 9–1 Differentiation of Primary and Secondary Dysmenorrhea

Characteristics	Primary Dysmenorrhea	Secondary Dysmenorrhea
Timing/age at onset of dysmenorrhea symptoms	As soon as 6–12 months after menarche but typically several years later; age 13–17 years for most girls	At least 2 years after menarche but more typically mid- to late 20s or older, or pain begins after years of normal cycles.
Cause	Idiopathic; no identifiable pelvic	Associated with pelvic pathology

Characteristics	Primary Dysmenorrhea	Secondary Dysmenorrhea
	pathology	
Menses	More likely to be regular with normal blood loss	More likely to be irregular; menorrhagia and intermenstrual bleeding more common
Pattern and duration of dysmenorrhea pain	Onset just before or coincident with onset of menses; pain with each or most menstrual periods, lasting only 2–3 days	Pattern and duration vary with cause; change in pain pattern or intensity also may indicate secondary disease.
Pain at other times of menstrual cycle	No	Yes; may occur before, during, or after menses
Response to NSAIDs and/or OCs	Yes	Depends on the cause of secondary dysmenorrhea. Pain with mild–moderate endometriosis may respond to OCs or other hormonal contraceptives, but response to NSAIDs often is absent or inadequate. Adenomyosis is not responsive to NSAIDs or hormonal contraceptives.
Other symptoms	Fatigue, headache, nausea, change in appetite, backache, dizziness, irritability, and depression may occur at same time as dysmenorrhea pain.	Vary according to cause of the secondary dysmenorrhea; may include dyspareunia, pelvic tenderness

Key: NSAID = Nonsteroidal anti-inflammatory drug; OC = oral contraceptive.

Treatment of Primary Dysmenorrhea

Many women use nonprescription products to self-treat dysmenorrhea. In one study examining in adolescents, 66% self-treated with analgesics; of those, 78% used nonsalicylate NSAIDs; fewer used acetaminophen or aspirin.¹⁰ Inadequate management of dysmenorrhea pain can lead to increased pain sensitivity at

times other than during menses and to increased sensitivity to nonuterine pain, thus having important implications for pain perception and quality of life.⁹

Treatment Goals

The goals of treating primary dysmenorrhea are to resolve or provide significant improvement in symptoms (pain) and to minimize the disruption of usual activities.

General Treatment Approach

An important initial step in managing dysmenorrhea is distinguishing between primary and secondary dysmenorrhea by obtaining a thorough patient history. The medical history should include age at menarche, menstrual cycle characteristics (length, regularity, amount of bleeding, correlation with pain symptoms), and length of time elapsed between menarche and the onset of dysmenorrhea.¹³ Associated symptoms (e.g., headache), other health conditions (e.g., sexually transmitted infections), allergies, medications (including previous therapies), and relevant social history such as smoking and sexual activity should be explored.

Self-care is appropriate for otherwise healthy young women who have a history consistent with primary dysmenorrhea and are not sexually active and for those who have been previously diagnosed with primary dysmenorrhea.⁴ Adolescents with pelvic pain who are sexually active are at risk for PID and should be referred for further medical evaluation. Referral also is warranted for women with characteristics suggesting secondary dysmenorrhea ([Table 9–1](#)).

A variety of therapies are indicated for the management of dysmenorrhea. NSAIDs and hormonal contraceptives are both viable first-line options.¹⁵ Treatment choice is influenced by whether or not the affected individual desires hormonal contraception, previous medication experience(s), and other patient preferences. An estimated 80%–90% of women with primary dysmenorrhea can be successfully treated with NSAIDs, hormonal contraceptives, or both. Other treatment options include use of dietary supplements (e.g., omega-3 fatty acids). [Figure 9–2](#) presents an algorithm for managing primary dysmenorrhea.

A patient with more severe dysmenorrhea, a change in the pattern or intensity of pain, or inadequate response or intolerance to NSAIDs should be referred to her primary care provider. An estimated 15% of women do not respond to NSAIDs, cannot tolerate therapy, or prefer not to use medication for dysmenorrhea.⁹Figure 9–2 lists exclusions for self-care.

Nonpharmacologic Therapy

Many women use nonpharmacologic measures adjunctively to help manage dysmenorrhea and menstrual discomfort. These strategies may be especially useful for women who cannot tolerate or do not respond to nonprescription medications. A study of adolescents found that these nonpharmacologic interventions included sleep, hot baths or a heating pad, and exercise.⁴ The use of heat is a commonly recommended nondrug therapy. Heat therapy is thought to relieve menstrual pain through vasodilation, which increases blood flow to the area and relaxes smooth muscle. An abdominal heat wrap has been tested for the treatment of dysmenorrhea and in one study provided 14% greater pain relief than acetaminophen.¹⁶ In another study, a heating patch plus placebo pill was found to be comparable in efficacy to ibuprofen plus unheated patch for pain relief. Combining the heating patch and ibuprofen conferred no additional benefit in terms of pain relief, however, time to onset was shorter.¹⁶ A recent systematic review examining the effectiveness of nondrug modalities in primary dysmenorrhea concluded that heat therapy has a moderate reduction in menstrual pain compared to placebo and only a small to moderate reduction in pain intensity when compared to analgesic medication control groups.¹⁶ Evidence regarding the benefit of exercise is conflicting; however, participation in regular exercise may lessen the symptoms of primary dysmenorrhea for some women.^{4,5} The mechanism by which exercise provides pain relief is not clear; however, many theories have been proposed, including stress reduction, antinociceptive effects, and decreased prostaglandin levels. Findings in studies examining low-intensity exercise have been more favorable, with yoga and stretching showing significant pain reduction when compared with no treatment.¹⁶

Smoking and exposure to secondhand smoke have been associated with more severe and/or chronic dysmenorrhea.^{4,16} The severity of dysmenorrhea symptoms reportedly increases with the number of cigarettes smoked per day. The basis for this effect is unknown, but nicotine-induced vasoconstriction may be involved. Discontinuing tobacco smoking or avoiding exposure to

tobacco smoke may decrease symptoms. Pharmacists can assist patients in smoking cessation efforts.

Pharmacologic Therapy

Unfortunately, in many women and adolescents with dysmenorrhea, their symptoms remain untreated or are inadequately treated. These patients continue to experience pain and limitations in their daily activity. Four nonprescription analgesic medications are commonly used by women in self-treatment for dysmenorrhea: acetaminophen, aspirin, ibuprofen, and naproxen sodium. [Table 9–2](#) lists their dosages for dysmenorrhea. [Chapter 5](#) provides further discussion of their adverse effects, contraindications, and drug interactions. The uses and properties of these four nonprescription agents are summarized next, followed by a brief discussion of dietary supplements.

Table 9–2 Treatment of Dysmenorrhea With Nonprescription Medications	
Agent	Recommended Nonprescription Dosage (maximum daily dosage)
Acetaminophen	650–1000 mg every 4–6 hours (4000 mg)
Aspirin	650–1000 mg every 4–6 hours (4000 mg)
Ibuprofen	200–400 mg every 4–6 hours ^b (1200 mg)
Naproxen sodium	220–440 mg initially; then 220 mg every 8–12 hours (660 mg)

Note: See Table 5–5 for information on clinically important drug interactions with nonprescription analgesic agents

^a If the dosage 200 mg every 4–6 hours is ineffective, the recommended dosage for dysmenorrhea (400 mg every 6 hours while awake) should be taken.

Aspirin

Aspirin may be adequate for treating mild symptoms of dysmenorrhea. In typical analgesic dosages, aspirin has only a limited effect on prostaglandin synthesis and is only moderately effective in treating more than minimal symptoms of dysmenorrhea. In fact, a Cochrane review found that aspirin was no better than placebo in providing pain relief.⁹ Aspirin also may increase

menstrual flow.

Acetaminophen

Acetaminophen may be adequate for treating mild symptoms of dysmenorrhea. Acetaminophen is a weak inhibitor of prostaglandin synthesis; the reduction of $\text{PGF}_2\alpha$ levels is much greater with nonsalicylate NSAIDs than with acetaminophen.^{17,18} Even in dosages of 4 g daily, acetaminophen is less effective than ibuprofen; therefore, lower dosages are less likely to be effective.¹⁷

Nonsalicylate NSAIDs

Nonsalicylate NSAIDs, the first-line agents for treatment for primary dysmenorrhea, include ibuprofen and naproxen sodium ([Table 9–2](#)). In clinical trials, these NSAIDs were effective in 64%–100% of patients.⁹ Relief of dysmenorrhea is typically obtained within the first cycle of use, and symptomatologic improvement is thought to be related to decreased prostaglandin levels with NSAID use. However, dosages used in clinical trials and dosages of prescription drugs for the treatment of dysmenorrhea often are higher than the labeled nonprescription dosages. Therefore, providers may recommend prescription therapy, or they may recommend that a patient who is using nonprescription products try a prescription dosage of an NSAID if the lower dosage does not provide adequate symptom relief.

Therapy with nonsalicylate NSAIDs should begin at the onset of menses or pain. If inadequate pain relief occurs, treatment beginning 1 or 2 days before expected menses may improve symptomatic relief.⁵ This timing often requires that patients track their menstrual cycles to know when to start NSAID use. If the possibility of pregnancy exists, therapy should be initiated only after menses begins (see later under “Special Populations” for more detail). Patients should be instructed that the NSAID is used to prevent cramps and to relieve pain. Optimal pain relief is achieved when these agents are taken on a schedule, rather than on an as-needed basis. Therefore, ibuprofen should be taken every 4–6 hours and naproxen sodium every 8–12 hours for the first 48–72 hours of menstrual flow, because that time frame correlates with maximum prostaglandin release ([Table 9–2](#)). The therapeutic effect usually is apparent 30–60 minutes after administration, and benefit will be optimal with continued regular use.

A patient with dysmenorrhea may respond better to one NSAID than to another. If the maximum nonprescription dosage of one agent does not provide adequate benefit, switching to another agent is recommended. The analgesic effect for most NSAIDs plateaus, so further dosage increases may increase the risk of adverse effects without providing additional benefit. Therapy with NSAIDs should be undertaken for three to six menstrual cycles, with changes made in the agent, dosage, or both before judging the effectiveness of these agents for a particular patient. If nonprescription NSAID therapy does not provide an adequate therapeutic effect, other therapies that may provide relief from primary dysmenorrhea may be tried. These include prescription NSAID therapy; prescription dosages of nonprescription NSAIDs; and/or use of a hormonal contraceptive. Examples of hormonal contraceptives are a combination OC agent, injectable or implantable progestin, an estrogen plus progestin vaginal ring or transdermal patch, and a levonorgestrel intrauterine contraceptive (IUC).¹⁹ In some cases, the combination of a hormonal contraceptive and an NSAID may be required for adequate symptom relief.

The usual adverse effects from a few days of intermittent NSAID use are gastrointestinal (GI) symptoms such as upset stomach, vomiting, heartburn, abdominal pain, diarrhea, and constipation. Adverse effects may also include headache and dizziness. Some GI adverse effects may be decreased by taking the drugs with food.

Dietary Supplements

Although a number of studies have evaluated the use of dietary supplements for dysmenorrhea management, high-quality evidence to support the safety and efficacy of such products is lacking.²⁰ Very limited evidence suggests that fish oil, fenugreek, ginger, valerian, vitamin B₁, vitamin D, zataria, and zinc sulfate may be beneficial.^{15,20,21} In the absence of more robust evidence for most of these supplements, only fish oil and vitamin D are considered here.

Omega-3 fatty acids are found in fish and fish oil and compete with arachidonic acid in the cyclooxygenase and lipoxygenase pathways, leading to a decrease in the production of the proinflammatory cytokines. Increased consumption of fish rich in omega-3 fatty acids from tuna, salmon, and sardines or use of fish oil supplements may reduce symptoms. One study showed that women who received an omega-3 fatty acid supplement (180 mg

eicosapentaenoic acid + 120 mg docosahexaenoic acid) daily for 3 months had improvement in pain intensity and required less ibuprofen than those receiving placebo.²²

Cholecalciferol (vitamin D₃) is known to decrease the production of prostaglandins and to increase prostaglandin inactivation.²³ One small study found a reduction in dysmenorrhea pain among women with low serum vitamin D levels who were given a single 300,000 IU dose of cholecalciferol 5 days before menses.²⁴ More recently, high-dose cholecalciferol (50,000 IU weekly for 9 weeks) was shown to reduce pain severity in adolescent girls.²¹ Because the safety of long-term, high-dose vitamin D₃ is uncertain, women should be counseled to ingest vitamin D₃ 600 IU daily, the recommended daily dietary allowance. These measures often serve as an adjunct to drug therapy.

Pharmacotherapeutic Comparison

A Cochrane review of 80 randomized, controlled trials (RCTs) demonstrated strong evidence to support NSAIDs as first-line agents for primary dysmenorrhea because of their consistent effectiveness in providing moderate to excellent pain relief over that obtained with placebo.¹⁸ There appear to be minimal differences with regard to either efficacy or safety among NSAIDs.¹⁸ Cost, duration of action, tolerability, and availability should guide agent selection. Ibuprofen and naproxen sodium are available without a prescription. Because of restrictions on taking medications to school, adolescents may benefit from naproxen's longer duration of action. Women at risk for GI ulceration should consider the use of a gastroprotective agent or another therapeutic option such as an OC. Acetaminophen may provide some relief for patients with hypersensitivity or intolerance to aspirin and for patients with intolerance to the GI and platelet-inhibition adverse effects of aspirin and other NSAIDs. OCs as well as intravaginal and intrauterine hormonal contraceptives are used for the management of dysmenorrhea. Some trials report benefits with OC therapy in up to 80% of women; however, a Cochrane review found limited evidence of effectiveness in the management of dysmenorrhea.⁸

Product Selection Guidelines

Special Populations

The U.S. Food and Drug Administration (FDA) recommends that aspirin and

aspirin-containing products not be given to children and adolescents who have or are recovering from chickenpox or influenza-like symptoms because of the risk of Reye syndrome.²⁵ (See [Chapter 5](#) for further information.) Pregnant or menopausal women do not experience dysmenorrhea; if cramping/pelvic pain occurs, these patients should be referred to their primary care provider. Women attempting to become pregnant should avoid use of NSAIDs, as these agents may impair implantation of the blastocyst. Acetaminophen and ibuprofen can safely be taken by breastfeeding women because the levels of both medications documented in breast milk are low.²⁶ Women who are breastfeeding should avoid use of high-dose aspirin; low-dose aspirin (75–325 mg daily) is associated with low salicylate levels, and with such regimens the drug does not appear to be excreted into breast milk.²⁶ Naproxen sodium is a less optimal choice for breastfeeding women; although levels in breast milk are low, this medication has a long half-life, and a serious adverse reaction in a neonate has been reported.²⁶ A nonpharmacologic approach such as topical heat application may also be a good choice for breastfeeding women.

Patient Factors

Because NSAIDs are used only temporarily and intermittently, the risk for GI toxicity is limited. However, patients who have active peptic ulcer disease, those at risk for GI bleeding, or those with a history of GI ulcers should discuss use of NSAIDs with their primary care provider. Treatment with acetaminophen, nonpharmacologic therapy, or an OC regimen may be more appropriate. NSAIDs also can inhibit platelet activity and increase bleeding time. Women on anticoagulants should avoid NSAID use, and caution is warranted in women on other agents that may increase bleeding. Women who consume 3 or more alcohol-containing beverages daily should discuss use of acetaminophen or aspirin with their primary care provider, because additive liver or GI toxicity, respectively, may occur.

Patient Preferences

Women may prefer to use an NSAID that they are familiar with, or they may wish to try another agent if adverse effects were experienced previously. Preferences also may be based on tablet/capsule preferences or cost of products.

Complementary Therapies

A Cochrane review found tentative evidence that use of transcutaneous electrical nerve stimulation (TENS) decreases acute pain compared with placebo.²⁷ Another Cochrane review, including 42 RCTs, evaluated the use of acupuncture or acupressure for the treatment of primary dysmenorrhea. Although limited, low-quality studies showed some benefit, the evidence was insufficient to permit overall conclusions regarding safety and efficacy.²⁸ All complementary therapies require further investigation to elucidate their role in the management of dysmenorrhea.

Algorithm: Primary Dysmenorrhea

Figure 9–2 Self-care for primary dysmenorrhea. Key: CAM = Complementary and alternative medicine; GERD = gastroesophageal reflux disease; GI = gastrointestinal; IUC = intrauterine contraceptive; NSAID = nonsteroidal anti-inflammatory drug; OTC = over-the-counter; PID = pelvic inflammatory disease; PCP = primary care provider; PUD = peptic ulcer disease.

Assessment of Primary Dysmenorrhea: A Case-Based Approach

Before recommending any product to a patient experiencing symptoms of dysmenorrhea, the health care provider should ascertain that the symptoms, particularly the onset and duration of pain in relation to the onset of menses, are consistent with primary dysmenorrhea ([Table 9–1](#)).

Case 9–1 illustrates the assessment of a patient with dysmenorrhea.

Patient Counseling for Primary Dysmenorrhea

Adolescents and young women who experience primary dysmenorrhea symptoms should be educated about this condition so they (1) realize primary

dysmenorrhea is normal, (2) recognize typical symptoms and symptoms that are inconsistent with primary dysmenorrhea and when to seek medical evaluation, (3) understand that NSAIDs are preferred therapy because of their efficacy, and (4) know how to use these agents for greatest benefit (e.g., appropriate dose and dosing frequency, when in menstrual cycle to initiate therapy). Patients also should be advised that nonprescription NSAIDs might be appropriate for initial therapy, but that not all women will respond. If response to the first agent is not adequate, another NSAID and/or an OC or a nondrug intervention can be tried. The health care provider should explain the proper use of these agents and their potential adverse effects. Nondrug measures (e.g., topical heat, exercise, dietary changes) also can be tried; however, patients should be advised that these strategies may not be adequate for effective management, so that combination with pharmacologic therapy may be necessary. The box “Patient Education for Primary Dysmenorrhea” lists specific information to provide during patient counseling.

Evaluation of Patient Outcomes for Primary Dysmenorrhea

Patient monitoring is accomplished by having the patient report whether symptoms are improved or resolved. Symptoms should improve within an hour or so of taking an NSAID. The optimal effect of drug therapy may not be seen until the woman has used the medication on a scheduled basis. If inadequate pain relief occurs, treatment beginning 1 or 2 days before expected menses may improve symptomatic relief. The patient with persistent symptoms should be advised to try another nonprescription NSAID, to add adjunct therapy, to consider use of an OC, or to see a primary care provider for evaluation.

Case 9–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms) including age at onset of symptoms	Patient is suffering from abdominal pain, describing it as "menstrual cramps." She regularly experienced menstrual cramping as a young teenager, but it resolved when she started combination OC therapy. The patient discontinued her OC regimen about 5 months ago because she and her husband are trying to conceive. This is the first time she has experienced painful "cramping" with menses since discontinuing the combination OC agent. She reports the pain started suddenly yesterday (day 4 of her menstrual period) and describes it as persistent, sharp, and severe. Her last menstrual period was about 6 weeks ago.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient is unable to identify anything that makes the pain better or worse.
c. Description of the patient's efforts to relieve the symptoms	"Yoga used to help when I was a teenager, so I attended a class this morning—but it did nothing."
d. Patient's identity	Jessica Bentley
e. Patient's age, gender, height, and weight	24 years, female, 5 ft 5 in., 130 lb
f. Patient's occupation	Social worker
g. Patient's dietary	Patient describes a well-balanced diet; no food allergies or restrictions.

Relevant Evaluation Criteria	Scenario/Model Outcome
habits	She usually has no issues with appetite, but has been in too much pain to eat anything substantial since yesterday.
h. Patient's sleep habits	She generally sleeps well—about 7 hours each night—but only slept 3 or 4 hours last night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Asthma</i> : well-controlled with budesonide 360 mcg BID and albuterol 90–180 mcg every 4–6 hours as needed; <i>prenatal care</i> : 1 prenatal vitamin daily.
j. Allergies	None known
k. History of other adverse reactions to medications	None known
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	The onset and severity of Mrs. Bentley's symptoms are not characteristic of primary dysmenorrhea. Sudden, sharp, and severe abdominal pain presenting on day 4 of menses may indicate underlying pelvic pathology.
3. Identify exclusions for self-treatment (Figure 9-2).	Sudden, sharp, and severe abdominal pain occurring after the onset of menses is inconsistent with primary dysmenorrhea, which generally manifests as dull, crampy pain coinciding with the onset of menses and lasting 2 or 3 days. A referral for further evaluation is necessary in this case to rule out other causes, including ectopic pregnancy, as Mrs. Bentley is actively trying to conceive.
4. Formulate a comprehensive list of therapeutic	Options include (1) Refer Mrs. Bentley to an appropriate health care

Relevant Evaluation Criteria	Scenario/Model Outcome
alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	provider. (2) Recommend self-care with nonprescription and nondrug measures. (3) Recommend self-care until Mrs. Bentley can see an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, considering patient preferences.	Refer Mrs. Bentley for urgent care to rule out ectopic pregnancy.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"The sudden onset and severity of the pain you've described is not typical of primary dysmenorrhea. Because you have been trying to become pregnant, it is important to rule out an ectopic pregnancy and/or any other serious conditions."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Primary dysmenorrhea—which can be self-treated—generally manifests as dull, crampy pain that begins with the onset of menses and lasts 2 or 3 days. With what you've described, there may be something more serious going on, like an ectopic pregnancy. Ectopic pregnancies can be life-threatening if left unidentified, so it is important that you seek medical attention as soon as possible."
Implement	

Relevant Evaluation Criteria	Scenario/Model Outcome
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	n/a
Solicit follow-up questions from the patient or caregiver.	"Could I take ibuprofen to help with the pain while I'm waiting to be seen at the walk-in clinic?"
Answer the patient's or caregiver's questions.	"NSAIDs like ibuprofen and naproxen sodium are not recommended for women trying to become pregnant, as they may make it harder to conceive. Acetaminophen or nondrug strategies like heat therapy may be more appropriate since you and your partner are trying to conceive. With acetaminophen, you can take 650-1000 mg every 4-6 hours, to a maximum of 4000 mg in 24 hours. However, even if this provides some relief, it is still critical that you be seen by a primary care provider to rule out an underlying cause for your pain. Additionally, NSAIDs should be used with caution in asthmatics, as these agents are associated with increased risk of bronchospasm."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	n/a

Key: n/a = Not applicable; NSAID = nonsteroidal anti-inflammatory drug; OC = oral contraceptive.

Patient Education for Primary Dysmenorrhea

The objective of self-treatment is to relieve or significantly lessen symptoms of dysmenorrhea, to limit discomfort and disruption of usual activities. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- If effective, apply topical heat to the abdomen, lower back, or other painful area.
- Stop smoking cigarettes and avoid secondhand smoke.
- Consider eating more fish high in omega-3 fatty acids or taking a fish oil supplement.
- Participate in regular exercise if it lessens the symptoms.
- No dietary supplements have been shown effective for primary dysmenorrhea.

Nonprescription Medications

- Ibuprofen and naproxen sodium are the best types of nonprescription medication for primary dysmenorrhea. These medications stop or prevent strong uterine contractions (cramping).
- Start taking the medication when the menstrual period begins or when menstrual pain or other symptoms begin. Then take the medication at regular intervals, following the product instructions, rather than just when the symptoms are present. See [Table 9–2](#) for recommended nonsteroidal anti-inflammatory drug (NSAID) dosages.
- Take the NSAID with food to limit upset stomach and heartburn.
- Do not take NSAIDs if you are allergic to aspirin or any other NSAID, or if you have peptic ulcer disease, gastroesophageal reflux disease, colitis, or any bleeding disorder.
- If you have hypertension, asthma, or heart failure, watch for early symptoms that the NSAID is causing fluid retention.
- Do not take a nonsalicylate NSAID if you also are taking anticoagulants or lithium.

When to Seek Medical Attention

- Seek medical attention if the pain intensity increases or if new symptoms occur.
- Seek medical attention if abdominal pain occurs at times other than just before or during the first few days of menses.

Premenstrual Disorders

Almost all women experience some mild physical or mood changes before the onset of menses, and these are normal signs of ovulatory cycles.²⁹ The changes may include physical symptoms; food cravings; and emotional lability, irritability, or lowered mood. In addition, some women report positive changes, including increased energy, creativity, work productivity, and sexual desire.³⁰

Premenstrual disorders are cyclic and composed of a combination of physical, mood, and behavioral symptoms that occur during the luteal phase of the menstrual cycle. Symptoms improve significantly or disappear by the end of menses and are absent during the first week following menses. The number and severity of symptoms and the extent to which they interfere with functioning distinguish typical premenstrual symptoms, PMS, and premenstrual dysphoric disorder (PMDD) from each other ([Table 9–3](#)).³¹ PMS is distinguished from normal physiologic premenstrual symptoms by its negative effect on daily functioning and the extent of distress caused by symptoms. PMDD is a severe form of PMS, and its diagnosis requires documentation of a specific constellation of symptoms that occurs on a cyclical basis, the presence of key psychological symptoms, and severity of symptoms sufficient to interfere with social and/or occupational functioning.²⁹

Of women with PMS, 60%–80% experience only mild, primarily physical symptoms that do not interfere with their lives.³² An estimated 20%–30% of women experience clinically significant symptoms of PMS, and 3%–8% report symptoms that cause significant impairment that interferes with relationships, lifestyle, or work.²⁹

Premenstrual disorders can occur any time after menarche. Symptoms usually begin in the teenage years up to the early 20s; typically, affected patients wait about a decade to seek care.^{4,32} Symptoms occur only during ovulatory cycles and disappear during events that interrupt ovulation, such as pregnancy and breastfeeding, and at menopause. The use of OCs can cause or exacerbate premenstrual disorders, and hormone therapy in postmenopausal women may result in recurrence of symptoms.³³

Many factors contribute to the development of a premenstrual disorder, including genetic predisposition. Twin studies have shown that premenstrual disorders are inherited, with women whose mothers had a premenstrual disorder being more likely to develop such a disorder.^{33,34} In addition, genetic differences exist in the serotonergic 5-hydroxytryptamine (5-HT_{1A}) receptor and the estrogen alpha-receptor gene in women with and without premenstrual disorder symptoms.³⁴ Stress and previous traumatic events, including sexual abuse, also are risk factors for premenstrual disorders. Different coping strategies for handling stress, as well as altered psychological and physiologic responses to stress, have been shown in persons with a history of life stress and abuse.³⁴ Sociocultural factors also can influence the experience of premenstrual symptoms. Exposure to negative expectations about premenstrual symptoms can lead patients to interpret normal symptoms more negatively.³⁴

Pathophysiology of Premenstrual Disorders

The etiology of premenstrual disorders is not fully understood. The current consensus is that the fluctuations of estrogen and progesterone caused by normal ovarian function are the cyclic trigger for premenstrual disorder symptoms. Although these symptoms are triggered by hormonal fluctuations, no known hormonal imbalances are present in women with a premenstrual disorder. Some women are biologically vulnerable or predisposed to experience this type of disorder because of a neurotransmitter sensitivity to physiologic changes in hormone levels.^{4,32,34} Serotonin, which is involved in mood and behavior regulation, is affected by estrogen and progesterone levels. Reduced serotonin in the brain may be linked to symptoms such as poor impulse control, irritability, carbohydrate craving, and dysphoria.^{4,33} Other neurotransmitters and systems that may be important are allopregnanolone and gamma-aminobutyric acid (GABA) receptors. Allopregnanolone is a

progesterone metabolite that binds the GABA receptor, leading to an anxiolytic action.³² Women who have a premenstrual disorder may be less sensitive to the sedating effects of allopregnanolone during the luteal phase and may have different GABA receptor sensitivity.^{32,34} These alterations may result in luteal phase symptoms such as anxiety and irritability.³³ In addition, selective serotonin reuptake inhibitors (SSRIs), which are known to relieve premenstrual disorders, affect the synthesis of allopregnanolone. Therefore, for symptoms severe enough to warrant prescription drug therapy, treatment is based on medications that affect the levels of serotonin or suppress ovulation and interrupt hormonal cycling. Finally, deficiency of certain vitamins and minerals, including pyridoxine (vitamin B₆), calcium, vitamin D, and magnesium, also has been implicated in premenstrual disorders, but studies are limited. The suggested role of these vitamins and minerals in the pathogenesis of premenstrual disorders and supplementation as a means of management are discussed in more detail under “Pharmacologic Therapy.”

Table 9–3 Differentiation of PMS and PMDD From Other Conditions With Luteal Phase Symptoms

Typical premenstrual symptoms	Mild physical (breast tenderness, bloating, low backache, food cravings) or mood (irritability, emotional lability, lowered mood, increased energy or creativity) changes before the onset of menses that do not interfere with normal life functions
Premenstrual syndrome	At least one mood (depression, irritability, anger, anxiety) or physical (breast tenderness, abdominal bloating) symptom during the 5 days before menses. Symptoms are virtually absent during cycle days 5–10. The symptom or symptoms are severe enough to cause significant distress and/or have a negative effect on normal daily functioning (e.g., interfere with work and school performance) or interpersonal relationships. Symptoms may range from mild-moderate to severe.
Premenstrual dysphoric disorder	Five or more symptoms (mood or physical) are present the last week of the luteal phase of the menstrual cycle, with at least one symptom being significant depression, anxiety, affective lability, or anger. The intensity of the symptoms interferes with work, school, social activities, and social relationships. Symptoms should be absent the week after menses and must not be an exacerbation of the symptoms of another disorder such as depression, panic disorder, or personality disorder.
Premenstrual exacerbation of other disorders	A worsening of the symptoms of other, typically psychiatric disorders, such as depression and anxiety or panic disorders. Conditions such as asthma, endometriosis, hypothyroidism, irritable bowel syndrome, attention-deficit/hyperactivity disorder, diabetes, rheumatoid arthritis, migraine headaches, seizure disorders, and perimenopause also can worsen premenstrually. However, symptoms do not occur only during the luteal phase of the menstrual cycle; there is

no symptom-free interval.

Source: References 4, 37, and Petersen N, London ED, Liang L, et al. Emotion regulation in women with premenstrual dysphoric disorder. *Arch Womens Ment Health*. 2016;19(5):891–898. doi: 10.1007/s00737-016-0634-4.

The pathophysiology of physical symptoms of premenstrual disorders (e.g., breast tenderness, bloating, joint/muscle pain) is not as well studied. Studies of fluid retention and breast enlargement have not found tissue changes; abdominal bloating often occurs without weight gain.³¹

Exogenous hormones may influence premenstrual symptoms. Women taking either OCs or postmenopausal replacement hormones may experience adverse effects similar to PMS symptoms as a result of altered hormone levels.^{30,33} Conversely, 71% of women reported that the use of their OC had no effect on their PMS symptoms.⁴ Certain OCs have been useful in reducing the symptoms of premenstrual disorders, particularly those containing drospirenone, formulations with a lower estrogen dose, and products with a shortened hormone-free interval between pill packs or featuring continuous or extended cycles.^{19,29}

Algorithm: Premenstrual Syndrome

Figure 9–3 Self-care for premenstrual syndrome. Key: AIDS = Acquired immunodeficiency syndrome; CAM = complementary and alternative medicine; HT = hormone therapy; MAOI = monoamine oxidase inhibitor; OC = oral contraceptive; OTC = over-the-counter; PMDD = premenstrual dysphoric disorder; PMS = premenstrual syndrome; PUD = peptic ulcer disease; SSRI = selective serotonin reuptake inhibitor; TCA = tricyclic antidepressant.

Clinical Presentation of Premenstrual

Disorders

The symptoms of premenstrual disorders are not unique to these conditions; however, the occurrence of specific symptoms and their fluctuation with the phases of the menstrual cycle are diagnostic. Premenstrual symptoms typically begin or intensify about a week before the onset of menses, peak near the onset of menses, and resolve within several days after the beginning of menses.³³ Symptoms typically are consistent from month to month. A woman with a premenstrual disorder should experience essentially a symptom-free interval during days 5–10 of her menstrual cycle.

Common symptoms of premenstrual disorders are listed in [Table 9–4](#). Women seeking symptom relief typically report multiple emotional, physical, and behavioral symptoms. Mood symptoms tend to cause more distress than physical symptoms because of their impact on work and personal relationships. A large crosssectional study conducted in multiple countries found that the most common PMS symptoms reported by women included abdominal bloating, cramps or abdominal pain, irritability, breast tenderness, and joint or back pain.³⁵ These symptoms may blur the distinction between dysmenorrhea and PMS, making the timing of symptom onset important for differentiation. Furthermore, the presence of dysmenorrhea may be associated with a greater severity of PMS.³⁶ Mild to moderate PMS generally responds well to self-treatment with nondrug and/or nonprescription therapies (see “Treatment of PMS” for details).

Table 9–4 Common Premenstrual Syndrome Symptoms
Most Common Negative Symptoms
Fatigue, lack of energy
Irritability, anger
Labile mood with alternating sadness and anger
Depression, decreased interest in usual activities
Anxiety, feeling stressed
Crying spells, oversensitivity

Difficulty concentrating
Abdominal bloating, edema of extremities
Breast tenderness
Appetite changes (overeating and food cravings)
Headache
Hypersomnia/insomnia
Joint/muscle pain
Feeling out of control/overwhelmed
Most Common Positive Symptoms
Increased energy, more efficient at work
Increased libido, more affectionate
Increased sense of control, more self-assured

Source: Adapted from [reference 29](#).

Symptoms of PMDD are similar to those of PMS. Compared with women who have PMS, women with PMDD experience more symptoms, symptoms of greater severity, and symptoms that impair personal relationships and the ability to function well at work or school to a greater degree. Among women with PMDD, the most common symptoms are affective in nature. The diagnosis of PMDD requires that a patient experience marked anger or irritability or depressed mood, anxiety, or emotional lability.³⁷ Other signs and symptoms of PMDD include difficulty concentrating, lethargy, hypersomnia or insomnia, and physical symptoms such as breast tenderness and bloating. The severity of symptoms must cause significant impairment in the ability to function socially or at work during the week before menses.³⁷ A daily rating of symptoms for several cycles establishes a diagnosis of PMS or PMDD, and these types of symptoms should have occurred during most menstrual cycles over the past year. PMDD symptoms during the last 7 days of the cycle should

be at least 30% worse than those experienced during the midfollicular phase (days 3–9 of the menstrual cycle). Criteria for a formal diagnosis of PMDD are outlined in the fifth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-5).³⁷ Patients with suspected PMDD require referral to a primary care provider to ensure proper diagnosis and management.

Premenstrual disorders should be distinguished from typical premenstrual symptoms and also from premenstrual exacerbations of other disorders, particularly mood disorders. Some medical conditions can be aggravated during the premenstrual phase (e.g., hypothyroidism, fibromyalgia).^{33,37} In addition, mood disorders not occurring solely during the luteal phase must be distinguished from cyclic mood symptoms ([Table 9–3](#)). The lack of a symptom-free interval may suggest that the patient has a psychiatric disorder, such as an anxiety or panic disorder, or another health condition such as the menopausal transition, rather than PMS.

Treatment of Premenstrual Syndrome (PMS)

PMS is a cyclic, multisymptom disorder that involves emotional, behavioral, and physical symptoms. A single therapeutic agent is unlikely to address all symptoms. Thus, treatment should be selected to address the patient's most bothersome symptoms. A symptom log or calendar is a useful tool for documenting such symptom(s) and the cyclic nature of this disorder. This information will also be useful in evaluating the efficacy of treatment. In women with severe symptoms, alleviation of symptoms is less likely with use of nonprescription therapies alone. In addition, PMS symptoms are chronic and, in most cases, will continue until menopause. Therefore, the cost of therapy, the possibility that a woman may become pregnant, and the likelihood of adverse effects are important considerations in selecting therapy.

Treatment Goals

The two intended outcomes for women with premenstrual disorders are (1) to better understand premenstrual disorders and (2) to improve or resolve symptoms to reduce the impact on activities and interpersonal relationships. Therapy typically is considered effective if symptoms are reduced by 50% or more.

General Treatment Approach

Mild to moderate PMS symptoms often are self-treatable and do not require prescription drug therapy. In these cases, initial treatment is generally conservative and consists of education and nonpharmacologic measures. Such measures include dietary and lifestyle modifications (e.g., physical exercise, stress management) as well as light therapy, cognitive behavioral therapy, and acupuncture.³³ Women should be educated about the syndrome and encouraged to identify techniques for coping with PMS symptoms and stress. Knowledge about this disorder can allow patients to exert some control over their symptoms. By tracking their menstrual cycle, patients can predict when symptoms will occur and plan accordingly. For example, scheduling more challenging tasks during the first half of the cycle may help limit the influence of this condition on social and work functioning.

Supplements with evidence of potential benefit include calcium, pyridoxine, and chasteberry (*Vitex agnus-castus*).^{33,34} Preliminary data suggest a potential benefit from ginkgo, magnesium pyrrolidone, St. John's wort, and saffron.³⁸

Prescription drug therapy should be considered if the treatments outlined in [Figure 9–3](#) are ineffective or if the patient suffers from moderate to severe PMS or PMDD. SSRIs used daily, only during the luteal phase of the menstrual cycle, or when symptoms occur are the first-line agents for prescription therapy.³⁹ Agents that suppress ovulation such as OCs and GnRH agonists also are used. Newer OC products containing drospirenone or formulated with shortened hormone-free intervals or extended cycling also may be considered first-line therapeutic agents for patients who prefer a gynecologic approach rather than a psychological approach.³⁹ Finally, hysterectomy with bilateral oophorectomy is effective for refractory severe symptoms.⁴⁰ Surgery may be appealing for women experiencing significant adverse drug reactions and/or costs.⁴⁰

Nonpharmacologic Therapy

Several nonpharmacologic therapies may decrease PMS symptoms, including aerobic exercise, dietary modifications, and cognitive behavioral therapy.³³ Exercise can increase endorphin levels and may help decrease PMS symptoms.³³ Although evidence supporting dietary changes is limited, many health care providers recommend eating a balanced diet while also avoiding salty foods and simple sugars, which may cause fluid retention, and avoiding

caffeine and alcohol, which can increase irritability.^{33,34} Cravings for foods high in carbohydrates, which contain the serotonin precursor tryptophan, are common in women with PMS. Two studies of a carbohydrate-rich beverage that increased tryptophan levels demonstrated a reduction of emotional symptoms in women with PMS.³⁴ Consuming foods rich in complex carbohydrates such as whole-grain foods during the premenstrual interval also may reduce symptoms.³⁴

Stress is reported to increase PMS symptoms. Cognitive behavioral therapy, which emphasizes relaxation techniques and coping skills, may be of benefit for stress reduction.^{33,34} These approaches may be helpful used singly or as adjuncts to other therapies. Data that suggest a possible benefit with light therapy, acupuncture, and massage are also available.³³

Pharmacologic Therapy

A survey of women with PMS found that 80% use some nonprescription therapeutic modality including vitamins, minerals, and herbs; a number of products claim benefits for the management of PMS, although little supporting evidence is available.³⁸

Pyridoxine

Pyridoxine (vitamin B₆) has been suggested to provide therapeutic benefit in PMS. Trials have reported mixed results, with no dose–response relationship shown, and no trials were performed in women with PMDD.^{34,38} One double-blind, placebo-controlled trial found that pyridoxine 80 mg daily improved subjective mood to a greater extent than placebo.³⁴ The dosage of pyridoxine should be limited to 100 mg daily because of the risk for peripheral neuropathy with higher dosages.³³

Calcium and Vitamin D

Data show an inverse relationship between both milk and vitamin D intake and PMS.⁴ An additional study reported that high dietary intake of both calcium and vitamin D may prevent the development of PMS symptoms.⁴¹ Calcium ingestion may reduce fluctuations in calcium levels across the menstrual cycle. Hypocalcemia causes affective symptoms (anxiety, irritability, depression) similar to those of premenstrual disorder.²⁹ Reduced levels of

vitamin D secondary to alterations in calcium and vitamin D metabolism during the luteal phase may trigger PMDD symptoms.

Several randomized trials have evaluated the effect of calcium supplementation on PMS symptoms. The largest trial studied the effect of calcium in a dosage of 600 mg twice daily in 466 women with moderate to severe PMS.⁴² Symptoms were significantly reduced by the second month of therapy, and by the third month, calcium had reduced overall symptoms by 48%. Emotional symptoms such as mood swings, depression, and anger, as well as food cravings and physical symptoms, were all reduced. More than one half of the women taking calcium had a greater than 50% reduction in symptoms; almost one third reported a greater than 75% symptomatologic improvement. Few women experienced adverse effects from calcium; five withdrew from the study because of nausea, and one woman each in the calcium and placebo groups developed kidney stones. The dosage of calcium used in the trial is consistent with the recommended daily calcium intake for women of reproductive age, which is between 1000 and 1300 mg daily. Similar improvements were noted in smaller studies.^{31,38,43} Patients should be encouraged to meet daily calcium recommendations through their diet first, but supplementation can be added as needed. Additionally, all health care providers should reinforce adequate calcium and vitamin D intake in women to help prevent osteoporosis.

Magnesium

Magnesium deficiency may lead to some PMS-type symptoms (e.g., irritability), and low magnesium levels in red blood cells have been found in women with PMS. Affective symptoms associated with PMS were reduced by magnesium pyrrolidone carboxylic acid in a dosage of 360 mg daily administered during the luteal phase.^{37,41} By contrast, two trials of magnesium oxide found no benefit. The dosage of magnesium pyrrolidone carboxylic acid used in the trial was similar to the recommended dietary allowance of magnesium for women (310–360 mg). About 50% of women regularly consume less than that amount, and obtaining adequate magnesium from food sources may be difficult. Food sources of magnesium include spinach, Swiss chard, nuts, legumes (e.g., beans, peas), and whole-grain cereals. Adverse effects other than diarrhea are uncommon.

Vitamin E

Although vitamin E deficiency has not been established in women experiencing PMS, limited evidence suggests that supplementation may improve symptoms in some patients. One double-blind, randomized trial, for example, showed that vitamin E at a dose of 100 mg daily for three cycles produced statistically significant reduction in physical and mental symptoms.⁴⁴ Vitamin E supplementation may be considered in the management of PMS; however, because the evidence for use is limited, other options are preferred.

Nonsteroidal Anti-inflammatory Drugs

NSAIDs reduce some of the physical symptoms such as headache and muscle/joint pains and mood symptoms associated with PMS when taken for several days before the onset of and during the first several days of menses.³³ The benefit from these agents may reflect the coexistence of dysmenorrhea and PMS, or PMS manifesting primarily as physical symptoms.

Diuretics

A common premenstrual symptom is the subjective sensation of fluid accumulation, particularly with abdominal bloating. However, most women do not experience any true sodium or water retention and do not experience weight gain.⁴⁵ Two factors may explain the sense of abdominal bloating. First, a distinction must be made between fluid redistribution (in which weight does not change) and fluid retention (which can be detected by weight gain). The abdominal bloating and swelling observed with PMS are primarily caused by a fluid shift to this area. As a result, diuretics that are indicated for relieving fluid retention are unlikely to be helpful for most women with PMS. Second, abdominal distention in this setting may be secondary to relaxation of the gut muscle caused by progesterone.⁴⁵ For women who have true water retention and resultant weight gain, however, a diuretic may be useful.

Over the years, three FDA-approved nonprescription diuretics have been marketed for relieving water retention, weight gain, bloating, swelling, and the feeling of fullness. These agents are ammonium chloride, caffeine, and pamabrom. The last agent is currently the most common diuretic found in nonprescription menstrual products ([Table 9–5](#)).

Table 9–5 Selected Combination Nonprescription Menstrual Products

Trade Name	Diuretic With Dose per Tablet/Capsule	Analgesic and/or Antihistamine With Dose per Tablet/Capsule
Aqua-Ban Tablets; Diurex Max; Diurex Aquagels;	Pamabrom 50 mg	
Diurex Ultra; Diurex Ultimate; Diurex XPL	Caffeine 100 mg	
Diurex Water Pills + Pain Relief	Caffeine 50 mg	Magnesium salicylate 162.5 mg
Pamprin Multi-symptom; Premsyn PMS	Pamabrom 25 mg	Acetaminophen 500 mg; pyrilamine maleate 15 mg
Pamprin Max	Caffeine 65 mg	Acetaminophen 250 mg; aspirin 250 mg
Midol	Pamabrom 25 mg	Acetaminophen 500 mg
Midol Complete	Caffeine 60 mg	Acetaminophen 500 mg; pyrilamine maleate 15 mg
Midol Long Lasting Relief		Acetaminophen (extended-release) 650 mg

Ammonium chloride is an acid-forming salt with a short duration of effect. The drug is taken in oral dosages of up to 3 g daily, divided into 3 doses, for no more than 6 consecutive days. Larger dosages of ammonium chloride can produce significant GI and central nervous system adverse effects. Ammonium chloride is contraindicated in patients with renal or liver impairment, because metabolic acidosis may result. Ammonium chloride is no longer available as a nonprescription drug but can be obtained as a dietary supplement.

Caffeine promotes diuresis by inhibiting the renal tubular reabsorption of sodium and water. In doses of 100–200 mg every 3–4 hours, caffeine is safe and effective, although patients may develop tolerance to its diuretic effect. Caffeine may cause anxiety, restlessness, or insomnia, and it may worsen PMS by causing irritability. Additive adverse effects might occur if other caffeine-containing medications, foods, or beverages, especially “energy drinks,” are consumed concurrently. Caffeine may also cause GI irritation; thus, it can

precipitate or worsen dyspepsia. Patients taking monoamine oxidase inhibitors (MAOIs) or theophylline should also avoid diuretics that contain caffeine.

Pamabrom, a derivative of theophylline, is found in combination products along with analgesics and antihistamines marketed for the treatment of PMS. Pamabrom also is available as a standalone agent in products such as Diurex Max. Pamabrom may be taken in dosages of up to 50 mg 4 times daily.

Combination Products

Multi-ingredient nonprescription products are marketed for women with PMS-type symptoms. Two of the most commonly used product brand names are Midol and Pamprin. Some products contain acetaminophen, caffeine/pamabrom, and pyrilamine, whereas others contain only an NSAID or a combination of an analgesic with a diuretic or an antihistamine ([Table 9–5](#)). Pain is a less common symptom of PMS, and no evidence exists that the sedative effect of an antihistamine, such as pyrilamine, will provide benefit to women experiencing the emotional symptoms of PMS. Therefore, these types of nonprescription products should not be recommended. More appropriate recommendations include the use of specific agents, such as those previously discussed, or referral for prescription drug therapy.

Pharmacotherapeutic Comparison

Calcium can be suggested for the initial treatment of PMS symptoms. If relief is inadequate, another agent from among those just discussed or a combination of two or more agents may be tried. Caffeine or pamabrom can be considered for women experiencing bloating with documented weight gain but may be inappropriate for those with irritability as a PMS symptom. Caffeine and pamabrom should also be used cautiously in patients with a history of peptic ulcer disease and those taking MAOIs or other xanthine medications such as theophylline. NSAIDs should be reserved for women who experience headache, joint and/or muscle pain, or concomitant dysmenorrhea. Use of combination products containing antihistamines should be discouraged, because the resulting drowsiness may impair job performance, schoolwork, and driving.

Product Selection Guidelines

Special Populations

PMS does not occur during pregnancy or after menopause. Adolescents and adult women should initially attempt to manage symptoms with lifestyle changes and therapies such as calcium supplementation. Adolescents should avoid combination products containing aspirin (see “Special Populations” under “Dysmenorrhea”). Women who are breastfeeding should avoid all herbal products, because information about their safety for nursing infants is limited. Vitamins and minerals in the dosages used for PMS are generally compatible with breastfeeding, and magnesium use is unlikely to cause diarrhea in breastfed infants.²⁵ Diuretics should be avoided during breastfeeding, as caffeine appears in breast milk about 1 hour after maternal ingestion. Caffeine may cause fussiness and poor sleep in infants, especially if consumed in high dosages or if the infant is preterm or younger than 3 weeks of age.²⁶

Patient Factors

Patients using proton pump inhibitors and histamine-₂ receptor antagonists should use calcium citrate rather than calcium carbonate products, because the latter products are less soluble with a higher gastric pH.

Patient Preferences

Patient preferences for PMS treatment can be accommodated. Women preferring to use dietary supplements should discuss their use with an HCP to ensure that drug–drug or drug–disease interactions do not exist.

Complementary Therapies

Trials have been conducted with botanical therapies, including chasteberry (*Vitex agnus-castus*), St. John’s wort (*Hypericum perforatum*), ginkgo (*Ginkgo biloba*), and saffron (*Crocus sativus*).³⁶ The first three dietary supplements are discussed in depth in [Chapter 51](#).

Chasteberry has shown efficacy in decreasing mild to moderate PMS symptoms; in four high-quality trials, chasteberry demonstrated a significant improvement over placebo.⁴⁶ Trials have used different formulations of chasteberry. Two trials using a standardized fruit extract, ZE 440, of chasteberry found a significant reduction in PMS symptoms including lower

mood, irritability/anger, pain/headache, breast tenderness, and fluid retention.⁴⁷ Two randomized, double-blind, placebo-controlled trials found that chasteberry extract reduced common PMS symptoms and did not cause any serious adverse effects.^{47,48} Symptoms, including negative affect, water retention, food cravings, and pain, were significantly less troublesome by the end of the third cycle of use.^{47,48} Chasteberry generally is well tolerated, with nausea and headache cited as the most common adverse effects.⁴⁹ Chasteberry may offer more benefit for patients with mild to moderate PMS and for women experiencing breast symptoms.^{49,50} Although evidence for chasteberry in the management of PMS appears favorable, a recent meta-analysis found that the treatment effect may be overestimated owing to study bias, heterogeneity, and potential publication bias. High-quality trials comparing chasteberry with established treatment options are needed to determine its relative efficacy.⁵¹

Chasteberry may affect estrogen receptors and inhibit prolactin.⁵⁰ Women who are pregnant or lactating should avoid chasteberry, and caution is warranted with its use in women taking hormones or who have hormone-sensitive cancers. See [Chapter 51](#) for additional interaction information.

One randomized trial of St. John's wort reported a reduction in anxiety-related symptoms in women with PMS, although its effect was not different from that of placebo.³⁸ St. John's wort may provide symptomatic improvement in persons with mild to moderate depression. Two high-quality trials did not find a benefit greater than that of placebo.⁴⁶ St. John's wort has many clinically significant drug interactions, including reduction in effectiveness of OCs.

A placebo-controlled randomized trial evaluated ginkgo in a dosage of 160–320 mg daily in 165 women with PMS. Breast pain, anxiety, irritability, and depression associated with PMS were improved with ginkgo.^{38,46} Ginkgo has antiplatelet effects and may increase the risk of bleeding.

In one randomized trial comparing saffron extract 30 mg daily with placebo, the saffron extract was found to significantly reduce PMS symptoms and depression symptoms.^{38,46}

Assessment of Premenstrual Syndrome: A Case-Based Approach

The health care provider should obtain a complete description of the patient's symptoms and their timing to determine whether the patient has PMS, PMDD, or another disorder with PMS-type symptoms. The severity of premenstrual disorder symptoms should also be considered in self-treatment. The HCP should identify medications that could be causing the symptoms reported or that may interact with nonprescription agents used to treat PMS (e.g., H₂ receptor antagonists and calcium salts). Previous treatments for the symptoms should also be explored.

Case 9–2 illustrates the assessment of a patient with PMS.

Case 9–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient reports the regular occurrence of PMS symptoms, including irritability, muscle pain, breast tenderness, and food cravings. She describes these symptoms as mild to moderate, affecting her productivity at work and ability to enjoy social events. The symptoms occur in a predictable pattern, starting about a week before menses and resolving within 1 or 2 days of menses onset. She has experienced these symptoms since her teenage years and reports that her mother did as well, before menopause. Currently, she says her irritability and food cravings are her most bothersome symptoms.
b. Description of any factors that seem to	"My symptoms seem to be worse when I'm busy at work and/or home and feeling overwhelmed. Snacking on things like chips and cookies helps with my food cravings, but then I feel guilty for eating junk food. I haven't

Relevant Evaluation Criteria	Scenario/Model Outcome
precipitate, exacerbate, and/or relieve the patient's symptom(s)	noticed anything that helps with my other symptoms."
c. Description of the patient's efforts to relieve the symptoms	"I've never tried anything to help with my symptoms—PMS is just something I've learned to expect and suffer through, but I'm hoping to change that."
d. Patient's identity	Lucy King
e. Patient's age, gender, height, and weight	30 years, female, 5 ft 2 in., 125 lb
f. Patient's occupation	Accountant
g. Patient's dietary habits	Ms. King reports that her diet is "good" overall: She eats a variety of foods (meats, fruits, vegetables, etc.) but is lactose-intolerant so she does not consume dairy products. She admits to snacking on junk food, particularly during the week before menses.
h. Patient's sleep habits	Ms. King has trouble falling asleep when she is feeling overwhelmed with her job or personal life but has no problems staying asleep once sleeping. On average, she sleeps 6–6.5 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Ms. King is lactose-intolerant. She takes ranitidine 75 mg twice a day as needed for acid reflux. She does not currently take any dietary supplements.
j. Allergies	Allergic to penicillin

Relevant Evaluation Criteria	Scenario/Model Outcome
k. History of other adverse reactions to medications	The patient has experienced development of hives with penicillin use.
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	The symptoms described (irritability, muscle pain, breast tenderness, food cravings), their negative effect on the patient's productivity and social functioning, and the timing of their onset (a week before menses) and resolution (within 1 or 2 days of menses) are consistent with mild to moderate PMS. The clinical picture is more severe than just typical premenstrual symptoms but does not meet criteria for PMDD or premenstrual exacerbation of other disorders.
3. Identify exclusions for self-treatment (Figure 9-3).	Ms. King has no exclusions for self-treatment: Symptoms occur only during the luteal phase of the menstrual cycle (i.e., there is a symptom-free interval); she is not experiencing significant depression, anxiety, or anger; and her symptoms do not appear to reflect an exacerbation of another disorder.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the	Options include (1) Refer Ms. King to an appropriate health care provider. (2) Recommend self-care with nonprescription and nondrug measures. (3) Recommend self-care until Ms. King can see an appropriate health care provider. (4) Take no action.

Relevant Evaluation Criteria	Scenario/Model Outcome
patient or caregiver.	
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Dietary and lifestyle modifications should be recommended as initial treatment. This approach includes consuming more foods that are rich in complex carbohydrates and avoiding simple sugars, increasing calcium intake, and implementing stress reduction strategies (e.g., CBT, massage, acupuncture). Keeping a symptom log or calendar also should be recommended to track the symptom pattern and the effectiveness of any interventions. Finally, education on PMS should be provided.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"What you are describing is consistent with mild to moderate PMS. This condition can generally be managed using nondrug and nonprescription therapies. Dietary and lifestyle modifications are often recommended first. To reduce your food cravings, try to eat foods that are rich in complex carbohydrates, like whole-grain foods. Because you are lactose-intolerant, it is also important to ensure you are getting enough calcium. Low calcium levels may contribute to irritability, and ensuring adequate intake can help with this, as well as some of your other PMS symptoms (e.g., physical symptoms and food cravings). Target a calcium intake of 1000–1300 mg daily. Nondairy sources of calcium include beans, almonds, and fortified beverages. Adequate vitamin D (at least 600 IU daily) is also recommended to improve calcium absorption and reduce the risk of osteoporosis. You mentioned that your symptoms are worse when you are overwhelmed at home and/or work, so implementing strategies to reduce stress, like having a massage, is also recommended. Finally, you should track your symptoms using a log or calendar, as this will allow us to identify patterns and evaluate the efficacy of interventions tried."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from	"You indicated that irritability and food cravings were currently your most bothersome symptoms, and these initial recommendations target those symptoms. Dietary and lifestyle modifications have been shown to be safe and effective in the management of PMS, so these strategies have been recommended first. Pharmacologic and complementary therapies can be considered if you do not notice improvement within a few months. Strategies for managing your less-bothersome symptoms (e.g., muscle pain) can be discussed during follow-up or sooner if needed."

Relevant Evaluation Criteria	Scenario/Model Outcome
the considered therapeutic alternatives.	
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	“Consume foods that are rich in complex carbohydrates during the premenstrual interval to reduce food cravings. Foods rich in complex carbohydrates include beans, whole grains, and starchy vegetables (e.g., sweet potatoes). Also ensure you are consuming adequate dietary calcium. Target an intake of 1000–1300 mg daily. Nondairy sources of calcium include beans, almonds, and fortified beverages. Vitamin D (at least 600 IU daily) is also recommended to improve calcium absorption and reduce the risk of osteoporosis.”
Solicit follow-up questions from the patient or caregiver.	“If I can’t get enough calcium from my diet, can I take a calcium supplement?”
Answer the patient’s or caregiver’s questions.	“Yes, but because you use ranitidine for acid reflux, calcium citrate would be preferred over calcium carbonate, as it is better absorbed in these situations. Do not take more than 500–600 mg of elemental calcium at a time.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	“Try these dietary and lifestyle modifications for several months to assess their effectiveness. If you are unable to meet the daily target for calcium intake from your diet alone, we can discuss supplementation with calcium citrate. If your other PMS symptoms (e.g., breast tenderness, muscle pain) become more bothersome and you would like to discuss management strategies before our follow-up, please let me know. Also contact me if you have questions or concerns about any of the strategies we have discussed

Relevant Evaluation Criteria	Scenario/Model Outcome
	today.”

Key: CBT = Cognitive behavioral therapy; n/a = not applicable; OC = oral contraceptive; PMS = premenstrual syndrome; PMDD = premenstrual dysphoric disorder.

Patient Counseling for Premenstrual Syndrome

Patients should receive education on the timing of PMS symptoms and be encouraged to track their symptoms using a symptom log and calendar. This approach will help predict symptom onset and may increase compliance with recommended therapies. Health care providers should be prepared to discuss management strategies for both the behavioral and physical symptoms of mild to moderate PMS. If the patient prefers to use nonprescription medications or vitamins, the proper use and potential adverse effects of these agents should be explained. However, patients should be informed of the limited evidence for efficacy of these agents in treating PMS, so that expectations can be managed accordingly. The patient also should be advised that treatment measures must be implemented during every menstrual cycle, because it may take several cycles for symptomatic relief to occur. The “Patient Education for Premenstrual Syndrome” box lists specific information to provide patients during counseling.

Evaluation of Patient Outcomes for Premenstrual Syndrome

Monitoring is accomplished by having the patient report whether the PMS

symptoms have decreased or resolved. It may take several menstrual cycles to ascertain whether lifestyle changes or nonprescription therapies are reducing the symptoms of PMS. Comparing the occurrence and/or severity of symptoms before and after vitamin or medication use can help determine the value of a therapy. Women should be encouraged to contact the health care provider to discuss treatment effectiveness and to clarify information or answer any questions. Reasons for advising the patient to see her primary care provider include persistent symptoms, symptoms that the patient reports are disruptive to personal relationships, or symptoms that affect the patient's ability to engage in usual activities or function productively at work/school.

Patient Education for Premenstrual Syndrome

The objective of self-treatment for premenstrual syndrome (PMS) is to achieve relief from or significant decrease in symptoms, to limit discomfort, distress, and the disruption of personal relationships or usual activities. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Try to avoid stress, develop effective coping mechanisms for managing stress, and learn relaxation techniques.
- If possible, participate in regular aerobic exercise.
- During the 7–14 days before the start of your menstrual period, reduce or eliminate intake of salt, caffeine, chocolate, and alcoholic beverages. Eating foods rich in carbohydrates and low in protein during the premenstrual interval also may reduce symptoms.

Nonprescription Medications

- Nonprescription medications and lifestyle modifications may not improve symptoms for all women, and it may take several months

to determine whether these therapies are working.

- Therapy with one nonprescription medication may improve only some of the symptoms; several medications may be needed for optimal symptom control. However, only add one agent at a time so that it is possible to determine which agent causes benefit or adverse effects.
- Follow the guidelines here for the agents that best control your symptoms:
 - Take 1200 mg of elemental calcium daily in divided doses. Calcium can be obtained from food or from supplements. Take no more than 500–600 mg at one time. Calcium may cause stomach upset (if this occurs, take with food) or constipation.
 - Take at least 600 IU of vitamin D daily.
 - Take 300–360 mg of magnesium pyrrolidone daily during the premenstrual interval only. Magnesium may cause diarrhea.
 - Take up to 100 mg of pyridoxine daily. Do not exceed this dosage; otherwise, neurologic symptoms caused by vitamin B₆ toxicity may occur.

When to Seek Medical Attention

- If you are taking vitamin B₆ and neurologic symptoms develop (e.g., a sensation of pricking, tingling, or creeping on the skin; bone pain; muscle weakness; or stinging, burning, or itching sensations), stop taking the vitamin and seek medical attention.
- If the PMS symptoms persist, or if they worsen, medical evaluation is suggested.

Toxic Shock Syndrome

Toxic shock syndrome (TSS) is a severe multisystem illness characterized by high fever, profound hypotension, severe diarrhea, mental confusion, renal failure, erythroderma, and skin desquamation. In the past, these symptoms and signs were recognized as affecting a relatively large number of young,

previously healthy, menstruating women. TSS is commonly divided into menstrual and nonmenstrual cases.

Menstrual TSS affects primarily young women between 13 and 19 years of age.⁵² Almost all cases of menstrual TSS have been associated with menstruation and tampon use, especially the use of high-absorbency tampons.⁵²

The decrease in cases of menstrual TSS has been attributed to several factors, including removal of superabsorbent tampons from the market; a change in the composition of tampons; an increased awareness of the recommendations to change tampons frequently and to alternate tampon and pad use; and FDA-required standardized labeling of tampons.⁵²

The strongest predictor of risk for menstrual TSS is the use of tampons, with risk increasing with tampon absorbency. For every 1 g increase in absorbency, the risk for TSS increases 34%–37%. Continuous uninterrupted use of tampons for at least 1 day during menses also has been shown to correlate with an increased risk for menstrual TSS. In addition, using tampons between menstrual periods (to manage vaginal discharge or nonmenstrual bleeding) can increase the likelihood of vaginal ulcers and the risk of TSS.⁵³ Besides tampons, TSS has been associated with the use of barrier contraceptives, including diaphragms, cervical caps and cervical sponges, IUC systems, and menstrual cups. The overall risk of TSS with menstrual cup use appears low, but limited evidence prevents comparison with other products, including tampons and diaphragms.⁵⁴

Pathophysiology of Menstrual TSS

Menstrual TSS is caused by the toxin-producing strains of *Staphylococcus aureus*.⁵⁵ TSS is an inflammatory immune response to the enterotoxins produced by these bacteria. Toxin-producing strains of *S. aureus* produce the superantigen toxin TSST-1. Most adults have a protective level of antibodies against the TSST-1 toxin. Younger people who lack this antibody protection and who become infected with a toxin-producing strain of *S. aureus* may develop TSS.⁵⁵

Four conditions promote toxin production: elevated protein levels, neutral pH,

elevated carbon dioxide levels, and elevated oxygen levels.⁵² During menses, menstrual blood provides an increase in protein and also increases vaginal pH to 7, or neutral pH. Tampon use may create the environment for development of TSS by introducing oxygen into the vagina; oxygen is trapped within the tampon, and higher-absorbency tampons carry more oxygen into the vagina.^{52,55} Oxygen is a critical factor for the production of TSST-1.⁵⁶ After the introduction of a tampon, the vagina takes hours to return to its anaerobic state, with elevated carbon dioxide levels. In addition, insertion and presence of tampons, IUC systems, and contraceptive sponges create microtrauma, which increases exposure of the toxins to the circulatory and immune systems. Exposure of immune cells to TSST-1 initiates the inflammatory cascade involving interleukin-1 and tumor necrosis factor. This inflammatory response results in the signs and symptoms of TSS.

Clinical Presentation of Menstrual TSS

By definition, menstrual TSS occurs within 2 days of the onset of menses, during menses, or within 2 days after menses. Prodromal symptoms, including malaise, myalgias, and chills, occur for 2–3 days before onset of the full-blown syndrome.⁵⁵ GI symptoms of vomiting, diarrhea, and abdominal pain typically occur early in the illness and affect almost all patients. After that, TSS evolves rapidly into high fever, myalgias, vomiting and diarrhea, erythroderma, decreased urine output, severe hypotension, and shock. Neurologic manifestations including headache, confusion, agitation, lethargy, and seizures also occur in almost all cases. Acute renal failure, cardiac involvement, and adult respiratory distress syndrome also are common.

Dermatologic manifestations are characteristic of TSS; both early rash and subsequent skin desquamation are required for a definitive diagnosis. The early rash often is described as a sunburnlike, diffuse, macular erythroderma that is not pruritic. Approximately 5–12 days after the onset of TSS, desquamation of the skin on the patient's face, trunk, and extremities (including the soles of the feet and the palms of the hands) occurs.

Prevention of Menstrual TSS

Menstrual TSS can be prevented almost entirely with use of sanitary pads instead of tampons during menstruation. Patients who use tampons can reduce the risk of developing TSS by following the guidelines in the box “Patient Education for Toxic Shock Syndrome.”

Women who have had TSS are at risk for recurrence. Rates of recurrence are reported as approximately 28%–64%.⁵³ Recurrence rates are lower for women who were treated with antibiotics during TSS. Prevention of TSS for these patients includes avoiding tampons, IUCs, diaphragms, cervical caps, and contraceptive sponges.

Assessment of Menstrual TSS: A Case-Based Approach

Obtaining prompt medical attention is an important aspect of care for patients with symptoms consistent with TSS. The health care provider can be alert for symptoms of TSS when patients seek nonprescription therapy for a severe “flu” with symptoms such as fever, vomiting, diarrhea, and dizziness, or when patients seek help for an unusual skin rash that occurs in conjunction with the previously described symptoms. If TSS is suspected, the patient should be advised to seek medical care immediately and to avoid use of NSAIDs for fever and myalgias, because these agents may advance the progression of TSS by increasing the production of tumor necrosis factor.

Patient Counseling for Menstrual TSS

Tampons are used by women of all ages during their reproductive years. Health care providers should counsel patients about the prevention of TSS as outlined in the box “Patient Education for Toxic Shock Syndrome.” In particular, patient counseling should emphasize the importance of washing the hands before inserting a tampon, which removes organisms causing TSS from the skin. Approximately 18%–36% of women report that they do not always change a tampon at least every 6 hours—another risk factor for TSS. Recommended preventive measures include changing tampons frequently, according to product instructions; alternating the use of tampons with the use of sanitary pads over a 24-hour period; and using the lowest-absorbency tampons

compatible with clinical needs. The health care provider should emphasize, however, that the risk for this condition is quite small. If a patient presents with early symptoms of TSS, she should be advised to remove the tampon or any barrier contraceptive device and to seek emergency medical treatment.

Patient Education for Toxic Shock Syndrome

The objective of self-treatment is to reduce the risk of developing toxic shock syndrome (TSS) associated with the use of tampons or contraceptive devices. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

- To reduce the risk of TSS to almost zero, use sanitary pads instead of tampons during your menstrual period.
- To lower the risk of TSS while using tampons, use the lowest-absorbency tampons compatible with your needs. Also, alternate the use of menstrual pads with the use of tampons (e.g., use pads at night) so that tampons are not used continuously for 24 hours.
- Change tampons 4–6 times a day and at least every 6 hours; overnight use should be for no longer than 8 hours.
- Wash your hands with soap before inserting anything into the vagina (e.g., tampon, diaphragm, contraceptive sponge, or vaginal medication). The bacteria causing TSS usually are found on the skin.
- Do not leave a contraceptive sponge, diaphragm, or cervical cap in place in the vagina longer than recommended; do not use any of these devices during menstruation.
- Do not use tampons, contraceptive sponges, or a cervical cap during the first 12 weeks after childbirth. It also may be best to avoid using a diaphragm.
- Read the insert on TSS enclosed in the tampon package, and become familiar with the early symptoms of this disorder.

When to Seek Medical Attention

- If you experience symptoms of TSS (high fever, pain or muscle

aches, a sunburn-like rash appearing after a day or two, weakness, fatigue, nausea, vomiting, and diarrhea), remove the tampon or contraceptive device immediately, and seek emergency medical treatment. If left untreated, TSS can cause shock and even death.

Key Points for Disorders Related to Menstruation

- Self-care is appropriate for otherwise healthy young women whose history is consistent with primary dysmenorrhea and who are not sexually active, and for patients previously diagnosed with primary dysmenorrhea. Adolescents with pelvic pain who are sexually active and thus at risk for PID and patients with characteristics indicating secondary dysmenorrhea or with persistent dysmenorrhea despite treatment with nonprescription agents should be referred for medical evaluation.
- NSAIDs are the drugs of choice for self-management of primary dysmenorrhea. These medications should be taken at the onset of or just before menses and should be used in scheduled doses for several days for optimal reduction in pain and cramping.
- The use of local topical heat also can provide relief from dysmenorrhea. Its analgesic effect has a faster onset than drug therapy, and it can add to the relief provided by an NSAID. Nonpharmacologic therapy may be especially useful for women who cannot tolerate or who prefer not to use drug therapy or whose symptoms do not respond to nonprescription NSAIDs.
- Premenstrual disorders should be distinguished from typical premenstrual symptoms and also from premenstrual exacerbations of other disorders, particularly mood disorders.
- Premenstrual disorder symptoms typically begin or intensify about a week before the onset of menses, peak on the 2 days

before menses, and resolve with menses initiation or shortly thereafter. A woman with a premenstrual disorder experiences a symptom-free interval during days 5–10 of her menstrual cycle.

- Mild to moderate PMS generally can be managed with self-treatment, including nondrug and/or nonprescription therapies; women with suspected PMDD are not candidates for self-care and should be referred to a primary care provider for appropriate diagnosis and management.
- Premenstrual disorder symptoms are chronic and, in most cases, will continue until menopause. Therefore, the cost of therapy, the possibility that a woman may become pregnant, and the likelihood of adverse effects from therapy are important considerations in selecting therapy.
- Use of calcium, pyridoxine, and chasteberry can be considered to reduce the symptoms of mild to moderate PMS. More severe PMS and PMDD symptoms may warrant referral to a primary care provider for further evaluation and/or prescription therapy.
- TSS has been linked to tampon use. To lower the risk for this potentially lethal disorder, women should use the lowest-absorbency tampons compatible with their needs and should alternate the use of sanitary pads with that of tampons over a 24-hour period.

Chapter 10: Prevention of Pregnancy and Sexually Transmitted Infections

Authors: Shareen Y. El-Ibiary, Erin C. Raney

Unprotected sexual activity can result in unintended pregnancy and sexually transmitted infections (STIs), either of which can exact a high physical, psychological, and financial toll on affected persons. As discussed in this chapter, vaccines and properly used nonprescription contraceptive products or methods can reduce the risks of such adverse outcomes.

An estimated 45% of pregnancies in the United States are unintended.¹ The 2015–2017 National Survey of Family Growth (NSFG) found that approximately 65% of female subjects 15–49 years of age used contraception. Of the 35% not using contraception, approximately 8% were sexually active or at risk for unintended pregnancy.² Pharmacists can play an important role in improving rates of contraceptive use through counseling and dispensing as permitted by state law.

Although contraceptive use is prevalent, a continuing concern is the high risk of pregnancy and STIs in adolescents. The NSFG study also found that between 2011 and 2013, 40%–50% of teenagers had engaged in sexual intercourse.³ Of sexually active teenagers, about one fifth did not use contraception during their first sexual encounter.³ Low levels of contraceptive use in these teens may be related to a lack of knowledge and planning, denial, and infrequent or unpredictable intercourse. The teenage pregnancy rate in the United States is one of the highest among developed countries.³ However, as of 2017, birth rates for teenagers had reached historic lows for all age and ethnic groups.⁴ Adolescents also are particularly vulnerable to STIs, with many of the new STI infections each year occurring in young people 15–24 years of age.⁵ Risk factors for these infections include having multiple sexual partners, unprotected intercourse, an inherent biological susceptibility to infection, and financial and other barriers to health care utilization.^{5,6}

Women of older reproductive age also are at risk for unintended pregnancies. NSFG found that among women 35 years of age or older, 34% of pregnancies were unintended.¹ Postmenopausal women and older men in sexual relationships that are not mutually monogamous are additional groups at risk

for development of STIs.

The availability and relatively low cost of nonprescription contraceptive methods are important, especially for those who are unwilling or unable to access family planning services or use prescription contraceptives. Even if a prescription product is chosen as the primary contraceptive method, low-cost and low-risk nonprescription methods may be appropriate at different times during a person's life. In addition, the widespread accessibility of pharmacist-administered immunizations offers another opportunity for STI prevention.

Overview of Pregnancy and STIs

Pregnancy can result only when a viable egg is available for fertilization by a sperm. (See [Chapter 9](#) for discussion of the reproductive process.) Conception may occur during a 6-day window that begins 5 days before ovulation through the day of ovulation. The estimated risk of pregnancy from unprotected sexual intercourse during this period ranges from 5% to 45%, with peak risk occurring the day before ovulation.⁷ Pregnancy can occur despite contraceptive use if the product is used incorrectly or it fails, such as with condom breakage.

STIs are contracted through contact with infected genital tissues, mucous membranes, and/or body fluids. [Table 10–1](#) summarizes the major infections.^{6,8,9} Although STIs affect both sexes, women are more prone to reproductive consequences and related conditions, including pelvic inflammatory disease, chronic pelvic pain, pregnancy complications, malignancies, and infertility. This likelihood is possibly related to difficulties in diagnosis, lack of patient recognition of symptoms, and a higher probability of asymptomatic infection in female patients.¹⁰

Prevention of STIs and Pregnancy: Methods and Strategies

Vaccines for STI Prevention

Pharmacist-administered vaccination has become more common. Depending on state laws and regulations, vaccines for STI prevention may be available for administration in the pharmacy by protocol or without a prescription. States may limit the age range of persons for whom such vaccination is permitted, but in the absence of any regulatory or patient-specific barriers, availability of this service will increase the community vaccination rate for STIs.

Human Papillomavirus Vaccine

Human papillomavirus (HPV) is a virus that may be transmitted by sexual contact and is a major cause of cervical cancer and genital warts.^{6,11} Of the more than 120 different subtypes of HPV identified, HPV subtypes 16 and 18 are responsible for approximately 70% of cervical cancers. HPV subtypes 6 and 11 are responsible for benign cervical cell changes, genital warts, and laryngeal papillomas.¹² HPV also is responsible for a subset of vaginal, vulvar, penile, anal, and some head and neck cancers. HPV infection is the most common STI in the United States, with an estimated 14 million new cases annually.¹² The risk of infection is highest during the first few years after initiation of sexual activity.¹²

Three HPV vaccines have been developed: Cervarix (bivalent HPV vaccine; effective against HPV subtypes 16 and 18), Gardasil (quadrivalent HPV vaccine; for HPV subtypes 6, 11, 16, and 18), and Gardasil 9 (9-valent HPV vaccine; for HPV subtypes 6, 11, 16, 18, 31, 33, 45, 52, and 58).¹¹ Currently, only the 9-valent HPV vaccine is marketed in the United States and is approved for use in females 9–45 years of age to prevent precancerous or dysplastic lesions associated with specific HPV subtypes, genital warts and cervical, vaginal, vulvar, and anal cancers.¹³ It also is approved for use in males 9–45 years of age to prevent precancerous or dysplastic lesions associated with certain HPV subtypes, genital warts, and anal cancer.¹³

The current recommendation of the Advisory Committee on Immunization

Practices (ACIP) is for all 11- and 12-year-old adolescents to receive the applicable HPV vaccine, with vaccination supported in children as young as 9 years if necessary.¹¹ ACIP recommends a two-dose schedule, with immunizations given at 0 and 6–12 months, for adolescents up to 15 years of age who are initiating the vaccine. Those who initiate the vaccine series at age 15 years and older, as well as persons with certain immunocompromising conditions, should follow a three-dose schedule with immunizations at 0, 1–2 months, and 6 months.¹¹ A “catch-up” series is recommended for all persons through 26 years of age.¹¹ The vaccine works best before any HPV exposure from sexual contact, but previous sexual intercourse does not preclude vaccination with expected benefit.¹²

ACIP’s recommendation for HPV vaccine use has had a profound impact on HPV subtype prevalence in the United States. Comparison of data from a prevaccine time period with data collected from 2009–2012 showed a decline in HPV subtypes 6, 11, 16, and 18 among girls 14–19 years of age (11.5%–4.3%, respectively) and among women 20–24 years of age (18.5%–12.1%, respectively).¹⁴ Adverse effects of the vaccine may include irritation at the site of administration, self-reported malaise, and syncope. Because of the risk of syncope, particularly in younger girls, patients should be monitored for at least 15 minutes after administration of the vaccine.¹²

Hepatitis B Vaccine

Infection with the hepatitis B virus is associated with longterm complications such as hepatitis, cirrhosis, hepatic carcinoma, and death. The virus can be transmitted through contact with blood and other body fluids, and 79% of new infections occur in association with high-risk sexual behaviors or injection drug use.¹²

The hepatitis B vaccine is available as inactivated injectable formulations, with an administration schedule of a three-dose series of injections at 0, 1, and 6 months or a two-dose series of injections at 0 and 1 month.^{12,15} The two-dose series is approved only for the HepB-CpG vaccine, which uses a different adjuvant from the traditional aluminum adjuvant vaccines and is available for adults 18 years of age and older.¹⁵ Recommended as a routine immunization for all infants starting at birth, hepatitis B vaccination also is provided to children and adolescents who did not receive the vaccine as infants or who did not complete the series. Adults who desire protection from hepatitis B

infection or those who meet risk criteria and who were not previously vaccinated should also receive the series. Candidates for the vaccine due to sexual exposure include partners of hepatitis B–infected persons, those not in long-term mutually monogamous sexual relationships, those in need of evaluation or treatment for a STI, and men who have sex with men. Other potential candidates include injection drug users; health care and emergency response personnel; patients with diabetes, end-stage renal disease, human immunodeficiency virus (HIV) infection, hepatitis C infection, or liver disease; international travelers; and residents of correctional facilities or facilities for developmentally disabled persons.¹⁵

Contraception for Pregnancy and STI Prevention

The goal of contraceptive use is to prevent unintended pregnancy and STIs with minimal adverse effects. No method of birth control except abstinence is 100% effective, and contraceptive choices may change during a lifetime.

The effectiveness of a contraceptive method in preventing pregnancy is reported in two ways: the accidental pregnancy rate in the first year of *perfect* use (method-related failure rate) and the rate in the first year of *typical* use (use-related failure rate). [Table 10–2](#) summarizes effectiveness data for various contraceptive methods.^{16–20} The pregnancy rate with perfect use is difficult to measure and indicates the method’s theoretical effectiveness. Perfect use assumes accurate and consistent use of the method every time intercourse occurs. The more realistic rate with typical use takes into account pregnancies that may have occurred because of inconsistent or incorrect use of the method. Reported use-related failure rates vary, depending on the population studied. Decreased coital frequency and declining fertility in older users may contribute to increased effectiveness rates in this population. Effectiveness also increases the longer an individual uses a particular method.¹⁸

Table 10–2 Failure and Use Rates for Various Contraceptive Methods

Method	Accidental Pregnancy Rate in First Year of Use (%)		% of Women Using Method ^c
	Typical Use ^a	Perfect Use ^b	
No method at risk for pregnancy	85	85	10.5

Method	Accidental Pregnancy Rate in First Year of Use (%)		% of Women Using Method ^c
	Typical Use ^a	Perfect Use ^b	
Withdrawal	20	4	7.1
Fertility awareness-based methods	15	–	1.9
Calendar method	15–19	3	–
Symptothermal method	2	0.4	–
Lactational amenorrhea method (first 6 months after giving birth)	2–3	0.5	
Standard days method	12	5	–
TwoDay Method	14	4–6	–
Natural Cycles app	8	1	–
Spermicides (foam, creams, gels, vaginal suppositories, vaginal film)	21	16	<0.2
Contraceptive sponge	<i>Parous women: 27</i>	<i>Parous women: 20</i>	<0.2
	<i>Nulliparous women: 14</i>	<i>Nulliparous women: 9</i>	
Male condom (without spermicide)	13	2	13
Female condom (without spermicide)	21	5	<0.2
Prescription methods (excluding diaphragm, cervical cap)	0.2–9	≤0.6	42.5
Sterilization (male/female)	≤0.5	≤0.5	11.6

^a Among typical couples who initiate use of a method (not necessarily for the first time), the percentage who experience an accidental pregnancy during the first year if they do not stop use for any other reason.

^b Among typical couples who initiate use of a method (not necessarily for the first time) and who use it consistently and correctly, the percentage who experience an

accidental pregnancy during the first year if they do not stop use for any other reason.

^c Percentage of female users 15–44 years of age.

The most effective way to avoid contracting a STI is either to abstain from risky sexual activity or to be involved in a longterm mutually monogamous sexual relationship with an uninfected partner.⁶ In the absence of those options, preventive strategies ([Table 10–3](#))^{6,10} in conjunction with use of selected contraceptives may provide the best method for reducing risk of infection ([Figure 10–1](#)).^{6,10,20–24}

Table 10–3 Prevention Strategies for Sexually Transmitted Infections

- Abstain from sexual activity.
- Avoid intercourse with a known infected partner.
- Avoid intercourse with an individual having multiple sex partners.
- Use a new condom with each episode of anal, oral, or vaginal intercourse.
- Seek a mutually monogamous relationship with an uninfected partner.
- Discuss partner's past sexual experiences.
- Examine partner for genital lesions.
- Practice genital self-examination.
- Avoid sexual activity involving direct contact with blood, semen, or other body fluids.
- Avoid sharing sexual devices that come in contact with semen or other body fluids.
- Choose safe and effective methods (e.g., mechanical barriers) to reduce the risk of STIs (consider adding more effective methods of pregnancy prevention when necessary).
- Avoid sexual activity if signs/symptoms of an STI are present.
- Consider vaccination for persons at high risk for a vaccine-preventable STI (e.g., HBV or HPV infection).

Key: HBV = Hepatitis B virus; HPV = human papillomavirus; STI = sexually transmitted infection.

Source: References 6 and 10.

The acceptability of any given contraceptive method is vital for correct and

consistent use of that method. Factors that affect acceptability include the user's religious beliefs and future reproductive plans, product effectiveness, partner's preference and support, degree of spontaneity permitted, ease of use, product accessibility, and cost. To help patients make informed decisions, health care providers should be cognizant of each method's safety, including potential adverse effects on future fertility and on the fetus, if unintended conception does occur, and the effectiveness, accessibility, and relative cost of different contraceptive methods. The algorithm in [Figure 10–1](#) can assist the health care provider in making appropriate contraceptive recommendations.

Nonprescription Contraceptive Products

Male Condoms

Condoms, also known as *rubbers*, *sheaths*, *prophylactics*, *safes*, *skins*, or *pros*, are the most important barrier contraceptive devices that help protect against STIs.¹⁸ Male condoms are available in several materials: latex, polyurethane, polyisoprene, and lamb cecum (natural membrane or skin) ([Table 10–4](#)).

Table 10–4 Selected Male Condoms	
Type	Trade Name
Synthetic, nonlatex condoms	Durex Avanti Bare RealFeel (polyisoprene), Trojan Supra (polyurethane), Lifestyles Skyn (polyisoprene)
Natural membrane condoms	Trojan Naturalamb (lamb cecum)
Latex condoms	Beyond Seven, Billy Boy, Crown, Durex, Kimono, LifeStyles, One, Sir Richard's, Trojan

Latex condoms come in various sizes, colors, styles, shapes, and thicknesses. Other features include reservoir tips, ribs, studs, spermicide coating with nonoxynol-9, and lubrication. Of note, latex condoms are degraded by oil-based lubricants. The list price at a major pharmacy chain for latex condoms is \$0.18–\$1.08 each.²⁴ Latex condoms also help protect against STIs.²⁰ Polyurethane condoms conduct heat well, are available prelubricated, are not subject to degradation by oil-based products but are not as elastic as latex

condoms.²⁵ Another form of synthetic condom is made of polyisoprene, which is more elastic than polyurethane but can be damaged by oil-based lubricants. Although synthetic and latex condoms are thought to provide similar protection against STIs, prevention of STIs with synthetic condoms has not been well studied. The U.S. Food and Drug Administration (FDA) labeling restricts synthetic condom use to latex-sensitive or latex-allergic persons.²⁰ At a cost of \$0.67–\$1.86 each, polyurethane and polyisoprene condoms are more expensive than latex condoms.²⁴

Lamb cecum condoms are labeled only for pregnancy prevention, because the presence of pores in the membrane may allow passage of viral organisms, including HIV and hepatitis B virus.²⁰ These condoms conduct heat well, are very strong, and are not degraded by oil-based lubricants. With a price of approximately \$2.55 each, these condoms also are more expensive than latex condoms.²⁴

FDA regulates condoms as medical devices, and they must meet performance standards for strength and integrity. The true incidence of condom breakage is unknown, and breakage rates from studies vary widely, ranging from zero to 22%.²⁶ The overall use-related failure rate for condoms is approximately 13 pregnancies per 100 women during the first year of use ([Table 10–2](#)). In some studies, a limited group of patients reported multiple instances of breakage, indicating that breakage may be related as much to the individual user as it is to manufacturing defects. Behaviors that have been associated with an increased risk of condom breakage are (1) incorrect placement of the condom/ failure to squeeze air from the receptacle tip; (2) use of an oil-based lubricant with latex condoms; (3) reuse of condoms; (4) longer duration or increased intensity or frequency of coitus; (5) previous history of condom breakage or slippage; (6) history of STI; (7) contact with sharp objects; (8) self-reported problems with fit of a condom; (9) impaired or intoxicated state, from drugs or alcohol, in either partner; and (10) brief acquaintance, less than 1 month, with the sexual partner.^{20,26–29} One study found a decreased incidence of breakage with continued use, indicating that correct technique may improve with experience.²⁶ The benefit of using additional lubrication with lubricated condoms is unclear. One study found that use of additional lubricant increased the risk of condom slippage. Another study, however, found that use of an additional water-based lubricant was associated with decreased breakage rates but caused no increase in condom slippage rates.²⁸ A review of comparative studies found that nonlatex synthetic condoms had a

significantly higher breakage rate than that with latex condoms.^{25,30,31} Two studies also reported a significantly higher pregnancy rate with use of nonlatex condoms compared with latex condoms.^{31,32} Accordingly, nonlatex condoms should be reserved for use by persons with intolerance to latex condoms.

Studies support the finding that consistent use of condoms protects against trichomoniasis, bacterial vaginosis, and gonorrhea infections in women, and against syphilis and chlamydial, HPV, and herpes simplex virus infections in both men and women.²⁰ Nonoxynol-9–coated (spermicide-coated) male condoms are no more effective than untreated condoms at preventing STIs and have not been shown to be more effective in pregnancy prevention.³³ Use of nonoxynol-9-treated condoms is discouraged because of the potential risk of irritation from the spermicide in both men and women, resulting in possible increased risk of infection.²⁰

Proper use of condoms is essential to their effectiveness in preventing pregnancy and STIs ([Table 10–5](#)). For example, a man using a polyurethane condom should be advised that it is not as elastic as the latex condom and will not fit as snugly. In addition, condoms without a reservoir require that a space be left at the condom tip.

Table 10–5 Usage Guidelines for Male Condoms

- Use only condoms that are fresh (not previously opened), that are within their expiration date, and that have been stored in a dry, cool place (not a wallet or vehicle glove compartment).
- Do not attempt to test the condom for leaks before using; this maneuver will weaken the condom.
- Be aware that long fingernails or jewelry may easily tear condoms.
- As shown in drawing A, unroll the condom onto the erect penis before the penis comes into any contact with the vagina. If you start to put the condom on incorrectly, with the exterior touching the penis, discard that condom and use a fresh one. (Note: Pre-ejaculate secretions may contain sperm.)
- If you are not using a reservoir-tipped condom, leave one-half inch of space between the end of the condom and the tip of the penis by pinching the top of the condom as you unroll it (drawing B). This method leaves space for the ejaculate (drawing C) and decreases the risk of breakage.
- If your partner has vaginal dryness, use additional lubrication, if desired. This step will help decrease the risk of tears and breakage. Use only water-based lubricants; oil-based

lubricants weaken latex condoms and increase the chance of breakage. Spermicidal agents may be used as lubricants with condoms (Table 10–8), and the combination may increase contraceptive effectiveness.

- After ejaculation, withdraw the penis immediately. To prevent the condom from slipping off, hold on to the rim of the condom as you withdraw.
- Check the condom for tears and then discard in a trash can, not a toilet.
- If a tear or break occurs, immediately insert spermicidal foam or jelly containing a high concentration of spermicide into the vagina. Do not use suppositories or a vaginal film in these cases, because the delay time for dissolution may decrease the product's efficacy. Your partner should not douche at this time, because any sperm that are present may be forced into the cervical canal. Consider use of emergency contraception as soon as possible and within 72–120 hours after unprotected intercourse if pregnancy is a concern.

Prelubricated condoms are a good choice when lubrication is desired. Additional lubrication for use with any latex condom should be selected from products that do not impair the strength and integrity of the condom (Table 10–6).

Table 10–6 Selected Lubricants/Products That Are Safe or Unsafe to Use With Latex Condoms

Safe	Unsafe
Contraceptive foams/gels	Topical oils (e.g., baby oil, mineral oil, massage oil)
Water-based personal lubricants, such as K-Y Jelly or Astroglide	Edible oils/fats (e.g., olive, peanut, corn, canola, and safflower oils; butter; margarine)
Silicone-based lubricants, such as Astroglide X, Replens lubricant	Hemorrhoidal ointments
Glycerin (USP)	Petroleum jelly (e.g., Vaseline)
Water	Vaginal creams (e.g., Monistat, others)
Saliva	Hand and body lotions; suntan lotions

Source: Reference 20.

Packaged condoms should be kept in their sealed packages until time of use and protected from light and excessive heat, which can rapidly compromise the integrity of the condom material. FDA requires that condoms be labeled with an expiration date or date of manufacture. The shelf life of packaged condoms under optimal conditions is 3–5 years. Condoms showing signs of discoloration, brittleness, or stickiness should be discarded, even if they are within their expiration date.

The most frequent complaints about condoms are decreased sensitivity of the glans penis, resulting in decreased sexual pleasure for the man, and sensitivity to the condom material. The use of very thin or ridged condoms, nonlatex synthetic condoms, or natural membrane condoms in a monogamous relationship with a partner screened for STI exposure may alleviate the problem of decreased sensitivity.

Contact dermatitis caused by latex allergy can occur in the male or female partner and may be characterized by immediate localized itching and swelling (urticarial reaction) or by a delayed eczematous reaction. The sensitizers in latex condoms are usually antioxidants or accelerators used in processing the rubber. In persons with severe sensitivity, the reaction may include systemic symptoms. Spermicide-treated condoms may be associated with enhanced latex allergy, or the spermicide may be the cause of the sensitivity reactions.³⁴

For most people, condoms are an effective, acceptable, inexpensive, safe, and nontoxic method of birth control. Given the range of condoms available, men should be encouraged to try a different style or brand if they are dissatisfied with a condom used previously. Before recommending a latex condom, health care providers should assess for latex allergy. Ways to assess for possible latex allergy include asking if the patient has had any reactions to latex gloves, for example, or has experienced any reactions when inflating balloons. In patients with an established sensitivity to latex products, an alternate type of condom should be recommended. Some men and women may be sensitized to components of the lubricant or spermicide. Because manufacturers use different processes, changing brands or using a condom without spermicide may resolve the problem.²⁰ If switching brands does not eliminate the irritation, the man may use nonlatex synthetic condoms. Natural skin condoms also may be used if their limitations in preventing STIs are recognized.

Other uses for barrier methods include prevention of STI transmission through oral sex. A dental dam (square piece of latex or silicone used to cover the

vagina or anus during oral sex) or a condom cut lengthwise and spread open also may be used for this purpose.³⁵ Intact condoms may be used on the penis during oral sex.

Female Condoms

A female condom is another nonprescription contraceptive product. The only female condom available is a second-generation female condom known as the FC2, which is made of nitrile, a synthetic latex.³⁶ The female condom consists of an outer ring, a sheath or pouch that fits over the vaginal mucosa, and an inner ring that secures the sheath by fitting like a diaphragm over the cervix. The female condom is designed for one-time use only and, at a cost of \$2.00 each, is more expensive than the latex male condom.²⁴

The breakage rate for the female condom has been lower than that for latex male condoms, but slippage rates may be higher, especially with initial use.²⁷ Although specific data regarding failure rates for the FC2 were not available when it was first released on the market, it was comparable to the first-generation female condom, the FC1.³⁷ The extrapolated annual failure rate for the FC1 is 21% for all users and 5% for perfect users (**Table 10–2**).^{21,37} A more recent study comparing three different female condom brands available outside the United States with the FC2 reported a failure rate of 3.43% for the FC2, confirming its similarity in effectiveness to the FC1.³⁸ The female condom is an effective barrier to sexually transmitted bacteria and viruses and is similar in efficacy to latex male condoms in decreasing the risk of STIs.²²

Table 10–7 provides instructions for proper use of the female condom.³⁶ Skills in correct insertion of the female condom improve with practice and continued use.³⁹ The condom may be inserted up to 2 hours before intercourse, but it is effective immediately on insertion.³⁶ Fresh condoms can be stored at room temperature in their unopened packages. Before inserting the female condom, the woman should ensure that the product is within its expiration date.

Table 10–7 Usage Guidelines for Female Condoms

- Remove the condom from the package. One end of the condom is closed to form a pouch, as shown in drawing A.
- Gently rub the sides together to evenly distribute the lubricant inside the pouch. If needed,

add additional lubrication at this point.

- Add a drop of lubricant on the outside of the pouch to improve the ease of insertion if needed. Oil- or water-based lubricants can be used with this condom.

To place the pouch properly, grasp the inner ring between the thumb and middle finger of one hand. Place the index finger on the sheath between the other two fingers. (See drawing B.)

- Be careful that jewelry or sharp fingernails do not tear the condom.
- Squeeze the inner ring, and with your other hand, spread the lips of the vagina. Then insert the squeezed condom into the vagina as far as possible. (See drawing C.)
- Be sure that the inner ring is placed beyond the pubic (pelvic) bone, that the pouch is not twisted, and that the outer ring is outside the vagina, as shown in drawing D.
- During intercourse, make sure that the penis enters the vagina inside the pouch and that the outer ring remains outside the vagina.
- If desired, add more lubricant during intercourse, without removing the condom.
- Until the couple is comfortable using the female condom, it is recommended that the penis be inserted by hand into the vagina.
- If the female condom is slipping out of the vagina during intercourse or if the outer ring is going into the vagina, stop intercourse. Remove the female condom and insert a new condom.

Remove the pouch before standing by twisting the outer ring and pulling gently. (See drawing E.)

- Discard the used condom in a trash can, not a toilet.
- Insert a new condom for each act of intercourse.
- Do not use a male condom with the female condom. The increased friction could cause displacement of the female condom.

Source: Reference 36.

The most common complaints about the female condom are vaginal irritation and increased noise (“squeaking”). Additional lubrication may resolve those problems. Some women may experience decreased sensation or even discomfort, which is caused by the outer ring during intercourse.

The female condom provides a method for women to protect themselves against pregnancy. Compared with vaginal spermicides, the female condom can be inserted much earlier before intercourse and is less messy to use.

However, some women may find the female condom cumbersome and unattractive. The female condom should not be used together with the male condom. Use of both products together may cause friction, thereby increasing the risk of breakage for either product.³⁶

Vaginal Spermicides

Vaginal spermicides use surface-active agents to immobilize and kill sperm. With gels and foams, the spermicide vehicle also acts as a physical barrier against sperm. The effective spermicides include nonoxynol-9, octoxynol-9, and menfegol, but in the United States, all products contain nonoxynol-9 (Table 10–8). Vaginal spermicide products differ in their application method, onset, and duration of action (Table 10–9). The price range of vaginal spermicides ranges is \$0.71–\$1.44 per dose.²³

Table 10–8 Selected Nonprescription Vaginal Spermicides Containing Nonoxynol-9	
Product Type	Trade Name
Spermicidal foams	VCF Vaginal Contraceptive Foam 12.5%
Spermicidal gels/jellies	Options Conceptrol Gel 4%, 100 mg VCF Vaginal Contraceptive Gel 4% Options Cynol II Extra Strength Vaginal Contraceptive Gel 3%, 150 mg
Spermicidal suppositories	Encare Vaginal Contraceptive Inserts 100 mg
Spermicidal film	VCF Vaginal Contraceptive Film 28%
Spermicidal sponge	Today Contraceptive Sponge 1000 mg

Vaginal gels (“jellies”) provide additional lubrication and are safe to use with latex condoms. For convenience, applicators may be prefilled before use. Prefilled unit-dose applicators are also available for some products. Vaginal foams distribute more evenly and adhere better to the cervical area and vaginal walls but provide less lubrication than jellies. A new canister should always be available, because it is difficult to determine when the canister is

nearly empty.

Vaginal suppositories are solid or semisolid dosage forms that are activated by moisture in the vaginal tract. Incomplete dissolution of the suppository may result in an unpleasant, gritty sensation. Although vaginal suppositories do not require refrigeration, in warmer climates, refrigeration may be desirable to prevent softening.

Vaginal contraceptive film contains nonoxynol-9 in paper-thin, 2-inch-square sheets. The film is activated by vaginal secretions. One film is used for each act of intercourse. The practice of inserting the film by placing it over the penis should be avoided, because this method does not ensure proper placement and does not allow adequate time for dissolution. In one comparison of spermicide formulations, the film was rated the most difficult to use but the least messy.⁴⁰ Similarly designed vaginal films for cleansing or lubrication do not contain spermicide and should not be used for contraception. Patients should be advised to verify that they are using the correct vaginal film product if they desire contraception.

Spermicides used alone carry a relatively high rate of typical usage-related failure among first-year users ([Table 10–2](#)). A review of clinical trials found similar pregnancy rates for products containing 100–150 mg nonoxynol-9 per dose.⁴¹ A gel containing 52.5 mg nonoxynol-9 per dose, which is not available in the United States, was significantly less effective at preventing pregnancy than the higher-dose formulations.⁴¹ Efficacy improves greatly if spermicides are used with barrier methods such as diaphragms, cervical caps, or condoms.

Although nonoxynol-9 can inactivate many sexually transmitted pathogens in vitro, clinical studies do not support a protective effect of vaginal spermicides against STI transmission.^{21,42} Higher rates of genital lesions, especially in frequent users, have been reported, raising concerns about an increased risk for STI transmission.^{21,42} In 2007, FDA ruled that vaginal spermicide products must carry a label stating that the product does not protect against HIV and other STIs.⁴² In persons with known risk factors for STIs, spermicides should be recommended only in conjunction with condom use.

[Table 10–9](#) provides guidelines for the proper administration of vaginal spermicides.^{21,43,44} With use of any vaginal spermicide, a woman should delay douching for at least 6 hours after intercourse. Although allergic reactions are rare, either partner may experience such reactions to spermicides. Couples

engaging in oral–genital sex may find the taste of some products unpleasant. Frequent use or use of high-concentration products may lead to irritation of or damage to vaginal and cervical epithelium,⁴² which may be associated with an increased risk for STIs. Despite initial concerns about a possible association between spermicide use and birth defects or miscarriage should an unintended pregnancy occur, current data do not support an increased risk of either attributable to spermicides.⁴⁵

Table 10–9 Administration Guidelines for Vaginal Spermicides

Dosage Form	Application Method	Onset/Duration of Action	Application Time Before Intercourse	Reapplication Requirements
Vaginal gel alone	Insert full dose near cervix.	Immediate/1 hour after application	Up to 1 hour	Reapply for each coital act.
Vaginal gel used with diaphragm/ cervical cap	Fill barrier device one-third full with gel and place it near cervix. Leave barrier in place for at least 6 hours after intercourse.	Immediate/ <i>diaphragm</i> : 6 hours; <i>cervical cap</i> : 48 hours	Up to 1 hour	<i>Diaphragm</i> : for each coital act that occurs within 6 hours of initial insertion of device, reapply spermicide without removing device; for coitus after 6 hours of initial insertion, remove and wash device, fill with new spermicide, and re-insert device.
				<i>Cervical cap</i> : remove and wash device; then reapply spermicide for each coital act that occurs 48 hours after initial insertion of device.
Vaginal foam	Insert full dose near cervix.	Immediate/1 hour	Up to 1 hour	Reapply for each coital act.
Vaginal suppository	Insert suppository	10–15 minutes/1 hour	10–15 minutes	Reapply for each coital act.

Dosage Form	Application Method	Onset/Duration of Action	Application Time Before Intercourse	Reapplication Requirements
	near cervix.			
Vaginal contraceptive film	Drape film over fingertip; place film near cervix.	15 minutes/3 hours	15 minutes	Reapply for each coital act. Insert at least 15 minutes but not more than 3 hours before intercourse. If 3 hours have elapsed from the time of insertion before intercourse, insert a new film.
Vaginal contraceptive sponge	Moisten with tap water; insert convex side against cervix.	Immediate/24 hours	Can be inserted up to 24 hours before intercourse.	Leave in for >6 hours after intercourse, but no longer than 30 hours total; use polyester loop to facilitate removal.

Source: References 21, 43, and 44.

The relatively low effectiveness rate for spermicides when used alone is their major disadvantage. Studies suggest, however, that simultaneous use of condoms and spermicides provides higher effectiveness rates than those for spermicides alone.¹⁷ Their ready availability and ease of use make spermicides a good choice for women who need a backup method. Spermicides are not recommended for women with vaginal anatomic abnormalities that would prevent the proper placement of the spermicide near the cervical opening. Product selection can be based on patient preference and specific product characteristics.

Contraceptive Sponge

The contraceptive sponge marketed as the Today Sponge is a small, circular,

disposable sponge made of polyurethane permeated with the spermicide nonoxynol-9. The sponge is believed to act as a contraceptive by serving as a mechanical barrier, providing a spermicide, and absorbing semen. The price range of contraceptive sponges is \$5–\$8 per sponge.²⁴

In two large trials, the failure rate for the contraceptive sponge ranged from 17.4 to 24.5 pregnancies per 100 women in the first year of use.⁴⁶ Women who had given birth previously (parous women) had a significantly higher pregnancy rate while using the sponge compared with women who had never given birth (nulliparous women). That finding may be related to poor fit in women who have delivered vaginally. If the sponge becomes dislodged during intercourse, its efficacy may be decreased.

The contraceptive sponge does not protect against STIs. One study found an increased risk of HIV infection in women with frequent sponge use, possibly because of an increased incidence of vaginal ulceration from the spermicide.²³

A woman must be able to locate her cervix with a reasonable degree of comfort and competence for correct placement of the sponge. **Table 10–9** provides instructions for proper use. The sponge has a loop attached to the convex side to facilitate its retrieval. Some women have difficulty removing the sponge, and it has been known to fragment on removal. The sponge may be inserted up to 24 hours before intercourse but must remain in place for 6 hours after intercourse. The sponge should be stored in its unopened package in a cool place and used before its expiration date.

Some adverse effects, such as vaginal dryness, have been reported with use of the contraceptive sponge. A well-recognized association is the development of toxic shock syndrome (TSS), although the incidence is low.²² Women should take special care to wash their hands before inserting the sponge. The sponge should not be used during menstruation or in the first 6 weeks after giving birth. Use should not exceed the maximum recommended retention time of 30 hours. Women also should be advised to make sure the entire sponge is removed, because fragments left in the vagina may serve as a source for infection.

The contraceptive sponge is convenient, safe, and portable. Contraindications to its use include spermicide sensitivity, anatomic abnormalities of the vagina, and a history of TSS. The contraceptive sponge should not be routinely recommended to parous women, because possible problems with adequate

cervical coverage may lead to increased risk of pregnancy.

Emergency Contraception

Emergency contraception (EC) involves the use of hormones in the form of oral tablets or a nonhormonal copper intrauterine contraceptive (IUC) to prevent pregnancy as soon as possible after unprotected intercourse and up to 3–5 days after unprotected sexual intercourse based on product labeling and current practice.⁴⁷ Hormones used in EC products may include progestin (synthetic progesterone) as a single agent, estrogen in combination with a progestin, or a selective progesterone receptor modulator. The progestin commonly found in the EC formulations is levonorgestrel. Nonprescription and prescription oral tablet formulations are available. This section focuses on nonprescription progestin-only products.

EC products should be recommended for girls and women of reproductive age who have had recent unprotected intercourse, who experienced method failure such as condom breakage, or who desire advance provision in the event of a need for EC.^{17,47} Some women may be seeking EC in the case of sexual assault. In addition to providing EC for immediate use, pharmacy staff should refer the patient to primary care providers who can evaluate her for STIs and report the incident to the authorities as required by state law.

EC products reduce the expected number of pregnancies by 52%–100% for levonorgestrel users.⁴⁷ The efficacy of EC is primarily due to the suppression of ovulation. Other possible mechanisms of action are those involving interference with transport of sperm or egg, including thickening of cervical mucus.^{16,47} Over-the-counter EC products will not affect an implanted embryo or increase the risk of malformations in the event of pregnancy.⁴⁷

Current nonprescription options that include levonorgestrel-containing tablets, available as single-tablet formulations in the generic branded products are Aftera, EContra EZ, My Way, New Day, Opcicon One-Step, Plan B One-Step, Preventeza, React, and Take Action.⁴⁷ Progestin-only products cost between \$40 and \$50 for single-incident use.²⁴ Nonprescription products each contain 1 tablet of levonorgestrel 1.5 mg labeled to be taken as a single dose within 72 hours after unprotected intercourse or contraceptive failure. Studies have shown effectiveness up to 120 hours after intercourse, although efficacy declines with more time after coitus.⁴⁷ Therefore, women presenting for EC within 120 hours of unprotected sex could be offered nonprescription EC

products or referred to their primary care provider for ulipristal acetate or insertion of the copper IUC. Body weight may influence the effectiveness of the levonorgestrel, which may not be as effective in patients with a body mass index (BMI) of 26 kg/m² or greater.⁴⁷ Alternative EC products available by prescription also may be an option ([Table 10–10](#)).⁴⁷

Table 10–10 Prescription Emergency Contraceptives Available			
Product Name	Dosage	Timing for Use	BMI and Effectiveness
Ulipristal acetate (ella)	30 mg	Within 120 hours post coitus	May start to lose effectiveness at BMI of 30, may become ineffective at BMI of 35; should not be with-held from patient on the basis of her BMI
Copper IUC (ParaGard T380A)	n/a	Off-label use; within 120 hours post coitus	No issue with BMI
Estrogen and progestin (combined regimen)	Varies: Ethinyl estradiol 100–120 mcg and levonorgestrel 0.5–0.6 mg (amount per dose; take 2 doses separated by 12 hours)	Off-label use; within 72 hours, although studies suggest up to 120 hours post coitus	No information

Key: BMI = Body mass index; IUC = intrauterine contraceptive; n/a = not applicable.

Source: [Reference 47](#).

The most common adverse effects reported with oral EC use are nausea and vomiting.^{16,47} Nausea occurs in approximately 25% of women using progestin-only products. Vomiting occurs in approximately 5% of progestin-only EC users. An antiemetic usually is not necessary for progestin-only EC but may be recommended 60 minutes before each dose with use of combination oral contraceptive regimens.^{16,47} If the patient vomits within 1–2 hours after taking the dose, she should repeat the dose.^{16,47} Headaches, breast tenderness,

menstrual changes, and dizziness also have been reported by users.⁴⁷ **Table 10–11** provides patient counseling points and information about levonorgestrel EC products.

Table 10–11 Counseling Points for Emergency Contraception (Levonorgestrel)

- Identify whether patient has had recent unprotected sex within the past 120 hours or is at risk for unprotected sex and does not want to get pregnant.
- Identify whether patient is an appropriate candidate for EC using nonprescription products.
- Explain how to take EC products: Aftera, EContra EZ, My Way, New Day, Opcon One-Step, Plan B One-Step, Preveneza, React, or Take Action is given as a single dose and should be taken as soon as possible. EC is most effective when the product is taken as soon as possible after unprotected intercourse. The method is effective when the product is taken up to 120 hours after unprotected intercourse, although package labeling states within 72 hours.
- Recommend an antiemetic for women using combination oral contraceptives for EC.
- If the woman has a BMI of 26 or greater, explain that the effectiveness of the nonprescription EC products may be reduced, but do not withhold product. Alternative options could include a prescription for ulipristal or referral to a primary care provider for insertion of the copper IUC.
- Discuss adverse effects of EC, which may include a change in menstrual cycle depending on when the product is used. Patients may have their next menstrual period early or late or experience no change. If menstruation has not occurred more than 21 days after use of an EC product, the patient should take a pregnancy test.
- Emphasize that EC is not to be used as a regular contraceptive method.
- Recommend that a sexually active woman begin using regular contraception after taking an EC product. Barrier methods should be used with each subsequent act of intercourse during rest of the current menstrual cycle. Hormonal contraceptive methods may be started with the next menses or may be started the day after levonorgestrel EC, with 7 days of a backup contraceptive method.
- Explain that EC products do not protect against STIs.
- Explain that EC is not 100% effective. Recommend using a pregnancy test if the menstrual period is more than 21 days late.
- Recommend a longer-term method of contraception if patient is using EC multiple times a month. Although such frequent usage of EC is safe, these products are not intended to be used in this way. A longer-term contraceptive method will provide better protection against pregnancy.
- Provide written instructions.

Key: BMI = Body mass index; EC = emergency contraception; IUC = intrauterine contraceptive; STI = sexually transmitted infection.

Source: References 16 and 47.

Patients presenting with pregnancy concerns between 5 and 7 days after unprotected intercourse should be referred to a primary care provider for possible insertion of a copper IUC.¹⁶ Although a copper IUC usually is placed up to 5 days after unprotected intercourse, the device can be inserted up to 8 days after intercourse if ovulation is known to have occurred more than 72 hours after intercourse.¹⁵ Therefore, if intercourse occurred 3 days before ovulation, the patient could potentially still have an IUC placed up to 5 days after ovulation, although in practice it is usually placed up to 5 days after unprotected intercourse.¹⁶

Fertility Awareness–Based Methods

Contraceptive methods that do not use a chemical or a barrier to prevent conception include calendar methods, cervical mucus methods, the symptothermal method, and the lactational amenorrhea method (LAM). *These fertility awareness–based (FAB) methods* use various techniques to determine a woman's fertile phase of the menstrual cycle, during which time intercourse should be avoided or another method of contraception used. Such techniques are typically chosen because they pose no health risks to the couple or to the fetus should pregnancy occur, or because of their lower cost or for religious reasons. In some cases, FAB methods are used by default because of a lack of access to or knowledge of other methods of contraception. Disadvantages of FAB methods include lack of STI protection, lower efficacy than for most other contraceptive methods, and the need for periods of abstinence or the use of another method of contraception, such as condoms, during fertile days.¹⁷

Calendar Methods

Calendar methods use a woman's monthly menstrual cycle length to calculate the fertile period. These methods factor in the viabilities of ovum (up to 24 hours) and sperm (3–5 days).¹⁸ Menstrual cycles may vary, so cycle lengths should be recorded for 6–12 cycles to predict the likely range of fertile days. The *calendar rhythm method* calculates the first fertile day in a woman's menstrual cycle by subtracting 18 from the number of days in her shortest cycle. The last fertile day is calculated by subtracting 11 from the number of days in her longest cycle. Women who have irregular cycles are not optimal candidates for this method, as an overestimation of unsafe fertile days could

occur.¹⁸ The *Standard Days Method* is a calendar method recommended only for women with cycles between 26 and 32 days in length. With the first day of menstruation counted as day 1, a woman should avoid intercourse on days 8–19 of her menstrual cycle or use another method of contraception, such as condoms, during this time.¹⁹

Cervical Mucus Methods

Cervical mucus methods rely on detection of changes in cervical secretions that take place during a normal menstrual cycle.¹⁹ Patients should be encouraged to work with trained instructors to ensure proper interpretation of mucus, as well as to avoid intercourse during the first cycle. Discussed next are two examples of such cervical mucus methods: the Billings Ovulation Method and the TwoDay Method.

With the *Billings Ovulation Method*, the woman observes the cervical mucus on a daily basis and charts its character and quantity. After menstruation, most women notice a sensation of vaginal dryness. Approximately 5–6 days before ovulation, estrogen levels rise, causing the cervical mucus to increase in quantity and elasticity and to become clear, resembling raw egg white. The peak symptom, correlated with the last day of detection of the clear, stretchy, estrogenic mucus, has been shown to occur within a day of ovulation for most women. With the postovulatory rise in progesterone, the mucus becomes thick and sticky or is absent. The woman is considered fertile from the first day after menstruation on which mucus is detected until 4 days after appearance of the peak symptom, during which time intercourse should be avoided.¹⁹ With experience and assistance, a woman learns to differentiate other vaginal secretions, such as seminal fluid after intercourse or an infectious discharge, from normal mucus, enabling her to seek early treatment for an infection. Patients should be informed that vaginal foams, gels, creams, and douches will interfere with cervical mucus.

Another method of monitoring cervical secretions is called the *TwoDay Method*.¹⁷ The woman should monitor for secretions on a daily basis, and if she notes any secretions that day or the day before, she is likely to be fertile. If she does not note any secretions, she is unlikely to be fertile. The TwoDay Method is a simple method that does not require keeping records or logs. However, patient education in identifying cervical secretions correctly is still important.¹⁸

Symptothermal Method

The symptothermal method combines cervical mucus tracking with basal body temperature (BBT) monitoring.¹⁹ Observation of the cervical mucus is used to identify the *onset* of the fertile period, whereas BBT charting is used to identify the *end* of the fertile period.¹⁶ Monitoring of BBT also can be used to predict ovulation for intended conception (see [Chapter 48](#)).

To monitor BBT, the woman charts her body temperature every morning, preferably with a digital thermometer calibrated in increments of 0.1°F (0.05°C), to detect small changes in body temperature.¹⁸ The temperature reading must be obtained at the same time every day, before getting out of bed, and is recorded on a chart or in an application for a smart phone ([Figure 10–2](#)). At least 3 hours of uninterrupted sleep are required for a reliable reading. The temperature may be taken orally, vaginally, or rectally, but the same site must be used each day.

Figure 10–2 Symptothermal variations during a model menstrual cycle.

(Source: Reprinted with permission from Jennings VH, Arevalo M, Kowal D. Fertility awareness–based methods. In: Hatcher RA, Trussell J, Stewart F, et al., eds. *Contraceptive Technology*. 18th rev ed. New York, NY: Ardent Media; 2004:327.)

In some women, the onset of ovulation may be detected by a drop in BBT 12–24 hours before ovulation. At the time of ovulation, BBT rises by at least 0.4°F (0.2°C) above the lowest point (the nadir).¹⁸ The postovulatory infertile time is typically identified once there have been at least 3–4 consecutive days of sustained elevated temperatures.¹⁸ Some women do not exhibit a definite or significant temperature dip or rise with ovulation. Stress, inadequate sleep, travel, fever, lactation, or perimenopause may affect BBT.¹⁸ For women who work rotating shifts, an accurate record of BBT may be difficult to maintain. At such times, couples should use an alternative method of contraception.

The Natural Cycles app for smartphones was approved by FDA in 2018 for use as a contraceptive strategy.⁴⁸ It is indicated for women 18 years and older who are premenopausal. For this method, daily BBT measurements are entered into the app, which also tracks the user's menstrual cycle. A proprietary

algorithm is employed to identify fertile and nonfertile days; the message “use protection” is displayed to signify the need for a contraceptive such as a condom or for abstinence during this period.⁴⁸ The app also can use data from urine luteinizing hormone (LH) test kits to improve the detection of ovulation, although this is not required for effectiveness. The Natural Cycles app is most appropriate for women with regular menstrual cycles, between 21 and 35 days in length, and is not meant for use with hormonal contraceptives or during breastfeeding, because ovulation is suppressed at that time.⁴⁸

Home Tests for Ovulation Prediction

Ovulation prediction tests are designed to aid couples in conceiving by detecting the surge in luteinizing hormone that occurs shortly before ovulation (see [Chapter 48](#)). These kits detect an increase in urinary excretion of the hormone, which usually occurs 8–40 hours before actual ovulation. These ovulation predictors do not give warning of impending ovulation with enough accuracy to be effective contraceptive agents and are not recommended for use other than as an aid for couples desiring pregnancy.¹⁸

Lactational Amenorrhea Method

In many developing countries, LAM is used as a contraceptive method for spacing the birth of children. When an infant younger than 6 months of age receives at least 90% of his or her nutrition from breastfeeding, and the mother is amenorrheic, LAM offers more than 98% protection against pregnancy.^{16,19} Because the suckling action of the infant on the breast at frequent intervals is necessary for LAM to be effective, milk extraction through a breast pump does not offer the same protection against pregnancy.¹⁹ Although menstrual periods in lactating women may be anovulatory, ovulation may occur before the return of menses. In general, if a breastfeeding woman is having menstrual periods, is supplementing her infant’s diet, or gave birth more than 6 months earlier, she should use an additional method of contraception.^{16,19} Among breastfeeding women whose infants receive almost all of their nutrition from breast milk, without supplementation, studies have reported pregnancy rates of 0.5%–2% for the 6-month period after giving birth. Once supplemental feedings begin, the efficacy rate decreases significantly.¹⁹

Effectiveness of Fertility Awareness–Based Methods

Overall, the pregnancy rate for typical use of FAB methods is approximately

15% (**Table 10–2**).¹⁷ In comparison with condoms, hormonal methods, or the nonhormonal IUC, the risk of pregnancy is higher with many of the FAB methods when used alone. Consequently, family planning professionals do not recommend relying on a single method; instead, they suggest using a combination of methods. FAB methods that specifically identify preovulatory and postovulatory changes, such as the symptothermal method, have better outcomes; with perfect use, the annual failure rate for the symptothermal method is less than 1%.¹⁷ The manufacturer information for the Natural Cycles app shows a “perfect use” failure rate of 1% and “typical use” failure rate of 7%–8%.^{17,48}

FAB methods also do not provide any protection against STIs and should be recommended solely for couples in mutually monogamous relationships.

Coitus Interruptus

For coitus interruptus (the withdrawal method), coital activity continues until ejaculation is imminent; then the penis is immediately withdrawn to allow ejaculation to occur away from the vagina or vulva. Method failures—that is, occurrence of pregnancy even when the method is used correctly and consistently—result in part because involuntary pre-ejaculation secretions may contain millions of sperm. Disadvantages of this method include the requirement for considerable self-control by the man, the potential for diminished pleasure for the couple related to interrupted lovemaking, and absence of STI protection. This method has failure rates of 4% with perfect use and 20% with typical use, comparable with those of barrier methods.⁴⁹

Algorithm: Unintended Pregnancy and STIs

Figure 10–1 Prevention of unintended pregnancy and sexually transmitted infections. Key: OTC = Over-the-counter; Rx = prescription; STI = sexually transmitted infection.

Assessment of Prevention of Pregnancy and

STIs: A Case-Based Approach

Before advising a couple on contraception and STI prevention, the health care provider must first identify their level of knowledge about these issues, because an understanding of their risk of pregnancy and STIs is essential to select an appropriate product or method. Persons who prefer FAB methods require basic knowledge of the reproductive cycle before they can use these methods effectively. Those who prefer nonprescription contraceptive products must know how to use them properly and be prepared to use them with every act of intercourse. The health care provider should identify individual preferences for products or methods on the basis of the timing of use or religious or cultural practices.

Case 10–1 illustrates the assessment of a man who is seeking advice on symptoms of a STI, whereas Case 10–2 deals with the use of EC.

Patient Counseling for Prevention of Pregnancy and STIs

Pharmacists are in a unique position to lower the incidence and consequences of unintended pregnancy and STIs in their communities. Many patient–provider interactions present opportunities for discussion of specific diseases or prevention strategies with persons who may be at high risk for unintended pregnancy and STIs. If possible, consultation involving both partners can improve their understanding and acceptance of selected contraceptive methods.

Health care providers must be familiar with the proper use of available nonprescription contraceptive products. Educational materials should be easily accessible by the patient, and opportunities for consultation should be maximized by removing potential barriers to open conversations (e.g., a noisy or overly structured physical environment that hinders personal encounters; a lack of personnel with second language skills as needed for effective provider–patient interactions). Pharmacists in some states may now provide hormonal contraception without a prescription, as summarized in the box “A Word About Provision of Hormonal Contraception by Pharmacists.”⁵⁰

In addition to an educational role, the health care provider may serve as a resource for access as needed to other medical and social supportive services. In cases of suspected domestic violence, child abuse, or sexual abuse, pharmacists often are designated mandatory reporters as specified by state law. Availability of a private area for education and counseling is important if adequate discussion is to take place.

Special efforts should be made to offer contraceptive information and services to adolescents. Health care providers who are uncomfortable discussing reproductive health in a nonjudgmental manner with young people should refer adolescents to a clinic that specializes in services for this age group. Adolescents need clear, accurate information on all aspects of reproductive health. An important consideration is that misconceptions about STIs and pregnancy risk as well as proper contraceptive use are common, especially among adolescents, so adequate education is very important. FAB methods are recommended for couples in a stable relationship. These methods, especially the symptothermal and cervical mucus methods, require extensive coaching and support from health care professionals who have experience with FAB methods. In addition to stocking spermicidal products, BBT thermometers, and monitoring charts, the pharmacist may serve as an educational resource for persons who want to use these methods of family planning. A pharmacist with the proper training might consider counseling patients on FAB methods as a unique practice possibility.

Case 10–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and	

Relevant Evaluation Criteria	Scenario/Model Outcome
medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient is asking for a recommendation for genital soreness and irritation. Patient states he has been experiencing some penile discharge and has had genital pain and irritation for 10 days. He states it started 2 days after having intercourse with his new girlfriend about 2 weeks ago. He states he thinks he has an allergy to the spermicide they were using instead of condoms. They recently had intercourse again, for which they did not use either a condom or the spermicide, but the discharge and pain are still present.
b. Patient's identity	Mark Stanton
c. Patient's age, gender, height, and weight	24 years, male, 5 ft 11 in., 160 lb
d. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None; history of multiple sexual partners
e. Allergies	NKA
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Patient describes genital irritation with a discharge present. There is an increased risk for STI due to unprotected intercourse. An allergy to a spermicide does not usually result in a discharge, so a medical evaluation is needed. The patient also stated that they did not use spermicide again, but that he still has the irritation and discharge.

Relevant Evaluation Criteria	Scenario/Model Outcome
3. Identify exclusions for self-treatment.	The symptoms of genital discharge, pain, and irritation exclude the patient as a candidate for self-care. The symptoms could be caused by an STI, which will necessitate a primary care provider referral for testing and treatment.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend STI screening, evaluation, and treatment by a primary care provider. For future intercourse, recommend use of a male condom (Tables 10–4 through 10–6) with or without an additional spermicide to provide STI protection as well as contraception. The use of spermicide (Tables 10–8 and 10–9), however, has not been shown to improve protection against STIs. (2) Recommend STI screening, evaluation, and treatment by a primary care provider. For future intercourse, recommend use of a female condom (Table 10–7) to provide STI protection as well as contraception. (3) Recommend avoiding spermicidal products to see if irritation improves. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Stanton agrees to see his primary care provider to rule out an STI. He prefers to use a nonspermicidal male condom with additional spermicide to provide contraception and STI protection for future acts of sexual intercourse (if no allergy is determined).
6. Describe the recommended therapeutic	"Make an appointment to see your primary care provider as soon as possible to get testing for an STI. Your primary care provider will be able to determine the cause of your symptoms and treat you appropriately. If it is

Relevant Evaluation Criteria	Scenario/Model Outcome
approach to the patient or caregiver.	determined that you have an STI, inform all of your recent sexual partners so that they can be screened as well. For future prevention of an STI, use a nonspermicidal male condom plus additional spermicide (if it is determined that you do not have an allergy to spermicides) for each act of sexual intercourse.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Genital irritation and discharge, especially appearing after unprotected intercourse, could be signs of an STI. Discharge is not usually a symptom of irritation from a spermicide, so you need to get a proper evaluation. If testing shows you have an STI, you will need medical treatment. You also will need to let any sexual partners know about your STI so that they can be evaluated and treated if necessary. Delaying evaluation by a primary care provider could result in worsening of the infection and also may put your sexual partners at risk. Your health depends on awareness of the need to prevent STIs. Of the various OTC methods of contraception, such as condoms, sponges, and spermicide, only the male or female condom provides protection from STIs. So issues of STI prevention, in addition to contraception, are major considerations in beginning a sexual relationship.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	“Use a fresh male condom and spermicide application (if it does not cause irritation for you or your partner) with each act of sexual intercourse.”
b. Product administration	See Tables 10–5 to 10–7 , and 10–9 .

Relevant Evaluation Criteria	Scenario/Model Outcome
procedures	
c. Expected time to onset of effect	"Once they are correctly placed, male condoms are effective immediately."
d. Degree of effectiveness that can be reasonably expected	See Table 10–2 for efficacy rates.
e. Most common adverse effects	"Irritation to the penis or vagina from exposure to latex or spermicide can occur. Some people have a sensitivity reaction to nonoxynol-9, the only spermicide currently available. The condom can also break or slip, allowing exposure to sperm and infection. Some men report reduced sensitivity and pleasure when using condoms."
f. Patient options in the event that condition worsens or persists	"Consult your primary care provider."
g. Product storage requirements	See Tables 10–5 and 10–7 .
Solicit follow-up questions from the patient or caregiver.	"Can I use lubricants with the condom?"
Answer the patient's or caregiver's questions.	"Yes, but the condom can be used with only certain lubricants that are water-based. Oil-based lubricants can damage the condom and should be avoided." (See Table 10–6 .)
Follow-up: Monitor and	

Relevant Evaluation Criteria	Scenario/Model Outcome
Evaluate	
9. Assess patient outcome.	Encourage Mr. Stanton to call the pharmacy if he has further questions.

Key: NKA = No known allergies; OTC = over-the-counter; STI = sexually transmitted infection.

Case 10–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient had unprotected intercourse with her spouse 2 days ago. She is concerned that she may become pregnant again, and she has a 10-week-old baby.

Relevant Evaluation Criteria	Scenario/Model Outcome
b. Patient's identity	Jenny Aronson
c. Patient's age, gender, height, and weight	27 years, female, 5 ft 2 in., 135 lb
d. Patient's occupation	College student
e. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	The patient gave birth 10 weeks ago. She is breastfeeding her infant and also using some formula supplementation.
	Occasional tension headaches: ibuprofen 200 mg 2 tablets orally every 8 hours as needed. Multivitamin 1 tablet daily; fluticasone (Flonase) nasal spray, 1 spray in each nostril daily as needed for seasonal allergies.
f. Allergies	Seasonal, NKDA
g. History of other adverse effects to medications	None
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Mrs. Aronson has an elevated risk of pregnancy due to unprotected intercourse.

Relevant Evaluation Criteria	Scenario/Model Outcome
3. Identify exclusions for self-treatment.	None. The patient's consultation is within therapeutic window of 120 hours after unprotected intercourse for OTC EC use.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend use of OTC levonorgestrel EC, because it is compatible with breastfeeding and she is within the window of 120 hours since unprotected intercourse occurred. Refer Mrs. Aronson to her primary care provider if her pregnancy test is positive. Recommend that she confirm her multivitamin has 400 mcg of folic acid to prevent neural tube defects in case she is pregnant. (2) Recommend against the use of OTC levonorgestrel EC, and refer Mrs. Aronson to her primary care provider for a prescription EC method and to discuss EC options while breastfeeding, such as ulipristal acetate or levonorgestrel. Recommend that Mrs. Aronson see her primary care provider if applicable for pregnancy testing and prenatal care. Also, if she is not pregnant, recommend that she seek a longer-term prescription contraceptive method, or recommend that she seek a self-administered hormonal contraceptive from a pharmacist if that is allowed in her state. Recommend that she confirm her multivitamin has 400 mcg of folic acid to prevent neural tube defects in case she is pregnant or becomes pregnant in the future. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient	Mrs. Aronson prefers to purchase an OTC EC product at this time. Recommend that she see her primary care provider to have pregnancy screening and for prenatal care, if applicable.

Relevant Evaluation Criteria	Scenario/Model Outcome
preferences.	
6. Describe the recommended therapeutic approach to the patient or caregiver.	“You should use the nonprescription EC products because you are within the window of time that the product is effective in preventing pregnancy.” (See Table 10–10.)
	“If you are concerned about pregnancy, you could use the pregnancy test at home. Use the test first thing in the morning when you urinate. If the test is positive as indicated in the package information, see your primary care provider promptly. Keep in mind that home pregnancy tests may show false negatives early in the pregnancy, and seeing your primary care provider is the best way to determine whether you are pregnant. Your primary care provider also can provide prenatal care or a long-term contraceptive product if needed. Check your multivitamin to make sure it has 400 mcg of folic acid to help prevent neural tube defects in the event you are pregnant or become pregnant in the future.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Nonprescription EC is 52%–100% effective in preventing pregnancy and works best the sooner it is taken. The nonprescription EC product (levonorgestrel product) should be taken as soon as possible within 120 hours of unprotected intercourse and is compatible with breastfeeding. EC is most effective the sooner you take it after unprotected intercourse. Seeing your primary care provider for a prescription will delay time of administration and will may decrease effectiveness. In addition, a breastfeeding woman who takes ulipristal acetate must wait 24 hours after taking the product before resuming breastfeeding. It is not intended to be used during pregnancy. If you are pregnant, it is important to see your primary care provider for prenatal care to ensure the best outcome for you and your child. Continue to take your multivitamin, and check to see that it has 400 mcg of folic acid.”
Implement	
8. When recommending self-care with nonprescription medications and/or	(1) “The levonorgestrel EC product is given as a single dose and should be taken as soon as possible after unprotected intercourse. It is compatible with breastfeeding. It is not 100% effective but most effective when taken as soon as possible after unprotected intercourse. The method is effective when taken within 120 hours (per package labeling, within 72 hours).” (See Table 10–11 for EC counseling points.)(2) “Adverse effects of EC may include

Relevant Evaluation Criteria	Scenario/Model Outcome
nondrug therapy, convey accurate information to the patient or caregiver.	a change in menstrual cycle, depending on when the EC product is used. Patients may have their next menstrual period early or late or experience no change. If menstruation has not occurred more than 21 days after EC, you should take a pregnancy test.”(3) “EC is as effective as a regular contraceptive method. If you are sexually active and would like to prevent pregnancy, it is recommended that you begin using regular contraception after taking an EC product. Barrier methods should be used with each subsequent act of intercourse during the rest of the current menstrual cycle. Hormonal contraceptive methods may be started with the next menstrual period or may be started the day after taking the levonorgestrel EC product, with 7 days of a backup contraceptive method.”(4) “Check your multivitamin to make sure it has 400 mcg of folic acid to help prevent neural tube defects in the event you are pregnant.”
Solicit follow-up questions from the patient or caregiver.	(1) “Can I use EC as a regular birth control method?”(2) “What can I use over-the-counter to prevent pregnancy until I get a prescription contraceptive?”
Answer the patient’s or caregiver’s questions.	(1) “EC is not intended to be a regular form of birth control. For more effective and less expensive ways of contraception, you should see your primary care provider to obtain a prescription for a more regular form of contraception if you are not pregnant. Nonprescription contraceptives such as condoms, spermicides, and the sponge may also be an option.”(2) “Male or female condoms, a contraceptive sponge, or spermicides may be used to prevent pregnancy. Use a fresh condom (female or male) with each act of sexual intercourse. If using a spermicide, make sure to use a new spermicide application with each act of sexual intercourse.” (See Tables 10-5 to 10-7 and 10-9 for directions on using these various products.)
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mrs. Aronson in a day or two to inquire if she has any questions regarding EC or needs assistance with obtaining a prescription for her usual contraceptive product.

Key: EC = Emergency contraception; NKDA = no known drug allergies; OTC = over-

the-counter; STI = sexually transmitted infection.

A Word About Provision of Hormonal Contraception by Pharmacists

Provision of hormonal contraception by a pharmacist has been shown to improve access to highly effective methods. This strategic health care approach is evolving and varies by state: Pharmacists in Washington have provided contraception through collaborative practice agreements for several decades. Oregon, California, Colorado, the District of Columbia, Hawaii, Maryland, Idaho, Utah, West Virginia, and New Mexico passed legislation allowing pharmacists to provide self-administered hormonal contraception without a prescription. Each state or district specifies which of the hormonal products, such as oral, transdermal, vaginal, and depot injectable, are available for pharmacist prescribing. As health care providers, pharmacists are involved in assessing women for potential medical contraindications to hormonal contraception before dispensing. Legislation to allow pharmacist contraceptive prescribing is being pursued in other states as well.

Evaluation of Patient Outcomes for Prevention of Pregnancy and STIs

Many sexually active persons are at risk for unintended pregnancy or STIs. The most important factor affecting the ability of a contraceptive to prevent pregnancy and STIs is correct and consistent use with each sexual encounter. Although any of the methods are effective for pregnancy prevention, use of male condoms (except for lamb cecum) or the female condom is the preferred

method for prevention of STIs. Patients who experience an adverse effect after use of a nonprescription contraceptive should switch to an alternative brand or agent. If the symptoms do not resolve or if they recur with the use of other agents, the affected person should seek medical attention. A sexually active woman who misses a menstrual period should be encouraged to perform a home pregnancy test or to seek medical attention. Symptoms of an STI in a sexually active person warrant medical referral ([Table 10-1](#)).

Key Points for Prevention of Pregnancy and STIs

- No method of contraception except abstinence is completely effective at preventing unintended pregnancy and STIs.
- The HPV vaccine is an effective method of preventing HPV infection–related consequences, including genital warts and cervical, vaginal, vulvar, penile, and anal cancers.
- Selection of a contraceptive product or method must be based on individual risk for undesired outcomes (pregnancy and STI) and efficacy, safety, and acceptability.
- Efficacy of nonprescription contraceptives is significantly increased by correct and consistent use of the product or method with each sexual encounter ([Tables 10-5](#) through 10-9).
- Male condoms (latex) and female condoms are the preferred contraceptive products for persons at recognized risk for STIs. Nonlatex condoms other than lamb cecum may be used in persons with latex hypersensitivity for STI prevention.
- Spermicides decrease risk of unintended pregnancy but may increase risk of STIs.
- Vaginal spermicides are available in different dosages and forms to improve patient acceptability.
- EC is an effective method of postcoital contraception that can

decrease the risk of unintended pregnancy, but not the risk of STIs. EC should not be used as routine contraception.

- FAB methods constitute an inexpensive, modestly effective approach to contraception that can be used by couples in a mutually monogamous relationship.

Chapter 11: Colds and Allergy

Authors: Kelly L. Scolaro

Colds

A *cold*, also known as the common cold, is a viral infection of the upper respiratory tract. According to some estimates, 1 billion cases of the common cold occur annually, making it one of the top five illnesses diagnosed in the United States.^{1,2} Adults usually have 2–3 colds per year, whereas children may experience 6 or more.² Colds may occur at any time of the year, but the incidence tends to be higher in winter months.²

Colds constitute the leading cause of work and school absenteeism. A cold is usually a self-limiting illness; however, because symptoms are bothersome, patients frequently self-medicate, with an estimated \$8 billion spent annually on nonprescription cold and cough products.³

Pathophysiology of Colds

More than 200 viruses are recognized to cause colds. A majority of colds in children and adults are due to rhinoviruses.^{1,2} Other viruses known to cause colds include coronaviruses, parainfluenza, respiratory syncytial virus, adenoviruses, and human metapneumovirus. Coinfection with bacteria (usually group A beta-hemolytic streptococci) occurs but is rare. Rhinoviruses are RNA viruses, with more than 100 serotypes. The viral infection is limited to the upper respiratory tract and primarily affects the following respiratory structures: pharynx, nasopharynx, nose, cavernous sinusoids, and paranasal sinuses. The respiratory tract's intricate host defense system usually protects the body from infectious and foreign particles. The respiratory tract, especially the nose, is well perfused by blood vessels and well innervated. The nose contains sensory, cholinergic, and sympathetic nerves. When stimulated by an infectious (e.g., a cold) or allergic (e.g., allergic rhinitis) process, those nerves play a role in the resulting symptoms and also serve as targets for some nonprescription therapies. Stimulation of sensory fibers by mechanical and thermal stimuli or by mediators such as histamine and bradykinin results in

sneezing. Cholinergic and sympathetic nerves are involved in congestion in that they innervate glands and arteries that supply the glands. Cholinergic stimulation dilates arterial blood flow, whereas sympathetic stimulation constricts arterial blood flow. The sensory, cholinergic, and sympathetic nerves also respond to a variety of neuropeptide neurotransmitters.

A cold develops after a rhinovirus (or similar virus) binds to intercellular adhesion molecule-1 receptors on respiratory epithelial cells in the nose and nasopharynx.⁴ Once inside the epithelial cells, the virus replicates, and infection spreads to other cells.⁴ Peak viral concentrations are achieved 2–4 days after initial inoculation, and viruses are present in the nasopharynx for 16–18 days.⁴ Infected cells release chemokine “distress signals,” and cytokines then activate inflammatory mediators and neurogenic reflexes. These activation processes result in recruitment of additional inflammatory mediators, vasodilation, transudation of plasma, glandular secretion, and stimulation of pain nerve fibers and sneeze and cough reflexes. Inflammatory mediators and parasympathetic nervous system reflex mechanisms cause hypersecretion of watery nasal fluid. Viral infection ends once enough neutralizing antibody (secretory immunoglobulin A [IgA] or serum IgG) leaks into the mucosa to end viral replication.

The most efficient mode of viral transmission is self-inoculation of the nasal mucosa or conjunctiva after contact with virus-laden secretions, typically present on the hands but also found on inanimate objects (e.g., doorknobs, telephones). Transmission by means of inhalation of aerosolized viral particles also is common. Increased susceptibility to colds has been linked to higher exposure rates (e.g., with increased population density in classrooms or day care centers); allergic disorders affecting the nose or pharynx; less diversity in today’s social networks, with restricted exposure to pathogens; and a weakened immune system secondary to smoking, a sedentary lifestyle, chronic (i.e., ≥ 1 month) psychological stress, or sleep deprivation (e.g., poor sleep quality or < 7 hours of sleep per night).^{2,5,6} Conflicting information has emerged about increased susceptibility related to cold environments, sudden chilling, or exposure to central heating (i.e., low humidity).⁷ Stressors such as walking outside barefoot, teething, and suffering from enlarged tonsils or adenoids have not been shown to increase susceptibility to viral upper respiratory infections.²

Clinical Presentation of Colds

A predictable sequence of clinical manifestations begins 1–3 days after infection.⁴ Sore throat is the first symptom to emerge, followed by nasal symptoms, which dominate 2–3 days later. Cough develops in 30% of patients by day 4 or 5. Physical assessment may yield the following findings: slightly red pharynx with evidence of postnasal drip, nasal obstruction, and mild to moderate tenderness to palpation of sinuses. During the first 2 days of a cold, the patient may report clear, thin, and/or watery nasal secretions. As the cold progresses, the secretions become thicker and the color may change to yellow or green with the influx of polymorphonuclear cells. This change does not indicate bacterial infection. When the cold begins to resolve, the secretions again become clear, thin, and/or watery. Low-grade fever may be present, especially in children, but colds are rarely associated with an oral temperature above 100.4°F (38°C) or rectal or tympanic temperature above 100.9°F (38.3°C). Rhinovirus cold symptoms persist for approximately 7–14 days.⁴ Signs and symptoms of a cold may be confused with those of influenza and other respiratory illnesses ([Table 11–1](#)).

Table 11–1 Differentiating Characteristics of Colds and Other Respiratory Disorders	
Illness	Signs and Symptoms
Allergic rhinitis	Watery eyes; itchy nose, eyes, or throat; repetitive sneezing; nasal congestion; watery rhinorrhea; red, irritated eyes with conjunctival injection
Asthma	Cough, dyspnea, wheezing
Bacterial throat infection	Sore throat (moderate–severe pain), fever, exudate, tender anterior cervical adenopathy
Colds	Sore throat (mild–moderate pain), nasal congestion, rhinorrhea, sneezing common; low-grade fever, chills, headache, malaise, myalgia, and cough possible
Croup	Fever, rhinitis, and pharyngitis initially, progressing to cough (may be “barking” cough), stridor, and dyspnea
Influenza	Myalgia, arthralgia, fever with oral T ≥100.4°F–102°F (38°C–38.9°C), sore throat, nonproductive cough, moderate–severe fatigue
Otitis	Ear popping, ear fullness, otalgia, otorrhea, hearing loss, dizziness

Illness	Signs and Symptoms
media	
Pneumonia or bronchitis	Chest tightness, wheezing, dyspnea, productive cough, changes in sputum color, persistent fever
Sinusitis	Tenderness over the sinuses, facial pain aggravated by Valsalva maneuver or postural changes, fever with oral T >101.5°F (38.6°C), tooth pain, halitosis, upper respiratory tract symptoms for >7 days with poor response to decongestants
West Nile virus infection	Fever, headache, fatigue, rash, swollen lymph glands, and eye pain initially, possibly progressing to gastrointestinal distress, central nervous system changes, seizures, or paralysis
Whooping cough	Initial catarrhal phase (rhinorrhea, mild cough, sneezing) of 1–2 weeks, followed by 1–6 weeks of paroxysmal coughing

Key: T = Temperature.

Most people do not experience complications from colds. However, such complications may be severe and, rarely, life-threatening. Disorders potentially resulting from colds include sinusitis, middle ear infections, bronchitis, pneumonia, and exacerbations of asthma or chronic obstructive pulmonary disease.

Treatment of Colds

Treatment Goals

Because there is no known cure for colds, the goal of therapy is to reduce bothersome symptoms while preventing transmission of cold viruses to other persons.

General Treatment Approach

Antibiotics are ineffective against viral infections, and the mainstay of

treatment is nonpharmacologic therapy. If the patient desires to self-treat, a stepwise approach using single-entity products targeting specific symptoms is preferred over the use of combination products (Figure 11-1), because symptoms appear, peak, and resolve at different times.⁴ Patient education regarding the administration of intranasal drugs (Table 11-2) and ophthalmic preparations (see Chapter 28) is an important component of management. Not all patients should self-treat for a cold (see the exclusions for self-treatment listed in Figure 11-1).

Table 11-2 Administration Guidelines for Nasal Dosage Formulations	
General Instructions • Clear nasal passages before administering the product. • Wash your hands before and after use. • Gently depress the other side of the nose with finger to close off the nostril not receiving the medication. • Aim tip of delivery device away from nasal septum to avoid accidental damage to the septum. • Breathe through mouth and wait a few minutes after using the medication before blowing the nose.	
Nasal Sprays • Gently insert the bottle tip into one nostril, as shown in drawing A. • Keep head upright. Sniff deeply while squeezing the bottle. Repeat with other nostril.	Nasal Inhalers • Warm the inhaler in hand just before use. • Gently insert the inhaler tip into one nostril, as shown in drawing B, while inhaling. • Wipe the inhaler after each use. Discard after 2-3 months if it smells medicinal.

A

C

Pump Nasal Sprays

- Prime the pump before using it the first time. Hold the bottle with the nozzle placed between the first two fingers and the thumb placed on the bottom of the bottle.
- Tilt the head forward.
- Gently insert the nozzle tip into one nostril, as shown in drawing B. Sniff deeply while depressing the pump once.
- Repeat with other nostril.

Nasal Drops

- Lie on bed with head tilted back and over the side of the head.
- Squeeze the bulb to withdraw medication from the bottle.
- Place the recommended number of drops into one nostril.
- Repeat with other nostril. Lie on bed for 1-2 minutes after use.
- Do not rinse the dropper.

Note: Do not share the drug or its dispenser with anyone. Discard solutions if discolored or if contamination is suspected. Remove caps before use and replace tightly after each use. Do not use expired products.

Table 11-3 Dosage Guidelines for Nonprescription Systemic Nasal Decongestants

Drug	Dosage ^a (maximum daily dosage)		
	Adults and Children ≥ 12 Years	Children 6 to < 12 Years	Children 2 to < 6 Years ^b
Phenylephrine HCl	10 mg every 4 hours (60 mg)	5 mg every 4 hours (30 mg)	2.5 mg every 4 hours (15 mg)
Phenylephrine bitartrate	15.6 mg every 4 hours (62.4 mg)	7.8 mg every 4 hours (31.2 mg)	Not recommended for children <6 years except under advice of HCP

Drug	Dosage ^a (maximum daily dosage)		
	Adults and Children ≥ 12 Years	Children 6 to < 12 Years	Children 2 to < 6 Years ^b
Pseudoephedrine	60 mg every 4–6 hours (240 mg)	30 mg every 4–6 hours (120 mg)	15 mg every 4–6 hours (60 mg)

^a Taken as needed.

^b FDA has advised that cough and cold medications not be used in children younger than 2 years of age.¹² Manufacturers have voluntarily updated cough and cold product labels to state “do not use” in children younger than 4 years of age.¹³

Key: FDA = U.S. Food and Drug Administration; HCP = health care provider.

Nonpharmacologic Therapy

Although evidence of efficacy is lacking, popular therapeutic measures include increased fluid intake, adequate rest, a nutritious diet as tolerated, and increased humidification with steamy showers, vaporizers, or humidifiers. Vaporizers superheat water to produce steam and can deliver medications such as Vicks VapoSteam (camphor 6.2%). By contrast, humidifiers use fans or ultrasonic technology to produce a cool mist and cannot accommodate liquid additives. Saline nasal sprays or drops moisten irritated mucosal membranes and loosen encrusted mucus; salt gargles may ease sore throats. Hot tea with lemon and honey, chicken soup, and vegetable and other broths are soothing. Limited evidence suggests that a number of substances in chicken soup could have anti-inflammatory activity.⁸ Milk products should not be withheld, in view of the lack of evidence that milk increases cough or congestion. Medical devices such as Breathe Right nasal strips are marketed for temporary relief from nasal congestion and stuffiness resulting from colds and allergies. Those devices lift the nares open, thereby enlarging the anterior nasal passages. Aromatic oils (e.g., camphor, menthol, eucalyptus) contained in products such as Vicks VapoRub (for patients 2 years of age and older) ease nasal congestion and improve sleep by producing a soothing sensation.⁹ Children should be supervised closely when these products are used because aromatic oils can irritate the eyes and skin, and extensive exposure through inhalation or accidental ingestion can lead to toxicity.

Nondrug therapy for all patients, especially for infants, includes upright positioning to enhance nasal drainage. Because children typically cannot blow their own noses until the age of approximately 4 years, carefully clearing the nasal passageways with a nasal aspirator (e.g., bulb syringe, NoseFrida) may be necessary if accumulation of mucus interferes with sleeping or eating. Nasal aspirators may be mechanically or manually operated. To use a bulb syringe and avoid harm to the child, the caregiver should squeeze the large end of the bulb *before* inserting it, continue this compression while gently inserting the tip into the infant's nose, and then slowly release the squeezing pressure to

draw out fluid. After the pressure is completely released, the syringe is removed from the infant's nose and the fluid expelled from the syringe by again compressing the bulb. By contrast, NoseFrida is placed against the child's nostril, creating a seal, and the caregiver uses oral suction to remove mucus.

Proper hand hygiene reduces the transmission of cold viruses. The Centers for Disease Control and Prevention (CDC) encourages frequent hand cleansing with soap or soap substitutes such as hand sanitizers.² Not all hand sanitizers are effective at eradicating rhinoviruses from the skin. In a review of the safety and effectiveness of consumer and health care antiseptics, FDA determined that only three ingredients were eligible to be marketed in consumer antiseptic rubs: benzalkonium chloride; alcohol (ethyl alcohol or ethanol, 60%–95%); and isopropyl alcohol (70%–91.3%).¹⁰ The agency also determined that 28 ingredients, including chlorhexidine gluconate, iodine complex, and triclosan, were ineligible. Alcohol-based nasal sanitizers (e.g., Nozin) are available, but evidence of their efficacy against cold viruses is lacking. Use of antiviral disinfectants such as Lysol (which kills <99% of rhinoviruses after contact for 1 minute) and antiviral tissues such as Kleenex Anti-Viral (incorporating a tissue layer containing citric acid and sodium lauryl sulfate) also may help prevent transmission of viruses.

Pharmacologic Therapy

Decongestants

Decongestants specifically treat sinus and nasal congestion. Decongestants are adrenergic agonists (sympathomimetics). Stimulation of alpha-adrenergic receptors constricts blood vessels, thereby decreasing sinusoid vessel engorgement and mucosal edema. Three types of decongestants are available. *Direct-acting* decongestants (e.g., phenylephrine, oxymetazoline, tetrahydrozoline) bind directly to adrenergic receptors. *Indirect-acting* decongestants (e.g., ephedrine) displace norepinephrine from storage vesicles in prejunctional nerve terminals, and tachyphylaxis can develop as stored neurotransmitter is depleted. *Mixed* decongestants (e.g., pseudoephedrine) have both direct and indirect activity.

Systemic nonprescription decongestants include pseudoephedrine and phenylephrine. Intranasal nonprescription decongestants include the short-

acting decongestants ephedrine, levmetamfetamine (L-desoxyephedrine), naphazoline, phenylephrine, and propylhexedrine, and the long-acting decongestants xylometazoline (8–10 hours) and oxymetazoline (12 hours). Ophthalmic nonprescription decongestants also are available (see [Chapter 28](#)).

Systemic decongestants are rapidly metabolized by monoamine oxidase (MAO) and catechol-O-methyltransferase in the gastrointestinal (GI) mucosa, liver, and other tissues. Pseudoephedrine is well absorbed after oral administration; phenylephrine has a low oral bioavailability (approximately 38%). Both pseudoephedrine and phenylephrine have short half-lives (pseudoephedrine: 6 hours; phenylephrine: 2.5 hours), and peak concentrations for both drugs are reached at 0.5–2 hours after oral administration.

Decongestants are indicated for temporary relief of nasal and eustachian tube congestion and for cough associated with postnasal drip. Nonprescription decongestants are not approved by the U.S. Food and Drug Administration (FDA) to self-treat nasal congestion associated with sinusitis.

FDA-approved dosages for decongestants are listed in Tables [11–3](#)^{11,12} and [11–4](#).¹¹ (Note: In 2008, manufacturers voluntarily updated cough and cold products labels to state “do not use” in children under 4 years of age.¹³) Nonprescription decongestants are marketed in a variety of dosage formulations, and many combination products are available ([Table 11–5](#)).

Table 11–5 Selected Nonprescription Products for Nasal Decongestion	
Trade Name	Primary Ingredient(s)
Topical Decongestants	
Afrin Original Nasal Spray	Oxymetazoline HCl 0.05%
Vicks Sinex Nasal Spray	Oxymetazoline HCl 0.05%
4-Way Fast Acting	Phenylephrine HCl 1%
Neo-Synephrine Mild Strength Nasal Spray	Phenylephrine HCl 0.25%
Little Remedies Decongestant Nose Drops	Phenylephrine HCl 0.125%
Otrivin Medicated Cold &	Xylometazoline 0.1%

Trade Name	Primary Ingredient(s)
Allergy Relief (Canada)	
Nasal Decongestant Inhalers	
Benzedrex Inhaler	Propylhexedrine 250 mg
Vapor Inhaler	Levmetamfetamine (l-desoxyephedrine) 50 mg/inhaler
Systemic Decongestants	
Sudafed PE Congestion	Phenylephrine HCl 10 mg
Sudafed 24 Hour	Pseudoephedrine HCl 240 mg
Sudafed 12 Hour	Pseudoephedrine HCl 120 mg
Nexafed ^a	Pseudoephedrine HCl 30 mg
Zephrex-D ^b	Pseudoephedrine HCl 30 mg
Combination Products	
Sudafed PE Pressure + Pain	Phenylephrine HCl 5 mg; acetaminophen 325 mg
Alka-Seltzer Plus Cold	Phenylephrine bitartrate 7.8 mg; aspirin 325 mg; chlorpheniramine maleate 2 mg
Vicks Dayquil Cold & Flu Relief Liquicaps	Phenylephrine HCl 5 mg; acetaminophen 325 mg; dextromethorphan hydrobromide 10 mg
Tylenol Cold Max Nighttime Cool Burst Liquid ^c	Phenylephrine HCl 5 mg/15 mL; acetaminophen 325 mg/15 mL; dextromethorphan hydrobromide 10 mg/15 mL; doxylamine succinate 6.25 mg/15 mL
Mucinex Children's Stuffy Nose & Chest Congestion Liquid	Phenylephrine HCl 2.5 mg/5 mL; guaifenesin 100 mg/5 mL
Aleve-D Sinus & Cold	Pseudoephedrine HCl 120 mg; naproxen sodium 220 mg
Mucinex D	Pseudoephedrine HCl 60 mg; guaifenesin 600 mg
Other Products	

Trade Name	Primary Ingredient(s)
Ocean Premium Saline Nasal Spray	Sodium chloride 0.65%
Vicks VapoRub	Camphor (4.8%); eucalyptus (1.2%); menthol (2.6%)

^a “Meth-detering” technology (Impede) (i.e., drug is designed to deter the conversion of pseudoephedrine to methamphetamine).

^b “Meth-detering” technology (Tarex).

^c Contains 0.5% alcohol.

Adhering to FDA-approved doses of decongestant products is very important in that acute overdose can be life-threatening, especially in children. Systemic decongestant overdoses cause excessive central nervous system (CNS) stimulation, paradoxical CNS depression, cardiovascular collapse, shock, and coma. Treatment for decongestant overdoses is supportive.

Adverse effects associated with decongestants include cardiovascular stimulation (leading to elevated blood pressure, tachycardia, palpitations, or arrhythmias) and CNS stimulation (causing restlessness, insomnia, anxiety, tremors, fear, or hallucinations). Children and older adults are more likely than persons in other age groups to experience adverse effects. Adverse effects are more common with systemic decongestants, because topical decongestants are minimally absorbed. However, accidental ingestion of nasal or ophthalmic decongestants can cause adverse effects ranging from nausea, vomiting, and drooling to more serious derangements including hypotension, hyperthermia, lethargy, sedation, and coma. Adverse effects specifically related to topical decongestants include propellant- or vehicle-associated effects (e.g., burning, stinging, sneezing, local dryness) and trauma from the tip of the administration device. Rhinitis medicamentosa (RM)—that is, rebound congestion—has been associated with use of topical decongestants. The exact cause is unknown, but short-acting products, preservative agents (e.g., benzalkonium chloride), and long duration of therapy are suspected as contributing factors.¹⁴ Depending on the active ingredient, limiting therapy to 3–7 days is the accepted approach to avoid RM. However, controversy exists,

and some studies show that treatment duration of 10 days to 8 weeks appears to be safe and does not cause RM.¹⁴ Further investigation is needed to determine the optimal duration of treatment. Treatment for RM consists of slowly withdrawing the topical decongestant (restricted to one nostril at a time); replacing the decongestant with topical normal saline, which soothes the irritated nasal mucosa; and, if needed, using topical corticosteroids and systemic decongestants. A withdrawal period of 2–6 weeks of such measures may be needed before mucous membranes return to normal. A nonprescription kit, RhinoStat, has been advertised to assist health care providers and patients with management for RM. The product creates a patient-specific mixture of the implicated topical decongestant product and a diluent; of note, however, the kit is not FDA approved.

Decongestants interact with numerous drugs, as summarized in [Table 11–6](#). Decongestants are contraindicated in patients receiving concomitant MAO inhibitors (MAOIs).

Table 11–6 Clinically Important Drug–Drug Interactions With Cold and Allergy Products

Drug/Drug Class	Potential Interaction (with drug-specific data)	Management/Prevention
Decongestants		
Ergot derivatives (e.g., dihydroergotamine and ergotamine)	Increased risk of hypertension and vasoconstriction	Avoid combination.
Linezolid	Increased risk of hypertension	Reduce dose of decongestant and monitor closely. Consider therapy modification.
MAOIs (e.g., phenelzine, selegiline)	Increased risk of hypertension	Avoid combination.
Serotonin/norepinephrine reuptake inhibitors	Increased risk of tachycardia	Consider therapy modification.
Antihistamines		
Amiodarone	Increased risk of QT interval prolongation (loratadine)	Avoid combination.

Drug/Drug Class	Potential Interaction (with drug-specific data)	Management/Prevention
Antacids (aluminum and magnesium salts)	Decreased efficacy (fexofenadine)	Separate doses by as much time as possible.
Anticholinergics (e.g., ipratropium, tiotropium, umecclidinium)	Enhanced anticholinergic effects (dry mouth, eyes, urinary retention, sedation)	Avoid combination.
Brexpiprazole	Increased risk of brexpiprazole toxicity (diphenhydramine)	Reduce brexpiprazole dose by 25% or avoid combination.
CNS depressants (alcohol, opiates, sedatives)	Increased sedation (sedating antihistamines; cetirizine, levocetirizine)	Avoid combination.
Erythromycin; ketoconazole	Increased fexofenadine plasma concentration	Monitor therapy closely.
Metoprolol	Increased metoprolol serum concentrations and risk of hypotension (diphenhydramine)	Reduce metoprolol dose or avoid combination.
Phenytoin	Decreased phenytoin elimination (chlorpheniramine)	Monitor therapy or avoid combination.
Potassium chloride (oral)	Increased risk of ulcers	Avoid combination.
Intranasal Corticosteroids		
Protease inhibitors (e.g., ritonavir, tipranavir, telaprevir)	Increased serum concentration of steroids (budesonide, fluticasone)	Avoid combination.

Key: CNS = Central nervous system; MAOI = monoamine oxidase inhibitor.

Source: Lexi-Comp Online. Hudson, OH: Wolters Kluwer. Available at: <https://online.lexi.com/lco/action/login>. (Subscription required.) Accessed June 7, 2019.

Decongestants may exacerbate diseases and conditions associated with sensitivity to adrenergic stimulation, such as hypertension, coronary heart

disease, ischemic heart disease, diabetes mellitus, hyperthyroidism, elevated intraocular pressure, and prostatic hypertrophy. Patients with hypertension should use decongestants only with medical advice, and no clear evidence has emerged to show that any one agent is safest in this population. Products specifically marketed for patients with hypertension (e.g., Coricidin HBP) do not contain decongestants. Those products usually consist of a combination of ingredients that may or may not be appropriate, depending on the patient's symptoms.

Health care providers should be aware of the possibility that purchase of large quantities of pseudoephedrine may be specifically for illegal use to produce methamphetamine. In 2005, passage of the Combat Methamphetamine Epidemic Act changed the classification of pseudoephedrine to "scheduled listed chemical products."¹⁵ That change in classification allowed limits to be placed on pseudoephedrine sales. All pseudoephedrine products must now be kept in secure areas (e.g., behind a pharmacy counter or in a locked cabinet), and purchases are limited to 3.6 g daily and 9 g per month per patient.¹⁵ The following information from each sale must be entered into a paper or electronic logbook: product name, quantity sold, patient's name and address, and time and date of sale.¹⁵ Patients must show valid identification to purchase pseudoephedrine and then sign the logbook. Some states and corporations have enacted stricter guidelines regarding the sale of pseudoephedrine.

Antihistamines

Monotherapy with nonprescription antihistamines may provide some benefit in adults if started early in the course of a cold (i.e., day 1 or 2 of symptom onset).¹⁶ Also, a combination of first-generation (sedating) antihistamines and decongestants showed some benefit in adults, but the significance of the data is questionable.¹⁷ Apart from questions of efficacy, an important issue is whether potential benefits of sedating antihistamines outweigh known risks associated with these drugs. (See later discussion of antihistamines for the topic "Allergic Rhinitis.")

Local Anesthetics

A variety of products containing local anesthetics (e.g., benzocaine, dyclonine hydrochloride) are available for the temporary relief of sore throats ([Table 11-7](#)).

Local anesthetic products may be used every 2–4 hours. Patients with a history of allergic reactions to anesthetics should be advised to avoid products containing benzocaine. Benzocaine also has been associated with methemoglobinemia, especially in children younger than 2 years, and should be avoided in this age group. Some products contain local antiseptics (e.g., cetylpyridinium chloride, hexylresorcinol) and/or menthol or camphor. Local antiseptics are not effective for viral infections. Emerging evidence suggests that menthol and camphor provide pain relief by stimulation of the TRPM8 or “menthol” receptor.¹⁸

Table 11-7 Selected Nonprescription Products for Sore Throat	
Trade Name	Primary Ingredient(s)
Lozenges	
Cepacol Sore Throat Extra Strength	Benzocaine 15 mg; menthol 3.6 mg
Chloraseptic Sore Throat	Benzocaine 6 mg; menthol 10 mg
Halls Fruit Breezers	Pectin 7 mg
Sucrets Sore Throat	Dyclonine HCl 2 mg
Vicks VapoDrops	Menthol 1.7 mg (cherry)
	Menthol 3.3 mg (menthol)
Throat Sprays	
Chloraseptic Sore Throat	Phenol 1.4%

Systemic Analgesics

Systemic analgesics (e.g., aspirin, acetaminophen, ibuprofen, naproxen) are effective for aches or fever sometimes associated with colds. Concerns that use of aspirin and acetaminophen may increase viral shedding and prolong illness have not been validated.¹⁹ Because of the risk of Reye syndrome, aspirin and aspirin-containing products should not be used in children or teenagers who have or are recovering from chickenpox or influenza-like symptoms. (See [Chapter 5](#) for a complete discussion of those products, including the manufacturer’s voluntary reduction of maximum daily dosages of Tylenol products sold in the United States [see under “Acetaminophen” and Table 5–3],

and developments in liquid infant acetaminophen products [see under “Patient Factors”].)

Antitussives and Protussives (Expectorants)

When present, cough associated with colds usually is nonproductive. Antitussive agents (codeine and dextromethorphan) are of questionable efficacy in colds, and their use in this setting is not recommended.²⁰ Guaifenesin, an expectorant, has not been proved effective in natural colds.²⁰ (See [Chapter 12](#) for a complete discussion of these products.)

Combination Products

Decongestants and antihistamines are marketed in many combinations, including combinations with analgesics, expectorants, and antitussives. Products also are marketed for daytime or nighttime use. Products for nighttime use usually contain a sedating antihistamine, whereas daytime products do not; rather they contain systemic decongestants to promote wakefulness. Combination products are convenient, but this benefit must be weighed against the risks associated with taking unnecessary drugs.

Pharmacotherapeutic Comparison

As stated earlier, evidence does not support the use of antitussives and expectorants and is limited for the use of antihistamines to treat symptoms related to colds. The use of local anesthetics and systemic analgesics for treatment of pain related to sore throat or of fever related to colds, however, is supported by good evidence.

Topical decongestants are convenient dosage forms and are effective in relieving nasal congestion; however, duration of their use is limited to 3–7 days owing to concerns about development of RM. The major differences between topical decongestants are in duration of action, dosage formulation (e.g., mist versus spray versus drops), moisture content, and preservative content.

Although many manufacturers have reformulated products with phenylephrine as a response to pseudoephedrine regulations, controversy remains with regard to the relative safety and efficacy of the systemic decongestants.^{21,22} Efficacy of the current FDA-approved dose of

phenylephrine has been extensively debated, and a citizen's petition was filed in 2015 to remove it from the nonprescription drug market.^{21,22}

Product Selection Guidelines

Special Populations

Drug use during pregnancy and lactation requires a balance between risk and benefit. (See the Preface for a detailed explanation of the pregnancy data.) Because most colds are self-limiting, with bothersome rather than life-threatening symptoms, many health care providers recommend nondrug therapy. When drugs are considered, agents with a long record of safety in animals and humans are preferred. To minimize possible adverse effects on the fetus or newborn, pharmacists should advise pregnant or lactating women to avoid products labeled “extra strength,” “maximum strength,” or “long-acting,” as well as combination products. Systemic decongestants also should be avoided, because human data suggest increased risk of adverse effects based on theoretically decreased fetal blood flow.²³ Oral use of phenylephrine during the first trimester has been associated with minor malformations (e.g., inguinal hernia, congenital hip dislocation).²³ Pseudoephedrine has been linked to abdominal wall defects (gastroschisis) in newborns.²³ No clear association has been found between birth defects and the use of intranasal decongestants during pregnancy.²³ Oxymetazoline is poorly absorbed after intranasal administration and is the preferred topical decongestant during pregnancy. Nonprescription cold products do not appear to affect male reproductive function.

The American Academy of Pediatrics has found pseudoephedrine to be compatible with breastfeeding.²³ No human data are available for intranasal phenylephrine and oxymetazoline, so they are considered “probably compatible” in lactating mothers.²³ Because decongestants may decrease milk production, lactating mothers should monitor their milk production and drink extra fluids as needed. Dextromethorphan, guaifenesin, benzocaine, camphor (topical), and menthol (topical) each carry a low risk of birth defects and have been found to be compatible with breastfeeding.²³

As stated earlier, older patients should be advised to use decongestants with caution, in that they may be more sensitive to adverse effects and may have a higher prevalence of concomitant disease states (e.g., cardiovascular disease)

in which nonprescription cold products may potentially have a negative impact. (See under “Special Populations” for the topic “Allergic Rhinitis” later in the chapter for a discussion of antihistamine use in the geriatric population.)

Using nonprescription cold products in children is controversial. FDA does not recommend use in children younger than 2 years because of concerns about efficacy and safety.¹² Manufacturers voluntarily updated product labeling to include the statement “Do not use in children under 4 years of age” and added warnings to antihistamine-containing products against their use for sedation purposes.¹³ However, a 2017 study showed a low incidence of adverse effects and no fatalities at therapeutic doses in children 2–11 years of age.²⁴ Patient counseling should emphasize nondrug measures in children, and if pharmacotherapy is deemed necessary, parents should follow dosing instructions carefully and avoid combination products to avoid overdose. To address the issue of inaccurate dosing of liquid nonprescription drug products (e.g., liquid analgesics, liquid cough and cold products, and lactase replacement drops), FDA issued guidelines in May 2011.²⁵ The key points of the guidelines are as follows:

- A dosing device (dropper, cup, syringe, or spoon) should be included with all oral liquid nonprescription products.
- The device should be calibrated to the dose recommended in the product directions.
- The device should be used only with the product in which it is packaged.
- The markings need to remain visible even when the liquid is in the device.

Patient Factors

As discussed earlier, it may be difficult to differentiate cold symptoms from those of some acute and chronic disorders ([Table 11–1](#)). If duration of symptoms is longer than 7–14 days or a chronic condition is suspected, self-treatment is contraindicated. Patients with chronic conditions exacerbated by adrenergic stimulation, or those overly sensitive to such stimulation, should avoid using decongestants. Persons who participate in organized sports need to be advised that oral decongestants are considered “doping” products and should be used only in accordance with sport regulations.

Patient Preferences

Lozenges, soft chews, and nasal drug delivery forms may be preferred by patients who have difficulty swallowing or when access to water is not convenient. Nasal delivery forms, however, may be difficult to use for patients with severe arthritis or coordination problems.

For patients who prefer a nasal delivery form, each dosage form has distinct advantages and disadvantages. Nasal sprays are simple to use, cover a large surface area, are relatively inexpensive, and have a fast onset of action. The disadvantages include imprecise dosage, a tendency for the tip to become clogged with repeated use, and a high risk of contamination from aspiration of nasal mucus into the bottle. Metered pump sprays deliver a more precise dose. Nasal drops are preferred for small children but can be difficult to use, cover a limited surface area, and pass easily into the larynx. A high risk of contamination stemming from the tendency to touch the dropper to the nasal mucosa during administration also is recognized. Nasal inhalers are small, but their use requires an unobstructed airway and sufficient air flow to distribute the drug to the nasal mucosa. Nasal inhalers lose efficacy after 2–3 months, even when tightly capped, because of dissipation of the active ingredient. Presence of nasal polyps, enlarged turbinates, and abnormalities such as septal deviation have been shown to be associated with reduced efficacy of topical dosage forms.

Complementary Therapies

Numerous complementary therapies are marketed for the treatment of colds (Table 11–8^{26–28}; see also Chapter 51). Zinc and high-dose vitamin C regimens are popular therapies.

Table 11–8 Selected Complementary Therapies for Colds and Allergies		
Botanical Natural Product [CAM Designation]	Risks	Effectiveness
African geranium [umckaloabo, active ingredient in Umcka ColdCare products] (<i>Pelargonium sidoides</i>)	Allergic reactions or gastrointestinal disturbances	Some evidence for alleviating symptoms of acute rhinosinusitis associated with colds in adults

Botanical Natural Product [CAM Designation]	Risks	Effectiveness
Ephedra [ma huang] (<i>Ephedra sinica</i>)	Tachycardia, hypertension, heart attack, stroke, seizure	Effective decongestant
Goldenseal (<i>Hydrastis canadensis</i>)	Potentially toxic, especially in patients with glucose-6-dehydrogenase deficiency	Some evidence of anti-inflammatory effects of active ingredient berberine for treatment of pulmonary inflammation

Key: CAM = Complementary and alternative medicine.

Source: [References 26–28](#).

High local concentrations of zinc ions purportedly block the adhesion of human rhinovirus to the nasal epithelium and also are thought to inhibit viral replication by disrupting viral capsid formation. However, in vitro studies have shown only a modest antiviral effect. Formulations include tablets, capsules, chews, lozenges, syrups, and oral sprays. Nasal formulations were removed from the market because of associated anosmia (loss of smell).²⁹ Oral formulations may be associated with GI adverse effects (e.g., nausea, upset stomach, bitter taste). Since the 1980s, the effectiveness of zinc has been highly debated. A meta-analysis of 17 trials concluded that oral zinc (as lozenges or syrup) was effective in reducing cold symptoms or duration of the cold if started within 24 hours of symptom onset and administered every 2 hours while the patient was awake. The study also reported that prophylaxis with zinc for at least 5 months reduced the incidence of colds in healthy patients.³⁰

The efficacy and safety of high-dose (e.g., ≥ 2 g daily) vitamin C (ascorbic acid) supplementation for prophylaxis and treatment of colds have been debated for more than 70 years. An analysis of 29 trials showed that although routine use of high-dose vitamin C does not appear to prevent colds in the general population, it did reduce the duration by approximately 8% in adults and 14% in children.³¹ By contrast, high-dose vitamin C prophylaxis was effective in preventing colds in a subgroup of patients under severe physical stress (e.g., marathon runners).³¹ Such use of vitamin C after the onset of a cold, however,

was not effective at reducing severity or duration of symptoms.³¹ Regular use of high doses may increase the risk of development of kidney stones in men.³² Doses of 4 g daily or greater are associated with diarrhea and other GI symptoms and therefore should not be recommended.

Products that claim to strengthen the immune system such as Airborne, Emergen-C Immune+, and others have not been proved to be effective in preventing or treating colds. Vitamin D supplementation to prevent colds is controversial, but emerging evidence suggests that regular use may prevent colds, especially in patients with low vitamin D levels.³³ Docosahexaenoic acid (DHA) supplementation during pregnancy may help to reduce the subsequent incidence and duration of colds in infants, but more studies are needed.³⁴ Homeopathic products (see also [Chapter 52](#)) containing Galphimia glauca, Sabadilla, and Luffa operculata (e.g., Zicam nasal swabs) are marketed to reduce severity if taken at the onset of symptoms, but evidence of efficacy and safety is lacking. Various probiotic products are available, and emerging research suggests that they may help support the immune system and prevent colds.³⁵ (See [Chapter 20](#) for a complete discussion of those products.)

Algorithm: The Common Cold

Figure 11–1 Self-care for the common cold. Key: AH = Antihistamine; AIDS = acquired immunodeficiency syndrome; CAM = complementary and alternative medicine; CHF = congestive heart failure; COPD = chronic obstructive pulmonary disease; OTC = over-the-counter.

Assessment of Colds: A Case-Based Approach

After interviewing the patient to identify symptoms, medical history, medication use (current and past), and the efficacy of past self-treatment for colds, the health care provider should conduct a brief physical assessment ([Table 11–9](#)). If the assessment and the patient's answers do not reveal exclusions for self-treatment, the provider should recommend medications that target the patient's most troublesome symptoms.

Table 11-9 Physical Assessment of Patient Presenting With Cold Symptoms

1. Observe patient (look and listen for signs of chronic conditions, such as red, watery eyes; wheezing; productive cough; barrel chest; poorly perfused areas; enlarged lymph nodes; rash).

If equipment and privacy allow, conduct the following:

2. Obtain vital signs (temperature, respiratory rate, pulse, and blood pressure).
3. Palpate sinuses and neck, and observe for any pain/tenderness.
4. Visually examine throat for redness or exudates. If bacterial pharyngitis is suspected, run rapid strep test.
5. Auscultate chest to detect wheezing, crackles, and rapid or irregular heartbeat.

Case 11-1 is an example of assessment of a patient with a possible cold.

Case 11-1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of fatigue, "runny nose," and nasal congestion that began 2 days ago. This morning, he is experiencing a mild headache in his sinus area.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	His symptoms seem to be worse at bedtime and first thing in the morning.
c. Description of the patient's efforts to relieve the symptoms	Patient tried pseudoephedrine 120 mg, which helped relieve his congestion but prevented him from sleeping. He also took ibuprofen 200 mg, 2 tablets, for the headache today.

Relevant Evaluation Criteria	Scenario/Model Outcome
d. Patient's identity	Dale Dunn
e. Patient's age, gender, height, and weight	47 years, male, 5 ft 9 in., 184 lb
f. Patient's occupation	Land surveyor
g. Patient's dietary habits	Patient eats a poor diet consisting of black coffee for breakfast, fast food for lunch, and meat and potatoes for dinner. Patient has 1–2 drinks of alcohol each night.
h. Patient's sleep habits	Normally sleeps well, except for the last few nights.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Hypertension</i> : lisinopril 20 mg daily; <i>nausea</i> : peppermint oil drops; super B complex once a day
j. Allergies	Penicillin (reaction included hives)
k. History of other adverse reactions to medications	Diarrhea with Bactrim DS
l. Other (describe) _____	Patient's temporal temperature currently is 99.6°F (37.5°C), and blood pressure is 128/86 mm Hg.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Cold signs and symptoms usually include sore throat, nasal congestion, rhinorrhea, and low fever. Patient has nasal congestion, headache, and low-grade fever (body temperature <100.4°F [38°C]); therefore, his symptoms are consistent with a cold.
3. Identify exclusions for self-treatment (Figure 11–1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend a combination product because the patient has multiple symptoms that are all severe. (2) Refer patient to an appropriate health

Relevant Evaluation Criteria	Scenario/Model Outcome
	care provider for evaluation and treatment. (3) Recommend self-care until patient can consult an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Recommend self-care, and counsel patient to see an appropriate health care provider if no improvement is obtained in 7–14 days.
6. Describe the recommended therapeutic approach to the patient or caregiver.	Patient should use Afrin 0.05% (oxymetazoline) 2–3 sprays in each nostril every 12 hours. Discontinue pseudoephedrine because of the insomnia. Continue to take ibuprofen 200 mg every 4–6 hours for pain and fever; may increase to 400 mg, for a maximum of 1.2 g daily.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You should use Afrin for its local effects, to avoid systemic effects. Discontinue pseudoephedrine because of its unwanted side effects. Continue ibuprofen for pain and fever since it has been effective for you."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Use Afrin 2–3 sprays in each nostril every 12 hours. Do not use more than twice a day, and use for no more than 3 days. If it is used longer than 3 days, this medication may cause rebound congestion."
Solicit follow-up questions from the patient or caregiver.	"Do I need antibiotics for this cold?"
Answer the patient's or caregiver's questions.	"No. Colds are due to viruses, so antibiotics will not help. If the cold continues for more than 14 days, it may progress to bacterial infection, and then you

Relevant Evaluation Criteria	Scenario/Model Outcome
	may require an antibiotic.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Dunn in 1 week for checkup to ensure his symptoms have resolved.

Patient Counseling for Colds

Nondrug measures may be effective in relieving the discomfort of cold symptoms. The health care provider should explain the appropriate nondrug measures for the patient’s particular symptoms. With use of nonprescription medications, the purpose of each medication should be described, and the patient should be counseled to use only medications that target specific symptoms. Also needed is a clear explanation of possible adverse effects, drug interactions, and precautions or warnings. Finally, the health care provider should highlight the signs and symptoms that indicate the disorder is worsening and that medical care should be sought. (See the box “Patient Education for Colds.”)

Patient Education for Colds

The objectives of self-treatment are (1) to reduce symptoms, (2) to improve functioning and sense of well-being, and (3) to prevent spread of the disease. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- To prevent spreading a cold to others, follow these steps:

- Frequently wash your hands with soap for at least 20 seconds.
- Use facial tissues to cover your mouth and nose when coughing or sneezing, and then promptly discard the tissues.
- Use antiviral products such as Lysol to clean surfaces (e.g., doorknobs, telephones) that you may have touched.
- The following measures may provide relief or speed up recovery from a cold:
 - Getting adequate rest may help you recover more quickly.
 - Drinking fluids and using a humidifier or vaporizer may loosen mucus and promote sinus drainage.
 - Sucking on hard candy, gargling with salt water ($\frac{1}{2}$ –1 teaspoon of salt per 8 ounces of warm water), or drinking fruit juices or hot tea with lemon may soothe a sore throat.

Nonprescription Medications

- Ask a health care provider to help you select medications that target the most bothersome symptoms.

Sore Throat and Cough

- Sore throat may be treated with anesthetic products and/or systemic pain relievers:
 - Allow lozenges, troches, and orally disintegrating strips to dissolve slowly in the mouth; do not chew or bite these products.
 - Benzocaine and dyclonine may numb the mouth and tongue. If this occurs, do not eat or drink until the numbness goes away.
 - Seek medical attention if any of the following occur with use of benzocaine products: pale, gray- or blue-colored skin, lips, and nail beds; headache; lightheadedness; shortness of breath; fatigue; and rapid heart rate.
- Cough related to rhinorrhea leading to postnasal drip may be treated with a sedating antihistamine and decongestant

combination.

Rhinorrhea and Sneezing

- See the box “Patient Education for Allergic Rhinitis” for treatment of rhinorrhea (“runny nose”) and sneezing.

Nasal Congestion

- Nasal congestion may be treated with topical or systemic decongestants, which constrict blood vessels in the nose to reduce congestion.
 - Systemic decongestants include pseudoephedrine and phenylephrine. Dosages are listed in [Table 11-3](#).
 - Topical decongestants include ephedrine, naphazoline, oxymetazoline, phenylephrine, and xylometazoline. Dosages are listed in [Table 11-4](#).
- Decongestants have the following adverse effects:
 - The most common adverse effects caused by systemic decongestants are cardiovascular stimulation (leading to elevated blood pressure, rapid heart rate, palpitations, or arrhythmias) and central nervous system stimulation (causing restlessness, insomnia, anxiety, tremors, fear, or hallucinations).
 - Topical decongestants may cause any of the adverse effects listed for systemic decongestants. However, less of the topical medication gets into the body, so these effects are less common.
 - Topical decongestants may irritate the nose, or the bottle tip can injure the nose if it is used with inappropriate pressure.
 - Topical decongestants can cause rebound congestion if they are used longer than 3–7 days.
- Note the following precautions for use of decongestants in persons with other medical conditions:
 - Persons with high blood pressure should be advised to use decongestants only with medical advice.

- Persons with thyroid disorders, heart disease, glaucoma, or an enlarged prostate may experience worsening symptoms of their underlying disease if they take decongestants.
 - Persons with diabetes need to closely monitor their blood glucose concentrations and may need to adjust their dose of insulin if they take decongestants.
- Note the following drug interactions for decongestants:
 - Persons taking MAOI antidepressants, ergot derivatives for headaches, and certain antibiotics (linezolid) should not take decongestants.
 - Persons taking SSRI or SNRI antidepressants should be counseled to use decongestants with caution, as these medications may increase heart rate.
- Store all medications according to the manufacturer's recommendations. Do not use expired medications.

When to Seek Medical Attention

- Seek medical attention for the following situations:
 - Sore throat persists more than several days, is severe, or is associated with persistent fever, headache, or nausea or vomiting.
 - Symptoms worsen while nonprescription medications are being taken.
 - Signs and symptoms of bacterial infections develop (e.g., thick nasal or respiratory secretions that are not clear; temperature higher than 101.5°F [38.6°C; oral]; shortness of breath; chest congestion; wheezing; rash; significant ear pain).

Note About Pediatric Dosing

- Manufacturers of cough and cold medications have revised the labeling to state that these products should not be used in children younger than 4 years, and FDA has mandated that dosing devices be included with products for children older than 4 years. The

dosing device should be used only with the product in which it is packaged. Health care providers should emphasize this information to caregivers of infants and young children.

Key: FDA = U.S. Food and Drug Administration; MAOI = monoamine oxidase inhibitor; SNRI = serotonin-norepinephrine reuptake inhibitor; SSRI = selective serotonin reuptake inhibitor.

Evaluation of Patient Outcomes for Colds

Most colds are self-limiting, so symptoms usually resolve on their own in 7–14 days. For a majority of patients, targeted nonprescription therapy will relieve cold symptoms. Patients should self-monitor for worsening symptoms and progression to complications by measuring body temperature, appraising nasal secretions, assessing respirations for wheezing or shortness of breath, identifying productive cough, and ascertaining the presence and character of any facial or neck pain. If complications are suspected, medical referral is necessary. Referral to a primary care provider also is required for patients who meet the exclusions for self-treatment in [Figure 11–1](#) or for whom the warnings listed in the box “Patient Education for Colds” apply.² Follow-up assessment usually is not necessary for patients with uncomplicated colds, but a subsequent telephone call from the health care provider’s office in 7–14 days may be deemed appropriate.

Allergic Rhinitis

Allergic rhinitis, a systemic disease with prominent nasal symptoms, is a worldwide problem that affects both adults and children. An estimated 8% of adults and 10% of children in the United States are newly diagnosed with allergic rhinitis annually.³⁶ Combined annual direct costs (e.g., for medications and office visits), indirect costs (e.g., those related to work and school absenteeism), and impaired quality of life create an estimated economic burden of \$25 billion annually.³⁷

Allergic rhinitis can be diagnosed at any age but usually starts after 2 years of age.³⁸ After the age of 65 years, the number of cases decreases. The prevalence of allergic rhinitis is higher in the southern United States.³⁸

Pathophysiology of Allergic Rhinitis

Allergic rhinitis affects the upper respiratory system. (The previous topic, “Colds,” includes a detailed discussion of the respiratory anatomy and physiology.) Risk factors for developing allergic rhinitis include family history of atopy (allergic disorders) in one or both parents; filaggrin (skin barrier protein) gene mutation; elevated serum immunoglobulin E (IgE) greater than 100 IU/mL before the age of 6 years; higher socioeconomic level; eczema; and positive reaction to allergy skin tests.^{39,40} Emerging evidence also suggests that diet may be a risk factor in children and adolescents. Children who consume three or more fast-food meals per week showed an increased incidence of allergic disorders.⁴¹ The exact mechanism for that increase is not known but is thought to be related to higher dietary content of fatty acids, especially trans fatty acids, which trigger an immune response.⁴¹

Allergic rhinitis is triggered by indoor and outdoor environmental allergens. Common outdoor aeroallergens (airborne environmental allergens) include pollen and mold spores. Other nonairborne pollens also have been implicated. Pollutants (e.g., ozone, tobacco smoke, diesel exhaust particles) are considered environmental triggers and are becoming more of a concern in highly populated areas. Common indoor aeroallergens include those from house-dust mites and cockroaches, mold spores, and pet dander. Occupational aeroallergens include wool dust, latex, resins, biologic enzymes, organic dusts (e.g., flour), and various chemicals (e.g., isocyanate, glutaraldehyde).

The pathogenesis of allergic rhinitis is complex, involving numerous cells and mediators, and consists of four phases.⁴² First is the *sensitization phase*, which occurs on initial allergen exposure. The allergen stimulates beta-lymphocyte-mediated IgE production. Second is the *early phase*, occurring within minutes of subsequent allergen exposure. The early phase consists of rapid release of preformed mast cell mediators (e.g., histamine, proteases), as well as the production of additional mediators (e.g., prostaglandins, kinins, leukotrienes, neuropeptides). [Figure 11–2](#) depicts the emergence of mediator-specific symptoms. The third phase is *cellular recruitment*. Circulating

leukocytes, especially eosinophils, are attracted to the nasal mucosa and release more inflammatory mediators. Fourth and last is the *late phase*, which begins 2–4 hours after allergen exposure; signs and symptoms include mucus hypersecretion secondary to submucosal gland hypertrophy and congestion. Continued persistent inflammation “primes” the tissue, resulting in a lower threshold for allergic- and nonallergic-mediated triggers (e.g., cold air, strong odors).

Algorithm: Mediator-specific symptoms

Figure 11–2 Mediator-specific symptoms and targeted drug therapy. Key: IgE = Immunoglobulin E; INCS = intranasal corticosteroids; PGD = prostaglandin. (Source: [Reference 42](#).)

Clinical Presentation of Allergic Rhinitis

Allergic rhinitis has been classified as seasonal allergic rhinitis (“hay fever”) and perennial allergic rhinitis. Allergic rhinitis is further classified as *episodic*, *intermittent* allergic rhinitis (IAR) and *persistent* allergic rhinitis (PER).^{39,40} Classification depends on the timing and duration of symptoms. Symptoms can be further classified as mild or moderate to severe ([Table 11–10](#)).^{39,40} Symptoms of allergic rhinitis and common physical findings in affected patients are summarized in [Table 11–11](#)^{39,40,42} and can be used to differentiate allergic from nonallergic rhinitis. [Table 11–12](#) lists causes of nonallergic rhinitis.^{39,40,42} Systemic symptoms include fatigue, irritability, malaise, and cognitive impairment.

Table 11–10 Classification of Allergic Rhinitis	
Duration	Severity
Intermittent	Mild
Symptoms occur ≤4 days per week or ≤4 weeks.	Symptoms do not impair sleep or daily activities ^a ; no troublesome symptoms.
	Moderate–Severe

Duration	Severity
	One or more of the following occurs: impairment of sleep; impairment of daily activities ^a ; troublesome symptoms.
Persistent	Mild
Symptoms occur <4 days per week <i>and</i> <4 weeks.	Symptoms do not impair sleep or daily activities ^a ; no troublesome symptoms.
	Moderate–Severe
	One or more of the following occurs: impairment of sleep; impairment of daily activities ^a ; troublesome symptoms.
Episodic	
Symptoms occur on exposure to or contact with potential allergen that is not normally a part of the person's environment (e.g., a cat at a friend's house).	Can be mild, moderate, or severe—based on symptoms

^a Daily activities include work, school, sports, and leisure.

Source: [References 39](#) and [40](#).

Table 11–11 Differentiation of Allergic Rhinitis From Nonallergic Rhinitis

Symptoms/Findings	Allergic Rhinitis	Nonallergic Rhinitis^a
Symptom presentation	Bilateral symptoms that are worst upon awakening, subside during the day, then may worsen at night	Unilateral symptoms common but can be bilateral; constant day and night
Sneezing	Frequent, paroxysmal	Little or none
Rhinorrhea	Anterior, watery	Posterior, watery or thick and/or mucopurulent (associated with an infection)
Pruritus (itching) of eyes, nose, and/or palate	Frequent	Not present

Symptoms/Findings	Allergic Rhinitis	Nonallergic Rhinitis^a
Nasal obstruction	Variable	Usually present and often severe
Conjunctivitis (red, irritated eyes with prominent conjunctival blood vessels)	Frequent	Not present
Pain	Sinus pain due to congestion may be present; throat pain due to postnasal drip irritation may be present.	Variable depending on cause
Anosmia	Rare	Frequent
Epistaxis	Rare	Recurrent
Facial, nasal, or throat features	“Allergic shiners” (periorbital darkening secondary to venous congestion)	Nasal polyps Nasal septal deviation Enlarged tonsils and/or adenoids
	“Dennie’s lines” (wrinkles beneath the lower eyelids)	
	“Allergic crease” (horizontal crease just above bulbar portion of the nose secondary to the “allergic salute”)	
	“Allergic salute” (upward “swipe” of tip of the nose with palm of the hand)	
	“Allergic gape” (open-mouth breathing secondary to nasal obstruction)	
	Nonexudative “cobblestone” appearance of posterior oropharynx	

^a Depending on the cause of the nonallergic rhinitis, not all signs and symptoms may be present.

Source: [References 39](#) and [42](#).

Table 11-12 Causes of Nonallergic Rhinitis

Hormonal	Systemic Inflammatory
Pregnancy, puberty, thyroid disorders	Eosinophilic nonallergic rhinitis (NARES)
Structural	Lesions
Septal deviation, adenoid hypertrophy	Nasal polyps, neoplasms
Drug-Induced	Traumatic
Cocaine, beta blockers, ACEIs, chlorpromazine, clonidine, reserpine, hydralazine, oral contraceptives, aspirin or other NSAIDs, overuse of topical decongestants	Recent facial or head trauma
	Autonomic (Vasomotor)
	Age-related; physical or chemical agent causing parasympathetic hyperactivity

Key: ACEIs = Angiotensin-converting enzyme inhibitors; NARES = nonallergic rhinitis with eosinophilia syndrome; NSAIDs = nonsteroidal anti-inflammatory drugs.

Source: [Reference 42](#).

Acute complications of allergic rhinitis include sinusitis and otitis media with effusion. Complications of a chronic nature include nasal polyp formation, sleep apnea, sinusitis, and hyposmia (diminished sense of smell).^{37,39,40} Allergic rhinitis and asthma share a common pathology, and allergic rhinitis has been implicated in the development of asthma and in exacerbations of preexisting asthma in children and adults. Depression, anxiety, sexual dysfunction, delayed speech development, and facial or dental abnormalities also have been linked to allergic rhinitis.^{37,39,40}

Algorithm: Allergic Rhinitis

Figure 11–3 Self-care for allergic rhinitis. Key: ADR = Adverse drug reaction; AH = antihistamine; AR = allergic rhinitis; COPD = chronic obstructive pulmonary disease; HCP = health care provider; IAR = intermittent allergic rhinitis; INCS = intranasal corticosteroids; PER = persistent allergic rhinitis; Rx = prescription.

Treatment of Allergic Rhinitis

Treatment Goals

Allergic rhinitis cannot be cured. The goals of therapy are to reduce symptoms and to improve the patient's functional status and sense of well-being. Treatment is individualized to provide optimal symptomatic relief and/or control.

General Treatment Approach

Allergic rhinitis is treated in three steps: allergen avoidance, pharmacotherapy, and immunotherapy.^{39,40,42} Patient education is an important part of all three steps, especially regarding continuous allergen avoidance and the administration of nonprescription medications (for instructions, see [Table 11–2](#) for intranasal preparations and [Chapter 28](#), “Ophthalmic Disorders,” for ophthalmic drugs). The algorithm in [Figure 11–3](#) outlines the self-treatment approach for episodic allergic rhinitis, IAR, and PER and lists exclusions for self-treatment.^{39,40} Because allergen avoidance alone typically is not sufficient to provide complete relief in allergic rhinitis, targeted therapy with single-entity drugs is usually initiated. Nonprescription therapy with intranasal corticosteroids (INCS), antihistamines, or decongestants usually can control most symptoms. Agents with different mechanisms of action or delivery systems may be added if single-drug therapy does not provide adequate relief, or if symptoms are already moderately severe, particularly intense, or long-lasting.

Nonpharmacologic Therapy

Allergen avoidance is the primary nonpharmacologic measure for

management of allergic rhinitis. Avoidance strategies depend on the specific allergen. House-dust mites (*Dermatophagoides* spp.), found in all but the driest regions of the United States, thrive in warm, humid environments. The main allergen is a fecal glycoprotein, but other mite proteins and proteases also are allergenic. Avoidance strategies, targeted at reducing the mite population, include lowering the household humidity to less than 40%, applying acaricides, and reducing mite-harboring dust by removing carpets, upholstered furniture, stuffed animals, and bookshelves from the patient's bedroom and other rooms if possible. Mite populations in bedding are reduced by encasing the mattress, box springs, and pillows with mite-impermeable materials. Bedding should be washed at least weekly in hot (131°F [55°C]) water.

Outdoor mold spores are prevalent in late summer and fall, especially on calm, clear, dry days. *Alternaria* and *Cladosporium* are common outdoor allergenic molds; *Penicillium* and *Aspergillus* are common indoor molds. Avoiding activities that disturb decaying plant material (e.g., raking leaves) lessens exposure to outdoor mold. Indoor mold exposure is minimized by lowering household humidity, removing houseplants, venting food preparation areas and bathrooms, repairing damp basements or crawl spaces, and frequently applying fungicide to obviously moldy areas.

Cat-derived allergens (the Fel d1 family of proteins, secreted through sebaceous glands in the skin) are small and light, and they stay airborne for several hours. Cat allergens can be found in the home months after the pet is removed. Although of unproven benefit, weekly cat baths may reduce the allergen load.

Cockroaches are a major source of urban allergens; their saliva, feces, and body parts all have been implicated. To eliminate cockroaches, patients should be encouraged to keep kitchen areas clean, to keep stored food tightly sealed, and to treat infested areas with baits or pesticides.

Pollutants (e.g., ozone, diesel fumes) are an additional concern in urban environments. Pollutants such as diesel exhaust particles are especially irritating to the respiratory tract and have been shown to increase the severity of allergic rhinitis.^{39,40} Patients whose allergies are triggered by air pollutants should be aware of the air quality index (AQI)—a measure of five major air pollutants per 24 hours—and should plan outdoor activities when the AQI is low.

In general, trees produce pollen in spring, grasses in early summer, and ragweed from mid-August to the first fall frost. Knowledge of pollen counts (the number of pollen grains per cubic meter per 24 hours) will help patients plan outdoor activities. Most patients are symptomatic when pollen counts are very high, and only very sensitive patients have symptoms when pollen counts are low. Pollen counts are highest early in the morning and lowest after rainstorms clear the air. Avoiding outdoor activities when pollen counts are high and closing house and car windows will reduce pollen exposure.

Ventilation systems with high-efficiency particulate air (HEPA) filters remove pollen, mold spores, and cat allergens from household air but not fecal particles from house-dust mites, which settle to the floor too quickly to be filtered. Filters need to be changed regularly to maintain effectiveness. The systems are expensive and not effective for all patients. HEPA filters also are found in some vacuum cleaners. Weekly vacuuming of carpets, drapes, and upholstery with a HEPA filter–equipped vacuum cleaner may help reduce household allergens, including those from house-dust mites.⁴²

Use of nasal wetting agents (e.g., saline, propylene, polyethylene glycol sprays, gels) or nasal irrigation with warm saline (isotonic or hypertonic) delivered using a syringe or Neti pot may relieve nasal mucosal irritation and dryness, thus decreasing nasal stuffiness, rhinorrhea, and sneezing. These measures also aid in the removal of dried, encrusted, or thick mucus from the nose. No significant adverse effects have been noted with use of nasal wetting agents. Mild stinging or burning has been noted with saline irrigation. Only distilled, sterile, or boiled tap water should be used to prepare nasal irrigation solutions because of the risk of rare but serious infections.

Pharmacologic Therapy

INCS regimens have been shown to be the most effective treatment for most symptoms of allergic rhinitis.^{39,40,42} Other nonprescription options include ocular and oral antihistamines, topical and oral decongestants, and mast cell stabilizers. Patients should start taking INCS, antihistamines, and mast cell stabilizers at least 1 week before symptoms typically appear or as soon as possible before expected allergen exposures. Length of the therapeutic course for these medications should be individualized according to duration and severity of symptoms, pattern of allergen exposure (episodic or continuous), and geographic location.

Intranasal Corticosteroids

INCS, also known as glucocorticoids, are very effective agents for treatment of nasal symptoms such as itching, rhinitis, sneezing, and congestion, because they inhibit multiple cell types and mediators, including histamine, and effectively stop the “allergic cascade.”^{39,40} Budesonide, fluticasone furoate, fluticasone propionate, and triamcinolone acetonide are FDA approved for nonprescription use for nasal symptoms.⁴³ Fluticasone furoate and fluticasone propionate have additional FDA approval status for nonprescription use to treat ophthalmic symptoms such as itchy or watery eyes.⁴³ FDA-approved dosages for INCS are listed in [Table 11–13](#).⁴³

Table 11–13 Nonprescription Intranasal Corticosteroid Products and Dosage Guidelines

Drug	Brand Name	Strength	Dosage ^a
Budesonide	Rhinocort Allergy Spray	32 mcg/spray	<i>Adults and children ≥ 12 years:</i> Use 2 sprays in each nostril once daily; once allergy symptoms improve, reduce to 1 spray in each nostril per day.
			<i>Children 6–11 years:</i> Use 1 spray in each nostril once daily; if allergy symptoms do not improve, may increase to 2 sprays in each nostril per day. Once allergy symptoms improve, reduce to 1 spray in each nostril per day.
			<i>Children < 6 years:</i> Do not use.
Fluticasone furoate	Flonase Sensimist	27.5 mcg/spray	<i>Adults and children ≥ 12 years:</i> Week 1: Use 2 sprays in each nostril once daily. Weeks 2–26: Use 1 or 2 sprays in each nostril once daily. After 26 weeks of daily use without improvement, consult appropriate HCP.
	Children's Flonase Sensimist		<i>Children 2–11 years:</i> Use 1 spray in each nostril once daily. After 8 weeks of daily use without improvement, consult appropriate HCP.
			<i>Child < 2 years:</i> Do not use.
Fluticasone propionate	Flonase Allergy Relief	50 mcg/spray	<i>Adults and children ≥ 12 years:</i> Week 1: Use 2 sprays in each nostril once daily. Weeks 2–26: Use 1 or 2 sprays in each nostril once daily. After 26 weeks of daily use without improvement, consult appropriate HCP.

Drug	Brand Name	Strength	Dosage ^a
	Children's Flonase Allergy Relief		<i>Children 4–11 years:</i> Use 1 spray in each nostril once daily. For persistent symptoms after 8 weeks of daily use, consult appropriate HCP.
			<i>Child < 4 years:</i> Do not use.
Triamcinolone acetonide	Nasacort Allergy 24HR	55 mcg/spray	<i>Adults and children ≥ 12 years:</i> Use 2 sprays in each nostril once daily; once allergy symptoms decrease, reduce to 1 spray in each nostril per day.
	Children's Nasacort Allergy 24HR		<i>Children 6–11 years:</i> Use 1 spray in each nostril once daily; if allergy symptoms do not subside, may increase to 2 sprays in each nostril per day. Once allergy symptoms decrease, reduce to 1 spray in each nostril per day.
			<i>Children 25 years:</i> Use 1 spray in each nostril once daily.
			<i>Children < 2 years:</i> Do not use.

^a Patients should be instructed to shake bottle before use to ensure suspension is mixed and uniform.

Key: HCP = Health care provider.

Source: [Reference 43](#).

INCS usually are well tolerated. Adverse effects typically are minor and include nasal discomfort or bleeding, sneezing, cough, and pharyngitis. INCS exhibit variable systemic absorption (e.g., fluticasone <2% versus budesonide 34%). Patients who are sensitive to INCS or who use higher-than-recommended doses may experience systemic effects such as headache, dizziness, nausea, and vomiting. Additionally, long-term use has been linked to changes in vision, glaucoma, cataract formation, increased risk of infection (e.g., *Candida*), and growth inhibition in children. INCS have few drug interactions, as listed in [Table 11–6](#).

Antihistamines

Since the 1940s, antihistamines have been used to treat allergies.^{39,40} These drugs are classified as sedating (first-generation, nonselective) or nonsedating (second-generation, peripherally selective). The role of sedating antihistamines in treating allergic rhinitis is controversial. Sedating antihistamines are effective, readily available without a prescription, and relatively inexpensive. However, these antihistamines expose patients to risks associated with their anticholinergic effects and should be used with caution.

Antihistamines compete with histamine at central and peripheral histamine type 1 (H₁) receptor sites, preventing the histamine receptor interaction and subsequent mediator release. In addition, second-generation antihistamines inhibit the release of mast cell mediators and may decrease cellular recruitment.

Differences among antihistamines relate to the rapidity and degree to which they penetrate the blood–brain barrier as well as to their receptor specificity. Sedating antihistamines are highly lipophilic molecules that readily cross the blood–brain barrier. Nonsedating antihistamines are large protein-bound lipophobic molecules with charged side chains that reduce their ability to cross the blood–brain barrier. Both types of antihistamines are highly selective for H₁ receptors but have little effect on H₂, H₃, or H₄ receptors. The sedating antihistamines have anticholinergic, antiserotonin, and anti- α -adrenergic effects.

Each antihistamine chemical class (Table 11-14) differs slightly in terms of its activity and adverse effect profile.^{44,45} Most sedating antihistamines are well absorbed after oral administration, with time to peak plasma concentrations in the range of 1.5–3 hours. Protein binding is in the range of 78%–99%, and sedating antihistamines undergo significant first-pass metabolism through the cytochrome P450 system. Half-lives vary widely—for example, 2–10 hours for diphenhydramine versus 20–24 hours for chlorpheniramine.

Table 11-14 Antihistamine Classes

Class With Specific Drug Entities	Properties
Alkylamines: brompheniramine, chlorpheniramine,	Moderately sedating; strong anticholinergic effects; higher risk of paradoxical CNS stimulation than with

Class With Specific Drug Entities	Properties
dexbrompheniramine, dexchlorpheniramine, pheniramine, triprolidine	other classes
Ethanolamines: diphenhydramine, doxylamine	Highly sedating; strong anticholinergic effects; with large doses, risk for seizures and arrhythmias
Ethylenediamines: pyrilamine, thonzylamine	Weak CNS effects; increased GI effects
Phenothiazines: promethazine	Highly sedating; strong anticholinergic effects; block alpha-adrenergic receptors; more likely to cause hypotension; other potential effects: akathisia and dystonic reactions
Piperidines: fexofenadine, loratadine	Nonsedating
Piperazines: cetirizine, chlorcyclizine, hydroxyzine, levocetirizine, meclizine	Minimally to moderately sedating

Key: CNS = Central nervous system; GI = gastrointestinal.

Source: [References 44](#) and [45](#).

The nonsedating antihistamines are also rapidly absorbed after oral administration, with time to peak plasma concentrations in the range of 1–3 hours. Loratadine has the highest protein binding at 97% and is extensively metabolized by the liver to an active metabolite (desloratadine), whereas cetirizine, fexofenadine, and levocetirizine are minimally metabolized. Half-lives range from 8 hours (for cetirizine, levocetirizine, loratadine) to 14 hours (for fexofenadine).

Antihistamines are indicated for relief of symptoms of allergic rhinitis (e.g., itching, sneezing, rhinorrhea) and other types of immediate hypersensitivity reactions. FDA-approved dosages for systemic antihistamines are listed in [Table 11–15](#).¹¹ Nonprescription antihistamines are marketed as immediate-release and sustained-release tablets and capsules, chewable tablets, oral disintegrating tablets, solutions, and syrups. Alcohol-free, sucrose-free, and

dye-free formulations are available. (See [Chapter 28](#) for a discussion of ophthalmic antihistamines.)

Table 11-15 Dosage Guidelines for Systemic Nonprescription Antihistamines

Drug	Dosage ^a (maximum daily dosage)		
	Adults/Children ≥ 12 Years	Children 6 to < 12 Years	Children 2 to < 6 Years ^b
Brompheniramine maleate	4 mg every 4–6 hours (24 mg)	2 mg every 4–6 hours (12 mg)	1 mg every 4–6 hours (6 mg)
Cetirizine HCl ^c	10 mg every 24 hours (10 mg)	5–10 mg every 24 hours (10 mg)	2.5 mg every 12 hours or 2.5–5.0 mg every 24 hours (5 mg)
Chlorcyclizine HCl ^d	25 mg every 6–8 hours (75 mg)	Not recommended for children <12 years except under advice of HCP	–
Chlorpheniramine maleate	4 mg every 4–6 hours (24 mg)	2 mg every 4–6 hours (12 mg)	1 mg every 4–6 hours (6 mg)
Dexbrompheniramine maleate	2 mg every 4–6 hours (12 mg)	1 mg every 4–6 hours (6 mg)	0.5 mg every 4–6 hours (3 mg)
Dexchlorpheniramine maleate	2 mg every 4–6 hours (12 mg)	1 mg every 4–6 hours (6 mg)	0.5 mg every 4–6 hours (3 mg)
Diphenhydramine citrate	38–76 mg every 4–6 hours (456 mg)	19–38 mg every 4–6 hours (228 mg)	9.5 mg every 4–6 hours (57 mg)
Diphenhydramine HCl	25–50 mg every 4–6 hours (300 mg)	12.5–25 mg every 4–6 hours (150 mg)	6.25 mg every 4–6 hours (37.5 mg)
Doxylamine succinate	7.5–12.5 mg every 4–6 hours (75 mg)	3.75–6.25 mg every 4–6 hours (37.5 mg)	1.9–3.125 mg every 4–6 hours (18.75 mg)
Fexofenadine ^e	60 mg every 12 hours or 180 mg every 24 hours (180 mg)	30 mg every 12 hours (60 mg)	30 mg every 12 hours (60 mg)
Levocetirizine ^e	5 mg every 24 hours (5 mg)	2.5 mg every 24 hours (2.5 mg)	1.25 mg every 24 hours (1.25 mg)
Loratadine	10 mg every 24	10 mg every 24 hours (10	5 mg every 24 hours

Drug	Dosage ^a (maximum daily dosage)		
	Adults/Children ≥ 12 Years	Children 6 to < 12 Years	Children 2 to < 6 Years ^b
	hours (10 mg)	mg)	(5 mg)
Phenindamine tartrate ^d	25 mg every 4–6 hours (150 mg)	12.5 mg every 4–6 hours (75 mg)	6.25 mg every 4–6 hours (37.5 mg)
Pheniramine maleate	12.5–25 mg every 4–6 hours (150 mg)	6.25–12.5 mg every 4–6 hours (75 mg)	3.125–6.25 mg every 4–6 hours (37.5 mg)
Pyrilamine maleate	25–50 mg every 6–8 hours (200 mg)	12.5–25 mg every 6–8 hours (100 mg)	6.25–12.5 mg every 6–8 hours (50 mg)
Thonzylamine HCl ^d	50–100 mg every 4–6 hours (600 mg)	25–50 mg every 4–6 hours (300 mg)	12.5–25.0 mg every 4–6 hours (150 mg)
Tripolidine HCl ^d	2.5 mg every 4–6 hours (10 mg)	1.25 mg every 4–6 hours (5 mg)	Age 4–6 years: 0.938 mg every 4–6 hours (3.744 mg)
			Age 2 to <4 years: 0.625 mg every 4–6 hours (2.5 mg)
			Age 4 months to <2 years: 0.313 mg every 4–6 hours (1.25 mg)

^a Taken as needed.

^b With the exception of cetirizine, fexofenadine, levocetirizine, and loratadine, these products are not recommended for children younger than 6 years, except with the advice and supervision of an HCP. FDA recommends that the labels on nonprescription products not provide dosing information for children younger than 6 years.

^c For adults older than 65 years, 10 mg cetirizine is not recommended, except with the advice and supervision of an HCP.

^d Drug is FDA approved but not currently marketed in the United States.

^e For adults older than 65 years, fexofenadine and levocetirizine are not recommended,

except with the advice and supervision of an HCP.

Key: FDA = U.S. Food and Drug Administration; HCP = health care provider.

Source: [Reference 11](#).

Sedating antihistamine overdoses are characterized by excessive H₁, cholinergic, alpha-adrenergic, and serotonergic receptor blockade.⁴⁵ Overdoses also cause excessive blockade of fast sodium channels and potassium channels, leading to cardiac symptoms (tachycardia and conduction abnormalities, including torsades de pointes).⁴⁵ CNS signs and symptoms include toxic psychosis, hallucinations, agitation, lethargy, tremor, insomnia, and tonic-clonic seizures. Children tend to be more sensitive to CNS excitatory effects, and adults are more likely to experience CNS depression.⁴⁵ Peripheral signs and symptoms include hyperpyrexia, mydriasis, vasodilation, decreased exocrine secretion, urinary retention, decreased GI motility, dystonic reactions, and rhabdomyolysis. Overdoses of nonsedating antihistamines are characterized by drowsiness, restlessness/hyperactivity, and tachycardia. Treatment of antihistamine overdoses is supportive.

The adverse effect profile of systemic antihistamines varies widely and depends on the receptor activity, chemical structure, and lipophilicity of the specific drug. The primary adverse effects, CNS effects (depression and stimulation) and anticholinergic effects, are common with first-generation antihistamines but are rarely seen with second-generation agents. CNS-depressive effects include sedation and impaired performance (e.g., impaired driving performance, poor work performance, incoordination, reduced motor skills, and impaired information processing).⁴⁵ CNS-stimulatory effects include anxiety, hallucinations, appetite stimulation, muscle dyskinesias, and activation of epileptogenic foci. Adverse effects associated with cholinergic blockage include dryness of the eyes and mucous membranes (mouth, nose, vagina), blurred vision, urinary hesitancy and retention, constipation, and reflex tachycardia. Skin eruptions may occur with use of second-generation antihistamines, especially in children. If such lesions appear, antihistamines should be stopped and subsequently reintroduced to establish or exclude an association.

Antihistamines interact with numerous drugs ([Table 11–6](#)).⁴⁴ All antihistamines decrease or prevent immediate dermal reactivity and should be discontinued at least 4 days before scheduled allergy skin testing. Fexofenadine should not be taken with any fruit juices (e.g., grapefruit, apple, orange). Fruit juice is thought to reduce absorption of fexofenadine by directly inhibiting intestinal organic anion–transporting polypeptides (OATPs), specifically OATP1A2.⁴⁶ Separating fexofenadine dose and fruit juice consumption by at least 2 hours will avoid this interaction.⁴⁶

Sedating antihistamines are contraindicated in newborns or premature infants, lactating women, and patients with narrow-angle glaucoma. Additional contraindications include acute asthma exacerbation, stenosing peptic ulcer, symptomatic prostatic hypertrophy, bladder neck and pyloroduodenal obstruction, and concomitant use of MAOIs. Formulations of 12- and 24-hour sustained-release loratadine/pseudoephedrine combination products are contraindicated in patients with esophageal narrowing, abnormal esophageal peristalsis, or a history of difficulty swallowing tablets.

In patients with lower respiratory tract diseases (e.g., emphysema, chronic bronchitis), caution is recommended with use of sedating antihistamines. People whose activities require mental alertness should not use sedating antihistamines and should be advised to use levocetirizine and cetirizine with caution. Function may be impaired even if the patient does not feel drowsy or took the dose the previous evening. The sedating antihistamines are photosensitizing drugs. Patients should be advised to use sunscreen and to wear protective clothing.

Combination Antihistamine Products

Antihistamines are marketed in combination with decongestants and analgesics. Those combinations are also available in sustained-release formulations, allowing convenient dosage regimens. These combination products should be used with caution, however, because of the increased risk of adverse effects, especially insomnia, which compounds the daytime fatigue already associated with allergic rhinitis.

Decongestants

Congestion is a common allergic rhinitis symptom controllable with systemic decongestants or with short-term (~5 days) use of topical nasal decongestants.

Patients with allergic rhinitis may also have mild intermittent asthma symptoms such as wheezing, chest tightness, and shortness of breath. Besides its decongestant properties, epinephrine is also a bronchodilator and is available as an oral inhaler (Primatene Mist), which delivers 0.125 mg/spray. The inhaler is FDA approved for temporary relief of symptoms in patients older than 12 years of age who have already been diagnosed with asthma by a medical provider. Patients may use 1–2 sprays every 4 hours, up to a maximum of 8 sprays in 24 hours. Patients should seek medical care or further evaluation if symptoms are not relieved in 20 minutes or worsen after use, or if they experience more than two exacerbations per week. (See earlier discussion of decongestants for the topic “Colds.”)

Cromolyn Sodium

Cromolyn is a mast cell stabilizer indicated for preventing and treating the symptoms of allergic rhinitis. Cromolyn is thought to work by blocking the influx of calcium into mast cells, thereby preventing mediator release. Less than 7% of an intranasal cromolyn dose is absorbed systemically, and what little is absorbed has no systemic activity. The absorbed drug is rapidly excreted unchanged in the feces and urine, with a half-life of 1–2 hours.

Cromolyn is approved for use in patients 2 years of age or older; the recommended dosage is 1 spray in each nostril 3–6 times daily at regular intervals.¹¹ Treatment is more effective if started before symptoms begin. It may take 3–7 days for initial clinical improvement to become apparent and 2–4 weeks of continued therapy to achieve maximal therapeutic benefit. Sneezing is the most common adverse effect reported for intranasal cromolyn. Other adverse effects include nasal stinging and burning. No drug interactions have been reported with intranasal cromolyn.

Pharmacotherapeutic Comparison

INCS have been shown to be the most effective agents for treatment of moderate to severe IAR and both types of PER. Monotherapy with INCS is considered first-line treatment.^{39,40,42} If additional symptom control is needed, combination therapy with antihistamines, decongestants, or mast cell stabilizers can be initiated. Owing to their quick onset of action, oral antihistamines are first-choice agents for symptom control in episodic allergic rhinitis. Both sedating and nonsedating antihistamines are effective. Some

evidence suggests greater efficacy for the sedating type in treating symptoms of allergic rhinitis.⁴⁷ However, this evidence is based on trials using the maximum daily dosage (50 mg) of diphenhydramine.⁴⁷ Sedating antihistamines have a rapid onset of action, but the duration of action also is shorter, and multiple daily doses are required. The risks of cognition impairment and sedation have been well established with this class of drugs.⁴⁵ The World Health Organization strongly recommends nonsedating antihistamines on the basis of their efficacy and safety profile, quick onset of action, and longer duration, which allows once-daily dosing.^{39,46}

Cetirizine has been shown to be a more potent antihistamine than either loratadine or fexofenadine.⁴⁶ However, it is more likely to cause sedation (occurring in approximately 10% of patients).

Product Selection Guidelines

Special Populations

Because pregnancy is a common cause of nonallergic rhinitis, pregnant women should be referred for differential diagnosis. If allergic rhinitis is confirmed and nonprescription therapy is approved by a primary care provider, several treatment choices are available.²³ (Please refer to the Preface for a detailed explanation of the pregnancy data.) Intranasal cromolyn is considered compatible with pregnancy and is a first-line option.²³ Diphenhydramine and chlorpheniramine also are considered compatible with pregnancy.²³ Levocetirizine, loratadine, and cetirizine are considered to carry a low risk for adverse fetal effects, whereas fexofenadine is associated with moderate risk.²³ INCS are considered compatible with pregnancy. However, systemic use of budesonide and triamcinolone has been linked to cleft lip and palate and low birth weight.²³ Nonprescription allergy products do not appear to affect male reproductive function.

Lactating women diagnosed with allergic rhinitis and approved for self-treatment by a primary care provider have fewer options. Because of its limited systemic absorption, intranasal cromolyn is a good choice, and adverse effects in nursing infants have not been reported.²³ INCS are low-molecular-weight molecules and are thought to be excreted in breast milk. Reports of INCS causing harm in nursing infants are lacking, however, and they are considered “probably compatible.”²³ Antihistamines are contraindicated during lactation

because of their ability to pass into breast milk. Short-acting chlorpheniramine, fexofenadine, or loratadine seems to be the best option if an oral antihistamine is needed, but such medication should be used with caution and under the supervision of a primary care provider. If an oral antihistamine is used during lactation, the mother should avoid long-acting and high-dose antihistamines and should take the dose at bedtime after the last feeding of the day.²³

Because of concerns regarding undiagnosed asthma, children younger than 12 years should be referred to a primary care provider for differential diagnosis.^{39,40} If nonprescription therapy is approved by a primary care provider, several treatment choices are available for children.^{39,40,46} Intranasal cromolyn, fluticasone furoate, and triamcinolone acetonide are safe for children 2 years of age and older, intranasal fluticasone propionate is safe for children 4 years and older, and intranasal budesonide is safe for children 6 years and older. However, these products may be difficult for children to self-administer. In addition, all three INCS have been linked to growth inhibition in children; FDA-mandated labeling for the nonprescription products encourages parents to speak to an appropriate health care provider if they plan to use these products in children for longer than 2 months per year.⁴³ Loratadine is the nonprescription antihistamine of choice, followed by fexofenadine, levocetirizine, and cetirizine. Sedating antihistamines should be avoided in children because of paradoxical excitation and risk for serious adverse events with misuse.⁴⁶

Sedating antihistamines should be avoided in older patients because they are more likely than younger adults to be taking concomitant medications with anticholinergic properties and are at increased risk for CNS-depressive adverse effects, including confusion as well as hypotension.⁴⁸ Those adverse effects contribute to a higher risk of falling in this population.⁴⁸ Loratadine and intranasal cromolyn are drugs of choice in older patients. Dosage of fexofenadine and levocetirizine should be adjusted in patients with renal impairment. Loratadine and cetirizine dosage should be adjusted in patients with renal and/or hepatic impairment.

Patient Factors and Preferences

The duration of treatment and the presence of concomitant symptoms will determine which antihistamine product is selected ([Table 11-16](#)). Product selection also may be based on adverse effect profiles and cost. For example,

all first-generation antihistamines are sedating, but the degree of sedation depends on chemical class ([Table 11-14](#)). Nonsedating antihistamines are more expensive but carry less risk of sedation and impairment, which may justify the additional cost. Some patients report that antihistamines are less effective after prolonged use. This decline is most likely not indicative of true tolerance but rather stems from several factors, including patient nonadherence to dosing regimens, an increase in antigen exposure, worsening of disease, limited effectiveness of antihistamines in severe disease, and the development of similar symptoms from unrelated diseases. Chemical class differences make it reasonable to suggest switching to a different class of antihistamine if the patient has a less-than-optimal response to a specific antihistamine agent. Patient sensory perception of INCS characteristics also may influence therapy. Alcohol-free formulations may be preferred by patients who are sensitive to smell, taste, or aftertaste of nasal preparations.

Table 11-16 Selected Nonprescription Products for Allergic Rhinitis

Trade Name	Primary Ingredient(s)
Systemic First-Generation Antihistamine Products	
Chlor-Trimeton Allergy (4, 8, or 12 Hour) Tablets	Chlorpheniramine 4, 8, or 12 mg, respectively
Benadryl Allergy Tablets	Diphenhydramine HCl 25 mg
Children's Benadryl Allergy Liquid	Diphenhydramine HCl 12.5 mg/5 mL
Systemic Second-Generation Antihistamine Products	
Zyrtec Tablets	Cetirizine 10 mg
Children's Zyrtec Allergy Syrup	Cetirizine 5 mg/5 mL
Allegra Allergy 24 hour Tablets	Fexofenadine 180 mg
Children's Allegra Meltable Tablets	Fexofenadine 30 mg
Xyzal Allergy 24HR Tablets	Levocetirizine 5 mg
Children's Xyzal Allergy 24HR Oral Solution	Levocetirizine 2.5 mg/5 mL
Claritin Non-Drowsy Tablets	Loratadine 10 mg

Trade Name	Primary Ingredient(s)
Alavert Allergy Orally Disintegrating Tablets	Loratadine 10 mg
Combination Systemic Products	
Children's Dimetapp Cold and Allergy	Brompheniramine 1 mg/5 mL; phenylephrine 2.5 mg/5 mL
Zyrtec D Tablets	Cetirizine 5 mg; pseudoephedrine HCl 120 mg
Advil Allergy Sinus Caplets	Chlorpheniramine 2 mg; pseudoephedrine HCl 30 mg; ibuprofen 200 mg
Allegra D 12-Hour Tablets	Fexofenadine 60 mg; pseudoephedrine HCl 120 mg
Claritin-D 24 Hour Tablets	Loratadine 10 mg; pseudoephedrine sulfate 240 mg
Nasal Products	
Ayr Saline Nasal Gel	Sodium chloride; aloe; propylene glycol; glycerin
NasalCrom Spray	Cromolyn sodium 5.2 mg/spray
Ocean Spray	Sodium chloride 0.65%

Complementary Therapies

Ephedra (ma huang) and feverfew are commonly suggested herbal remedies for allergic rhinitis. Ephedra-containing products are banned by FDA owing to their serious adverse effects (e.g., stroke). Parthenolide, feverfew's biologically active component, may have anti-inflammatory properties, but its safety and efficacy in allergic rhinitis are unproved. (For further discussion of these types of products, see [Chapter 51](#).) Capsaicin-based nasal sprays (e.g., Sinus Buster) have shown promise in treating nonallergic rhinitis but not allergic rhinitis. Using local honey or homeopathic products containing known allergens (e.g., bioAllers Animal Hair and Dander Allergy Relief Liquid contains cat, cattle, dog, horse, and sheep wool extracts) to induce long-term resistance by repeated exposure to controlled amounts of allergen has not been proved to be safe or effective. Safety and efficacy data also are lacking for symptom-specific homeopathic remedies such as Sabadilla for nasal and ocular symptoms (red, watery eyes) and Wyethia for itching (See [Chapter 52](#) for a complete discussion of homeopathic products). The role of vitamin D in prevention and treatment

of allergic disorders is an emerging area of research.⁴⁹ Several small studies have shown patients with low dietary intake and low plasma vitamin D levels, especially in children, were more likely to have allergic rhinitis.⁴⁹ More research is needed on the role of vitamin D in the pathophysiology of allergies.

Assessment of Allergic Rhinitis: A Case-Based Approach

Asking the patient for a detailed description of signs and symptoms and obtaining the patient’s medical and medication use (previous and current) history are essential to determining whether the patient has allergic rhinitis or rhinitis related to other causes and is eligible for self-care ([Tables 11–11](#) and [11–12](#)).

The medical history may uncover other respiratory illnesses that complicate treatment of allergic rhinitis. The patient’s current medication list will alert the health care provider to possible interactions with nonprescription allergy medications. Any nonprescription products the patient has used to treat episodic allergic rhinitis, IAR, or PER should be identified, as well as whether they were effective and without adverse effects.

Case 11–2 presents an example of the assessment of a patient with allergic rhinitis.

Case 11–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of severe daytime fatigue and “runny nose” for the past 3 months.

Relevant Evaluation Criteria	Scenario/Model Outcome
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms started while patient was pregnant and she gave birth 3 weeks ago. Nothing seems to help.
c. Description of the patient's efforts to relieve the symptoms	Patient has tried Zicam nasal spray, Afrin nasal spray, and diphenhydramine.
d. Patient's identity	Elizabeth McKay
e. Patient's age, gender, height, and weight	36 years, female, 5 ft 7 in., 210 lb
f. Patient's occupation	Psychologist
g. Patient's dietary habits	Patient describes a well-balanced diet.
h. Patient's sleep habits	Patient reports disrupted sleep and probably only gets 4 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Multivitamin 1 tablet every morning
j. Allergies	No known allergies
k. History of other adverse reactions to medications	None
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Allergic rhinitis commonly manifests as sneezing, itchy nose or eyes, and a "runny nose." Symptoms usually are worse in the morning and at night, with some relief during the day. Nonallergic rhinitis symptoms typically are present the entire day and do not include sneezing or itchy eyes and nose.
3. Identify exclusions for self-treatment (Figure 11-3).	Ms. McKay has symptoms of nonallergic rhinitis.
4. Formulate a comprehensive list of therapeutic alternatives for the	Options include

Relevant Evaluation Criteria	Scenario/Model Outcome
primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	(1) Refer patient to an appropriate health care provider. (2) Recommend self-care with a nonprescription antihistamine and nondrug measures. (3) Recommend self-care until patient can see an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. McKay should consult an appropriate health care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult your primary care provider or other medical provider for treatment."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best, because your problem started when you were pregnant and has not resolved with various nonprescription products."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	n/a
Solicit follow-up questions from the patient or caregiver.	"Is this contagious?"
Answer the patient's or caregiver's questions.	"No. Your condition appears to be nonallergic rhinitis and may be due to anatomic changes in your nose

Relevant Evaluation Criteria	Scenario/Model Outcome
	related to your pregnancy.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Ms. McKay in 1–2 days to ensure that she sought medical care and made an appointment.

Key: n/a = Not applicable.

Patient Counseling for Allergic Rhinitis

The health care provider should emphasize that the best method of treating allergic rhinitis is to avoid allergens. Many patients, however, have no control over their work environment or are unable to implement all of the preventive measures at home. Such patients usually rely on allergy medications for symptom control. Patient counseling should include information about proper use of recommended medication(s) and about possible adverse effects, drug–drug and drug–disease interactions, and other precautions and warnings. The health care provider also should be aware of duplication of therapy with prescription INCS. Patient counseling should especially emphasize signs and symptoms indicating that the disorder has progressed to the point at which medical care is needed. The box “Patient Education for Allergic Rhinitis” presents specific information to provide in patient counseling.

Patient Education for Allergic Rhinitis

The primary objective of self-treatment is to prevent or reduce symptoms, which in turn will improve functioning and enhance the patient’s sense of

well-being. In some cases, prescription therapy such as a short course of oral corticosteroids may be needed to help control symptoms; other therapies and measures may be initiated when symptoms are especially severe. For most patients, carefully following instructions for nonprescription allergy medications and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Avoidance of allergens is important regardless of whether allergy medications are being taken.
- For symptoms that develop mainly when the patient is outdoors:
 - Frequently check local pollen counts and air quality index.
 - Keep house and car windows shut; avoid yard work and outdoor sports on days with high levels of pollen (spring/summer), mold (late summer/fall), or pollution.
- For symptoms that occur mainly when the patient is indoors:
 - Try to remove the symptom trigger(s) (e.g., cats, house-dust mites, tobacco smoke, molds) from rooms.
 - Lower the humidity in the home to reduce molds. Use lower settings on humidifiers, repair damp basements and crawl spaces, vent kitchens and bathrooms, and remove houseplants.
 - Wash bedding in hot water (131°F [55°C]) every week, and encase mattresses and pillows in coverings resistant to house-dust mites.
- Nasal saline solutions may relieve nasal irritation and dryness, and aid in the removal of dried, encrusted, or thick mucus from the nose.

Nonprescription Medications

- Ask a health care provider for help in selecting an allergy medication that treats the most bothersome symptoms. If needed, additional medications can be added for other symptoms:
 - Intranasal steroids are effective for itchy eyes and noses,

sneezing, runny nose, and congestion.

- Antihistamines are effective for itching, sneezing, and runny nose but have little effect on nasal congestion.
 - Decongestants are effective for nasal congestion but have little effect on other symptoms.
 - Combination therapy with intranasal steroids, antihistamines, and decongestants is common.
 - Intranasal and ocular preparations are available to reduce nasal and eye symptoms, respectively.
 - Intranasal cromolyn is the preferred initial drug of choice during pregnancy and lactation. This medication is not absorbed into the body.
 - For intranasal products, follow the dosing and administration directions carefully. (See [Table 11–2.](#))
 - The most common adverse effects of nasal preparations include nasal stinging and burning.
- Allergy medications are more effective if they are used regularly rather than episodically:
 - If you have episodic or intermittent allergies, start allergy medications as soon as possible, before specific exposure to the allergen.
 - If you have persistent allergies, take allergy medications on a regular basis.

Nasal Congestion

- See the box “Patient Education for Colds” for information about relieving nasal congestion.

Rhinorrhea (Runny Nose) and Sneezing

- Many factors cause a “runny nose,” and depending on the causes, nonprescription steroids or antihistamines may only partially treat this symptom. Because some nonprescription antihistamines may make you very drowsy, the potential benefits of the medication must be weighed against the potential risks.

- Sneezing is a common and sometimes bothersome symptom. Sneezing may be reduced with nonprescription intranasal steroids or antihistamines. The potential benefits of using antihistamines must be weighed against the potential risks.
- Intranasal steroids and oral antihistamines are the preferred initial therapeutic agents for runny nose and sneezing in persons who are eligible for self-care (see exclusions in [Figure 11-3](#)).
- Note the following precautions for use of nonprescription intranasal corticosteroids:
 - Intranasal corticosteroids may irritate the nose or the bottle tip can injure the nose if it is used forcefully.
 - Follow the package labeling carefully and use the lowest dose for the shortest amount of time, especially in children.
 - If you have HIV infection/AIDS and are being treated with protease inhibitors, check with your primary care provider before using intranasal corticosteroids.

Antihistamines

- There are two types of antihistamines: sedating and nonsedating. Cetirizine, fexofenadine, levocetirizine, and loratadine are nonsedating antihistamines and usually do not cause significant drowsiness.
- Note the following adverse effects for antihistamines:
 - The sedating antihistamines cause drowsiness and impair mental alertness. Mental alertness is impaired even if you do not feel drowsy or if you took the dose the previous evening. While taking these medications, do not drive a vehicle, operate machinery, or engage in other activities that require alertness.
 - Sedating antihistamines may cause sensitivity to sunlight. Use sunscreens and wear protective clothing when outdoors.
 - Use of sedating antihistamines may cause dryness in your mouth, nose, and other areas of the body.
 - Children and older persons may experience unexpected and paradoxical excitement with sedating antihistamines.
 - Older patients should avoid sedating antihistamines and

may need lower doses of nonsedating antihistamines because they are more sensitive to the effects of these agents and more often take other medications that interact with these drugs.

- Do not use antihistamines:
 - If you are allergic to antihistamines or similar medications
 - If you are breastfeeding
- Do not give antihistamines to newborns or premature infants unless directed to do so by a qualified health care provider.
- Note the following precautions for use of nonprescription antihistamines:
 - Persons with glaucoma, stenosing peptic ulcer, symptomatic enlarged prostate, bladder neck obstruction, or stomach or intestinal blockage should not use sedating (first-generation) antihistamines.
 - Persons with lower respiratory tract disease (e.g., emphysema or chronic bronchitis) should be advised to use sedating antihistamines with caution.
 - Persons with esophageal narrowing, abnormal esophageal peristalsis, or problems swallowing tablets should not take the 12- or 24-hour sustained-release dosage forms of loratadine combined with pseudoephedrine. Esophageal obstruction and perforation have been reported with use of these sustained-release dosage forms.
- All antihistamines interact with the following drugs:
 - Alcohol, sedatives, opioid analgesics, and other central nervous system depressants may cause additive depressive effects when taken with antihistamines.
 - Anticholinergic drugs (e.g., ipratropium)
 - Potassium chloride, which may increase the risk of ulcer formation when taken with antihistamines
- Specific sedating antihistamines interact with certain drugs as follows:

- Chlorpheniramine may increase the adverse effects of phenytoin.
- Diphenhydramine may increase the adverse effects of metoprolol and brexpiprazole.
- Nonsedating antihistamines interact with specific drugs as follows:
 - Fexofenadine interacts with ketoconazole, erythromycin, and antacids. Also avoid taking with fruit juice.
 - Loratadine interacts with amiodarone.
- Store all medications according to the manufacturer's instructions.

When to Seek Medical Attention

- Seek medical attention in the following situations:
 - Your allergy symptoms worsen while you are taking nonprescription medications or do not decrease after 2–4 weeks of treatment.
 - You develop signs or symptoms of secondary bacterial infections (e.g., thick nasal or respiratory secretions that are not clear, oral temperature higher than 101.5°F [38.6°C], shortness of breath, chest congestion, wheezing, significant ear pain, rash).

Evaluation of Patient Outcomes for Allergic Rhinitis

Many patients achieve symptomatic relief with initial nonprescription drug therapy in 3–4 days, but complete relief of symptoms may take 2–4 weeks. After this time frame, a follow-up telephone call from the health care provider or a scheduled office appointment is recommended to determine whether symptom control has been achieved or if the patient is encountering any adverse effects or problems. A validated instrument such as the Rhinitis Control Assessment Test may be used to monitor response to therapy.⁵⁰

Patients who respond poorly to treatment should be assessed to determine whether they are practicing recommended allergen avoidance strategies and are adhering to medication regimens. Options for patients who do not achieve relief include increasing current medications to maximally effective dosages and changing to a different medication or dosage formulation. Patients who do not respond to nonprescription therapy should be referred back to their primary care providers for prescription medications such as intranasal antihistamines, systemic corticosteroids, leukotriene inhibitors, anticholinergics, or immunotherapy. In such cases, clinical reassessment also is indicated, and the diagnosis of allergic rhinitis may need to be reconsidered. Patients who demonstrate any of the warning signs or symptoms listed in the box “Patient Education for Allergic Rhinitis” should be referred to an appropriate health care provider.

Key Points for Disorders Related to Colds and Allergic Rhinitis

- Colds are self-limiting viral infections characterized by initial sore throat followed by nasal symptoms and nonproductive cough.
- Medical referral is appropriate for patients with suspected colds who are immunocompromised, have underlying cardiopulmonary diseases, or exhibit so-called alarm symptoms or signs (high fever, chest pain, shortness of breath, or wheezing).
- Treatment for colds is symptomatic and targeted at the most bothersome symptoms.
- Decongestants are the most common nonprescription agents for treatment for congestion related to colds and allergic rhinitis, but caution is advised with their use in patients with hypertension, diabetes, and other chronic diseases.
- The treatment approach to allergic rhinitis is sequential and consists of allergen avoidance, pharmacotherapy, and allergen immunotherapy.
- Medical referral is appropriate for patients with symptoms

suggestive of nonallergic rhinitis, otitis media, sinusitis, or lower respiratory tract problems such as pneumonia, asthma, or bronchitis, and for those patients who fail to respond to nonprescription medications.

- Antihistamines are commonly used to control allergic rhinitis symptoms. Nonsedating (second-generation) antihistamines are preferred over sedating (first-generation) antihistamines on the basis of safety and efficacy data.

Chapter 12: Cough

Authors: Karen J. Tietze

Cough is an important defensive respiratory reflex for airway protection. As a clinical problem, however, cough has potentially significant adverse physical and psychological consequences, as well as substantial economic impact. Cough is the most common symptom for which patients seek outpatient medical care.¹ It also is a common reason for emergency department visits. In 2015, cough was the second most common reason among children younger than 15 years for emergency department visits and the fourth most common reason for adult visits.² Americans spend more than \$8.6 billion annually on nonprescription cough and cold and related medications, more than for any other nonprescription sales category.³

Pathophysiology of Cough

Cough is initiated by stimulation of chemically and mechanically sensitive, vagally mediated bronchopulmonary and extrapulmonary sensory nerves in the pharynx, larynx, esophagus, and tracheobronchial airway epithelium.⁴ The number of afferent nerves activated and the intensity of activation may influence the cough threshold. Receptors in the larynx, trachea, and proximal large airways are more sensitive to mechanical stimulation, whereas distal airway receptors are more sensitive to chemical stimulation.⁵ A complex medullary brainstem network (“cough control center”) processes the sensory input and stimulates the motor efferents. Voluntary cough is controlled by the cerebral cortex.⁵ In viral infections, cough is mediated by a different, though not well understood, mechanism.⁶ The term *cough hypersensitivity syndrome* describes the proposed neural dysregulation resulting in cough associated with some chronic medical conditions.⁷

A cough starts with a deep inspiration, followed by closure of the glottis and forceful contraction of the chest wall, abdominal wall, and diaphragmatic muscles against the closed glottis; pressure within the thoracic cavity may reach 300 mm Hg.⁸ With reopening of the glottis, air is expelled with a velocity of approximately 11–15 m/second, propelling mucus, cellular debris, and foreign material out of the respiratory system.⁹ Cough may occur in epochs (“coughing

fits”).

Cough, classified as *acute* (duration of less than 3 weeks), *subacute* (duration of 3–8 weeks), or *chronic* (duration of more than 8 weeks), is a symptom of diverse infectious and noninfectious disorders ([Table 12-1](#)).^{10,11} In children, cough also may be a symptom of aspiration caused by poor coordination of sucking and swallowing or esophageal motility disorders. Angiotensin-converting enzyme inhibitors cause dry cough in approximately 13.5% of persons taking these medications, with a higher rate of cough (28%) for patients with heart failure.¹² Systemic and ophthalmic beta-adrenergic blockers may cause cough in patients with obstructive airway diseases such as asthma and chronic obstructive pulmonary disease (COPD).

Clinical Presentation of Cough

Coughs are described as productive or nonproductive. A *productive* cough (a wet or “chesty” cough) serves a useful physiologic purpose: evacuation of secretions from the lower respiratory tract that, if retained, could impair ventilation and the lungs’ ability to resist infection. Productive coughs may be effective, with easily expelled secretions, or ineffective to a variable degree, with secretions that are difficult to expel. The appearance of the expectorated secretions is not always a reliable diagnostic indicator, but this material typically is clear with bronchitis and purulent with bacterial infection. Anaerobic bacterial infections are associated with a distinct putrid malodor. *Nonproductive* cough (dry or “hacking” cough), which may be associated with viral and atypical bacterial infections, gastroesophageal reflux disease (GERD), cardiac disease, and some medications, serves no useful physiologic purpose.

Common complications of cough include exhaustion, sleep deprivation, musculoskeletal pain, hoarseness, excessive perspiration, social embarrassment, and urinary incontinence. Less common complications include cardiac dysrhythmias, syncope, stroke, pneumothorax, and rib fractures. Mechanical irritation from coughing may cause sore throat. Cough may lead to prolonged absence from work or school, withdrawal from social activities, and anxiety from fear that the cough is a symptom of a serious illness, such as cancer or tuberculosis.

Figure 12–1 Self-care for cough. Key: CHF = Congestive heart failure; COPD = chronic obstructive pulmonary disease; HIV = human immunodeficiency virus; T = temperature; UACS = upper airway cough syndrome; URI = upper respiratory infection.

Treatment of Cough

Treatment Goals

The primary goal of self-treatment for cough is to reduce the number and severity of coughing episodes. The secondary goal is to prevent complications.

Treatment is symptomatic. Recognition of the underlying disorder or condition—the basis for the cough—is required for effective and definitive management.

General Treatment Approach

Selection of a medication for self-care for cough depends on the nature and underlying cause of the cough. [Figure 12–1](#) lists exclusions for self-care.^{13–16} These exclusions are based on the presence of signs and symptoms of potentially serious medical conditions associated with cough that require further evaluation. *Antitussives* (cough suppressants) control or eliminate cough and are the drugs of choice for treatment of nonproductive cough. Antitussives should not be used to treat productive cough unless the potential benefit outweighs the risk (as with significant nocturnal cough). Suppression of productive coughs may lead to retention of lower respiratory tract secretions, increasing the risk of airway obstruction and secondary bacterial infection. *Protussives* (expectorants) change the consistency of mucus and increase the volume of expectorated sputum and may provide some relief for patients in whom coughing expels thick, tenacious secretions from the lungs with difficulty.

Table 12–1 Common Causes of Cough

Classification	Etiologic Contributors
Acute	Viral URTI (common cold), acute bacterial sinusitis, acute bronchitis, pertussis, allergic rhinitis, COPD exacerbations, pneumonia, environmental irritants
Subacute	Postinfectious (e.g., <i>Mycoplasma pneumoniae</i> , <i>Bordetella pertussis</i>), congestive heart failure with fluid overload
Chronic	UACS, asthma or asthma-like conditions, GERD, COPD, chronic bronchitis

Key: COPD = Chronic obstructive pulmonary disease; GERD = gastroesophageal reflux disease; UACS = upper airway cough syndrome; URTI = upper respiratory tract infection.

Source: [References 10](#) and [11](#).

Cough medications are marketed in a variety of dosage forms—syrups, liquids, solutions, suspensions, tablets, capsules, liquid gels, lozenges, oral granules, oral strips, topical ointments and creams, topical patches, and vaporizer solutions. Generic formulations are widely available. The U.S. Food and Drug Administration (FDA) permits various combinations of antitussives, protussives, analgesics, decongestants, and antihistamines. Of note, however, combinations of antitussives and protussives are potentially counterproductive. Unnecessary active ingredients contribute to increased risk for avoidable adverse effects and drug interactions.

Nonpharmacologic Therapy

Nonpharmacologic therapy includes use of nonmedicated lozenges and hard candies, humidification, interventions to promote nasal drainage, and hydration. Nonmedicated lozenges and hard candies may reduce cough by stimulating production of saliva, thereby decreasing throat irritation. Humidifiers (ultrasonic, impeller, and evaporative) increase the amount of moisture in inspired air, which may soothe irritated airways. However, high humidity may increase environmental mold, dust mites, white dust from minerals released into the air, and microorganisms. Vaporizers (humidifiers with a medication well or cup for volatile inhalants) produce a medicated vapor. Cool-mist humidifiers and vaporizers are preferred because fewer bacteria grow at the cooler temperatures and the risk of scalding with use of a hot water–based device is eliminated. Humidifiers and vaporizers require daily cleaning and weekly disinfection.

Babies and young children up to approximately 2 years of age cannot blow their noses; a rubber bulb nasal syringe may be used to clear the nasal passages and reduce cough caused by postnasal drip. Propping infants upright when they sleep and raising the head of the bed at night will promote drainage of nasal secretions.

Maintaining adequate hydration promotes formation of less viscous secretions that are easier to expel. Caution is warranted, however, with measures to increase hydration in patients with lower respiratory tract infections, heart failure, renal failure, or other medical conditions potentially exacerbated by overhydration.

Pharmacologic Therapy

Table 12–2 lists examples of antitussive and expectorant products.

Oral Antitussives

FDA-approved nonprescription oral antitussives include codeine (codeine, codeine phosphate, codeine sulfate), dextromethorphan (dextromethorphan, dextromethorphan hydrobromide), diphenhydramine (diphenhydramine citrate, diphenhydramine hydrochloride), and chlorpheniramine hydrochloride.¹⁷ Nonprescription oral antitussives typically are used as needed within the limits of the maximum recommended daily dose. Nonprescription topical antitussives also are typically used on an as-needed basis, not to exceed the maximum recommended daily dose.

Codeine

At antitussive dosages, codeine is a Schedule V narcotic available without a prescription in some states. Codeine-containing Schedule C–V products must contain no more than 200 mg of codeine per 100 milliliters.¹⁸

Codeine acts centrally on the medulla to increase the cough threshold. Codeine is methylmorphine; one or more metabolites (morphine, norcodone, and others) may be the active antitussive. Codeine is well absorbed orally, with a 15- to 30-minute time to onset of action and a 4- to 6-hour duration of effect. The elimination half-life is 2.5–3 hours. Ten percent of a codeine dose is demethylated in the liver to form morphine; approximately 3%–16% of the drug is eliminated unchanged in the urine. The complicated metabolic pathway includes cytochrome P450 (CYP) 2D6, CYP3A4, and uridine 5'-diphospho-glucuronosyltransferase (UGT) 2B7. CYP2D6 polymorphisms lead to unpredictable clinical response and potential toxicity in affected persons. Poor metabolizers may not benefit from codeine. Extensive metabolizers are at increased risk for sedation and respiratory depression.

Codeine is indicated for the suppression of nonproductive cough caused by chemical or mechanical respiratory tract irritation. In 2018, FDA limited the use of prescription opioid cough and cold medicines to adults 18 years and older.¹⁹ FDA did not address nonprescription codeine product labeling. Table 12–3 lists FDA-approved dosages for codeine and other nonprescription cough products.

Reduced doses are appropriate for patients of advanced age and the debilitated. Codeine is available as oral solutions, liquids, suspensions, and syrups in combination with other active ingredients, including guaifenesin, antihistamines, and decongestants. Alcohol-, dye-, gluten-, and sucrose-free formulations also are available.

Usual antitussive codeine dosages are associated with low toxicity and little risk of addiction. The most common adverse effects associated with antitussive codeine dosages are nausea, vomiting, sedation, dizziness, and constipation. The black box warning for codeine includes the risk of serious, life-threatening, or fatal respiratory depression and the risk of opioid addiction, abuse, and misuse. Codeine syrup containing the antihistamine promethazine hydrochloride, when mixed with soft drinks and/or alcohol and sometimes candy (common street names include “purple drank,” “sizzurp,” “syrup,” and “lean”), is abused for the sedative effect. The lethal dose of codeine in adults is 0.5–1 g, with death from marked respiratory depression and cardiopulmonary collapse. Concomitant use of codeine and central nervous system (CNS) depressants causes additive CNS depression. Strong CYP2D6 inhibitors may block the conversion of codeine to the active metabolites. [Table 12–4](#) lists clinically important codeine–drug interactions.²⁰ Codeine is contraindicated in patients with known codeine hypersensitivity and during labor when a premature birth is anticipated. Patients with impaired respiratory reserve (as in asthma or COPD) or preexisting respiratory depression, drug addicts, and persons who take other respiratory depressants or sedatives, including alcohol, should use codeine with caution.

Table 12-2 Selected Nonprescription Products for Cough	
Trade Name	Primary Ingredient(s)
Single-Ingredient Products	
Delsym, Robitussin Nighttime Cough DM, Hold DM, Robafen DM	Dextromethorphan
Robafen, Mucinex for Kids, Tussin	Guaifenesin
Vicks VapoDrops, Halls Mentho-Lyptus Drops	Menthol
Combination Products	
Vicks VapoRub, Mentholatum	Camphor/menthol/

Trade Name	Primary Ingredient(s)
	eucalyptus oil
Chlo Tuss EX	Chlophedianol/ guaifenesin
Guaiatussin AC, Virtussin A/C, Cheratussin AC	Codeine/guaifenesin
Mucinex-DM, Cheracol D, Vicks 44E, Robitussin Cough & Chest Congestion DM, Triaminic Cough and Cold Congestion	Dextromethorphan/ guaifenesin
Benylin Chesty Coughs	Diphenhydramine/ levomenthol

Dextromethorphan

Dextromethorphan is a nonopioid with no analgesic, sedative, respiratory depressant, or addictive properties at usual antitussive doses.

Dextromethorphan, the methylated dextrorotatory analogue of levorphanol (itself a codeine analogue), acts centrally in the medulla to increase the cough threshold. It is well absorbed orally, with a 15- to 30-minute time to onset of action and a 3- to 6-hour duration of effect. Dextromethorphan undergoes polymorphic metabolism, with a usual elimination half-life of 1.2–2.2 hours. However, the half-life may be as long as 45 hours in people with a poor metabolism phenotype.

Dextromethorphan is indicated for the suppression of nonproductive cough caused by chemical or mechanical respiratory tract irritation. The efficacy and safety of dextromethorphan as an antitussive drug in children have not been established.²¹ **Table 12–3** lists FDA-approved dextromethorphan dosages.

Table 12–3 Dosage Guidelines for Nonprescription Oral Antitussives and Expectorants

Drug	Dosage (maximum daily dose)		
	Adults/Children ≥12 Years	Children 6 to <12 Years	Children 2 to <6 Years ^a
Chlophedianol ^{b,c}	25 mg every 6–8 hours PRN (100 mg)	12.5 mg every 6–8 hours PRN (50 mg)	12.5 mg every 6–8 hours PRN (50 mg)
Codeine ^d	Adults 18 years of age and	Contraindicated	Contraindicated

Drug	Dosage (maximum daily dose)		
	Adults/Children ≥12 Years	Children 6 to <12 Years	Children 2 to <6 Years ^a
	older: 10–20 mg every 4–6 hours PRN (120 mg)		
Dextromethorphan hydrobromide ^b	10–20 mg every 4 hours or 30 mg every 6–8 hours PRN (120 mg)	5–10 mg every 4 hours or 15 mg every 6–8 hours PRN (60 mg)	2.5–5 mg every 4 hours or 7.5 mg every 6–8 hours PRN (30 mg)
Diphenhydramine citrate ^{b,c}	38 mg every 4 hours PRN (228 mg)	19 mg every 4 hours PRN (114 mg)	9.5 mg every 4 hours PRN (57 mg)
Diphenhydramine HCl ^{b,c}	25 mg every 4 hours PRN (150 mg)	12.5 mg every 4 hours PRN (75 mg)	6.25 mg every 4 hours PRN (37.5 mg)
Guaifenesin ^b	200–400 mg every 4 hours PRN (2.4 g)	100–200 mg every 4 hours PRN (1.2 g)	50–100 mg every 4 hours PRN (600 mg)

^a The Consumer Health Care Products Association announced in October 2008 that manufacturers were voluntarily updating cough and cold product labels to state “do not use” in children younger than 4 years.⁴⁵ These actions have not changed the official monograph for cold, cough, allergy, bronchodilator, and antiasthmatic drug products.¹⁷

^b Not recommended for use in children younger than 2 years; no FDA-approved dosing recommendations.

^c FDA recommends that the labels on nonprescription products not provide dosage information for children younger than 6 years.

^d Prescription cough and cold medications containing codeine or hydrocodone are contraindicated in children younger than 18 years of age.¹⁹

Key: CFR = *Code of Federal Regulations*; FDA = U.S. Food and Drug Administration; PRN = as needed.

Source: [Reference 17](#).

Table 12–4 Clinically Important Drug–Drug Interactions With Nonprescription Antitussive Agents^a

Antitussive	Drug/Drug Class	Potential Interaction	Management/Preventive Measure(s)
Codeine	Alvimopan	Opioid use increases the risk of alvimopan adverse reactions.	Discontinue opioids at least 7 days before initiating alvimopan.
Codeine	CNS depressants, including alcohol, benzodiazepines, sedating antihistamines, antipsychotics, antianxiety agents, cannabidiol	CNS depressants enhance the CNS depressant effect of codeine.	Avoid concurrent use if possible.
Codeine	Strong CYP2D6 inhibitors (e.g., bupropion, fluoxetine, paroxetine, quinidine, gerbinafine, dacomitinib)	Strong CYP2D6 inhibitors may block the metabolism of codeine to the active metabolites leading to a reduced effect.	Avoid concurrent use if possible.
Codeine	Strong CYP3A4 inducers (e.g., rifampin, phenytoin)	Strong CYP3A4 inducers may increase the metabolism of codeine to inactive metabolites, leading to a reduced effect.	Avoid concurrent use if possible.
Codeine	Eluxadoline	Codeine may enhance eluxadoline-associated constipation.	Avoid concurrent use if possible.
Codeine	Mixed agonist/antagonist opioids (e.g., buprenorphine)	Mixed agonist/antagonists may reduce the therapeutic effect of codeine.	Avoid concurrent use if possible.
Codeine	Naltrexone	Naltrexone may reduce the therapeutic effect of codeine.	Avoid concurrent use if possible.

Dextromethorphan	Strong CYP2D6 inhibitors (e.g., bupropion, fluoxetine, paroxetine, quinidine, terbinafine, dacomitinib)	Strong CYP2D6 inhibitors may decrease dextromethorphan metabolism, increasing the psychoactive effects of dextromethorphan.	Avoid concurrent use if possible.
Dextromethorphan	Serotonin reuptake inhibitors (e.g., citalopram, escitalopram, fluoxetine, sertraline, vilazodone)	Serotonin modulators may increase the risk of serotonergic (psychoactive) effects of dextromethorphan.	Avoid concurrent use if possible.
Dextromethorphan	MAO inhibitors, including rasagiline, selegiline, isocarboxazid, phenelzine, and tranylcypromine	MAO inhibitors may increase dextromethorphan-associated serotonergic adverse effects.	Avoid concurrent use if possible.

^a See [Chapter 11](#) (Table 11–6) for diphenhydramine–drug interactions.

Key: CNS = Central nervous system; CYP = cytochrome P450; MAO = monoamine oxidase.

Source: [Reference 20](#).

Dextromethorphan, as a single ingredient and in combination with active ingredients such as guaifenesin, acetaminophen, antihistamines, and decongestants, is marketed in the form of syrups, liquids, solutions, extended-release oral suspensions, elixirs, drops, gels, liquid-filled gel caps, tablets, capsules, powders, granules, strips, and lozenges. Alcohol-, sucrose-, gluten-, and dye-free formulations are available.

Dextromethorphan has a wide margin of safety. Adverse effects with usual doses are uncommon but may include drowsiness, nausea or vomiting, stomach discomfort, or constipation. Dextromethorphan overdoses cause confusion, excitation, nervousness, irritability, restlessness, and drowsiness, as well as severe nausea and vomiting; respiratory depression may occur with very high doses. Additive CNS depression occurs with alcohol, antihistamines, and psychotropic medications. The combination of monoamine oxidase

inhibitors (MAOIs) and dextromethorphan may cause *serotonergic syndrome* (manifested as increased blood pressure, hyperpyrexia, arrhythmias, and myoclonus). Dextromethorphan should not be taken for at least 14 days after the MAOI is discontinued. [Table 12–4](#) lists clinically important dextromethorphan–drug interactions. Patients who have known hypersensitivity to dextromethorphan or who have a previous history of dextromethorphan dependence should not take this drug.

Dextromethorphan is abused for its phencyclidine-like euphoric effect (“robotripping”).²² At least 17 states limit the sale of nonprescription cough medicine containing dextromethorphan to adults 18 years of age and older.²³ The usual requirement for sale is proof of age. Four progressive dose-related plateaus starting with doses as low as 1.5 mg/kg are described.²⁴ Each plateau is characterized by euphoric manifestations, ranging from mild stimulation and alcohol-like intoxication to dissociative hallucinations. Abuse of dextromethorphan may be associated with psychosis and mania; such abuse is especially common among male adolescents.²⁵

Diphenhydramine

Diphenhydramine, a nonselective (first-generation) antihistamine with significant sedating and anticholinergic properties, acts centrally in the medulla to raise the cough threshold. Second-generation antihistamines (e.g., loratadine, fexofenadine) lack antitussive activity. Diphenhydramine is well absorbed after oral administration, with a bioavailability of 40%–70%, a time to onset of action of approximately 15 minutes, and a duration of action of approximately 4–6 hours. The volume of distribution is 3.3–4.5 L/kg. Approximately one half of a dose of diphenhydramine is hepatically metabolized to *N*-demethyl, acetyl, and methoxyacetic acid, with a clearance rate of 0.4–0.7 L/kg per hour; the remainder is excreted unchanged in the urine.

Diphenhydramine is indicated for the suppression of nonproductive cough caused by chemical or mechanical respiratory tract irritation. [Table 12–3](#) lists FDA-approved diphenhydramine dosages. A common ingredient in cold and allergy products, diphenhydramine is available in multiple dosage formulations, including an alcohol-free syrup specifically indicated for cough. Signs and symptoms of diphenhydramine overdose include mild to severe CNS depression (e.g., mental confusion, sedation, respiratory depression),

hypotension, and CNS stimulation (e.g., hallucinations, convulsions).

Adverse effects of diphenhydramine include drowsiness, disturbed coordination, respiratory depression, blurred vision, urinary retention, dry mouth, and dry respiratory secretions. Uncommon adverse effects reported with use of this drug include acute dystonic reactions such as oculogyric crisis (sustained upturning of the eyeballs), torticollis (involuntary intermittent or sustained neck muscle contraction, often with a head tilt), and catatonia-like states, as well as allergic and photoallergic reactions. Diphenhydramine may cause excitability, especially in children. It also potentiates the depressant effects of narcotics, nonnarcotic analgesics, benzodiazepines, tranquilizers, and alcohol on the CNS, and it intensifies the anticholinergic effect of MAOIs and other anticholinergics. (See Table 11–6 in [Chapter 11](#) for clinically important diphenhydramine–drug interactions.) Diphenhydramine is contraindicated in patients with known hypersensitivity to diphenhydramine or structurally similar antihistamines. Diphenhydramine should be used with caution in patients with diseases or conditions potentially exacerbated by drugs with anticholinergic activity, including narrow-angle glaucoma, stenosing peptic ulcer, pyloroduodenal obstruction, symptomatic prostatic hypertrophy, bladder neck obstruction, asthma and other lower respiratory tract disease, elevated intraocular pressure, hyperthyroidism, cardiovascular disease, and hypertension. Because of the associated increased risk of toxicity, diphenhydramine-containing antitussives should not be used with any other diphenhydramine-containing product, including topical products.

Chlophedianol

Chlophedianol is a centrally acting oral antitussive originally marketed in 1960 as a prescription drug. Reintroduced as a nonprescription product in late 2009, chlophedianol is an alkylamine antihistamine derivative with antitussive, moderate local anesthetic, and mild anticholinergic effects. Chlophedianol is indicated for the suppression of nonproductive cough caused by chemical or mechanical respiratory tract irritation. [Table 12–3](#) lists the FDA-approved chlophedianol dosages. Chlophedianol is marketed in combination with guaifenesin, antihistamines, and/or decongestants in the form of oral liquids, syrups, and tablets. Sugar-, alcohol-, dye-, and gluten-free products are available.

Published data for chlophedianol are limited. Its time to onset of maximal

effect is longer than that for codeine (4 hours versus 30 minutes), in addition to a longer duration of action.²⁶ Chlophedianol is metabolized hepatically and eliminated renally. Adverse effects include excitation, hyperirritability, nightmares, hallucinations, hypersensitivity, and urticaria. Dry mouth, vertigo, visual disturbances, nausea, vomiting, and drowsiness have been associated with large doses. Chlophedianol–drug interactions have not been evaluated. Chlophedianol is contraindicated in patients with known chlophedianol hypersensitivity.

Protussives (Expectorants)

Guaifenesin (glyceryl guaiacolate), the only FDA-approved expectorant, is indicated for the symptomatic relief of acute, ineffective productive cough.¹⁷ Guaifenesin is not indicated for chronic cough associated with chronic lower respiratory tract diseases such as asthma, COPD, or emphysema, or for smoker's cough. Guaifenesin purportedly loosens and thins lower respiratory tract secretions, making minimally productive coughs more productive. Recent randomized, placebo-controlled trials in adults with cough associated with respiratory tract infections failed to demonstrate significant effects on sputum biophysical properties.^{27,28} Although its pharmacokinetic properties are not well described, guaifenesin appears to be well absorbed after oral administration, with a half-life of approximately 1 hour.

Table 12–3 lists FDA-approved dosages of guaifenesin. Guaifenesin is marketed as oral liquids, syrups, solutions, granules, and immediate-release and extended-release tablets. Alcohol-, sucrose-, and dye-free formulations also are available. Most reports of guaifenesin overdose involve combinations of drugs and therefore are difficult to assess. However, signs and symptoms of overdose appear to be extensions of the adverse effects.

Guaifenesin generally is well tolerated. Adverse effects include nausea, vomiting, dizziness, headache, rash, diarrhea, drowsiness, and stomach pain. Large doses of this agent, either alone or in combination with ephedrine or pseudoephedrine, have been associated with development of renal calculi.²⁹ No guaifenesin–drug interactions have been reported. Guaifenesin is contraindicated in patients with a known hypersensitivity to guaifenesin.

Topical Antitussives

Camphor and menthol are the only FDA-approved topical antitussives.¹⁷ Other volatile oils (e.g., eucalyptus), common in many cough and cold preparations, impart a strong medicinal odor to products but are not FDA-approved antitussives. At subtherapeutic doses, menthol is a common flavoring agent. Although the mechanism of action is not well described, inhaled camphor and menthol vapors stimulate afferent sensory neuron “cold and menthol receptors” (TRPM8) within the nose and mucosa, creating a local anesthetic sensation and a sense of improved airflow; cough reflex sensitivity may be suppressed with these agents.³⁰ However, objective evidence of antitussive efficacy is very limited. Skin, nose, or eye burning sensations and/or irritation may occur with topical application. A possible drug interaction between menthol cough drops and warfarin resulting in reduced warfarin response has been reported.³¹ Table 12–5 provides administration guidelines for these agents.

Camphor- and menthol-containing ointments, creams, and solutions may splatter and cause serious burns if used near an open flame or placed in hot water or in a microwave oven. Camphor and menthol vapors may be ciliotoxic and proinflammatory throughout the upper and lower airways, especially in young children.³² These products also are toxic if ingested. Toxic effects include burning sensations in the mouth, nausea and vomiting, epigastric distress, restlessness, excitation, delirium, seizures, and death. Lethal oral doses in adults, children, and infants are approximately 4 grams, 0.5–1 gram, and 70 mg/kg, respectively.³³

Table 12–5 Administration Guidelines for Nonprescription Topical Antitussives (Adults and Children ≥2 Years^a)

Formulation	Administration
Ointments ^b	Apply a thick layer and rub on the throat and chest; application may be repeated PRN up to 3 times daily or as directed by primary care provider; loosen clothing around throat and chest so vapors reach the nose and mouth; cover with a warm, dry cloth (optional). Do not use in the nostrils, under the nose, by the mouth, on damaged skin, or with tight bandages.
Lozenges ^c	Allow lozenge to dissolve slowly in mouth; repeat hourly or as needed or as directed by a primary care provider.
Inhalation ^d	For products intended to be added directly to cold water for use in a steam vaporizer: Add measured solution to cold water; place the mixture in the vaporizer;

	breathe in the medicated vapors up to 3 times daily PRN.
	For products to be placed in the medication chamber of a hot steam vaporizer: Add water to vaporizer; place solution in medication chamber; breathe in the medicated vapors up to 3 times daily PRN.

^a For children younger than 2 years of age, consult a primary care provider.

^b Camphor 4.7%–5.3%; menthol 2.6%–2.8%.

^c Menthol lozenges, available in 5- or 10-mg formulation.

^d Camphor 6.2%; menthol 3.2%.

Key: PRN = As needed.

Source: [Reference 17](#).

Product Selection Guidelines

Efficacy

Although antitussives and expectorants have been marketed for decades, efficacy has been difficult to prove and may depend on the underlying cause of the cough. No good evidence is available to show that dextromethorphan, codeine, diphenhydramine, and guaifenesin are effective for treatment of acute cough in either adults or children^{34,35}; even less evidence is available for the efficacy of menthol, camphor, and chlophedianol.³⁶ Also lacking is evidence for or against the efficacy of nonprescription antitussives as adjuncts to antibiotics for the treatment of acute pneumonia.³⁷ Factors such as taste, smell, color, viscosity, sugar content, and personal expectation may contribute to a large placebo response (up to 85%).³⁸ Proof of efficacy will require data from well-designed trials in subjects with natural disease who are assessed with standardized objective outcome parameters. The American College of Chest Physicians (ACCP) publishes a series of evidence-based condition-specific cough guidelines.³⁹ With certain medical conditions, appropriate referral and assessment are required before initiation of nonprescription drug therapy.

Recommendations for the management of cough associated with specific

medical conditions include

- *Acute cough associated with the common cold:* Nondrug therapy is recommended for the generally benign and self-limiting cough associated with the common ⁴⁰ Antitussives, expectorants, antihistamines, and nonsteroidal anti-inflammatory drugs are ineffective.⁴¹
- *Postinfectious cough:* Nondrug therapy is recommended for management of subacute cough following an acute viral upper respiratory tract infection (“postinfectious cough”).⁴¹ An empiric trial of a first-generation antihistamine plus decongestant followed by a centrally acting antitussive (codeine or dextromethorphan) may be considered for cough persisting after a viral upper respiratory tract infection, but medical referral and assessment are required before initiation of such therapy.⁴¹ If necessary, codeine or dextromethorphan may be considered for postinfectious cough not due to bacterial sinusitis or *Bordetella pertussis* infection.⁴²
- *Upper airway cough syndrome (UACS):* In this syndrome, cough is caused by a variety of allergic and nonallergic conditions associated with upper airway irritation or inflammation, including postnasal drip (PND). Management is directed at eliminating the cause rather than controlling the cough. Following medical referral, empiric treatment of nonallergic UACS may include a first-generation antihistamine with or without an oral decongestant.⁴³
- *Cough associated with lower respiratory tract infection:* Provider assessment is needed before antitussives can be recommended for coughs associated with lower respiratory tract infections. The potential benefits from cough suppression (e.g., improved sleep) with centrally acting antitussives such as dextromethorphan or codeine may outweigh the potential risks (e.g., respiratory depression, retained secretions).

Dosage Formulations

Cough products are marketed in a variety of dosage formulations. Efficacy appears to be the same for all dosage formulations; patients may select a specific product on the basis of preference and convenience. Most products are formulated for dosage intervals of 4–6 hours, but some liquid and tablet dosage forms are specifically formulated for an extended dosage interval. For

example, some dextromethorphan products are formulated with polymer complexes (e.g., sulfonated styrene–divinylbenzene copolymer), conferring an extended dosage interval (8–12 hours). Patients self-treating nocturnal cough may prefer a product with this advantage.

Special Populations

In January 2008, FDA issued a public health advisory recommending that because of the risk of serious side effects, nonprescription cough and cold medicines should not be used in infants and children younger than 2 years.⁴⁴ In October 2008, the Consumer Healthcare Products Association (CHPA) announced that manufacturers were voluntarily updating cough and cold product labels to state “do not use” in children younger than 4 years.⁴⁵ To address the issue of inaccurate dosing, FDA released guidelines in May 2011 for liquid nonprescription drug products that include any type of dispensing device (dropper, cup, syringe, or spoon).⁴⁶ These products include liquid analgesics, liquid cough and cold products, and lactase replacement drops. The key points of the guidance are recommendations that

- A dosing device be included with all oral liquid nonprescription products
- The device be calibrated to the dose recommended in the product directions
- The device be used only with the product in which it is packaged
- The markings remain visible even when the liquid is in the device

Codeine’s efficacy and safety as an antitussive drug in children are not established. In 2018, FDA limited the use of prescription opioid cough and cold medicines to adults 18 years and older.¹⁹ FDA did not address nonprescription codeine product labeling.

An increased risk of congenital birth defects has been recognized with use of codeine during the first trimester of pregnancy. Codeine should be used during pregnancy only if the potential benefits outweigh the risks.

Nonteratogenic concerns include the risk of neonatal respiratory depression if codeine is taken close to the time of delivery and neonatal withdrawal if codeine is used regularly during the pregnancy. Codeine is excreted in breast milk and is associated with drowsiness in nursing infants.⁴⁷ (See the Preface for a detailed explanation of the pregnancy data.) Because older adults may be more susceptible to the sedating effects of codeine, dosing in this age group

should be started at the lower end of the recommended range and titrated as tolerated, with careful monitoring.

Dextromethorphan is viewed as probably safe for use during pregnancy.⁴⁸ It is not known whether dextromethorphan is excreted in breast milk. (See the Preface for a detailed explanation of the pregnancy data.) Because older adults may be more susceptible to the sedating effects of dextromethorphan, dosing in this age group, as with codeine, should be started at the lower end of the recommended range and titrated as tolerated, with careful monitoring.

Diphenhydramine is commonly used during pregnancy, although no controlled studies have been conducted in pregnant women. Diphenhydramine is excreted in breast milk and may cause unusual excitation and irritability in the infant; it may also decrease the flow of milk. (See the Preface for a detailed explanation of the pregnancy data.) Compared with the general population, elderly persons are more likely to experience dizziness, excessive sedation, syncope, confusion, and hypotension with diphenhydramine. The 2019 American Geriatrics Society Beers Criteria identify diphenhydramine, along with other nonprescription and prescription first-generation histamine-1 (H₁) receptor antihistamines, as potentially inappropriate medications in older adults.⁴⁹ Children and the elderly may experience paradoxical excitation, restlessness, and irritability with diphenhydramine. Dosing for the latter age group should be started at the lower end of the dosage range and titrated as tolerated, with careful monitoring.

Controlled studies on the use of guaifenesin or chlorpheniramine during pregnancy or breastfeeding are lacking. (See the Preface for a detailed explanation of the pregnancy data.) No special considerations have emerged regarding use of guaifenesin by older adults. Chlorpheniramine should be used with caution in sedated or debilitated patients.

Some cough formulations contain alcohol. Alcohol is a known teratogen and should be avoided during pregnancy.

Patient Factors

Cough is a symptom of many acute and chronic diseases ([Table 12–6](#)). Patients with identified exclusions for self-care

Table 12–6 Signs and Symptoms of Medical Conditions Associated With Cough

Disorder	Signs and Symptoms
Acute bronchitis ("chest cold")	Nonproductive cough initially but becomes productive; mucus initially clear (later becomes white, yellow or green); cough persisting for 1–3 weeks; mild dyspnea, mild wheezing; usually afebrile though may have a low-grade fever
Asthma	Wheezing or chest tightness; shortness of breath; nonproductive cough predominantly at night; cough in response to specific irritants such as dust, smoke, or pollen
Chronic bronchitis	Productive cough most days of the month at least 3 months of the year for at least 2 consecutive years
COPD	Persistent progressive dyspnea; chronic productive cough (may be intermittent or nonproductive)
GERD	Heartburn, regurgitation with sour taste in mouth; dysphagia, chest pain, chronic nonproductive cough; worsening symptoms with supine position
HF	Exertional dyspnea and shortness of breath; chronic nonproductive cough; fatigue; dependent edema
Lower respiratory tract infection UACS	Fever (mild to high); productive cough (thick, purulent, discolored mucus); shortness of breath
Viral URTI ("common cold")	Chronic nonproductive cough (persisting 8 weeks or longer) with sensation of mucus in throat
Acute bronchitis ("chest cold")	Acute sneezing, sore throat, nasal congestion; low-grade fever, nonproductive cough

Key: COPD = Chronic obstructive pulmonary disease; GERD = gastroesophageal reflux disease; HF = heart failure; UACS = upper airway cough syndrome; URTI = upper respiratory tract infection.

([Figure 12–1](#)) should be referred for further evaluation. Patients with known chronic diseases associated with cough, or with signs and symptoms suggestive of such diseases, should not attempt to self-treat cough, even if it is caused by an acute viral upper respiratory tract infection (URTI), because the acute infection may exacerbate the underlying disease. Patients with smoker's cough should be counseled regarding smoking cessation options; antitussives and expectorants are not indicated (see [Chapter 47](#)).

Dextromethorphan and diphenhydramine should not be taken concurrently with MAOIs. Diphenhydramine is highly sedating and should be avoided by patients for whom the anticholinergic properties of the drug present a risk of adverse effects or complications. First-generation antihistamines and decongestants should be used only if the potential benefit outweighs the risk (see [Chapter 11](#)).

Complementary Therapy

Hundreds of herbal and other complementary therapies are marketed for cough. However, available evidence does not support the use of complementary therapies for treating cough, and for some products, potential safety issues have been recognized. (See [Chapters 51](#) and [52](#), respectively, for information on such therapies.) For example, honey, a common but unproven home remedy,⁵⁰ should not be given to children younger than 1 year because of the risk of botulism from ingestion of honey contaminated with *Clostridium botulinum*.⁴⁰

Assessment of Cough: A Case-Based Approach

Before recommending any treatment, the health care provider needs to determine the duration of the cough (acute, subacute, or chronic), the nature of the cough (productive or nonproductive), and the presence of any associated signs or symptoms suggesting that the patient has an acute or chronic medical condition requiring referral ([Figure 12–1](#)). The health care provider's assessment also should review the patient's current prescription and nonprescription medications, medication allergies, and history of adverse drug reactions. In addition, the health care provider should ascertain how the

patient has treated the current cough, as well as previous coughs, and whether these treatments were satisfactory or effective.

Cases 12–1 and 12–2 provide examples of the assessment of two different patients with cough.

Case 12–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptoms(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient presented to her PCP 3 weeks ago with a several-day history of fever and gradually worsening pharyngitis, sore throat, hoarseness, and dry cough. Her PCP told her she had "walking pneumonia" and prescribed antibiotics. All of her symptoms have resolved except for a dry hacking cough. Today her PCP recommended she try a nonprescription cough medicine.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptoms	The cough bothers her at night.
c. Description of the patient's efforts to relieve the symptoms	The patient tried Halls honey-lemon cough drops and homemade horehound-peppermint cough drops without relief.
d. Patient's identity	Rebecca Wynter
e. Patient's age, gender, height, and weight	25 years, female, 5 ft 5 in., 125 lb
f. Patient's occupation	Elementary school teacher (second grade)

Relevant Evaluation Criteria	Scenario/Model Outcome
g. Patient's dietary habits	Cereal (with milk), whole grain breads, green salads, lean meats, fresh vegetables and fruit, low-fat yogurt
h. Patient's sleep habits	Sleeps 8-9 hours a night
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	The patient has a history of seizures currently treated with Dilantin (diphenylhydantoin). No routine nonprescription medications.
	No supplements.
j. Allergies	No known drug allergies
k. History of other adverse reactions to medications	None
l. Other (describe): _____	None
Assess	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problems(s).	Rebecca is likely experiencing postinfectious subacute cough.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Take no action. (2) Recommend that the patient call her PCP for further assessment. (3) Recommend nondrug therapy (e.g., use a vaporizer at night). (4) Recommend self-care with a cough medication

Relevant Evaluation Criteria	Scenario/Model Outcome
	containing dextromethorphan or codeine.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Rebecca may treat her cough as needed with an antitussive containing dextromethorphan. The recommended dose for adults is dextromethorphan 10–20 mg every 4 hours as needed. Dextromethorphan is available in multiple dosage forms, including immediate- and extended-release tablets and capsules; lozenges; strips; and oral liquids, suspensions, and syrups. Single-entity products are preferred, to avoid potential side effects from unnecessary active ingredients.
6. Describe the recommended therapeutic approach to the patient or caregiver.	“Cough following pneumonia may be treated with a central-acting cough medication such as dextromethorphan or codeine. In our state, codeine-containing cough medications are available without a prescription. However, there is a known drug interaction between codeine and Dilantin resulting in reduced codeine effect. Avoid the combination if possible.”
	“Take dextromethorphan as needed for cough. Use an extended-release product before bedtime to help suppress cough throughout the night. Do not take more than the recommended dose for the specific product. Some medications may interact with dextromethorphan and some nonprescription medications (e.g., cold medications) may contain dextromethorphan. Ask your health care provider or PCP before starting any new medication.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Centrally active cough medications such as dextromethorphan and codeine may reduce post-pneumonia cough.”
Implement	
8. When recommending self-care with nonprescription	See the box “Patient Education for Cough.”

Relevant Evaluation Criteria	Scenario/Model Outcome
medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
Solicit follow-up questions from the patient or caregiver.	"Will dextromethorphan make me sleepy?"
Answer the patient's or caregiver's questions.	"Although dextromethorphan in usual doses is generally well tolerated, some people may experience dizziness, drowsiness, restlessness, nausea and vomiting, and stomach pain. Use caution when driving or performing tasks that require you to be awake and alert."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Rebecca to call to update you on her response to treatment.

Key: PCP = Primary care provider.

Case 12-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	

Relevant Evaluation Criteria	Scenario/Model Outcome
a. Description of symptoms(s) (i.e., nature, onset, duration, severity, associated symptoms)	A concerned spouse asks for something for her husband's cough. She states that his cough is worse than usual. He was diagnosed with COPD several years ago and did relatively well until about 6 months ago, when she noticed he was coughing more than usual. He coughs a lot, especially in the morning, when he brings up a large amount of clear mucus.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptoms.	The cough is worse in the mornings. His condition improved and his coughing was much less troublesome when he first started taking his COPD medications, but they do not seem to be working as well as they used to.
c. Description of the patient's efforts to relieve the symptoms	She states that her husband is very stoic. He has not told his pulmonologist about the worsening cough and has not tried any cough medications.
d. Patient's identity	Roger Marplewood
e. Patient's age, gender, height, and weight	56 years, male, 5 ft 10 in., 230 lb
f. Patient's occupation	Computer software engineer
g. Patient's dietary habits	Meat and potatoes; he does not like most fruits and vegetables.
h. Patient's sleep habits	Sleeps 10 hours a night
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	COPD diagnosed about 8 years ago. He currently takes Spiriva Respimat (tiotropium bromide) two inhalations once daily in the morning. He takes Motrin (ibuprofen) 2 tablets once or twice a week as needed for headaches. He does not take any dietary supplements.
j. Allergies	No known drug allergies
k. History of other adverse reactions to medications	None
l. Other (describe): _____	Used to smoke 2 packs a day but quit when he was diagnosed with COPD
Assess	

Relevant Evaluation Criteria	Scenario/Model Outcome
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problems(s).	Mr. Marplewood is likely experiencing worsening COPD symptoms.
3. Identify exclusions for self-treatment.	COPD
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Take no action. (2) Recommend that the patient see his primary care provider (PCP) or pulmonologist for further evaluation and treatment. (3) Recommend nondrug treatments (nonmedicated lozenges, take steamy baths/showers). (4) Recommend self-care with a nonprescription centrally acting antitussive or expectorant. (5) Recommend a combination of nondrug treatments, self-care with a nonprescription centrally acting antitussive or expectorant, and medical referral to his PCP or pulmonologist.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer Mr. Marplewood to his PCP or pulmonologist for further evaluation and management of his chronic cough. COPD is a progressive medical condition; changes in prescribed medication are common over time. Centrally acting antitussives may suppress respiration and therefore are not indicated for patients with COPD. The patient has a productive cough; expectorants are not indicated. Nondrug treatments are unlikely to reduce or resolve cough caused by COPD.
6. Describe the recommended therapeutic approach to	"Mr. Marplewood should consult with his pulmonologist about his worsening cough."

Relevant Evaluation Criteria	Scenario/Model Outcome
the patient or caregiver.	
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"It is common for patients with COPD to need to have their medications adjusted over time. Worsening cough may indicate that his COPD is getting worse and that his medications need to be reassessed."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"Are there any supplements for COPD that might help with the cough?"
Answer the patient's or caregiver's questions.	"No. Some Internet sites state that COPD may be treated with supplements such as ginseng, turmeric, or fish oil, but there is no evidence for their effectiveness, and risks are recognized with use of each of these supplements."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mrs. Marplewood to let you know if she or her husband has any questions.

Patient Counseling for Cough

The health care provider should identify appropriate drugs and describe nondrug measures for treating the patient's type of cough. After a product is

recommended, the dosage guidelines, drug administration techniques (for topical drugs), and possible adverse effects, drug–drug interactions, and precautions or warnings should be fully explained. The health care provider should ensure that the patient understands when self-care for the cough is no longer adequate and that medical care must be sought. For patients with underlying medical disorders, the health care provider should identify which nonprescription medications are contraindicated, with specific reasons as appropriate, and what symptoms indicate the need to seek medical care. The box “Patient Education for Cough” lists specific information for patients.

Patient Education for Cough

The goals of self-treatment are (1) to reduce the number and severity of cough episodes and (2) to prevent complications. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- Stay well hydrated.
- Reduce throat irritation by slowly dissolving nonmedicated lozenges and candies in the mouth.
- Use humidifiers and vaporizers to increase the moisture in the air and possibly soothe irritated airways.
- Treat the underlying cause of cough (e.g., allergies).

Nonprescription Medications

- Cough is a symptom of an underlying disorder. Contact your primary care provider if you have any exclusions for self-care (listed in [Figure 12-1](#)).
- Select a product on the basis of the active ingredients and dosage formulation. Brand names frequently change and may not clearly represent the active ingredients.
- Slowly dissolve medicated lozenges in your mouth; do not chew.
- Swallow tablets and capsules whole; do not crush or chew.

- Follow the recommended dosing guidelines for each medication.
- Store all of these medications according to the manufacturer's recommendations. Do not use any expired drug.

Cough Suppressants (Antitussives)

- Cough suppressants control or eliminate cough and are the drugs of choice for treatment of nonproductive cough.
- Oral nonprescription cough suppressants include codeine (available without a prescription in some states), dextromethorphan, diphenhydramine, and chlorpheniramine.
- Topical nonprescription antitussives include camphor and menthol.
- Do not heat or microwave topical antitussives or add these preparations to hot water. Do not use topical antitussives near an open flame. Topical antitussive ointments and liquids are toxic if ingested.
- The most common adverse effects of codeine include nausea, vomiting, sedation, dizziness, and constipation.
- Dextromethorphan's adverse effects are uncommon but may include drowsiness, nausea, vomiting, stomach discomfort, and constipation.
- The most common diphenhydramine adverse effects include drowsiness, disturbed coordination, decreased respiration, blurred vision, difficult urination, and dry mouth.
- The most common chlorpheniramine adverse effects include nausea, dizziness, and drowsiness.
- Codeine, dextromethorphan, diphenhydramine, and chlorpheniramine interact with drugs that cause drowsiness (e.g., narcotics, sedatives, some antihistamines, alcohol).
- Dextromethorphan interacts with monoamine oxidase inhibitors (e.g., phenelzine, tranylcypromine, isocarboxazid). Do not take dextromethorphan within 14 days of taking one of these medications.
- Diphenhydramine and chlorpheniramine interact with drugs that have anticholinergic activity.
- Patients with impaired respiratory reserve (e.g., asthma, chronic obstructive pulmonary disease) should use codeine and

diphenhydramine with caution.

- Patients with narrow-angle glaucoma, stenosing peptic ulcer, pyloroduodenal obstruction, symptomatic prostatic hypertrophy, bladder neck obstruction, elevated intraocular pressure, hyperthyroidism, heart disease, or hypertension should use diphenhydramine with caution.
- Talk with your primary care provider before using any medication while pregnant.
- Codeine and diphenhydramine are excreted in breast milk and may cause adverse effects in the child.
- Older adults and children may exhibit paradoxical excitation, restlessness, and irritability with use of diphenhydramine or chlorpheniramine. Older adults are more likely than the general population to experience adverse effects from diphenhydramine.

Expectorants (Protussives)

- Guaifenesin is the only available nonprescription protussive.
- Guaifenesin generally is well tolerated, but adverse effects may include nausea, vomiting, dizziness, headache, rash, diarrhea, drowsiness, and stomach pain.
- There are no reported drug interactions with guaifenesin.
- Guaifenesin is contraindicated in patients with a known hypersensitivity to the medication.
- Guaifenesin is not indicated for chronic cough associated with chronic lower respiratory tract diseases such as asthma, chronic obstructive pulmonary disease, or emphysema, or for smoker's cough.

Note About Pediatric Dosing

Manufacturers of cough and cold medications have revised product labeling to state that these products should not be used in children younger than 4 years. Health care providers should emphasize this information to caregivers of infants and young children.

Evaluation of Patient Outcomes for Cough

For most patients with cough who are candidates for selfmanagement, 7 days of nonprescription drug therapy should relieve cough. If, after 7 days of self-management, the cough persists but has lessened in severity, the patient may continue the self-management regimen until the cough resolves. Cough associated with viral URTIs usually resolves within 2 weeks but may persist for 3 weeks or longer. Cough associated with other respiratory infections typically resolves in 3–4 weeks. In all cases, the patient should be referred for further medical evaluation if the cough worsens or if other exclusions for self-treatment become apparent ([Figure 12–1](#)).

Key Points for Cough

- Cough is an important respiratory defensive reflex.
- Antitussives (cough suppressants) are the drugs of choice for treatment of nonproductive cough.
- Protussives (expectorants) are the drugs of choice for treatment of cough associated with thick, tenacious secretions expelled from the lungs with difficulty.
- Antitussives, expectorants, antihistamines, and nonsteroidal anti-inflammatory drugs have not been shown to be effective for acute cough associated with viral URTIs in either adults or children.
- In 2008, manufacturers voluntarily updated labels for cough and cold products to state “do not use” in children younger than 4 years of age.
- In 2018, FDA limited the use of prescription opioid cough and cold medicines to adults 18 years of age and older.
- Combination products are convenient but generally are more expensive per dose and are associated with increased risk of adverse effects and drug interactions.

- Referral to a primary care provider is warranted if the cough worsens or if signs or symptoms of a medical condition requiring further evaluation develop.
- Referral to a primary care provider also is warranted for patients with cough and a history or symptoms suggestive of a chronic underlying disease (e.g., asthma, COPD, chronic bronchitis, heart failure).

Chapter 13: Heartburn and Dyspepsia

Authors: Tara Whetsel, Gretchen Garofoli

Editor's Note: This chapter is based on the 19th edition chapter of the same title, written by Tara Whetsel and Ann Zweber.

Heartburn (pyrosis), one of the most common gastrointestinal (GI) complaints, is often described as a burning sensation in the stomach or lower chest that extends up toward the neck and occasionally to the back.¹ Patients also may describe it as indigestion, acid regurgitation, sour stomach, or bitter belching. Heartburn is the main symptom of gastroesophageal reflux disease (GERD), but similar symptoms also may occur in patients with peptic ulcer disease (PUD), delayed gastric emptying, gallbladder disease, or numerous other GI disorders. *Dyspepsia*, defined as symptoms originating from the gastroduodenal region, may manifest as bothersome postprandial fullness, early satiation, epigastric pain, or epigastric burning.² Patients with dyspepsia may report many of these symptoms, as well as anorexia, belching, nausea, vomiting, or upper abdominal bloating. Heartburn and regurgitation also can occur with dyspepsia. Dyspepsia can be organic (i.e., has an identifiable cause) or functional (i.e., has no identifiable organic, systemic, or metabolic disease that is likely to explain the dyspeptic symptoms).

Although reflux-related disturbances are rarely a cause of death, dyspepsia, heartburn, and GERD are associated with considerable morbidity, complications, and cost. Patients with GERD have a decreased quality of life, with symptoms often affecting activity, work, and sleep.^{1,3} Patients with heartburn may limit their activities and restrict food choices to reduce symptom frequency and severity. Nocturnal symptoms may impair a patient's functioning the next day owing to poor sleep quality.^{1,3,4} Patients with intense GERD symptoms miss an average of 2 hours of work per week as a direct result of their symptoms.¹ In 2014 there were over 5.2 million office visits for GERD.⁵ Health care expenditures for esophageal disorders were \$18.1 billion in 2015, with 54% accounted for by prescription medications.⁵ Consumers spent over \$2.6 billion in 2017 on nonprescription heartburn medications.⁶

The prevalence rates for heartburn and acid regurgitation (as reported over a 1-year period) in a healthy, predominantly white population were 42% and 45%, respectively.¹ Weekly symptoms were reported by 20% of the respondents.¹

Most subjects reported their heartburn to be moderate in severity, which was defined in the study as a level that cannot be ignored but does not affect lifestyle. A survey in an urban American city found that 50% of Hispanics, 37% of Caucasians, 31% of African Americans, and 20% of Asians experienced heartburn at least monthly.¹ Although men and women are affected almost equally by GERD, rates of esophagitis and Barrett's esophagus (a precancerous condition) are higher among male patients.³ GERD complications also are more frequent among older persons, but this population may experience fewer symptoms because they have decreased sensitivity to refluxed acid. The prevalence of GERD has been increasing in Western countries over the past 30 years, which parallels the increase in obesity within these regions.¹ Heartburn is common during pregnancy, with 30%–80% of women complaining of heartburn.¹

The reported prevalence of dyspepsia varies, ranging between 10% and 45%.² Much of this variation is influenced by criteria used to define dyspepsia. When heartburn is excluded, the prevalence of uninvestigated dyspepsia is 5%–15%.² Compared with men, women have a slightly higher prevalence. The incidence of dyspepsia has been estimated at 1%–6% per year.² Among patients with dyspepsia, 5%–10% also have a peptic ulcer and 20%–25% have erosive esophagitis.² The estimated annual health care expenditure in the United States for dyspepsia is over \$18 billion, and societal costs are thought to be double this amount.⁷ An estimated 2%–5% of patients miss work because of symptoms associated with this disorder.⁷

Pathophysiology of Heartburn and Dyspepsia

Esophageal defense mechanisms—antireflux barriers, esophageal acid clearance, and tissue resistance—help protect the esophageal mucosa from acid damage.¹ Antireflux barriers include the intrinsic lower esophageal sphincter (LES), the diaphragmatic crura, the intra-abdominal location of the LES, the phrenoesophageal ligaments, and the acute angle of His ([Figure 13–1](#)). These anatomic structures and features work together to provide a physical barrier against reflux of gastric contents into the esophagus. The major component is the LES, which is contracted at rest but relaxes on swallowing to permit the flow of food, liquids, and saliva into the stomach. Transient relaxations occur when there is no swallowing or esophageal peristalsis, allowing retrograde movement of stomach contents into the esophagus. The

crural diaphragm provides an extrinsic squeeze to the LES, contributing to resting pressure and augmenting LES contractile function during periods of increased abdominal pressure, such as with coughing, sneezing, or bending over. The angle of His creates a flap valve effect that contributes to the antireflux barrier.

Figure 13–1 Esophageal defense mechanisms—specifically, anatomic antireflux barriers—and physiologic factors associated with heartburn.

When reflux of acidic gastric material does occur, physiologic mechanisms help protect the esophageal mucosa from damage.¹ Esophageal acid clearance occurs when peristalsis moves refluxed material into the stomach, and saliva and esophageal gland secretions neutralize residual acid. Gravity also helps clear the esophagus. Tight junctions in esophageal mucosa and the intercellular space matrix further reduce epithelial damage from hydrogen ions. Epithelial cells also are capable of buffering and extruding hydrogen ions

that do penetrate the cell membrane. Tissue resistance is further aided by the esophageal blood supply, which delivers oxygen, nutrients, and bicarbonate, and removes hydrogen and carbon dioxide, thereby maintaining normal tissue acid–base balance. Even though gastroesophageal reflux is common, particularly postprandially, symptoms and esophageal damage are uncommon because of these esophageal defense mechanisms.⁸

Heartburn is likely related to stimulation of esophageal mucosal chemoreceptors.⁸ Acid reflux, weakly acidic reflux, bile reflux, and mechanical stimulation of the esophagus can cause heartburn symptoms.^{1,8} It is unclear why some reflux episodes produce symptoms while most do not. Possible contributing factors include mucosal disruption, decreased acid clearance, inflammation, reduced salivary bicarbonate concentration, volume of refluxate, frequency of heartburn, and interaction of pepsin with acid.⁸ One theory is that the esophagus becomes hypersensitive from repeated acid exposure, causing symptoms to occur with smaller boluses of acid.⁸

Any disruption in the esophageal defense mechanisms can lead to increased acid exposure. Distention of the proximal stomach by either food or gas is a major stimulus for transient LES relaxation episodes. Some patients may have decreased LES pressure that can be overcome by an abrupt increase in intra-abdominal pressure from coughing, straining, or bending over. A hiatal hernia occurs when the upper part of the stomach pushes upward through the diaphragm. The resultant mass effect impairs LES function and esophageal acid clearance. A hiatal hernia displaces the LES from the crural diaphragm, reduces LES pressure, and results in more frequent transient relaxations of the LES, all of which contribute to increased reflux. Although the role of a hiatal hernia in GERD is unclear, its presence is a recognized contributing factor in patients with Barrett's esophagus and esophageal cancer.

Prolonged exposure of esophageal tissue to refluxed material can occur in a lying or sleeping position, with decreased salivation, or with peristaltic dysfunction. Although the impact of delayed gastric emptying is controversial, large volumes of refluxate from delayed gastric emptying or overeating also can increase esophageal acid exposure. The resulting damage to the tight intercellular junctions of the esophageal mucosa can lead to increased cellular permeability to hydrogen ions, with subsequent cellular injury. This increased permeability partly explains the development of heartburn in the absence of overt esophagitis.¹ The composition of the refluxate is an important

determinant of the degree of esophageal damage. Pepsin and/or bile salts combined with acid produce greater injury than that seen with acid alone. *Helicobacter pylori* infection lowers gastric acidity, thereby possibly protecting against development of heartburn, GERD, and related complications.¹

A number of risk factors are weakly associated with the occurrence of heartburn (Table 13–1).^{1,8–12} Foods (e.g., fat, chocolate, peppermint) and medications (e.g., theophylline, morphine, calcium channel blockers, diazepam) can decrease LES pressure, leading to increased reflux. Citrus, tomato-based, and spicy foods irritate inflamed esophageal mucosa. Tobacco smoke contributes to heartburn by relaxing LES pressure and decreasing salivation. Anxiety, fear, and worry may lower visceral sensitivity thresholds, leading to increased pain perception. Bending over, straining to defecate, lifting heavy objects, and performing isometric exercises may increase intra-abdominal pressure above the LES pressure, leading to reflux. Obesity increases intra-abdominal pressure, and epidemiologic studies suggest that the prevalence of GERD is considerably higher in obese patients.¹ Central obesity, as measured by waist-to-hip ratio, may be a better predictor for the development of GERD than body mass index (BMI).¹ Daytime naps are associated with increased esophageal acid exposure and symptoms compared with nocturnal sleep.⁴ Sleeping on the right side is associated with increased reflux.⁸ Genetics also may play a role in the development of GERD, as family clustering of GERD along with its complications has been reported.¹

Table 13–1 Risk Factors That May Contribute to Heartburn and GERD

Dietary	Medications
Alcohol (ethanol)	Alpha-adrenergic antagonists
Caffeinated beverages	Anticholinergic agents
Carbonated beverages	Aspirin/other NSAIDs
Chocolate	Barbiturates
Citrus fruit or juices	Benzodiazepines
Coffee	Beta ₂ -adrenergic agonists
Fatty foods	Bisphosphonates
Garlic or onions	Calcium channel blockers

Mint (e.g., spearmint, peppermint)	Chemotherapy
Spicy foods	Dopamine
Sugars	Doxycycline
Tomatoes/tomato juice	Estrogen
Lifestyle	Iron
Emotions (anxiety, fear, worry)	Narcotic analgesics
Exercise (isometric, running)	Nitrates
Obesity	Oral contraceptives
Smoking (tobacco)	Potassium
Stress	Progesterone
Supine body position	Prostaglandins
Tight-fitting clothing	Quinidine
Diseases	TCA's
Insulin resistance (e.g., pre-diabetes, diabetes, PCOS)	Tetracycline
Motility disorders (e.g., gastroparesis)	Theophylline
PUD	Zidovudine
Scleroderma	Other
Sjögren disease	Genetics
Zollinger–Ellison syndrome	Pregnancy

Key: GERD = Gastroesophageal reflux disease; NSAIDs = nonsteroidal anti-inflammatory drugs; PUD = peptic ulcer disease; TCAs = tricyclic antidepressants.

Source: [References 1](#) and [8–12](#).

Dyspepsia may be caused by PUD, GERD, celiac disease (rarely), gastric or

esophageal malignancy (rarely), or other GI disorders. Specific foods (e.g., spicy food, coffee, alcohol) and excessive food intake have not been established as causing dyspepsia. However, certain medications (e.g., iron, antibiotics, narcotics, digoxin, estrogens and oral contraceptives, theophylline, levodopa, nonsteroidal anti-inflammatory drugs [NSAIDs]) commonly cause dyspepsia through direct gastric mucosal injury, changes in GI function, exacerbation of reflux, or some other mechanism.² The pathophysiology of functional dyspepsia is unclear but may include delayed gastric emptying, impaired gastric accommodation to food intake, hypersensitivity to gastric distention, altered duodenal sensitivity, abnormal intestinal motility, or central nervous system dysfunction.² One or more of these disturbances can occur in individual patients. The cause of symptoms in patients with functional dyspepsia has not been established, but population studies have suggested a genetic predisposition, infectious factors, and psychological components. *H. pylori* may play a role in functional dyspepsia, as evidenced by a small improvement in symptoms after eradication of the infection.

Patients who have recovered from gastroenteritis may suffer from postinfection functional dyspepsia. Psychosocial factors are an important contributor to symptom severity. Patients with functional dyspepsia also may have anxiety disorders, depression, somatoform disorders, or a recent or remote history of physical or sexual abuse. The exact mechanism is unknown, but some studies have suggested a relationship between psychosocial factors and visceral hypersensitivity.²

Clinical Presentation of Heartburn and Dyspepsia

Heartburn may occur alone or as a symptom of other GI disorders, such as GERD or PUD ([Table 13–2](#)). Heartburn is noted most frequently within 1 hour after eating, especially after a large meal, or with ingestion of offending foods or beverages. Lying down or bending over may exacerbate heartburn. Regurgitation and, less commonly, water brash may occur. Regurgitation is characterized by a bitter acidic fluid in the back of the throat; this phenomenon occurs more commonly after meals, at night, or upon bending over. It differs from vomiting in that nausea, retching, or abdominal contractions do not occur.^{1,8} *Water brash* is the sudden filling of the mouth

with clear, slightly salty fluid secreted from the salivary glands. Burping, hiccups, nausea, and vomiting are less common signs and symptoms that may occur with heartburn. Severity with any of these problems is subjective, and no standard definitions exist for classifying symptoms as “mild,” “moderate,” or “severe.” In general, symptoms may be considered *mild* if they bother the patient a little but do not interfere with normal activities. Symptoms that are somewhat bothersome or annoying, or that interfere with normal activities, may be considered *moderate*. Heartburn symptoms that occur two or more times per week are suggestive of GERD.¹ GERD can be complicated by erosive esophagitis, hemorrhage, esophageal ulcers, strictures, Barrett’s esophagus, and esophageal adenocarcinoma. Heartburn severity is poorly correlated with esophageal damage, especially in older patients who on presentation may have no or mild symptoms despite severe erosive esophagitis or other complications.¹ Upper endoscopy is the standard for determining the presence and extent of esophageal damage.

Table 13–2 Differentiation of Simple Heartburn From Other Acid-Related Disorders

	Simple Heartburn	GERD	Dyspepsia	PUD
Etiology	See Table 13–1 .	See Table 13–1 .	Possible contributing factors: food, alcohol, caffeine, stress, and medications Chronic dyspepsia: associated with PUD, GERD, celiac disease, and gastric cancer; or lacking an identifiable cause (functional dyspepsia)	Gastric or duodenal ulcer caused most commonly by <i>Helicobacter pylori</i> infection and/or NSAID use
Typical symptoms	Burning sensation behind the breastbone that may radiate toward the neck, throat, and, occasionally, the back	Heartburn, acid regurgitation	Primary: postprandial fullness, early satiation, epigastric pain, epigastric burning Other: belching, bloating, nausea, vomiting	Gnawing or burning epigastric pain, occurring during day and frequently at night; may be accompanied by heartburn and dyspepsia

Key: GERD = Gastroesophageal reflux disease; NSAID = nonsteroidal anti-inflammatory drug; PUD = peptic ulcer disease.

“Alarm symptoms” include dysphagia, odynophagia, vomiting, GI bleeding, and unexplained weight loss. These severe signs and symptoms can indicate more serious disease and/or complications. *Dysphagia* (difficulty swallowing) is slowly progressive for solid food and usually is associated with long-standing heartburn. The most common cause is peptic stricture or Schatzki’s ring, but severe esophagitis, peristaltic dysfunction, and esophageal cancer are other potential etiologic conditions.¹ *Odynophagia* (painful swallowing) is less common and may indicate severe ulcerative esophagitis, pill-induced injury (e.g., from tetracycline, potassium chloride, vitamin C, NSAIDs including aspirin, or bisphosphonates), or infection. Signs of GI bleeding include hematemesis, melena, occult bleeding, and anemia. Patients also may present with atypical or extraesophageal signs and symptoms related to gastroesophageal reflux. These include noncardiac chest pain, asthma, laryngitis, hoarseness, *globus sensation* (subjective sensation of a lump in the throat), chronic cough, recurrent pneumonitis, disordered sleep, and dental erosion.^{1,8} Alarm symptoms or atypical symptoms warrant evaluation by a primary care provider, with likely referral to a gastroenterologist.

Dyspepsia can manifest with one or more of four main symptoms. *Postprandial fullness* is an unpleasant sensation perceived as the prolonged persistence of food in the stomach. *Early satiation* (early satiety) is the feeling of fullness that occurs soon after eating begins and that is out of proportion to the amount of food ingested.² *Epigastric pain* is an unpleasant sensation between the umbilicus and lower end of the sternum. *Epigastric burning* refers to an unpleasant, subjective sensation of heat. Less specific manifestations may include bloating, nausea, vomiting, or belching. Symptoms are mostly intermittent and may or may not be related to meals. Weight loss is considered an alarm symptom that should prompt referral for further investigation. Other alarm symptoms include anemia, blood loss, and dysphagia.²

Algorithm: Heartburn

Figure 13–2 Self-care for heartburn. Key: H2RA = Histamine type 2 receptor antagonist; OTC = over-the-counter; PPI = proton pump inhibitor.

Treatment of Heartburn and Dyspepsia

Treatment Goals

The goals of self-treatment for heartburn and dyspepsia are (1) to provide complete relief of symptoms, (2) to reduce recurrence of symptoms, and (3) to prevent and manage unwanted effects of medications.

General Treatment Approach

The approach to self-treatment for heartburn and dyspepsia requires an initial assessment to determine whether the patient is a candidate for self-care (Figure 13–2). Patients with exclusions for self-treatment should be referred for further medical evaluation. When self-treatment is deemed appropriate, specific nondrug measures discussed in the section “Nonpharmacologic Therapy” should be recommended and continued throughout treatment. If indicated, a recommendation also should be made for a nonprescription medication. The selection of the medication should be based on frequency, duration, and severity of symptoms; the cost of the medication; potential drug–drug interactions and adverse effects; and the patient’s preference. Antacids or nonprescription histamine type 2 (H_2) receptor antagonists (H2RAs) should be recommended for patients with mild to moderate, infrequent heartburn or dyspepsia. Antacids are advantageous because they provide rapid relief of symptoms, but relief is short-lived when antacids are taken on an empty stomach (Table 13–3). When used in recommended doses, the different types of antacids are interchangeable despite differences in component salts and potency. Antacid/alginic acid combinations are more effective than antacids alone in reducing heartburn symptoms.^{12,13}

Table 13–3 Onset and Duration of Symptomatic Relief With Nonprescription Medications for Relieving Heartburn

Medication	Onset of Relief	Duration of Relief
Antacids	<5 minutes	20–30 minutes ^a
H2RAs	30–45 minutes	4–10 hours
H2RA + antacid	<5 minutes	8–10 hours
PPIs	1–3 hours	12–24 hours

^a Food prolongs duration of relief.

Key: H2RA = Histamine type 2 receptor antagonist; PPIs = proton pump inhibitors.

A nonprescription H2RA is preferable to an antacid when patients with mild to moderate episodic heartburn require more prolonged relief of symptoms. H2RAs do not relieve heartburn or dyspepsia as rapidly as antacids do ([Table 13–3](#)), but they may be used with an antacid if both quick relief and longer duration of action are desired. H2RAs also may be used to prevent heartburn and acid indigestion if they are given 30 minutes to 1 hour before situations in which heartburn is anticipated. Lower dose nonprescription H2RA products (e.g., famotidine 10 mg up to twice daily) should be recommended for patients with mild, infrequent heartburn. Higher dose nonprescription products (e.g., famotidine 20 mg up to twice daily) should be reserved for moderate symptoms. Patients should not exceed 14 days of self-treatment with an antacid or H2RA without consulting their primary care provider.

Nonprescription proton pump inhibitors (PPIs) can be used for treating frequent heartburn (occurring ≥ 2 days per week).¹⁴ PPIs work best when taken daily, unlike antacids and H2RAs, which are taken as needed. The onset of symptomatic relief after a PPI dose is slower than with an H2RA dose ([Table 13–3](#)), and complete relief of symptoms may take several days after initiation of therapy. However, compared with H2RAs, PPIs provide better symptomatic relief, with a prolonged duration of action. Self-treatment with a PPI should be limited to a duration of 14 consecutive days and retreatment to every 4

months.¹⁵

Nonpharmacologic Therapy

Lifestyle and dietary modifications are often recommended for management of heartburn or dyspepsia despite a lack of evidence for most interventions.^{1,8–10} Weight loss is associated with reduced esophageal acid exposure and should be recommended to obese patients as well as patients with recent weight gain. Weight loss of 10% can lead to a significant decrease in symptoms of heartburn, regurgitation, and belching.¹⁰ Patients with nocturnal symptoms should avoid eating within 2–3 hours of bedtime and sleep on their left side. Elevating the head of the bed by placing 6- to 8-inch blocks underneath the legs at the head of the bed or placing a foam wedge (e.g., GERD pillow) beneath the patient's upper torso and head also is beneficial. Use of traditional pillows to elevate the upper torso may worsen symptoms because they cause the patient to bend at the waist, which contributes to an increase in intragastric pressure. Smoking cessation reduces symptoms in normal-weight subjects but has not been shown to result in the same improvements in obese patients.¹⁰ Owing to numerous health benefits, however, smoking cessation should be encouraged for all patients regardless of weight. A Mediterranean diet (high intake of vegetables, legumes, fruits, whole grains, fish, and olive oil; low intake of red or processed meat) also is associated with lower risk for development of GERD symptoms.¹⁰

Current evidence does not support advising all patients to avoid all foods and beverages listed in [Table 13–1](#).^{1,8–11} Patients should be advised to keep a symptom diary to help determine foods, beverages, and activities that correlate with symptom onset and severity. Lifestyle and dietary modifications can then be made to avoid “triggers.” Prescription and nonprescription medications should be evaluated for their potential to cause or exacerbate heartburn and dyspepsia ([Table 13–1](#)). When other options are available, patients should be advised to switch to less troublesome nonprescription medications; they also should consult their prescriber about prescription drugs that may be exacerbating their symptoms. See the box “Patient Education for Heartburn and Dyspepsia” for additional strategies that may be helpful in preventing or reducing symptoms.

Pharmacologic Therapy

Antacids

Antacids relieve heartburn and dyspepsia by neutralizing gastric acid. Nonprescription antacid products contain at least one of the following salts: magnesium (hydroxide, carbonate, or trisilicate); aluminum (hydroxide or phosphate); calcium carbonate; or sodium bicarbonate ([Table 13–4](#)). Most antacids are relatively inexpensive, making them affordable products for the temporary relief of mild and infrequent heartburn and dyspepsia.

Table 13–4 Selected Nonprescription Antacid and Bismuth Products and Their Dosage Regimens

Trade Name	Primary Ingredient(s)	Dosage (maximum daily dosage)
Adults/Children ≥ 12 Years		
Alka-Seltzer Heartburn	Sodium bicarbonate 1940 mg; anhydrous citric acid 1000 mg	Dissolve 2 tablets in 4 ounces of water every 4 hours PRN (8 tablets)
Alka-Seltzer Original	Sodium bicarbonate 1916 mg; anhydrous citric acid 1000 mg; aspirin 325 mg	Dissolve 2 tablets in 4 ounces of water every 4 hours PRN (8 tablets)
Gaviscon Extra Strength Liquid	Each 5 mL contains ^a aluminum hydroxide 254 mg; magnesium carbonate 237.5 mg	10–20 mL 4 times a day, after meals and at bedtime PRN (80 mL)
Gelusil Tablets	Aluminum hydroxide 200 mg; magnesium hydroxide 200 mg; simethicone 25 mg	Chew 2–4 tablets; repeat hourly if symptoms return (12 tablets)
Mylanta Maximum Strength Liquid	Each 10 mL contains aluminum hydroxide 800 mg; magnesium hydroxide 800 mg; simethicone 80 mg	10–20 mL between meals and at bedtime PRN (60 mL)
Pepto-Bismol Ultra Liquid	Each 15 mL contains bismuth subsalicylate 525 mg	15 mL every 30 minutes PRN (8 doses or 120 mL)
Pepto-Bismol Chewable Tablets	Bismuth subsalicylate 262 mg	Chew or dissolve in mouth 2 tablets every 30–60 minutes PRN (8 doses or 16 tablets)
Rolaids Regular	Calcium carbonate 550 mg; magnesium hydroxide 110 mg	Chew 2–4 tablets PRN (12 tablets)

Trade Name	Primary Ingredient(s)	Dosage (maximum daily dosage)
Strength Tablets		
Tums Extra Strength 750 Tablets	Calcium carbonate 750 mg	Chew 2–4 tablets PRN (10 tablets)
Tums Chewy Delights Soft Chews	Calcium carbonate 1177 mg	Chew 2–3 soft chews PRN (6 soft chews)
Children ≤ 12 Years		
Pepto Kids Chewable Tablets	Calcium carbonate 400 mg	Age 2–5 years: 1 tablet (3 tablets)
		Age 6–11 years: 2 tablets (6 tablets)

^a Sodium alginate (alginic acid) is listed as an inactive ingredient.

Key: PRN = As needed—*pro re nata* (L., “as the need arises”).

Antacids act as buffering agents in the lower esophagus, gastric lumen, and duodenal bulb and increase LES pressure.¹ The cations react with chloride, but the anionic portion of the molecule reacts with hydrogen ions to form water and other compounds. Sodium bicarbonate reacts rapidly with gastric acid to form sodium chloride, carbon dioxide, and water. This agent’s duration of action is shortened by its quick elimination from the stomach.¹⁶ Of the magnesium salts, magnesium hydroxide is used most often. Magnesium hydroxide reacts rapidly with gastric acid to form magnesium chloride and water. This agent has a shorter duration of action than that of calcium carbonate and aluminum hydroxide. Calcium carbonate is a potent antacid that dissolves slowly in gastric acid to form calcium chloride, carbon dioxide, and water. This agent’s onset of action is slower but its duration of effect is longer than that of magnesium hydroxide or sodium bicarbonate. Aluminum hydroxide reacts with hydrochloric acid to form aluminum chloride and water. This agent has a slower onset and a longer duration than for magnesium

hydroxide. As a result of these reactions, a small but noticeable increase in intragastric pH occurs.

Compared with tablets, liquid antacids usually have a faster onset of action, because they are already dissolved or suspended, allowing contact with a maximal surface area for action. Of the tablet dosage forms, the quick-dissolving antacid tablets may provide the most rapid relief of symptoms. The duration of action for all antacids is transient, lasting only as long as the antacid remains in the stomach. The presence of food affects the duration of action of antacids. When these agents are administered on an empty stomach, relief can last for 20–60 minutes. When taken within 1 hour after a meal, antacids may remain in the stomach for up to 3 hours.¹⁶

Differences in efficacy, onset, duration, and adverse effects of antacids are determined primarily by the cation, specific salt, and potency. Antacid potency is based on the number of milliequivalents of *acid-neutralizing capacity* (ANC), defined as the amount of acid buffered per dose over a specified period of time. Factors that contribute to the ANC include product formulation, ingredients, and concentration.¹⁶ Consequently, the ANC is product-specific; the same number of antacid tablets or equal volumes of different liquid antacids are not necessarily equal in potency.

Most antacids are absorbed minimally into the systemic circulation.¹⁶ Approximately 90% of calcium is converted to insoluble calcium salts; the remaining 10% is absorbed systemically. About 15%–30% of magnesium and 17%–30% of aluminum may be absorbed and then excreted renally; therefore, accumulation may occur in patients with renal insufficiency. Sodium bicarbonate is absorbed readily and is eliminated renally.

Antacids are indicated for the treatment of mild, infrequent heartburn, sour stomach, and acid indigestion. Combination products containing aspirin or acetaminophen are approved by the U.S. Food and Drug Administration (FDA) for overindulgence in food and drink and for hangover, although product effectiveness has not been demonstrated. Patients with mild dyspepsia may experience some relief with antacids, but no studies demonstrate their effectiveness for this disorder.²

Antacids are administered orally. The effective dose of an antacid varies depending on product ingredients, milliequivalents of ANC, formulation, and the frequency and severity of symptoms. Patients should be instructed to take

product-specific recommended doses at the onset of symptoms. Dosing may be repeated in 1–2 hours, if needed, but should not exceed the maximum daily dosage for a particular product ([Table 13–4](#)). Patients should be reevaluated if antacids are used more than twice a week or regularly for more than 2 weeks. Frequent antacid users may need to be switched to a longer-acting product, such as an H2RA, an H2RA plus an antacid, or a PPI, or referred to an appropriate health care provider.

Antacids usually are well tolerated. Adverse effects generally are related to the specific cation. The most common adverse effect associated with magnesium-containing antacids is dose-related diarrhea. The occurrence of diarrhea may be reduced by combining magnesium-containing antacids with aluminum hydroxide. However, when higher dosages of this combination are used, the predominating adverse effect is diarrhea. Magnesium excretion is impaired in patients with renal disease, which may result in systemic accumulation of magnesium. Magnesium-containing antacids should not be used in patients with a creatinine clearance of less than 30 mL/minute.¹⁶

Aluminum-containing antacids are associated with dose-related constipation. Aluminum hydroxide binds dietary phosphate in the GI tract, increasing phosphate excretion in the feces. Frequent and prolonged use of aluminum hydroxide may lead to hypophosphatemia.¹⁶ Chronic use of aluminum-containing antacids in patients with renal failure may lead to aluminum toxicity and should be avoided.

Calcium carbonate may cause belching and flatulence as a result of carbon dioxide production. Constipation occurring during use of calcium antacids has been reported, but little evidence is available to support this correlation. Calcium stimulates gastric acid secretion and is hypothesized to cause increased acidity when calcium-containing antacids are used to treat acid-related disorders. The clinical importance of this finding, however, remains uncertain.¹⁶ If renal elimination is impaired, hypercalcemia may occur, and accumulation of calcium may result in the formation of renal calculi. Because many antacids have been reformulated to contain calcium, there is a risk of hypercalcemia when high and frequent dosages of calcium-containing antacids are taken with other calcium supplements or foods such as milk or orange juice with added calcium. The upper limit for calcium intake for adults with normal renal function is 2500 mg/day for those 19–50 years of age and 2000 mg/day for those 51 years of age and older.¹⁷ (See [Chapter 23](#) for a

discussion of calcium supplementation.)

Sodium bicarbonate frequently causes belching and flatulence that result from the production of carbon dioxide.¹⁶ The high sodium content (274 mg sodium/g sodium bicarbonate) may cause fluid overload in patients with congestive heart failure, renal failure, cirrhosis, or pregnancy, and in those on sodium-restricted diets. Patients with normal renal function excrete additional bicarbonate, whereas patients with impaired renal function retain bicarbonate, which may cause systemic alkalosis. A high intake of calcium along with an alkalinizing agent (e.g., sodium bicarbonate, calcium carbonate) may lead to development of hypercalcemia, alkalosis, irritability, headache, nausea, vomiting, weakness, and malaise (milk–alkali syndrome).¹⁶ Patients who take calcium supplements should avoid using sodium bicarbonate as an antacid. Antacid–aspirin combination products can increase the risk of serious bleeding and should be avoided in patients with bleeding risks or salicylate sensitivities. (For a complete discussion of salicylate risk, see [Chapter 5](#).) [Table 13–5](#) lists clinically significant drug–drug interactions.^{18–23}

Table 13–5 Clinically Important Drug–Drug Interactions With Nonprescription Heartburn and Dyspepsia Agents

Antacid/Acid Reducer	Drug(s)/Drug Class	Potential Interaction	Management/ Preventive Measures
Antacids	Itraconazole, ketoconazole, iron, atazanavir	Increased gastric pH may decrease disintegration, dissolution, or ionization of drug leading to decreased absorption.	Separate doses by at least 2 hours.
	Amphetamines	Absorption of amphetamines is increased and excretion decreased.	Avoid concurrent use or monitor response to therapy.
	Rosuvastatin	Absorption of rosuvastatin is decreased	Separate doses by at least 2 hours. Infrequent use of antacids is unlikely to cause clinically significant interaction.
	Enteric-coated medications	Increased gastric pH may cause premature breakdown of enteric	Separate doses by at least 2 hours.

Antacid/Acid Reducer	Drug(s)/Drug Class	Potential Interaction	Management/ Preventive Measures
		coating.	
Calcium carbonate, magnesium hydroxide, aluminum hydroxide	Levothyroxine	Absorption of levothyroxine is delayed or impaired.	Separate doses by at least 4 hours.
	Tetracyclines	Absorption of antibiotic is decreased.	Separate doses by at least 4 hours.
	Fluoroquinolones	Absorption of antibiotic is decreased.	Take antibiotic 2 hours before or 6 hours after taking antacid.
Magnesium hydroxide, aluminum hydroxide	Azithromycin	Absorption of antibiotic is decreased.	Separate doses by at least 2 hours.
Sodium bicarbonate	Quinidine	Increased urinary pH may decrease renal excretion of quinidine.	Avoid concurrent use or monitor response to therapy.
	Salicylates	Increased urinary pH may increase renal excretion of salicylates.	Avoid concurrent use or monitor for decreased response to salicylates.
Antacids, H2RAs, PPIs	Erlotinib, dasatinib, gefitinib, other TKIs, rilpivirine, ledipasvir/sofosbuvir	Increased gastric pH decreases absorption	Avoid concurrent use of PPI or H2RA; separate from antacids by several hours
H2RAs, PPIs	Itraconazole, ketoconazole, atazanavir, iron sulfate, calcium carbonate	Increased gastric pH may decrease disintegration, dissolution, or ionization of drug, leading to decreased absorption.	Avoid concurrent use or monitor response to therapy.
Cimetidine	Phenytoin, warfarin, amiodarone, clopidogrel, nifedipine, theophylline, tricyclic	Cimetidine inhibits CYP450 1A2, 2C19, and to a lesser extent, 2D6, 3A4.	Avoid use of cimetidine in patients taking medications metabolized by these CYP enzymes.

Antacid/Acid Reducer	Drug(s)/Drug Class	Potential Interaction	Management/ Preventive Measures
	antidepressants, others		
Cimetidine, esomeprazole, lansoprazole, omeprazole	Citalopram	Inhibition of CYP450 2C19 increases citalopram concentrations and dose-dependent risk of QT prolongation.	Citalopram dose should not exceed 20 mg per day if used concomitantly.
PPIs	Warfarin, theophylline, tacrolimus, mycophenolate mofetil	PPI inhibition of CYP2C19 may result in increased concentrations of target drugs.	Avoid concurrent use or check with prescriber.
	Digoxin	PPIs may increase digoxin absorption.	Check with prescriber before use.
	Methotrexate	Concurrent use increases risk of toxicity of methotrexate.	Avoid concurrent use of high-dose methotrexate. Clinically significant toxicity is unlikely with lower weekly doses.
Omeprazole, esomeprazole	Clopidogrel	Inhibition of variants of CYP2C19 reduces conversion of clopidogrel to its active form.	Avoid concurrent use or check with prescriber. Clinically significant interaction is unlikely.
	Cilostazol, diazepam	Inhibited metabolism may result in increased concentration of target drug.	Avoid concurrent use. Lansoprazole may be a safer alternative.

Key: CYP = Cytochrome P450; H2RA = histamine type 2 receptor antagonist; PPI = protein pump inhibitor; TKI = tyrosine kinase inhibitor.

Source: References [18–23](#).

Alginic acid reacts with sodium bicarbonate in saliva to form a viscous layer of sodium alginate that floats on the surface of gastric contents, forming a

protective barrier against esophageal irritation. Although alginic acid does not neutralize acid, the combination of alginic acid and an antacid provides better symptomatic relief than that obtained with the antacid alone.^{12,13} Because evidence supporting alginic acid's efficacy as a single agent is insufficient, FDA has not granted it Category I (generally recognized as safe and effective) status. However, alginic acid may be found as an inactive ingredient in several antacid preparations ([Table 13–4](#)). Some antacid products also contain simethicone to decrease discomfort related to intestinal gas. (See [Chapter 14](#) for a more detailed description of simethicone.)

Histamine Type 2 Receptor Antagonists

Cimetidine, ranitidine, famotidine, and nizatidine are approved for nonprescription use ([Table 13–6](#)). Nonprescription products containing nizatidine currently are not available in the United States. Since the autumn of 2019, FDA had been finding that many lots of nonprescription and prescription ranitidine, including the brand-name product Zantac, contained N-nitrosodimethylamine (NDMA), a probable human carcinogen. On April 1, 2020, FDA issued a decision requesting that all manufacturers of ranitidine immediately remove their products from the marketplace.²⁴ At the time of publication of this book, it was unknown when or whether ranitidine would return to the market. Any mention or reference to ranitidine in this chapter is informational only and does not indicate the product is available for purchase. When used in recommended dosages, the H₂RAs are considered interchangeable despite minor differences in potency, onset, duration of symptomatic relief, and adverse effects. H₂RAs reduce acid secretion by inhibiting histamine on the H₂ receptor of the parietal cell.¹² They are effective in relieving fasting and nocturnal symptoms. Their bioavailability is not affected by food but may be reduced modestly by antacids. Onset of symptomatic relief with H₂RAs is not as rapid as with antacids, but H₂RAs have a longer duration of effect ([Table 13–3](#)). Cimetidine is the shortest acting (4–8 hours); ranitidine, famotidine, and nizatidine have a somewhat longer duration of effect. Tolerance to the gastric antisecretory effect may develop when H₂RAs are taken daily (versus as needed) and may be responsible for diminished efficacy.^{1,12} Therefore, it is preferable to take an H₂RA on an as-needed basis rather than regularly, every day. All four H₂RA drugs are eliminated by a combination of renal and hepatic metabolism, with renal elimination being more important. A reduced daily H₂RA dose is recommended in patients with impaired renal function (creatinine clearance

<50 mL/minute).

Table 13–6 Selected Nonprescription H2RA and PPI Products and Dosage Regimens

Trade Name	Primary Ingredient(s)	Dosage (maximum daily dose)
H2RA Products (adults/children ≥ 12 years)		
Tagamet HB, various generic	Cimetidine 200 mg	1 tablet with a glass of water (2 tablets)
Pepcid AC, various generic	Famotidine 10 mg	1 tablet with a glass of water (2 tablets)
Pepcid AC Maximum Strength, various generic	Famotidine 20 mg	1 tablet with a glass of water (2 tablets)
Pepcid Complete, various generic	Famotidine 10 mg; calcium carbonate 800 mg; magnesium hydroxide 165 mg	Chew and swallow 1 tablet (2 tablets)
Zantac 75, various generic	Ranitidine 75 mg	1 tablet with a glass of water (2 tablets)
Zantac 150, various generic	Ranitidine 150 mg	1 tablet with a glass of water (2 tablets)
PPI Products (adults ≥ 18years)		
Prilosec OTC, various generic	Omeprazole magnesium 20.6 mg	1 tablet with a glass of water 30 minutes before morning meal; take daily for 14 days (1 tablet)
Zegerid, various generic	Omeprazole 20 mg; sodium bicarbonate 1100 mg	1 capsule with a glass of water 1 hour before morning meal; take daily for 14 days (1 capsule)
Prevacid 24HR, various generic	Lansoprazole 15 mg	1 capsule with a glass of water 30 minutes before morning meal; take daily for 14 days (1 capsule)
Nexium 24HR, various generic	Esomeprazole 20 mg	1 capsule with a glass of water 30 minutes before morning meal; take daily for 14 days (1 capsule)

Key: H2RA = Histamine type 2 receptor antagonist; PPI = proton pump inhibitor.

Nonprescription H2RAs are indicated for the treatment of mild to moderate infrequent or episodic heartburn and for the prevention of heartburn associated with acid indigestion and sour stomach. H2RAs are more effective than placebo for relief of heartburn and provide modest improvement in patients with mild, infrequent uninvestigated dyspepsia.^{1,2} These agents may be used at the onset of symptoms or 30–60 minutes before an event (e.g., meal, exercise) in which heartburn is anticipated. The combination H2RA–antacid product (Pepcid Complete [famotidine plus magnesium hydroxide and calcium carbonate]; [Table 13–6](#)) is indicated for patients with postprandial heartburn who have not premedicated with an H2RA. This combination product provides quick relief and a longer duration of effect. Self-treatment dosing should be limited to no more than 2 times a day. If routine self-treatment with an H2RA is needed for more than 2 weeks, medical referral is recommended.

H2RAs are well tolerated and are associated with a low incidence of adverse effects. The most common adverse effects reported with all four H2RAs are headache, diarrhea, constipation, dizziness, and drowsiness.

Thrombocytopenia is a rare but serious adverse effect associated with all four H2RAs, but this condition is reversible upon discontinuation of the drug.

Cimetidine is associated with a weak antiandrogenic effect; accordingly, when taken in high doses, it may result in decreased libido, impotence, or gynecomastia in men. [Table 13–5](#) lists drug-drug interactions for H2RAs.

Proton Pump Inhibitors

PPIs are potent antisecretory drugs that relieve heartburn and dyspepsia by decreasing gastric acid secretion. They inhibit hydrogen potassium ATPase (the proton pump), thereby irreversibly blocking the final step in gastric acid secretion and providing a more potent and prolonged antisecretory effect than that obtained with the H2RAs ([Table 13–3](#)).^{1,12} PPIs are rapidly absorbed after oral administration. The bioavailability of PPIs is increased with continued daily dosing but is reduced if taken after a meal compared to fasting. Onset of

symptomatic relief after an oral dose may occur in 1–3 hours, but complete relief may take 1–4 days.

Omeprazole magnesium 20.6 mg (Prilosec OTC) was the first PPI to become available for nonprescription use in the United States ([Table 13–6](#)). It is available as a delayed-release tablet containing enteric-coated pellets (for protection against intragastric degradation) and rapidly dissociates to omeprazole 20 mg. Immediate-release omeprazole (Zegerid) is formulated with omeprazole 20 mg and sodium bicarbonate 1100 mg. The sodium bicarbonate in Zegerid raises intragastric pH, permitting rapid absorption of omeprazole from the duodenum, but the available evidence is insufficient to confirm that this action results in a quicker onset of symptomatic relief. Esomeprazole magnesium 22.3 mg (Nexium 24HR) is the S-isomer of omeprazole and is available as a delayed-release capsule and tablet. Lansoprazole 15 mg (Prevacid 24HR) is available as a capsule formulation containing enteric-coated granules and as a delayed-release orally disintegrating tablet. Differences in efficacy among the PPIs have not been established. PPI tablets and capsules should not be chewed or crushed, because the enteric coating will be compromised, thereby decreasing the effectiveness of the drug.

Nonprescription PPIs are indicated for the treatment of frequent heartburn, defined as the occurrence of symptoms 2 or more days a week. These drugs are not intended for immediate relief of occasional or acute episodes of heartburn and dyspepsia. Because PPIs inhibit only those proton pumps that are actively secreting acid, they are most effective when taken 30–60 minutes before a meal, preferably before breakfast.^{9,25} Self-treatment should be limited to 14 days, and frequency of use should be no greater than once every 4 months. If heartburn continues during treatment with a nonprescription PPI, persists for more than 2 weeks, or recurs within 4 months, a medical evaluation is recommended.

Adverse effects with short-term use of PPIs are uncommon and may include headache, abdominal pain, diarrhea, constipation, or flatulence. Rare cases of acute interstitial nephritis and subacute cutaneous lupus erythematosus have been reported within weeks or months of initiation of PPI therapy.²¹ PPIs may increase the risk of infectious traveler's diarrhea by decreasing gastric acid and potentially altering gut flora.²¹ Travelers to high-risk areas should discuss the risks and benefits of continuing PPI use with a knowledgeable health care provider before the planned trip. The use of PPIs also has been linked to

increased risk of *Clostridioides difficile* infection, although the overall quality of evidence for this potential adverse effect is low.^{21,26} An increased risk of *C. difficile* infection with proper use of nonprescription PPIs is unlikely, but caution is warranted in high-risk scenarios such as a history of *C. difficile* infection and/or concomitant treatment with broad-spectrum antibiotics.²¹ Patients in whom PPI use is accompanied by severe diarrhea or symptoms of gastroenteritis should stop taking the drug and seek medical evaluation. Patients with ascites secondary to cirrhosis should consult a health care provider before using PPIs owing to the slightly increased associated risk for spontaneous bacterial peritonitis.²¹ Other potential PPI safety concerns that have emerged are unlikely to arise with proper use of nonprescription PPIs, including hypomagnesemia, vitamin B₁₂ deficiency, reduced bone mineral density, cardiovascular events, community-acquired pneumonia, chronic kidney disease, and dementia.²¹ **Table 13–5** lists important drug–drug interactions with PPIs.

Bismuth Subsalicylate

Bismuth subsalicylate (BSS) is indicated for heartburn, upset stomach, indigestion, nausea, and diarrhea. FDA has tentatively determined that BSS is safe and effective for the relief of upset stomach associated with belching and for gas associated with overindulgence in food and drink.²⁷ The mechanism by which BSS relieves heartburn has not been established, but for upset stomach, it is believed to have a topical effect on the stomach mucosa. When this agent is used to treat acid-related symptoms, the adult dose of BSS is 262–525 mg every 30–60 minutes as needed (**Table 13–4**). BSS generally is not recommended for children and should be avoided in patients with salicylate sensitivities or bleeding risks. Because of the risk of Reye syndrome, children and teenagers who have or are recovering from chickenpox or influenza-like symptoms should not use BSS. (For a complete discussion of salicylate risk in children, see **Chapter 5**.) Periodically, some nonprescription products are reformulated to contain BSS in place of an antacid, or vice versa. It is therefore important for patients and health care providers to review product ingredients before initiation of self-treatment to avoid potential complications. Patients taking bismuth salts should be made aware that bismuth may cause the stool and tongue to turn black. Dark-colored stools may be interpreted as a GI bleed, prompting needless medical procedures. (For a complete discussion of BSS, see **Chapter 16**.)

Product Selection Guidelines

Special Populations

Careful consideration of potential risks specific to the geriatric population is indicated before self-treatment for heartburn or dyspepsia can be recommended. Older patients are more likely to take medications that can contribute to heartburn and dyspepsia. They also are at higher risk for developing complications and may have a more severe underlying disorder despite presenting with mild symptoms. A careful assessment to identify potentially problematic medications and exclusions to self-treatment should be performed. If self-treatment is appropriate, potential drug–drug interactions and renal function should be considered in developing recommendations for nonprescription medications. Aluminum- or magnesium-containing antacids should be used sparingly, if at all, in patients with decreased renal function; if an H2RA is appropriate, the lower dose should be selected. Cimetidine should be avoided because of associated increased risks for adverse effects and drug–drug interactions. Omeprazole, esomeprazole, and lansoprazole may be used in patients with renal impairment. Sodium bicarbonate should be avoided in patients with sodium-sensitive comorbidity. The 2019 updated American Geriatrics Society (AGS) Beers Criteria for Potentially Inappropriate Medication (PIM) Use in Older Adults recommend avoiding H2RAs in geriatric patients with or at high risk for delirium, owing to their potential for inducing or worsening delirium.²⁸ A short course of a PPI, consistent with nonprescription labeling, is acceptable.

In children older than 2 years with mild, transient, and infrequent heartburn, acid indigestion, or sour stomach, children's formulas of calcium carbonate-containing antacids may be tried. Lifestyle modifications as discussed in the “Nonpharmacologic Therapy” section also should be recommended. If symptoms are frequent or not responsive to treatment, the child should be referred to an appropriate health care provider for further evaluation.²⁹ If antacids are recommended, an assessment of the child's average daily intake of calcium may help guide the recommendation. The recommended daily intake of calcium for children 2–3 years of age is 700 mg, 4–8 years is 1000 mg, and 9–18 years is 1300 mg.¹⁷ Nonprescription H2RAs are labeled for patients 12 years of age and older, and nonprescription PPIs are indicated for patients 18 years of age or older.

Infrequent and mild heartburn in pregnant women should be treated initially with dietary and lifestyle modifications.³⁰ Calcium- and magnesium-containing antacids may be used safely if the recommended daily dosages are not exceeded. Special attention should be given to the recommended intake of calcium during pregnancy (1000–1300 mg/day).¹⁷ If the pregnant woman's diet already meets this recommendation, the addition of a calcium-containing antacid may cause her to exceed the upper limit of 2500 mg of calcium per day. H2RAs are considered to be compatible with pregnancy. Data are limited but indicate no increased risk of congenital malformations.³¹ Data on use of PPIs during pregnancy are limited. Epidemiologic studies of omeprazole do not demonstrate increased risk of major congenital malformations or other adverse pregnancy outcomes with first-trimester use.^{32,33} The risk associated with lansoprazole also appears to be low.^{31,34} Human data on the safety of esomeprazole in pregnancy are lacking, but no teratogenicity was noted in animal reproduction studies.³³ A meta-analysis of observational studies of H2RA or PPI use during pregnancy suggested an association with increased risk of childhood asthma.³⁵ (See the Preface for a detailed explanation of pregnancy data.) Pregnant women with frequent or moderate to severe heartburn should be referred for medical evaluation.

Aluminum-, calcium-, or magnesium-containing antacids are considered safe in women who are breastfeeding.³⁶ The American Academy of Pediatrics considers cimetidine to be compatible with breastfeeding. However, famotidine is less concentrated in breast milk and may be preferable to cimetidine or ranitidine.³¹ Limited data indicate that low levels of omeprazole and esomeprazole appear in breast milk.^{33,37,38} The amount an exclusively breastfed infant would receive is well below the usual dose of these medications used to treat neonates.^{37,38} There is no information regarding the use of lansoprazole during lactation.³⁴

Patient Factors

Medication selection should be based on the patient's reported frequency, duration, and severity of symptoms; the cost of the medication; potential drug–drug interactions and adverse effects; and the patient's preference. The adverse effect profile is especially important in the selection of antacids. For example, if a patient has a tendency toward constipation, a less constipating antacid, such as magnesium hydroxide, would be more appropriate, and constipating antacids, such as calcium carbonate, should be avoided.

Patient Preferences

Antacids and antisecretory drugs are available in a wide range of prices, flavors, and dosage forms. Once the most appropriate nonprescription medication is determined, the patient should be involved in picking a product that is affordable, palatable, and practical to administer. Presence of inactive ingredients such as dyes, sodium, and sugar should be considered in selection of medications for patients with allergies, sensitivities, certain medical conditions, or dietary restrictions.

Complementary Therapies

Acupuncture may reduce reflux and improve GERD-related symptoms as well as dyspepsia.^{39,40} Limited data suggest that melatonin may be effective for reducing reflux and improving GERD-related symptoms.^{39,41} A blend of 9 botanicals (STW5 [Iberogast]) has been used in Germany for more than 50 years. Clinical trials support its use for symptom reduction in patients with dyspepsia and acid regurgitation.^{39,40,42} Rikkunshito, a traditional Japanese herbal medicine, reduces abdominal pain, heartburn, and abdominal distention in patients with functional dyspepsia.⁴⁰ A peppermint oil–caraway oil combination product also significantly relieved symptoms of dyspepsia compared with placebo.⁴⁰ Of note, these complementary and alternative agents and modalities are used chronically, not as needed. They may have a role in the treatment of patients diagnosed with GERD or functional dyspepsia. There is no evidence for as-needed use of botanicals in managing intermittent heartburn or dyspepsia. (See [Chapter 51](#) for a more thorough discussion of natural products.)

Assessment of Heartburn and Dyspepsia: A Case-Based Approach

Cases 13–1 and 13–2 illustrate the assessment of two different patients presenting with heartburn and dyspepsia.

Case 13–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of recurring substernal burning sensation after eating large meals. It occurs 3 times per week. The discomfort is rated a 5 on a scale of 1-10 and is associated with a feeling of fullness and occasional hiccups. Symptoms typically last 3-4 hours after eating.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms occur after eating dinner and often are associated with large meals, especially when eating out with her friends, which she does 2-3 times per week.
c. Description of the patient's efforts to relieve the symptoms	Patient has tried Tums Extra Strength (calcium carbonate 750 mg) after meals approximately 3 times per week to help relieve the symptoms. It works sometimes but wears off within an hour. She also does not like the chalky taste.
d. Patient's identity	Denise Johnson
e. Patient's age, gender, height, and weight	39 years, female, 5'2", 150 lb
f. Patient's occupation	Elementary school teacher of English as a second language
g. Patient's dietary habits	Normal balanced diet; drinks one cup of coffee every morning; drinks two glasses of wine per week with her friends.
h. Patient's sleep habits	Sleeps 6-8 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Hypertension:</i> lisinopril 10 mg daily <i>Depression:</i> escitalopram 20 mg daily <i>Pain:</i> ibuprofen 200 mg as needed for headaches and muscle or joint pain
j. Allergies	Penicillin

Relevant Evaluation Criteria	Scenario/Model Outcome
k. History of other adverse reactions to medications	None
l. Other (describe) _____	
Assess	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Moderate frequent postprandial substernal burning more than twice per week is consistent with heartburn.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Johnson to her primary care provider. (2) Recommend lifestyle modifications. (3) Recommend discontinuation of NSAID use. (4) Recommend a nonprescription acid-reducing product. (5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	A nonprescription acid-reducing product should provide relief of symptoms for the desired duration, without undesirable adverse effects. A PPI would be appropriate because Ms. Johnson's symptoms occur more often than 2 times per week. She should stop NSAID use and consider lifestyle modifications.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Take esomeprazole 20 mg 30 minutes before your morning meal every day for 14 days. Lifestyle changes also can help manage symptoms."
7. Explain to the patient or caregiver the rationale for selecting	"Because you are experiencing moderate but frequent heartburn, a PPI such as esomeprazole may work best."

Relevant Evaluation Criteria	Scenario/Model Outcome
the recommended therapeutic approach from the considered therapeutic alternatives.	Other heartburn medications may not provide complete relief. Seeing a primary care provider may not be necessary if you obtain adequate relief and your symptoms do not become more severe or frequent.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
Solicit follow-up questions from the patient or caregiver.	“Is there anything else that I can do to help with my symptoms besides taking a medication?”
Answer the patient’s or caregiver’s questions.	“You can try to cut out coffee and alcohol from your diet and also try to eat smaller portions when you go out to dinner with your friends. Additionally, weight loss may help to relieve symptoms.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Ms. Johnson to update you by phone or text on her response to the esomeprazole, or call the patient in 1 week to evaluate her response.
Key: H2RA = Histamine type 2 receptor antagonist; NSAID = nonsteroidal anti-inflammatory drug.	

Case 13–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	

Relevant Evaluation Criteria	Scenario/Model Outcome
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient suffers from ongoing upper abdominal discomfort. Patient describes a chronic cough that persisted when his lisinopril was stopped 3 months ago and a burning pain that fluctuates throughout the day. Pain severity varies at 2-4 on a scale of 1-10. Symptoms started about 6 months ago.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Eating a large meal and having a beer tend to make it worse.
c. Description of the patient's efforts to relieve the symptoms	Patient has tried esomeprazole 20 mg daily for 2 weeks with some relief.
d. Patient's identity	Peter Payne
e. Patient's age, gender, height, and weight	58 years, male, 6'2", 220 lb
f. Patient's occupation	Banker
g. Patient's dietary habits	Normal balanced diet; drinks 2 cups of coffee every day; occasional alcohol consumption.
h. Patient's sleep habits	Sleeps 5-6 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Hypertension:</i> irbesartan 150 mg daily <i>Diabetes:</i> metformin 500 mg twice daily <i>Hyperlipidemia:</i> rosuvastatin 10 mg daily <i>General health:</i> multivitamin daily <i>Hypertension:</i> irbesartan 150 mg daily
j. Allergies	NKDA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	

Relevant Evaluation Criteria	Scenario/Model Outcome
Assess	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Late-onset and ongoing GI symptoms; chronic cough. Not consistent with uncomplicated heartburn or uncomplicated dyspepsia.
3. Identify exclusions for self-treatment.	Symptom onset after age 45, chronic cough, and lack of improvement after completing a course of a nonprescription PPI indicate need for medical referral.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	(1) Refer Mr. Payne to an appropriate health care provider for medical evaluation. (2) Recommend a nonprescription product with lifestyle modifications. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer Mr. Payne to an appropriate health care provider for a differential diagnosis.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Call your primary care provider for a medical evaluation."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You need to see your primary care provider, as your symptoms may indicate a more serious medical condition that needs to be evaluated. Further treatment with a nonprescription medication is not appropriate."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient	Criterion does not apply in this case.

Relevant Evaluation Criteria	Scenario/Model Outcome
or caregiver.	
Solicit follow-up questions from the patient or caregiver.	“Why can’t I take more of the esomeprazole since it helped somewhat before?”
Answer the patient’s or caregiver’s questions.	“Esomeprazole is approved to be used as a nonprescription product for only 2 weeks; after that, if no improvement occurs, further evaluation is needed.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Payne in 1-2 days to ensure that he has contacted his primary care provider for an appointment.

Key: NKDA = No known drug allergies; PPI = proton pump inhibitor.

Patient Counseling for Heartburn and Dyspepsia

Many cases of uncomplicated heartburn and dyspepsia are self-treatable. For optimal outcomes, patients need to understand how to treat symptoms appropriately and when to seek additional care. This information is provided in the box “Patient Education for Heartburn and Dyspepsia” To avoid duplication of therapies, patients should be advised to avoid taking nonprescription antacids, H2RAs, or PPIs with a prescription H2RA or PPI.

Evaluation of Patient Outcomes for Heartburn and Dyspepsia

Patients with infrequent heartburn and dyspepsia should obtain symptomatic

relief within 5 minutes when treated with an antacid or within 30–45 minutes when treated with an H2RA. Patients taking PPIs may require up to 4 days for complete relief of symptoms, but most patients are asymptomatic within 1–2 days. Self-treating patients should be encouraged to contact their primary care provider or pharmacist to report the effectiveness of therapy and any problems that arise during treatment (e.g., adverse effects). In some cases, the provider may make a follow-up contact to assess therapeutic outcomes. If the patient reports an inadequate response to therapy, increased frequency of symptoms, or new symptoms, reevaluation is indicated to determine whether a different therapy is suitable or whether medical referral is necessary. Adverse effects may be managed by adjusting the dose or switching to another product. Patients in whom atypical or alarm symptoms ([Figure 13–2](#)) develop should be referred to their primary care provider for further evaluation.

Patient Education for Heartburn and Dyspepsia

Heartburn and dyspepsia (indigestion) are often self-treatable conditions. Heartburn is characterized by a burning sensation in the chest, usually occurring after meals. Dyspepsia is characterized by discomfort in the upper abdomen. The goals of self-treatment are (1) to provide complete relief of symptoms, (2) to reduce recurrence of symptoms, and (3) to prevent and manage unwanted effects of medications.

Nondrug Measures

- Avoid food, beverages, and activities that may precipitate or increase the frequency and severity of symptoms.
- If possible, avoid the use of medications that may aggravate heartburn or dyspepsia.
- Avoid eating large meals.
- Stop smoking.
- Lose weight if overweight and not pregnant.
- Reduce intake of dietary fat.
- If nocturnal symptoms are present:

- Avoid lying down within 2–3 hours of a meal.
- Elevate the head of the bed using 6- to 8-inch blocks, or use a foam pillow wedge under the upper body.
- Lie on your left side.

Nonprescription Medications

- Store all medications at 68°–77°F (20°–25°C), and protect them from heat, humidity, and moisture. Discard after expiration date.

Antacids

- Antacids (sodium bicarbonate, calcium carbonate, magnesium hydroxide, and aluminum hydroxide) are available alone and in combination with each other and other ingredients.
- Antacids work by neutralizing acid in the stomach.
- Antacids may be used for relief of mild, infrequent heartburn or dyspepsia (indigestion).
- Antacids usually are taken at the onset of symptoms. Relief of symptoms typically begins within 5 minutes.
- Because antacids come in a variety of strengths and concentrations, it is essential to consult the label of an individual product for the correct dose and frequency of administration. Generally antacids should not be used more than 4 times a day, or regularly for more than 2 weeks.
- If symptoms are not relieved with recommended dosages, consult a health care provider.
- Diarrhea may occur with magnesium- or magnesium/aluminum-containing antacids; constipation may occur with aluminum- or calcium-containing antacids. Discontinue use if these effects are troublesome or do not resolve in a few days.
- In children older than 2 years, mild transient and infrequent heartburn, acid indigestion, or sour stomach may be treated with children's products containing calcium carbonate if they are used according to package directions.
- Pregnant women with mild and infrequent heartburn may use calcium- and magnesium-containing antacids safely if

recommended daily dosages are not exceeded.

- Patients with kidney dysfunction should consult their primary care provider before self-treatment with antacids.
- Patients taking tetracyclines, fluoroquinolones, azithromycin, ketoconazole, itraconazole, iron supplements, or levothyroxine should not take antacids with these medications. (See [Table 13–5](#) for specific information on drug–drug interactions with antacids.)

Histamine Type 2 Receptor Antagonists (H2RAs)

- H2RAs—cimetidine, famotidine, and ranitidine—may be used to relieve symptoms of or prevent heartburn and indigestion associated with meals.
- H2RAs work by decreasing acid production in the stomach.
- H2RAs usually are taken at the onset of symptoms or 30–60 minutes before symptoms are expected. Relief of symptoms can be expected to begin within 30–45 minutes after the medication is taken. A combination product that contains both an antacid and an H2RA provides faster relief of symptoms.
- H2RAs generally relieve symptoms for 4–10 hours.
- H2RAs can be taken when needed, up to twice daily for 2 weeks.
- H2RAs should be used for relief of mild to moderate, infrequent, and episodic heartburn and indigestion when a more prolonged effect is needed. Use lower dosages for mild heartburn and higher dosages for moderate symptoms.
- Adverse effects are uncommon but may include headache, diarrhea, constipation, dizziness, or drowsiness. If any of these effects occurs, stop use and consult a health care provider for an alternative product.
- Cimetidine may interact with many medications. Consult a health care provider if you also are taking theophylline, amiodarone, warfarin, clopidogrel, ketoconazole, phenytoin, or other medications.

Proton Pump Inhibitors (PPIs)

- Nonprescription PPIs are indicated for mild to moderate frequent

heartburn that occurs 2 or more days a week. These drugs are not intended for the relief of mild, occasional heartburn.

- PPIs—omeprazole, esomeprazole, and lansoprazole—work by decreasing acid production in the stomach.
- PPIs should be taken with a glass of water every morning 30–60 minutes before breakfast for 14 days. Make sure to take the full 14-day course of treatment.
- Do not take more than 1 tablet a day. If a dose is missed, take as soon as possible within 12 hours; if it has been more than 12 hours, then skip that dose and resume with next scheduled dose.
- Complete resolution of symptoms should be noted within 4 days of initiating treatment.
- If symptoms persist, worsen, are not adequately relieved after 2 weeks of treatment, or recur before 4 months has elapsed since treatment, consult your primary care provider.
- Do not crush or chew tablets or capsules because this may decrease the effectiveness of the PPI.
- Adverse effects are uncommon but may include headache, abdominal pain, diarrhea, constipation, or gas. If these effects occur, stop use and consult a health care provider for an alternative product.
- Consult a health care provider if you also are taking warfarin, clopidogrel, cilostazol, ketoconazole, diazepam, antiretroviral medications, methotrexate, theophylline, tacrolimus, mycophenolate mofetil, digoxin, or other medications.

When to Seek Medical Attention

- Consult your primary care provider if you experience any of the following:
 - Heartburn or dyspepsia (indigestion) that lasts longer than 3 months
 - Heartburn or dyspepsia (indigestion) that occurs with recommended dosages of nonprescription medications
 - Heartburn or dyspepsia (indigestion) that still occurs after 2 weeks of continuous treatment with a nonprescription medication

- Heartburn that awakens you during the night
- Difficulty or pain on swallowing foods
- Black tarry feces or vomiting of blood or black material
- Chest pain or shoulder, arm, or neck pain, with shortness of breath
- Chronic hoarseness, cough, choking, or wheezing
- Unexplained weight loss
- Continuous nausea, vomiting, or diarrhea
- Severe stomach pain
- Occurrence of troublesome side effects that do not resolve on discontinuing the nonprescription medication

Key Points for Heartburn and Dyspepsia

- Self-treatment of heartburn and dyspepsia should be limited to mild or moderate symptoms, including postprandial burning in the upper abdomen and centralized abdominal discomfort.
- Patients with atypical or alarm symptoms ([Figure 13–2](#)) should be referred for further evaluation.
- In children older than 2 years, treatment of mild transient and infrequent heartburn, acid indigestion, or sour stomach symptoms should be limited. Prompt referral should be made if symptoms are frequent or persist despite treatment.
- Pregnant women may self-treat for mild and infrequent heartburn with calcium- and magnesium-containing antacids.
- Patients with heartburn should be counseled on nondrug measures, such as the dietary and lifestyle modifications listed in the box “Patient Education for Heartburn and Dyspepsia.”
- Self-treating patients should be advised about the advantages and disadvantages of various antacids and acid-reducing

products so that they can select a product that is best suited to their needs.

- Antacids provide temporary relief for mild and infrequent heartburn and dyspepsia. Dosages are product-specific because of variability in antacid ingredients and concentrations.
- H2RAs are indicated for infrequent, mild to moderate heartburn or dyspepsia. They may be taken at the onset of symptoms or 30–60 minutes before an event (e.g., meal, exercise) that may cause symptoms.
- PPIs are indicated for treatment of frequent heartburn (occurring ≥ 2 days a week) and should be used for a maximum of 14 consecutive days, no more frequently than every 4 months. They are not intended for immediate relief or infrequent symptoms.
- Patients with self-treatable symptoms should be advised to contact their primary care provider if symptoms worsen or if frequent symptoms persist after 14 days of self-treatment.

Chapter 14: Intestinal Gas

Authors: Rebekah Jackowski, Traci M. Poole

Intestinal gas–related symptoms and conditions that predispose affected patients to intestinal gas formation are common and may be associated with considerable discomfort and lifestyle impairment. The most frequent clinical manifestations are *eructation* (belching of swallowed air), *bloating* (uncomfortable fullness, often with abdominal distention, particularly after eating), and *flatulence* (excessive passage of air from the stomach or intestines through the anus). Differentiation of temporary symptoms from a chronic gastrointestinal (GI) disorder or condition such as irritable bowel syndrome (IBS), lactose intolerance, or celiac disease is important in recommending appropriate nonprescription treatment.

The primary categories of nonprescription pharmacologic agents for intestinal gas are antiflatulence medications (simethicone, activated charcoal), digestive enzymes (lactase replacement and α -galactosidase products), and probiotic products (containing *Bifidobacterium*, *Lactobacillus*, *Saccharomyces*, or *Streptococcus thermophilus* or other species, alone or in combination).

A significant proportion of the U.S. population is affected by conditions that may be associated with intestinal gas symptoms. Intestinal gas can be caused by lactose malabsorption (affecting 29% of the population), IBS (5%–15%), and other, less common medical conditions such as celiac disease (1%–3% of the general population and 10% of first-degree relatives of persons with celiac disease) and pancreatic insufficiency (<1%).^{1–5}

Pathophysiology of Intestinal Gas

Healthy persons and patients who complain of distention carry a volume of approximately 200 mL of gas in the intestinal tract in both the fasting and postprandial states.^{6–8} The composition of intestinal gas is primarily nitrogen (N_2), oxygen (O_2), carbon dioxide (CO_2), hydrogen (H_2), and methane (CH_4).⁶ Increased intestinal gas may be attributable to excessive aerophagia (air swallowing), increased intraluminal production within the bowel, decreased gas absorption due to obstruction, or expansion of intraluminal gas related to

atmospheric pressure changes.

Aerophagia is a major etiologic mechanism for accumulation of intestinal gas (primarily as O₂ and N₂). Contributory factors include eating quickly or gulping beverages, consuming carbonated beverages, anxiety, gum chewing, and smoking.⁹

Diet, underlying medical conditions, genetics, alterations in intestinal flora, and drugs may precipitate or aggravate symptoms attributable to intestinal gas.

Certain foods can increase intestinal gas production, leading to bothersome symptoms.^{10,11} Dietary sugars may be incompletely absorbed in the healthy human small intestine. These sugars are the principal substrates for H₂ gas production in the colon. Similarly, malabsorption may be a problem with other foods, including fatty foods; foods rich in complex carbohydrates; and indigestible oligosaccharides. These substances remain in the intestinal lumen and are passed into the colon, where they provide a substrate for bacterial fermentation and colonic production of H₂, CO₂, and CH₄.⁵ Bacterial fermentation in the small intestine resulting from bacterial overgrowth may lead to production of excessive amounts of intestinal gas. Fermentation in the colon is the primary process for generating intestinal gas and is influenced by the type and quantity of foods ingested (Tables 14–1 and 14–2).

Table 14–1 Gas-Producing Foods

Foods Associated With Minimal Gas Production

- Meats: fowl, fish
- Vegetables: lettuce, peppers, avocado, tomato, asparagus, zucchini, okra, olives
- Fruit: cantaloupe, grapes, berries, fruit juice
- Carbohydrates: refined white sugar and refined white flour
- Other: all nuts, eggs, gelatin

Foods Associated With Moderate Gas Production

- Fruits: citrus, apples
- Carbohydrates: refined white sugar and refined white flour

Foods Associated With Major Gas Production

- Vegetables: onions, celery, carrots, brussels sprouts, cucumbers, cabbage, cauliflower,

- radishes, leeks, parsnips, peas, leafy greens such as kale, beans, potatoes, eggplant
- Fruit: raisins, bananas, apricots, prunes, dried fruit
- Carbohydrates: whole grains, wheat germ, bran, brown rice
- Dairy products: milk, ice cream, cheese (in patients who have trouble digesting lactose; check food labels of processed foods for added lactose or milk-derived ingredients)
- Other: carbonated beverages

High-fiber diets may lead to bloating and flatulence. Soluble fiber absorbs water and stabilizes intestinal contractions; however, its supplementation does not appear to decrease GI symptoms.¹² Patients who experience adverse GI effects (bloating, flatulence) from natural fiber preparations (e.g., psyllium) may prefer a soluble semisynthetic fiber supplement (e.g., calcium

polycarbophil).¹²

The odor attributable to flatulence may be worsened by the ingestion of sulfate-containing foods, such as cruciferous vegetables (e.g., broccoli, cabbage); breads and beers containing sulfate additives; and proteins with a high content of the sulfur-containing amino acids methionine and cysteine (e.g., eggs, macadamia nuts, peanuts, pistachio nuts, red meats). Sulfur-based gases (e.g., hydrogen sulfide [H₂S]), methanethiol, and dimethyl sulfide are produced through the action of sulfate-reducing bacteria.¹³ Rating foods by their potential to cause intestinal gas symptoms is difficult, but clinical experience suggests that certain foods are generally more problematic than others (Table 14–1).

Gas-related signs and symptoms may be associated with intake of an excessive amount of air into the upper GI tract with swallowing. Smoking, chewing gum, sucking on hard candies, drinking carbonated beverages, wearing poor-fitting dentures, hyperventilating, or being overly anxious may contribute to swallowing larger-than-normal amounts of air.¹³ Poor eating habits (e.g., “wolfing down” food, gulping beverages) may cause larger amounts of air to enter the stomach.

A number of medical conditions cause or predispose patients to the formation of intestinal gas. Some conditions (e.g., carbohydrate malabsorption, pancreatic insufficiency) lead to production of an increased amount of gas from bacterial fermentation in the colon. The most common cause of carbohydrate malabsorption is lactase deficiency. Lactase is the enzyme that normally breaks down lactose in the intestinal lumen so that it can be absorbed. Physiologic lactase enzyme activity peaks at birth and starts to decline after the first few months of life as infants are slowly weaned from their mother’s milk.

In patients with lactase deficiency, the lactase enzyme is not available in sufficient quantities to break down lactose in dairy products before it reaches the colon. In the colon, the malabsorbed lactose remains in the intestinal lumen, where it is available to colonic bacteria for fermentation to H₂ and other substances. People with lactase deficiency experience GI symptoms (e.g., gas pains, bloating, nausea, diarrhea) on exposure to dairy and other foods containing milk or milk-derived carbohydrates (e.g., caramel).¹⁴ Milk-derived protein (e.g., whey powder, caseinate, other lactoproteins) does not cause lactose-associated GI symptoms unless the product is contaminated with a

milk-derived carbohydrate (i.e., lactose).

Other conditions such as IBS may predispose affected patients to intestinal gas symptoms. Gas pains and bloating are very common in patients with IBS and may be caused by a number of interrelated factors, including heightened sensation of the GI tract to intestinal stretch (i.e., visceral hypersensitivity), altered intestinal motility, activated intestinal immunity, altered brain–gut interaction, and autonomic dysfunction.¹² Small bowel bacterial overgrowth has been proposed as a unifying theory linking these factors, which has stimulated promising research that aims to further define the relationship between intestinal bacterial overgrowth and the onset of IBS symptoms.¹² Probiotic bacteria (e.g., lactobacilli, saccharomycetes, bifidobacteria) are part of the normal “healthy” flora of the intestinal tract. They are thought to maintain intestinal health through a variety of mechanisms, including shifting the intestinal bacterial content in favor of nonpathologic organisms; producing beneficial substances (e.g., short-chain fatty acids); and acting primarily as carbohydrate-fermenting bacteria, thereby reducing symptoms of intestinal gas (see [Chapter 20](#)). Substances such as oligofructose (a “prebiotic”) are used as nutrients by the normal intestinal bacterial flora and by probiotic organisms; with use of prebiotics, however, the normal flora produces greater amounts of CO₂, CH₄, and H₂, which may result in increased symptoms of intestinal gas.^{5,10}

Intestinal gas symptoms may result from other, less common medical conditions such as celiac disease and diabetic gastroparesis. Patients with celiac disease have an intolerance to gluten (a protein present in wheat, rye, barley, and oats). Intestinal gas symptoms may result from the inflammatory response in the GI tract that occurs after exposure to gluten. Once a diagnosis of celiac disease has been made, and after gluten intolerance has been confirmed with accurate testing, affected patients should follow a strict gluten-free diet, preferably under the supervision of an experienced dietitian.¹ The most common sources of gluten are baked goods containing the causative grains (wheat and oat cereals, noodles, and pastas); however, many other food products (especially processed foods containing thickeners) and some medications contain gluten.

A variety of drugs may cause intestinal gas symptoms. These drugs can be categorized broadly by the mechanism of action leading to symptoms caused by physiologic changes:

- Agents that affect intestinal flora (lactulose, antibiotics)

- Drugs that affect metabolism of glucose and other dietary substances (α -glucosidase inhibitors, including acarbose and miglitol; the biguanides, including metformin); and GI lipase inhibitors, such as orlistat
 - Drugs that affect GI motility (narcotics, anticholinergics, calcium channel blockers), including agents that are high in fiber (psyllium) and nonabsorbable polymers (cholestyramine)
 - Products that contain or release gas (effervescent solutions such as Alka-Seltzer)
-

Clinical Presentation of Intestinal Gas

The most frequent clinical manifestations of increased intestinal gas are eructation (belching or burping), bloating and abdominal distention, abdominal discomfort or cramping, and flatulence. Less common signs and symptoms include nausea, borborygmi (audible bowel sounds), and dyspepsia or indigestion.

Eructation is defined as an audible escape of air from the esophagus into the pharynx that can be either involuntary or voluntary. It is classified into two types: supragastric belching and gastric belching. Supragastric belching occurs with air swallowing and release before reaching the stomach. Gastric belching results from escape of air from the esophagus during times of lower esophageal sphincter relaxation. Gastric belching typically is involuntary and commonly occurs 25–30 times per day. Some people experience excessive belching, which may be annoying or embarrassing because of its frequency, intensity, and/or unexpected occurrence.

Gas pains often are described as a generalized, crampy discomfort associated with gaseousness. Passing gas or having a bowel movement may relieve gas pains. In some patients, symptoms may be brought on by stress or anxiety. In others, the size of a meal may affect onset and severity of gas pains, with larger meals causing more bothersome symptoms. Patients who complain of recurrent gas pains (occurring at least 3 days per month in a 3-month period) that are associated with either diarrhea or constipation may have IBS.⁴

Bloating may be characterized as a sensation of tension or fullness in the abdominal area after eating or as a subjective perception that the abdomen is

larger than normal. Patients with bloating may observe that clothes fit more tightly or are uncomfortable to wear. Patients with diabetes who complain that their bloating symptoms are accompanied by a sensation of early satiety or fullness after the ingestion of only a small amount of food may be experiencing diabetic gastroparesis and should be referred to their primary care provider.

Flatulence, or the uncontrollable or frequent passage of typically odiferous intestinal gas through the anus, is normal, although socially taboo in most settings, and occurs either consciously or unconsciously 10–20 times per day, even during sleep.

Algorithm: Intestinal Gas Symptoms

Figure 14–1 Self-care for intestinal gas symptoms. Key: GI = Gastrointestinal; OTC = over-the-counter.

Treatment for Intestinal Gas

Treatment Goals

The goals of therapy are (1) to reduce the frequency, intensity, and duration of intestinal gas symptoms and (2) to reduce the impact of intestinal gas symptoms on the affected person's lifestyle. Because intestinal gas production is normal and necessary for GI tract function, the complete elimination of intestinal gas is not a realistic or attainable goal.

Treatment Approach

Self-treatment for intestinal gas symptoms should begin with an assessment of the patient's history and severity of symptoms, diet, eating habits, medication use, and relevant medical conditions. Most patients will be able to control their symptoms if they understand the basis for these symptoms, follow steps to reduce predisposing factors, and make informed decisions regarding the use of nonprescription medications. Identification of the

underlying cause of intestinal gas will guide treatment decisions for both the patient and the health care provider (Figure 14–1). Inquiry into the patient's diet (including a review of eating habits and the frequency, amount, and type of food and beverages ingested) often can lead to non-drug therapy-based suggestions for controlling the problem. Symptoms that are related to eating habits or diet often will subside quickly once the source of the problem is identified and the necessary changes are made.

Patients for whom symptoms are associated with ingestion of foods containing lactose or oligosaccharides and who have no exclusions for self-treatment (Figure 14–1) may use digestive enzymes (e.g., lactase replacement or α -galactosidase products). The primary categories of nonprescription pharmacologic agents for control of intestinal gas symptoms are antifatulence medications (simethicone, activated charcoal), digestive enzymes (lactase replacement and α -galactosidase products), and probiotic products (e.g., *Bifidobacterium*, *Lactobacillus*, *Saccharomyces*, *Streptococcus thermophilus*, and other species). Although several nonprescription antifatulence products are available (e.g., activated charcoal, simethicone), their use is largely empirical, and evidence supporting a beneficial effect is limited.

Probiotics (see Chapter 20) maintain GI tract health by protecting against pathologic GI flora; they may be useful in some patients to relieve intestinal gas complaints.¹⁶ No consensus has emerged on whether probiotics or prebiotics are beneficial in patients with lactose intolerance or chronic abdominal bloating. Increasing evidence, however, suggests that probiotics may be beneficial for treatment of intestinal gas symptoms in patients with IBS because these agents have favorable effects on the bacterial content of the small intestine and colon.^{15,16} The benefit of probiotics may potentially be linked to specific bacterial strains. More research is needed to identify the true value of individual probiotic products.

Referral for medical evaluation is indicated if any of the exclusion criteria for self-management are present (Figure 14–1). Because gas pains can mimic symptoms of other conditions (e.g., biliary colic and other diseases of the gallbladder and biliary tract, diabetic gastroparesis, peptic ulcer disease, intestinal obstruction, neoplastic disease, pancreatic insufficiency, heart disease), referral to a primary care provider is indicated if the patient is experiencing new-onset, persistent, or frequent and/or severe symptoms. Owing to an increased risk of colorectal cancer after the age of 40 years,

complaints of new or recurrent gas pains constitute a specific age-related risk factor that warrants further medical evaluation.

Patients with diabetes who complain that their bloating symptoms are accompanied by a sensation of early satiety or fullness after the ingestion of only a small amount of food may be experiencing diabetic gastroparesis and should be referred for further evaluation.

Exclusions for self-treatment ([Figure 14–1](#)) should be ruled out in the initial patient assessment before recommendation of any therapy. Referral to a primary care provider for further evaluation should be considered for patients with exclusions for self-treatment and for patients whose symptoms persist after initiation of simple treatment options (e.g., dietary modification, nonprescription medications).

Nonpharmacologic Therapy

General information for controlling intestinal gas symptoms is provided in [Table 14–3](#).¹⁹ Patients may benefit from changes in eating habits and changes in diet. Reducing the consumption of gas-producing foods ([Tables 14–1](#) and [14–2](#)) may be appropriate, depending on the dietary history. Some people are unable to tolerate gas-producing foods and need to completely avoid such foods. Patients with lactose intolerance either should avoid milk and dairy products or should use lactase replacement products. Low-lactose milk products (e.g., Lactaid Milk, Dairy Ease Milk), fortified soy milk, almond milk, or rice milk products may be used as milk substitutes. Low-lactose milk is a prehydrolyzed milk product (i.e., lactose is already hydrolyzed) and contains the same nutrients as in regular milk, but the product is not entirely lactose-free. Soy milk, almond milk, and rice milk products are lactose-free milk alternatives that are low in fat and may be fortified to include calcium and vitamin D. Similarly, patients who are unable to tolerate foods with a high oligosaccharide content should attempt to reduce consumption of such foods or to remove them from the diet.

Table 14–3 Useful Information to Support Patient Self-Management of Intestinal Gas Symptoms

Eating Habit Suggestions

- Avoid the temptation to rush through a meal. Eat and drink slowly in a calm environment.
- Chew food thoroughly.
- Avoid “washing down” solids with a beverage.
- Avoid gulping and sipping liquids, drinking out of small-mouthed bottles or straws, or drinking from water fountains.
- Eliminate pipe, cigar, and cigarette smoking.
- Avoid chewing gum and sucking hard candy, especially those that contain artificial sweeteners (e.g., sorbitol, mannitol).
- Check dentures for proper fit.
- Attempt to be aware of and avoid deep sighing.
- Do not attempt to induce belching or strain to pass gas.
- Do not overload the stomach at any one meal.

Diet

- Keep a food journal for a few days while tracking intestinal gas symptoms.
- Avoid gas-producing foods ([Table 14–1](#)).
- Avoid foods with air whipped into them (e.g., whipped cream, soufflés, sponge cake, milkshakes).
- Avoid carbonated beverages (e.g., sodas, beer).
- Avoid caffeinated beverages (e.g., coffee, energy drinks).

Medication Use and Lifestyle Habits

- Avoid long-term or frequent intermittent use of medications intended for relief of cold and allergy symptoms (e.g., anticholinergic antihistamines such as brompheniramine, chlorpheniramine, doxylamine, and diphenhydramine).
- Avoid or minimize the use of drugs affecting gastrointestinal motility (narcotics and calcium channel blockers).
- Avoid or minimize the use of drugs affecting glucose metabolism (orlistat; α -glucosidase inhibitors, including acarbose and miglitol; and the biguanides, including metformin).
- Avoid or minimize the use of drugs that affect the intestinal flora (lactulose and antibiotics).
- Avoid or gradually increase intake of new foods or medications that are high in fiber (psyllium).
- Avoid nonabsorbable polymers (cholestyramine).
- Avoid medications that contain or release gas (e.g., Alka-Seltzer).
- Avoid tight-fitting garments, girdles, and belts.
- Do not lie down or sit in a slumped position immediately after eating.
- Develop a regular routine of exercise and rest.

Source: [References 10, 11, and 26](#).

An understanding of common food choices made by people of different cultures, ethnicities, and socioeconomic backgrounds can lead to improved identification of dietary patterns known to contribute to intestinal gas symptoms. This knowledge may allow the health care provider to identify and explain, in a culturally sensitive manner, why problematic gas-forming foods are not appropriate options for a specific patient. Addressing dietary issues with family members may be a better approach for developing healthy eating habits over time, especially for children experiencing intestinal gas symptoms.

Pharmacologic Therapy

Simethicone and activated charcoal may relieve symptoms after intestinal gas has formed. α -Galactosidase and lactase enzymes are taken with foods to prevent gas from forming. Lactase replacement products may be beneficial for reducing frequency and severity of excessive intestinal gas and prevention of diarrhea associated with lactose intolerance. These products are used as digestive aids, allowing people with lactose intolerance to incorporate dairy foods into the diet without experiencing intolerable symptoms. Most lactose maldigesters can tolerate some milk (up to 1 cup at a time), so use of these products should be individualized according to the patient's symptoms.

Simethicone

Simethicone (a mixture of inert silicon polymers) is used as a defoaming agent to relieve gas. Simethicone acts in the stomach and intestine to reduce the surface tension of gas bubbles that are embedded in the mucus of the GI tract. As surface tension changes, the gas bubbles are broken or coalesced, allowing them to be eliminated more easily by belching or passing gas through the anus.

The U.S. Food and Drug Administration (FDA) considers simethicone to be safe and effective as an antifatulence agent. In patients with acute, nonspecific diarrhea, the combination of simethicone with loperamide produced quicker relief from gas-related discomfort than either agent alone.¹⁷ However, simethicone's ability to reduce intestinal gas symptoms for all patients with symptoms is questionable.¹⁸ The use of simethicone on a trial basis may be encouraged, because some patients report benefit. The usual adult and pediatric dosages for simethicone are provided in [Table 14-4](#).

Table 14–4 Dosage Guidelines for Products for Self-Management of Intestinal Gas

Agent	Adults	Children > 12 Years	Children 2 to ≤ 12 Years	Children < 2 Years
Simethicone	40–125 mg orally after meals and at bedtime, as needed	40–125 mg orally 4 times daily after meals and at bedtime, as needed	40–50 mg orally 4 times daily after meals and at bedtime, as needed	20 mg orally 4 times daily, after meals and at bedtime, as needed
Activated charcoal	500–520 mg orally after meals, as needed; may repeat hourly	Specific guidelines not available	Specific guidelines not available	Specific guidelines not available
α-Galactosidase	300–450 units orally per serving of food	Specific guidelines not available	Specific guidelines not available	Specific guidelines not available
Lactase enzyme	3000–18,000 units orally at first bite of food or drink containing lactose	3000–18,000 units orally at first bite of food or drink containing lactose	Specific guidelines not available	Specific guidelines not available
Probiotics	Specific guidelines not available	Specific guidelines not available	Specific guidelines not available	Specific guidelines not available

Many antacid products contain a combination of simethicone and antacids; therefore, patients should follow the label instructions for dosages of these products. Use of both agents often is unnecessary, however, and the efficacy of such combination products has not been well studied. Furthermore, single-ingredient antiflatulence products ([Table 14–5](#)) usually contain a higher concentration of simethicone than that found in combination products. Because simethicone is not absorbed from the GI tract, it has no known systemic adverse effects; its safety has been well documented. Of note, however, simethicone is contraindicated in patients with a known hypersensitivity to simethicone products or with suspected intestinal perforation and obstruction.

Activated Charcoal

Activated charcoal is promoted for relief of intestinal gas; however, it is neither approved nor shown to be effective for this indication.¹⁹ The usual adult dosages for this agent are provided in [Table 14–4](#). The proposed antifatulence properties of activated charcoal are related to the adsorbent effects of the substance and its potential to facilitate the elimination of intestinal gas from the GI tract. Activated charcoal has been purported to be beneficial for the elimination of malodorous, sulfur-based gases.¹⁹ However, activated charcoal has poor palatability. External devices containing activated charcoal are available to reduce the odor of flatus in patients with ostomies (see [Chapter 22](#)).

α-Galactosidase

Another FDA-approved agent available for use as an antifatulent is the enzyme α-galactosidase. This enzyme, which is derived from the *Aspergillus niger* mold, hydrolyzes oligosaccharides into their component parts before they can be metabolized by colonic bacteria. α-Galactosidase products are classified as a food. The usual adult and pediatric dosages for this enzyme preparation are provided in [Table 14–4](#).

Because high-fiber foods contain large amounts of oligosaccharides, α-galactosidase is recommended for prophylaxis against excessive intestinal gas production associated with high-fiber diets or consumption of foods that contain oligosaccharides ([Table 14–2](#)). A randomized, double-blind, placebo-controlled trial of α-galactosidase demonstrated that the agent significantly reduced gas-related symptoms in healthy persons who consume oligosaccharide-containing foods.²⁰

The safety of α-galactosidase remains to be determined. Although this enzyme has been used in food processing for years and is regarded as safe by FDA, the amount contained in available pharmacologic products is much greater than that in processed foods. Because the enzyme produces galactose, it should not be used by patients with *galactosemia* (an inherited metabolic disorder in which galactose accumulates in the blood because of deficiency of an enzyme that catalyzes conversion of galactose into glucose). As noted, α-galactosidase is derived from mold, so allergic reactions are possible in patients allergic to molds.

Lactase Replacement Products

Lactase replacement products are used in patients with lactose intolerance (see [Chapter 16](#)). Lactase enzymes break down lactose, a disaccharide, into the monosaccharides glucose and galactose, which are absorbed. Lactase replacement products should be used in patients with lactose intolerance to aid in the digestion of dairy products. No adverse effects are listed for lactase replacement products. The usual adult dose for lactase enzymes is provided in [Table 14–4](#).

Product Selection Guidelines

Special Populations

Several pediatric formulations of simethicone are indicated for the relief of intestinal gas. These products, which contain simethicone 40 mg per 0.6 mL suspension formulation, often are promoted and used to relieve gas associated with colic. However, simethicone has not been found to be superior to placebo for intestinal gas and/or infantile colic.¹⁸ Although its efficacy is questionable, simethicone is not absorbed from the GI tract, and it is considered safe for use in infants and children. No reports linking simethicone to congenital defects have been published to date.¹⁸ Simethicone is considered to be safe for use by nursing mothers.

Safety and efficacy of α -galactosidase products have not been evaluated in infants. However, a small randomized study in 52 children 4–17 years of age found these products to be safe and effective. A large research study would be needed to confirm this result.²⁰ This product should not be used in pediatric patients younger than 4 years of age but may be safely used in older children. Manufacturers recommend that pregnant or nursing women consult their primary care provider before using α -galactosidase. (Please refer to the Preface for a detailed explanation of the pregnancy data.)

No special population considerations are listed for lactase replacement products. Patients should consult their primary care provider if symptoms continue after using a lactase replacement product, or if symptoms are unusual and seem unrelated to eating dairy products.

Patient Factors

α -Galactosidase and lactase replacement products are used to prevent the onset of symptoms in patients unable to tolerate problematic foods.

Simethicone is recommended for patients with gas-related symptoms who need immediate relief and patients who cannot correlate their symptoms with ingestion of certain foods. Activated charcoal may be an alternative to simethicone for patients with gas symptoms, and it may be beneficial for patients who experience malodorous gas production. Because α -galactosidase produces carbohydrates, patients with galactosemia should avoid its use, and patients with diabetes should consult an appropriate health care provider before initiation of self-treatment. Patients with lactase maldigestion who experience symptoms of lactose intolerance should consider taking lactase replacement products at the time of exposure to dairy products.

Patient Preferences

Most products for self-management of intestinal gas are available in a variety of strengths and dosage forms. A liquid formulation of simethicone is available for infants. (See [Chapter 11](#) under “Special Populations” for FDA requirements for dispensing devices included in liquid nonprescription products.)

Simethicone is available as chewable tablets, softgels, edible filmstrips, and liquid drops. Liquid dosage forms and alternative solid dosage forms are generally more expensive than standard solid oral dosage forms (e.g., tablets, capsules) but may be preferable. Activated charcoal is available in two solid oral dosage forms—tablets and capsules—and in a combination product with simethicone.

α -Galactosidase is available as tablets and as meltaway tablets. No difference in effectiveness between these dosage forms has been found, so the choice of a specific product is left entirely to personal preference and convenience.

Several dosage forms of lactase replacement products are available for patients with lactose intolerance. Some products can be added to milk or dairy products to reduce the amount of lactose in the product, or they can be ingested along with dairy products in an effort to reduce the amount of lactose produced when the food is consumed. Additionally, patients may elect to switch to one of the available milk alternatives (e.g., low-lactose milk, fortified soy milk, almond milk, rice milk).

Complementary Therapies

A variety of probiotic and dietary supplements may be used for GI complaints, including intestinal gas and bloating.¹⁶ The most common formulations for intestinal gas ([Table 14–5](#)) are single-bacterium capsules (e.g., *Bifidobacterium infantis*) and capsules containing multiple bacterial species (e.g., a combination of *Lactobacillus acidophilus*, *Lactobacillus paracasei*, *Lactobacillus rhamnosus*, *Bifidobacterium*, and *Streptococcus thermophilus*). Functional fermented food products with live active cultures of probiotic species (e.g., kombucha tea, kefir products) also are available. In patients with IBS and those with lactose intolerance, limited but increasing evidence suggests that specific probiotics provide temporary relief from GI symptoms.¹⁶ Probiotic bacteria leave the intestine soon after therapy is discontinued. With probiotic therapy, daily administration is required to maintain bacterial populations in the intestinal flora. A trial of 14 days is generally recommended for patients embarking on a probiotic regimen. Research shows that probiotics are effective in reducing the incidence of antibiotic-associated diarrhea. More studies are required to identify the probiotic strains that are most efficacious for patients receiving specific antibiotics.²¹ (For more information on probiotics, see [Chapter 20](#).)

Table 14–5 Selected Nonprescription Antiflatulence Products	
Trade Name	Primary Ingredient(s)
Single-Entity Simethicone Products	
Gas-X Extra Strength Chewable Tablets	Simethicone 125 mg
Gas-X Extra Strength Softgels	Simethicone 125 mg
Mylanta Gas Maximum Strength Chewable Tablets	Simethicone 125 mg
Gas-X Ultra Strength Softgels	Simethicone 180 mg
Little Remedies for Tummys Gas Relief Drops	Simethicone 40 mg/0.6 mL

Trade Name	Primary Ingredient(s)
Activated Charcoal Products	
CharcoCaps Capsules	Activated charcoal 260 mg
α-Galactosidase Replacement Products	
Beano Tablets	α-Galactosidase 400 units (1 tablet)
Beano Meltaways Tablets	α-Galactosidase 450units (1 tablet)
Lactase Replacement Products	
Lactaid Original Strength Caplets	Lactase enzyme 3000 units (1 caplet)
Lactaid Fast Act Caplets	Lactase enzyme 9000 units (1 caplet)
Lactase Fast Act Chewable Tablets	Lactase enzyme 9000 units (1 tablet)
Probiotic Products	
Activia Probiotic Yogurt	<i>Lactobacillus bulgaricus</i> ; <i>Streptococcus thermophilus</i> ; <i>Bifidobacterium animalis</i> DN173010/CNCM I-2494 (1 × 10 ⁸ live bacteria per gram of yogurt)
Align Digestive Care Probiotic Supplement Capsules	<i>Bifidobacterium infantis</i> 35624 (4 mg = 1 × 10 ⁹ live bacteria per capsule)
Culturelle Digestive Health Capsules	<i>Lactobacillus rhamnosus</i> (1 × 10 ¹⁰ live bacteria per capsule)
Culturelle Kids Chewable Tablets	<i>Lactobacillus rhamnosus</i> (5 × 10 ⁹ live bacteria per tablet)
DanActive Probiotic Dairy Drink	<i>Lactobacillus bulgaricus</i> ; <i>Streptococcus thermophilus</i> ; <i>Lactobacillus casei</i> DN-114 001 (1 × 10 ¹⁰ live bacteria per 93 mL)
Florastor	<i>Saccharomyces boulardii</i> (lyophilized) CNCM I-745 freeze-dried capsules 250 mg
Florastor Kids Granules	<i>Saccharomyces boulardii</i> (lyophilized) CNCM I-745 freeze-dried oral granules 250 mg (1 packet)

Herbal carminatives (e.g., fennel seed, Japanese mint, peppermint, spearmint) also are commonly used for self-management of intestinal gas symptoms.²² Despite insufficient evidence, these agents are widely used for self-treatment for intestinal gas and IBS.^{22,23} Carminatives may reduce the tone of the lower esophageal sphincter, so consumption of these preparations should be minimized or avoided by patients with gastroesophageal reflux disease (see [Chapter 13](#)); however, this effect on lower esophageal sphincter tone may be less problematic in healthy persons with intestinal gas symptoms.²⁴ Fennel seed can cause photodermatitis and is contraindicated during pregnancy; moreover, the active herbal principle enters breast milk in lactating women. If fennel seed is used, patients should be advised to avoid excessive sunlight and to cease use during pregnancy and lactation. (Please refer to the Preface for a detailed explanation of the pregnancy data.) In addition, coadministration of fennel with ciprofloxacin may lead to reduced ciprofloxacin levels through a chelation mechanism, so doses should be spaced appropriately in patients using both agents.²⁵

Assessment of Intestinal Gas Complaints: A Case-Based Approach

When a patient complains of intestinal gas symptoms, it is important to try to discern any contributing factors and the duration, severity, and frequency of symptoms ([Table 14–6](#)). Behaviors and products that produce relief may provide clues to the underlying cause. A thorough review to identify dietary habits, existing medical problems, and use of prescription and nonprescription medications is warranted.

Table 14–6 Differentiation of Intestinal Gas Discomfort and Irritable Bowel Syndrome

Criterion	Intestinal Gas Discomfort	Irritable Bowel Syndrome
Location	Generalized discomfort in the upper, mid-, or lower abdomen	Generalized discomfort, bloating, and/or pain in the lower abdomen or colon
Signs	Eructation (upper abdomen): belching of air; bloating (mid-abdomen): increased abdominal	No physical signs of disease; no fever, melena, hematochezia,

Criterion	Intestinal Gas Discomfort	Irritable Bowel Syndrome
	girth; flatulence (lower abdomen, colon): excessive air or other gas in the stomach and intestines	or signs of other gastrointestinal disorders
Symptoms	Sensation of accumulated intestinal gas; may manifest as minimal physical discomfort but with significant negative psychosocial effects	Vary widely but are commonly described as abdominal pain that is relieved after a bowel movement, is accompanied by either diarrhea or constipation, and usually lasts at least 3 months
Onset	May begin at any age	Begins in early adulthood or, rarely, after the age of 60 years
Etiology	Symptoms commonly believed to be caused by an excessive amount of gas in the stomach (leading to eructation) and intestines (with bloating or flatulence); other potential causes: lactase deficiency, overgrowth of intestinal bacteria, and excessive air swallowing (aerophagia)	UnknownMay result from altered gastrointestinal motility, heightened visceral sensitivity, and/or overgrowth of intestinal bacteria
Exacerbating factors	Diet; underlying medical conditions; and certain drugs (e.g., lactulose, antibiotics, α -glucosidase inhibitors, orlistat, narcotics, anticholinergics, calcium channel blockers, psyllium or cholestyramine, effervescent solutions)	Stress; overeating; problem foods (e.g., alcohol, chocolate, caffeinated beverages, dairy products, sugar-free products that contain sorbitol or mannitol); foods high in fat
Modifying factors	Minimization of exacerbating factors	Minimization of exacerbating factors; primary care provider evaluation and treatment

Cases 14–1 and 14–2 are examples of the assessment of two different patients with intestinal gas complaints.

Case 14–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient complains of occasional stomach pain, bloating, and flatulence. She states these symptoms started 4–5 weeks ago and have been progressively getting worse. Symptoms now include nausea and occasional vomiting.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The patient states that the symptoms seem to be consistently present throughout the day and notes that the pain is sometimes diffuse. She has not been able to identify any cause.
c. Description of the patient's efforts to relieve the symptoms	She has tried simethicone 125 mg 4 times a day to alleviate the gas symptoms. She also has tried to keep a food diary to identify any cause.
d. Patient's identity	Michelle Laster
e. Patient's age, gender, height, and weight	45 years, female, 5 ft 2 in., 185 lb
f. Patient's occupation	Accountant
g. Patient's dietary habits	She follows an intermittent fasting diet and frequently consumes prepackaged meals.
h. Patient's sleep habits	7–8 hours a night
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Depression:</i> citalopram 40 mg, 1 tablet daily
j. Allergies	No known allergies
k. History of other adverse reactions to medications	None
l. Other	Over the past several months, the patient reports

Relevant Evaluation Criteria	Scenario/Model Outcome
	losing 10 lb without changing her diet or increasing exercise.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 14-6).	Abdominal symptoms are consistent with intolerance to multiple foods, suggesting the presence of lactose intolerance, oligosaccharide intolerance, and possibly gluten sensitivity (celiac disease). Fatigue and weight loss support a disorder with a nutritional deficiency component, possibly IBS.
3. Identify exclusions for self-treatment (Figure 14-1).	Unintended weight loss; presence of symptoms for a prolonged period; increasing severity of symptoms; onset of symptoms after the age of 40 years
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer patient to an appropriate health care provider. (2) Recommend that patient keep a food, stress, and symptom journal. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. Laster should be referred to an appropriate health care provider for a definitive diagnosis.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should immediately follow up with your primary care provider or gastroenterologist."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Available over-the-counter treatment will not adequately address the severity of the current symptoms you have. It is important that you follow up with your primary care provider to identify the cause of your complaints and associated weight loss."

Relevant Evaluation Criteria	Scenario/Model Outcome
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“Is there anything that I can do right now to address my symptoms before getting in to see the doctor?”
Answer the patient’s or caregiver’s questions.	“You’ve tried all the products I would recommend, and there is really nothing else that would help at this point. Immediately following up with your primary care provider is the best course of action.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Ms. Laster in 1-2 days to ensure that she sought medical care and made an appointment.

Key: IBS = Irritable bowel syndrome.

Case 14–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient presents with complaints of bloating, “burping,” and flatulence for the past few weeks. These symptoms are mild but uncomfortable.

Relevant Evaluation Criteria	Scenario/Model Outcome
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms seem to be worse after large meals. Patient notices less bloating after episodes of burping or flatulence.
c. Description of the patient's efforts to relieve the symptoms	The patient hasn't tried anything yet.
d. Patient's identity	Marco King
e. Patient's age, gender, height, and weight	42 years, male, 6 ft, 260 lb
f. Patient's occupation	Insurance agent
g. Patient's dietary habits	Mr. King states he "loves food," especially Mexican and Italian dishes, and his preferred beverages are soda and sparkling water.
h. Patient's sleep habits	7 hours a night
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Hyperlipidemia</i> : atorvastatin 40 mg, 1 tablet daily
j. Allergies	No known allergies
k. History of other adverse reactions to medications	None
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 14-6).	Patient is currently experiencing intestinal gas and bloating that may be due to dietary choices.
3. Identify exclusions for self-treatment (Figure 14-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to	Options include (1) Refer patient to an appropriate health care

Relevant Evaluation Criteria	Scenario/Model Outcome
determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	provider. (2) Recommend self-care until patient can see an appropriate health care provider. (3) Recommend self-care with antifatulence product. (4) Recommend that patient keep a food journal and decrease intake of problematic foods. (5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. King should take a simethicone product to address his bloating, "burping," and flatulence. He should also keep a food journal and should be advised to decrease his intake of problematic foods and avoid large meals and carbonated beverages.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Gas-X Extra Strength softgels can be taken with meals or snacks to help with flatulence. You should keep a food journal to identify problematic foods. Avoid eating large meals and drinking carbonated beverages."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"The simethicone in the Gas-X softgels can help expel the gas bubbles formed in your stomach and intestine, which will help with belching, flatulence, or bloating. Keeping a food journal will help you identify problematic foods to avoid. Reducing meal size and intake of carbonated beverages should also help decrease the bloating you have been experiencing."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	

Relevant Evaluation Criteria	Scenario/Model Outcome
a. Appropriate dose and frequency of administration	See Table 14-4 .
b. Maximum number of days the therapy should be employed	No maximum, so long as the symptoms are relieved and do not worsen.
c. Product administration procedures	Take the product by mouth.
d. Expected time to onset of relief	Soon after administration
e. Degree of relief that can be reasonably expected	"The simethicone in the Gas-X softgels should help prevent or reduce your symptoms."
f. Most common adverse effects	None
g. Adverse effects that warrant medical intervention should they occur	None
h. Patient options in the event that condition worsens or persists	See Figure 14-1 .
i. Product storage requirements	Store in a cool, dry place out of children's reach.
Solicit follow-up questions from the patient or caregiver.	"Can I take too much of this product?"
Answer the patient's or caregiver's questions.	"Taking more doses than recommended by the manufacturer will not provide any additional relief. Follow the dosing instructions listed on the package."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Call Mr. King in 1 week to evaluate his symptoms and response to treatment. Make sure you have his current phone number on file.

Key: n/a = Not applicable.

Patient Education for Intestinal Gas

The objectives of self-treatment are (1) to quell the symptoms of intestinal gas and (2) to reduce the chance of recurrence of symptomatic episodes. For most patients, carefully following product instructions and the self-care measures listed below will help ensure optimal therapeutic outcomes.

Nondrug Measures

- If possible, avoid foods known to cause intestinal gas.
- Avoid activities and dietary habits known to introduce gas into the digestive system, such as drinking carbonated beverages.

Nonprescription Medications

- Lactase replacement products and α -galactosidase should be taken with foods to prevent intestinal gas from forming.
- Simethicone is used to treat intestinal gas symptoms after onset.

α -Galactosidase

- Do not cook with α -galactosidase products. Add to food after it has cooled, because food temperatures higher than 130°F (55°C) may inactivate the enzyme.
- With drop-specific formulations, add drops to the first bite of problem foods.
- With tablets, swallow, chew, or crumble the recommended number of tablets for consumption with the first bite of problem foods.
- An average meal may contain three servings of a problem food. If needed, use more tablets for larger meals, up to the maximum recommended dose.

Lactase Replacement Products

- Take at first bite of dairy- or lactose-containing food.
- Dosing may vary according to the amount of lactase in the product

and the level of lactose intolerance.

- Do not take more than the recommended maximum daily dose.
- Low-lactose milk or fortified soy milk products also may be consumed to supplement dietary intake of calcium.

Simethicone

- For infants, to ease administration, mix the suspension with 1 ounce of cool water, infant formula, or other liquid.
- Discontinue simethicone if adequate relief is not obtained within 24 hours.

When to Seek Medical Attention

- Seek medical attention if symptoms do not resolve or if they worsen.

Patient Counseling for Intestinal Gas

Patient counseling is important to ensure the appropriate selection and use of nonprescription medications for self-management of intestinal gas. Patients should be encouraged to keep a food journal in an effort to identify those that are problematic. Avoidance of foods or other substances that cause intestinal gas is the best advice to give patients. The health care provider should explain the proper use of medications for intestinal gas symptoms and should warn the patient about possible adverse effects. The box “Patient Education for Intestinal Gas” contains specific information to include in patient counseling.

Evaluation of Patient Outcomes for Intestinal Gas

Many patients with excessive intestinal gas experience mild to moderate distress, and the discomfort is generally self-limiting, with resolution within 24

hours. Mild to moderate gas symptoms and bloating are managed primarily with diet modification, and some relief may be obtained with nonprescription drug therapy. With effective treatment, the patient can expect reduced intensity and duration of gas-related signs and symptoms such as belching, abdominal pain, bloating, and flatulence. Patients who achieve symptomatic relief should be advised to continue self-care measures as needed.

The health care provider should ask the patient to return or call after 1 week of self-treatment with dietary measures, nonprescription antiflatulents, or digestive enzymes so that outcomes can be assessed. Medical referral is necessary if any of the following is noted before or during treatment:

- Intestinal gas symptoms that are bothersome and or occur more often than occasionally (e.g., 3 times a month) and are associated with diarrhea or constipation
- Sudden change in the location of abdominal pain
- Significant increase in the severity or frequency of symptoms
- Sudden change in bowel function (suggestive of IBS)
- Emergence of accompanying signs and symptoms such as severe or persistent diarrhea or constipation; greasy or malodorous stools; GI bleeding (e.g., hematemesis, melena, hematochezia); fatigue; unintentional weight loss; or frequent nocturnal symptoms

Key Points for Intestinal Gas Complaints

- Limit self-treatment for intestinal gas to management of minor symptoms, and identify any exclusions for self-treatment ([Figure 14-1](#)).
- Counsel patients on dietary and other measures ([Table 14-3](#)) that may reduce the amount of intestinal gas. Certain foods ([Tables 14-1](#) and [14-2](#)) are more likely to cause gas formation and contribute to symptoms.
- Patients who experience symptoms with ingestion of lactose- or oligosaccharide-containing foods and who have no exclusions for self-treatment may use digestive enzymes (lactase replacement or α -galactosidase products).

- Probiotics or prebiotics may be helpful for patients with lactose intolerance who experience bloating or for patients with bloating associated with IBS.
- Antiflatulents such as activated charcoal and simethicone may be used, although the available evidence is contradictory regarding the ability of these agents to reduce the amount of intestinal gas formed.
- Referral to a primary care provider for further evaluation should be considered for patients with exclusions for self-treatment and for patients whose symptoms persist after initiation of simple treatment options (e.g., dietary modification, nonprescription medications).

Chapter 15: Constipation

Authors: Kristin Weitzel, Sharon Gatewood

Editor's Note: This chapter is based on the 19th edition chapter of the same title, written by Kristin W. Weitzel and Jean-Venable "Kelly" R. Goode.

Constipation is a common gastrointestinal (GI) complaint. Although individual bowel habits differ, *constipation* in adults generally is defined as occurrence of fewer than 3 bowel movements per week, accompanied by straining and difficult passage of hard, dry stools.^{1,2} Patient descriptions of constipation may include (1) straining to have a bowel movement; (2) hard, dry stools; (3) small stools; (4) feeling as though bowel evacuation is incomplete; or (5) decreased stool frequency.^{2,3}

Constipation is common in male and female patients of all ages, with a wide range of reported prevalence rates in the general population of 2%–28%.^{1,4–6} Constipation is the reason for at least 2.5 million physician visits per year in the United States, with direct costs of diagnosis and treatment estimated at billions of dollars annually.⁷ It is reported more often in women, persons of non-White ancestry, children, and older people.^{1,4,8} Older adults (>65 years of age) are 5 times more likely to experience constipation than younger adults, and women are more than 3 times as likely as men to be affected.² Constipation also is a frequent complaint in late pregnancy and after childbirth.⁸ If untreated, constipation can lead to development of hemorrhoids or anal fissures, rectal prolapse, fecal impaction, or other complications.⁹

Pathophysiology of Constipation

Ingested food is retained in the stomach for about 3 hours and then in the small intestine for the same amount of time in persons with normal gastric motility (Figure 15–1). Tonic contractions of the stomach wall churn and knead ingested food, and peristaltic waves move along partially digested matter toward the duodenum.¹⁰

Figure 15–1 Anatomy of the digestive system.

Contractions in the small intestine promote movement of nondigestible material into the large intestine. Fecal matter is stored in the sigmoid colon until defecation, which is controlled by both voluntary and involuntary reflexes.¹⁰ With normal gastric motility, fecal content within the colon triggers an involuntary peristaltic movement that propels fecal matter into the rectum, with relaxation of the internal anal sphincter. Voluntary tightening of the abdominal wall muscles with relaxation of the external anal sphincter then allows stool to pass. When defecating, the person may use the *Valsalva maneuver*, which entails a forceful increase in intra-abdominal pressure, actuated with an exhalation attempt against a closed glottis, to voluntarily initiate and promote passage of stool. Difficulty passing stool with constipation can lead to straining with significant force in an effort to promote defecation.¹⁰

Constipation may stem from primary or secondary mechanisms, with *primary*

constipation characterized as slower-than-normal GI transit time or a defecatory disorder (e.g., from pelvic floor dysfunction).^{2,6,8} *Secondary* causes include systemic, neurologic, and psychological disorders and/or structural abnormalities^{1-3,5,6} (**Table 15-1**). Inadequate dietary fiber and fluid intake may contribute to constipation. Dietary fiber dissolves or swells in the intestinal fluid, which increases fecal bulk to aid in stimulating peristalsis and eliminating stool. A diet low in calories, carbohydrates, or fiber may be associated with decreased fecal bulk and constipation. Inadequate intake of fluids may lead to development of dehydration, with consequent constipation.¹

Table 15-1 Selected Conditions Associated With Constipation

Structural
Colorectal or anorectal injury, inflammation, or damage (e.g., anal fissure)
Pelvic floor disorders
Structural abnormalities (e.g., tumors, hernias, strictures) leading to bowel obstruction
Systemic
Thyroid disorders
Diabetes mellitus
Irritable bowel syndrome
Neurologic disorders
Autonomic neuropathy
Multiple sclerosis
Parkinsonism
Postsurgical (anesthesia, immobility, fluid/electrolyte imbalance)
Cerebrovascular accident (stroke)
Dementia
Psychological
Depression

Eating disorders
Situational stress

Source: [References 1–3, 5, and 6](#).

Failing to respond to the urge to empty the bowel also can lead to constipation. When this urge is suppressed, rectal muscles can lose tonicity and become less effective, and nerve pathways stop sending the signal to defecate. Medication-associated constipation also can occur in the setting of multiple concomitant medical conditions or therapies^{2,3,11,12} ([Table 15–2](#)).

Table 15–2 Selected Drugs That May Induce Constipation

Analgesics (including nonsteroidal anti-inflammatory drugs)	Hematinics (especially iron)
Antacids (e.g., calcium and aluminum compounds, bismuth)	Hyperlipidemics (e.g., cholestyramine, pravastatin, simvastatin)
Anticholinergics (e.g., benztropine, glycopyrrolate)	Hypotensives (e.g., angiotensin-converting enzyme inhibitors, beta blockers)
Anticonvulsants (e.g., carbamazepine, divalproate)	Muscle relaxants (e.g., cyclobenzaprine, metaxalone)
Antidepressants (specifically, tricyclics such as amitriptyline, bupropion)	Opiates (e.g., morphine, codeine)
Antihistamines (e.g., diphenhydramine, loratadine)	Parkinsonism agents (e.g., bromocriptine)
Antimuscarinics (e.g., oxybutynin, tolterodine)	Polystyrene sodium sulfonate
Antineoplastics (e.g., vinca alkaloids)	Psychotherapeutic drugs (e.g., phenothiazines, butyrophenones)
Benzodiazepines (especially alprazolam and estazolam)	Sedative–hypnotics (e.g., zolpidem, benzodiazepines, phenobarbital)
Calcium channel blockers (e.g., verapamil, diltiazem)	Serotonin agonists (e.g., ondansetron)

Calcium supplements (e.g., calcium carbonate)	Sucralfate
Diuretics (e.g., hydrochlorothiazide, furosemide)	

Source: [References 2, 3, 11](#), and [12](#).

Clinical Presentation of Constipation

Constipation may manifest as self-reported decreased frequency or difficulty passing stools, anorexia, dull headache, lassitude, low back pain, abdominal discomfort, bloating, flatulence, and/or psychosocial distress.¹ Occasional bouts of temporary constipation usually can be managed with self-care measures. Constipation continuing over several weeks to months or that is complicated by concomitant conditions requires more sustained and aggressive therapy.^{13,14}

Long-standing or untreated constipation can lead to complications such as hemorrhoids, anal fissures, or rectal prolapse, fecal impaction, or rectal ulcers. Straining to defecate may be accompanied by blood pressure surges or precipitate cardiac rhythm disturbances secondary to altered hemodynamics.⁹

Algorithm: Constipation

Figure 15-2 Self-care for constipation. Key: CAM = Complementary and alternative medicine; OTC = over-the-counter; PCP = primary care provider; PEG = polyethylene glycol; Rx = prescription.

Treatment of Constipation

Treatment Goals

The primary goals of treatment are (1) to relieve constipation and reestablish normal bowel function, (2) to establish dietary and exercise habits to help prevent recurrence, and (3) to promote the safe and effective use of laxative products if indicated.

General Treatment Approach

Initial management of constipation involves lifestyle changes, such as increasing intake of high-fiber food and fluids and regular exercise^{1-3,8} (Figure 15-2). Pharmacologic intervention can be used if more immediate relief is desired. Laxatives should be selected according to the age and health status of the patient, as well as the mechanism of action of the individual product. U.S. Food and Drug Administration (FDA) labeling for nonprescription products limits their use to short-term (<7 days) treatment without medical referral, which is consistent with the need for medical supervision of chronic constipation treatment.^{13,14} Accordingly, patients should not use any nonprescription laxative product for more than 7 days unless the therapy is directed by a health care provider. If rectal bleeding occurs at any time during the use of a laxative, or if constipation persists despite an appropriate laxative regimen, the patient should stop using the laxative and be referred for medical evaluation.^{1,15}

Nonpharmacologic Therapy

A balanced diet that incorporates fruits, vegetables, and whole grains helps to prevent constipation. The American Dietetic Association recommends an adult daily dietary fiber intake of 14 g per 1000 kcal, or 25 g for adult women and 38 g for adult men.^{16,17} (See Chapter 24 for information on dietary fiber types, sources, intake, and benefits.)

Added fiber increases stool mass and normalizes frequency of bowel movements. The longer stool is retained in the bowel, the more water is absorbed out of the bowel contents and into the intestinal cells, leading to hard stool consistency and difficulty in passing stool.¹⁷ Patients with the complaint of constipation should gradually increase their dietary intake of insoluble fiber (e.g., incorporating more whole grains, wheat bran, fruits, and vegetables into meals) and limit consumption of foods without fiber.^{8,17}

If dietary modifications are not effective, patients may use a commercially available fiber supplement. Many newer flavorless and texture-free fiber supplements (e.g., inulin) are classified as dietary supplements (Table 15-3).⁸ Other added-fiber supplements (e.g., psyllium, methylcellulose) are bulk-forming laxatives approved by FDA as nonprescription drugs (see “Pharmacologic Therapy”). A high-fiber diet or fiber supplement may take 3–5

days or longer for its effects to be realized. Significantly increasing dietary fiber initially may lead to erratic bowel movement frequency, flatulence, and abdominal discomfort. Gradually increasing fiber intake over a period of 1–2 weeks can improve tolerance.^{1,8,17} When adding dietary fiber, patients also should increase their fluid intake to approximately eight 8-ounce glasses per day. In pregnant and lactating women, an additional 300 mL and 750–1000 mL of fluid, respectively, are recommended.¹⁷

Table 15–3 Types of Fiber Supplements	
Type of Fiber	Example(s) of Common Brands
Products Classified as Bulk-Forming Laxatives ^a	
Methylcellulose	Citrucel
Calcium polycarbophil	FiberCon
Psyllium	Metamucil, Konsyl
Products Classified as Dietary Supplements	
Inulin	FiberChoice, Metamucil Clear & Natural
Partially hydrolyzed guar gum	Sunfiber
Powdered cellulose	Unifiber
Wheat dextrin	Benefiber

^a Products classified as bulk-forming laxatives are FDA labeled to treat constipation.

Source: Adapted with permission from [reference 8](#).

Behavior modifications (as “bowel training”) also can help promote bowel movements. Gastrocolic reflexes are strongest first thing in the morning and 30 minutes after a meal, so attempting a bowel movement at these times promotes defecation consistent with the body’s normal physiologic response. Low levels of physical activity have been shown to be associated with greater risk for constipation, so increasing beneficial activities in accordance with the

patient's capabilities can reduce this risk.^{1,18}

Pharmacologic Therapy

Recommendations for laxative products depend on the underlying cause of the constipation and individual patient factors and preferences. Constipation medications are classified by mechanism of action and include bulk-forming, hyperosmotic, emollient, lubricant, saline, and stimulant agents ([Table 15–4](#)).

Table 15–4 Dosage Guidelines for Nonprescription Laxative Products^a

Agent	Dosage Form/ Strength	Adults/ Children ≥12 Years	Children 6 to <12 Years ^b	Children 2 to <6 Years ^{b,c}
Bulk-Forming Agents				
Methylcellulose	Caplet: 500 mg	2 caplets up to 6 times daily	1 caplet up to 6 times daily	Not recommended for children <6 years, except under advice of a PCP
	Powder: 2 g/heaping tablespoon	Starting dose: 1 rounded tablespoon; increase as needed, 1 rounded tablespoon at a time, up to 3 times daily	Starting dose: 2.5 level teaspoons; increase as needed, 2.5 level teaspoons at a time, up to 3 times daily	Not recommended for children <6 years except under advice of a PCP
Calcium polycarbophil	Caplet: 625 mg	2 caplets 1–4 times daily	1 caplet 1–4 times daily	Not recommended for children <6 years, except under advice of a PCP
Psyllium (plantago seeds, ispaghula husks)	Capsule: psyllium husk, 0.52 g	5 capsules with 8 ounces of liquid (swallow 1 capsule at a time), up to 4	Not recommended for children <12 years except under advice of	Not recommended for children <6 years except under advice of

Castor oil ^d	<i>Liquid</i>	1–4 tablespoons (15–60 mL) in a single daily dose; maximum of 4 tablespoons daily ^d	1–3 teaspoons (5–15 mL) in a single daily dose; maximum of 3 teaspoons daily ^d	Not recommended for children <6 years except under advice of a PCP	

^a All doses are based on FDA-labeled instructions and are for oral products, unless indicated otherwise.

^b All doses for children are listed as those for ages 2 to <6 years or 6 to <12 years, unless otherwise indicated in FDA-labeled dosing instructions. In these cases, FDA-labeled age ranges are provided within the table.

^c No recommended dosages exist for children <2 years of age, except under the advice and supervision of a PCP.

^d Although magnesium sulfate (Epsom salt) and castor oil are approved as nonprescription laxatives, they are not recommended, because safer, better-tolerated, and well-studied alternatives are available. Self-care use of mineral oil also is discouraged in most cases. See text under “Pharmacologic Therapy” for specific recommendations on appropriate use of each agent.

^e Liquid senna products vary in concentration and dosing. Take care to ensure that patients are following FDA-labeled dosing instructions with use of these products, especially in pediatric patients.

Key: FDA = U.S. Food and Drug Administration; OTC = over-the-counter; PCP = primary care provider.

Bulk-Forming Agents

Bulk-forming laxatives include methylcellulose, polycarbophil, and psyllium-containing products. These agents are most often recommended for treatment of constipation, because their effects most closely approximate the body's physiologic process.^{1,5,8} Available dosage forms include tablets or capsules, powders to be mixed with water or other liquids, and fiber chews, wafers, or “gummies.”

The usual time to onset of action for bulk-forming laxatives is 12–24 hours, but effects may take up to 72 hours. These agents are indicated for short-term therapy and may be useful in (1) patients on low-fiber diets, (2) new mothers in the postpartum period, (3) older adults, and (4) patients with colostomies, irritable bowel syndrome, or diverticular disease. This type of laxative also is used prophylactically in patients who should avoid straining during a bowel movement (e.g., with recent surgery). Dosages vary according to the type of product ([Table 15–4](#)). Exceeding the recommended dose may lead to increased flatulence or obstruction if appropriate fluid intake is not maintained.

Bulk-forming agents have few systemic adverse effects, with abdominal cramping and flatulence most commonly reported. If not taken with adequate fluid, bulk-forming laxatives may swell in the throat or esophagus, potentially causing choking. These products should be avoided by patients with swallowing difficulties or esophageal strictures or those on fluid-restricted diets.¹⁹ Because of the danger of fecal impaction or intestinal obstruction, patients with intestinal ulcerations, stenosis, or disabling adhesions should not take bulk-forming products. The onset of chest pain, vomiting, difficulty swallowing, or difficulty breathing after use warrants immediate medical attention.²⁰ Acute bronchospasm has been associated with accidental inhalation of dry hydrophilic mucilloid, as well as hypersensitivity reactions to psyllium characterized by anaphylaxis.²¹ Persons with a recognized sensitivity

to inhaled or ingested psyllium should avoid these products.

Calcium polycarbophil can contain up to 150 mg (7.6 mEq) calcium per tablet, which may be clinically relevant in patients at risk for hypercalcemia (e.g., renal disease). The sugar content of bulk-forming agents should be considered in patients with diabetes or restricted caloric intake. Although bulk-forming laxatives are not systemically absorbed, they can interfere with the absorption of oral medications as a consequence of physical binding in the GI tract or other mechanisms ([Table 15–5](#)).

Table 15–5 Clinically Important Drug–Drug Interactions With Nonprescription Laxative Agents

Laxative Agent	Interacting Drug(s)	Potential Mechanism of Interaction	Management/ Preventive Measures
Bulk-forming laxatives (e.g., psyllium)	Digoxin, anticoagulants, salicylates, and potentially other oral drugs	Interference with drug absorption	Separate dosing of prescription oral medications by at least 2 hours
Docusate salts	Mineral oil	Increased absorption of mineral oil	Avoid concurrent use
Magnesium citrate	Fluoroquinolone and tetracycline antibiotics	Decreased drug absorption	Avoid oral magnesium citrate within 1–3 hours of ingestion of oral tetracyclines or fluoroquinolones
Magnesium hydroxide	Captopril, cefdinir, some oral bisphosphonates, gabapentin, iron salts, nitrofurantoin, phenothiazines, phenytoin, rosuvastatin	Decreased oral bioavailability and/or rate or extent of drug absorption	Separate dosing by at least 2 hours for most agents
Magnesium hydroxide	Ketoconazole, itraconazole, fluoroquinolone, and tetracycline antibiotics, levothyroxine	Decreased drug absorption	Avoid magnesium hydroxide for at least 4 hours before or up to 3 hours after ingestion of interacting agent
Bisacodyl	Milk products or drugs that raise gastric pH (e.g., proton	Premature dissolution of the bisacodyl	Avoid milk products or interacting drugs within

Laxative Agent	Interacting Drug(s)	Potential Mechanism of Interaction	Management/ Preventive Measures
	pump inhibitors)	enteric coating, leading to gastric irritation or dyspepsia	1 hour before or after ingestion of bisacodyl

Hyperosmotic Agents

Hyperosmotic agents include polyethylene glycol 3350 (PEG 3350) and glycerin ([Table 15–4](#)). These products contain large, poorly absorbed ions or molecules that draw water into the colon or rectum through osmosis to stimulate a bowel movement.²²

PEG 3350 is available for self-care use in patients 17 years of age or older. It is supplied as a powder for oral administration and usually is taken as 17 g of powder (approximately 1 capful or 1 packet) mixed into 4–8 ounces of water, once daily as needed. PEG 3350 has minimal systemic absorption, with less than 1% of each dose absorbed and excreted in the urine. PEG 3350 usually produces a bowel movement in 12–72 hours, but onset of effect may take up to 96 hours.

PEG 3350 is safe and effective for the short-term treatment of occasional constipation, with few adverse effects.²³ The most common adverse effects are bloating, abdominal discomfort, cramping, and flatulence. FDA-approved labeling indicates that patients who have renal disease or irritable bowel syndrome should be cautioned to consult their primary care provider before using PEG 3350. No clinically significant drug–drug interactions have been reported with PEG 3350.

Glycerin is available as a suppository for lower bowel evacuation ([Table 15–4](#)). Glycerin suppositories usually produce a bowel movement within 15–30 minutes and are safe for occasional use in all approved age groups. Adverse effects are limited, although rectal irritation is possible with overdose. Glycerin suppositories should be avoided in patients with preexisting rectal irritation.

Emollients

Emollients, also called stool softeners, are anionic surfactants that act in the small and large intestine to increase the wetting efficiency of intestinal fluid, facilitating a mixture of aqueous and fatty substances to soften the fecal mass (Table 15–4). They can be used to prevent straining and painful defecation in patients with anorectal disorders or in those who should avoid straining (e.g., with recent abdominal or rectal surgery). Although stool softeners can be taken for occasional constipation, these agents are used more often in combination with a stimulant laxative (e.g., senna, bisacodyl) for opioid-induced constipation.^{19,24} (See the box “A Word About Opioid-Induced Constipation.”)

Docusate, available as a sodium and a calcium salt, usually works within 12–72 hours, up to 3–5 days may be required for complete effects to be obtained.⁸ Although no clinical differences between the salt forms are recognized, availability of docusate sodium in multiple strengths and dosage forms leads to its more frequent use. Docusate sodium is supplied as a capsule or syrup in multiple strengths; docusate calcium is available as a 240 mg capsule. Docusate is not appreciably absorbed from the GI tract and does not hamper absorption of nutrients from the intestinal tract. It generally is well tolerated and is associated with minimal drug interactions (Table 15–5). Larger-than-recommended doses may result in weakness, sweating, muscle cramps, and irregular heartbeat.

Lubricants

Mineral oil (liquid petrolatum) is the only nonprescription lubricant product. Mineral oil softens fecal contents by coating stool and preventing colonic absorption of fecal water. It is available in liquid form for oral or rectal administration (Table 15–4). Time to onset of action for mineral oil is approximately 6–8 hours after oral administration and 5–15 minutes after rectal administration.

The most significant acute safety concern with mineral oil is lipid pneumonia resulting from aspiration into the lungs after an oral dose. Mineral oil should not be taken before lying down and should be avoided in patients at risk for aspiration. FDA labeling for mineral oil products includes a warning against its use in patients younger than 6 years, pregnant women, immobile or older

adults, and persons with difficulty swallowing.

Taking larger-than-recommended doses of mineral oil can cause oil leakage through the anal sphincter, anal pruritus (pruritus ani), cryptitis, or other perianal conditions. With repeated and prolonged use of mineral oil, the droplets may be deposited in the mesenteric lymph nodes and potentially the intestinal mucosa, liver, and spleen as well, where they may elicit a typical foreign body reaction. Mineral oil may impair the absorption of fat-soluble vitamins A, D, E, and K. Because of these and other safety concerns, potential drug interaction with docusate ([Table 15–5](#)), and the availability of better treatment alternatives, use of mineral oil to treat constipation should be avoided if possible.⁸

Saline Laxatives

Saline laxatives include magnesium citrate, magnesium hydroxide, dibasic sodium phosphate, monobasic sodium phosphate, and magnesium sulfate. They are available in liquid or solid form for oral administration and in liquid form for rectal administration ([Table 15–4](#)). Saline laxatives draw water into the small and large intestine (oral products) or colon (rectal forms) by osmosis, thereby increasing intraluminal pressure and promoting GI motility. Saline laxatives are used to treat constipation or for acute bowel evacuation required before a procedure (e.g., colonoscopy).

Oral magnesium hydroxide is appropriate for occasional constipation in otherwise healthy patients. At standard doses, magnesium hydroxide produces a bowel movement within 30 minutes to 6 hours of administration.⁸ Other saline laxatives such as magnesium citrate are more commonly used for acute catharsis (e.g., as preparation for a colonoscopy). With use of saline agents for these purposes, the time to onset of action is 30 minutes to 3 hours for oral doses and 2–15 minutes for rectal doses. Although magnesium sulfate (Epsom salt) is labeled for nonprescription use, it should be avoided, because safer laxatives are available.

Adverse effects of saline laxatives may include abdominal cramping, nausea, vomiting, or dehydration. Patients who cannot tolerate fluid loss of significant degree should not use saline laxatives. In patients who are not on fluid restriction, oral doses of magnesium salts should be followed by at least 8 ounces of water to prevent dehydration. If used long-term or at higher-than-

recommended doses, saline laxatives containing magnesium can cause electrolyte imbalances, including hypermagnesemia.⁸ Magnesium-containing laxatives should be avoided in patients on sodium-, phosphate-, or magnesium-restricted diets and in persons at increased risk for magnesium toxicity (e.g., newborns, older adults, patients with renal impairment). In making recommendations for such products, health care providers should consider potential drug–drug interactions with magnesium-containing laxatives ([Table 15–5](#)).

Products containing sodium phosphate can cause hyperphosphatemia, hypocalcemia, and hypernatremia. Caution is warranted with use of such products in persons with renal impairment, those on sodium-restricted diets, and/or patients taking medications that may affect serum electrolyte levels (e.g., diuretics).⁸ Sodium phosphate products are contraindicated in patients with congestive heart failure. Additionally, rectally administered sodium phosphate should be avoided in patients with megacolon, GI obstruction, imperforate anus, or colostomy.²⁵

Acute phosphate nephropathy and renal impairment have been reported with use of sodium phosphate products for bowel cleansing, and the use of nonprescription oral sodium phosphate solutions is restricted to treatment of constipation only (i.e., not in bowel preparations). In 2014, an FDA drug safety communication recommended that patients not exceed one dose of such agents in a 24-hour period and advised caution with use in high-risk populations (e.g., age older than 55 years, baseline kidney disease).²⁵

Stimulant Agents

Stimulant laxatives are classified according to their chemical structure and pharmacologic activity as anthraquinones (e.g., senna) or diphenylmethanes (e.g., bisacodyl). FDA has deemed formerly available products containing cascara sagrada, casanthranol, and phenolphthalein as “not safe and effective.”^{26,27} Because some of these unapproved agents are marketed as dietary supplements, they may be available in some pharmacies but should not be recommended as therapeutics. Although rhubarb and aloe were not included in FDA rulings, neither of these should be recommended by the health care provider.

Stimulant laxatives ([Table 15–4](#)) work primarily in the colon to increase

intestinal motility by local mucosal irritation by acting on the intramural nerve plexus of intestinal smooth muscle. They also increase secretion of water and electrolytes in the intestine.⁵ The time to onset of action for senna and bisacodyl is usually 6–10 hours after oral administration, but onset of effect may take up to 24 hours. Bisacodyl suppositories usually take effect 15–60 minutes after administration.

Bisacodyl, administered orally or rectally, also is a component of bowel preparation regimens before colonoscopy or other procedures. Stimulant laxatives also may be used with docusate to prevent or treat constipation in patients taking chronic opioids.^{19,24} (See the box “A Word About Opioid-Induced Constipation.”) Overdoses of stimulants may lead to sudden vomiting, nausea, diarrhea, or severe abdominal cramping and require prompt medical attention.

Major hazards of stimulant laxative use include severe cramping, electrolyte and fluid deficiencies, enteric loss of protein, malabsorption caused by excessive hypermotility and catharsis, and hypokalemia. At very high doses, all stimulants may produce cramping, colic, increased mucus secretion, and in some patients, excessive evacuation of fluid. Stimulants can be effective but may be overused.^{28–31} (See the box “A Word About Laxative Overuse.”)

Prolonged use of senna also can cause a harmless, reversible melanotic pigmentation of the colonic mucosa (melanosis coli), which may be seen at sigmoidoscopy or colonoscopy or in rectal biopsy specimens. Senna may color urine pink to red, red to violet, or red to brown, and its presence may affect interpretation of the phenolsulfonphthalein test.

Enteric-coated bisacodyl tablets prevent irritation of the gastric mucosa. Such products should not be broken, crushed, chewed, or given with agents that increase gastric pH. The administration of bisacodyl tablets within 1 hour of ingestion of antacids, histamine type 2 (H₂) receptor antagonists, proton pump inhibitors, or milk results in rapid erosion of the tablet’s enteric coating, which may lead to gastric or duodenal irritation.

Although castor oil historically has been viewed as a stimulant laxative, its exact mechanism is unknown.³¹ Castor oil acts quickly and has significant laxative effects. Prolonged use of castor oil may result in excessive loss of fluid, electrolytes, and nutrients. Its use in the self-care setting is discouraged, because safer and better-tolerated alternatives are available.^{8,19}

Combination Products

Combination laxative products also are available ([Table 15–6](#)). For example, some products contain a stimulant and an emollient (e.g., senna with docusate sodium) or a stimulant and psyllium. Other available combination oral products include those with psyllium, bisacodyl, docusate, or another agent as the principal ingredient and glycerin as an adjunctive agent.

Table 15–6 Selected Nonprescription Laxative Products	
Trade Name	Primary Ingredient(s)
Bulk-Forming Laxatives	
Citrucel Powder	Methylcellulose 2 g/heaping tablespoon
Citrucel Sugar Free Powder	Methylcellulose 2 g/heaping tablespoon
FiberCon Caplets	Calcium polycarbophil 625 mg/caplet
Metamucil Smooth Texture, Sugar Free Orange Flavor Powder/Individual Packets	Psyllium fiber 3 g/packet
Emollient Laxatives	
Colace Capsules	Docusate sodium 100 mg/capsule
Lubricant Laxatives	
Fleet Mineral Oil Enema	Mineral oil 100%
Kondremul Emulsion	Mineral oil 55%
Saline Laxatives	
Magnesium Citrate Oral Solution	Magnesium citrate 1.745 g/30 mL
Fleet Enema	Monobasic sodium phosphate 19 g/118 mL; dibasic sodium phosphate 7 g/118 mL
Pedia-Lax Enema	Monobasic sodium phosphate 9.5 g/59 mL; dibasic sodium phosphate 3.5 g/59 mL
Phillips' Milk of Magnesia Suspension	Magnesium hydroxide 400 mg/5 mL
Hyperosmotic Laxatives	

Trade Name	Primary Ingredient(s)
Fleet Glycerin Suppository (adult size)	Glycerin 2 g/suppository
MiraLAX	Polyethylene glycol 3350 17 g/capful
Stimulant Laxatives	
Dulcolax Tablets	Bisacodyl 5 mg/tablet
Senokot Tablets	Sennosides 8.6 mg/tablet
Fletcher's Laxative for Kids	Senna concentrate 33.3 mg/mL
Combination Laxatives	
Senokot-S Tablets	Sennosides 8.6 mg/tablet; docusate sodium 50 mg/tablet

Patients should be counseled that combining laxatives is associated with a greater likelihood of adverse effects, because most such products contain a stimulant. If a stimulant and a stool softener are combined, the potential for adverse effects depends largely on the stimulant. However, if a stimulant and a saline product are combined, the potential for such effects is enhanced, because both agents have significant effects on the intestine.

Pharmacotherapeutic Comparison

Head-to-head comparison studies of solely nonprescription laxatives are largely lacking, because most nonprescription laxative ingredients became available before the current emphasis on comparative evidence. With many products, much of what is practiced has been learned through observation and a common-sense approach. For example, a bulk-forming product should soften the stool by its normal action. Because both a stool softener and a bulk-forming agent take approximately the same length of time to work, a bulk-forming agent may be the correct choice for some patients who require stool softening. Although stimulants and saline-type laxatives have been used widely for self-care, the health care provider should recommend a product with the lowest likelihood of untoward effects. Of the available nonprescription agents, PEG 3350 is considered by many professional groups and practitioners

to have the strongest evidence for efficacy and safety.³²

Product Selection Guidelines

In decisions regarding the use of any laxative to treat uncomplicated constipation, an important consideration is that normal defecation empties only the rectum and the descending and sigmoid segments of the colon. A bulk-forming laxative exerts its effects in a manner that most closely duplicates this normal physiologic process, and the use of bulking agents often is recommended as the initial treatment choice for self-care for acute constipation. However, bulk-forming laxatives may take up to 72 hours or longer for onset of effect. If faster onset is desired, or if a bulk-forming agent is ineffective or inappropriate, the hyperosmotic PEG 3350 also is considered a first-line agent, in view of its effectiveness and favorable adverse effect profile. If PEG 3350 is unable to produce a satisfactory response, addition of a stimulant (e.g., bisacodyl) should be considered.^{6,8,9} In each case, the lowest effective dose should be used, and the dose should be reduced once symptoms subside. Patients who fail to achieve a therapeutic response after 7 days of self-treatment require medical referral.

Special Populations

CHILDREN. Constipation in children generally is defined as a delay or difficulty in achieving bowel movements over a period of 2 weeks or longer; [Table 15–4](#) provides age-based definitions and laxative dosing recommendations for children.^{33,34} Constipation affects 16%–37% of children and is the most common cause of abdominal pain in this age group.^{15,35} Factors that can alter bowel habits in children include unavailability of toilet facilities, emotional distress, febrile illness, chronic medical conditions (e.g., cystic fibrosis, hypothyroidism), family conflict, dietary changes (e.g., switching from human to cow milk), fear of defecation (or the associated environment), or a change in daily routine or environment.³³ Children who experience pain on straining to pass stools may further avoid bowel movements or withhold stool, resulting in worsening symptoms and a fear of toileting.^{15,33}

Evaluation of constipation in children should begin with determination of exclusions for nonprescription therapy ([Figure 15–2](#)). Constipation in children may manifest as fecal impaction, and children with suspected impaction (as indicated by abdominal cramping; rectal bleeding; small, semifformed stools;

fecal soiling; and/or constipation accompanied by watery diarrhea) should be referred for further evaluation.^{15,33}

Mild constipation in children often can be relieved with dietary or behavioral modifications, such as increasing intake of fluid and fruit juices containing sorbitol (e.g., prune, apple).^{15,33} Once solid foods are introduced, incorporation of high-fiber cereals or grains, vegetables, and fruits into the diet also may relieve symptoms. The recommended dietary fiber intake (in grams) for children older than 2 years should equal or exceed their age plus 5 g/day.¹⁷ Parents or caregivers should establish a regular stooling time for toilet-trained children (usually after a morning meal) and develop a supportive system (e.g., charts, stickers) for positively reinforcing bowel movements. Children should be encouraged to promptly heed the urge to pass a bowel movement, to avoid negative consequences of retaining stool in the rectum (e.g., increased hardening, pain, abdominal distention).^{33,34} In older children, laxatives often can be avoided altogether with adherence to suggested dietary and fiber guidelines.

If dietary or behavior modifications are insufficient, pharmacologic therapy is indicated ([Table 15–4](#)). Nonprescription laxatives approved for self-care in children 2 to <6 years of age include oral docusate sodium, magnesium hydroxide, and senna. Rectal use of glycerin, mineral oil, or sodium phosphate products also is approved in this age group. Oral products approved for children 6 up to 12 years of age include methylcellulose, calcium polycarbophil, docusate sodium, mineral oil, magnesium citrate, magnesium hydroxide, magnesium sulfate, senna, bisacodyl, and castor oil. (See “Pharmacologic Therapy” for recommendations on use of individual agents. See also [Chapter 11](#), under “Special Populations,” for FDA requirements for dispensing devices included in liquid nonprescription products.) Oral use of PEG 3350 is not FDA-approved for patients younger than 17 years, but its off-label use in children is increasing. Rectal products approved for children 6 up to 12 years of age include glycerin suppositories, mineral oil, sodium phosphate, and bisacodyl.

If medication is needed for the occasional relief of temporary constipation in children 2 to <6 years of age, oral docusate sodium or magnesium hydroxide can be recommended first.^{15,33} Docusate sodium may be especially helpful if the primary complaint is difficulty passing dry, hard stools. If faster relief is needed, the health care provider can recommend pediatric-size glycerin suppositories. Oral senna or magnesium citrate and rectal mineral oil or

sodium phosphate enemas should be reserved for use when other treatments fail or at the direction of a health care provider.^{15,33–36}

In children 6 up to 12 years of age, bulk-forming agents, docusate sodium, or magnesium hydroxide can be recommended for the occasional relief of temporary constipation, with oral stimulants reserved for when other treatments fail.^{15,33–36} For faster relief, glycerin or bisacodyl suppositories can be recommended, with mineral oil or sodium phosphate enemas reserved for when other treatments fail, or at the direction of a health care provider.¹⁵ Use of magnesium sulfate (Epsom salt) and castor oil should be avoided owing to the availability of safer, better-tolerated, and well-studied laxatives.^{33,34}

PATIENTS OF ADVANCED AGE. Prevalence of constipation among persons 65 years of age and older is higher than in the general population, with 15%–20% of community-dwelling older adults and up to 50% of nursing home residents reporting constipation.⁵ Older people are at greater risk for constipation because of aging-related dietary changes (e.g., reduced caloric, fiber, and/or fluid intake); decreased physical activity; presence of comorbid conditions (e.g., parkinsonism, depression); increased use of medications that cause constipation (e.g., opioids, anticholinergics); and physiologic changes with age (e.g., absorption, distribution, metabolism, excretion).^{5,18}

Pharmacists should conduct a medication review to identify comorbid conditions and drug therapies (see also [Chapter 2](#)). Lifestyle modifications should be recommended first, including slowly increasing fiber and fluid, adding prunes or prune juice to the diet, physical activity as tolerated, and bowel training.^{5,19} An important clinical consideration is recognition of fluid or other restrictions associated with comorbid conditions (e.g., congestive heart failure, renal failure) in older adults.⁵

If medication adjustments and/or lifestyle changes are insufficient, the health care provider should recommend pharmacologic therapy, starting with bulk-forming laxatives. Patients who are dehydrated, very frail, immobile, or unable to drink adequate fluid to prevent mechanical obstruction or fecal impaction should not use bulk-forming laxatives. If these laxatives cannot be used or do not provide sufficient relief, or if faster onset of effect is desired, PEG 3350 also is used as a first-line option because of its efficacy and tolerability.^{5,37} Stool softeners (e.g., docusate) may be helpful along with other first-line options in older adults with anal fissures or hemorrhoids associated with painful defecation.¹⁸

Some nonprescription laxatives should be avoided or used only with caution in older adults, including mineral oil (increased risk of aspiration) and saline laxatives (risk of fluid or electrolyte depletion, magnesium toxicity, or drug interactions).⁵ Older adults are sensitive to fluid and electrolyte shifts, particularly those on diuretics or with fluid restrictions.^{5,18}

Older adults may require rectally delivered therapy with a suppository or enema, especially if fecal impaction is suspected. Rectal preparations generally are considered to be safe in this age group, although comparative safety and effectiveness evidence is limited.^{5,38} Older adults may be more susceptible to adverse effects from sodium phosphate products, and these agents should be avoided or used with caution in this population (see the box “A Word About Laxative Overuse”).³⁸

PREGNANCY AND LACTATION. Constipation affects up to one third of women throughout pregnancy and the postpartum period.³⁹ Contributing factors include compression of the colon by the growing uterus, increasing progesterone levels, low fluid and fiber intake, and the constipating effects of iron and calcium in prenatal supplements.³⁹

Dietary measures (e.g., increasing fiber and fluids) are first-line interventions. The addition of a laxative is indicated only after a nondrug approach is determined to be insufficient.³⁹ (Refer to the Preface for a detailed explanation of the pregnancy data.) Bulk-forming laxatives should be recommended first.^{39–41} Docusate also may be used for patients who have primarily dry, hard stools.⁴¹ If needed, short-term use of senna or bisacodyl is considered a low-risk approach in pregnancy.^{40,41} Some experts also consider PEG 3350 to be a first-line choice in pregnancy because very little is absorbed systemically.⁴¹ Short-term use of senna or bisacodyl is preferred by some practitioners, however, because more data are available for use of these agents in pregnancy.^{39,40} In more severe cases, or when the safety of a laxative product is questionable, consultation with the patient’s regular health care provider is recommended before laxative use.

Of note, with certain laxatives, including castor oil, mineral oil, and saline laxatives, specific risks have been recognized with use in pregnancy, so such products should be used only very cautiously or perhaps avoided altogether in this setting. Castor oil has been associated with uterine contraction and rupture, and mineral oil may impair maternal fat-soluble vitamin absorption. High doses or long-term use of saline laxatives (e.g., magnesium hydroxide)

may cause electrolyte imbalances and generally should be avoided.^{40,41}

Laxatives also may be used post partum to reestablish normal bowel function. Senna, bisacodyl, PEG 3350, and docusate are considered to be compatible with breastfeeding or to carry a low risk of adverse effects in this setting.^{40,42,43} These agents are minimally absorbed or do not accumulate in significant concentrations in breast milk, and no data point to infant toxicity with their use.^{40,42,43} Castor oil and mineral oil should be avoided during breastfeeding.⁴⁰

Patient Factors

Laxative products are available in a wide array of oral dosage forms, which may be useful to improve acceptability of laxatives. The glucose and calorie contents of laxatives available as chewing gum, wafers, gummy candy, or chocolate tablets should be considered in patients with diabetes or calorie restrictions.

Patients with fluid restrictions should avoid use of bulk-forming laxatives. Patients on sodium-restricted diets should ascertain the sodium content of laxative products (especially saline laxatives) to avoid ingesting additional sodium.⁴⁴ Patients with severely limited mobility (e.g., postoperative patients, older adults) are at increased risk for constipation and may require regular use of stool softeners or laxative products to promote laxation.

Enemas are used routinely to prepare patients for surgery, obstetric delivery, and GI radiologic or endoscopic examinations. The mechanism of laxation with enemas varies by agent. Vegetable oil enemas lubricate and soften fecal matter, whereas tap water, normal saline, and sodium phosphate enemas have osmotic effects. Sodium phosphate enemas are more efficient and effective than tap water, soapsuds, saline, or vegetable oil enemas. When properly administered ([Table 15–7](#)), enemas clean only the distal colon. Improper use or administration may result in adverse effects (e.g., mucosal changes, spasm of the intestinal wall, colonic perforation).

Table 15–7 Administration of Enemas and Rectal Suppositories

Enemas	Suppositories
1. If someone else is administering the enema, lie on your left side with knees bent or assume the knee-to-chest position (drawings A and B, respectively). The	1. Gently squeeze the suppository to determine if it is firm enough to insert. Chill a soft suppository by placing it in the

Enemas	Suppositories
side-lying position (drawing A) is preferred for children younger than 2 years. If self-administering the enema, lie on your back with knees bent and buttocks raised (drawing C). A pillow may be placed under the buttocks.	refrigerator for a few minutes, or by holding it under cool running water.
2. If using a concentrated enema solution, dilute solution according to the product instructions. Prepare 1 pint (500 mL) for adults or ½ pint (250 mL) for children.	2. Remove the suppository from its wrapping.
3. Lubricate the enema tip with petroleum jelly or other nonmedicated ointment/cream. Apply the lubricant to the anal area as well.	3. Dip the suppository in lukewarm water for a few seconds to soften the exterior.
4. Gently insert the enema tip 2 inches (recommended depth for children) to 3 inches into the rectum.	4. Lie on your left side with knees bent or assume the knee-to-chest position (drawings A and B). The side-lying position (drawing A) is best for self-administration of a suppository. Small children can be held in a crawling position.
5. Allow the solution to flow into the rectum slowly. If you experience discomfort, the flow is probably too fast.	5. To ease insertion, relax the buttocks just before inserting the suppository. Gently insert the tapered end of the suppository high into the rectum. If the suppository slips out, it was not inserted past the anal sphincter (the muscle that keeps the rectum closed). In this case, reinsert the suppository correctly.
6. Retain the enema solution until the urge to evacuate is strong (usually 1–5 minutes).	6. Continue to lie down for a few minutes while holding the buttocks together, to allow the suppository to dissolve in the rectum. (For suppository administration in a child, the parent/caregiver may have to gently hold the buttocks closed.)
	7. Try to avoid a bowel movement for up to 1 hour after insertion of the suppository so that maximum intended action can occur.

Enemas**Suppositories****A****B****C**

Suppositories containing bisacodyl are used for postoperative and antepartum and postpartum care and are adequate in preparing for proctosigmoidoscopy. Glycerin suppositories are useful in initiating the defecation reflex in children and in promoting rectal emptying in adults.

Those patients who are allergic to gluten, wheat, milk or milk protein, or soy should be encouraged to review the inactive ingredient sections of the product packaging before selecting a specific agent. If it cannot be determined if the product contains such ingredients, the manufacturer can be contacted at the phone number on the packaging.

Patient Preferences

Palatability and convenience are important considerations with laxative products. Liquid formulations of emollients may be made more palatable if mixed with juices or milk. Mixing gritty, bulk-forming laxative powders (e.g., psyllium) with orange juice instead of water may increase their taste and texture palatability. Patients also may prefer wafer or “single-serving” packets of bulk-forming laxative powders for convenience and ease of use. Patients should be reminded that many fiber products marketed as grit-free, flavor-free, or taste-free may contain ingredients that have not been studied as bulk-forming laxatives and are approved only as dietary supplements (e.g., inulin). Most laxative ingredients are available in some form as generic products. However, patients with a specific desired dosage form or other preference may need to choose a brand-name product.

Complementary Therapies

Dietary supplements commonly used to treat constipation include flaxseed, aloe, cascara, and probiotics.⁴⁵ Evidence supporting the safety and efficacy of these products varies in extent and quality. A single double-blind trial demonstrated the superiority of flaxseed over psyllium in decreasing constipation, bloating, and abdominal pain over a 3-month period in patients with irritable bowel syndrome. However, a much larger body of evidence supports psyllium’s effectiveness, and practitioners should not recommend flaxseed on the basis of limited efficacy and safety data.⁴⁵

Although many commercially available stimulant laxatives are derived from

plants, patients should be advised to choose FDA-approved products if a stimulant laxative is indicated. FDA has banned the use of aloe and cascara in nonprescription stimulant laxatives, and both agents are classified as generally unsafe and not effective. Senna is available in dietary supplement form, but use of standardized, FDA-approved senna drug products is preferred.

Probiotics are thought to work in constipation through alteration of GI flora, stimulation of motility and peristalsis, and/or acceleration of gut transit.^{5,46} However, limited safety and efficacy evidence are available on probiotics in constipation, and these agents should be considered investigational for treatment of constipation at present (see also [Chapter 20](#)).^{5,46,47}

Assessment of Constipation: A Case-Based Approach

In the initial patient interview, the health care provider should obtain as much lifestyle and medical information as possible before making any recommendations for preventing or treating constipation. Appropriate information allows the provider to make rational recommendations that are based on knowledge of the patient, the clinical problem, and available products, as well as on the provider's own judgment and experience. A patient who presents with constipation should initially be evaluated for any signs of significant GI problems that may warrant medical evaluation or in which laxative use is inappropriate ([Figure 15–2](#)). Initial assessment should include questions about diet, fluid intake, physical activity, and any underlying pathologic conditions that may produce constipation as a symptom.

Also essential is information about the patient's bowel movements, including the caliber, color, and texture of stools, as well as frequency of elimination, along with use of any other medications or natural products and previous laxative use. For patients without a history of constipation, more in-depth evaluation is needed to determine whether an acute case of constipation resulted from new or old disease or from the use of medications. When information is insufficient to assess the cause of the symptoms, or if any doubt exists regarding the patient's disease status, medical referral is appropriate. Cases 15–1 and 15–2 provide sample assessments for two different patients presenting with constipation.

A Word About Opioid-Induced Constipation

Opioid use is common in the treatment of noncancer and cancer pain. Constipation is experienced by approximately 40% of patients taking opioid drugs and is the most common adverse effect with use of these agents. Opioid-induced constipation may prevent patients from receiving appropriate pain-relieving dosages or may lead to discontinuation of therapy despite the need for pain relief. Opioids cause constipation by binding to bowel and central nervous system receptors to decrease GI motility and intestinal secretions, leading to longer retention time of fecal matter in the intestines with consequent drying of the stool. Unlike with other opioid-induced adverse effects, patients generally do not develop tolerance to these constipating effects over time. Constipating effects of opioids are dependent on the drug dose and duration of use.^{19,24} Oral opioids generally are more constipating than parenteral agents. Transdermal fentanyl patches are less constipating than oral opioids and may be an option for outpatients requiring chronic opioid therapy.^{11,24}

Patients on a chronic opioid regimen will require a long-term laxative regimen to prevent and/or treat constipation. Stimulant laxatives (e.g., senna or bisacodyl, with or without docusate) are most commonly recommended.²⁴ Typically, a stool softener alone is not effective. Polyethylene glycol preparations or other osmotic agents also may be used for prevention and treatment of opioid-induced constipation. Saline laxatives or rectally administered preparations may be needed intermittently for acute evacuation, but not for long-term management. Bulk-forming laxatives are unlikely to be adequately effective if used alone and may not be tolerated because of fluid restrictions or immobility in some patients on chronic opioid therapy (e.g., those under palliative care).^{19,24}

Identify patients at risk for opioid-induced constipation to help prevent problems, and provide counseling about nondrug preventive measures. Educate patients to determine when the pain is not severe and a different pain medication could be used that does not cause constipation. For patients on chronic opioid therapy, emphasize the importance of bowel

regimen adherence, and explain the need for long-term laxative therapy with chronic opioid use. If appropriate, suggest alternative opioids (e.g., transdermal fentanyl) that may be less constipating. Educate patients on short-term opioid therapy about constipation, especially those with other risk factors for constipation (e.g., recent abdominal surgery or childbirth).

A Word About Laxative Overuse

Identify patients at risk for laxative overuse, such as those who do not have symptoms of constipation but inappropriately take laxatives frequently to achieve regular bowel movements (e.g., daily) or a softer stool consistency. Other patients may desire to “detoxify the system” with colon-cleansing regimens that contain laxatives.²⁸ Factors that contribute to laxative overuse include older age, misconceptions about normal bowel movement frequency, fear of constipation, and presence of comorbid conditions (e.g., eating disorders).^{29,30}

Excessive use of laxatives can cause acute-onset episodes of diarrhea and vomiting, fluid and electrolyte losses (especially hypokalemia), and dehydration. Concerns about long-term consequences of chronic stimulant laxative use have been disproved in the literature. Although earlier reports pointed to adverse effects associated with chronic use of stimulant laxatives, recent well-designed clinical trials do not support an increased risk of colonic muscle or nerve damage or colorectal cancer with use of these laxatives.^{30,31}

On the other hand, acute adverse effects have been recognized as a potential risk in patients who take large doses of laxatives for purging, colon cleansing, or detoxification purposes. Colon-cleansing preparations are available in many pharmacies and are promoted for a wide range of potential benefits, including removing toxins, losing weight, and preventing disease. No data have emerged to support these claims, and

acute overuse of colon-cleansing regimens can cause serious adverse effects. Unwarranted enemas, colonic irrigation, and “colon hydrotherapy” carry additional risks (e.g., bowel perforation or infection) and are not recommended.²⁸ If laxative overuse for purging related to anorexia or bulimia is suspected, medical referral for appropriate care is needed.

Educate patients whose misperceptions about the need for a daily bowel movement contribute to unnecessary laxative use. Explain to patients that normal bowel patterns vary and that daily bowel movements are not a physical necessity. Encourage lifestyle changes that can promote regularity, such as increased fluid intake, fiber intake, and physical activity.³⁰

Note that chronic laxative use may be appropriate in some patients (e.g., those on a chronic opioid regimen). A thorough medical history can help determine if laxative use and choice of agent are appropriate in individual cases.

Case 15–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A mother seeks advice regarding her preschool-age daughter, who has been constipated for the past 10 days. The child has not been able to pass any stool despite repeated straining. Her abdomen also is bloated, and she is “cranky.” She is not interested in eating because of feeling “full.”

Relevant Evaluation Criteria	Scenario/Model Outcome
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The child recently started preschool and is eating new foods during the day.
c. Description of the patient's or caregiver's efforts to relieve the symptoms	The mother has been giving her daughter prune juice for the last 3 days.
d. Patient's identity	Allison Carter
e. Patient's age, gender, height, and weight	4 years, female, 3 ft 4 in., 40 lb
f. Patient's occupation	n/a
g. Patient's dietary habits	Eats pasta, pizza, chicken nuggets, and occasional fruit.
h. Patient's sleep habits	10 hours
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) -----	Allison typically has 2-3 bowel movements per day.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the	The patient is experiencing constipation, most likely precipitated by the change in her routine and environment and her consumption of different foods during the day. Also, her regular

Relevant Evaluation Criteria	Scenario/Model Outcome
patient's primary problem(s).	diet at home lacks sufficient fiber. Constipation in children is common with a change in routine and/or environment.
3. Identify exclusions for self-treatment (Figure 15-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to her pediatrician or other appropriate health care provider. (2) Recommend nondrug measures a. Institute a balanced diet with adequate fiber, fruits, and vegetables. b. At a minimum, drink fruit juices with sorbitol, which increases risk of diarrhea. c. Establish a regular stooling time for toilet-trained children (usually after a morning meal), and develop a supportive system (e.g., charts, stickers) for positively reinforcing bowel movements. d. Recommend strategies to prevent future recurrences of constipation. (3) Recommend docusate sodium 50–150 mg daily in single or divided doses to help facilitate resolution of symptoms. (4) Recommend a pediatric glycerin suppository. The glycerin suppository will offer the fastest resolution if the parent is able and willing to use that dosage form. (5) Recommend magnesium hydroxide chewable tablet 311 mg (2 tablets) or 400 mg (1–2 tablets) at bedtime daily to help facilitate resolution of symptoms. (6) For resolution of the symptoms, recommend senna 8.6 mg sennosides (½ tablet), senna liquid pod concentrate pediatric formulation 5 mL or 10 mL, or liquid sennosides 3.75 mL (2.5–3.75 mL) once daily. A

Relevant Evaluation Criteria	Scenario/Model Outcome
	stimulant laxative also will offer fast relief of symptoms. (7) Recommend self-care measures until the patient can see an appropriate health care provider. (8) Refer the patient to an appropriate health care provider if the therapeutic option and lifestyle changes do not alleviate symptoms within a week or if symptoms worsen with progression to self-care exclusions. (9) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	For fast relief of Allison's symptoms, she should be given a stimulant laxative, and Mrs. Carter should institute the recommended nondrug measures.
6. Describe the recommended therapeutic approach to the patient or caregiver.	Mrs. Carter should administer senna pediatric liquid concentrate formulation 5 mL (use the supplied measuring cup) once daily for resolution of Allison's symptoms. The medication usually takes effect in about 6–10 hours.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"The senna liquid concentrate pediatric formulation will provide quick relief within 6–10 hours. Once your child has become used to her new routine and environment, the constipation will most likely resolve. However, it is important to continue a healthy diet with fruits, vegetables, and fiber. It also may be helpful to establish a regular stooling time for toilet-trained children (usually after a morning meal) and to develop a supportive system (e.g., charts or stickers) for positively reinforcing bowel movements."
Implement	
8. When recommending self-care with	"For most patients, carefully following the product instructions and the self-care measures listed here will help achieve these

Relevant Evaluation Criteria	Scenario/Model Outcome
nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	goals.”
a. Appropriate dose and frequency of administration	“Read and carefully follow labeled dosage and administration instructions for all laxative products.”
b. Maximum number of days the therapy should be employed	“If symptoms continue after 7 days of laxative treatment, contact your health care provider.”
c. Product administration procedures	“Oral laxatives are available as tablets, capsules, thin-film strips, chewing gum, wafers, effervescent granules, gummy candy, chocolate tablets, and other forms. Choose the best form for you.”
d. Expected time to onset of relief	“The medication should take effect in 6 to 10 hours.”
e. Degree of relief that can be reasonably expected	“The constipation symptoms should be relieved.”
f. Most common adverse effects	“The most common adverse effects of laxatives are abdominal cramping, gas, bloating, and diarrhea.”
g. Adverse effects that warrant medical intervention should they occur	“Patients—who fail to achieve a therapeutic response after 7 days of self-treatment require medical referral. See Figure 15-2 and the box ‘Patient Education for Constipation’ for additional information.”
h. Patient options in the event that condition worsens or persists	“If constipation symptoms continue after 7 days of laxative treatment, contact your health care provider.”
i. Product storage requirements	“Store the medication in a cool, dry place out of children’s reach.”
j. Specific nondrug measures	“To promote regular bowel movements, use nondrug strategies such as initiation of a high-fiber diet (slowly increase intake to 25–35 g/day), intake of plenty of fluids, and regular exercise.”

Relevant Evaluation Criteria	Scenario/Model Outcome
Solicit follow-up questions from the patient or caregiver.	"Can the liquid laxative be mixed in fruit juice or milk to make it easier to give to my daughter?"
Answer the patient's or caregiver's questions.	"No—the senna liquid concentrate pediatric formulation has a root beer flavor to make it easier to administer to children."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mrs. Carter to call to update you on Allison's response to your recommendations. Alternatively, you could call her in a few days to evaluate the outcome.

Case 15–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient says that she is having a very difficult time passing stool. She reports straining to pass "normal-looking" but soft stools. She has been having only about 1 bowel movement per week and is feeling bloated. She has been experiencing these symptoms for the past month.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Patient notes that her problem really started when she broke her ankle in a bicycle accident and then began taking a pain medication prescribed by her regular health care provider.
c. Description of the patient's efforts to relieve the symptoms	The patient has been using a stool softener for the past 2 weeks.

d. Patient's identity	Margaret Thomas
e. Age, gender, height, and weight	30 years, female, 5 ft 7 in., 150 lb
f. Patient's occupation	Works in an office for a nonprofit organization.
g. Patient's dietary habits	Usual diet consists of lots of vegetables and salad, pastas, occasional whole-grain breads, meat and fish, caffeinated coffee, diet sodas, and desserts.
h. Patient's sleep habits	Sleeps about 8 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Vicodin (hydrocodone 7.5 mg/acetaminophen 325 mg) 1 tablet every 6 hours for pain; docusate 100 mg daily; multivitamin with iron
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Before her ankle injury, she typically had 3–4 bowel movements every week. She takes about 4 Vicodin tablets per day.

Assess

2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Ms. Thomas recently started taking an opioid medication, Vicodin, which can cause constipation. The patient's constipation appears to be correlated with the start of this medication. She also takes a multivitamin with iron, which can contribute to constipation.
3. Identify exclusions for self-treatment (Figure 15–2).	Unexplained changes in bowel habits; bowel symptoms that persist for more than 2 weeks.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to an appropriate health care provider. (2) Recommend self-care with a nonprescription laxative and nondrug measures.

	(3) Recommend self-care until the patient can see an appropriate health care provider. (4) Refer the patient to an appropriate health care provider if the selected therapeutic option and lifestyle changes do not alleviate symptoms within 1 week. (5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. Thomas has experienced constipation secondary to the initiation of an opioid medication. She has been experiencing constipation-related symptoms for 1 month. She should consult an appropriate health care provider. However, she also should implement nondrug measures to help prevent constipation and to promote a healthy lifestyle.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a health care provider since these symptoms have been going on for a month. You also should modify your diet to include more fiber, fruits, and vegetables. You should add a fiber supplement to your diet, and you should increase your fluid intake. Also, you should establish a regular exercise routine once your ankle is healed."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"This option is best because your constipation began after you started your new pain medication, and it has been occurring for a month. Therefore, nonprescription laxative therapy may not be the best choice right now. You should be evaluated by your health care provider."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Even though you need to see your health care provider, you can still implement nondrug measures that promote a healthy lifestyle, such as eating more fiber, fruits, and vegetables, and beginning a regular exercise routine when your ankle is healed. You should consult your health care provider about these measures as well."

Solicit follow-up questions from the patient or caregiver.	“Should I stop taking my pain medication?”
Answer the patient’s or caregiver’s questions.	“I would discuss this with your primary care provider. It may be time to decrease or stop your pain medication, especially if you are not experiencing severe pain. Your primary care provider also may be able to prescribe a different pain medication that does not cause constipation.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact the patient in 1-2 days to ensure that she made an appointment for further medical care.

Patient Counseling for Constipation

Patient education about laxative products is important for all patients (particularly for children and their caregivers and older adults). Before recommending a laxative product, health care providers should inform the patient of available nondrug measures, including information on proper diet, adequate fluid intake, and reasonable exercise. If a laxative is needed, the provider should explain why a particular type of laxative is appropriate for the present situation, how to use the laxative, when to expect results, what adverse effects could occur, and what precautions to take. The box “Patient Education for Constipation” lists specific information to include in patient counseling.

Evaluation of Patient Outcomes for Constipation

Once therapy has been selected, treatment effectiveness is determined by how rapidly constipation is relieved and to what degree normal bowel habits have been restored. With acute constipation, dietary changes, exercise, or bulk-forming laxatives may take several days to weeks to provide relief. Most

hyperosmotic, saline, or stimulant laxatives will provide relief within 3–72 hours. Enemas can produce evacuation within minutes. If initial treatment of constipation is ineffective, therapy should be repeated according to product-specific directions.

If an adequate response is not achieved after a short period of laxative use (usually within 7 days), assessment of whether the patient needs medical referral is indicated at the follow-up contact. If a laxative must be continued for an extended period, the patient should be referred for further evaluation, because the need for frequent use may be a sign of (1) a more severe form of constipation, (2) a medication adverse effect, or (3) an underlying medical problem.

Patient Education for Constipation

The primary goals of treatment are (1) to relieve constipation and reestablish normal bowel function, (2) to establish dietary and exercise habits to help prevent recurrence, and (3) to promote the safe and effective use of laxative products if needed. For most patients, carefully following the product instructions and the self-care measures listed here will help achieve these goals.

Nondrug Measures

- To promote regular bowel movements, use nondrug strategies such as initiation of a high-fiber diet (slowly increase intake to 25–35 g/day), intake of plenty of fluids, and regular exercise.
- Increase dietary fiber by eating foods with whole grains, oats, fruits, and vegetables.
- Avoid constipating foods, such as processed cheeses and concentrated sweets.
- Drink plenty of fluids (six to eight 8-ounce glasses a day) to help soften stool and move food through the GI tract.
- Develop and maintain a routine exercise program. Walking can be helpful if your heart is healthy and if you have no other apparent health risks.

- Establish a regular pattern for bathroom visits. Do not delay in responding to the urge to use the toilet; allow adequate time for elimination in a relaxed, unhurried atmosphere.
- Maintain general emotional well-being and avoid stressful situations.

Nonprescription Medications

- Bulk-forming laxatives (e.g., methylcellulose, psyllium)
- Hyperosmotic laxatives (e.g., polyethylene glycol [PEG] 3350, glycerin)
- Emollient laxatives, or “stool softeners” (e.g., docusate sodium)
- Lubricant laxative (mineral oil)
- Saline laxatives (e.g., magnesium citrate, magnesium hydroxide)
- Stimulant laxatives (e.g., bisacodyl, senna)

Complementary Therapies

- Not routinely recommended for self-treatment of constipation

Disease Information

- Constipation usually is defined as having fewer than 3 bowel movements per week that involve straining and the difficult passage of dry, hard stools. In most cases, constipation is temporary. Self-treatment for constipation is safe for short-term symptoms in patients without other underlying disorders or conditions.
- You do not need to take laxatives routinely if your bowel habits are interrupted for 1 or 2 days, nor do you need to routinely “clean your system.”

Drug Information

Bulk-Forming Laxatives

- Unless a rapid effect is needed (e.g., to clean out the bowel before a diagnostic endoscopic procedure or x-ray study), take a bulk-forming laxative. Be sure to drink at least 8 ounces of fluid with

each dose to prevent an intestinal blockage. If you have swallowing difficulties, alert your health care provider before taking a bulk-forming laxative.

- If you have diabetes or are on a carbohydrate- or calorie-restricted diet, choose sugar-free bulk-forming agents, if possible. Many bulk-forming agents contain sugar and have a high caloric content per dose.
- Do not give sugar-free bulk-forming products to patients with phenylketonuria.

Hyperosmotic Laxatives

- If you have irritable bowel syndrome, do not take PEG 3350 without the supervision of your primary care provider.
- When using PEG 3350, use the provided cap to measure the dose, or use 1 packet of powder of “single-serving” products. Mix the powder with 4–8 ounces of a hot, cold, or room-temperature beverage (e.g., water, juice, soda, coffee, tea).
- Consult a primary care provider before using glycerin suppositories if you have previously had a condition that caused rectal irritation.

Emollient Laxatives

- Do not take docusate if you are taking mineral oil unless told to do so by a primary care provider. Taking these together can increase the amount of mineral oil that gets into your body.

Lubricant Laxative

- Although some patients use mineral oil for occasional bouts of constipation, its use in self-care is strongly discouraged because safer agents that work just as well are available.
- Do not give mineral oil to children younger than 6 years, pregnant women, older adults, or immobile patients without the supervision of a primary care provider. These patients are at a higher risk for adverse effects from mineral oil.
- Do not take mineral oil with emollient laxatives (e.g., docusate). Taking these together can increase the amount of mineral oil that

gets into your body.

- To avoid impairing or delaying the absorption of foods, nutrients, and vitamins, do not take mineral oil within 2 hours of eating.
- Stop use and consult your health care provider if anal leakage of oil occurs. This adverse effect may indicate that your dose is too high.

Saline Laxatives

- Take doses with an 8-ounce glass of water, if possible, to prevent dehydration.
- Consult your health care provider before using a saline laxative if you are taking a diuretic (“water pill”) for high blood pressure (e.g., hydrochlorothiazide, furosemide), if you are taking other drugs that can cause electrolyte changes, or if you are on a sodium-, phosphate-, or magnesium-restricted diet.
- If you are an older adult, you may be at increased risk for dehydration or electrolyte imbalances with use of saline laxatives. Consult a health care provider before using these agents.
- Do not use magnesium sulfate (Epsom salt) to treat constipation except under the advice of a primary care provider.

Stimulant Laxatives

- Do not use castor oil to treat constipation except under the advice of a health care provider.
- Do not chew or crush bisacodyl tablets, which may cause stomach discomfort, fainting, and cramps. Do not use bisacodyl within 1 hour after taking an antacid or milk. Doing so can cause the tablet’s coating to break down too quickly.

Administration of Medication/Safe Usage

- Read and carefully follow labeled dosage and administration instructions for all laxative products.
- Oral laxatives are available as tablets, capsules, thin-film strips, chewing gum, wafers, effervescent granules, gummy candy, chocolate tablets, and other forms. Choose the best form for you, and consider glucose and caloric content if you have diabetes or

calorie restrictions.

- Rectal laxatives (enemas, suppositories) should be used according to administration instructions ([Table 15–6](#)).
- If constipation symptoms continue after 7 days of laxative treatment, contact your health care provider.
- Do not give laxatives to children younger than 2 years unless their use is recommended by a primary care provider.
- Take most laxatives at bedtime, especially if more than 6–8 hours will be needed to produce results.
- Do not take any laxatives at doses higher than the recommended amounts.

Warning Signs/Symptoms

- Do not take laxatives if you have marked abdominal pain, nausea, vomiting, significant abdominal distention, cramping, or fever—any of these may be evidence of a more serious condition (e.g., appendicitis).
- Do not take laxatives if you have a sudden change in bowel habits that persists for longer than 2 weeks, because such changes can be a sign of a more serious condition. See your primary care provider for treatment recommendations.
- With any rectal bleeding, presence of blood in your stool, or passage of black, tarry stools, see your health care provider. These may be signs of an underlying medical condition.
- If you have kidney or liver disease, heart failure, hypertension, or other conditions requiring sodium, potassium, magnesium, or calcium restriction, do not use laxative products with a maximum daily dose of more than 345 mg (15 mEq) sodium, 975 mg (25 mEq) potassium, 600 mg (50 mEq) magnesium, or 1800 mg (90 mEq) calcium.
- Consult your health care provider before using laxatives if you currently have or have a history of any condition that may affect self-treatment for constipation (e.g., paraplegia or quadriplegia, inflammatory bowel disease, colostomy, megacolon, ileostomy).
- Some laxatives require you to drink a lot of water with each dose. Patients with fluid restrictions should avoid bulk-forming or other

laxatives that require abundant fluid intake.

Adverse Effects

- The most common adverse effects of laxatives are abdominal cramping, gas, bloating, and diarrhea.

Interactions

- Avoid taking laxatives within 2 hours of ingestion of other medications.
- To make sure you avoid any potential drug–drug interactions, alert your health care provider if you are taking anticoagulants (blood thinners), digoxin (a heart medicine), sodium polystyrene sulfonate (an agent for treatment for high potassium levels), or other drugs that need to be maintained at precise levels.

Storage of Medications/Expiration Date/Signs of Instability

- Discard any medications that are outdated, that appear to have been tampered with, or that have an unusual appearance.

Key Points for Constipation

- Nonprescription laxative treatment should not be recommended if exclusion criteria for self-treatment are present ([Figure 15–2](#)). Patients in whom such exclusions are identified require medical referral.
- Special circumstances and patient characteristics (e.g., pregnancy, advanced age) should be considered in assessing the need for self-medication.
- For most cases of simple constipation, a balanced diet, exercise, and adequate fluid intake are helpful.

- Bulk-forming laxatives and PEG 3350 taken as directed are first-line choices for most adults with constipation, but they may take up to 72 hours to work. Glycerin suppositories or stimulant laxatives provide faster relief, if needed.
- Therapy with any laxative product should be limited to 7 days, unless supervised by a health care provider.
- If rectal bleeding occurs at any time during use of a laxative, or if constipation persists despite therapy, patients should stop using the laxative and consult a health care provider.¹⁵
- To reduce the potential for drug interactions, patients should avoid taking most laxatives within 2 hours of ingestion of other medications.

Chapter 16: Diarrhea

Authors: Paul C. Walker, Richard H. Dang

Diarrhea is a gastrointestinal (GI) disturbance characterized by an abnormal increase in stool frequency, liquidity, weight (greater than 200 g per 24 hours), or volume (200 mL per 24 hours).¹ Although the “normal” frequency of bowel movements varies with individual physiology, more than 3 bowel movements per day is considered abnormal.

Diarrhea may be acute, persistent, or chronic. *Acute* diarrhea, defined as presence of symptoms for fewer than 14 days, generally can be managed with fluid and electrolyte replacement, dietary interventions, and nonprescription drug treatment. In *persistent* diarrhea, symptoms last 14 days to 4 weeks. *Chronic* diarrhea, by definition, lasts more than 4 weeks. Chronic and persistent diarrheal illnesses often are secondary to other chronic medical conditions or treatments and necessitate medical care, so these illnesses are not considered in this chapter.

Worldwide, 2.4 billion episodes of acute diarrhea occur annually, making diarrhea a significant contributor to morbidity and mortality, especially for children younger than 5 years of age, in whom it causes 500,000 deaths each year.² The overall monthly prevalence of acute gastroenteritis (an irritation of the GI tract commonly caused by viruses or bacteria that often results in diarrhea) in the United States is 8.3%, with an annual incidence of approximately 1 episode per person per year.³ Prevalence rates are highest in children younger than 5 years of age and lowest in older adults (i.e., 65 years of age and older). Most patients experiencing diarrheal illness do not seek medical attention. However, in the United States, acute gastroenteritis and its complications result in 600,000 hospitalizations and 5,000 deaths, with an estimated cost of \$145 billion each year.³

Pathophysiology of Diarrhea

Table 16–1 highlights some of the common viral, bacterial, and protozoal infections associated with diarrhea and their treatment. Epidemiologic factors that increase the risk for particular infectious diarrheal diseases or their spread

include attendance or employment at daycare centers, occupation as a food handler or caregiver, congregate living conditions (e.g., nursing homes, prisons, multifamily dwellings), consumption of unsafe foods (e.g., raw or undercooked meat, eggs, shellfish), and presence of medical conditions such as acquired immunodeficiency syndrome (AIDS) or diverticulitis. Acute diarrhea also may be caused by poisoning, medications, intolerance of certain foods, or various non-GI acute or chronic illnesses. [Table 16–2](#) lists selected medications that may cause diarrhea.

Table 16–1 Common Infectious Diarrheas and Their Treatment

Type	Epidemiologic/ Etiologic Factors	Symptoms	Treatment	Usual Prognosis
Viral				
Rotavirus	Infects infants; oral-fecal spread	Onset at 24–48 hours after exposure; vomiting, fever, nausea, acute watery diarrhea	Vigorous fluid and electrolyte replacement	Self-limiting, usually lasts 5–8 days
Norovirus	Infects all ages; frequently spread person to person by the fecal–oral route; causes “24-hour stomach flu”	Onset at 24–48 hours after exposure; sudden-onset vomiting, nausea, headache, myalgia, fever, watery diarrhea	Fluid and electrolytes	Self-limiting, usually lasts 12–60 hours
Bacterial				
<i>Campylobacter jejuni</i>	Ingestion of contaminated food or water; oral-fecal spread; immunocompromised host	Onset at 24–72 hours after exposure; nausea, vomiting, headache,	Fluid and electrolytes; in severe or persistent diarrhea, antibiotics may be required ^a	Self-limiting, usually lasts <7 days

Type	Epidemiologic/ Etiologic Factors	Symptoms	Treatment	Usual Prognosis
		malaise, fever, watery diarrhea		
<i>Salmonella</i>	Ingestion of improperly cooked or refrigerated poultry and dairy products; immunocompromised host	Onset at 12–24 hours after exposure; diarrhea, fever, chills, malaise, myalgia, epigastric pain, anorexia	Fluid and electrolytes for mild cases; antibiotics reserved for complicated cases ^b	Self-limiting
<i>Shigella</i>	Ingestion of contaminated vegetables or water; frequently spread person to person; immunocompromised host	Onset at 24–48 hours after exposure; nausea, vomiting, diarrhea, (stool may contain blood or mucus), fever	Fluid and electrolytes; antibiotics ^c	Self-limiting, usually lasts <7 days
<i>Escherichia coli</i> (enterotoxigenic <i>E. coli</i> [ETEC], enteroaggregative <i>E. coli</i> [EAEC])	Ingestion of contaminated food or water; recent travel outside the United States or to a U.S. border area	Onset at 8–72 hours after exposure; watery diarrhea, fever, abdominal cramps, bloating, malaise, occasional vomiting	Fluid and electrolytes; antibiotics ^d	Self-limiting, usually within 3–5 days
Shiga toxin-producing <i>E. coli</i> (STEC), including <i>E. coli</i> O157:H7 and non- O157 strains	Ingestion of contaminated food or water; direct person- to-person spread	Onset at 8–72 hours after exposure; watery and often bloody diarrhea,	Fluid and electrolytes	Self-limiting, usually within 5–10 days

Type	Epidemiologic/ Etiologic Factors	Symptoms	Treatment	Usual Prognosis
		abdominal cramps, hemolytic uremic syndrome		
<i>Clostridioides difficile</i>	Antibiotic-associated diarrhea leading to pseudomembranous colitis	Onset during or up to several weeks after antibiotic therapy; watery or mucoid diarrhea, high fever, cramping	Fluid and electrolytes; discontinuation of offending agent; antibiotics	Self-limiting; tends to recur
<i>Clostridium perfringens</i>	Ingestion of contaminated food, especially meat and poultry	Onset at 8–14 hours after exposure; watery diarrhea without vomiting, cramping, mid-epigastric pain	Fluid and electrolytes	Self-limiting; usually resolves within 24 hours
<i>Staphylococcus aureus</i>	Ingestion of improperly cooked or stored food	Onset at 1–6 hours after exposure; nausea, vomiting, watery diarrhea	Fluid and electrolytes	Self-limiting
<i>Yersinia enterocolitica</i>	Ingestion of contaminated food	Onset within 16–48 hours of exposure; fever, abdominal pain, diarrhea, vomiting	Fluid and electrolytes; antibiotics may be needed in severe cases	Self-limiting, although diarrhea may persist for up to 3 weeks

Type	Epidemiologic/ Etiologic Factors	Symptoms	Treatment	Usual Prognosis
<i>Vibrio cholerae</i>	Ingestion of contaminated food, including undercooked or raw seafood; recent travel outside the United States	Onset within 24–48 hours of exposure; painless, watery, and often voluminous diarrhea, vomiting	Fluid and electrolytes; antibiotics needed in moderate to severe cases	Self-limiting, although severe, fatal illness may occur
<i>Bacillus cereus</i>	Ingestion of contaminated food	Onset within 10–12 hours of exposure; abdominal pain, watery diarrhea, tenesmus, nausea, vomiting	Fluid and electrolytes	Self-limiting
Protozoal				
<i>Giardia intestinalis</i>	Ingestion of water contaminated with human or animal feces; frequently spread person to person; immunocompromised host	Onset at 1–3 weeks after exposure; acute or chronic watery diarrhea, nausea, vomiting, anorexia, flatulence, abdominal bloating, epigastric pain	Fluids and electrolytes; antimicrobial therapy ^e	Resolves with treatment
<i>Cryptosporidium</i> spp.	Frequently spread person to person; travel outside the United States; AIDS, immunocompromised host	Onset at 2–14 days after exposure; acute or chronic watery diarrhea,	Fluid and electrolytes; antimicrobial therapy ^f	Self-limiting, lasting up to 3 weeks, except in patients with AIDS or other immunosuppressive diseases

Type	Epidemiologic/ Etiologic Factors	Symptoms	Treatment	Usual Prognosis
		abdominal pain, flatulence, malaise		
<i>Entamoeba histolytica</i>	Travel outside the United States; fecal-soiled food or water; immunocompromised host	Chronic watery diarrhea, abdominal pain, cramps	Fluid and electrolytes; antibiotics ^a	Good, except for immunocompromised host
<i>Isospora belli</i>	Ingestion of contaminated food or water; immunocompromised host	Onset at approximately 1 week after exposure; profuse watery diarrhea, malaise, anorexia, weight loss, abdominal cramps	Fluid and electrolytes; antibiotics	Self-limited, remitting in 2–3 weeks

^a Empiric therapy with prescription antibiotics (e.g., azithromycin, erythromycin) should be considered for patients with febrile diarrheal illness, especially if moderate to severe invasive disease is suspected, and for patients in whom supportive therapy fails to manage symptoms. Ciprofloxacin and doxycycline have been recommended but are no longer considered first-line agents because many *Campylobacter* strains are resistant to these antibiotics.

^b Antibiotics are not indicated routinely for *Salmonella* gastroenteritis; antibiotic therapy is used in infants and young children who fail to respond to supportive treatment, who do not spontaneously remit, or who are at increased risk of disseminated disease. Antibiotic therapy also is indicated for suspected bacteremia in patients at high risk for this complication. Such patients include those who appear to be toxic with high fever (temperature >102.2°F [39.0°C]); infants (<3 months); older adult patients (≥65 years); patients with cancer, immunodeficiency (e.g., AIDS), or hemoglobinopathy (e.g., sickle cell disease); immunocompromised persons (including transplant recipients and patients taking corticosteroids); patients who are on

hemodialysis; and patients with vascular grafts or prosthetic joints. Fluoroquinolones are used for adults if infection is *not* acquired in Asia; with Asia-acquired infections, azithromycin or ceftriaxone is recommended. Ceftriaxone is used for children. Duration of antimicrobial therapy is usually 7–14 days. Alternatively, azithromycin can be used for 5–7 days.

^c Antibiotic therapy should be reserved for immunocompromised patients or those with severe or complicated disease. A fluoroquinolone (ciprofloxacin, levofloxacin) or ceftriaxone is recommended for adults; azithromycin or ceftriaxone is recommended for children.

^d Antibiotic treatment with azithromycin, ceftriaxone, or rifaximin is given for moderate to severe traveler's diarrhea caused by *E. coli*; mild, self-limited infection usually can be managed symptomatically without antibiotics. Fluoroquinolones are no longer recommended as first-line agents in many regions of the world because of increasing resistance; trimethoprim–sulfamethoxazole is no longer recommended at all on account of resistance. Antibiotic treatment is not recommended for gastroenteritis caused by *E. coli* O157:H7, because such treatment is likely to enhance toxin release, which may increase risk for hemolytic uremic syndrome. Because antibiotic treatment of traveler's diarrhea also has been associated with increased risk for colonization by multidrug-resistant organisms, including extended-spectrum β -lactamase-producing and carbapenemase-producing strains of Enterobacteriaceae, single-dose regimens (azithromycin, fluoroquinolones) are equivalent to multidose regimens and may be more convenient for the traveler.³⁰ Adverse GI effects may limit use of single-dose azithromycin.

^e Self-treatment for giardiasis is not appropriate; tinidazole, metronidazole, and nitazoxanide are effective prescription alternatives for treating this condition.

^f Self-treatment for cryptosporidiosis is not appropriate. Nitazoxanide is the drug of choice for immunocompetent and human immunodeficiency virus (HIV)-negative patients. It is not approved for use in immunocompromised persons (including HIV-positive patients), in whom it is contraindicated; effective antiretroviral therapy is recommended as the best treatment for these patients.

^g Self-treatment for amebiasis is not appropriate; prescription therapy with metronidazole or tinidazole followed by either paromomycin or iodoquinol is preferred.

Key: AIDS = Acquired immunodeficiency syndrome; GI = gastrointestinal.

Viral Gastroenteritis

Noroviruses constitute the most common cause of diarrheal illness in adults and children, with the highest incidence in children younger than 5 years of

age. Noroviruses are responsible for 18% (or 685 million) of acute gastroenteritis infections occurring annually worldwide; one fifth of such infections in young children are caused by noroviruses. Globally, norovirus infection causes 212,000 deaths annually and imposes an economic burden of \$4.2 billion in direct health system costs and over \$60 billion in societal costs.⁴⁻⁷ Each year in the United States, noroviruses cause as many as 800 deaths, 71,000 hospitalizations, 400,000 emergency department visits, 1.9 million outpatient visits, and 21 million total illnesses.⁸

Norovirus gastroenteritis occurs year-round; in the United States, a seasonal peak of infection is seen each winter. The symptoms, clinical course, and treatment are described in [Table 16-1](#). Although most often transmitted by contaminated water or food, norovirus also can be transmitted from person to person and through contact with contaminated environmental surfaces. Outbreaks of infection frequently occur in health care institutions and long-term care facilities, on cruise ships and college campuses, and among military personnel and immunocompromised patients. Chronic norovirus infection is recognized as a significant risk in persons with compromised immune systems, who may experience symptomatic infection with chronic diarrhea for 4 weeks to 9 years.^{9,10}

Other viral causes of gastroenteritis include adenoviruses, astroviruses, enterovirus, hepatitis A virus, parechovirus, rotaviruses, and sapoviruses. Rotavirus causes gastroenteritis in patients of all ages; worldwide, it is the most common cause of severe diarrhea disease in infants and young children. Vaccines to prevent rotavirus gastroenteritis are available and are recommended for routine use in healthy infants. Vaccination rates among U.S. children 19–35 months of age range from 71% to 74% (for 2013 to 2017).¹¹ Despite this epidemiologically low vaccination rate, rotavirus is now detected in only about 3% of children with acute gastroenteritis.¹² Vaccination has lowered the burden of rotavirus disease significantly in the United States, reducing hospitalizations, emergency department visits, and outpatient visits.

Rotavirus tends to be a seasonal infection, with peaks of gastroenteritis occurring between November and February. It is spread by the fecal–oral route, can cause severe dehydration and electrolyte disturbances, and may result in death. Clinical features are presented in [Table 16-1](#).

Bacterial Gastroenteritis

Bacterial pathogens cause approximately 10% of acute diarrheal illnesses in the United States each year; most cases result from foodborne transmission.

Pathogens most commonly responsible, in order of decreasing causality, are *Campylobacter* spp.; *Salmonella* spp.; *Shigella* spp.; *Escherichia coli* (including O157:H7, non-O157:H7 Shiga toxin-producing *E. coli* [STEC], enterotoxigenic *E. coli* [ETEC], enteroaggregative *E. coli* [EAEC]), diffusely adherent *E. coli* [DAEC], and other diarrheagenic strains); *Clostridium* spp.; *Clostridioides difficile*; *Bacillus* spp.; *Staphylococcus* spp.; *Yersinia enterocolitica*; *Vibrio* spp.; and *Listeria* spp.^{13,14} In addition, *Aeromonas* spp., *Arcobacter* spp., enterotoxigenic *Bacteroides fragilis*, *Klebsiella oxytoca*, *Laribacter hongkongensis*, and *Plesiomonas shigelloides* also may cause acute diarrhea.

Bacteria cause diarrhea through elaboration of enterotoxin (e.g., ETEC, *Staphylococcus aureus*), by attachment and production of localized inflammatory changes in the gut (e.g., EAEC, enteropathogenic *E. coli*, STEC, *C. difficile*), or by directly invading the mucosal epithelial cells (e.g., *Shigella*, *Salmonella*, *Yersinia*, *Campylobacter jejuni*, invasive *E. coli*). Patients with diarrheal illness caused by toxin-producing pathogens have a watery diarrhea, with infection primarily involving the small intestine. If the large intestine is the primary site of infection, invasive organisms produce a dysentery-like (bloody diarrhea) syndrome characterized by fever, abdominal cramps, tenesmus (straining), and the frequent passage of small-volume stools that may contain blood and mucus. Clinical features of common bacterial diarrheas are presented in [Table 16–1](#).

Acute infectious gastroenteritis, most notably infection caused by *C. jejuni*, *Shigella*, *Salmonella*, diarrheagenic *E. coli*, norovirus, and *Giardia intestinalis*, is one of the strongest known risk factors for development of irritable bowel syndrome (IBS).¹⁵ Postinfection IBS develops in approximately 10% of patients with previous enteric infection and usually is diagnosed 1–2 years after an episode of acute gastroenteritis. The prognosis usually is favorable for most patients; IBS symptoms resolve 4–8 years after diagnosis.¹⁶ Acute gastroenteritis also may unmask or exacerbate underlying chronic GI disorders, such as celiac disease, Crohn disease, or ulcerative colitis.

Protozoal Diarrhea

Diarrhea also may be caused by protozoa, including *G. intestinalis*, *Entamoeba histolytica*, *Isospora belli*, and *Cryptosporidium* spp. Nonprescription therapies are not available to manage diarrhea caused by these pathogens, and self-management is inappropriate.

Foodborne Gastroenteritis

Foodborne transmission of pathogens causes 47.8 million episodes of acute gastroenteritis, more than 127,000 hospitalizations, and approximately 3000 deaths in the United States each year.¹⁷ When pathogens are identified, 59% of these infections are caused by viruses (predominantly noroviruses), 39% by bacteria, and 2% by protozoa.¹⁷ Recent surveillance statistics (all per 100,000 population) on the incidence of foodborne illnesses confirm that *Salmonella* and *Campylobacter*, which caused 15.45 and 13.45 cases of illness in 2012, respectively, are the most frequently diagnosed bacterial pathogens. These are followed by *Shigella* (5.81 cases), *Cryptosporidium* (2.44 cases per), STEC non-O157 (1.43 cases), STEC O157:H7 (0.92 case), *Vibrio* (0.45 case), *Yersinia* (0.28 case), and *Listeria* (0.24 case).¹⁸ Other causes of foodborne gastroenteritis include *Cyclospora cayetanensis* and rotavirus.

Outbreaks of foodborne bacterial infection have been traced to poor sanitation and manufacturing practices in food production facilities and contamination of foods in various community locations, such as grocery stores and restaurants. Outbreaks of infection also have been associated with specific foods listed in [Table 16–3](#). Accordingly, obtaining a thorough history of the patient’s food intake 48–72 hours before the onset of diarrhea is essential in identifying a possible cause.

Table 16–3 Specific Foods Associated With Foodborne Gastroenteritis	
Organism	Associated Foods
Shiga toxin-producing <i>Escherichia coli</i> (STEC), including <i>E. coli</i> O157:H7 and non-O157 strains	Apple cider, unpasteurized
	Bologna
	Clover sprouts, raw

Organism	Associated Foods
	Eggs
	Gouda cheese
	Ground beef (undercooked)
	Lettuce
	Milk, raw
	Cookie dough, raw, refrigerated prepackaged
	Spinach
<i>Salmonella</i>	Chicken
	Dry dog food ^a
	Eggs
	Ground beef
	Ground turkey
	Jalapeno peppers
	Mangoes
	Melons (e.g., cantaloupe)
	Papayas
	Peanut butter
	Pine nuts
	Pistachio nuts
	Red and black pepper spice
	Yellowfin tuna, raw, scraped, ground
<i>Campylobacter</i>	Milk
	Chicken

Organism	Associated Foods
<i>Listeria</i>	Cold cuts
	Hummus
	Melons
	Milk
	Ricotta cheese
	Soft cheeses
<i>Cyclospora</i>	Raspberries

^a *Salmonella* infection is a zoonotic disease—that is, the infection can be transmitted from animals to people, and people have acquired *Salmonella* infections after contact with contaminated dry pet food or with an animal that has eaten contaminated dry pet food. Spread is by the fecal–oral route.

Outbreaks of acute foodborne illness caused by *E. coli* O157:H7 and other STECs constitute a major public health issue. Toxins produced by these organisms cause an acute bloody diarrhea and may be associated with serious, potentially fatal systemic complications, such as hemolytic uremic syndrome or thrombotic thrombocytopenic purpura.

Traveler’s Diarrhea

Traveler’s diarrhea is an acute, secretory diarrhea (i.e., the pathogen or its toxin affects the ion transport processes of the epithelial cells, thereby stimulating the active secretion of electrolytes and water into the intestines).¹⁹ This type of diarrhea is acquired mainly through ingestion of food or water contaminated with bacterial enteropathogens. It is the most predictable and common travel-related illness, with rates as high as 70%, and most often is of bacterial origin.²⁰ Traveler’s diarrhea can be caused by (in decreasing order of frequency) ETEC, *C. jejuni*, *Shigella* spp., *Salmonella* spp., EAEC, and DAEC; viral pathogens (e.g., norovirus); or parasites (e.g., *Giardia* spp., *Cryptosporidium* spp., *Entamoeba* spp.).²¹ Other causative bacterial pathogens include *Shigella* spp., *Salmonella*

spp., *C. jejuni*, *Aeromonas* spp., *Plesiomonas* spp., enterotoxigenic *B. fragilis*, and non-cholera *Vibrio* spp. Causative pathogens often are found on fruits, vegetables, raw meat, and seafood, and even in hot sauces, as well as in local water, including ice cubes made from tap water. The diarrheal disorders caused by these organisms are characterized in [Table 16–1](#). Bacterial and viral pathogens have an incubation period of 6–72 hours and thus result in a quicker onset of diarrhea than that typical for protozoal pathogens. Protozoal pathogens generally have an incubation period of 1–2 weeks, with onset of diarrhea rarely seen in the first few days of travel. A potential exception is *Cyclospora cayetanensis*, for which diarrheal illness can manifest quickly in areas of high risk.²⁰ The characteristic course includes production of 3–8 (or more) watery stools per day, with symptoms usually subsiding over 3–7 days.

Food-Induced Diarrhea

Food intolerance can provoke diarrhea and may result from a food allergy or ingestion of foods that are excessively fatty or spicy or contain a high amount of dietary fiber or many seeds. Dietary carbohydrates (e.g., lactose, sucrose) normally are hydrolyzed to monosaccharides by the enzyme lactase. If not hydrolyzed, these carbohydrates pool in the lumen of the intestine, where they produce an osmotic imbalance. The resulting hyperosmolarity draws fluid into the intestinal lumen, causing diarrhea. Lactase activity may be reduced by infectious diarrhea; thus, acute viral diarrhea may cause temporary milk intolerance in patients of all ages. Lactase deficiency resulting from viral gastroenteritis is short-lived, but it is particularly problematic during the first few days of the disease. Infants born with lactase deficiency and adults who acquire lactase deficiency are intolerant of cow milk and milk-based products. Lactase enzyme products are effective treatments for some patients (see “Treatment of Diarrhea”).

Clinical Presentation of Diarrhea

The most common signs and symptoms of acute infectious diarrheal illnesses are shown in [Table 16–1](#). Variability in the causes of diarrhea makes identification of the pathophysiologic mechanisms difficult. The etiology, and subsequently the pathophysiology, can be determined by obtaining a thorough medical history in most cases. However, a complete medical

assessment, including clinical laboratory evaluation, may be required to identify the cause in a subset of patients with severe or persistent diarrhea.

Diarrhea can be classified as osmotic, secretory, inflammatory, or motor, depending on the underlying pathophysiologic mechanisms that disrupt normal intestinal function. The common mechanisms of acute diarrhea are osmotic and secretory, whereas motor and inflammatory mechanisms commonly underlie chronic diarrheal illnesses. **Table 16–4** correlates the clinical groups and mechanisms with their most common causes.

Table 16–4 Clinical Classification of Diarrhea

Type	Mechanism(s)	Common Causes
Osmotic	• Unabsorbed solutes in intestines increase luminal osmotic load, retarding fluid absorption. • Decreased absorption of solutes and fluid can be secondary to brush border damage caused by lactase deficiency or infection. • Viral-induced damage to epithelial cells accelerates migration of immature crypt cells to the tip of the villus; altered epithelial turnover also decreases absorption.	Infections: noroviruses, rotaviruses, <i>Escherichia coli</i> , <i>Campylobacter jejuni</i> ; lactase deficiency, excess magnesium antacid intake
Secretory	• Stimulation of crypt cells produces net flow of electrolytes and fluids into intestinal lumen. • Tumors can secrete GI hormones and peptides that act as secretagogues.	Infections: <i>C. jejuni</i> , <i>Clostridioides difficile</i> , <i>E. coli</i> , <i>Salmonella</i> , <i>Shigella</i> , <i>Vibrio</i> , rotaviruses, <i>Giardia intestinalis</i> , <i>Cryptosporidium</i> spp., <i>Isospora</i> ; ileal resection, thyroid cancer
Inflammatory	• Impaired fluid absorption and leaking of mucus, blood, and pus into lumen caused by	Infections: <i>C. jejuni</i> , <i>E. coli</i> , <i>Salmonella</i> , <i>Shigella</i> , <i>Yersinia</i> , <i>Entamoeba histolytica</i> ; ulcerative colitis, Crohn disease

Type	Mechanism(s)	Common Causes
	inflammation of intestinal mucosa (e.g., IBD) or bacterial infection (i.e., dysentery).	
Motor	Abnormally rapid intestinal transit time reduces contact time between luminal contents and absorptive areas of intestinal wall.	IBS, diabetic neuropathy

Key: GI = Gastrointestinal; IBD = inflammatory bowel disease; IBS = irritable bowel syndrome.

Bacterial enterotoxins play a role in the pathophysiology of secretory diarrheas. Enterotoxins elaborated by *E. coli* and *Vibrio cholerae* evoke the release of endogenous secretagogues that mediate secretory reflexes, including serotonin, substance P, and vasoactive intestinal peptide. Some enterotoxins, such as cholera toxin, can directly stimulate GI secretomotor neurons to increase intestinal secretion. *Clostridioides difficile* enterotoxin A also injures enterocytes and evokes a necroinflammatory response that causes a secretory diarrhea. Although viruses, such as rotavirus, also produce enterotoxins, the role of viral enterotoxins in the disease pathophysiology is uncertain. In addition, inflammatory mediators (e.g., interleukins 1 and 6, prostaglandins, substance P, tumor necrosis factor α , platelet-activating factor) evoked by enteric infection stimulate a characteristic GI motility pattern that leads to the urgent defecation associated with diarrhea and that causes abdominal cramps.

Stool characteristics give valuable information about the pathophysiology of the diarrheal illness. For example, undigested food particles in the stool suggest disease of the small intestine. Black, tarry stools may indicate upper GI bleeding, and red stools suggest possible lower bowel or hemorrhoidal bleeding or simply recent ingestion of red food (e.g., beets) or drug products

(e.g., rifampin). In secretory diarrhea of the small bowel, chloride secretion and inhibition of sodium absorption appear to be the major events; thus, stools will be high in sodium content. Passage of many small-volume stools suggests a colonic disorder. Yellowish stools may indicate the presence of bilirubin and potentially serious pathology of the liver. A whitish tint to the stool points to a fat malabsorption disease.

Fluid and electrolyte imbalance is the major complication of diarrheal illness. Therefore, assessment of the patient's risk for dehydration and the degree of dehydration present is key to determining the appropriateness of self-care and the need for medical referral. The specific signs and symptoms of dehydration correlate with the severity of the diarrhea, as well as the etiology and degree of fluid and electrolyte losses ([Table 16-5](#)).²²

Table 16-5 Assessment of Dehydration and Severity of Acute Diarrhea			
Assessment Feature	Self-Treatable		Not Self-Treatable
	Minimal or No Dehydration	Mild to Moderate Dehydration/Diarrhea	Severe Dehydration/Diarrhea
Degree of dehydration (% loss of body weight)	<3%	3%–9%	>9%
Signs of dehydration ^a			
Mental status	Good, alert	Normal, fatigued or restless, irritable	Apathetic, lethargic, unconscious
Thirst	Drinks normally, might refuse liquids	Thirsty, eager to drink	Drinks poorly, unable to drink
Heart rate	Normal	Normal to increased	Tachycardia, bradycardia in most severe cases

Assessment Feature	Self-Treatable		Not Self-Treatable
	Minimal or No Dehydration	Mild to Moderate Dehydration/Diarrhea	Severe Dehydration/Diarrhea
Quality of pulses	Normal	Normal to decreased	Weak, thready, impalpable
Breathing	Normal	Normal, fast	Deep
Eyes	Normal	Slightly sunken ^b	Deeply sunken ^b
Tears	Present	Decreased ^b	Absent
Mouth and tongue	Moist	Dry	Parched
Skin fold	Instant return (recoil) to normal on release	Recoil in <2 seconds	Recoil in >2 seconds
Capillary refill	Normal	Prolonged	Prolonged, minimal
Extremities	Warm	Cool	Cold, mottled, cyanotic
Urine output	Normal to decreased	Decreased ^b	Minimal ^b
Number of unformed stools/day	<3	3–5	6–9
Other signs/symptoms	Afebrile, normal blood pressure, no orthostatic changes in blood pressure/pulse	May be afebrile or may develop fever with temperature >102.2°F (39.0°C); normal blood pressure; possible mild orthostatic blood pressure/pulse changes with or without mild orthostatic-related symptoms ^c ; sunken fontanelle ^d	Fever with temperature >102.2°F (39.0°C), low blood pressure, dizziness, severe abdominal pain

^a If signs of dehydration are absent, rehydration therapy is not required. Maintenance therapy and replacement of fluid losses in stool should be undertaken.

^b Signs and symptoms experienced, especially by young children.

^c Postural (orthostatic) hypotension is defined as a drop in the systolic and/or diastolic pressure of >15–20 mm Hg on movement from a supine to an upright position and may be associated with lightheadedness, dizziness, or fainting. On rising, the diastolic pressure normally remains the same or increases slightly, and the systolic pressure drops slightly. If the blood pressure drops, the pulse should be checked simultaneously; the pulse rate should increase as blood pressure drops. Failure of the pulse to rise points to a neurogenic problem (e.g., in diabetic patients with peripheral neuropathy) or may indicate that the patient is taking a beta blocker. The presence of orthostatic hypotension suggests that the patient has lost ≥ 1 L of vascular volume, and referral for medical care is necessary.

^a Signs and symptoms of concern in young infants. Source: Adapted from reference 20.

Children younger than 5 years and adults older than 65 years are at greater risk for complications than other age groups. In the United States, most children recover completely from diarrhea; however, approximately 1.7 per 100,000 young children die annually from complications of acute gastroenteritis.²³ Children 2 years of age and younger are more likely to suffer complications that necessitate hospitalization. In newborns, water may make up 75% of total body weight; severe diarrhea may cause water loss equal to 10% or more of body weight. After 8–10 bowel movements within a 24-hour period, a 2-month-old infant can potentially lose enough fluid to result in circulatory collapse and renal failure.

People 65 years of age and older are likely to experience more severe diarrhea than other adults and also may experience the highest rate of death from enteric infections.

Algorithm: Acute Diarrhea in Children 6 Months to 5 Years

Figure 16–1 Self-care for acute diarrhea in children 6 months to 5 years. Key: AIDS = Acquired immunodeficiency syndrome; BW = body weight; CVD = cardiovascular disease; D/C = discontinue; I.V. = intravenous; ORS = oral rehydration solution. (Source: Adapted from [references 24–26](#).)

Algorithm: Acute Diarrhea in Children Older than 5 Years

Figure 16–2 Self-care for acute diarrhea in children older than 5 years, adolescents, and adults. Key: D/C = Discontinue; ORS = oral rehydration solution.

Treatment of Diarrhea

Treatment Goals

The goals of self-treatment for diarrhea are to (1) prevent or correct fluid and electrolyte loss and acid–base disturbance, (2) control symptoms, (3) identify and treat the cause, and (4) prevent acute morbidity and mortality.

General Treatment Approach

Infectious diarrhea is often self-limiting. Initial self-management in both adults and children with mild to moderate, uncomplicated diarrhea should focus on fluid and electrolyte replacement by administering commercially available oral rehydration solutions (ORSs) in adequate doses ([Table 16–6](#)). Simultaneous implementation of oral rehydration and specific dietary measures is appropriate for treating mild to moderate diarrheal illness. Symptomatic control also can be achieved by using nonprescription antidiarrheal drugs, such as loperamide, in carefully selected patients. Patients with uncomplicated acute diarrhea who are otherwise healthy usually improve clinically within 24–48 hours; normal bowel function often is restored in 24–72 hours without additional treatment. If the condition remains the same or

worsens after 48 hours of onset, medical referral is necessary to prevent complications.^{24–26} Specific exclusions for self-treatment that require referral for medical evaluation are listed in [Figure 16–1](#).

Table 16–6 Composition of Selected Oral Rehydrating Solutions (ORSs) and Common Household Fluids

Solution/Fluid	Osmolarity (mOsm/L)	Sodium (mEq/L)	Potassium (mEq/L)	HCO₃[−] (mEq/L)	Carbohydrate (g/L)
WHO Recommendations					
Standard-osmolarity ORS	310	90	30	30	20
Reduced-osmolarity ORS	245	75	20	20	13.5
<i>Acceptable range</i>	200–310	60–90	15–25		
Commercially Available Products					
Ceralyte	235	70	20	10	40
Enfalyte	200	50	25	30	30
Pedialyte	250	45	20	30	25
Rehydralyte	310	75	20	30	25
Common Household Remedies					
Apple juice	700	3	20	0	100–150
Chicken broth	450	250	5	0	0
Colas	700	2	0.1	13	100–150
Gatorade	330	20	3	3	45
Ginger ale	565	3.5	0.1	3.6	90
Tea	5	0	0	0	0

Key: HCO₃[−] = Bicarbonate; WHO = World Health Organization.

With diarrhea of any severity in infants younger than 6 months of age, moderate diarrhea in children 2 years of age and younger, and unusually high fluid output, significant fever, or mental status changes in young children, evaluation by a primary care provider or a health care provider in an emergency department is always indicated (Figure 16–1).²² Severe diarrhea in any patient constitutes a medical emergency and necessitates immediate referral for medical evaluation and treatment with intravenous (IV) fluid therapy. Presence of blood or mucus in the stool also warrants medical evaluation. Certain medical conditions can increase the risk for dehydration. Referral for medical care should be considered for patients with diabetes, severe cardiovascular or renal diseases, concurrent respiratory tract infection, or multiple unstable chronic medical conditions. Patients with severe abdominal pain or cramping (particularly those older than 50 years of age) or abdominal tenderness or distention may have a complicating acute abdominal process, such as ischemic bowel disease, and should be referred for medical evaluation.²⁷ Immunocompromised patients, such as those receiving cancer treatment, organ transplant recipients, and patients with AIDS, also need medical evaluation, because their diarrheal illness often will be complicated and difficult to manage.

Self-care during pregnancy is not appropriate. Although diarrhea can be a normal physiologic occurrence during pregnancy, it may be a symptom of GI infection.²⁸ *C. jejuni* and *Salmonella* may cause severe, even fatal maternal infection. Furthermore, *C. jejuni*, *Salmonella*, and *Listeria* are recognized causes of intrauterine infection and perinatal death.^{28,29} Pregnant women experiencing diarrhea should consult a primary care provider or an obstetrician.

Nonpharmacologic Therapy

Fluid and Electrolyte Management

Rehydration using reduced osmolarity ORS is the preferred, first-line treatment for mild to moderate diarrhea. This approach is as effective as IV replacement therapy in managing fluid and electrolytes in children with mild to moderate dehydration secondary to diarrhea. Health care providers can safely recommend an ORS for mild to moderate diarrhea in patients with no exclusions to self-care.

Water absorption in the small intestine is passive and depends on the absorption of electrolytes and selected solutes such as sodium, chloride, glucose, small peptides, and amino acids. As these substances are absorbed, water accompanies their movement to maintain an isotonic state. Sodium ion transport is the primary mechanism controlling water movement. An active sodium–potassium adenosine triphosphatase pump present in enterocytes moves sodium into the cell in exchange for potassium ions. Other transport mechanisms include the sodium–glucose and sodium–amino acid cotransport processes (each of which transports these substances into the enterocytes) and the sodium luminal exchange mechanism. The sodium–glucose cotransport mechanism, in which glucose absorption is coupled with active transport of sodium, is important in the management of diarrhea. Unlike other sodium transport systems, the sodium–glucose cotransport mechanism is not adversely affected by most diarrheal diseases, and hypotonic ORSs containing low concentrations of glucose or dextrose (2%–2.5%) can be useful in managing fluid and electrolyte balance. The sugar molecules provide little caloric support but facilitate intestinal sodium and water absorption. Maximal sodium absorption occurs at a molar glucose-to-sodium ratio close to 1.

Depending on the patient's fluid and electrolyte status, oral treatment may be carried out in two phases: rehydration therapy and maintenance therapy. Rehydration over 3–4 hours quickly replaces water and electrolyte deficits to restore normal body composition. In the maintenance phase, electrolyte solutions are given to maintain normal body composition until adequate dietary intake is reestablished. [Figures 16–1](#) and [16–2](#) outline rehydration and maintenance therapies, including fluid and electrolyte recommendations for children and adults. Although use of an ORS generally is recommended for adults with diarrhea, little evidence supports this practice, and ORSs may not provide any real benefit to otherwise healthy adults with mild diarrhea who can maintain an adequate fluid intake. For these patients, fluid and electrolyte status can be maintained by increasing intake of fluids such as clear juices, soups, or sports drinks.

A variety of oral rehydration products are available ([Table 16–6](#)). Most products are premixed solutions; a few are available as dry powders of glucose and electrolytes that require the addition of water. The premixed products are preferred for use in children because they are safe and convenient; improper mixing of dry powders by caregivers has led to fluid and electrolyte complications and injury. All available premixed solutions are equally safe and

effective; there is no evidence that one product is clinically superior to another for rehydration. The World Health Organization (WHO) and United Nations Children's Fund (UNICEF) recommend use of an ORS containing 75 mEq/L of sodium.^{30,31} Compared with the previously recommended ORSs (which contained 90 mEq/L of sodium), this reduced-osmolality ORS significantly reduces the need for unscheduled IV therapy, the duration of diarrhea, stool output, and the incidence of vomiting in children with non-cholera diarrhea. This type of ORS also is effective in children and adults with cholera, although transient, asymptomatic hyponatremia may develop in adults. Rehydration solutions available in the United States contain 70–90 mEq/L of sodium; maintenance solutions contain 45–50 mEq/L of sodium.

Some cereal-based products use complex carbohydrates (e.g., rice syrup solids) instead of glucose. Complex carbohydrates are converted into glucose at the intestinal brush border and provide more cotransport molecules while reducing the osmotic load of the ORS. Cereal-based ORS therapy potentially reduces stool volume by 20%–30% in children with cholera but may not significantly alter stool volume in children with non-cholera acute diarrhea.

A variety of common household oral solutions also have been used for oral rehydration and maintenance ([Table 16–6](#)). These solutions may be sufficient to manage mild, self-limiting diarrhea in some patients, but they should be avoided if dehydration is a feature or in cases of moderate to severe diarrhea. Unlike commercial ORSs, these remedies are not formulated on the basis of the physiology of acute diarrhea. The content of these fluids is not equivalent to that of ORSs and may be inappropriate. The high carbohydrate content and osmolality of these solutions can worsen diarrhea, and their low sodium content can contribute to the development of hyponatremia. Sports drinks may be used in children older than 5 years and adults if additional sources of sodium, such as crackers or pretzels, are used concomitantly. Colas, ginger ale, apple juice, sports drinks, and similar products are not recommended for infants and young children (6 months to 5 years of age) with diarrhea. Tea, another popular household remedy, also is inappropriate for children because of its low sodium content. Chicken broth is not recommended because of its inappropriately high sodium content.

Dietary Management

Oral intake does not worsen diarrhea, and clinically significant nutrient

malabsorption is uncommon in acute diarrhea. In fact, during acute diarrhea, patients are able to absorb 80%–95% of dietary carbohydrates, 70% of fat, and 75% of the nitrogen from protein. Furthermore, early refeeding, in combination with maintenance oral rehydration, improves outcomes in children by reducing the duration of the diarrhea, decreasing stool output, and improving weight gain. If necessary, food should be withheld for no longer than 24 hours and be reintroduced using a normal, age-appropriate diet once the patient has been rehydrated, which should take no longer than 3–4 hours to accomplish.²² Most infants and children with acute diarrhea can tolerate full-strength breast milk and cow milk. The BRAT diet (bananas, rice, applesauce, and toast) is not recommended; it provides insufficient calories, protein, and fat, especially in situations of strict or prolonged use.²² Patients (or their parents or other caregivers) should be advised to avoid fatty foods; foods rich in simple sugars (e.g., carbonated soft drinks, juice, gelatin desserts), which can cause osmotic diarrhea; spicy foods, which may cause GI upset; and caffeine-containing beverages, which can promote fluid secretion and may worsen diarrhea.

There is no evidence that fasting or dietary modification influences outcomes of acute diarrhea in adults; however, the previous recommendations about foods to avoid can be applied if a normal diet is not tolerated.²²

Preventive Measures

Infectious diarrhea, especially acute viral gastroenteritis, often occurs in congregate living conditions such as daycare centers and nursing homes through person-to-person transmission. Isolation of the person affected with diarrhea, strict attention to handwashing, and use of sterile techniques are basic preventive measures that reduce the risk of transmission among such populations, including caregivers. Proper food handling, sanitation, and other hygienic practices help control transmission of bacteria and other infectious agents.

Although short-term bismuth subsalicylate (BSS) prophylaxis is frequently recommended to provide protection against travelers' diarrhea, the U.S. Food and Drug Administration (FDA) has deemed that available data are insufficient to support prophylactic use of BSS. However, the American College of Gastroenterology (ACG) has published a guideline on the use of BSS or loperamide to prevent and manage mild to moderate traveler's diarrhea.²⁴ Unless BSS is contraindicated (e.g., salicylate allergies; patients <12 years old

unless under medical supervision; children or teenagers recovering from influenza or varicella; current use of a salicylate product), the recommended dosing is 2.1 g 4 times daily (at meals and bedtime). This regimen may reduce risk by up to 60% and is most effective for trips lasting up to 2 weeks. Neither lower doses nor preventive use during trips lasting longer than 2 weeks has been shown to offer benefit. ACG recommends dosing of loperamide for a maximum of 48 hours and titration to maximum benefit while attempting to avoid drug-induced constipation. For patients with dysentery, use of loperamide, even when given concomitantly with antibiotics, may not be indicated in some cases of worsening symptoms.²⁴ Antibiotics with reliable activity against endemic enteropathogens (e.g., fluoroquinolones, rifaximin) provide effective prophylaxis. However, prophylactic antimicrobial agents are not currently recommended for most travelers.³² Prophylactic antibiotics may be considered for short-term travelers who are high-risk hosts (e.g., immunosuppressed patients) or travelers with underlying conditions that may be complicated by diarrheal illness, or for critical trips during which even a short bout of diarrhea could adversely affect the purpose of the trip.³²

Pharmacologic Therapy

Although in most cases acute, nonspecific diarrhea in the United States is self-limiting, nonprescription antidiarrheal products may provide symptom control and will usually do no harm when used according to label instructions. [Table 16–7](#) lists dosage and administration guidelines for these agents. However, evidence is lacking to show that pharmacologic agents other than loperamide and BSS reduce stool frequency or duration of disease in adults. [Table 16–8](#) lists available trade-name products that contain loperamide and BSS. No antidiarrheal drugs have been shown to significantly improve clinical outcomes for acute, nonspecific diarrhea in infants and children 5 years of age and younger.

Table 16–7 Recommended Dosages of Nonprescription Antidiarrheal Agents for Acute Diarrhea				
Medication	Dosage Forms	Adult Dosages (maximum daily dosage)	Pediatric Dosages	Duration of Use
Loperamide	Caplets (2 mg), liquid (1	Caplets: 4 mg initially, followed by 2 mg after each loose stool (not to exceed 8 mg/day)	Consult product instructions; not recommended	48 hours

Medication	Dosage Forms	Adult Dosages (maximum daily dosage)	Pediatric Dosages	Duration of Use
	mg/7.5 mL)	Liquid: 4 mg (30 mL) initially, followed by 2 mg (15 mL) after each loose stool (not to exceed 8 mg/day [60 mL/day])	for children <6 years except under medical supervision 6–8 years (48–59 lb [22–27 kg]): Caplets: 2 mg initially, followed by 1 mg after each loose stool (not to exceed 4 mg/day) Liquid: 2 mg (15 mL) initially, followed by 1 mg (7.5 mL) after each loose stool. Do not give >4 mg (30 mL) in 24 hours. 9–11 years (60–95 lb [27–43 kg]): Caplets: 2 mg initially, followed by 1 mg after each loose stool (not to exceed 6 mg/day) Liquid: 2 mg (15 mL) initially, followed by 1 mg (7.5 mL) after each loose stool. Do not give >6 mg (45 mL) in 24 hours.	
Bismuth subsalicylate	Tablets (262 mg), caplets (262 mg), liquids (262 mg/15 mL, 525 mg/	Tablets/caplets: 525 mg every 30–60 minutes up to 4200 mg/day (8 doses/day) Liquid: 262 mg/15 mL strength: 525 mg (30 mL) every 60 minutes up to 240 mL/day (8 doses/day); 525 mg/15 mL strength: 1050 mg (30 mL)	Not recommended for children <12 years except under medical supervision	48 hours

Medication	Dosage Forms	Adult Dosages (maximum daily dosage)	Pediatric Dosages	Duration of Use
	15 mL)	every 60 minutes up to 120 mL/day (4 doses/day)		
Digestive enzymes (lactase)	Chewable tablets, caplets, liquids	Tablets: 1-3 with first bite of dairy product Capsules: 1-2 with first bite of dairy products Liquid: 5-15 drops placed in or taken with dairy product	Same as adult dosage	Taken with each consumption of dairy product

Table 16–8 Selected Nonprescription Antidiarrheal Products

Trade Name	Primary Ingredient(s)
Loperamide Products	
Imodium A-D Caplets/Imodium EZ Chews (Tablets)	Loperamide HCl 2 mg
Imodium Advanced Caplets/Chewable Tablets	Loperamide HCl 2 mg; simethicone 125 mg
Imodium A-D Liquid	Loperamide HCl 1 mg/7.5 mL
Bismuth Subsalicylate Products	
Kaopectate Flavored Liquid (Cherry, Peppermint, Vanilla)	Bismuth subsalicylate 262 mg/15 mL (contains 130 mg of salicylate)
Kaopectate Extra Strength Peppermint Flavor Liquid	Bismuth subsalicylate 525 mg/15 mL (contains 236 mg of salicylate)
Kaopectate Antidiarrheal Caplets	Bismuth subsalicylate 262 mg (contains 99 mg of salicylate)
Maalox Total Relief Flavored Liquid (Peppermint, Strawberry)	Bismuth subsalicylate 525 mg/15 mL (contains 232 mg of salicylate)
Pepto-Bismol Caplets	Bismuth subsalicylate 262 mg (contains 99 mg of salicylate)
Pepto-Bismol Cherry Chewable Tablets	Bismuth subsalicylate 262 mg (contains 99 mg of salicylate)
Pepto-Bismol Chewable Tablets (Original,	Bismuth subsalicylate 262 mg (contains 102 mg of

Trade Name	Primary Ingredient(s)
InstaCool Peppermint)	salicylate)
Pepto-Bismol Liquid (Original, Cherry)	Bismuth subsalicylate 262 mg/15 mL (contains 130 mg of salicylate)
Pepto-Bismol Max Strength Liquid	Bismuth subsalicylate 525 mg/15 mL (contains 236 mg of salicylate)

Note: Pepto-Bismol adult formulations contain bismuth subsalicylate, but the products for children that contain calcium carbonate as the active ingredient are not listed.

Loperamide

The opioid agonist loperamide is a nonprescription antidiarrheal agent that provides symptomatic relief of acute, nonspecific diarrhea. When used according to the labeled instructions, loperamide is safe and effective. Loperamide reduces daily fecal volume, increases viscosity and bulk volume, and reduces fluid and electrolyte loss. It reduces peristalsis and increases intestinal transit time by stimulating peripheral micro-opioid receptors on the intestinal circular muscles to slow intestinal motility and allow absorption of electrolytes and water. Disruption of cholinergic and noncholinergic mechanisms involved in the regulation of peristalsis also may contribute to this effect. Loperamide also inhibits calcium channels and has antisecretory effects.

Loperamide undergoes extensive first-pass metabolism by cytochrome P450 (CYP) 3A4 and CYP2C8 to inactive metabolites and is a substrate for the efflux transporter P-glycoprotein (P-gP). These characteristics limit its bioavailability to 0.3%.^{33,34} P-gP also limits its distribution into the central nervous system (CNS), which minimizes risk for CNS adverse effects at the usual doses. When taken at very high doses or with inhibitors of CYP3A4, CYP2C8, or P-gP, loperamide can produce CNS effects and its plasma concentrations can reach toxic concentrations. At these concentrations, loperamide disrupts cardiac conduction to cause life-threatening and sometimes fatal cardiac dysrhythmias, including torsades de pointes.^{33–35}

Loperamide is increasingly being misused and abused to achieve euphoria or

to prevent opioid withdrawal symptoms, with such use often resulting in patient harm or death.^{36–38} In response, FDA requires a Boxed Warning about torsades de pointes and sudden death with use of higher-than-recommended doses in the prescription product labeling and limits the number of doses in a package of nonprescription-strength loperamide.³⁹

Loperamide may be used when the patient is afebrile or has a low-grade fever and does not have bloody stools. Nonprescription loperamide is labeled for use in children 6 years of age and older; the label for prescription loperamide provides directions for use in children as young as 2 years of age. However, use of loperamide in children younger than 6 years is not recommended because it produces only modest, clinically insignificant effects on stool volume and duration of illness but carries an unacceptably high risk for adverse effects, including life-threatening ileus and toxic megacolon.

Loperamide also is indicated for treatment of traveler's diarrhea (in combination with antibiotics) and chronic diarrhea associated with IBS and inflammatory bowel disease, as well as to reduce the volume of discharge from high-output ileostomies. Off-label uses include control of chronic diarrhea secondary to diabetic neuropathy and other conditions and control of toddler diarrhea (defined as diarrhea of at least 1 month's duration in an otherwise healthy, active, well-nourished child in whom stool examination has revealed no bacterial, viral, or protozoal pathogens). Off-label uses require medical supervision.

At usual doses ([Table 16–7](#)), loperamide has few adverse effects other than occasional dizziness and constipation. Infrequently occurring adverse effects include abdominal pain, abdominal distention, nausea, vomiting, dry mouth, fatigue, and hypersensitivity reactions. Loperamide generally is not recommended for use in patients with invasive bacterial diarrhea (due to enteroinvasive *E. coli*, *Salmonella*, *Shigella*, or *C. jejuni*) or antibiotic-associated diarrhea (due to *C. difficile*), because it may worsen the diarrhea or cause toxic megacolon or paralytic ileus. However, there is no evidence that these complications occur in actual practice when loperamide is used with appropriate antimicrobial therapy. Patients with signs or symptoms suggestive of infection with invasive organisms or antibiotic-associated diarrhea (i.e., positive fecal leukocyte smear, high fever, presence of blood or mucus in the stool) require medical evaluation for proper management. If abdominal distention, constipation, or ileus develops, loperamide should be discontinued.

Clinically significant drug–drug interactions are reported for loperamide ([Table 16–9](#)). Interactions with P-gP inhibitors (e.g., quinidine, ketoconazole, ritonavir) may result in a 2- to 3-fold increase in loperamide plasma concentrations. Concurrent administration of loperamide with other substrates for CYP3A4 and CYP2C8 (e.g., protease inhibitors, cyclosporine, erythromycin, clarithromycin) also may elevate loperamide plasma concentrations. These drug interactions do not appear to cause clinically significant CNS depression or toxicity when loperamide is used in the recommended doses; however, monitoring for loperamide-related adverse effects, especially when used with a P-gP inhibitor, is recommended.⁴⁰ Taking high doses of loperamide with P-gP inhibitors or CYP3A4 inhibitors may increase risk of cardiovascular events. Persons misusing or abusing loperamide have purposefully taken P-gP and CYP3A4 inhibitors with high doses of loperamide to enhance bioavailability and distribution of the drug into the CNS.³³ Loperamide may significantly decrease saquinavir concentrations, and patients taking saquinavir should be advised not to use loperamide, especially for long periods of time.

Bismuth Subsalicylate

BSS is FDA approved for management of acute diarrhea, including traveler’s diarrhea, in adults and children 12 years of age and older; it is not recommended for use in young children. BSS is also indicated for indigestion and as an adjuvant to antibiotics for treating *Helicobacter pylori*-associated peptic ulcer disease. The salicylate moiety exerts antisecretory antidiarrheal effects that reduce fluid and electrolyte losses, the frequency of unformed stools, nausea, and vomiting; increase stool consistency; and relieve abdominal cramping. Its antisecretory effects may be mediated by inhibition of prostaglandin synthesis, inhibition of intestinal secretion through stimulation of sodium and chloride reabsorption, or disruption of calcium-mediated processes that regulate intestinal ion transport. The bismuth moiety exerts direct antimicrobial effects against ETEC and EAEC, *C. jejuni*, and other diarrheal pathogens. These antimicrobial effects appear to be unimportant in the treatment of traveler’s diarrhea, although they may play a role in the benefits of prophylactic use of this drug. BSS also directly binds to enterotoxins produced by *E. coli* and other diarrheal pathogens; the clinical significance of this effect in the treatment of diarrhea is not clear.

[Table 16–7](#) provides dosing information for BSS. BSS is available in several dosage forms, with variable amounts of salicylate ([Table 16–8](#)). BSS should not

be used in patients taking aspirin or other salicylates because toxic salicylate levels may be reached, even when labeled dosing directions for each medication are followed.

Mild tinnitus, a dose-related adverse effect, may be associated with moderate to severe salicylate toxicity. If tinnitus occurs, the product should be discontinued and the patient referred for medical evaluation. Salicylates may cause adverse effects that are independent of the dose. In susceptible patients, salicylate-induced gout attacks have occurred. Patients who are sensitive to aspirin (i.e., experience asthmatic bronchospasm) should not use BSS.

Because of the risk of Reye syndrome, a rare but serious illness, children and adolescents who have or are recovering from chickenpox or influenza-like illness should not use BSS.⁴¹ BSS also should not be taken within 6 weeks of receiving the chickenpox or influenza vaccine, as these vaccines may enhance the adverse effect of salicylates. With use of BSS in pediatric patients, changes in behavior with nausea and vomiting should prompt referral for medical evaluation, as these disturbances may be early signs of Reye syndrome. Children's Pepto Antacid contains calcium carbonate as the active ingredient and, unlike other forms of Pepto-Bismol, is not associated with Reye syndrome; however, it is not labeled for treatment of diarrhea. (See [Chapter 5](#) for further information.)

BSS has rarely been associated with neurotoxicity. Encephalopathy characterized by slow onset of tremors, postural instability, ataxia, myoclonus, poor concentration, confusion, memory impairment, seizures, visual and auditory hallucinations, psychosis, delirium, and depression, potentially eventuating in death, can occur when bismuth concentrations in the blood exceed 50 mcg/L. Use of BSS in the recommended doses, even for several weeks, such as in prophylaxis for traveler's diarrhea, produces mean blood concentrations well below 50 mcg/L and does not result in bismuth-related neurotoxicity. However, patients with AIDS who are experiencing acute diarrhea may be at particular risk for bismuth encephalopathy, perhaps resulting from altered GI absorption, and should not use BSS.

Harmless black staining of stool (which should not be confused with melena) and darkening of the tongue are seen in more than 10% of patients treated with BSS. Bismuth salts react with hydrogen sulfide produced by bacteria in the mouth and colon to produce the discoloration. Stains may be removed by

brushing the tongue with a soft-bristled brush, or the discoloration will cease on discontinuation of the BSS.

Bismuth is radiopaque and may interfere with radiographic intestinal studies. BSS may interact adversely with a number of other drugs, particularly those that potentially interact with aspirin (Table 16–9). The salicylate moiety can increase the risk of toxicity with warfarin, valproic acid, and methotrexate by significantly decreasing plasma protein binding of these drugs in vivo. Salicylate also can increase the plasma concentration of methotrexate by decreasing its renal clearance. The uricosuric effects of probenecid may be inhibited by the salicylate moiety. The bismuth moiety is a trivalent cation and may decrease absorption of other medications, such as tetracycline and quinolone antibiotics, by forming complexes with them in the GI tract. Solid dosage forms of BSS contain calcium carbonate, which may enhance this interaction. When fluoroquinolones are used to treat traveler’s diarrhea, the patient should be instructed to discontinue BSS.

Table 16–9 Clinically Important Drug–Drug Interactions With Nonprescription Antidiarrheal Agents

Antidiarrheal	Drug/Herbal Product	Potential Interaction	Management/Preventive Measures
Bismuth subsalicylate	Carbonic anhydrase inhibitors (e.g., acetazolamide, methazolamide) ^a	Increased risk for severe metabolic acidosis and/or salicylate toxicity	Avoid high-dose salicylate therapy; if concurrent administration is necessary, monitor closely for toxicity.
	Insulin ^b	Increased risk of hypoglycemia	Monitor glucose levels more frequently and adjust insulin dose, if necessary.
	Methotrexate	Increased risk of methotrexate toxicity	Avoid salicylate therapy within 10 days of high-dose methotrexate; if concurrent administration is necessary, monitor closely for toxicity.
	Pramlintide	Increased risk of hypoglycemia	Give bismuth subsalicylate 1 hour before or 2 hours after pramlintide; monitor glucose levels more frequently and adjust insulin dose, if necessary.

Antidiarrheal	Drug/Herbal Product	Potential Interaction	Management/Preventive Measures
	Probenecid	Increased risk of hyperuricemia	Avoid persistent high-dose salicylate therapy; occasional small doses are not clinically significant.
	Sulfinpyrazone	Increased risk of hyperuricemia	Avoid persistent high-dose salicylate therapy; occasional small doses are not clinically significant.
	Tetracyclines (systemic)	Decreased tetracycline effectiveness	Avoid concurrent use; if such use cannot be avoided, tetracycline should be taken at least 2–3 hours before bismuth subsalicylate dose. Monitor for antibiotic efficacy.
	Warfarin	Increased risk of bleeding	Avoid concurrent use, if possible. Monitor international normalized ratio (INR) closely whenever bismuth subsalicylate is added or discontinued, and adjust warfarin dose as necessary.
Loperamide	Eliglustat	Increased loperamide concentrations with enhanced central effects	Avoid concurrent use. If such use cannot be avoided, monitor for loperamide-related CNS adverse effects.
	Lomitapide	Increased loperamide concentrations with enhanced central effects	Avoid concurrent use. If such use cannot be avoided, monitor for loperamide-related CNS adverse effects.
	Nilotinib	Increased loperamide concentrations with enhanced central effects	Avoid concurrent use. If such use cannot be avoided, monitor for loperamide-related CNS adverse effects; consider ECG monitoring for patients at high risk for QT interval prolongation.
	Saquinavir	Decreased saquinavir plasma concentrations and increased loperamide plasma	Avoid concurrent use. If such use cannot be avoided, consider ECG monitoring for patients at high risk for QT interval prolongation.

Antidiarrheal	Drug/Herbal Product	Potential Interaction	Management/Preventive Measures
		concentrations.	
	Simeprevir	Increased loperamide concentrations with enhanced central effects	Avoid concurrent use. If such use cannot be avoided, monitor for loperamide-related CNS adverse effects.
	St. John's wort	Increased risk of delirium with confusion, agitation, and disorientation	Monitor for signs of altered mental status.
	Valerian	Increased risk of delirium with confusion, agitation, and disorientation	Monitor for signs of altered mental status.

^a Although this interaction has not been reported with ocular carbonic anhydrase inhibitors, the possibility should be considered.

^b Including insulin, insulin lispro, insulin aspart, recombinant, insulin glulisine, insulin detemir, and insulin degludec.

Key: CNS = Central nervous system; ECG = electrocardiogram.

Digestive Enzymes

For patients with lactase deficiency who are intolerant of milk products, lactase enzyme preparations (**Table 16–10**) may be taken with milk or other dairy products to prevent osmotic diarrhea.

Table 16–10 Selected Lactase Enzyme Products

Trade Name	Primary Ingredient
Lactaid Original Caplets	Lactase enzyme 3000 FCC units ^a /caplet
Lactaid Fast Act Caplets	Lactase enzyme 9000 FCC units ^a /caplet
Lactaid Fast Act Chewable Tablets	Lactase enzyme 9000 FCC units ^a /tablet
Lacteeze Children's	Lactase enzyme 3000 FCCLU/tablet
Lacteeze Drops	Lactase enzyme 80 FCCLU/5 drops
Lacteeze Extra Strength Tablets	Lactase enzyme 4000 FCCLU/tablet
Lacteeze Ultra Caplets	Lactase enzyme 9000 FCCLU/tablet
Lactrase Capsules	Lactase enzyme 250 mg/capsule

^a FCC units are standardized units established by the Food Chemicals Codex, a compendium of internationally recognized standards for purity and identity of food ingredients published by the United States Pharmacopeia.

Key: FCC = Food Chemicals Codex; FCCLU = FCC lactase units.

Product Selection Guidelines

Table 16–7 provides a quick reference for the recommended dosage and duration of therapy for selected antidiarrheal agents. **Tables 16–8** and **16–10** list dosage forms and primary ingredients of selected trade-name products.

In May 2011, FDA released final guidance on nonprescription liquid products that include any type of measuring device, such as the dropper packaged with lactase drops.⁴² Other devices mentioned include cups, syringes, and spoons. The key points of the guidance are the following recommendations:

- A dosing device should be included with all oral liquid nonprescription products.
- The device should be calibrated to the dose recommended in the product directions.
- The device should be used only with the product in which it is

- packaged.
- The markings should remain visible even when the liquid is in the device.

Special Populations

For young children (up to 5 years of age), self-care measures are limited to treating dehydration with ORS; antidiarrheal medications are not recommended. BSS-containing products should not be used in children and adolescents, especially those recovering from chickenpox or influenza, because of the risk of Reye syndrome. (See [Chapter 5](#) for further information.)

If diarrhea persists despite ORS therapy, a primary care provider must be consulted.

Older patients (65 years of age and older) should be strongly cautioned against self-treatment with antidiarrheal medications. Diarrhea in these patients is more likely to be severe or possibly fatal; therefore, patients in this age group should be referred for medical evaluation.

Use of nonprescription antidiarrheals may be inappropriate during pregnancy; therefore, pregnant women also should be referred for medical evaluation before self-treating, especially if signs and symptoms of persistent diarrhea, weight loss, malnutrition, or fever or manifestations of volume depletion are present.^{43–45} (See the Preface for a detailed explanation of the pregnancy data.)

BSS-containing products are contraindicated during pregnancy because of concerns that the salicylate component may inhibit platelet function and, in the third trimester, cause premature closure of the fetal ductus arteriosus. Nursing women generally should avoid BSS.

Patient Factors and Preferences

Selection of antidiarrheal products for older children and adults should be based on factors such as the etiology of the diarrhea (if known), prominent signs and symptoms, potential interactions with prescribed medications, and applicable contraindications. For example, BSS is suggested to be the preferred agent when vomiting is the predominant clinical sign of acute gastroenteritis. BSS should not be used to treat diarrhea in

immunocompromised patients (e.g., those with AIDS, transplant recipients), because they are at increased risk for bismuth encephalopathy. Patient preference for a particular dosage form and products requiring fewer doses also should be considered.

Complementary Therapies

Probiotics may be used to reduce the severity and duration of symptoms in immunocompetent adults and childrens.³⁰ Convincing evidence suggests that probiotics, including several *Lactobacillus* species, *Bifidobacterium lactis*, and *Saccharomyces boulardii*, are effective in preventing and treating mild acute, uncomplicated diarrhea, in previously healthy infants and children, especially rotavirus diarrhea and antibiotic-associated diarrhea.^{46,47} (See [Chapter 20](#) for a discussion of probiotics.) Probiotics support gut health by several mechanisms: They release antimicrobial substances in the intestines, produce acids (e.g., lactic acid) and short-chain fatty acids that lower intestinal pH and suppress growth of pathogenic bacteria, enhance mucosal barrier integrity and immune responses, and compete with pathogenic bacteria for intestinal mucosal binding sites. However, a role for these products in the management of moderate to severe diarrhea is not supported conclusively by available evidence.⁴⁸

Probiotics appear to be safe for most patients. Major adverse effects, such as *Lactobacillus* or *Saccharomyces* sepsis, rarely occur. Older, critically ill, and immunocompromised patients and patients with severe bowel diseases are at risk for systemic infection from probiotic use. The American Academy of Pediatrics has a conservative recommendation for the use of probiotics to be considered in special circumstances, such as for children in long-term health care facilities or care centers.⁴⁹ Probiotics are recognized by FDA as dietary supplements or components of functional foods, which limits the health claims that can be made for them, and they should not be recommended for self-treatment for or prevention of acute, uncomplicated diarrhea.

Compelling evidence demonstrates that daily zinc supplementation reduces the duration, severity, and persistence of acute diarrhea in children younger than 5 years of age, especially in countries with a high incidence of zinc deficiencies. Since 2004, WHO and UNICEF have recommended routine zinc supplementation for 10–14 days in children with acute diarrhea, in addition to ORS.³⁶ Zinc produces antidiarrheal effects by stimulating intestinal water and

electrolyte absorption, preventing villous atrophy, and enhancing overall immunity, perhaps in part through upregulation of T-helper cell (Th1 cell) immune responses, including macrophage activation and cell-mediated immunity. Zinc supplementation may be of no benefit in developed countries, where zinc deficiency is rare; therefore, its use is not routinely recommended.²⁹ Of note, zinc supplementation is associated with an increased risk for vomiting.

There is no evidence to substantiate the safety and effectiveness of herbal products and homeopathic remedies in the management of acute diarrheal diseases. Therefore, their use cannot be recommended.

Assessment of Diarrhea: A Case-Based Approach

To evaluate patients with diarrhea, the health care provider identifies relevant signs and symptoms and then makes clinical judgments. This assessment is based on the patient's responses to questions designed to help determine the cause of the specific signs and symptoms, their characteristics, and their severity (**Tables 16–1** and **16–4**). Important information to ascertain includes onset, duration, severity, degree of dehydration, vital signs (to determine the presence of fever), recently ingested foods or recent international travel destinations, current medications, and other symptoms to determine the patient's susceptibility to complications. Persistent or chronic diarrhea precludes self-treatment and necessitates immediate medical referral, as does the presence of high fever (temperature $>102.2^{\circ}\text{F}$ [39.0°C]), protracted vomiting, abdominal pain in patients older than 50 years, or blood or mucus in the stool. In the absence of any of these significant findings, the degree of dehydration should then be assessed (**Table 16–4**); the provider should ask about the nature and amount of fluid intake. Severity of dehydration can be accurately assessed by evaluating changes in body weight. For example, in children, mild dehydration is associated with a 3%–5% loss of body weight, whereas severe dehydration is associated with a loss of more than 9%. However, the patient (or the parent or caregiver) seldom knows the exact weight before the onset of diarrhea for comparison, and distinguishing between mild and moderate dehydration may be difficult.

The initial assessment of a pediatric patient also should seek to determine plausible causes of signs and symptoms. The common clinical manifestations of acute gastroenteritis (e.g., vomiting, loose stools, fever) are nonspecific findings associated with many other childhood diseases (e.g., acute otitis media, bacterial sepsis, meningitis, pneumonia, urinary tract infections). This determination is a key factor in recommending a proper course of action, which may include self-treatment or referral for medical evaluation. A complete medication history must be obtained before a product is selected.

Physical assessment of a patient with symptoms of diarrhea can provide information useful in assessing the severity of the diarrhea ([Table 16–4](#)). Checking skin turgor and moistness of oral mucous membranes will help determine the degree of dehydration. Vital signs (e.g., pulse, temperature, respiration, blood pressure) are important indicators of illness severity and should be routinely measured. Symptoms of moderate to severe dehydration may include postural (orthostatic) hypotension, defined as a drop in the systolic and/or diastolic pressure of greater than 15–20 mm Hg when a patient moves from a supine to an upright position. Normally, the diastolic pressure remains the same or increases slightly and the systolic pressure drops slightly on rising. If the blood pressure drops, the pulse should be checked simultaneously; the pulse rate should increase as blood pressure drops. Failure of the pulse to rise suggests that the problem is neurogenic (e.g., in diabetic patients with peripheral neuropathy) or that the patient may be taking a beta blocker. The presence of orthostatic hypotension suggests that the patient has lost 1 L or more of vascular volume, and referral for medical care is necessary.

Cases 16–1 and 16–2 provide examples of assessment of two different patients with diarrhea.

Case 16–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms	

Relevant Evaluation Criteria	Scenario/Model Outcome
and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient describes intermittent diarrhea occurring for the past 3 years. She also reports abdominal cramping with watery bowel movements with a large amount of flatulence several times per week. Denies vomiting, fever, blood in stool, weight loss, or other relevant signs or symptoms. Has not traveled internationally recently.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Ingestion of milk products
c. Description of the patient's efforts to relieve the symptoms	None. She acknowledges: "I thought it would get better by itself, but it hasn't."
d. Patient's identity	Alice Kim
e. Patient's age, gender, height, and weight	27 years, female, 5 ft 6 in., 150 lb (68.04 kg)
f. Patient's occupation	Teacher
g. Patient's dietary habits	She eats a well-balanced diet, although she likes dessert (especially ice cream); drinks wine and beer several times weekly.
h. Patient's sleep habits	Sleeps 8 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	n/a
Assess	

Relevant Evaluation Criteria	Scenario/Model Outcome
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 16-1).	Patient appears to have food-induced diarrhea, likely as a consequence of lactose intolerance.
3. Identify exclusions for self-treatment (Figure 16-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Kim to an appropriate health care provider. (2) Recommend self-care with a nonprescription lactase enzyme product and nondrug measures, such as keeping a food log and dietary modifications. (3) Recommend self-care with a nonprescription lactase enzyme product and nondrug measures, such as keeping food log and dietary modifications, until the patient can see an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. Kim has no exclusions for self-care. It is appropriate to recommend self-care with a nonprescription product.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Lactase enzyme products are the preferred treatment for symptomatic relief of your diarrhea. You may continue your regular diet during treatment, but you should avoid the consumption of foods high in lactose (such as milk or ice cream)."
7. Explain to the patient or caregiver the rationale for selecting the recommended	"Nonprescription antidiarrheal products are safe and effective in managing symptoms of food-induced diarrhea when no fever or signs of serious infection are present."

Relevant Evaluation Criteria	Scenario/Model Outcome
therapeutic approach from the considered therapeutic alternatives.	
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	See the box “Patient Education for Diarrhea.”
b. Maximum number of days the therapy should be employed	See the box “Patient Education for Diarrhea.”
c. Product administration procedures	See the box “Patient Education for Diarrhea.”
d. Expected time to onset of relief	See the box “Patient Education for Diarrhea.”
e. Degree of relief that can be reasonably expected	See the box “Patient Education for Diarrhea.”
f. Most common adverse effects	See the box “Patient Education for Diarrhea.”
g. Adverse effects that warrant medical intervention should they occur	See the box “Patient Education for Diarrhea.”
h. Patient options in the event that condition worsens or persists	See the box “Patient Education for Diarrhea.”
i. Product storage requirements	Store in a cool, dry place out of children’s reach.
j. Specific nondrug measures	See the box “Patient Education for Diarrhea.”

Relevant Evaluation Criteria	Scenario/Model Outcome
Solicit follow-up questions from the patient or caregiver.	"What kind of changes to my diet should I make?"
Answer the patient's or caregiver's questions.	"Avoid or minimize foods high in lactose content. If you are not sure, you should check food labels to note if a product contains lactose, milk products, dry milk solids, or whey. You can take the lactase enzymes with the first bite or drink of a dairy product to prevent symptoms. You may also continue to take another dose after 30–45 minutes if you continue to eat that product."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Ms. Kim in 1–2 days to evaluate her response to your recommendations.

Key: n/a = Not applicable; NKA = no known allergies.

Case 16–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A patient comes to the pharmacy for a recommendation. She complains of diarrhea starting the previous night and reports an average of 3 loose stools since. She went to a local Italian restaurant yesterday for lunch, where she had Alfredo pasta with chicken. She feels nauseous but has not vomited.
b. Description of any factors	None noted

Relevant Evaluation Criteria	Scenario/Model Outcome
that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	
c. Description of the patient's efforts to relieve the symptoms	"I borrowed some of my friend's Lactaid this morning, but it didn't work."
d. Patient's identity	Laura Richards
e. Patient's age, gender, height, and weight	25 years, female, 5 ft 2 in., 175 lb (78.18 kg)
f. Patient's occupation	Waitress
g. Patient's dietary habits	Reports a well-balanced diet that is mostly plant-based. Eats 3 meals a day. Drinks alcohol occasionally in social situations. Drinks 1 cup of coffee every morning.
h. Patient's sleep habits	Sleeps 6–7 hours nightly.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Medical conditions:</i> none
	<i>Medications:</i> An OTC women's daily vitamin
j. Allergies	Penicillin (rash)
k. History of other adverse reactions to medications	None
l. Other (describe) _____	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Table 16-1).	Patient appears to have acute diarrhea, most likely of viral etiology.
3. Identify exclusions for self-treatment (Figure 16-1).	None

Relevant Evaluation Criteria	Scenario/Model Outcome
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Mrs. Richards to an appropriate health care provider. (2) Recommend self-care with a nonprescription antidiarrheal product, such as loperamide, and nondrug measures, such as maintaining hydration with an ORS. (3) Recommend self-care with a nonprescription antidiarrheal product, such as loperamide, and nondrug measures, such as taking an ORS, until patient can see an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Patient has mild to moderate diarrhea and no exclusions for self-care. It is appropriate to recommend self-care with a nonprescription antidiarrheal product. The patient needs appropriate education on the use of Lactaid.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Loperamide is the preferred treatment for symptomatic relief of your diarrhea. You should take 4 mg (2 tablets) now, and then 2 mg (1 tablet) with each subsequent loose stool. Do not take more than 8 mg (4 tablets) per day. You may continue your regular diet during treatment, but you should increase your intake of fluids to prevent dehydration."
	"Lactaid is not an antidiarrheal agent and will likely not help with your current symptoms. Lactaid is used for people with intolerance to dairy products and is meant to be taken with the first bite of food containing dairy, to help prevent symptoms such as gas and bloating in those with intolerance to dairy."
7. Explain to the patient or caregiver the rationale for selecting the recommended	"Nonprescription antidiarrheal products are safe and effective in managing symptoms of acute diarrhea when no fever or signs of serious infection are present. If no

Relevant Evaluation Criteria	Scenario/Model Outcome
therapeutic approach from the considered therapeutic alternatives.	improvement occurs within 2 days, or if symptoms worsen with nonprescription therapies, you may need to see an appropriate health care provider for further evaluation and treatment of your symptoms.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	“You should take 4 mg (2 tablets) now, and then 2 mg (1 tablet) with each subsequent loose stool. Do not take more than 8 mg (4 tablets) per day. You may continue your regular diet during treatment, but you should increase your intake of fluids to prevent dehydration.”
b. Maximum number of days the therapy should be employed	8 mg/24 hours. Maximum duration of use is 48 hours.
c. Product administration procedures	Administer by oral route.
d. Expected time to onset of relief	Time to onset of effect is 1–3 hours.
e. Degree of relief that can be reasonably expected	No unformed stools within 48–72 hours of starting loperamide
f. Most common adverse effects	Loperamide generally is well tolerated. Adverse effects may include dizziness, constipation, nausea, or abdominal cramping, dry mouth, or fatigue.
g. Adverse effects that warrant medical intervention should they occur	Hypersensitivity reactions, severe abdominal pain, abdominal distention, severe or frequent nausea/vomiting
h. Patient options in the event that condition worsens or persists	“See an appropriate health care provider for further evaluation and treatment. Stay well hydrated in the meantime with an ORS until you can be seen.”

Relevant Evaluation Criteria	Scenario/Model Outcome
i. Product storage requirements	Store in a cool, dry place out of children's reach.
j. Specific nondrug measures	Rehydration using an ORS is the preferred nonpharmacologic treatment for symptoms of mild to moderate diarrhea.
Solicit follow-up questions from the patient or caregiver.	"Would it help if I changed my diet until this resolves?"
Answer the patient or caregiver's questions.	"Changes to your diet usually are not needed nor are they recommended in mild to moderate diarrheal disease. You may want to avoid fatty foods or foods that aggravate your symptoms, but I would encourage you continue to eat a normal, healthy diet, because it provides adequate nutrition to help your intestines to heal."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mrs. Richards in 1-2 days to evaluate her response to your recommendations.

Key: n/a = Not applicable; ORS = oral rehydration solution; OTC = over-the-counter.

Patient Counseling for Diarrhea

Patients with diarrhea may focus on the need for a nonprescription medication to stop the frequent bowel movements. The health care provider should emphasize that most episodes of acute diarrhea stop after 48 hours and that preventing dehydration is the most important component of treatment. Counseling on the two-step treatment of dehydration and the need for dietary management should follow. For infants and children, educating parents and caregivers on the appropriate use of an ORS (including appropriate volumes to administer, rates of administration, and use in vomiting) and of dietary management is very important. For patient safety reasons, premixed solutions are preferred. If dry powder ORS is selected, however, the provider should give parents or other caregivers explicit

directions for mixing and verify that they understand the directions. For families with infants, CDC recommends maintaining a household supply of an ORS, because its early administration at home is vital if hospitalization is to be avoided. If travelers are using ORS dry powder in developing countries, only potable water should be used to reconstitute the powder.

If an antidiarrheal product is recommended:

Review label instructions with the patient or caregiver.

Calculate an appropriate dosage on the basis of the patient's age and weight, and emphasize the maximum number of doses that can be taken in 24 hours.

Explain potential drug interactions, adverse effects, contraindications, and the maximum duration of treatment before the patient should seek medical help.

The box "Patient Education for Diarrhea" contains specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Diarrhea

Many patients have mild to moderate diarrhea that generally is self-limiting within 48 hours. Mild to moderate diarrhea is managed with ORSs, symptomatic drug therapy, and dietary measures. The patient should be monitored for dehydration by measuring body weight, vital signs, and mental alertness. With effective symptomatic treatment, the patient can expect reduced stool frequency and return to normal consistency of stools, as well as a reduction in generalized symptoms such as lethargy and abdominal discomfort. As the diarrhea resolves, the patient's appetite will return to normal and the patient can resume a regular diet.

Medical referral is necessary if any of the following signs and symptoms occur before or during treatment: high fever, worsening illness, bloody or mucoid stools, persistence of diarrhea beyond 48 hours, or signs of worsening dehydration (e.g., low blood pressure, rapid pulse, mental confusion). Also, medical referral is advised for infants, young children, frail patients of advanced age, pregnant patients, and patients with chronic illness (e.g., diabetes) at risk for secondary complications.

Patient Education for Diarrhea

The primary objective of self-treatment is to prevent excessive fluid and electrolyte losses. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal outcomes.

Nondrug Measures

Infants and Children 6Months to 5Years of Age

- For mild to moderate diarrhea, indicated by passage of 3–5 unformed bowel movements per day, give the child or infant an oral rehydration solution (ORS) at a volume of 50–100 mL/kg of body weight over 2–4 hours to replace the fluid deficit. Give additional ORS to replace ongoing losses. Continue to give the solution for the next 4–6 hours or until the child is rehydrated.
- If the child is vomiting, give 1 teaspoon of the ORS every few minutes.
- If the child is not dehydrated, give 10 mL/kg or ½–1 cup of the ORS for each bowel movement, or 2 mL/kg for each episode of vomiting. As an alternative, to replace ongoing fluid losses, children weighing less than 22 lb (10 kg) should be given ¼–½ cup (60–120 mL) of ORS for each vomiting or diarrheal episode, and children weighing more than 22 lb (10 kg) should be given ½–1 cup (120–240 mL) for each vomiting or diarrheal episode.
- After the child is rehydrated, reintroduce food appropriate for the child's age, while also administering an ORS for maintenance therapy.
- If breastfeeding an infant with diarrhea, continue the breastfeeding. If the infant is bottle-fed, consult your primary care provider or pediatrician about replacing a milk-based formula with a lactose-free formula.
- Give children complex carbohydrate-rich foods, yogurt, lean meats, fruits, and vegetables. Do not give them fatty foods or sugary foods. Sugary foods can cause osmotic diarrhea.

- Do not withhold food for more than 24 hours.

Adults and Children Older Than 5 Years of Age

- For mild to moderate dehydration, indicated by a 3%–9% drop in body weight or passage of 3–5 unformed stools per day, drink 2–4 L of an ORS over 4 hours.
- If not dehydrated, drink $\frac{1}{2}$ –1 cup (120–240 mL) of an ORS or household fluids after each unformed bowel movement.
- If no medical conditions exist, sports drinks (with salty crackers or similar sodium source), diluted juices, soups, and broths may be consumed until the diarrhea stops.
- Do not withhold food for more than 24 hours.

Nonprescription Medications

- See [Table 16–6](#) for dosages of loperamide and bismuth subsalicylate.

Loperamide

- Note that loperamide can cause dizziness and constipation.
- Nonprescription loperamide is not recommended for children younger than 6 years, except under the supervision of a primary care provider or pediatrician.
- If loperamide is not effective in treating your diarrhea (if no clinical improvement is observed in 48 hours), check with your primary care provider or pharmacist about using a different nonprescription medication. You may have a bacterial diarrhea or pseudomembranous colitis; these conditions require specific antibiotic therapy that loperamide cannot treat.

Bismuth Subsalicylate

- Note that bismuth subsalicylate can cause a dark discoloration of the tongue and stool.
- Do not take this medication if you also are taking tetracyclines or other medicines for gout (uricosurics).

- Do not give this medication to children younger than 12 years.
- Do not give this medication to children or teenagers who have or are recovering from chickenpox or influenza-like symptoms, because of the risk of Reye syndrome.
- Do not give this medication to patients with AIDS.
- Do not take this medication if you are sensitive to aspirin, have a history of gastrointestinal bleeding, or have had problems with blood coagulation.

When to Seek Medical Attention

- If the diarrhea has not resolved after 72 hours of initial treatment, see your primary care provider.
- Monitor for excessive number of bowel movements, signs of dehydration, high fever, or blood in the stool. If any of these complications are present, discontinue bismuth subsalicylate, and consult your primary care provider.

Key Points for Diarrhea

- Self-treatment of diarrhea should be limited to patients with mild to moderate acute diarrhea who have minimal, mild, or moderate dehydration. Patients who appear volume-depleted, weak, dizzy, febrile (temperature $>102.2^{\circ}\text{F}$ [39.0°C]), or hypotensive should be referred for evaluation.
- ORS is the mainstay of therapy and should be used to rehydrate patients with minimal or mild to moderate dehydration.
- Rehydration should be performed rapidly (i.e., within 3–4 hours). Additional ORS should be given to maintain hydration and replace ongoing fluid losses resulting from diarrheal stools and/or vomiting (Figures 16–1 and 16–2).
- Patients or their caregivers should be instructed how to prepare

and administer an ORS.

- An age-appropriate, unrestricted diet should be initiated as soon as the patient is rehydrated. Food should be withheld for no more than 24 hours.
- Loperamide and BSS may be used to help control acute diarrhea in carefully selected patients.
- Antibiotic therapy generally is not indicated for patients with acute diarrhea unless it is traveler's diarrhea.

Chapter 17: Anorectal Disorders

Authors: Juliana Chan

Anorectal disorders are common and may be observed in any patient population. Most often, anorectal complaints involve the perianal canal, anal canal, and/or lower rectum. The most common conditions affecting the anorectal area include hemorrhoids; anal fistula, fissure, or abscess; and pruritus ani.^{1,2} Because these disorders affect the anus, patients often feel embarrassment in seeking medical attention. It is therefore imperative for the health care provider to be confident and discreet in conveying reassurance that anorectal symptoms are commonplace and warrant appropriate assessment and treatment as with any other health problem.

Of all the anorectal disorders, hemorrhoids constitute the most common complaint for which patients seek medical attention in the outpatient setting.^{1,3,4} Men and women, especially those older than 45 years of age, are equally likely to experience hemorrhoidal symptoms.^{4,6} Although epidemiologic data may vary and the true prevalence may be underreported in the United States, approximately 4.4% of the general population have hemorrhoids.^{2,4,6} In a cross-sectional study evaluating the employer-insured population, an estimated 1.4 million ambulatory care visits in 2014 were due to hemorrhoids, equating to an annual cost of more than \$700 million.⁴ This cost may be underestimated, however, because the relevant study was retrospective in design, and not all payer groups were evaluated; with proper extrapolation of the data, the financial burden may amount to more than \$1.6 billion.⁴ In 2004 the National Institutes of Health reported that approximately 2 million prescriptions were obtained to treat hemorrhoids.^{4,7} In 2014, an estimated \$88 million was devoted to hemorrhoid prescriptions; of interest from a global perspective, in 2017, \$136 million was spent worldwide on Preparation H.⁴

Pathophysiology of Anorectal Disorders

Relevant Anatomy

Anorectal disorders affect the perianal area (the portion of the skin

immediately surrounding the anus), the anal canal, and the lower portion of the rectum (Figure 17–1). The anal canal is approximately 2–4 cm long and connects the rectum with the outside of the body.¹ Two different types of epithelia line the anal canal; their junction is defined by the dentate line (also known as the pectinate line). The dentate line divides squamous epithelium from columnar epithelium, thus localizing sensory pain fibers in the anal canal.¹ Anorectal disorders occurring below the dentate line may be associated with pain, whereas disorders above the line rarely cause any discomfort.¹ The area proximal to the dentate line contains several longitudinal folds known as the columns of Morgagni.¹ In between and next to these columns are small pockets or crypts containing ducts and glands that may become obstructed and/or undergo other pathologic changes to cause infection (e.g., abscesses, fistulas).

Figure 17–1 Disorders of the anorectal canal.

FIGURE 17–1 Disorders of the anorectal canal.

The external anal sphincter is a voluntary muscle located at the end of the anal canal that remains closed under normal conditions to prevent involuntary passage of feces. The internal sphincter is an involuntary muscle innervated by the autonomic nervous system.¹ When the sphincters are relaxed, defecation occurs. In healthy persons, mucosa covering the anal canal serves as a barrier

against absorption of substances into the body. If the protective barrier breaks, the absorptive properties of the anal skin may be altered, diminishing its protective capabilities.

The rectum, which lies above the anal canal, is approximately 12–15 cm long and constitutes the terminal portion of the large intestine.¹ The highly vascular rectal mucosa is lined with a semipermeable membrane to protect the body from fecal bacteria. Three hemorrhoidal arteries and their accompanying veins are the most prominent parts of the vasculature. Blood returns to the heart through the hemorrhoidal veins; therefore, rectal medications may be absorbed and enter the systemic circulation without passing through the liver.¹

Hemorrhoids

Hemorrhoids are conglomerations of inflamed, swollen blood vessels and other tissue that project into the bowel lumen during defecation.^{2,6,8} With increasing age or poor bowel habits (e.g., prolonged sitting and straining at defecation), muscle fibers weaken, causing the vascular cushions to slide, become congested, bleed, and eventually protrude.² Downward pressure during defecation and a high resting anal pressure are common contributory factors in the development of hemorrhoids.²

Internal hemorrhoids originate from the superior hemorrhoidal vein and are located above the dentate line, an area that is covered with columnar epithelium and lacks sensory fibers (Figure 17–1).^{2,6} Internal hemorrhoids are graded by severity of prolapse into the anal canal, as follows^{2,6}:

- Grade 1 hemorrhoids enlarge but do not prolapse into the anal canal.
- Grade 2 hemorrhoids protrude into the anal canal on defecation and retract spontaneously afterward.
- Grade 3 hemorrhoids protrude into the anal canal on defecation but can be returned to their original position manually.
- Grade 4 hemorrhoids are permanently prolapsed and cannot be reintroduced into the anus.

External hemorrhoids develop from the inferior hemorrhoidal vein and originate below the dentate line (Figure 17–1).² These hemorrhoids are classified either as nonthrombosed, in which the affected blood vessels are

pink and symptoms and signs may include bleeding and/or itching, or as thrombosed, in which the hemorrhoid has a purple-blue hue and often is associated with pain.²

Nonhemorrhoidal Anorectal Disorders

Potentially serious nonhemorrhoidal anorectal disorders (e.g., abscesses, fistulas, fissures, anal carcinoma) may manifest with hemorrhoid-like symptoms. With these disorders, self-treatment is not an option; referral for immediate medical evaluation is warranted (Table 17-1).^{1-3,9,10}

Table 17-1 Nonhemorrhoidal Anorectal Disorders

Disorder	Definition	Common Signs and Symptoms	Comments
Anal abscess	Collection of pus causing an obstruction of the anal glands, resulting in a bacterial infection	Pain, perirectal swelling, discharge, fever, or chills; pain worsens with sitting and defecation	Possible life-threatening sepsis if not identified and treated promptly
Anal fistula (or groove)	Abnormal internal opening that connects with an external opening (i.e., tubelike appearance between the rectum and anus)	Chronic, persistent drainage; pain; possible bleeding on defecation; perianal itching; seepage of stool through external opening	Surgical repair required
Anal fissure	Slitlike ulcer in anal canal resulting from a traumatic tear during passage of stool or explosive diarrhea	Severe or burning pain during and after defecation, lasting several minutes to hours; anal spasms; blood may be seen on toilet tissue	Young or middle-aged individuals affected; equal frequency in women and men
Anal neoplasms	Include a variety of histologic types classified as epidermoid carcinomas	Rare and usually asymptomatic in 25% of patients; bleeding; changes in bowel habits; anal discharge; anal mass; pain; pruritus; rash	Relatively uncommon, accounting for 4% of all GI malignancies; most are curable, but poor prognosis with anorectal melanomas
Pruritus ani	Itching sensation localized to anorectal area	Persistent itching, scratching in perianal region; more bothersome	More common in men, more than 100 recognized etiologic

Disorder	Definition	Common Signs and Symptoms	Comments
		at bedtime or when patient is not preoccupied	disorders

Key: GI = Gastrointestinal.

Clinical Presentation of Anorectal Disorders

The U.S. Food and Drug Administration (FDA) Advisory Review Panel has identified signs and symptoms for which a nonprescription anorectal product is indicated.¹¹ These ailments include itching, discomfort, irritation, burning, soreness, inflammation, pain, dry anal tissue, and swelling in the perianal area.¹¹ By contrast, abdominal pain, bleeding, seepage, change in bowel patterns, prolapse, and thrombosis may indicate a more serious condition and necessitate immediate medical referral ([Table 17-2](#)).¹²

Table 17-2 Signs and Symptoms of Anorectal Disorders

Sign/ Symptom	Definition/Etiology
Usually Self-Treatable	
Itching (pruritus)	Mild stimulation of sensory nerve fibers; associated with many anorectal disorders, including hemorrhoids (typically with a mucoid discharge from prolapsing internal hemorrhoids).
	Common causes include poor hygiene (e.g., incomplete wiping/cleaning after defecation); diarrhea; parasitic or fungal infections; allergies (e.g., sensitivity to fabrics, soaps, laundry detergents, dyes, perfumes in toilet tissue); anorectal lesions; and moisture in anal area.
	May be secondary to swelling; diet (e.g., caffeinated beverages, chocolate, citrus fruits); or oral broad-spectrum antibiotics.

Sign/ Symptom	Definition/Etiology
	Rarely, may be of psychogenic origin.
Discomfort	May result from burning, itching, pain, irritation, inflammation, and swelling.
Irritation	Uncomfortable feeling associated with stimulation of sensory nerve fibers.
Burning	Greater degree of irritation of sensory nerve fibers than what is commonly experienced with anal itching; often associated with hemorrhoids; sensation of warmth or intense heat. May be constant or occur only on defecation.
Inflammation	Tissue reaction characterized by heat, redness or discoloration, pain, and swelling; often associated with trauma, allergy, or infection.
Swelling	Temporary enlargement of cells and/or tissue resulting from excess fluid; may be accompanied by pain, burning, and itching.
Necessitating Medical Referral	
Pain	Intense stimulation of sensory nerve fibers caused by inflammation or irritation. Internal hemorrhoids usually are painless; external hemorrhoids often cause mild to moderate pain; acute, severe perianal pain may be from a thrombosed external hemorrhoid. Pain from anal fissure during bowel movement often described as “being cut with sharp glass.”
	Other possible causes of pain include abscess, fistula, or anorectal neoplasm.
Bleeding	Hemorrhoids most common cause of minor bleeds (e.g., from straining or passage of hard stool, or ulceration of perianal skin overlying thrombosed external hemorrhoid).
	Appears as bright red spots or streaks on toilet tissue, or bright red blood around stool or in toilet.
	Black or tarry stools (melena) may indicate possible upper GI bleeding (e.g., from peptic ulcer disease, erosive esophagitis, or gastric varices).
	Large amounts of red blood (hematochezia) in toilet bowl indicative of lower GI bleeding (e.g., from fissure, inflammatory bowel disease, polyps, or malignant disease of the colon or rectum).
	Possible indications of large-volume blood loss include shortness of breath, dizziness, fatigue, and light-headedness, especially upon standing (orthostatic hypotension).
Seepage	Involuntary passage of fecal material or mucus through an incompletely closed anal

Sign/ Symptom	Definition/Etiology
	sphincter, or discharge of pus or feces from a fistula connecting the rectum to the anal canal.
Change in bowel pattern	Unexplained change in bowel frequency or in stool form; may signal serious underlying GI disorder (e.g., IBD) or colorectal cancer.
Prolapse (protrusion)	Protrusion of hemorrhoidal or rectal tissue of variable size into anal canal; usually appears after defecation, prolonged standing, unusual physical exertion, or swelling of hemorrhoidal tissue with loss of muscular support; painless except when accompanied by thrombosis, infection, or ulceration.
Thrombosis	Strangulation of protruded (external) hemorrhoid by anal sphincter, possibly leading to thrombosis; pain is most acute during first 48–72 hours but usually resolves after 7–10 days.
	Minimal pain with thrombosed internal hemorrhoids; patient likely to be unaware of condition unless sudden change in bowel habits occurs.
	If a thrombosed hemorrhoid persists, ulcers or gangrene may develop and cause bleeding, especially during defecation.

Key: GI = Gastrointestinal; IBD = inflammatory bowel disease; PUD = peptic ulcer disease.

Treatment of Anorectal Disorders

Treatment Goals

The primary goal of treatment for anorectal disorders is to resolve associated symptoms of pain, discomfort, and burning. Maintaining soft stools and preventing straining during a bowel movement are paramount in minimizing anorectal symptoms^{13–16} (see [Chapter 15](#)). Additional goals are to maintain remission of anorectal symptoms and to prevent complications.

General Treatment Approach

[Figure 17–2](#) presents an algorithm for self-care for minor anorectal symptoms and lists exclusions for self-treatment. If symptoms qualify for self-treatment, then the health care provider may recommend nonpharmacologic measures and a nonprescription agent to treat the symptoms. Patients should be advised to maintain adequate fluid intake and a well-balanced, high-fiber diet. Practicing good perianal hygiene and avoiding prolonged sitting on the toilet also may minimize anorectal symptoms.^{13–16} [Table 17–3](#) outlines guidelines for applying anorectal products.^{11,17}

Table 17–3 Guidelines for Applying or Inserting Anorectal Products

- Wash hands before and after application of any anorectal product.
- Empty bladder and bowels before using any anorectal product, if possible.
- Clean affected anorectal area after bowel movement with mild, nonmedicated, unscented soap and warm water; rinse thoroughly.
- Clean anorectal area before applying products containing aluminum hydroxide gel or kaolin. Be sure to remove any previously used petrolatum-containing or greasy ointment.^a
- Dry anorectal area gently by patting or blotting with unscented and uncolored toilet tissue or a soft cloth before applying product.
- Apply a thin layer to the perianal area and anal canal when using an external anorectal product.
- Insert anorectal products indicated for intrarectal use by using an intrarectal applicator or a finger. Intrarectal applicators are preferred to digital application because use of an applicator allows application of the drug product to the rectal mucosa (which cannot be reached with a finger)
- Clean anorectal applicator per product instructions between uses.
- Ensure that intrarectal applicators have lateral openings and holes in the tip to facilitate anorectal application and coverage of the rectal mucosa with inserted product.
- Lubricate intrarectal applicator by spreading product around the applicator tip before insertion into the anorectal area.
- Avoid using the intrarectal applicator in the anorectal area if it causes additional pain.

- Do not exceed the recommended daily dosage unless directed by a primary care provider.

^a *Ointment* refers to all semisolid preparations. Source: References 19, 30, and 31.

Nonpharmacologic Therapy

Nondrug measures for treating anorectal disorders include dietary modifications, surgical interventions, and nonoperative methods.^{2,13–16} Patients diagnosed with or suspected of having hemorrhoids should avoid lifting heavy objects and discontinue foods that aggravate symptoms (e.g., alcohol, caffeinated beverages, citrus, fatty foods).¹⁵

Dietary fiber softens stool and may prevent further irritation of symptomatic hemorrhoids and other anorectal disorders. A high-fiber diet (25–40 g of fiber per day) will help prevent bleeding and contribute to overall symptomatic anorectal relief by permitting the passage of softer stools, thereby reducing and preventing irritation and straining at defecation.^{15,18,19} Dietary fiber intake should be increased slowly; however, if the intake amount cannot be increased, fiber supplements such as psyllium or methylcellulose can be considered (see [Chapter 15](#)). Additionally, it is important for patients to drink an adequate amount of noncaffeinated fluid (daily intake of 8 eight-ounce cups) to soften hard stool.¹⁸

Proper bowel habits should be identified and encouraged. Suppressing or ignoring the urge to defecate should be discouraged because doing so may lead to constipation, resulting in anorectal discomfort. Limiting time sitting on the toilet to 2–5 minutes reduces strain and decreases prolonged pressure on the hemorrhoidal vessels.^{16,18,19} Proper hygiene of the anal area (e.g., cleaning the area regularly, but not excessively, after each bowel movement using mild, unscented soap and water) may help relieve anorectal symptoms.^{18,19} Use of commercially available hygienic and lubricated wipes or pads is not recommended because they may be more irritating to the anal area, especially in patients with pruritus ani.¹⁹ Excessive scrubbing should be discouraged to minimize aggravation.^{2,19} A nonpharmacologic measure often recommended to promote good anal hygiene and to reduce pain and itching, despite a lack of supporting evidence, is sitting in warm water ($\leq 120^{\circ}\text{F}$ [48.89°C]) in a bathtub or

sitz bath (a small basin that fits over the toilet rim, available at pharmacies and medical supply vendors) for 10–20 minutes 2–4 times a day.^{18,20} In a few systematic reviews of randomized controlled trials, no evidence supported the use of sitz baths to relieve pain or assist in wound healing in patients with anorectal disorders; however, health care providers commonly recommend this option.²⁰

Large and prolapsed hemorrhoids (grade 3 or 4) often are treated surgically. Accordingly, patients with more severe hemorrhoids usually are referred to a colorectal specialist for further evaluation.^{14–16}

Pharmacologic Therapy

Local anesthetics, vasoconstrictors, protectants, astringents, keratolytics, analgesics, anesthetics, antipruritics, and corticosteroids are commonly used to relieve anorectal symptoms.¹¹ Certain astringents, protectants, and vasoconstrictors may be used only intrarectally and should be administered with an applicator (i.e., “pile pipe”) so that the product can reach the affected area.¹¹ Use of suppositories may be considered as another method of administering a drug to the anal area; however, their effectiveness is in question, as suppositories may not stay in place after insertion. The remaining agents—local anesthetics, keratolytics, analgesics, anesthetics, and antipruritics—are for external use only and are not indicated for the relief of anorectal pain, bleeding, seepage, prolapse, or thrombosis.¹¹ **Table 17–4** provides FDA-approved dosages for anorectal drug products.¹¹

Table 17–4 Dosage Guidelines for Anorectal Products		
Ingredient	Concentration per Dosage Unit (%)	Frequency of Use (with maximum daily dosage)
Local Anesthetics		
Benzocaine	5–20	Up to 6 times/day (2.4 g)
Benzyl alcohol	1–4	Up to 6 times/day (480 mg)
Dibucaine, dibucaine hydrochloride	0.25–1	Up to 3–4 times/day (80 mg)
Dyclonine hydrochloride	0.5–1	Up to 6 times/day (100 mg)

Ingredient	Concentration per Dosage Unit (%)	Frequency of Use (with maximum daily dosage)
Lidocaine	2-5	Up to 6 times/day (500 mg)
Pramoxine hydrochloride ^a	1	Up to 5 times/day (100 mg)
Tetracaine, tetracaine hydrochloride	0.5-1	Up to 6 times/day (100 mg)
Vasoconstrictors		
Ephedrine sulfate	0.1-1.25	Up to 4 times/day (100 mg)
Epinephrine, epinephrine hydrochloride	0.005-0.01	Up to 4 times/day (800 mg)
Phenylephrine hydrochloride	0.25	Up to 4 times/day (2 mg)
Protectants		
Aluminum hydroxide gel, cocoa butter, glycerin, hard fat, kaolin, lanolin, mineral oil, white petrolatum, calamine, ^c petrolatum, shark or cod liver oil, ^d zinc oxide, ^e topical starch, white petrolatum	See footnote b.	Petrolatum/white petrolatum as often as needed; other protectants up to 6 times/day or after each bowel movement
Astringents		
Calamine ^c	5-25	Up to 6 times/day or after each bowel movement
Zinc oxide	5-25	Up to 6 times/day or after each bowel movement
Witch hazel	10-50	Up to 6 times/day or after each bowel movement
Keratolytics		
Alcloxa	0.2-2	Up to 6 times/day
Resorcinol	1-3	Up to 6 times/day
Analgesics, Anesthetics, Antipruritics		
Menthol	0.1-1	Up to 6 times/day
Juniper tar	1-5	Up to 6 times/day

Ingredient	Concentration per Dosage Unit (%)	Frequency of Use (with maximum daily dosage)
Camphor	0.1-3	Up to 6 times/day
Corticosteroids		
Hydrocortisone	0.25-1	Up to 3-4 times/day

^a External dosage forms may include aerosol foams, ointments, creams, and jellies (water-miscible base).

^b Any two, three, or four protectants may be combined, provided that the combined percentage by weight of all protectants in the combination is at least 50% of the final product. Any protectant ingredient included in the combination must be present at a level that contributes at least 12.5% by weight (e.g., 0.25 g of a 2-g dosage unit), except for cod liver oil and shark liver oil. If cocoa butter is included in the combination, it must not exceed the concentration limit for calamine,^c cod liver oil,^d or shark liver oil.^d

^c Calamine not to exceed 25% by weight per dosage unit (based on the zinc oxide content of calamine).

^d Provided that the product is labeled so that the amount of the product that is used in a 24-hour period represents a quantity that provides 10,000 USP units of vitamin A and 400 USP units of cholecalciferol.

^e Any product containing calamine or zinc oxide for use as a protectant and/or as an astringent may not have a total weight of zinc oxide exceeding 25% by weight per dosage unit.

Key: USP = United States Pharmacopeia.

Source: Reference 11.

Local Anesthetics

Local anesthetics are approved for the temporary relief of external anal symptoms (e.g., itching, irritation, burning, discomfort, soreness, and pain); they provide relief by reversibly blocking transmission of nerve impulses (Table 17-4).^{11,17} Caution is advised with use of these products because they may mask the pain of more severe anorectal disorders.¹⁷

Local anesthetics may produce allergic reactions (e.g., burning, itching) that are indistinguishable from the anorectal symptoms. Several cases of contact dermatitis associated with hemorrhoidal anesthetics have been reported.²¹⁻²³ Patients who have an allergic reaction to a local anesthetic may try another agent with a different chemical structure (e.g., pramoxine) or avoid such agents completely. These preparations must carry a warning stating that allergic reactions may occur.¹¹ Local anesthetics should be avoided on open sores because they are rapidly absorbed through abraded skin, with the potential for cardiovascular and central nervous system effects. Accidental oral ingestion of dibucaine-containing anorectal products has been reported in children, resulting in lethargy, seizures, and cardiorespiratory arrest; these products should be kept out of children's reach.^{23,24}

Vasoconstrictors

Topical vasoconstrictors (ephedrine, epinephrine) are structurally related to the endogenous catecholamines epinephrine and norepinephrine. With application to the anorectal area, stimulation of α -adrenergic receptors in the vascular beds constricts arterioles, producing a modest and transient reduction of swelling. These agents are indicated ([Table 17-4](#)) for relief of itching, discomfort, and irritation and to shrink and decrease swelling of the hemorrhoidal tissues.¹¹ Ephedrine sulfate and phenylephrine HCl are safe and effective for external and intrarectal use, and epinephrine or epinephrine HCl is approved for external use only.¹¹

Adverse effects of ephedrine and epinephrine include increased cardiac rate and contractility, as well as bronchodilation, if absorbed systemically. By contrast, because phenylephrine HCl is structurally related to norepinephrine, effects on the central nervous system and cardiac rhythm are minimal. When used in recommended topical dosages, ephedrine sulfate may cause nervousness, tremors, sleeplessness, nausea, and loss of appetite.¹¹ Serious adverse effects (e.g., elevation of blood pressure, aggravation of hyperthyroidism, cardiac arrhythmias, irregular heart rate) are less likely to occur with topical than with oral administration.¹⁷ Prolonged use may lead to rebound vasodilation, anxiety, and (rarely) paranoia. Contact dermatitis also may occur.

Rectally administered vasoconstrictors may attenuate the effects of oral antihypertensive agents and increase blood pressure. Alternatively, the

hypertensive effects of vasoconstrictors may be potentiated by monoamine oxidase inhibitors and tricyclic antidepressants which may lead to serious and even lethal outcomes, including cerebral hemorrhage or stroke.¹⁷ Patients with diabetes, thyroid disease, heart disease, or hypertension, or those having difficulty with urination due to an enlarged prostate, as well as those taking antidepressants, antihypertensive agents, or cardiac medications, should first consult with their primary care provider before using these vasoconstrictors.¹¹

Protectants

Protectants are ingredients that provide a physical protective barrier over inflamed anal tissue and soften the lining of the anal canal by preventing fecal matter from irritating or drying the perianal mucosa.¹¹ This drug class includes absorbents, adsorbents, demulcents, and emollients. Approved indications for most protectants include the temporary relief of discomfort, irritation, and burning with external and internal hemorrhoids (one exception is glycerin, which is for external use only) ([Table 17–4](#)).¹¹ Kaolin and aluminum hydroxide gel are indicated for the temporary relief of itching associated with moist anorectal conditions.¹¹

Systemic absorption of protectants is minimal; therefore, adverse reactions to agents of this class are uncommon. Lanolin is a natural product obtained from the fleece of sheep, so it may cause allergic reactions.¹¹ Chemically modified lanolin is available and may be less sensitizing.

A warning statement for aluminum hydroxide gel and kaolin products states that any greasy ointments or petrolatum-based products should be removed before application so that the protectant can adhere properly to the anorectal skin area.¹¹

Astringents

Astringents are products that promote coagulation of surface protein in the anorectal skin cells to protect the underlying tissue. Astringents also act to decrease cell volume, making the affected anorectal environment drier to prevent further irritation, and form a thin protective layer over the injured mucosal membrane.¹¹ Astringents listed in [Table 17–4](#) are approved for the temporary relief of itching, irritation, and burning symptoms associated with anorectal disorders.¹¹ Witch hazel (known as hamamelis water before January 1,

1995) is indicated for external use, whereas calamine and zinc oxide may be used for external and internal anorectal disorders.¹¹

Adverse effects with the topical use of astringents are uncommon. Upon application, witch hazel may cause a slight stinging sensation from the alcohol, or contact dermatitis may result from the small amount of volatile oil used to prepare the compound. If calamine or zinc oxide is used for prolonged periods of time (especially for internal anorectal disorders), systemic zinc toxicity (nausea, vomiting, lethargy, and/or severe pain), although rare, may develop.¹¹

Keratolytics

Keratolytics are agents that cause desquamation and debridement (or sloughing) of epidermal surface cells. By fostering cell turnover and loosening surface cells, low concentrations of keratolytics may expose the underlying tissue. When other anorectal ingredients are used in combination with keratolytics, they reduce itching and inflammation ([Table 17-4](#)).¹¹ Because mucous membranes do not contain a keratin layer, intrarectal use of keratolytics is not justified and may be harmful.^{11,17}

With repeated dosing, the absorption of the keratolytic resorcinol has led to methemoglobinemia, exfoliative dermatitis, death in infants, and myxedema in adults.¹⁷ Other adverse effects range in severity from tinnitus, increased pulse rate, diaphoresis, and shortness of breath to circulatory collapse, unconsciousness, and seizures. Products containing resorcinol must include the following warnings to minimize absorption through abraded mucosal lining and to decrease the potential for systemic toxicity: (1) “Certain persons can develop allergic reactions to ingredients in this product. If the symptoms being treated do not subside, or if redness, irritation, swelling, pain, or other symptoms develop or increase, discontinue use and consult a doctor.” (2) “Do not use on open wounds near the anus.”¹¹ Although keratolytics are available in selected anorectal preparations, the potential benefit must be weighed against their potentially serious adverse effects.

Analgesics, Anesthetics, and Antipruritics

Formerly classified as “counterirritants,” menthol, juniper tar, and camphor are safe and effective when used for external perianal disorders. These agents

(Table 17–4) are approved for the temporary relief of burning, pain, or itching by producing a cool, warm, or tingling sensation.¹¹ These agents should not be used internally because the rectum has no identifiable nerve fibers. Menthol-containing products must carry the following warning: “Certain persons can develop allergic reactions to ingredients in this product. If the symptoms being treated do not subside, or if redness, irritation, swelling, pain, or other symptoms develop or increase, discontinue use and consult a doctor.”¹¹ Extensive application of menthol to the trunk of the body has caused laryngospasm, dyspnea, and cyanosis; therefore, menthol should be used only sparingly.¹⁷ Juniper tar, which contains phenol, also should be used sparingly; and it should not be ingested orally because organ failure and cardiac rhythm abnormalities may result.²⁵ Camphor is readily absorbed through mucous membranes and stimulates the central nervous system, which may lead to convulsions or death. Fatalities have occurred mostly with accidental oral ingestion, especially in children.¹⁷

Corticosteroids

Approximately 60% of the topical anorectal agents contain hydrocortisone, which acts as a vasoconstrictor and antipruritic by producing lysosomal membrane stabilization and antimitotic activity.²⁶ The onset of action may take up to 12 hours, but the effect has a longer duration than that of most other agents (e.g., local anesthetics). Hydrocortisone, in concentrations of no more than 1%, is the only corticosteroid approved for nonprescription use in anorectal preparations for the temporary relief of minor external anal itching caused by minor irritation or rash.²⁷ Local adverse effects include rare skin reactions and skin atrophy with prolonged use. Hydrocortisone also may mask the symptoms of bacterial and fungal infections.

Combination Products

Federal regulations state that a nonprescription anorectal product may combine two or more active ingredients; combination products generally are recognized as safe and effective when (1) each active ingredient contributes to the claimed effect; (2) the combination of active ingredients does not decrease the safety or effectiveness of any individual active ingredient; and (3) the combination, with adequate directions for use and warning against unsafe use, provides rational, concurrent therapy for a significant proportion of the target population.^{11,17} FDA restrictions on combination anorectal products can

be found by accessing the *Federal Register*.¹¹ Use of combination products is reasonable in that some self-treatable anorectal disorders may be associated with concurrent symptoms. However, a combination of active ingredients has not been shown to be any more effective than a preparation containing a therapeutic amount of a single agent.^{11,17} Additionally, restricting the number of ingredients should decrease the risk of interactions and adverse drug reactions.²⁶

Product Selection Guidelines

Table 17–5 contains examples of products by category that can be recommended for hemorrhoids.

Table 17–5 Selected Nonprescription Products for Hemorrhoids	
Trade Name	Primary Ingredient(s)
Local Anesthetics	
Americaine Ointment ^a	Benzocaine 20%
Nupercainal Hemorrhoidal Ointment	Dibucaine 1%
Tronolane Anesthetic for Hemorrhoids ^b	Pramoxine HCl 1%; zinc oxide 5%
Vasoconstrictors	
Preparation H Cooling Gel ^c	Witch hazel 50%; phenylephrine HCl 0.25%
Preparation H Suppositories ^c	Phenylephrine HCl 0.25%; cocoa butter 88.44%
Skin Protectants

^e Currently, no U.S. Food and Drug Administration (FDA)-approved nonprescription product contains ephedrine sulfate

Knowledge of the patient's medical history, medication profile, and relevant socioeconomic factors is necessary to determine what product to recommend and how that patient may respond to self-treatment. Selection of a product should be based on (1) the type, location, and severity of the anorectal disorder; (2) diseases or significant past medical history; (3) current medications and nutritional supplements and/or herbal products; (4) allergies; (5) ability to apply or insert the medication (with consideration of physical, mental, and emotional

limitations); and (6) any other factors that may affect treatment (e.g., diet, daily activities, cost of the product).

Special Populations

The most common anorectal disorder in pregnancy is hemorrhoids.^{28,29} Approximately 25% of all pregnant females will complain of hemorrhoids, and this increases to 85% at the time of birth.²⁸ Pregnant and breastfeeding women should use products recommended for external use; an exception is those agents that act as protectants (but not those containing glycerin), which may be used internally. Nonpharmacologic interventions, including increasing dietary fiber and fluid intake to minimize constipation, may be beneficial throughout pregnancy and the postpartum period.²⁸

Anorectal disorders in children younger than 12 years are not common, and patients should be referred to a specialist for further medical evaluation.^{11,29,30} Because constipation is more common in the older population, these patients may be more prone to development of hemorrhoids.^{28,29} Of note, patients who are older than 40 years and have rectal bleeding or a positive family history of colon cancer should be evaluated for colorectal carcinoma.^{15,29} Additionally, patients with a family history of inflammatory bowel disease (i.e., Crohn's disease, ulcerative colitis) should be referred for medical evaluation.¹⁵ Otherwise, treatment for persons in any special population is similar to treatment for an adult patient.

Patient Factors

FDA does not require comparison trials between combination and individual products, so therapeutic differences have not been established. However, when used to treat anorectal symptoms for the preceding FDA indications, combination products containing approved ingredients in appropriate dosages are most likely therapeutically similar to individual drug products.^{11,17} Any perceived differences probably are related to personal preference for a specific product or dosage form. Using more than one product, or a product containing multiple ingredients, is reasonable because patients may have multiple symptoms that may not be adequately addressed by one product alone.^{11,17}

Medications used to treat anorectal disorders are available in many dosage forms. Creams, suppositories, gels, pastes, liquids, foams, and ointments are

primarily used externally. However, the term *ointment* used in this chapter refers to all semisolid preparations designed for intrarectal or external use in the anorectal area for its protectant and emollient properties. Additionally, ointments may be used to provide a vehicle for the safe and efficient delivery of the active ingredients.

Applicators, intrarectal applicators, or the patient's fingers can be used to apply anorectal preparations. Considerable pharmaceutical differences among the various dosage forms are recognized, but no clinical differences have been established.¹¹

Suppositories are solid dosage forms that deliver drugs into body orifices, typically in the anorectal area.^{17,31} Suppositories should not be recommended as an initial dosage form because they may leave the affected anal region and ascend into the rectum and lower colon when the patient is in an upright position.^{13,31} If the patient remains upright after insertion of a suppository or ointment, the active ingredients may not distribute evenly over the anal mucosa. Therefore, after insertion, the patient should lie on the left side with knees bent so that the preparation remains in the affected area for at least 15–20 minutes.³² Suppositories have a relatively slower onset of action than with other dosage forms because the solid product must dissolve to release the active ingredients (see [Chapter 15](#)). To prolong retention rates in the anorectal area, some health care providers recommend introducing the base of the suppository first, rather than the tapered end.³¹ A suppository that is too soft to administer can be hardened in the refrigerator for at least 30 minutes before use.³¹

Foam products theoretically should provide more rapid release of active ingredients compared with ointments.¹⁷ Foams are more expensive than ointments, however, and do not offer any specific advantage. Also, foams may not remain in the affected area, and differences in the size of the foam bubbles may result in variable concentrations of the active ingredient.¹⁷

Complementary Therapies

The use of dietary supplements, including herbal products, to manage hemorrhoids has not been researched properly, although evidence of benefit has been reported for several preparations.³³

The combination of diosmin and hesperidin (a micronized purified flavonoid fraction) has been used to stop acute bleeding and decrease symptoms associated with hemorrhoids.^{34,35} The mechanism of action is still in question, but animal models suggest that this product inhibits prostaglandin and thromboxane mediators, thereby decreasing the inflammation.³⁵ The combination appears to be safe when taken orally for less than 6 months, with the most common adverse effects being headache, muscle cramps, asthenia, abdominal pain, diarrhea, and gastritis.³⁵ Although rare, allergic dermatitis may occur if such preparations are applied topically.³⁵ Diosmin administered in lower doses with a bulk laxative has some effect on reducing symptoms of hemorrhoids, but its efficacy is greater when given with hesperidin.³⁶ Common adverse effects associated with diosmin include abdominal pain, diarrhea, gastritis, headache, and dizziness. Dermatologic and cardiac symptoms including arrhythmias as well as hemolytic anemia have also been rarely observed.³⁶

Horse chestnut seed extract (HCSE) has been used to support the management of hemorrhoids.³⁷ When HCSE is processed properly and used for less than 3 months, it is relatively safe, with adverse effects including itching, nausea, and vomiting. Improperly prepared HCSE preparations, especially with ingestion of raw seed, bark, flower or leaf, may be poisonous, with the potential for fatal reactions.³⁷

Assessment of Anorectal Disorders: A Case-Based Approach

To accurately assess whether the anorectal disorder is amenable to self-treatment, the health care provider should obtain a thorough description of the patient's signs and symptoms. Other important information to ascertain before recommending self-treatment includes the presence of certain concomitant diseases (e.g., hypertension, diabetes, benign prostatic hyperplasia, psychiatric illness); the patient's current or recent prescription and nonprescription medications, including nutritional supplements and complementary and alternative medicine preparations; and diet, lifestyle, and exercise factors.

Cases 17-1 and 17-2 illustrate assessment of anorectal disorders in two different

patients.

Case 17-1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient, who is pregnant, complains of burning, itching and some blood on toilet paper after having a bowel movement, which started in her third trimester. She also describes a feeling of pressure in the "bottom."
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Bowel movement causes pain and discomfort. Stool usually is hard, but when it is soft, symptoms are less severe. Drinking water and eating greens help with symptoms.
c. Description of the patient's efforts to relieve the symptoms	Not sitting on toilet for longer than 10 minutes
d. Patient's identity	Jenny Nok
e. Patient's age, gender, height, and weight	32 years, female, 5 ft 4 in., 166 lb
f. Patient's occupation	Surgical ICU nurse

g. Patient's dietary habits	Eats meat daily with minimal fruits and vegetables. Fluid intake has been decreased recently.
h. Patient's sleep habits	6-7 hours nightly
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Healthy. Prenatal multivitamin daily, folate acid 1 mg daily, docusate sodium twice daily.
j. Allergies	Sulfa
k. History of other adverse reactions to medications	None
l. Other (describe) -----	Patient exercise has diminished as she continues into the pregnancy.

Assess

2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Tables 17-1 and 17-2).	Ms. Nok may have anorectal symptoms, including those due to hemorrhoids and pruritus ani, as her diet and exercise regimen has changed, thus causing her to have hard stools and having to increase pressure while defecation.
3. Identify exclusions for self-treatment (Figure 17-2).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required and share this information with	Options include (1) Recommend self-care with an appropriate OTC anorectal product and advise on nondrug measures. (2) Recommend self-care with an appropriate OTC anorectal product and advise on nondrug measures until patient can contact her primary care or other health care provider.

the patient or caregiver.	(3) Refer patient to her primary care provider for further evaluation of her symptoms. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	The second option is the best: self-care and nondrug measures until the patient can contact her primary care provider. Recommend an external hemorrhoidal agent only. If internal-use agents are preferred, recommend products with protectants (except glycerin). Recommend patient increase fluid intake (water), dietary fiber (fruits, vegetables), and, if possible, exercise. Sitz baths used 3 times a day may resolve anorectal symptoms. Encourage patient to wear soft, loose-fitting clothing. Also educate patient to use unscented, undyed (white) toilet paper and to use gentle technique in wiping the anal area.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your symptoms, including itching, pain, and bleeding, may be related to hemorrhoids and anal itching. The hemorrhoids may have developed as the baby continues to grow, which causes pressure in the anal area. The changes in your body with pregnancy cause increased internal pressure, especially during a bowel movement, which may produce hemorrhoids. I'm recommending you use a self-care product for now; however, you should contact your primary care provider for further evaluation in a few days if your symptoms do not decrease or resolve."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"If symptoms do not resolve in a week, seek medical attention. Although your symptoms, including having bowel movement discomfort, pain, and anal itching, may be related to hemorrhoids, you should contact your primary care provider or OB/GYN specialist for further evaluation. Other conditions also may cause similar symptoms."
Implement	
8. When recommending self-care with	

nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	See Table 17-4 .
b. Maximum number of days the therapy should be employed	“Contact your primary care provider if after 7 days the symptoms do not resolve. Be sure to let your provider know what self-care measures you have taken.”
c. Product administration procedures	See Table 17-3 .
d. Expected time to onset of relief	“The irritation, burning, and discomfort may be relieved within a few days of applying the topical agent as directed.” Advise the patient to avoid straining and to drink adequate fluids and eat a healthy diet that is high in dietary fiber. “If required, keep using the stool softener, or add a fiber supplement, as needed. Although the bleeding may stop with treatment, be sure to contact your primary care provider for further evaluation.”
e. Degree of relief that can be reasonably expected	“Your anorectal symptoms should resolve a few months after giving birth.”
f. Most common adverse effects	“Products applied to the anal area are usually well tolerated.”
g. Adverse effects that warrant medical intervention should they occur	“If you develop an allergic reaction to the product, such as redness, swelling, increased irritation, or pain, discontinue use, and contact your primary care provider as soon as possible.”
h. Patient options in the event that condition worsens or persists	“If your symptoms worsen, contact your primary care provider as soon as possible.”
i. Product storage requirements	“Store medication out of the reach of children and at a controlled room temperature.”

j. Specific nondrug measures	"Practice good anal hygiene, use sitz baths, and consider increasing fluid intake. Incorporate an exercise regimen if possible."
Solicit follow-up questions from the patient or caregiver.	"Will this affect my baby?"
Answer the patient's or caregiver's questions.	"Probably not. If you practice good anal hygiene, use sitz baths, and increase fluid intake and exercise, your stools should be soft, so that the local stress of having a bowel movement will not irritate the anal canal. Use of the recommended product should not affect the baby."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Ms. Nok to call to update you on her response to your recommendations. Alternatively, you could call her in a week to evaluate her response and make sure that she touched base with her primary care provider.
Key: OB-GYN = Obstetrics-gynecology; OTC = over-the-counter.	

Case 17-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient complains of bleeding in the anal area for 1 week and seeing blood in the toilet bowl. Patient describes blood on the toilet paper with each wiping. He has a low-grade fever (temperature of 99.9°F [37.2°C]; oral). He has had these symptoms before but says the abdominal pain is new.
b. Description of any factors that seem to precipitate,	Symptoms are worst when he is unable to have a bowel movement. He states that the stomach pain, on a scale of

exacerbate, and/or relieve the patient's symptom(s)	1-10 (10 being worst), feels like a 6. He has not changed his diet or exercise regimen but has lost about 10 pounds in a few weeks.
c. Description of the patient's efforts to relieve the symptoms	The patient has tried topical hydrocortisone cream in the anorectal area without relief for the past 2 days.
d. Patient's identity	Matt Knowling
e. Patient's age, gender, height, and weight	28 years, male, 5 ft 8 in., 149 lb
f. Patient's occupation	Graduate student (master's degree program in business administration)
g. Patient's dietary habits	Eats healthy meals, including meat, fruits, and vegetables. Eats sweets while studying. Does not smoke. Drinks socially at parties.
h. Patient's sleep habits	5-6 hours nightly
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Acne diagnosed at age 21; takes a multivitamin daily.
j. Allergies	Penicillin (anaphylactic reaction)
k. History of other adverse reactions to medications	None
l. Other (describe) _____	Mr. Knowling's father is alive with colon cancer at the age of 56. His mother also is living and diagnosed with depression. He has a brother who has ulcerative colitis. He is single.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s) (Tables 17-1 and 17-2).	Mr. Knowling experiences abdominal pain on defecation and has blood in his stool, along with low-grade fever. There is a family history of colon cancer and ulcerative colitis.
	He states that his diet, fluid, and exercise regimens have not changed, yet he has continued to lose weight over the past

	few weeks. Given that Mr. Knowling is in his late 20s and has a family history of colon cancer and a brother with ulcerative colitis, it is possible that he has an oncologic condition or IBD.
3. Identify exclusions for self-treatment (Figure 17-2).	Blood in toilet, abdominal cramping, experiencing pain with each bowel movement. Strong family history of colon cancer.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required and share this information with the patient or caregiver.	Options include (1) Recommend self-care with an appropriate OTC anorectal product and advise on nondrug measures. (2) Recommend self-care with an appropriate OTC anorectal product and advise on nondrug measures until patient can contact his usual health care provider. (3) Refer patient to an appropriate health care provider for medical evaluation of his symptoms immediately. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Mr. Knowling should consult an appropriate health care provider immediately for medical evaluation to rule out bleeding from a source other than a hemorrhoid or anal fissures or fistulas. He is young and has significant abdominal pain with each bowel movement. Mr. Knowling may have colon cancer or IBD, because there is a strong family history of cancer and GI conditions (Figure 17-2).
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a health care provider for immediate medical evaluation. I'm concerned about your symptoms and your family history."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic	"Because you tried using the hydrocortisone cream with no relief, the best option is for you to see your usual health care provider immediately. You have a strong family history of colon cancer and stomach issues. The signs and symptoms you are complaining about may be symptoms of IBD. Please

alternatives.	see your primary care provider to have your symptoms evaluated and testing done as soon as possible.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	“What is IBD?”
Answer the patient’s or caregiver’s questions.	“IBD is inflammatory bowel disease. This is not an unlikely cause of your symptoms because your brother has ulcerative colitis, a type of IBD. The way to determine if you have this medical condition is by seeing an appropriate specialist in gastrointestinal disorders to do more tests.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Knowing in 1-2 days to ensure that he made an appointment and sought immediate and appropriate medical care.
Key: IBD = Inflammatory bowel disease; GI = gastrointestinal; OTC = over-the-counter; PCP = primary care provider.	

Patient Counseling for Anorectal Disorders

The most appropriate drug and nondrug measures for treating specific anorectal signs and symptoms should be explained to the patient. Counseling should include dosage and frequency of administration, administration technique, onset of action, possible adverse effects, precautions or warnings, and product storage. Patients should understand when self-care should be discontinued and when to consult a primary care provider. If the topical nonprescription agents do not resolve the anorectal symptoms within 7 days, medical referral is appropriate.¹¹ Patients should be advised not to exceed the

recommended daily dosage unless their primary care provider recommends a higher dosage.¹¹ The box “Patient Education for Anorectal Disorders” lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Anorectal Disorders

Self-treatment for anorectal disorders should be limited to management of minor symptoms. If serious or severe symptoms are present, or if symptoms become progressively worse, the patient should be advised to contact a primary care provider. In addition, if so-called alarm signs or symptoms are present, including blood in the stool or severe anal pain, or if symptoms persist beyond 7 days of self-treatment, the patient should be counseled to seek immediate medical attention.¹¹ If symptoms resolve, the patient should be encouraged to maintain a well-balanced diet, proper personal hygiene, and good bowel habits to avoid recurrence of symptoms.^{11,14,15,17}

Patient Education for Anorectal Disorders

The objectives of self-treatment are (1) to relieve specific signs and symptoms and (2) to prevent complications leading to serious problems. The primary goal of treatment is to prevent straining during defecation. For most patients, carefully following product instructions and the self-care measures listed here will help ensure relief of symptoms.

Nondrug Measures

- Maintain hydration and a healthy diet. If you are experiencing hard stools, straining, or constipation, increase the amount of fiber and fluids in the diet to reduce or prevent straining during bowel movements (see [Chapter 15](#)).
- Avoid medications that cause constipation, if possible (see [Chapter 15](#)).
- Clean anorectal area after each bowel movement with moistened,

unscented, white toilet tissue or wipe.

- Use a sitz bath, or soak in a bathtub 2–4 times a day, which may help relieve mild anal itching, burning, irritation, and discomfort. Avoid the use of soaps, salts, and oils.

Nonprescription Medications

- Select products containing only the ingredients needed to relieve specific anorectal symptoms.
- See [Table 17–3](#) for guidelines for applying anorectal products.
- See [Table 17–4](#) for recommended dosages of these products.
- Use only selected vasoconstrictors (ephedrine and phenylephrine), protectants (not glycerin), and astringents (calamine and zinc oxide) intrarectally.
- *If the patient is pregnant:* Use only products approved for external use. If internal use is required, any of the protectant class of drugs, with the exception of glycerin, may be used.
- *If the patient has a history of cardiovascular disease, diabetes, hyperthyroidism, hypertension, depression, or difficulty urinating because of prostate problems:* Avoid topical products that contain vasoconstrictors.
- *If the patient is taking medications for hypertension or depression:* Avoid using any anorectal product containing vasoconstrictors without first consulting your primary care provider.
- Self-monitor for nervousness, tremor, sleeplessness, nausea, and possible loss of appetite with use of an anorectal product containing ephedrine sulfate or phenylephrine.
- Expect a reduction or relief of symptoms within a few days of initiation of self-treatment.
- To support personal preferences, determine if a choice among an ointment, a cream, or a suppository is possible, or if generic products are available.

When to Seek Medical Attention

- Stop using the anorectal product and contact a primary care provider as soon as possible if insertion of a product into the

anorectal area causes pain.

- Contact a primary care provider if symptoms worsen, if new symptoms (e.g., bleeding) develop, or if symptoms do not resolve after 7 days of self-treatment.
- Discontinue using product and contact a primary care provider at the first occurrence of adverse effects (e.g., a new rash or increased itching, redness, burning, or swelling in the anorectal area).
- Discontinue product and contact a primary care provider immediately if allergic or hypersensitivity reactions to the anorectal product develop.

Key Points for Anorectal Disorders

- Self-treatment for anorectal disorders should be restricted to management of minor symptoms such as burning, itching, discomfort, swelling, and irritation.
- Immediate referral to a primary care provider is warranted when symptoms include anorectal seepage, bleeding, thrombosis, severe pain, fever, or a change in bowel patterns.
- The patient should be advised to seek medical attention if anorectal symptoms worsen or do not lessen after 7 days of self-treatment.
- Pregnant and breastfeeding women should be counseled to use only products for external use (except for protectants that do not contain glycerin, which can be used internally).
- Parents and caregivers of children younger than 12 years with anorectal symptoms need to seek further medical evaluation from their primary care provider.
- In selecting an anorectal product for self-treatment, opting for a preparation containing the fewest number of ingredients

necessary to treat specific symptoms will minimize the risk of undesirable effects.

- Patient education should include instruction in the proper use or application of specific anorectal products ([Table 17-3](#)).
- Counseling should identify effective nondrug management strategies (e.g., dietary measures, perianal hygiene) (see the box “Patient Education for Anorectal Disorders”).
- Medications with a vasoconstrictor effect should be avoided in patients who have conditions such as diabetes, hypertension, cardiac disease, thyroid disease, and enlarged prostate, or who are using antidepressants, to avoid the possibility of systemic adverse effects.
- Awareness of the advantages and disadvantages of various anorectal dosage forms will promote selection of the best product for the anorectal symptoms.

Chapter 18: Pinworm Infection

Authors: Connie Kang, Karl M. Hess

Editor's Note: This chapter is based on the 19th edition chapter of the same title, written by Jeffrey A. Goad and Edith Mirzaian.

Enterobius vermicularis, commonly referred to as pinworm, seatworm, or threadworm, is an intestinal roundworm (nematode) and the primary agent that causes human pinworm infection (enterobiasis, also known as oxyuriasis).^{1,2} This chapter focuses on the detection and management of pinworm infection, as it is the most common intestinal helminthic (parasitic worm) infestation in the United States and the only helminthic infection for which a nonprescription medication has been approved for treatment by the U.S. Food and Drug Administration (FDA).^{1,3} Pinworm infection is common worldwide; in the United States, it is found with a high prevalence (estimated 40 million persons infected) in child care settings and urban areas owing to its highly contagious nature.^{2,4–8} Nearly 50% of all *E. vermicularis* cases occur among persons who are institutionalized (e.g., in child care facilities or in hospitals) and among household members.^{2,9,10} Enterobiasis is seen at all socioeconomic levels and, in contrast with other helminthic infections, has no apparent predilection for any particular racial or cultural group.¹ Although pinworms are a nuisance, the pinworm infection presents little risk to the infected person or to the public.

Pathophysiology of Pinworm Infection

Humans are the only known hosts of *E. vermicularis*.² Unlike with most other helminthic infections, pinworms do not live in the soil or water and are not transmitted through contact with animal feces. However, animal fur of household dogs and cats may be a carrier of infective eggs.¹⁰ The most common pinworm transmission route is through the fecal–oral ingestion of eggs from direct anus-to-mouth transfer by fingers or indirect egg transfer from the perianal region through fomites (e.g., clothes, bedding, bathroom fixtures). Reinfection may occur readily because eggs often are found under fingernails of infected children who have scratched the anal area. Finger sucking also may be a source of infection, particularly in children with

recurring symptoms.¹⁰ Nail biting and nose picking have not been associated with the initial infection; however, they certainly can contribute to reinfection.¹¹ Owing to their small size, pinworm eggs sometimes can become airborne in dust and reach the intestinal tract through the nose with respiration.^{2,4} Eggs can remain viable outside the intestinal tract for up to 20 days and can spread during that time within a household, school, or other micro-community, particularly under humid conditions.¹

After infective eggs are ingested, they may hatch and release larvae in the small intestine. The time lapse between ingestion of the eggs to oviposition (deposition of eggs) by adult females is approximately 1–2 months.⁴ After this period, the adult pinworm emerges as a small, white, thread-like worm with a pin-shaped, pointed tail from which the name is derived (see [Color Plates](#), photograph 5A); its lifespan is approximately 2 months.^{1,9} Adult male and female worms inhabit the ileocecum but seldom cause damage to the intestinal wall. The mature female, approximately 8–13 mm in length, usually stores approximately 11,000 eggs in her body (see [Color Plates](#), photograph 5B). After her nocturnal migration down the colon and through the anus, she deposits her sticky eggs in the perianal region and dies shortly afterward. The smaller males (2–5 mm) live about 2 weeks and do not migrate. If the eggs are not washed off, they hatch within a few hours, and larvae may return to the large intestine through anal retroinfection. Within 2–6 weeks of egg ingestion, larvae are released and mature into gravid females, thus continuing the cycle indefinitely unless appropriate behavioral and pharmacotherapeutic interventions are instituted.⁹ Extraintestinal infestations are rare but pinworms may mistakenly crawl into the genitourinary tract in females.⁴ Genitourinary pinworm infections are harder to treat because of the low systemic absorption of antiparasitic agents.¹

Clinical Presentation of Pinworm Infection

Patients with minor pinworm infections often are asymptomatic. Nocturnal perianal or perineal pruritus is the most common symptom.⁴ Perianal itching occurs predominantly at night and is caused by an inflammatory reaction to the presence of adult worms and eggs on the perianal skin.⁸ Major infections may produce clinical manifestations ranging from abdominal pain, insomnia, and restlessness to anorexia, diarrhea, and intractable localized itching.^{10,11} Patients with severe symptoms or extraintestinal infestation should be referred

for further evaluation. Before recommending treatment or medical referral, the pharmacist should ask appropriate assessment questions to rule out diaper dermatitis (see [Chapter 36](#)) in children, as well as constipation (see [Chapter 15](#)) and hemorrhoids (see [Chapter 17](#)) in older patients, because these conditions also can cause inflammation in the anorectal region, leading to itching and discomfort.

In addition to physical signs and symptoms, psychological trauma (previously referred to as *pinworm neurosis*) to patients and parents can occur when worms are found near the affected child's anus. Patients and parents need to be assured that pinworm infections are common and curable, and no social stigma should be attached to their occurrence.¹¹

Scratching to relieve itching from pinworm infection also may lead to secondary bacterial infection of the perianal and perineal regions.¹ Helminthic infections in the genital tract may progress to endometritis, salpingitis, tubo-ovarian abscess, pelvic inflammatory disease, vulvovaginitis, and possibly infertility.^{1,12,13} Pinworms also may migrate into the peritoneal cavity, where they may form granulomas. Rarely, pinworms may cause appendicitis in children.¹⁴

Figure 18–1 Self-care for pinworm infection. Key: OTC = Over-the-counter; PCP = primary care provider.

Treatment of Pinworm Infection

Treatment Goals

The goals of self-treatment are (1) to eradicate the pinworm infection, thereby relieving symptoms, (2) to prevent reinfection, and (3) to prevent transmission to other persons.

General Treatment Approach

The management of pinworm infection to include prevention of reinfection begins with treatment with pyrantel pamoate for the patient and for every household member. Strict hygiene (e.g., washing linens, disinfecting toilet

seats) is an integral part of the treatment plan. [Figure 18–1](#) outlines self-care for this infection and lists exclusions for self-treatment.

Nonpharmacologic Therapy

Once pinworm infection is suspected, the patient or caregiver should follow the nondrug measures in [Table 18–1](#) to minimize the occurrence of family and household infections and reinfections. Children usually can return to school after the first dose of an appropriate antihelminthic agent and after their fingernails are cut and cleaned. Health care providers are in an ideal position to inform patients and caregivers of behaviors that may increase their risk of helminthic infections.

Table 18–1 Nondrug and Preventive Measures for Pinworm Infection

- Educate patients in personal hygiene, particularly regarding the need to wash hands before eating or preparing food and after using the toilet. Encourage keeping fingernails short to prevent harboring of eggs and autoinoculation (hand-to-mouth reinfection); discourage biting nails and scratching in the anorectal region.
- Eggs are destroyed by sunlight and ultraviolet light, so ensure that blinds or curtains are open in the affected room(s) to enhance cleansing the environment.
- Wash bed linens, underwear, bedclothes, and towels of the infected person and entire household in hot water daily during treatment. Pinworm eggs are killed by exposure to temperatures of 131°F (55°C) for a few seconds, so the “hot” cycle should be used for washing and drying.
- Bathe daily in the morning; showers are preferred over baths.
- Change underwear, nightclothes, and bed sheets daily for several days after treatment.
- Clean and vacuum (do not sweep) the house daily for several days after treatment. Wet mopping before or instead of vacuuming may limit spread of pinworm eggs into the air.

Source: Heymann D. *Control of Communicable Diseases Manual*. 19th ed. Washington, DC: American Public Health Association; 2008.

Pharmacologic Therapy

Pyrantel Pamoate

Pyrantel pamoate is the only FDA-approved nonprescription medication for treatment of pinworm infection. Pyrantel pamoate was first used in veterinary

practice as a broad-spectrum drug for eradication of pinworms, roundworms, and hookworms. Pyrantel pamoate has a cure rate of 90%–100% when used for treatment of enterobiasis.¹⁵ The drug's less than perfect expected efficacy may be a result of a variable effect on pinworm eggs and larvae or reflect the viability of this helminth's eggs (up to 20 days), which may lead to reinfection.

Pyrantel pamoate is a depolarizing neuromuscular agent that stimulates the release of acetylcholine and inhibits cholinesterase, thereby paralyzing adult worms in the gastrointestinal (GI) tract. The paralyzed adult worms loosen their hold on the intestinal wall and are subsequently passed out in the stool. The drug is poorly absorbed, with 50% excreted unchanged in the feces and approximately 7% excreted in the urine as unchanged drug and metabolite (*N*-methyl-1,3-propanediamine).¹⁵

Pyrantel pamoate is indicated for nonprescription use in patients aged 2 years and up who weigh at least 25 lb (11 kg). The weight-based dosage chart on the package label, which is based on 11 mg/kg of pyrantel base, should be followed, up to the maximum dose of 1 g to be given as a single oral dose. Product labeling includes a schedule of recommended dosages based on a range of body weights. Dosing can be repeated in 2 weeks if symptoms do not resolve, because reinfection can occur; however, the repeat dose should be administered only after consultation with a primary care provider. Pyrantel pamoate may be taken at any time of day without regard to meals, and it may be taken or mixed with milk or fruit juice.¹⁵ Liquid formulations (containing the equivalent of 50 mg/mL of pyrantel base) must be shaken before the dose is measured with the measuring device enclosed with the product packaging.

Adverse effects of pyrantel pamoate usually are mild, infrequent, and transient. The most common adverse effects involve the GI tract: nausea, vomiting, gastralgia, abdominal cramps, diarrhea, and anorexia.¹⁶ These adverse effects may be related to expulsion of helminths from the GI tract. Less common adverse effects include headache, dizziness, drowsiness, insomnia, rash, fever, and weakness. In very rare circumstances, transient increases in aspartate aminotransferase (AST) have been reported. Patients who experience severe or persistent adverse effects after taking this medication should be referred for further medical evaluation. Patients who do not respond to pyrantel pamoate should be advised to see their primary care provider, and the use of prescription medications (e.g., albendazole, mebendazole) should be considered.

Product Selection Guidelines

Pyrantel pamoate is a safe and effective agent for treatment for pinworms. The medications listed in [Table 18–2](#) are comparatively priced and generally less expensive overall than prescription antihelminthics. Pyrantel pamoate is contraindicated in patients with hypersensitivity to this medication. Patients with preexisting liver dysfunction, severe malnutrition, or anemia should not use pyrantel pamoate without first consulting a primary care provider. Use of pyrantel pamoate in pregnancy and during breastfeeding should be limited to situations in which the potential benefit justifies potential risk to the child and then is allowed only under the direction of a primary care provider. Finally, pyrantel pamoate should not be used on a self-care basis in patients younger than 2 years of age or those weighing less than 25 lb (11 kg).

Table 18–2 Selected Nonprescription Pyrantel Pamoate Products	
Trade Name ^a	Primary Ingredient
Reese’s Pinworm Medicine Liquid	Pyrantel pamoate 50 mg/mL (base) [banana flavored]
Reese’s Pinworm Medicine Family Pack	Pyrantel pamoate 50 mg/mL (base); contains two bottles (each containing 1 fluid ounce) to treat the entire family [banana flavored]

^a Various store brand and other generic formulations also are available.

Complementary Therapies

Numerous home remedies (e.g., applying a combination of garlic paste and petroleum jelly to the anus, ingesting coconut or castor oil) and complementary therapies (e.g., white willow bark, green tea, turmeric) have been used to treat pinworm infection. These remedies are not recommended, however, because evidence of their efficacy and safety is lacking to support their use to treat pinworm infections.

Assessment of Pinworm Infection: A Case-

Based Approach

Before recommending treatment, the health care provider should explain how to confirm a pinworm infection by any of the following methods: (1) nighttime perianal or perineal itching in a child, (2) visual inspection of the perianal or perineal area for the adult worm, or (3) a cellophane tape or an adhesive paddle test. Adult pinworms and eggs are seldom found in the feces, so looking for worms in the stool is not a reliable way to diagnose enterobiasis.¹⁷ When symptoms of pinworms (e.g., nocturnal perianal, perineal itching) are present in children, nonprescription therapy may be initiated. With more vague complaints such as sleep disturbances or GI symptoms, the patient should first be evaluated by a primary care provider before initiation of nonprescription therapy.

Asymptomatic disease is common in enterobiasis; therefore, a visual inspection may be necessary for confirmation. The parent should inspect the anal area during the night with a flashlight while the child is sleeping or in the very early morning before the child arises. White, thread-like, wriggling worms, about the size of a staple, may be seen; this finding confirms the infection and prompts initiation of treatment. Finally, if pinworms are suspected but symptoms are vague in nature or the visual inspection fails to show confirmatory evidence, obtaining a cellophane tape sample may be warranted. The parent should apply the sticky side of the tape to the perianal area (usually with a tongue depressor) and then place it sticky side down on a glass slide. Commercially available kits use a sticky paddle instead of tape to affix to a slide (see [Color Plates](#), photograph 5C). Samples should be taken over 3 consecutive days upon the child's awakening, which may increase the likelihood of detection to around 90%.¹¹ The samples should then be taken to an appropriate health care provider to submit for microscopic examination. If the test result is positive, treatment for pinworm infection should be initiated. Cases 18–1 and 18–2 illustrate the assessment of two different patients with symptoms of pinworm infection.

Case 18–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patients' symptoms, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A woman presents to the pharmacy requesting assistance in selecting a nonprescription product. She reports that her daughter was diagnosed as having pinworms by her pediatrician, who recommended a nonprescription medication for treatment. The mother says her daughter has been complaining about perianal itching that gets much worse at night. The mother and her husband have no current symptoms. The mother asks for a liquid or chewable formulation since her daughter has a hard time swallowing tablets or capsules.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patients' symptom(s)	No precipitating factors
c. Description of the patients' efforts to relieve the symptoms	The parents gave their daughter liquid Benadryl for the itching, with no relief.
d. Patients' identity	The family consists of daughter Jenny, mother Theresa North, and father Robert North.
e. Patients' age, gender, height, and weight	<i>Daughter:</i> 6 years, female, 3 ft 6 in., 40 lb (18 kg)
	<i>Mother:</i> 36 years, female, 5 ft 6 in., 143 lb (65 kg)
	<i>Father:</i> 38 years, male, 5 ft 11 in., 190 lb (86 kg)
f. Patients' occupations	Jenny is in first grade in elementary school. Mrs. North is an attorney, and Mr. North is a mechanical engineer.
g. Patients' dietary	All family members report normal diet and appetite.

Relevant Evaluation Criteria	Scenario/Model Outcome
habits	
h. Patients' sleep habits	<i>Daughter:</i> frequent awakenings at night caused by perianal itching; <i>parents:</i> normal sleep habits
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Daughter:</i> daily children's chewable multivitamin; <i>mother:</i> daily multivitamin; <i>father:</i> fish oil capsule daily, baby aspirin
j. Allergies	<i>Daughter:</i> amoxicillin allergy (rash); <i>mother:</i> NKA; <i>father:</i> NKA
k. History of other adverse reactions to medications	None
l. Other (describe) -----	n/a
Assess	
2. Differentiate patients' signs/symptoms, and correctly identify the patient's primary problem(s).	Jenny is experiencing perianal itching from a pinworm infection, which results in restless sleep at night.
3. Identify exclusions for self-treatment (Figure 18-1).	Patients should be excluded from eligibility for self-treatment if they (1) are allergic to the nonprescription product, (2) are younger than 2 years of age (unless treatment is approved by a primary care provider), (3) weigh less than 25 lb (11 kg) (unless treatment is approved by a primary care provider), (4) have liver disease, (5) are pregnant, (6) are breastfeeding, (7) have vague symptoms and no evidence of infection on visual inspection, (8) have severe symptoms, (9) have anemia, (10) have malnutrition, or (11) have symptoms outside of the perineal region.
	Jenny does not have any exclusions for self-treatment, and neither do Mr. and Mrs. North, who also should be treated because pinworm infection can spread within a household.

Relevant Evaluation Criteria	Scenario/Model Outcome
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patients or caregiver.	Options include (1) Recommend an appropriate nonprescription product (i.e., pyrantel pamoate) at the proper dose for each member of the family, along with nondrug measures. (2) Recommend that the parents see a primary care provider for a prescription medication while Jenny receives nonprescription pyrantel pamoate. (3) Counsel only on environmental control measures and nondrug strategies for all family members. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patients' problem, taking into account patient preferences.	Nonprescription treatment with pyrantel pamoate is appropriate for all three patients. The child is not comfortable swallowing tablets or caplets, but she can take chewable tablets or a liquid formulation. Pyrantel pamoate liquid formulation is therefore an appropriate option.
6. Describe the recommended therapeutic approach to the patients or caregiver.	"Several medications are effective in the treatment of pinworms. Pyrantel pamoate is available without a prescription. Because a family member was recently diagnosed with pinworm infection and the primary care provider instructed that the patient be treated with a nonprescription medication, all family members should also be treated, since infection can spread within the household. Therefore, pyrantel pamoate is a reasonable option."
7. Explain to the patients or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Pinworm infection is not life-threatening. However, if the infection is untreated, your daughter may reinfect herself or infect other family members. She also may experience some complications of infection if she is not treated. Pyrantel pamoate is a reasonable treatment option because it is available without a prescription. Pyrantel pamoate is available as an oral suspension, which offers flexible dosing based on weight for multiple family members."

Relevant Evaluation Criteria	Scenario/Model Outcome
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patients or caregiver.	
a. Appropriate dose and frequency of administration	Follow the dosage chart found on the medication package label to take a single weight-based dose; do not exceed more than 1 g of pyrantel pamoate base. Use the enclosed measuring device for any liquid formulations. • Jenny weighs 40 lb (18 kg), so the dose is 1 teaspoonful according to the medication package dosage chart. • Mrs. North weighs 143 lb (65 kg), so the dose is 3 teaspoonfuls according to the medication package dosing chart. • Mr. North weighs 190 lb (86 kg), so the dose is 4 teaspoonfuls according to the medication package dosing chart. [Note: It is important to reinforce to the parents that pinworms are very common and rarely cause serious problems, but that the infection will continue and potentially spread to others if it is not properly treated.]
b. Maximum number of days the therapy should be employed	“Treatment usually consists of a single dose. If symptoms persist after 2 weeks, contact your primary care provider for evaluation and, if needed, a recommendation for a second dose.”
c. Product administration procedures	“Pyrantel pamoate may be taken at any time of day without regard to meals. It may be mixed with milk or fruit juice. If using the oral suspension, shake well before administering.”
d. Expected time to onset of relief	“Relief of symptoms may take several days. A repeat dose should not be administered until 2 weeks have elapsed and should be administered only if recommended by your primary care provider.”

Relevant Evaluation Criteria	Scenario/Model Outcome
e. Degree of relief that can be reasonably expected	Perianal itching should decrease after several days, with complete pinworm eradication after at least 2 weeks.
f. Most common adverse effects	Adverse effects are usually mild and may consist of nausea, vomiting, loss of appetite, diarrhea, or abdominal cramps.
g. Adverse effects that warrant medical intervention should they occur	Severe or persistent abdominal symptoms require medical attention.
h. Patient options in the event that condition worsens or persists	“Contact the appropriate health care provider if a family member’s condition worsens, or if, after taking the medication, a family member experiences any severe adverse effects, such as severe or persistent abdominal symptoms.”
i. Product storage requirements	Store at room temperature away from direct light with container sealed tightly.
j. Specific nondrug measures	See Table 18-1 .
Solicit follow-up questions from the patients or caregiver.	“Should my daughter receive a prescription medication instead because she has an active infection?”
Answer the patients’ or caregiver’s questions.	“Both the prescription and nonprescription medications are equally effective in treating pinworms. You can use either the prescription medication or the nonprescription pyrantel pamoate, depending on your preferences (such as cost).”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	You can call the parents in 1–2 weeks to assess the child’s response to the medication. If symptoms have resolved, reinforce the importance of hygienic measures. If symptoms persist, another single dose of pyrantel pamoate can be administered, but only after reevaluation by the child’s pediatrician or the family’s regular health care provider.

Key: n/a = Not applicable; NKA = no known allergies.

Case 18–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A woman comes to the pharmacy requesting assistance in choosing a product to help with diarrhea. She says she has had diarrhea, itching around the perianal region, and generalized abdominal pain for about 4 days. The itching, which began roughly 1 week before the diarrhea started, tends to be worse at night. She also tells you that her grandchildren, whom she visited in another state about 2 weeks ago, had similar symptoms of itching as well and that her daughter was going to take them to see their pediatrician.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	No precipitating factors
c. Description of the patient's efforts to relieve the symptoms	She tried bismuth subsalicylate for 3 days without much relief. She took 3 doses of loperamide, which helped with the diarrhea but did not stop the itching. She tried applying hemorrhoidal ointment and hydrocortisone ointment to the region to help with the itching, with limited relief.
d. Patient's identity	Letty Whitaker
e. Patient's age, gender, height, and weight	61 years, female, 5 ft 4 in., 132 lb (60 kg)
f. Patient's occupation	Dance instructor
g. Patient's dietary habits	Normal diet, high in fruits, vegetables, and whole grains

Relevant Evaluation Criteria	Scenario/Model Outcome
h. Patient's sleep habits	Frequent awakenings at night caused by perineal itching
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Daily multivitamin; occasional ibuprofen or acetaminophen for pain
j. Allergies	NKA
k. History of other adverse reactions to medications	None
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Ms. Whitaker's symptoms, such as perianal itching at night, are consistent with pinworm infection, but diarrhea and abdominal pain are unusual symptoms in this setting and warrant evaluation by an appropriate health care provider. A tape test or a slide test should be done to confirm pinworm infection.
3. Identify exclusions for self-treatment (Figure 18-1).	Eligibility for self-treatment is ruled out by any of the following: (1) allergy to the nonprescription product, (2) age younger than 2 years (unless treatment is approved by a primary care provider), (3) body weight less than 25 lb (11 kg) (unless treatment is approved by a primary care provider), (4) liver disease, (5) pregnancy, (6) breastfeeding, (7) vague symptoms with no findings on visual inspection, (8) severe symptoms, (9) anemia, (10) malnutrition, or (11) symptoms outside of the perineal region.
	Ms. Whitaker is excluded from self-treatment because she has vague symptoms and negative visual inspection.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care	Options include (1) Recommend an appropriate nonprescription product at the proper dose, along with nondrug therapies.

Relevant Evaluation Criteria	Scenario/Model Outcome
provider is required, and share this information with the patient or caregiver.	(2) Refer Ms. Whitaker to an appropriate health care provider for further evaluation, diagnosis, and recommended treatment. (3) Counsel Ms. Whitaker on environmental control measures and nondrug strategies only. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Medical evaluation by an appropriate health care provider is warranted because of the perineal and gastrointestinal symptoms, which may necessitate prescription treatment.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should see your primary care provider for further evaluation of your symptoms, appropriate diagnosis, and recommended treatment."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Because you do not have a documented pinworm infection and because you have other symptoms that may be complications of other conditions, self-treatment is not appropriate. Your symptoms may be consistent with pinworm infection, but other possibilities need to be ruled out."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Self-treatment is not appropriate, but you should start environmental control and nondrug measures [see Table 18–1] and seek medical care."

Relevant Evaluation Criteria	Scenario/Model Outcome
Solicit follow-up questions from the patient or caregiver.	(1) "Are there any complications associated with pinworms?"
	(2) "How are pinworms normally treated?"
Answer the patient's or caregiver's questions.	(1) "If untreated, pinworm infection could lead to secondary bacterial infections in the perianal and perineal regions. Pinworm infections also can lead to pelvic inflammatory disease, endometritis, and urinary tract infections. In addition, other possible symptoms associated with pinworm infection include insomnia, restlessness, and anorexia."
	(2) "Patients with pinworm infection may be treated with a single dose of nonprescription (pyrantel pamoate) or prescription (albendazole, mebendazole) medications. Along with medications, patients also must follow specific nondrug measures to prevent reinfection."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Ms. Whitaker to call you in 1 week, or initiate a follow-up call to ensure she was evaluated by an appropriate health care provider and whether her symptoms are resolving.

Key: NKA = No known allergies.

Patient Counseling for Pinworm Infection

Once the decision to treat the pinworm infection with pyrantel pamoate is made, the package insert material should be reviewed with the patient or caregiver. The insert explains the pinworm life cycle, symptoms of pinworm infection, and methods of transmitting the infection. Doses should be calculated for the patient and all family members, and the need to treat the whole family should be emphasized. The patient or caregiver will need to implement strict hygienic measures to prevent reinfection or transmission of the infection to other family members ([Table 18–1](#)). In addition, it should be

explained that the adverse effects of pyrantel pamoate usually are mild and infrequent, but that medical referral may be necessary if more severe or persistent effects occur. Patients and caregivers should be advised that symptoms should resolve within 2 weeks of treatment. They should be further advised that persistence or worsening of symptoms that include systemic manifestations (e.g., abdominal discomfort, insomnia, nervousness) warrants further medical evaluation. The box “Patient Education for Pinworm Infection” lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Pinworm Infection

Patients or caregivers should be instructed to contact their primary care provider if anal itching persists beyond 2 weeks, if the itching recurs, or if new symptoms develop. Because of pyrantel pamoate’s variable cure rate, a second dose may be required. It should be given 2 weeks after the first dose and only with the recommendation of a primary care provider. In addition, the importance of implementation of and adherence to hygienic measures should be emphasized to patients or caregivers. Following these measures is crucial for preventing reinfection.

Patient Education for Pinworm Infection

The objectives of self-treatment are (1) to eradicate pinworms in the infected patient, (2) to prevent reinfection, and (3) to prevent transmission of the infection to others. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- See [Table 18–1](#) for nondrug/preventive measures.

Nonprescription Medications

- Read package insert for pyrantel pamoate information carefully; this information is provided to help prevent reinfection or transmission of the infection.
- Consult a primary care provider before giving the medication to a person with liver disease, severe malnutrition, or anemia; a child who is younger than 2 years of age or weighs less than 25 lb (11 kg); a woman who is pregnant or breastfeeding; or someone who has vague or rare symptoms and no evidence of infection on visual inspection.
- Treat all household members to ensure elimination of the infection. Medical referral may be necessary if any household member meets criteria for exclusion for self-treatment (e.g., malnutrition, pregnancy, liver disease, anemia, age younger than 2 years).
- Take only 1 dose as shown on the dosage chart included with the product. For adults and children older than 2 years, oral dosing is based on 11 mg/kg of pyrantel base. The maximum dose is 1 g.
- Shake the liquid formulation well and use the measuring device enclosed within packaging to ensure an accurate dose.
- If desired, pyrantel pamoate may be taken with food, milk, or fruit juices or on an empty stomach, at any time of day. The liquid formulation may be mixed with milk or fruit juice.

When to Seek Medical Attention

Seek medical attention if you experience any of the following:

- Abdominal cramps, nausea, vomiting, anorexia, rash, diarrhea, headache, drowsiness, or dizziness occurs or persists after you take the medication.
- Symptoms of the pinworm infection that persist beyond 2 weeks after the initial dose of pyrantel pamoate. A second dose of pyrantel pamoate can be given if symptoms are present beyond 2 weeks, but only if recommended by a primary care provider.
- Rare symptoms and signs such as vaginal itching or bleeding, pain upon urination, urinary tract infection, and hives occur.

Key Points for Pinworm Infection

- Pinworm infections are common in the United States and rarely cause significant morbidity.
- Health care providers should be familiar with common helminthic infections, their symptoms, and their treatment.
- A medical referral is necessary when helminths other than pinworms are suspected.
- Although pyrantel pamoate may be used in treating other helminthic infections, only patients with pinworm infection should be evaluated for self-treatment with this nonprescription agent.
- Health care providers can aid patients and caregivers in self-diagnosis, counseling, and self-treatment with nonprescription medication for pinworm infection.

Chapter 19: Nausea and Vomiting

Authors: Adam C. Welch

Nausea, a subjective feeling of the need to vomit, and *vomiting*, a forceful expulsion of the contents of the gastrointestinal (GI) tract, also called emesis, can occur in both adults and children in association with a variety of circumstances and medical disorders. Common self-care disorders that involve nausea and vomiting (N/V) are motion sickness, “morning sickness” in pregnancy (nausea and vomiting of pregnancy [NVP]), acute viral gastroenteritis, and “upset stomach” (GI distress related to overeating or indigestion). Nonprescription antiemetics can be used to prevent or treat N/V associated with these disorders. Other causes of nausea are included in those listed in [Table 19–1](#). Nausea accounts for 324,000 emergency department visits for women aged 65 years and older, or 1.4% of all visits.¹ Vomiting accounts for 1.9% of all emergency department visits in the United States. Each year, nearly 2.8 million people, mostly children younger than 15 years, visit a hospital emergency department for vomiting.¹ Accurate data on the epidemiology of N/V are not available, because nausea as well as vomiting may occur in various medical disorders, and many affected persons do not report these disturbances to a health care provider.

Table 19–1 Primary Causes of Nausea and Vomiting

GI Tract Disorders^a	CNS Disorders	Other Disorders
Mechanical Obstruction GI obstruction (e.g., PUD, gastric carcinoma, pancreatic disease); small intestine obstruction Motility Disorders Gastroparesis (e.g., diabetes, drug-induced, postviral); chronic intestinal pseudo-obstruction; IBS; anorexia nervosa; idiopathic gastric stasis Peritoneal Irritation Appendicitis; bacterial peritonitis; pancreatitis Infections Viral gastroenteritis ^b (e.g., norovirus, rotavirus); food poisoning (e.g., bacterial	Vestibular Disorders Labyrinthitis; Ménière syndrome; motion sickness ^a Increased Intracranial Pressure CNS tumor; subdural or subarachnoid hemorrhage; pseudotumor cerebri Infections Meningitis; encephalitis Psychogenic Anticipatory vomiting; bulimia; psychiatric	Cardiac disease (e.g., MI, HF); urologic disease (e.g., stones, pyelonephritis); overeating ^a Diabetes (e.g., DKA); renal disease (e.g., uremia); adrenocortical crisis (e.g., Addison disease); pregnancy ^a Chronic cannabis use (e.g., CHS)

Source: Reference 7.

Motion sickness rarely occurs in children younger than 2 years. An apparent gender predilection has been noted, with an increased susceptibility to motion sickness reported in females, as well as in children 2–15 years of age.² It is reported that NVP affects 70%–80% of pregnant women. Typically these symptoms occur during pregnancy between weeks 9 and 16, but they may begin as early as 2 weeks. They generally resolve by 22 weeks but may extend for the entire pregnancy in up to 10% of women.³ A severe form of pregnancy-related vomiting, *hyperemesis gravidarum*, occurs in less than 2%; however, it is the most common reason for hospitalization in the first half of pregnancy.³ Hyperemesis gravidarum may lead to maternal morbidity and adverse birth outcomes.³

Viral gastroenteritis is an inflammation of the stomach and small intestines that commonly manifests with acute vomiting and diarrhea.⁴ Often caused by

rotavirus or norovirus, this illness may affect any age group and usually is self-limiting, but pediatric patients may experience serious consequences from associated dehydration.⁴ Routine vaccination in infants can prevent rotavirus infection. Before availability of an effective vaccine, it was estimated that 3 million cases of rotavirus infection occurred each year, leading to more than 400,000 primary care visits.⁵ [Chapter 16](#) describes gastroenteritis in more detail.

The remaining self-care condition that involves N/V is indigestion or abdominal distention associated with overeating. An overview of treatment options for this condition is presented in this chapter. A more comprehensive discussion is provided in [Chapter 13](#).

Pathophysiology of Nausea and Vomiting

The pathophysiology of N/V is highly complex and involves the physiologic state, GI tract, central nervous system (CNS), and autonomic nervous system.⁶ The threshold at which a person can experience nausea is variable, potentially changing from moment to moment. Anxiety or anticipation can induce nausea (butterflies in the stomach). Stimuli arising from visceral (gut) or vestibular (inner ear) loci or in the chemoreceptor trigger zone (brain) can lead to nausea. Nauseogenic stimuli originating viscerally or in the chemoreceptor trigger zone typically are mediated by serotonin and dopamine. Vestibular stimuli related to the body's motion and position are mediated by histamine type 1 (H₁) receptors and acetylcholine.⁷ When the inner ear labyrinth apparatus detects a body position that conflicts with sensory inputs such as vision, motion sickness can occur. Vomiting, mediated largely by the autonomic nervous system, often is preceded by signs and symptoms of sweating, pallor, salivation, increased blood pressure and heart rate, and decreased gastrointestinal motility.⁷ Vomiting, or emesis, occurs on detection of emetic agents in the blood by chemosensitive receptors. A rise in vasopressin levels also has been shown to precede vomiting.⁷ The mechanism of NVP is less known and may be multifactorial, with genetic, endocrine, and gastrointestinal influences.³ In N/V related to overeating, gut distention and a decrease in GI motility may stimulate mechanoreceptors, leading to symptoms.⁶

Clinical Presentation of Nausea and Vomiting

Three different processes are recognized in N/V: (1) *nausea* (characterized by a person's subjective feeling of a need to vomit); (2) *retching* (involuntary rhythmic diaphragmatic and abdominal contractions prior to vomiting); and (3) *vomiting* (rapid, forceful expulsion of GI tract contents).⁸ Although most cases of N/V are self-limiting, the presence of certain signs and symptoms warrants medical referral. Possible acute complications of vomiting include dehydration, esophageal rupture manifested by blood in the vomitus, aspiration, malnutrition, electrolyte and/or acid–base abnormalities, diaphragmatic herniation, and Mallory–Weiss syndrome.⁹ Dehydration and electrolyte imbalances are the major concerns associated with vomiting. Signs and symptoms of dehydration include dry mouth, decreased skin turgor, excessive thirst, limited or cessation of urine output, dizziness, lightheadedness, fainting, and reduced blood pressure.^{9,10} These findings warrant medical referral for further evaluation.

In infants and small children, recurrent or protracted N/V (with accompanying diarrhea) may lead to marked dehydration and electrolyte imbalances; clinical manifestations of such disturbances must not be ignored. Parents should be educated to recognize signs and symptoms of dehydration, such as dry mucous membranes, decreased skin turgor, irritability, altered mental status, and weight loss ([Table 19–2](#)).¹⁰ Referral for further evaluation is indicated if the child has any exclusions for self-care management of N/V.

Table 19–2 Signs and Symptoms of Dehydration in Children

- Restlessness or irritability
- Rapid or deep breathing
- Tachycardia
- Dry mouth and tongue
- Sunken and/or dry eyes
- Sunken fontanelle
- Decreased urine output (dry diapers for several hours)
- Dark urine
- Thirst (drinks extremely eagerly)
- Absence of tears when crying
- Decreased skin turgor
- Prolonged capillary refill in the fingertip after release of a gentle squeeze

- Weight loss
 - Noticeable decrease in abdominal (“tummy”) size
 - Loose fit of clothing or diaper
 - <3% body weight loss, indicating minimal or no dehydration
 - 3%–9% body weight loss, indicating mild to moderate dehydration
 - >9% body weight loss, indicating severe dehydration

Treatment of Nausea and Vomiting

Treatment Goals

The goals of treating N/V are (1) to provide symptomatic relief, (2) to identify and correct the underlying cause, (3) to prevent and correct complications, and (4) to prevent future occurrences.

General Treatment Approach

Most acute cases of N/V are self-limiting and will resolve spontaneously. A careful evaluation is indicated to determine whether a patient is a candidate for self-treatment. The algorithms in [Figures 19–1](#) and [19–2](#) outline the self-treatment options and exclusions for self-care for N/V in adults and children,^{11–14} respectively. Severe cases of vomiting can result in dehydration or electrolyte imbalances, which may necessitate further evaluation or hospitalization. Treatment of N/V can involve pharmacologic prescription and nonprescription therapies, as well as nonpharmacologic options. Pharmacologic nonprescription options are limited and include antihistamines.

Nonpharmacologic Therapy

Because most cases of N/V are acute, nonpharmacologic treatment is directed primarily at correcting dehydration and electrolyte imbalances. Commercial oral rehydration solutions (ORSs) should be recommended to prevent these

complications. These products contain sodium, chloride, potassium, citrate, and a carbohydrate such as glucose or dextrose to restore loss of electrolytes and also restore loss of fluids. ORSs can be used for dehydration associated with vomiting or diarrhea.¹⁵ In cases of vomiting, absorption of fluids may be compromised by continuous emesis in some patients. Details on ORSs can be found in [Chapter 16](#). Sports drinks, such as Gatorade or Powerade, often do not contain the recommended balance of electrolytes. The preferred ratio of sugar to sodium is 3:1. Original-formula Gatorade contains a sugar-to-sodium ratio of 15:1. Dilution of sports drinks with water by the patient may be an option, but it is difficult to achieve accurate sugar-to-sodium ratios, and sports drinks often are available in multiple formulations. Too much sugar may draw water into the GI tract, facilitating further dehydration. Similarly, sodas, such as ginger ale or cola, and fruit juices, such as apple, also may contain too much sugar.^{16,17}

The typical dosing for ORSs varies according to the level of dehydration and the age and weight of the patient. For minimal dehydration, children weighing less than 10 kg should be given 60–120 mL of solution after each vomiting episode; children weighing 10 kg or more should be given 120–240 mL per episode. All children with mild to moderate dehydration should receive an ORS at a dosage of 50–100 mL/kg over 3–4 hours. Those with severe dehydration should be referred to emergency care centers for intravenous rehydration.¹⁸ Adults also should receive ORS therapy for rehydration, but the amount of replacement fluid needed generally can be gauged according to thirst. Replacing 30%–50% of the fluid loss in the first 24 hours is preferred.¹⁸

ORSs should be offered 10 minutes after the last episode of vomiting and provided in small increments. In general, 5 mL of an ORS may be given to children every 5 minutes, and 15 mL may be given to older children and adults every 5 minutes.¹⁸ Dosage forms such as Pedialyte Freezer Pops may allow the slow administration desirable with active vomiting.

For minimizing motion sickness, preventive measures can be found in [Table 19–3](#).

Table 19–3 Nonpharmacologic Measures to Prevent Motion Sickness

- Avoid reading during travel.
- Focus the line of vision fairly straight ahead (e.g., seat the patient in a position that allows vision out of the car window).

- Avoid excess food or alcohol before and during extended travel.
- Sit where motion is least experienced (e.g., front of the car; near the wings of an airplane; or midship [midway between bow and stern], preferably on deck).
- Avoid strong odors, particularly from food or tobacco smoke.
- Drive the vehicle if possible.

Source: Reference 2.

Pharmacologic Therapy

Selection of a nonprescription medication for N/V is largely determined by the potential cause. No specific nonprescription medications have been recommended for the treatment of viral gastroenteritis or food poisoning. Management options for these conditions are aimed at oral rehydration and are described under “Nonpharmacologic Therapy.”

Nausea Associated With Motion Sickness

Antihistamines are effective and generally safe and well tolerated for N/V related to motion sickness.² A detailed description of antihistamines can be found in [Chapter 11](#). Meclizine, dimenhydrinate, and diphenhydramine are U.S. Food and Drug Administration (FDA)-approved nonprescription agents for the prevention of nausea, vomiting, or dizziness associated with motion sickness.¹⁹ Second generation antihistamines are ineffective for treating motion sickness.² Doxylamine has been used for off-label treatment for nausea. [Table 19–4](#) lists age-specific dosages and maximum daily limits for these antiemetics.^{20,21} Through their anticholinergic effects, antihistamines may thicken bronchial secretions and should therefore be used with caution in patients with respiratory conditions such as asthma, chronic bronchitis, and emphysema. In addition, the mydriatic effects of antihistamines may exacerbate angle-closure glaucoma. The urinary retention effects of antihistamines also may worsen symptoms of benign prostatic hypertrophy. Other adverse effects of nonprescription antihistamines include dry mouth, confusion, dizziness, tremors, and constipation.²² Drowsiness also is a common adverse effect of antihistamines. Patients should avoid concomitant use of antihistamines with other CNS depressants, such as alcohol, hypnotics, and sedatives. This drowsiness, coupled with the potential for blurred vision, may impair the ability

to drive safely or operate heavy machinery. Meclizine may be less sedating and longer acting than dimenhydrinate.¹⁹ Meclizine also may be less sedating than doxylamine and diphenhydramine. Paradoxical stimulatory reactions such as insomnia, nervousness, and irritability may occur in some patients.

Table 19–4 Dosage Guidelines for Nonprescription Antiemetic Antihistamines^a

Agent	Dosage (maximum daily dosage)		
	Adults and Children ≥ 12 Years	Children 6 to < 12 Years	Children 2 to < 6 Years
Cyclizine	50 mg 30 minutes before travel, then 50 mg every 4–6 hours (200 mg)	25 mg every 6–8 hours (75 mg)	Not recommended
Dimenhydrinate	50–100 mg every 4–6 hours (400 mg)	25–50 mg every 6–8 hours (150 mg)	12.5–25 mg every 6–8 hours (75 mg)
Diphenhydramine	25–50 mg every 6–8 hours (300 mg)	12.5–25 mg every 6–8 hours (150 mg)	Not recommended
Meclizine	25–50 mg 1 hour before travel (50 mg)	Not recommended	Not recommended
Doxylamine ^b	In pregnancy, 10–12.5 mg with or without pyridoxine every 8 hours	Not recommended	Not recommended

^a Take antihistamines at least 30–60 minutes before travel; then take continuously for the duration of travel.

^b Off-label use for nausea and vomiting of pregnancy.

Source: References 2 and 19.

Nausea Associated With Food or Beverages

N/V may be associated with overindulgence in food or beverage or consumption of spoiled or other disagreeable foods, and it may manifest as heartburn, indigestion, and upset stomach. Antacids and histamine type 2 (H₂) receptor antagonists (H₂RAs) are approved for relief of symptoms associated

with acid indigestion and “sour stomach.” However, antacids have marginal efficacy for the treatment of N/V secondary to nonulcer dyspepsia. Patients with prolonged and predominant nausea and bloating should be referred for further evaluation, because such disturbances may be a sign of GI motility dysfunction, *H. pylori* infection, duodenal abnormalities, or other conditions that would require prescription treatments.^{23,24}

Bismuth subsalicylate (BSS) may be of some benefit for relief of nausea associated with consumption or nonulcer dyspepsia.²³ BSS is approved to treat various GI symptoms, including nausea, heartburn, and fullness. In-depth discussion of use of BSS can be found in [Chapters 13](#) and [16](#).

Phosphorated carbohydrate solution (PCS) also may be useful in combating nausea associated with food or beverage consumption. PCS is a mixture of dextrose (glucose), levulose (fructose), and phosphoric acid.²⁵ This hyperosmolar solution is believed to relieve N/V by direct local action on the GI tract wall, to decrease smooth muscle contraction and delay gastric emptying.^{26,27}

Alternatively, concentrated cola syrup, which also contains the sugars and phosphoric acid that are in PCS, has been used. Because commercially available carbonated cola beverages often have a 5:1 water-to-syrup ratio, substituting such drinks, even if allowed to go “flat,” is not recommended. In adults, PCS should be given at a dosage of 15–30 mL every 15 minutes until distress subsides. Taking more than 5 doses in 1 hour is not recommended. Children 2–12 years of age can take 5–10 mL every 15 minutes. Dosing fluids should not be diluted, and intake of other fluids should be avoided immediately before or after taking PCS.²⁶

Possible adverse effects with PCS are stomach pain and diarrhea. Each 5 mL of PCS contains 3.74 g of total sugar,²⁶ so caution is indicated with use of this solution in patients with diabetes. Similarly, patients with hereditary fructose intolerance should avoid using PCS.

Product Selection Guidelines

Specific factors to be considered in the choice of antiemetic products include pregnancy and lactation status; patient age, especially with the pediatric and geriatric populations; and presence of any therapeutic limitations, such as hepatic or renal impairment. These factors may particularly affect drug

selection and dosing. Furthermore, the product should be compatible with the patient's lifestyle, concurrent medication use, sensitivity to certain product ingredients such as dyes or fructose, and preference for frequency of dosing. Hence, product selection guidelines should be relevant for special populations and other considerations, such as the potential for drug interactions, and should include patient preferences such as whether the product is liquid or chewable or contains alcohol (Table 19–5).

Table 19–5 Selected Nonprescription Antiemetic Products and Common Drug Interactions			
Antiemetic	Drug/Drug Class	Potential Interaction	Management and Prevention Measures
Bismuth subsalicylate	Tetracyclines (tetracycline, doxycycline, minocycline, demeclocycline)	Decreased antibacterial effect caused by impaired absorption	Avoid concurrent administration; take doxycycline 2–3 hours before bismuth subsalicylate.
	Warfarin	Increased risk of bleeding (elevations of INR)	Avoid concurrent use; monitor INR closely near times of administration and discontinuation of bismuth subsalicylate.
	Live vaccines containing varicella or influenza	Increased risk of Reye syndrome	Avoid concurrent administration with live vaccines.
Antihistamines (cyclizine, doxylamine, dimenhydrinate, diphenhydramine, meclizine)	Anticholinergics (ipratropium, tiotropium)	May increase anticholinergic adverse effects	Monitor for signs of altered mental status, dry skin, dry mouth, constipation, mydriasis, and tachycardia.
	Opioid-related agents (fentanyl, hydrocodone, hydromorphone, methadone, morphine, oxycodone)	May increase sedative adverse effects	Monitor for signs of respiratory suppression, sedation, and hypotension. Consider lower doses of the concomitant agents.
	Bupropion	May lower seizure threshold	Use lowest therapeutic dose of bupropion and

Antiemetic	Drug/Drug Class	Potential Interaction	Management and Prevention Measures
			increase slowly.
	Donepezil	May lower seizure threshold	Use lowest therapeutic dose of donepezil and increase slowly.
Ginger	Warfarin	Increased risk of bleeding (elevation of INR), possibly seen at higher doses of ginger exceeding 4 g/day	Avoid use of ginger if possible.
Pyridoxine	Altretamine	Reduced anticancer effects of altretamine	Avoid concurrent use.

Key: INR = International normalized ratio.

Source: References 2, 22, 26, and 37.

Special Populations

Pregnant Women. Several nonpharmacologic recommendations can be made to help control NVP ([Table 19–6](#)). In patients with typically mild symptoms, nausea can be avoided by eating frequent small meals and avoiding spicy or fatty foods or sensory stimuli that may provoke symptoms. Consumption of bland carbohydrates, such as crackers, and high-protein snacks may be beneficial, especially in the morning. However, published evidence supporting dietary changes for prevention of N/V is very limited. In patients with a history of NVP, the American College of Obstetricians and Gynecologists (ACOG) recommends taking a multivitamin for at least 1 month before planned conception to decrease the severity of NVP.²⁰ This measure may not be useful in pregnant patients presenting with nausea, but it may be an option for future preconception counseling.

Table 19–6 Nonpharmacologic Measures to Prevent Nausea and Vomiting of Pregnancy

- Take a prenatal multivitamin for 1 month before planned conception.

- Before getting out of bed, eat several dry crackers and relax in bed for 10–15 minutes.
- Get out of bed very slowly and do not make any sudden movements.
- Before eating breakfast, nibble on dry toast or crackers.
- Make sure there is plenty of fresh air in the area where meals are prepared and eaten.
- Eat small meals every 1–2 hours to avoid a full stomach.
- Avoid areas of excessive heat or humidity.
- When nauseated, try small sips of carbonated beverages or fruit juices.
- Avoid greasy or fatty foods such as fried foods, gravy, mayonnaise, and salad dressing, as well as spicy or acidic foods (citrus fruits and beverages, tomatoes).
- Avoid sensory stimuli such as odors, noises, or flickering lights.
- Avoid iron-containing supplements.
- Eat dry, bland, and high-protein foods.

Source: References 17 and 28.

Evidence exists to support the use of nonprescription antiemetics, such as doxylamine and pyridoxine, for NVP.²⁸ ACOG recommends pyridoxine with or without doxylamine as first-line pharmacotherapy for NVP.²⁰ Additionally, the use of doxylamine and pyridoxine preemptively may reduce the recurrence of symptoms.²⁸ Pyridoxine also is excreted in breast milk. Extremely high doses of pyridoxine (600 mg/day) may inhibit prolactin secretion.²⁹ Other antihistamines, such as dimenhydrinate and diphenhydramine have been shown to be effective in controlling NVP, with no association with the development of birth defects.²⁰ (Please refer to the Preface for a detailed explanation of the pregnancy data.) Of note, ginger may be as effective as pyridoxine for treating NVP. Some evidence supports the safety of ginger for pregnant women, with no significant increase in risk for spontaneous abortion, congenital malformation, or low birth weight.^{30,31} (See [Chapter 51](#) for further discussion of this treatment.)

Geriatric Patients. Antihistamines should be used with caution in patients of advanced age because of the associated increased risk of adverse effects. The anticholinergic and sedative effects may not be tolerable in this patient population. The American Geriatrics Society considers these medications potentially inappropriate and strongly recommends avoiding use of antihistamines in persons of advanced age.³² In addition, a comprehensive medication review may be necessary for patients in this age group to identify

and resolve any potential drug-related problems, including drug interactions.

PCS may be used if the patient does not have uncontrolled blood glucose levels or hereditary fructose intolerance. Neither acupressure nor any acustimulation product, such as acupressure bands, should be used in patients with pacemakers. Other nonpharmacologic options such as avoidance of trigger foods and scents also could be considered.

Lactating Women. Antihistamines may adversely affect the mother's milk supply, so nursing mothers should not use these agents. For bismuth subsalicylate (BSS), it is estimated that less than 1% of maternal dose is absorbed by the infant. Alternatives to BSS are preferred for lactating women.³³ Little evidence is available to support the safety of the use of ginger by lactating women.³⁴

Pediatric Patients. In newborns and older infants, vomiting may lead rapidly to dehydration and acid–base disturbances. Vomiting is different from simple regurgitation, which is common in infants, in being more forceful and producing larger amounts of emesis. In newborns, vomiting may be caused by GI tract obstruction. In infants, vomiting may be a sign of gastroesophageal reflux disease (GERD).³⁵ N/V can occur in children for a variety of reasons, including GI obstruction, CNS abnormalities, and infection.³⁶

The Centers for Disease Control and Prevention (CDC) classifies dehydration in children as mild if less than 3% of body weight is lost, moderate if 3%–9% is lost, and severe if greater than 9% is lost.¹³ Moderate to severe cases of dehydration warrant a medical referral. Mild to moderate dehydration can be managed with oral rehydration therapy as described in this chapter and in [Chapter 16](#). Antihistamines may diminish mental alertness and occasionally produce paradoxical excitation in young children.²² BSS is not recommended in children or teenagers who have or are recovering from chickenpox or an influenza-like illness because of the risk of Reye syndrome.³⁷ (See [Chapter 5](#), subsection “Salicylates” for further information.)

Complementary Therapies

Some evidence supports the use of ginger, pyridoxine (vitamin B₆), and acupressure bands in the treatment of nausea.

Ginger

Ginger (*Zingiber officinale*) has been used for nausea related to pregnancy, motion sickness, and surgery.³⁸ A 2015 Cochrane review of this use of ginger found limited and inconsistent evidence for its efficacy, although several studies suggested that ginger may be superior to placebo in preventing NVP.³⁹ The review reported no difference in rates of spontaneous abortion, congenital abnormalities, or other fetal adverse outcomes, although the included studies may have had insufficient power.³⁹ Other data regarding the safety of the use of ginger in pregnancy are limited. Larger doses of ginger may lead to mild adverse GI effects, including heartburn, belching, and discomfort.³¹ Some evidence suggests that ginger may have anticoagulant and hypotensive effects.

Ginger can be given at 250 mg up to 2 g daily in 3–4 divided doses, although it appears that doses of approximately 1 g/day are more effective than placebo.³¹ Ginger may be as effective as pyridoxine for treating N/V. Compared with dimenhydrinate, ginger may cause fewer adverse effects.³⁰ (See [Chapter 51](#) for an in-depth discussion of use of ginger as a herbal product.)

Most ginger ale drinks are artificially flavored or contain amounts of ginger that are too insignificant to be therapeutic.

Pyridoxine (Vitamin B₆)

Pyridoxine is a water-soluble B vitamin that is important in various metabolic functions, including protein metabolism, hemoglobin synthesis, and neurotransmitter function.²⁹ The Dietary Reference Intake of pyridoxine for healthy adults is 1.3–2 mg/day. Pyridoxine may be useful in NVP. Typical dosing of pyridoxine for relief of nausea is 10–25 mg 3 times a day.

Pyridoxine generally is well tolerated. Large doses (>200 mg/day) of pyridoxine over longer periods of time (>2 months) may result in adverse effects such as peripheral neuropathy, weakness, lethargy, and nystagmus.

Pyridoxine has had mixed results for efficacy in treating N/V. Overall data suggest that pyridoxine is effective.²⁹ NVP is an off-label indication for pyridoxine. Pyridoxine is available as a combination product with doxylamine, available by prescription.⁴⁰

Acupressure

The use of acupressure involves direct pressure on the pericardium-6 (P6) point on either wrist. The P6 point is located approximately three fingerwidths from the middle crease of the wrist (see <https://exploreim.ucla.edu/self-care/acupressure-point-p6/>). Pressure can be applied between the two tendons using either the finger or a wristband. Acupressure at P6 may be more effective for prevention of postoperative N/V than for treating NVP.⁴¹ The “dosing” for acupressure can vary widely, ranging from as-needed, to 10 minutes 3 times a day, to continuous pressure. The different dosing regimens have shown mixed results for efficacy.⁴¹

Cannabinoids

Oral cannabinoids, available by prescription, may have similar efficacy against N/V to that of conventional prescription antiemetics.⁴² Users of cannabidiol (CBD) oil may perceive benefits for its use as an antiemetic.^{43,44} Caution is indicated in recommending CBD, however, because standardization of such products is lacking. In 2018, the Agriculture Improvement Act (Farm Bill) removed products that contained no more than 0.3% of low-tetrahydrocannabinol (THC), such as CBD, from the definition of marijuana, a schedule I drug.⁴⁵ Studies on the safety and quality of CBD are lacking, and FDA is working to answer questions about its safety and good manufacturing practices. Patients should be aware of the potential risks of liver injury, drug interactions, and male reproductive toxicity that are associated with use of CBD products.⁴⁶ FDA also is exploring lawful marketing of CBD products.⁴⁶

Algorithm: N/V in Adults

Figure 19–1 Self-care for N/V in adults. Key: AH = Antihistamine; B6 = pyridoxine; BG = blood glucose; BPH = benign prostatic hyperplasia; CNS = central nervous system; DKA = diabetic ketoacidosis; GERD = gastroesophageal reflux disease; GI = gastrointestinal; HHS = hyperosmolar hyperglycemic syndrome; H2RA = histamine type 2 receptor antagonist; NSAID = nonsteroidal anti-inflammatory drug; N/V = nausea and vomiting; ORS = oral rehydration solution; PCP = primary care provider.

Algorithm: N/V in Children

Figure 19–2 Self-care for N/V in children. Key: AH = Antihistamine; CNS = central nervous system; GI = gastrointestinal; N/V = nausea and vomiting; ORS = oral rehydration solution; PCP = primary care provider.

Assessment of Nausea and Vomiting: A Case-Based Approach

Vomiting is a symptom produced not only by benign processes but also by serious illnesses, and it may lead to various complications. Physical assessment of the patient may help to determine whether such complications, as listed in the section “Clinical Presentation of Nausea and Vomiting” have occurred. Important factors in this assessment are the patient’s general appearance, mental status, and volume status and the presence and severity of any abdominal pain. Evaluation of vital signs such as blood pressure, heart rate, temperature, and weight also is pertinent. Recognition of concurrent signs and symptoms is essential to identify the likely etiologic condition. With acute onset of vomiting, it is vital to determine whether a toxin could be the cause. In such cases, careful questioning of the patient or caregiver about possible ingestion or exposure, especially in preschoolers and adolescents, often will reveal the responsible toxin. Detailed information about the patient’s medical history related to the GI tract is especially helpful in determining potential causes.

A major concern with vomiting is the loss of fluids and the inability to eat or drink. This situation may result in dehydration and electrolyte disturbances. Self-care is inappropriate for patients with dehydration, severe anorexia, weight loss, or poor nutritional status. Medical evaluation for dehydration is indicated when severe vomiting or diarrhea persists for more than several hours in children or for 48 hours in adults.^{2,4,13}

The health care provider should be aware that some patients may use nonprescription antiemetics for self-treatment in the early stages of a serious illness. To avoid potential additive toxicity, it is essential to identify what

products the patient has already used for symptom relief. Many patients choose to self-medicate with various nonprescription products to avoid a medical office visit. Caution is warranted, however, in recommending self-medication for N/V symptoms, and a crucial component of assessment with N/V is determining whether medical referral is indicated.

Cases 19–1 and 19–2 provide examples of assessment of two different patients presenting with vomiting.

Case 19–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has complained of being nauseous for the past week, especially during late morning, but it persists through most of the day. She has vomited twice during that time. She has maintained her appetite.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms are worse in the morning or when she smells food cooking. She also is symptomatic at work.
c. Description of the patient's efforts to relieve the symptoms	The patient eats a few crackers with a few sips of ginger ale at home. At work she goes to the restroom and closes her eyes for a few minutes.
d. Patient's identity	Alicia Franklin
e. Patient's age, gender, height, and weight	27 years, female, 5 ft 7 in., 150 lb

Relevant Evaluation Criteria	Scenario/Model Outcome
f. Patient's occupation	Graphic designer
g. Patient's dietary habits	Balanced diet with plenty of fruits and vegetables. Patient is able to eat well between nausea episodes.
h. Patient's sleep habits	Averages 7-8 hours per night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Patient has no chronic conditions. She just found out she is 9 weeks pregnant and began a prenatal vitamin. She denies use of dietary supplements.
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Nausea persisting throughout the day; occasional vomiting. She does not like the smell of certain foods; NVP is likely.
3. Identify exclusions for self-treatment (Figure 19-1).	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this	Options include (1) Recommend self-care with- Nondrug strategies (dietary and environmental changes [Table 19-6])- Acupressure or acustimulation bands- OTC pyridoxine- OTC doxylamine- OTC phosphorated carbohydrate solution- Ginger

Relevant Evaluation Criteria	Scenario/Model Outcome
information with the patient or caregiver.	(2) Recommend lifestyle modifications until a health care provider can be consulted. (3) Make a medical referral. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Because the patient does not appear dehydrated and can drink small amounts of ginger ale and can tolerate crackers, encourage her to continue to take sips of liquids and eat small meals. She does not have signs/symptoms of dehydration, such as tachycardia, decreased skin turgor, noticeable weight loss, or clothes that fit loosely. She can try doxylamine 12.5 mg 3 times a day and vitamin B ₆ 10 mg 3 times a day. Other nonpharmacologic suggestions in Table 19–6 should be followed. If symptoms persist, she should consult her provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	“You probably have nausea and vomiting of pregnancy, or NVP. You can take vitamin B ₆ orally every 8 hours. In addition, you may add doxylamine 12.5 mg orally every 8 hours. You also may benefit from other nonpharmacologic techniques (Table 19–6), such as continuing to eat crackers or eating bland foods in the morning before arising, sleeping in a well-ventilated room, and avoiding strong odors. If you do not feel better, you may want to contact your regular health care provider.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“The American College of Obstetricians and Gynecologists states that doxylamine plus vitamin B ₆ , up to 3 tablets daily, may help your symptoms. Because you are able to drink fluids and are not dehydrated, seeking medical care may not be necessary at this time. However, if nausea or vomiting worsens, medical attention for further evaluation is necessary.”
Implement	
8. When recommending self-	

Relevant Evaluation Criteria	Scenario/Model Outcome
care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	"Add vitamin B ₆ 10 mg combined with 12.5 mg of doxylamine (½ of a 25 mg tablet). Doxylamine is available in the United States as a nonprescription sleep aid (doxylamine succinate [Unisom SleepTabs] 25 mg)."
b. Maximum number of days the therapy should be employed	"There are no limits to the number of days that vitamin B ₆ and doxylamine can be taken. Nausea associated with pregnancy typically resolves after week 16."
c. Product administration procedures	"Take vitamin B ₆ and doxylamine with a small glass of water 3–4 times a day."
d. Expected time to onset of relief/degree of relief that can be reasonably expected	"Expected time to onset of relief and degree of relief are variable for all products and measures."
e. Most common adverse effects	"Vitamin B ₆ is not likely to cause any adverse effects. Drowsiness is the most common side effect of doxylamine; therefore, it is important not to drive or operate machinery while taking doxylamine. Other possible adverse effects include dry mouth, dry eyes, nasal congestion, urinary retention, and constipation."
f. Patient options in the event that condition worsens or persists	"Medical attention is necessary if the NVP does not subside or if adverse effects from the nonprescription product occur."
g. Product storage requirements	"Store this product at 59°–86°F."
h. Specific nondrug measures	See Table 19–6 for dietary and other measures.
Solicit follow-up	(1) "Will any of these products hurt my baby?"

Relevant Evaluation Criteria	Scenario/Model Outcome
questions from the patient or caregiver.	
	(2) "What other products could I use instead?"
Answer the patient's or caregiver's questions.	(1) "These products have been used by many other pregnant women and have not caused harm to the mother or baby. Pregnant women have been exposed to these products hundreds of thousands of times without evidence of harm to the baby."
	(2) "Another product used for nausea during pregnancy is an acupressure band that is worn on the wrist for a short period of time, such as 5 minutes, or throughout the day. Ginger also can be considered. Phosphorated carbohydrate solution also may be tried. If these products do not work, then you will need medical attention to obtain a prescription product for your nausea."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Monitor for episodes of nausea and vomiting.

Key: n/a = Not applicable; NVP = nausea and vomiting of pregnancy; OTC = over-the-counter.

Case 19–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the	

Relevant Evaluation Criteria	Scenario/Model Outcome
patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient is a child who has vomited 6 times in the past 12 hours. The child has been crying and is inconsolable for about 20 minutes around each vomiting episode. Tears are not present with crying.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Symptoms worsen when the patient's mother attempts to provide grape juice.
c. Description of the patient's efforts to relieve the symptoms	Patient's mother tried to get him to eat a few bites of cereal and drink juice.
d. Patient's identity	Hunter Neilson
e. Patient's age, gender, height, and weight	16 months, male, 23 in., 20 lb (23 lb on previous day)
f. Patient's occupation	n/a
g. Patient's dietary habits	Normal healthy diet; consists of cereals, mashed vegetables, pasta, rice, chicken, yogurt, milk, and juice.
h. Patient's sleep habits	Up at 7:00 AM; in bed at 7:30 PM; naps for 2 hours, 1-3 PM.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Children's multivitamin with fluoride; patient is current with all recommended childhood vaccines, including rotavirus.
j. Allergies	Eggs: stomach upset
k. History of other adverse reactions to medications	None

Relevant Evaluation Criteria	Scenario/Model Outcome
I. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Patient has had several episodes of vomiting. He is drowsy and unusually lethargic, and his body is floppy when he is held. The child appears to be dizzy when he stands up, and his abdomen seems somewhat flat. His mother reports he has had a dry diaper for most of the day. When the child cries, few tears are noted. He appears dehydrated and may have viral gastroenteritis.
3. Identify exclusions for self-treatment (Figure 19-2).	The patient is severely dehydrated (Table 19-2), as evidenced by signs and symptoms including weight loss of >9%.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Recommend that the patient's mother administer- an OTC ORS- an OTC phosphorated carbohydrate solution- an acupressure band (2) Recommend that the patient's mother administer self-care modalities until an appropriate health care provider can be consulted. (3) Refer the patient for further medical evaluation. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient or caregiver preferences.	Hunter is unable to drink small amounts of fluid or eat small amounts of food (cereal). He also has signs/symptoms of dehydration (appears drowsy and lethargic; has a floppy body, dizziness, flat abdomen; has lost 3 lb, approximately 13% of his body weight since the previous day; has a dry diaper and sheds few tears). On the basis of these signs/symptoms, Mrs. Neilson should immediately take the child for medical evaluation and attempt to administer small sips of ORS fluid on the way to urgent or emergency care.

Relevant Evaluation Criteria	Scenario/Model Outcome
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Your child needs to be seen by an appropriate health care provider because he appears dehydrated. Please have someone drive you and Hunter to the urgent care facility. On the way, administer 1 teaspoonful of ORS fluid, not grape juice, every 1-2 minutes."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Hunter's signs and symptoms (floppy body, flat abdomen, weight loss, dry diaper, few tears) indicate that he is dehydrated. Because he has been unable to drink sufficient fluids or eat anything to counter the dehydration, he needs medical attention."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	"Oral rehydration solutions such as Pedialyte are not the same as sports drinks such as Gatorade or Powerade. If all that is available is a sports drink, mix with water to one-half strength and offer 1 teaspoonful every 5 minutes."
Solicit follow-up questions from the patient or caregiver.	"Is there a nonprescription medication that might work so that I don't have to take Hunter to the urgent care?"
Answer the patient's or caregiver's questions.	"No. Hunter is dehydrated; he needs urgent medical care so that he can feel better and get well, without serious complications."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Provider should contact Mrs. Neilson to monitor for signs of dehydration, including weight loss, and for resumption of normal behaviors and activities.

Key: n/a = Not applicable; ORS = oral rehydration solution; OTC = over-the-counter.

Patient Counseling for Nausea and Vomiting

The health care provider should stress that treatment for N/V must focus on identifying and, if possible, correcting the underlying cause. Patients prone to overeating, eating disorders, or motion sickness should be advised to avoid behaviors or situations that lead to N/V. An important point to emphasize in patient counseling is that acute vomiting typically requires only symptomatic treatment, because the problem usually is self-limiting and will resolve spontaneously. If the cause of the N/V symptoms is known and self-treatment with nonprescription medication is appropriate, proper use of the recommended product should be explained. Patient education also should include information about possible adverse effects of recommended products, as well as signs and symptoms indicating that further medical attention is warranted. The box “Patient Education for Nausea and Vomiting” lists specific information to provide in patient counseling.

Evaluation of Patient Outcomes for Nausea and Vomiting

After the provider has provided information on or suggestions for self-management and treatment for N/V, follow-up assessment of the patient should occur within 24 hours of the initial encounter. A validated assessment tool, established by Rhodes and McDaniel, can be used to monitor clinical status; this tool is available at <https://helper.org/downloads/rhodes-index.pdf>.⁴⁷ The follow-up evaluation should ascertain whether the N/V has diminished or abated; whether the patient has any residual signs or symptoms, especially those related to dehydration; whether abnormalities in vital signs, such as tachycardia, have returned to normal; and whether the patient is afebrile. If the patient had prolonged N/V (>24–48 hours) or experienced a change in or worsening of symptoms that required immediate referral for medical evaluation, follow-up contact is indicated to determine whether the patient sought medical help and what type of treatment was administered. It also is important for the provider to assess whether any further counseling is needed or if the patient has additional questions. The provider also can use this opportunity to provide reassurance and support.

Patient Education for Nausea and Vomiting

The objectives of self-treatment are (1) to improve the symptoms of occasional, self-limited nausea and vomiting (N/V), (2) to identify and correct the underlying cause, (3) to prevent and correct complications of vomiting, and (4) to prevent future occurrences. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Nondrug Measures

- To prevent N/V in pregnancy, eat small, frequent meals that are low in fat content. Sleep in a room with fresh air. Also, try eating crackers or a high-protein snack before getting up in the morning. Try lying down to relieve the symptoms once they occur ([Table 19–6](#)).
- To prevent motion sickness in young children, place them in a car seat that allows them to look out the windows ([Table 19–3](#)). Try acupressure wristbands to prevent motion sickness in adults or older children.
- To prevent nausea associated with overeating, consume foods and beverages in moderation, and avoid foods or beverages known to cause nausea.

Nonprescription Medications

Antacids, Histamine Type 2 Receptor Antagonists (H2RAs), and Bismuth Subsalicylate

- Take antacids, H2RAs (e.g., ranitidine or famotidine), or bismuth subsalicylate for nausea caused by overeating. Follow product instructions for dosages. (See [Chapters 13](#) and [16](#) for additional information on these medications.)

Phosphorated Carbohydrate Solution

- Take phosphorated carbohydrate solution for nausea and vomiting

associated with upset stomach caused by viral gastroenteritis, food indiscretions, and pregnancy.

- Give 1–2 tablespoonsful (15–30 mL) of the solution to adults at 15-minute intervals until vomiting stops. For children ages 2–12 years of age, give 1–2 teaspoonful (5–10 mL). Do not give more than 5 doses in 1 hour.
- Do not dilute the solution, and do not allow the patient to consume other liquids for 15 minutes after taking a dose.
- Patients with hereditary fructose intolerance should not take this product.
- Patients with diabetes should consult their medical provider before taking this product.

Antihistamines

- Take antihistamines for self-treatment of N/V caused by motion sickness.
- To prevent motion sickness, take antihistamines at least 30–60 minutes before departure. Continue taking the medication during travel. Follow the dosage guidelines in [Table 19–5](#).
- While using antihistamines, avoid driving or operating hazardous machinery or engaging in tasks that require a high degree of mental alertness. Drowsiness is the most common adverse effect of these medications.
- Patients with asthma, narrow-angle glaucoma, obstructive disease of the gastrointestinal or genitourinary tract, or benign prostatic hypertrophy should consult an appropriate health care provider before using antihistamines.
- Caution patients that antihistamines may increase the sedative effects of alcohol, tranquilizers, hypnotics, and sedatives. Antihistamines may produce excitability in children or mental confusion in persons of advanced age.
- Do not take oral diphenhydramine products if topical (external) diphenhydramine preparations are being used.

Oral Rehydration Solution (ORS)

- If needed, take an ORS to prevent dehydration secondary to vomiting and diarrhea.
- Consider placing the ORS in the refrigerator to improve taste. Alternatively, the patient can use ORS freezer pops or another dosage form to improve palatability.

When to Seek Medical Attention

- Seek medical attention if you notice signs and symptoms of serious dehydration associated with N/V.
- Seek medical attention if vomiting does not stop after 5 doses of phosphorated carbohydrate solution.

Key Points for Nausea and Vomiting

- N/V are manifestations of an underlying disorder or disturbance; therefore, treatment should focus on identifying and correcting the underlying cause.
- Nonprescription antiemetic medications are suitable for preventing and controlling the symptoms of occasional self-limiting N/V.
- Overeating, food poisoning, viral gastroenteritis, and motion sickness may cause self-limiting N/V.
- Antacids, nonprescription H₂RAs, or PCS may help to relieve symptoms associated with indigestion from overeating.
- Antihistamines are the agents of choice to treat N/V secondary to motion sickness. Second-generation antihistamines, however, are ineffective in treating N/V.
- Methods and agents that are safe for treating NVP and N/V in most patients 2 years of age and older include use of acupressure/acustimulation devices and PCS.

- Uncomplicated NVP may be treated with pyridoxine, doxylamine, PCS, ginger, or acupressure/acustimulation devices.
- Loss of fluids and the inability to eat or drink due to N/V may result in dehydration associated with electrolyte disturbances. This primary complication of N/V should be treated with ORS therapy.
- A patient who presents with complications related to N/V may not be a candidate for self-treatment but instead should be referred for medical evaluation.

Chapter 20: Prebiotics and Probiotics

Authors: Sheila Wilhelm, Pramodini Kale-Pradhan

In today's climate of self-management for optimal health and wellness, use of prebiotics and probiotics has become increasingly popular. Multiple studies have confirmed their beneficial effects on various aspects of gastrointestinal (GI) tract function, as well as in treatment and prevention of certain disorders, although much remains to be elucidated. In brief, *prebiotics* are substrates selectively utilized by host microorganisms—the enteric microflora—to support gut health, and *probiotics* are nonharmful living microorganisms also recognized to have beneficial health effects when ingested in sufficient amounts. A basic understanding of GI microflora characteristics, summarized next, is recommended for health care providers to assist patients in the selection or use of appropriate prebiotic and probiotic products.

The Gut Microbiota

The microflora of the GI tract is known as the enteric *microbiota*. The GI tract hosts approximately 300–500 species of commensal bacteria, with concentrations of up to 10^9 colony-forming units (CFU)/mL in the terminal ileum and 10^{12} CFU/mL in the colon.¹ In composition, however, the enteric microbiota may be far more diverse than has been recognized to date. Only within the past 20 years or so have the GI microbiota and its role in human health and disease been explored in earnest. The extent of microbiota influence on health maintenance and disease development appears to be significant. Although understanding of the complex interactions between the GI tract and enteric microbiota remains incomplete, the paradigm of human biology is shifting to embrace the ecology of the individual, including processes of transgenomic and epigenomic co-metabolism with that person's unique GI microbiome.^{2,3} More recently, a view of the microbiome as a “superorganism” in a symbiotic relationship with the gut mucosa has been advanced.⁴

Prebiotics

Prebiotics support the enteric microbiota and typically are substances fermented in the colon. As noted, they are substrates that are selectively utilized by host microorganisms, conferring a health benefit. Some types of fiber act as prebiotics. The undigested fiber enters the colon and is fermented by bacteria, primarily bifidobacteria and lactobacilli. Fermentation products, including short-chain fatty acids (acetate, butyrate, and propionate) and lactate, produce an environment favorable to growth of these beneficial bacteria. To be considered a prebiotic, fiber must selectively stimulate the growth and/or activity of one or a limited number of health-promoting bacterial species residing in the colon and benefit the host.^{1,4-6}

Sources and Intake

Inulin-type fructans, including their partial hydrolysis product fructooligosaccharides (FOS), are the most common prebiotics.⁷ These substances are found in small amounts in asparagus, bananas, chicory, Jerusalem artichoke, leek, onion, soy, and wheat.⁶ Inulin-type fructans are isolated from such sources and added to foods to attain concentrations contributing to prebiotic effects. Other sources of prebiotics are conjugated linoleic acid, polyunsaturated fatty acid, and human milk oligosaccharides.^{7,8}

Health Effects

Both inulin-type fructans and FOS significantly increase bifidobacteria in the human gut.^{7,8} Doses vary greatly in studies. The use of prebiotics generally should not result in adverse effects such as abdominal distention and discomfort.

Beneficial effects of prebiotics supported by some human data include stool bulking and decreased constipation, better absorption of calcium and magnesium, reduced triglycerides in mildly hypercholesterolemic persons, and stimulation of bifidobacteria growth.^{4,8,9} Studies using prebiotics for treatment or prevention of diarrhea have yielded conflicting results, which may depend on the underlying disorder.⁹ Improved vaccine response, decreased GI infections, stimulation of intestinal hormonal peptides, clinical improvement in inflammatory bowel disease (IBD), and reduced tumor growth are other possible benefits of prebiotics. Some beneficial effects may be enhanced with synbiotics, a mixture of both prebiotics and probiotics that together appear to improve health and well-being.⁶

Probiotics

As noted earlier, probiotics are nonpathogenic, living microorganisms that have a beneficial effect on the host when consumed in adequate amounts.^{1,6,10} These products must withstand the stresses inherent in processing, storage, and delivery without degradation, and the probiotic microorganisms must survive gastric acidity, bile acid lysis, and pancreatic enzyme digestion.^{4,5} Lactic acid-producing bacteria, especially those of the genera *Lactobacillus*, *Bifidobacterium*, and *Streptococcus*, are most often used in commercially available foods and for studies. Beyond early infancy, these microorganisms do not permanently colonize the GI tract and must be ingested regularly in sufficient quantity to maintain their presence. When such bacteria are present in adequate or optimal numbers, colonization by pathogenic organisms is reduced and mucosal defenses in the GI tract are enhanced. **Table 20–1** lists possible protective effects of probiotics and postulated mechanisms of action.^{4,9,11} For health care providers attempting to interpret data in the clinical setting, caution is warranted: Multiple species and strains of common probiotic bacteria exist, and effects cannot be extrapolated across species or even across different strains.⁶ Dosing may explain variance in treatment response in published studies. The optimal dose for a given probiotic is not known; however, studies showing efficacy typically use a minimum of 10⁷–10¹⁰ CFU per dose or 10⁸–10¹⁰ CFU daily.^{6,12} In a dose-ranging study, the probiotic capsule dosage form used exhibited poor dissolution characteristics, leading to reduced probiotic efficacy at higher doses relative to that at lower doses.¹³ This finding demonstrates the need to be vigilant in choosing an appropriate probiotic formulation that has been studied in patients.

Table 20–1 Possible Protective Effects of Probiotics	
Effect of Probiotic	Possible Mechanism(s)
GI Barrier Function	
Induce production of protective cytokines mediating EC regeneration and inhibiting apoptosis	Action through TLRs; intestinal homeostasis and EC protection requires recognition of commensal bacteria by TLRs
	Induction of IL-6

Effect of Probiotic	Possible Mechanism(s)
Redistribute and increase expression of factors involved in maintaining EC tight junctions	Altered protein kinase C signaling
Counteract effects or inhibit production of inflammatory cytokines associated with increased EC permeability	IL-10 upregulation (regulatory cytokine)
	Reduced effect of TNF-alpha and INF-gamma
	Reduce TNF-alpha production
	Stimulation of IgA secretion
Antimicrobial Activity	
Inhibit growth of potential pathogens	Decreased luminal pH
	Production of bactericidal proteins (bacteriocins)
Inhibit adhesion of pathogenic bacteria to EC	Increased mucin production
	Reduced transepithelial resistance associated with binding of some pathogens
	Competitive exclusion of pathogens from EC surface binding sites due to nonspecific binding associated with the hydrophobic cell surface properties; mucus-binding pili enhance binding to mucosal surface
	Binding to pathogenic microorganisms, thereby preventing interaction between the microorganism and EC surface
Influence production of cryptdins by Paneth cells	Antibacterial action of cryptdins
Alter virulence	Altered secretion of molecules influencing expression of genes controlling virulence
EC Inflammatory Responses	
Alter EC cytokine production	Downregulation of bacteria-induced protein kinase C and IL-6

Effect of Probiotic	Possible Mechanism(s)
	Inhibition of TNF-alpha-induced IL-8 production
	Downmodulation of genes associated with proinflammatory signal induction
	Attenuation of nuclear factor-kappa B activation
Lymphoid Cell	
Enhance antiviral activity	Inhibition of T-cell proliferation
	Induction of macrophages to express increased amounts of inflammatory cytokines and nitric oxide
	Stimulation of granulocyte colony-stimulating factor release by macrophages
	Increased natural killer T-cell activity
Activate macrophages	Increased antigen presentation to B lymphocytes
Regulatory T-Cell Induction	
Increase CD4+ (regulatory) T cells with cell-surface TGF-beta (regulatory cytokine)	Monocyte-derived dendritic cells inducing IL-10 production by T cells

Key: EC = Epithelial cell; GI = gastrointestinal; IgA = immunoglobulin A; IL = interleukin; INF = interferon; TGF = transforming growth factor; TLR = Toll-like receptor; TNF = tumor necrosis factor.

Sources

Many traditional foods are fermented by bacteria and contain high concentrations of lactobacilli. Corn, cassava, millet, leafy vegetables (cabbage), and beans commonly serve as basic foodstuffs for fermentation. A few fermented foods are occasionally eaten in the United States, such as brined olives, kimchi (Korean fermented cabbage), miso, sauerkraut, and tempeh;

however, the major food source of probiotic bacteria is “cultured” dairy foods. Many major brands of yogurt contain probiotic bacteria, although viable cultures are not required for yogurt in the United States, and labels do not list the number of viable probiotic organisms. Liquid yogurt drinks (kefir) and cultured fluid milk, such as sweet acidophilus milk and buttermilk, can contain variable amounts of viable organisms; however, most provide adequate amounts (10^8 viable organisms per g of product). With the expanding interest in probiotics, new products with added probiotic organisms are appearing regularly, sometimes with limited or no data on the organisms contained or on the efficacy of the combinations used.

Health Effects

Interest in probiotics has increased dramatically in the past decade. Research covers a wide range of disease states and subjects of all ages (premature neonates to the older adult). Clinical data, for the most part, are preliminary; however, moderate-quality evidence supports the use of probiotics to prevent or treat certain gastrointestinal disease states, as well as metabolic and respiratory syndromes, and to modify cardiovascular risk factors. In addition to the indications for probiotics with robust evidence, as discussed thus far, [Table 20–2](#) also includes additional indications for probiotics and associated organisms. Results may be influenced by the dose, frequency of dosing, and/or organisms in any specific probiotic product. Most studies have been small and have used isolated bacteria (classified as nutritional supplements) or foods with added probiotics, rather than foods that naturally contain the beneficial bacteria.

Table 20–2 Uses of Probiotics

Condition/ Disease	Probiotics and Dosages	Comments
Allergy		
Atopic dermatitis in infants, prevention and treatment	<i>L. rhamnosus</i> GG 10^{10} CFU daily for 2–4 weeks before delivery, then infant administration	Conflicting results; several studies show decreased severity; most studies were small limited studies with good design and adequate power to support effectiveness for atopic eczema associated with cow milk allergy. Meta-analysis indicated reduced frequency of eczema with selected probiotics supplied to mothers in the third trimester or during breastfeeding, or to their infants. With recognized high risk for

Condition/ Disease	Probiotics and Dosages	Comments
	for 6 months	atopic dermatitis, probiotic administration to the mother during pregnancy and to the infant for several months after birth, under the supervision of a health care provider, may be of benefit.
Diarrhea		
Acute, non-antibiotic- associated treatment in pediatrics and infants	<i>L. rhamnosus</i> GG at least 10 ¹⁰ CFU in 250 mL of oral rehydration solution; 10 ¹⁰ -10 ¹¹ CFU twice daily for 2-5 days	Multiple studies and meta-analyses; duration of diarrhea was reduced by about 1 day. Evidence of benefit is stronger for viral gastroenteritis than for bacterial infection. Timing of administration may affect efficacy. Evidence is stronger for treatment than for prevention.
	<i>L. reuteri</i> 10 ¹⁰ -10 ¹¹ CFU daily for up to 5 days	
Antibiotic- associated, prevention (not <i>Clostridioides</i> <i>difficile</i>)	<i>S. boulardii</i> 4 × 10 ⁹ -2 × 10 ¹⁰ CFU daily for 1-4 weeks	Multiple studies in both adults and pediatric patients have yielded some conflicting results; however, literature supports benefit overall.
	<i>L. rhamnosus</i> GG 6 × 10 ⁹ -4 × 10 ¹⁰ CFU daily for 1-2 weeks	
	<i>L. acidophilus</i> + <i>L. bulgaricus</i> 2 × 10 ⁹ CFU daily for 5-10 days	
	<i>L. acidophilus</i> + <i>B. longum</i> 5 × 10 ⁹ CFU daily for 7 days	

Condition/ Disease	Probiotics and Dosages	Comments
	<i>L. acidophilus</i> + <i>B. lactis</i> 1×10^{11} CFU daily for 21 days	
<i>Clostridioides difficile</i> infection	<i>S. boulardii</i> 2×10^{10} CFU daily $\times 4$ weeks with antibiotic therapy	Meta-analysis shows benefit. Promising role as adjuvant in treatment of recurrent <i>C. difficile</i> diarrhea.
Traveler's diarrhea	<i>L. rhamnosus</i> GG 2×10^9 CFU daily starting 2 days before and continued during travel	Results in randomized controlled studies are conflicting; modest positive results with some strains.
	<i>S. boulardii</i> 5×10^9 – 2×10^{10} CFU daily starting 5 days before and continued during travel	
Lactose intolerance	Yogurt with live cultures of <i>L. delbrueckii</i> + <i>Strep. thermophilus</i> $\geq 10^8$ CFU/g of yogurt	Reduced symptoms of lactose intolerance. Microbial beta- galactosidase improves lactose hydrolysis.
Radiation enteritis	<i>L. acidophilus</i> NDC01748 1.5×10^9 3 times daily for 7 days	A limited number of studies provide promising results; probiotic may reduce severity of diarrhea or improve stool consistency without decreasing the incidence of diarrhea. Overall, data are inadequate to establish effectiveness at this time.
	VSL#3 4.5×10^{11} CFU 3 times daily	

Condition/ Disease	Probiotics and Dosages	Comments
IBD		
Crohn's disease, induce and maintain remission	<i>S. boulardii</i> 1 g daily for 6 months with concurrent mesalamine	Small clinical studies, some with up to 1 year of follow-up; several randomized controlled trials, with equivocal results. Data are inadequate to establish effectiveness.
Pouchitis, preventing and maintaining remission	VSL#3 1.8×10^{12} CFU daily for 9–12 months	Meta-analysis data support probiotics for maintaining remission of chronic pouchitis. Inadequate studies to establish effectiveness for inducing remission or preventing pouchitis.
Ulcerative colitis	<i>E. coli</i> Nissle Active UC: 5×10^{10} CFU twice daily for up to 12 weeks, then 5×10^{10} CFU daily up to 12 months; Inactive UC: 5×10^{10} CFU daily for 12 weeks	Clinical evidence has not demonstrated benefit for inducing or maintaining remission. Some positive studies with similar efficacy to anti-inflammatory medications; however, data are inadequate to establish effectiveness.
	<i>S. boulardii</i> Active UC: 250 mg 3 times daily for 4 weeks with concurrent mesalamine	
	VSL#3 Active UC: 1.8×10^{12} CFU twice daily for 6 weeks with conventional therapy	
IBS		
Motility	VSL#3 9×10^{11}	May normalize muscle hypercontractility. Decreased bloating

Condition/ Disease	Probiotics and Dosages	Comments
disorders	CFU daily for 8 weeks	and flatulence in multiple studies; reduced abdominal pain or relief of constipation or diarrhea in some studies; however, other studies have yielded conflicting results. Most studies are small with an open label design. Meta-analyses demonstrate benefit in diarrhea, constipation, or IBS with mixed symptoms.
	<i>B. infantis</i> 10 ⁶ -10 ¹⁰ CFU daily for 4 weeks	
	<i>L. rhamnosus</i> GG + <i>L.</i> <i>rhamnosus</i> LC705 + <i>B.</i> <i>breve</i> + <i>P.</i> <i>freudenreichii</i> 8-9 × 10 ⁹ CFU daily for 6 months	
Infection		
<i>Helicobacter pylori</i>	<i>L. rhamnosus</i> GG 6 × 10 ⁹ CFU twice daily	Probiotic appears to reduce treatment-related side effects and to improve compliance. Meta-analyses indicate that probiotics may increase eradication when used with antibiotic therapy, especially in cases involving previous treatment failure.
	<i>B. clausii</i> 2 × 10 ⁹ spores 3 times daily	
	<i>S. boulardii</i> 2-4 × 10 ⁹ CFU/ day	
	<i>L. reuterii</i> 10 ⁸ CFU/day	
	Kefir 250 mL twice daily	
Vaginosis and vaginitis	<i>L. acidophilus</i> 8 oz yogurt containing	Decreased recurrence of vaginosis was shown in women with recurrent disease in one study; however, other studies have yielded conflicting results; evidence is inadequate to support

Condition/ Disease	Probiotics and Dosages	Comments
	≥10 ⁸ CFU/mL daily for 6 months	effectiveness.
	<i>L. rhamnosus</i> GR-1 + <i>L.</i> <i>fermentum</i> RC-14 10 ⁹ CFU in skim milk twice daily for 14 days	
	<i>L. rhamnosus</i> GG 10 ⁹ CFU per vaginal suppository twice daily for 7 days	
Intestinal Permeability		
NEC prevention	<i>B. bifidum</i> NCDO 1453, <i>L.</i> <i>acidophilus</i> NCDO 1748 10 ⁹ CFU twice daily	Strong support for effectiveness in preterm infants; meta-analysis supports supplementation of probiotics for reducing risk of severe NEC and death in premature infants.
	<i>L. acidophilus</i> + <i>B. infantis</i> 10 ⁸ CFU twice daily	
	<i>B. infantis</i> + <i>B.</i> <i>bifidum</i> + Strep. <i>thermophilus</i> 10 ⁹ CFU once daily	
Neurology		
Depression	<i>L. acidophilus</i> (2 × 10 ⁹), <i>L.</i> <i>casei</i> (2 × 10 ⁹),	Based on limited data, probiotics may be beneficial for reducing depression scores when given for add-on therapy with antidepressants for up to 8 weeks.

Condition/ Disease	Probiotics and Dosages	Comments
	<i>B. bifidum</i> , (2 × 10 ⁹)/g daily	
	<i>L. helveticus</i> + <i>B. longum</i> (≥2 × 10 ⁹)/g, 1.5 g sachet daily	
	<i>L. helveticus</i> + <i>B. longum</i> (≥2 × 10 ⁹)/g, 5 g sachet daily	
Multiple sclerosis	<i>L. acidophilus</i> , <i>L. casei</i> , <i>B. bifidum</i> , and <i>L. fermentum</i> (each 2 × 10 ⁹ CFU/g)	As suggested by limited data, probiotics may improve clinical and metabolic outcomes in multiple sclerosis.

^a VSL#3 contains four lactobacilli strains, three bifidobacteria strains, and *Streptococcus thermophilus*. VSL#3 is marketed as a probiotic medical food.

Key: *B.* = *Bifidobacterium*; CFU = colony forming units; *E.* = *Escherichia*; IBD = inflammatory bowel disease; IBS = irritable bowel syndrome; *L.* = *Lactobacillus*; NEC = necrotizing enterocolitis; *P.* = *Propionibacterium*; *S.* = *Saccharomyces*; *Strep.* = *Streptococcus*.

Indications (With Available Data for Prebiotics)

Inflammatory Bowel Disease

Inflammatory bowel disease (IBD) comprises two disorders, ulcerative colitis (UC) and Crohn's disease (CD), both of which are relapsing and remitting inflammatory diseases. Both disorders may require costly therapies that are associated with potentially severe adverse effects. It is hypothesized that changes in the gut microbiota contribute to the inflammation within the GI

tract.¹⁴ Probiotics may restore the balance in microbiota and reduce the inflammatory response. Several strains of probiotics have been evaluated for the treatment of IBD, including *Lactobacillus* spp., *Bifidobacterium* spp., and multispecies products such as VSL#3, which contains four strains of *Lactobacillus* (*L. casei*, *L. plantarum*, *L. acidophilus*, and *L. delbrueckii* subsp. *bulgaricus*), three strains of *Bifidobacterium* (*B. longum*, *B. breve*, and *B. infantis*), and one strain of *Streptococcus* (*S. thermophilus*).^{14–17}

According to a meta-analysis of IBD data, probiotic therapy was better than placebo for reducing symptoms of UC but not for the induction of UC remission (relative risk [RR] 1.72, 95% CI 1.35–2.20; and RR 1.56, 95% CI 0.95–2.59, respectively).¹⁶ Continued treatment with probiotics in patients who achieved remission did not prevent relapses of UC (RR 0.97, 95% CI 0.78–1.20). This analysis included studies that used a variety of the probiotics previously mentioned. In a more recent meta-analysis, probiotics were not more beneficial than placebo in achieving remission of UC (RR for failure to achieve remission 0.86, 95% CI 0.68–1.08), with the exception of VSL#3, which outperformed placebo in 319 patients across three trials (RR 0.74, 95% CI 0.63–0.87).¹⁸ By contrast, probiotics were found to perform similarly to 5-aminosalicylate for the prevention of relapse of UC (RR 1.02, 95% CI 0.85–1.23). In this analysis, probiotics were not effective in inducing or maintaining remission of CD.

Patients with severe UC who require surgical colectomy may need an ileoanal anastomosis. After this procedure, symptoms of pouchitis, or inflammation of the surgically created pouch or artificial rectum, may develop in some patients. *Lactobacillus* GG did not alleviate acute pouchitis symptoms compared with placebo.¹⁷ VSL#3 performed better than placebo for the maintenance of remission of chronic pouchitis in an analysis of data for 76 subjects (RR 20.24, 95% CI 4.28–95.81). Findings regarding the prevention of pouchitis with VSL#3 appear to be equivocal. In contrast with UC, CD does not appear to be responsive to probiotics (RR 1.03, 95% CI 0.71–1.48).¹⁶ Additionally, prebiotics, such as FOS, inulin, and lactulose, have been evaluated for the treatment of UC and CD; however, on the basis of the limited data currently available, they do not seem to provide significant symptom reduction.¹⁹ Current UC treatment guidelines suggest the need for further study before the use of probiotics can be widely recommended.²⁰

Irritable Bowel Syndrome

Irritable bowel syndrome (IBS) is a functional GI disorder that manifests as a diarrhea- or constipation-predominant syndrome or as a mixed-symptom picture. IBS symptoms may be secondary to an imbalance in the composition of the GI microbiota, manifested as an increase in potentially harmful organisms (*Clostridium*, *Escherichia coli*, *Salmonella*, *Shigella*, and *Pseudomonas*) and a corresponding reduction in beneficial ones (lactobacilli and bifidobacteria).²¹ In an analysis of data on patients with diarrhea-, constipation-, or mixed-symptom type IBS, treatment with *Lactobacillus* was beneficial in both adult and pediatric patients (odds ratio [OR] 17.62, 95% CI 5.12–60.65 and OR 3.71, 95% CI 1.05–13.11, respectively).²² A meta-analysis of results reported in 23 trials comprising 2575 subjects who received either single strains or a combination showed a beneficial effect of probiotics on global IBS symptom, abdominal pain, bloating, and flatulence scores, with an RR of symptom persistence with probiotics compared with placebo of 0.79 (95% CI 0.70–0.89).²³ These findings have been supported in a more recent meta-analysis.²⁴ Prebiotics also have been assessed in a meta-analysis and have been found not to relieve GI symptoms or improve quality of life in patients with IBS.²⁵ According to the American College of Gastroenterology monograph on the subject, prebiotics are not recommended for IBS owing to insufficient evidence.²⁶

Hepatic Disorders

In the presence of alcoholic liver disease, consumption of alcohol causes alterations in gut microbiota composition, resulting in endotoxemia and worsening hepatic function.²⁷ The use of probiotics such as VSL#3, *Lactobacillus* spp., *E. coli* Nissle, and *B. bifidum* is associated with reductions in liver function test abnormalities and improvement in Child-Pugh scores (assessing severity of liver disease) and in MELD (model for end-stage liver disease) scores. In a study in patients with cirrhosis, use of VSL#3 showed a reduction in hospitalization necessitated by hepatic encephalopathy.²⁸ Reduced risk of hepatic encephalopathy with probiotic use also was supported by a meta-analysis (OR 0.42, 95% CI 0.26–0.70); however, mortality rate and serum ammonia concentrations were not affected (OR 0.73, 95% CI 0.38–1.41; weighted mean difference [WMD] –3.67, 95% CI –15.71 to 8.37, respectively).²⁹ The beneficial effects of probiotics may not be limited to alcoholic liver disease: A meta-analysis of data on nonalcoholic fatty liver disease (NAFLD) showed

similar reductions in the transferase enzymes aspartate transaminase (AST) and alanine transaminase (ALT) (respective mean differences of -19.77 , with 95% CI -32.55 to -7.00 , and -23.71 , with 95% CI -33.46 to -13.95).³⁰ The prebiotic lactulose is a mainstay of therapy for hepatic encephalopathy, which is available by prescription rather than over the counter; this clinical scenario is beyond the scope of this chapter.³¹ A recent meta-analysis also has shown benefit of prebiotics and probiotics for reducing infections after hepatic resection.³²

***Clostridioides difficile* Infection**

Antimicrobials disrupt the normal function and composition of the intestinal microbiota. This disturbance enables colonization by *Clostridioides difficile*, an anaerobic, gram-positive, spore-forming bacillus. Its etiopathogenetic mechanism is production of toxin, which causes inflammation and diarrhea.

Some evidence suggests that probiotics may be useful in the primary prevention of *C. difficile* infection (CDI) when administered concurrently with antimicrobials. A meta-analysis of 23 trials comprising 4213 subjects compared probiotics and placebo for the primary prevention of CDI.³³ CDI occurred in 2.0% of the probiotics group, compared with 5.5% of the control group (RR 0.36, 95% CI 0.26–0.51). The results were similar in comparisons of adult and pediatric subjects, lower and higher doses, and different probiotic species. Subjects in the probiotics group experienced lower rates of abdominal cramping, nausea, fever, soft stools, flatulence, and taste disturbance (RR 0.80, 95% CI 0.68–0.95). In many of the trials, the probiotic regimen was started within 3 days of initiation of antibiotics and continued for at least the entire duration of antibiotic treatment.³⁴

Overall, however, according to CDI-specific guidelines from the Society for Healthcare Epidemiology of America, the Infectious Diseases Society of America, and the American College of Gastroenterology, the evidence is insufficient to recommend administering probiotics for primary prevention of CDI.³⁵ As reported in the most recent literature, recommendations have been published for the use of Bio-K+, a product approved in Canada, containing 50 billion CFUs of *L. acidophilus* CL1285 and *L. casei* LBC80R to prevent nosocomial CDI in hospitalized patients.³⁶ As the older guidelines are updated, further recommendations on use of probiotics to prevent CDI may become available. To date, relevant data are limited, and no specific recommendation

regarding probiotics for the treatment of CDI or prevention of recurrence has been issued.^{35,36}

Antibiotic-Associated Diarrhea

Diarrheal disease is a common adverse effect of antibiotics and is referred to as antibiotic-associated diarrhea (AAD). AAD is due to a disruption of normal intestinal microbiota. Concomitant probiotic use may mitigate this disruption. In a pooled analysis of data for 4097 adult and pediatric subjects from 25 trials, probiotics reduced the incidence of AAD (RR 0.60, 95% CI 0.49–0.72).³³ Similarly, in an analysis of 22 trials comprising 4155 pediatric patients, probiotics reduced the incidence of AAD (RR 0.42, 95% CI 0.33–0.53).³⁷ No significant effect by type of antibiotic or by dose of probiotic (greater than or less than 10¹⁰ CFU/day) was observed. Neither of these analyses reported results for use of a specific probiotic; rather, the results are based on various probiotic regimens. The use of probiotics with antibiotics may be of benefit, but a specific strain cannot be recommended.

Necrotizing Enterocolitis

Necrotizing enterocolitis (NEC) involves bowel wall necrosis and potential bowel wall perforation, especially in preterm infants of low birth weight, and is associated with increased mortality.³⁸ Probiotics may be beneficial in reducing the complications of NEC. In a meta-analysis of randomized, controlled trials in preterm infants (born at less than 37 weeks of gestation or weight less than 2500 g, or both), the use of probiotics for more than 7 days significantly reduced the incidence of severe NEC (RR 0.43, 95% CI 0.33–0.56 for 20 studies with 5529 infants) and mortality (RR 0.65, 95% CI 0.52–0.81 for 17 studies with 5112 infants).³⁸ Probiotics did not affect the development of sepsis (RR 0.91, 95% CI 0.80–1.03 for 19 studies with 5338 infants).

In a subgroup analysis based on the type of probiotic evaluated, *Lactobacillus* species or a mixture of two or three probiotic species significantly reduced the incidence of severe NEC (RR 0.45, 95% CI 0.27–0.75 for five studies with 1955 infants and RR 0.37, 95% CI 0.25–0.54 for nine studies with 2807 infants), whereas change in incidence with *Bifidobacterium* species and *Saccharomyces boulardii* did not reach significance (RR 0.48, 95% CI 0.16–1.47 and RR 0.72, 95% CI 0.34–1.55, respectively); however, these strains were evaluated in fewer subjects (409 and 357, respectively), which may have limited

the power of the analyses.³⁸ Another meta-analysis reported similar findings based on 12 cohort studies comprising 10,800 premature infants.³⁹ The use of probiotics was associated with a reduction in occurrence of NEC (RR 0.55, 95% CI 0.39–0.78) and death (RR 0.72, 95% CI 0.61–0.85) but did not affect sepsis rates (RR 0.86, 95% CI 0.74–1.00). The use of probiotics in preterm infants appears to prevent severe NEC and to reduce all-cause mortality rates. *Lactobacillus* species or mixtures of probiotics were most effective, but more studies are needed to determine the efficacy of other strains, as well as optimal dose and duration. Two recent systematic reviews and meta-analyses assessed use of probiotic therapy with *Bifidobacterium* species and found that these strains were effective and safe for preventing NEC in preterm infants.^{40,41}

***Helicobacter pylori* Infection**

Helicobacter pylori is an infective organism that colonizes the upper GI tract, causing peptic ulcer disease in susceptible patients. *H. pylori* also is a known carcinogen, so patients who test positive for *H. pylori* infection require treatment for eradication of the pathogen. Combination therapy with an antisecretory agent such as a proton pump inhibitor, plus a combination of antibiotics and potentially bismuth, for 7–14 days is currently recommended.⁴² Increasing antimicrobial resistance rates and adverse effects related to combination therapy affect eradication rates and patient tolerance of these regimens. The use of probiotics may increase eradication rates and reduce the occurrence of adverse effects.

A meta-analysis of 45 randomized controlled trials and 6997 participants showed higher rates of *H. pylori* eradication with 7 days of triple therapy (one proton pump inhibitor and two antibiotics) plus probiotics compared with triple therapy alone (82.31% versus 72.08%, respectively; eradication RR 1.11, 95% CI 1.08–1.15).⁴³ Additionally, the rate of adverse effects was much lower with probiotics plus triple therapy than with triple therapy alone (21.44% versus 36.27%, respectively; RR 0.59, 95% CI 0.48–0.71). Although eradication rates were higher, with fewer adverse effects, the addition of probiotics to triple therapy did not have an effect on patient compliance (RR 0.98, 95% CI 0.68–1.39). This may be due in part to the short duration of therapy. These findings are consistent with those of another meta-analysis, which evaluated 11 studies with 2392 participants.⁴⁴ The eradication rates were reported as 83% for 7 days of triple therapy plus probiotics and 73% for 7 days of triple therapy (RR 1.14, 95% CI 1.07–1.20). Adverse effects also were similar to those in the

foregoing analysis (RR 0.65, 95% CI 0.47–0.87). This analysis also evaluated subgroups based on probiotic strain used. Eradication rates were significant for a number of probiotic strains including *Lactobacillus*, *Bifidobacterium*, *Streptococcus*, and *Saccharomyces*. It would be reasonable to consider the addition of probiotics to standard therapy for the duration of the treatment course. The current *H. pylori* treatment guidelines recognize the potential value of probiotics for adjuvant therapy. However, limited evidence precludes recommending their use for the treatment of *H. pylori* infection at present.⁴²

Diabetes Mellitus

Probiotics have been evaluated for the treatment of diabetes. It has been proposed that probiotics reduce inflammation and prevent pancreatic beta cell destruction, resulting in a reduction of blood glucose.⁴⁵ In a meta-analysis of eight trials comprising 429 subjects, the probiotics users experienced a significant reduction in fasting plasma glucose (FPG) compared with subjects in the control groups (change in FPG –15.92 mg/dL, 95% CI –29.75 to –2.09).⁴⁵ HbA_{1c} (glycated hemoglobin) also was significantly reduced in the probiotics group in a subgroup analysis of three trials comprising 158 subjects (HbA_{1c} reduction 0.54%, 95% CI 0.82–0.25). The use of preparations with multiple strains of probiotics maintained a significant reduction in FPG, whereas the use of single-strain preparations did not (FPG weighted mean difference [WMD] with multiple strains –35.41 mg/dL, 95% CI –51.93 to –18.48; FPG WMD with single strains 2.67 mg/dL, 95% CI –18.78 to 24.13). Additionally, the use of probiotics for 8 weeks resulted in a reduction in FPG, whereas shorter durations of therapy did not (FPG WMD for 8 weeks –20.34 mg/dL, 95% CI –35.92 to –4.76; FPG WMD for <8 weeks –14.29, 95% CI –65.83 to 37.26). These results concur with those for a previous meta-analysis, which reported similar reductions in FPG in subjects receiving probiotics compared with the control subjects.⁴⁶

Cardiovascular Risk Factors

Probiotics may play a role in management of cardiovascular disease by affecting lipid levels. It has been hypothesized that probiotics may assimilate cholesterol during growth, bind cholesterol, disrupt cholesterol micelles, and deconjugate bile salts.⁴⁷ In a meta-analysis of 13 trials comprising 485 subjects that evaluated probiotics' effects on cholesterol in patients with normal, borderline high, and high cholesterol levels, probiotics significantly reduced

total blood cholesterol (mean net change -6.40 mg/dL; 95% CI -9.93 to -2.87).⁴⁸ Low-density lipoprotein (LDL) cholesterol also was significantly reduced in the probiotics group (mean net change -4.90 mg/dL, 95% CI -7.91 to -1.90). Two other recent meta-analyses corroborate these findings.^{47,49} Although probiotics significantly decreased total cholesterol and LDL, these meta-analyses did not address clinical outcomes. Also, the trials included in the analyses were of short duration, with the longest trial lasting 10 weeks.

Probiotics may have an effect on other cardiovascular risk factors. A meta-analysis of four studies comprising 234 subjects reported a significant reduction in body mass index (BMI) with use of probiotics (-0.52 kg/m², 95% CI -0.80 to -0.24 kg/m²).⁴⁹ It also found that waist circumference decreased significantly with probiotic use in 304 subjects across four studies (mean decrease -2.11 cm, 95% CI -3.54 to -0.68 cm).

Probiotics also have been evaluated in the management of hypertension. Data are limited, but modest reduction in blood pressure was demonstrated in one meta-analysis of data for patients with hypertension who received probiotic supplementation.⁵⁰

Eczema and Dermatitis

Development of eczema was shown to be less likely in infants who were exposed to probiotics—either through the pregnant mother’s receiving probiotics during the third trimester, the mother’s receiving probiotics while breastfeeding, or the infant’s receiving probiotics after birth, or some combination of these—was less likely than in infants without probiotic exposure. Probiotics did not reduce the incidence of other types of allergic diseases in infants in this analysis.⁵¹

Probiotic use by pregnant mothers or some form of exposure in infants up to 6 months of age was found to significantly reduce the incidence of eczema in in these infants in a meta-analysis of data for 2797 subjects (RR 0.74, 95% CI 0.67–0.82).⁵²

Atopic Dermatitis

In a meta-analysis evaluating use of probiotics for the primary prevention of atopic dermatitis (AD), supplementation with probiotics based on 16 studies was protective against the development of AD (OR 0.64, 95% CI 0.56–0.74).⁵³ In

subgroup analyses, the protective effects of probiotics were maintained in the general population, as well as in subjects who were at high risk for development of allergies. Administration of prenatal plus postnatal probiotics was effective, whereas administration of probiotics only in the prenatal or the postnatal period was not. The results did not differ with the probiotic strain used. On the basis of this analysis, probiotics seem to be beneficial for AD prevention if they are administered during the pre- and postnatal periods in both the general population and in those at risk for allergy. These findings are supported by another meta-analysis.⁵⁴ Additionally, a meta-analysis of 14 studies evaluated the effects of probiotic supplementation during pregnancy or in infancy on the development of AD.⁵⁵ Among the subjects who received probiotics, the development of AD was less likely than in those in control groups (RR 0.79, 95% CI 0.71–0.88). The benefit of probiotics was essentially the same whether they were administered during only during pregnancy or during pregnancy and also in infancy.

Probiotics also have been evaluated in the treatment of AD.⁵⁶ A meta-analysis included 25 randomized controlled trials comprising a total of 1599 subjects and reported a significant improvement in the standardized SCORAD (SCORing Atopic Dermatitis) value for all subjects receiving probiotics compared with placebo (WMD –4.51, 95% CI –6.78 to –2.24). Probiotics' beneficial effects were seen in two of three age-related subgroups: in children 1 to 18 years of age (WMD –5.74, 95% CI –7.27 to –4.20) and in adults (WMD –8.26, 95% CI –13.28 to –3.25). The benefit was not seen in infants younger than 1 year (WMD 0.52, 95% CI –1.59 to 2.63).

For atopy and dermatitis, *Lactobacillus rhamnosus* GG is the most researched and most often recommended, although *L. acidophilus* and *Bifidobacterium lactis* also have been shown to be of benefit.^{57,58} Lactobacilli and bifidobacteria are dosed at 1–10 billion CFU per day, given in divided doses. *S. boulardii* is dosed at 250–500 mg 2–4 times daily.

Respiratory Syndromes

Probiotics have been assessed in the treatment of allergic rhinitis: An analysis of 23 studies (1919 subjects) showed that probiotics improved Rhinitis Quality of Life (RQLQ) scores compared with placebo (standard mean difference [SMD] –2.23, 95% CI –4.07 to –0.4).⁵⁹ The RQLQ is a 7-point scale, with lower scores indicating better quality of life. A change of 0.5 point is considered to be a

minimally important difference; a change of 2 or more points represents a substantial effect.⁶⁰ In a recent meta-analysis of data for *Lactobacillus paracasei* versus placebo, probiotics were effective in reducing nasal and ocular symptom scores and total nasal and ocular quality of life scores.⁶¹

Probiotics also may be of benefit in the setting of upper respiratory tract infections (URIs). In a meta-analysis of 12 trials comprising 3720 subjects of different ages, ranging from children to older adults, use of probiotics was associated with a lower risk for development of a URI compared with placebo (OR for development of one URI 0.53, 95% CI 0.37–0.76, OR for development of at least three episodes 0.53, 95% CI 0.36–0.8).⁶² Probiotic therapy also had positive effects on the mean duration of URI episodes (mean difference –1.89 days, 95% CI –2.03 to –1.75), rate of antibiotic prescriptions (OR 0.65, 95% CI 0.45–0.94), and common cold–related school absences (OR 0.10, 95% CI 0.02–0.47). Adverse effects were similar for the probiotics and placebo groups (OR 0.88, 95% CI 0.65–1.19), with the most common adverse effects reported as minor gastrointestinal disturbances. Similar findings were reported in an analysis of 11 studies comprising 2417 pediatric subjects younger than 10 years of age.⁶³ A later meta-analysis showed that *Lactobacillus rhamnosus* (formerly thought to be a subspecies of *L. casei*) was the only probiotic to reduce the incidence of respiratory tract infections compared with placebo.⁶⁴

Assessment of Safe Use of Probiotics

Probiotics may be associated with minor GI adverse effects including cramping, nausea, soft stools, flatulence, and taste disturbance.⁶⁵ However, it has been reported that patients who receive probiotics to treat CDI are less likely to experience GI adverse effects than patients who are not treated with probiotics. Additionally, it often is difficult to determine whether these GI effects are due to the administered probiotic or to the underlying GI disease state being treated.

A concern with the use of probiotic therapy is the development of systemic infection with organisms in the live culture being administered. In a number of case reports, immunocompromised patients have acquired serious infections (e.g., sepsis, endocarditis, fungemia) with infectious organisms consistent with the administered probiotic.⁶⁵ Even though probiotic administration has become more common, an increase in infection risk has not been supported

by population-based data of the rates of infections due to commonly administered probiotic strains. Although some data support the use of probiotics in immunocompromised patients, such products should be avoided in this population because of reports of associated systemic infection.⁶⁶

A multicenter randomized, double-blind, placebo-controlled study called the Probiotics in Pancreatitis Trial (PROPATRIA) assessed the effects of probiotics for the prevention of infectious complications in patients with predicted severe acute pancreatitis.⁶⁷ This trial demonstrated that probiotics had no effect on the rate of infectious complications. However, the mortality rate was more than doubled in the probiotics group, with a relative risk of 2.53 (95% CI 1.22–5.25). Bowel ischemia and associated mortality were significantly higher in the probiotic group ($P = 0.004$). Therefore, probiotics should be avoided in such at-risk patients. By contrast, no harmful effects have been observed in women in late-stage pregnancy or in breast-feeding infants during long-term use.⁶⁸ Additionally, providing probiotics via a jejunostomy tube has been reported to potentially increase risk of adverse effects. This association may be due to the lack of contact of the probiotics with gastric acid, resulting in increased exposure of the GI tract to viable probiotic organisms.⁶⁹

Cases 20–1 and 20–2 illustrate two different situations in which probiotics are useful and detail how both potential safety and efficacy should be evaluated.

Case 20–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient reports severe epigastric pain, especially at night and after eating a spicy or fried meal. Over-the-counter antacids seem to reduce the pain, but it recurs soon after. She also complains of pain with swallowing (dysphagia) and sometimes has difficulty swallowing (odynophagia). She

	underwent esophagogastroduodenoscopy (EGD) and was found to be positive for <i>Helicobacter pylori</i> infection.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Her symptoms worsen when she eats spicy or fried foods, or when she is under a lot of stress at work.
c. Description of the patient's efforts to relieve the symptoms	The patient has been taking Tums or Mylanta as needed to relieve her symptoms.
d. Patient's identity	Mary Carpenter
e. Patient's age, gender, height, and weight	52 years, female, 5 ft 2 in., 130 lb (59 kg)
f. Patient's occupation	Air traffic controller
g. Patient's dietary habits	Does not cook for herself; relies on prepared foods or takeout from fast food restaurants for most of her meals.
h. Patient's sleep habits	6 hours per night
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	She is having a prescription filled today for clarithromycin 500 mg bid, amoxicillin 1 g bid, and omeprazole 20 mg bid for 10 days. She will discontinue taking Tums and Mylanta with initiation of her <i>H. pylori</i> antibiotic/acid suppression regimen.
j. Allergies	NKDA
k. History of other adverse reactions to medications	None
l. Other (describe) _____	None
Assess	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Ms. Carpenter has been diagnosed with <i>H. pylori</i> infection, for which appropriate treatment with triple therapy has been prescribed.
3. Identify exclusions for self-treatment.	None

4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Carpenter to an appropriate health care provider. (2) Recommend self-care with a probiotic. (3) Recommend stress reduction through activities such as yoga or meditation. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Ms. Carpenter may consider adding a probiotic to her <i>H. pylori</i> regimen such as <i>Lactobacillus rhamnosus</i> GG: 6×10^9 CFU twice daily for 10 days.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"Probiotics taken in combination with an <i>H. pylori</i> eradication regimen have been shown to increase its effectiveness and to reduce any adverse effects of the drugs in this regimen (such as diarrhea)."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Probiotics are a good option for you because they treat the specific symptoms you are experiencing."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
Solicit follow-up questions from the patient or caregiver.	"Will I get an infection from taking a probiotic since you told me this is a live microorganism?"
Answer the patient's or	"In patients like you with a healthy immune system,

caregiver's questions.	probiotics are safe to use and won't cause an infection. They are not recommended for patients with weakened immune systems such as those receiving chemotherapy or who have had organ transplant."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Ms. Carpenter to call to update you on her response to your recommendations. Alternatively, you could call her in 1 week to evaluate how she is progressing and tolerating therapy.

Key: CFU = Colony-forming units; NDKA = no known drug allergies.

Case 20-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient complains of new-onset cramping abdominal pain, which started 6 weeks ago. He also reports passage of 2-3 bloody loose stools per day.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	His symptoms worsened when he recently quit smoking.
c. Description of the patient's efforts to relieve the symptoms	The patient tried loperamide for his diarrhea without any relief.
d. Patient's identity	Harry Smith

e. Patient's age, gender, height, and weight	40 years, male, 5 ft 10 in., 190 lb (86.4 kg)
f. Patient's occupation	Engineer
g. Patient's dietary habits	Mr. Smith generally eats a well-balanced diet.
h. Patient's sleep habits	5-6 hours nightly
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	None
j. Allergies	None
k. History of other adverse reactions to medications	None
l. Other (describe) _____	None
Assess	
2. Differentiate patient's signs/symptoms and correctly identify the patient's primary problem(s).	Mr. Smith's signs and symptoms include new-onset cramping abdominal pain and passage of 2-3 bloody loose stools per day.
3. Identify exclusions for self-treatment.	Mr. Smith has blood in his stool, which warrants referral for more invasive testing such as with colonoscopy. This specific finding is an exclusion for self-treatment.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to an appropriate health care provider. (2) Recommend self-care with a probiotic and nonprescription antidiarrheal medication. (3) Recommend self-care until

	the patient can see an appropriate health care provider. (4) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer Mr. Smith to an appropriate health care provider.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"You should consult a health care provider for treatment."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Your symptoms of blood in the stool require further evaluation. Once a diagnosis is made, we can recommend further appropriate therapies."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	Criterion does not apply in this case.
Answer the patient's or caregiver's questions.	Criterion does not apply in this case.
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Smith in 1–2 days to ensure that he made an appointment to seek medical care.

Patient Counseling

Many probiotic preparations with one or multiple species and wide dosing

ranges are available. Health care providers and consumers should be thoughtful when selecting probiotic formulations and should base this decision on clinical trial data and the strains used in these trials. Patients should be counseled to avoid probiotics if they have risk factors for systemic infections or other complications.⁶⁵ This high-risk group includes persons with valvular heart disease, premature infants, patients with central venous access ports, and immunocompromised patients.

Product quality has been a concern because some studies found products containing few or no live cultures; refrigerated products have been recommended as perhaps less likely to have suffered from degrading temperatures.⁷⁰ However, recent research suggests that nonviable probiotics also may offer benefit.⁷¹

Key Points for Prebiotic and Probiotic Use

- Prebiotics are substrates that are selectively utilized by host microorganisms in processes that support gut health and include fermentable dietary components that selectively stimulate the growth and/or activity of one or a limited number of bacterial strains in the colon (bifidobacteria and lactobacilli), thereby benefiting the host.
- Probiotics are nonpathogenic, living microorganisms that have beneficial health effects when consumed regularly in adequate amounts. They often are present in fermented products from milk (yogurt and kefir) or plants (sauerkraut and miso).
- Probiotics have shown beneficial effects in a number of diseases; however, the particular species and strain and the dose necessary for beneficial effects often remain controversial and may vary from condition to condition.

Chapter 21: Poisoning

Authors: Barbara Insley Crouch, Wendy Klein-Schwartz

Poisoning is the leading cause of injury-related death in the United States, surpassing motor vehicle crashes and firearms injuries in this etiologic category. As such, it constitutes a major public health problem.^{1,2} Drug-related morbidity also is significant.

Use of nonprescription medications carries a risk for adverse effects and poisoning in all age groups, but especially in persons at the extremes of age. Health literacy, level of cognitive function, visual acuity, and personal knowledge base, attitudes, and beliefs are factors that may influence how people take a nonprescription medication and therefore their risk for adverse effects.³ Consumers often are unaware of ingredients in combination nonprescription products, particularly pain relief and upper respiratory tract products.⁴ Studies of patient perceptions of nonsteroidal anti-inflammatory drugs (NSAIDs), with their associated risks and specific indications, have found general understanding to be relatively poor, potentially resulting in inappropriate use, dosing that exceeds daily limits, or concomitant self-administration of several different NSAIDs.^{5,6} Restrictions and label changes on pediatric cough and cold preparations have led to a reduction in pediatric unintentional poison exposures and hospital emergency department visits.^{7,8}

Acetaminophen is one of the leading nonprescription pain relievers. Misuse of acetaminophen also is a major cause of poisoning, both unintentional and intentional, reported to U.S. poison control centers. The Acetaminophen Awareness Coalition, whose members include the American Pharmacists Association, the National Association of Boards of Pharmacy, and the National Community Pharmacists Association, launched a website (www.knowyourdose.org) to educate patients and consumers about how to use acetaminophen correctly. Initiatives to promote safe use of this drug include converting pediatric liquid acetaminophen preparations to one standardized concentration and highlighting the ingredient acetaminophen on nonprescription labels. Most poisonings in young children are unintentional, whereas poisonings in other age groups may be unintentional or intentional (e.g., with suicide attempts or medication misuse). Use of nonprescription cough and cold medications for their psychoactive effects, to obtain a pharmaceutical “high,” remains an issue identified through the

Monitoring the Future study, with 3.2% of 12th graders indicating use of these medications in the past year.⁹ A majority of poisonings are a result of ingestion of a substance, but poisonings also may occur after a toxin is inhaled or comes into contact with the skin and eyes. Bites and envenomations are other potential sources of toxin exposures. First aid for poisonings focuses on minimizing the extent of the exposure and stemming the progression or development of toxicity.

Poison control centers are 24-hour resources for poison information, clinical toxicology consultation, and poison prevention education. They are staffed around the clock with pharmacists, nurses, physicians, and physician assistants who have additional training in clinical toxicology. The centers are available for consultation to both health care providers and the public. The entire United States and its territories are covered by a network of poison control centers. An area-specific poison control center should always be contacted for assessment and treatment of poisonings; these centers also constitute an excellent source of educational materials on poisoning prevention. [Figure 21-1](#) shows the nationwide poison control center number and logo.

Figure 21–1 Nationwide toll-free telephone number for contacting a poison control center. (Source: Reprinted with permission from the American Association of Poison Control Centers, Alexandria, Virginia.)

In 2018, a total of 55 poison control centers serving the United States and territories reported 2,099,751 cases to the National Poison Data System of the American Association of Poison Control Centers.¹⁰ A majority of poison exposures (44.17%) occur in children younger than 6 years, of which 73.7% involve children younger than 3 years of age.¹⁰ Nonprescription and prescription medications are frequently responsible for potentially toxic exposures reported to poison control centers. Nonprescription products such as analgesics, dietary supplements, topical preparations, vitamins, and antihistamines are among the most common substances ingested by young children. The large number of nonprescription medications involved in pediatric exposures reflects the common use and availability of these products in the home. Other common substances and items involved in potential poison exposures in children younger than 6 years include cosmetics and personal care products, cleaning substances, foreign bodies or toys, pesticides, and plants.

A majority (65.6%) of poison exposures reported to poison control centers are managed at the site of the exposure, usually in a residence; only 12.5% of children younger than 6 years are managed in a health care facility. Major effects or fatal outcomes were reported in 1.5% of cases recorded for 2017.¹⁰ Consultations with poison control centers are cost-effective, with a favorable cost-to-benefit ratio.¹¹ A significant portion of the cost savings results from home observation, as well as from the reduction in unnecessary emergency medical transport and treatment costs. A policy analysis group showed that poison center consultations resulted in improved outcomes and a reduction in length of stay by 0.43 day among Medicare beneficiaries.¹² The same group previously reviewed the existing literature on the cost savings associated with use of a poison control center and estimated medical care savings and reduced productivity loss of \$13.39 per year per dollar of poison control center funding.¹³ Health care providers are encouraged to work closely with their local poison control centers to ensure the most appropriate, cost-effective care for the poisoned patient.

Consumers and/or health care providers also can use an online/smart phone app to assist them in deciding whether to call their poison control center. For those who prefer this approach, such tools can be useful and cost-effective. [WebPoisonControl.org](https://www.webpoisoncontrol.org) is a free application that was launched in December 2014. In 1 year, more than 9000 public cases have been logged, and in 73.3% of these cases, self-treatment for poisoning events at home was determined to be safe with the appropriate precautions.¹⁴ In 24.5% of the cases, the user was referred to a poison control center, and in 2.1% of cases, the user was referred directly to a hospital emergency department. A survey of users demonstrated that more than 91% thought the tool was quick and easy to use. Another online resource launched in 2017 is poisonhelp.org. Other online/smart phone apps may be available in the near future.

Unintentional childhood poisonings remain a common cause of injury-related morbidity, requiring significant expenditures of health care dollars for inpatient and outpatient care. Unintentional poisonings remain one of the leading causes of injury-related hospitalizations in preschool children; however, fatalities among preschoolers have declined significantly since the early 1970s. According to an analysis of the National Electronic Injury Surveillance System–All Injury Program (NEISS–AIP), an estimated 58,000 children younger than 6 years are evaluated in emergency departments annually for unintentional medication-related exposures.¹⁵ Hospitalization or

specialized medical care was required in nearly 16% of cases. The most common categories of medications were acetaminophen, cough and cold medications, antidepressants, and NSAIDs.

The National Safety Council reported 38 deaths caused by unintentional poisoning in children younger than 5 years in 2017.¹⁶ Only 25 of the 3208 fatalities reported by poison control centers in 2017 involved children younger than 6 years.¹⁰ Medications and illicit drugs (excluding ethanol) were the primary substances responsible for fatalities involving persons of all ages. Child-resistant closures (CRCs) legislated through the Poison Prevention Packaging Act (PPPA) of 1970 help prevent unintentional poisonings. Incorporating CRCs into packaging has been responsible for a decline in pediatric fatalities from both prescription and nonprescription medications.¹⁷ Although CRCs have improved child safety, exemptions to the law allow dispensing medications without CRCs.¹⁸ An analysis of NEISS data revealed that an estimated 55% of nonfatal poisonings in children younger than 5 years treated in an emergency department involved a product regulated by the PPPA.¹⁹ Whereas CRCs may reduce unintentional pediatric poisoning, use of nonstandard liquid measuring devices and caregiver misinterpretation of nonprescription medication labels are recognized to increase the risk for pediatric poisoning. Further work is needed to improve the format and content of nonprescription labels to optimize caregiver understanding of the medication and dosing instructions.^{3–6}

Clinical Presentation of Poisoning

Poisons can affect every organ system. Signs and symptoms of poisoning can range in severity from mild to life-threatening. For some drugs, manifestations of toxicity after overdose are similar to adverse effects associated with therapeutic use. For example, ibuprofen overdose is characterized primarily by nausea, vomiting, and abdominal pain. Patients with diphenhydramine overdose may exhibit sedation or stimulation (e.g., agitation, hallucinations), tachycardia, hypertension, dry mouth, and dilated pupils from the drug's antimuscarinic properties. Overdoses of other drugs, such as aspirin, result in multiorgan system effects, including gastrointestinal (GI), central nervous system, metabolic, cardiovascular, pulmonary, and hematologic toxicity. A lack of symptoms immediately after a poison exposure does not preclude toxicity. Patients may be asymptomatic initially, but severe toxicity may develop hours

after ingestion of some sustained-release or enteric-coated products or of medications that delay gastric emptying or slow GI motility (e.g., antihistamines). For other drugs (e.g., acetaminophen) and some chemicals (e.g., methanol, acetonitrile), clinical effects are delayed while the substance is metabolized to active or toxic metabolites. The time course of acetaminophen overdose is related to formation and covalent binding of a toxic metabolite to hepatic cells. As a result, a relatively mild initial clinical course characterized by nausea, vomiting, anorexia, and malaise can be followed by onset of severe hepatic and renal toxicity 3–5 days later. An important consideration in any setting is that symptoms may be due to causes other than poisoning. If symptoms are serious, they warrant medical attention.

Figure 21–2 Self-care for poisoning. Key: CNS = Central nervous system.

Treatment of Poisoning

Most unintentional poison exposures in small children result in minimal, if any, adverse effects and require no treatment, and observation is a sufficient approach to management. Although self-treatment may be appropriate, health care providers, caregivers, and patients are encouraged to seek advice from the nearest poison control center before attempting any treatment.

Treatment Goals

The primary goal of at-home or prehospital therapy is to prevent absorption of toxins or stem the progression of toxicity, thereby minimizing morbidity and mortality risks.

General Treatment Approach

The first step in assessing a potential poison exposure is to determine whether the patient has symptoms and whether the exposure puts the patient at risk for toxicity. Many exposures are, in fact, nontoxic or minimally toxic, because either the substance has very low inherent toxicity or the amount consumed is too low to cause toxicity. A decision regarding the option for self-treatment depends on the reason or circumstance of the poison exposure, toxicity of the agent, and general health status of the patient. Self-treatment should be considered only if the ingestion is unintentional and the potential for toxicity is assessed as minor. With any inadvertent exposure to a toxin that potentially can result in moderate to severe toxicity, as well as all intentional exposures, the patient should be referred immediately to a hospital. If the patient exhibits potentially life-threatening clinical effects (e.g., coma, convulsions, syncope), transportation to a hospital emergency department should be arranged immediately through the emergency 911 system. Additional exclusions for self-treatment can be found in [Figure 21–2](#). Hospital care includes observing the patient, supporting vital functions (e.g., airway, breathing, circulation), preventing absorption, enhancing elimination, and using available antidotes.

Suicide is a serious public health problem in the United States. Intentional ingestions of medications often represent a cry for help. Persons who are trying to harm themselves or are abusing or misusing drugs on purpose are

not always truthful about what they ingested. It is important to be vigilant and recognize when a patient has taken a medication purposefully and to refer the person immediately for evaluation in an emergency department.

A majority of patients who do not require immediate hospital referral are managed with on-site observation only, with no specific treatment.¹⁰ In some instances, the optimal approach is to attenuate the exposure by irrigation or prevention of further absorption. The nonprescription product activated charcoal may prevent or reduce the absorption of some ingested substances. However, its routine use is not recommended without consultation with a poison control center. [Figure 21–2](#) outlines self-care for exposure to poisons.

Nonpharmacologic Therapy

Inhalation exposures are managed by removing the patient from the toxic fumes to fresh air. Irrigation may be beneficial to decrease the contact time of a chemical with skin or mucosal surfaces. Exposed skin should be washed with soap and water (usually twice) to decrease the contact time with the offending chemical, with care taken to include nail beds and hair when appropriate. Irrigation of the eye with water should be initiated immediately after an ocular exposure to a chemical or drug not intended for ocular use (e.g., inadvertent ocular administration of an otic preparation). If an irritating chemical has been swallowed, administration of a small amount of fluids may decrease the contact time of the chemical with the mucosal surface. Neutralization after a chemical contacts skin or eyes or for ingested substances is not recommended.

Administration of oral fluids after ingestion of a drug is not usually recommended. Giving a large amount of fluids should be discouraged, because with a full stomach, spontaneous vomiting is more likely, which can be risky in some situations. The fluids theoretically may facilitate dissolution of a solid dosage form, thereby enhancing its absorption. Administering fluids after toxic ingestions should be considered for drugs recognized to be associated with a high risk of esophageal impaction, such as bisphosphonates, or those that may cause renal injury owing to dehydration, such as ibuprofen or other NSAIDs. Manually stimulating the gag reflex at the back of the throat with either a blunt object or a finger may induce vomiting, but this practice is not recommended because it can lead to soft palate injury.

Pharmacologic Therapy

Activated charcoal, an adsorbent, and ipecac syrup, an emetic, are the only approved agents for self-treatment for ingested poisons. Ipecac syrup does not improve outcomes for poisoned patients, however, and its use should be avoided.²⁰ Although the Code of Federal Regulations still states that ipecac syrup is considered the emetic of choice for certain poisoning scenarios, the American Academy of Pediatrics stopped recommending its use for poison treatment in 2003.²¹ Pharmacists should recommend discarding any existing supplies in the home. Controversy surrounds the use of activated charcoal as a self-treatment, in view of the lack of evidence that it improves outcome and its poor tolerability. Pharmacists should encourage consultation with a poison control center regarding first aid recommendations for poisoning.

Treatment With Activated Charcoal

Activated charcoal is a tasteless, gritty, fine, black insoluble powder made by pyrolysis of various organic materials.²² Its large surface area of 950–2000 m²/g makes activated charcoal a highly effective adsorbent.²²

Activated charcoal has been shown to be an effective adsorbent for a large number of commonly ingested drugs and many other toxic agents. These substances are bound in the internal surface of the pores of the charcoal particle, thereby preventing their absorption. Activated charcoal is not absorbed from the GI tract. As the ratio of activated charcoal to toxin increases, the proportion of bound toxin increases.²² Highly ionized substances, such as potassium and lithium, are poorly adsorbed by activated charcoal. Activated charcoal does not bind well to alcohols or glycols (e.g., ethanol, methanol, ethylene glycol), hydrocarbons, mineral acids and alkali, heavy metals (e.g., iron, lead, arsenic), or cyanide ([Table 21-1](#)). The presence of food in the GI tract may reduce the efficacy of activated charcoal.

Table 21-1 Contraindications to GI Decontamination With Activated Charcoal as Self-Treatment

Category	Inclusion Criteria	Recommendation
Patient condition	Coma, convulsions, syncope, airway or breathing problems, blood pressure or pulse irregularities, hallucinations, severe agitation; history of bariatric surgery	Refer to hospital for evaluation.

Category	Inclusion Criteria	Recommendation
Reason or circumstance	Intentional self-harm, substance abuse, malicious intent	Refer to hospital for medical and psychiatric or social service evaluation.
Ingestion of low-viscosity hydrocarbons and terpenes	Gasoline, kerosene, mineral seal oil (furniture polish), naphtha (lighter fluid), pine oil (cleaners), turpentine (paint removers), mineral oil	Contact poison control center.
Ingestion of caustic substances	Methacrylic acid (artificial nail primers), sodium silicate and carbonate (automatic dishwashing detergents), sulfuric acid (automotive battery, drain cleaners, toilet bowl cleaners), sodium hydroxide (drain cleaners, oven cleaners, hair relaxers), hypochlorites (bleach, pool chlorine), thioglycolates (hair relaxers), hydrofluoric acid (rust removers), hydrochloric acid (toilet bowl cleaner)	Contact poison control center.
Ingestion of substances not adsorbed by charcoal	Ethanol (alcoholic beverages, colognes, mouthwashes, aftershaves, hand sanitizers), isopropyl alcohol (rubbing alcohol), methanol (windshield washer fluid), ethylene glycol (antifreeze), ionized substances (potassium), metals (iron, lithium, lead, arsenic), cyanide (potassium cyanide, acetonitrile artificial nail remover, laetrile)	Contact poison control center.

Key: GI = Gastrointestinal.

Activated charcoal is approved by the U.S. Food and Drug Administration (FDA) for use as an emergency antidote for treatment of poison ingestion. Home administration of activated charcoal should never include more than 1 dose. The usual dose of activated charcoal is approximately 1 g/kg ([Table 21-2](#)).²² This dosage provides an estimate of the amount (rounded to the nearest full or half-full bottle) of activated charcoal to administer. Activated charcoal is available premixed either with water or with water and carboxymethylcellulose. Activated charcoal combined with sorbitol also is available to improve palatability and to act as a cathartic, shortening transit time of the activated charcoal complex through the GI tract and preventing constipation; however, most activated charcoal products marketed specifically

for home use do not contain sorbitol. Examples of nonprescription activated charcoal products are Actidose-Aqua and Liqui-Char with or without sorbitol; they generally are available at strengths of 15 g/72 mL, 25 g/120 mL, and 50 g/240 mL. Activated charcoal slurries are prone to settling, so they should be shaken vigorously before administration. Failure to shake the slurry adequately can result in delivery of less than 60% of the total dose being administered.²³ Activated charcoal also is available as a powder for reconstitution into an oral suspension just before use; this product should be stirred thoroughly or shaken vigorously after water is added. Flavoring agents have been used to try to increase the palatability of activated charcoal. Activated charcoal capsules or tablets marketed as a dietary supplement for GI symptoms or other ailments should not be used to manage poisonings, because the surface area of charcoal in these products is too small to effectively adsorb toxins.

Table 21-2 Activated Charcoal Dosing Information

Age	Dose
0–12 months ^a	10–25 g
1–12 years	25–50 g
> 12 years	25–100 g

^a Used primarily in a health care setting in this age group.

Source: Reference 22.

The most common adverse effects of activated charcoal are vomiting and black stools. Vomiting occurs in 12%–20% of patients receiving activated charcoal.²² One fifth of children younger than 18 years who were given activated charcoal for poisoning vomited at a median of 10 minutes after initiation of charcoal administration. More serious complications, such as pulmonary aspiration and GI obstruction, are associated more often with administration of multiple doses of activated charcoal.

Use of activated charcoal is contraindicated in patients in whom the GI tract is not anatomically (e.g., secondary to caustic injury) or functionally (e.g., ileus)

intact. After bariatric surgery, patients may not tolerate charcoal or may need smaller, more frequent doses. Activated charcoal also is contraindicated in patients at high risk for aspiration without airway protection ([Table 21-1](#)). Activated charcoal should not be administered after ingestion of substances that it does not adsorb unless the presence of other ingestants that are adsorbed by charcoal is suspected.

Pharmacotherapeutic Considerations for Activated Charcoal

Studies have demonstrated that the effectiveness of GI decontamination decreases significantly with increasing time interval since ingestion. For most overdoses, GI decontamination with activated charcoal should be performed early, usually within 1 hour of the ingestion.²⁴⁻²⁶

There is no convincing evidence that activated charcoal improves patient outcomes, and its utility in adults who intentionally overdose has been questioned, particularly in patients with mild to moderate poisoning.^{26,27} In some subgroups of patients with severe poisoning, activated charcoal may be beneficial; however, self-treatment has no place in the management of such poisonings.²⁶ A position statement by the American Academy of Clinical Toxicology and the European Association of Poisons Centres and Clinical Toxicologists concluded that activated charcoal may be considered for a potentially toxic amount of a poison ingested up to 1 hour before treatment. Insufficient data are available to support or exclude use of charcoal when poison ingestion occurred more than 1 hour previously.²² A majority of studies on which the position statement was based were conducted in a controlled research or hospital environment. A Cochrane Systematic Review on first aid interventions by laypersons for acute poisoning identified uncertainty about the effect of single-dose activated charcoal compared with no intervention on the incidence of adverse effects in general, incidence and severity of poisoning, and rate of intensive care unit (ICU) admissions, as well as drug absorption²⁸

Although activated charcoal is sold as a nonprescription drug, it is not available in most homes, nor is it routinely recommended for home use by poison control centers. The American Academy of Pediatrics does not recommend maintaining a supply of activated charcoal in the home as part of its anticipatory guidance for poisoning. Sometimes activated charcoal is given in

the home setting to provide early prehospital GI decontamination in patients who subsequently are transported to a hospital emergency department. Health care providers should consult their local poison control center to determine whether to promote routine availability of activated charcoal in the home.

To date, experience with home administration of activated charcoal has shown it to be relatively safe. GI effects have been reported, with vomiting as the main adverse effect. Before any recommendation for use of activated charcoal, the health care provider should consult a poison control center.

Assessment of Poisoning: A Case-Based Approach

After obtaining the history of the exposure to a poison and performing an initial assessment of the patient's condition, the health care provider must decide whether to refer the patient directly to an emergency treatment facility, to manage the case in the home environment, or not to recommend any specific treatment. Clearly, patients with serious clinical effects including altered mental status (e.g., stupor, coma, seizures, agitation, hallucinations), respiratory distress, or changes in cardiovascular status (e.g., syncope, hypotension) are not candidates for self-care and should be transported immediately to the emergency treatment facility. Alternatively, recognizing nontoxic or minimally toxic exposures that can be managed outside a health care facility is an essential component of self-treatment for poisoning. Involving the poison control center in this assessment and treatment decision is important, because staff at such centers have considerable experience managing poisoned patients and specialized resources that are not usually available to providers. The nationwide toll-free poison control center number, 800-222-1222, connects callers to the center that serves their area ([Figure 21-1](#)).

Self-treatment at home is primarily intended for unintentional poison exposures in children younger than 6 years in whom no or, at most, minimal toxicity is expected. In addition, some unintentional therapeutic dosing errors, or inhalation or skin or eye exposures in any age group, with possible minimal toxicity, often are amenable to self-treatment.

For any patient inquiries about purchasing activated charcoal, the pharmacist must determine whether intended use of such preparations is for an acute situation, in which case the poison control center should be contacted to assess the appropriateness of self-treatment. The poison control center will need information about the patient (age, weight, medical history, any ongoing clinical effects), the toxin (name of the offending drug or other substance, dose, route of exposure, time since exposure), and what treatment, if any, has already been administered.

Cases 21–1 and 21–2 provide examples of assessment of two different patients who have experienced a potentially toxic exposure.

Case 21–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A mother calls the pharmacist and asks what to do for her 2-year-old son, who just ingested a naproxen 220 mg tablet that was placed on the counter to give a teenaged sibling. Only one 220 mg tablet was available. The ingestion happened 5 minutes ago. The son is currently active and playful and does not appear to be in any distress.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	The mother stuck her finger down the back of her son's throat to induce vomiting, but no pill or pill fragments were seen in the vomitus.
c. Description of the patient's efforts to relieve the symptoms	n/a
d. Patient's identity	Jackson Smart
e. Patient's age, gender, height,	2 years, male, 34 in., 26 lb (12 kg)

and weight	
f. Patient's occupation	n/a
g. Patient's dietary habits	Normal
h. Patient's sleep habits	Sleeps approximately 12 hours a night and usually has a 1-hour nap at midday.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Healthy; takes no medications.
j. Allergies	No known allergies
k. History of other adverse reactions to medications	None
l. Description of other medications or products in the vicinity	No other medications or products present were identified by the patient's mother.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Acute unintentional ingestion of no more than 220 mg (18.3 mg/kg) of naproxen
3. Identify exclusions for self-treatment (Figure 21-2).	The mother is well known to the pharmacist, and child abuse is not suspected. Therefore, there are no exclusions for self-treatment.
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer the patient to a hospital emergency department for possible GI decontamination and further evaluation. (2) Contact the poison control center for recommendations. (3) Have the patient's mother administer an over-the-counter treatment to decrease drug absorption at home.

	(4) Have the patient's mother administer oral fluids to dilute the naproxen. (5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient or caregiver preferences.	Contact the poison control center for recommendations.
6. Describe the recommended therapeutic approach to the patient or caregiver.	The mother should be directed to call the poison control center at 800-222-1222.
	"The poison control center specialist can quickly assess the situation and determine whether it is safe to manage this situation at home or whether a trip to the emergency department is necessary. The maximum amount of naproxen that was available is 220 mg, or 18.3 mg/kg. This is likely below the threshold for referral for most poison control centers."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Naproxen may be irritating to the stomach. However, it is best to discuss this with the poisoning experts, who can quickly assess whether or not Jackson is likely to experience any adverse effects and tell you what to watch for."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Solicit follow-up questions from the patient or caregiver.	"I have activated charcoal at home. Should I give it to Jackson to be on the safe side?"
Answer the patient's or	"No—do not give activated charcoal unless directed by the

caregiver's questions.	poison control center. In many situations it is not necessary or may introduce other risks such as injury from vomiting."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	n/a

Key: GI = Gastrointestinal; n/a = not applicable.

Case 21-2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient is a 26-year-old man who brings 8 bottles of loperamide to the pharmacy register for purchase. When the pharmacist asks why he is buying so many bottles, the patient admits to using 300–400 mg of loperamide recreationally daily, to "get high." He took approximately 80 mg of loperamide 1 hour before coming to the pharmacy. He appears pale and shaky. He then complains of generalized weakness, dizziness, and nausea and asks about treatment options.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	On those days when he uses larger doses of loperamide (up to 600 mg), he sometimes feels worse. He mentions that occasionally he feels that he has a rapid heartbeat.

c. Description of the patient's efforts to relieve the symptoms	He states that he sometimes feels better lying down.
d. Patient's identity	Eric Jones
e. Patient's age, gender, height, and weight	26 years old, male, 6 ft 1 in., 201 lb (91.4 kg)
f. Patient's occupation	Construction worker
g. Patient's dietary habits	Normal
h. Patient's sleep habits	Sleeps approximately 6 hours a night.
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	Mr. Jones injured his back on the job several months ago; he initially was treated with acetaminophen/hydrocodone, then with ibuprofen. He no longer has a prescription for acetaminophen/hydrocodone. He uses an albuterol inhaler occasionally for exacerbations of asthma.
j. Allergies	No known allergies
k. History of other adverse reactions to medications	None
l. Description of other medications or products in the vicinity	No other medications or products are identified by the patient.
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Chronic misuse/abuse of dangerously high doses of loperamide for its psychoactive effects and possibly to alleviate opioid withdrawal subsequent to use of prescription opioids for back injury. It is possible that Mr. Jones's weakness, dizziness, and palpitations are due to dysrhythmias associated with high doses of loperamide.
3. Identify exclusions for self-treatment (Figure 21-2).	This is an abuse situation with possibility of life-threatening dysrhythmias, which is an exclusion for self-treatment.
4. Formulate a comprehensive list of therapeutic alternatives	Options include (1) Refer the patient to an emergency department for

for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	possible GI decontamination, ECG, and evaluation. (2) Contact the poison control center for recommendations. (3) Take the patient's blood pressure and pulse in the pharmacy and recommend a nonprescription product such as meclizine for nausea and dizziness. Recommend that he taper his use of loperamide. (4) Recommend oral fluids and refer the patient to a substance abuse counselor immediately. (5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Refer Mr. Jones to a hospital emergency department for evaluation and treatment.
6. Describe the recommended therapeutic approach to the patient or caregiver.	The pharmacist should inform Mr. Jones that he needs to be seen in the closest hospital emergency department immediately for evaluation and treatment.
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"You are using a toxic dose of loperamide and may be experiencing serious cardiac effects. It is not safe to treat you with an over-the-counter product. You must go immediately to the closest hospital emergency department."
Implement	
8. When recommending self-care with nonprescription medications and/or	Criterion does not apply in this case.

nondrug therapy, convey accurate information to the patient or caregiver.	
Solicit follow-up questions from the patient or caregiver.	"I would like to go home and lie down. If I don't feel better in a few hours, I'll go the emergency department. Is that okay?"
Answer the patient's or caregiver's questions.	"No—immediate evaluation is critical. I will call 911 for you now."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	n/a

Key: ECG = Electrocardiography; GI = gastrointestinal; n/a = not applicable.

Patient Counseling for Poisoning

With inhalation exposures, after patients are removed from toxic fumes, they should be advised about when to seek medical attention (e.g., for difficulty breathing or worsening or persistent symptoms). In the home or other nonindustrial setting, fumes often are soluble, irritant gases (e.g., chlorine), so clinical effects are evident immediately and usually resolve soon after exposure stops. Patients also should be counseled on the need for thorough ventilation of the room to disperse the vapor. If the exposure resulted from mixing products such as bleach and ammonia, counseling should include a warning never to use such household products in combination. If carbon monoxide exposure is suspected, the patient should be instructed to have the source turned off or removed (e.g., malfunctioning furnace, stove, vehicle). The poison control center should be contacted to assess the severity and expected duration of clinical effects in symptomatic patients and the possibility of delayed onset in asymptomatic patients. Home carbon monoxide detectors are important home safety devices, and homeowners should be encouraged to install them to prevent or minimize carbon monoxide exposures.

With eye exposures, the patient should be counseled on how to irrigate the eye at home under the faucet. Contact lenses should be removed before irrigation. Instructions should include running the water at room temperature and at a low pressure. Irrigating the eyes in the shower or using a clean cup to pour water into the eyes may be an easier alternative in children. Placing a damp washcloth on the eye or irrigating with small-volume nonprescription eyewashes is ineffective. Finally, eye drops, including topical vasoconstrictors, should *not* be used after irrigation.

With skin exposures, the patient should be counseled to remove clothing in contact with involved skin, if necessary, and to wash affected areas thoroughly. With both eye and skin exposures, the importance of immediate irrigation and washing of the affected area, as appropriate, should be emphasized.

If the regional poison control center recommends activated charcoal for home use, pharmacies in that area should stock the appropriate product, and pharmacists should educate parents that activated charcoal should never be used without first consulting a poison control center staff member. Patients who purchase activated charcoal for immediate use on the recommendation of a poison control center should receive adequate counseling about this treatment to ensure appropriate use of the product, including instructions on preparation (depending on the formulation). The pharmacist also should explain potential adverse effects, as well as signs and symptoms that indicate the need to seek medical attention.

Counseling older adults on self-managing their medications can prevent poisonings and adverse drug reactions. Polypharmacy may place older adults at risk for errors relating to dose, dosage regimen, and possibly administration techniques. Educating these patients about the potential for interactions, including drug–drug, drug–food, and drug–alcohol, is important. They should be reminded to seek advice from an appropriate health care provider before mixing nonprescription or herbal products with prescription medications. Counseling older adults also should emphasize the importance of ongoing communication with their providers to ensure both efficacy and safety of their medication regimen.

Patients who are taking multiple prescriptions and using a regular “pill minder” should be advised to purchase a locking version if they are around young children. When loading the device, they should place a sheet of paper or cardboard underneath it to catch stray tablets or capsules that might

otherwise fall on the floor. Pharmacists also can prevent therapeutic 10-fold error types of poisonings by always dispensing 1 mL oral syringes for prescription medications that are dosed in infants at less than 1 mL, such as metoclopramide. The box “Patient Education for Toxic Exposures” lists specific information to provide in counseling parents, caregivers, or patients.

Counseling should include providing the nationwide toll-free number for the area-specific poison control center (Figure 21–1) and promoting poisoning prevention practices, including purchase of nonprescription drugs and household products with child-resistant packaging. However, caregivers should be reminded that child-*resistant* is not child-*proof*, even products with CRCs should be stored well out of reach and view of small children and preferably in a locked cabinet. The Up and Away campaign (www.upandaway.org) is a child safety initiative developed by PROTECT (Preventing Overdoses and Treatment Errors in Children Taskforce), a public–private collaboration, in partnership with the Centers for Disease Control and Prevention.

Evaluation of Patient Outcomes for Poisoning

Patients who have inhaled potentially toxic fumes or spilled or splashed a substance on their skin or in their eyes should be reassessed for symptoms after removal to fresh air or irrigation of the affected area. If clinical effects are minimal and resolve within a relatively short period (e.g., <30 minutes), the patient may be observed at home. If symptoms persist or worsen, the patient should be referred to a health care provider or an emergency department, depending on the severity of symptoms and apparent immediacy of need for medical evaluation. The poison control center can facilitate the referral to the appropriate health care facility and provide treatment recommendations to the health care provider.

Patients who receive activated charcoal, or their caregivers, should be contacted afterward at least once to determine whether any symptoms related to the exposure have developed. The timing of the call depends on what substance was ingested, how rapidly it is absorbed, and when emergence of symptoms would be anticipated. If clinical effects develop and are minor, the patient may be observed at home. If more significant effects develop, the patient should be referred to an emergency department for

treatment. If the poison control center recommended self-treatment with activated charcoal, the center staff should remain involved in subsequent decisions regarding the appropriateness of continued at-home treatment for the patient.

Patient Education for Toxic Exposures

The objectives of self-treatment are (1) to minimize exposure and reduce development of toxicity by removing the patient to fresh air, irrigating the skin or eyes, or preventing absorption of potentially toxic agents in the gastrointestinal (GI) tract and (2) to manage patients with minimally toxic ingestions at home under the supervision of a poison control center. With most toxic exposures, carefully following the self-care measures listed here will help ensure optimal therapeutic outcomes.

Treatment

- For eye exposures, immediately irrigate with water for 10–15 minutes.
- For skin exposures, immediately wash with soap and water.
- For inhalation exposures, immediately remove the patient to fresh air.

When to Seek Medical Attention

- Referral to a hospital emergency department by contacting 911 directly is appropriate if the patient
 - Is lethargic or comatose or is having convulsions or hallucinations
 - Has decreased respirations or is having difficulty breathing
 - Has abnormal blood pressure or pulse
 - Has taken medications that may produce a rapid decline in consciousness or convulsions

Key Points for Poisoning

- Poison exposures are a common cause of pediatric and adult injury.
- Persons who purposely misuse, abuse, or use medications as a means of self-harm are not candidates for self-care and should be referred for medical care on an urgent basis.
- All patients who exhibit potentially life-threatening clinical effects (e.g., seizures, coma) should be referred to a hospital emergency department through the emergency 911 system.
- Medication errors are a common cause of drug-related toxicity, especially in persons at the extremes of age (infants and older adults).
- Minimizing the duration or limiting the extent of the exposure is the rationale for most self-treatment practices.
- No evidence has emerged showing that self-treatment for poisoning with activated charcoal improves patient outcomes. This treatment should be used only on recommendation of a poison control center.
- Self-treatment should be considered only for unintentional poison exposures that are likely to cause no or minimal toxicity—that is, no serious or life-threatening symptoms ([Figure 21-2](#)).
- The health care provider should consult with the poison control center for guidance on patient assessment and on decisions for the appropriateness of self-treatment.
- Direct referral to a poison control center should be considered for complicated cases, including those in which the patient history is unclear or specific product or toxin information is lacking, and to ensure patient follow-up.

Chapter 22: Ostomy Care and Supplies

Authors: Sharon Wilson, Janice C. Colwell

An *ostomy* is an opening or outlet through the abdominal wall created surgically for the purpose of eliminating waste. The ostomy usually is made by bringing a portion of the bladder, colon, small intestine, or ureter out through the abdominal wall. This abdominal opening is called the *stoma* (the Greek word for “mouth”).

The establishment of an ostomy, temporary or permanent, to replace normal elimination anatomy may be a dramatic, life-changing event. The health care provider is a crucial resource for the reassurance, support, and education needed by the patient and family. Understanding improvements in surgical procedures, ostomy supplies, and outcomes can help allay the patient’s fear and anxiety. The goal in ostomy care is to enable resumption of the previous lifestyle as much as possible—to be a person, not a patient. In encounters with providers, the person with an ostomy will notice their reaction to the presence of the stoma. Any negative response—even unconscious signals such as a hurried interaction or avoidance of eye contact—may contribute to the patient’s difficulties with altered self-image related to the ostomy, so special care should be taken to convey acceptance and knowledgeability about various aspects of stoma management.

More than 725,000 to 1 million Americans are currently living with an ostomy.¹ Ostomy surgery is performed in people of all ages and for many conditions, both acquired and congenital. When medically advisable, the current trend is laparoscopic surgery, a type of minimally invasive surgery that uses smaller-scale instruments, placed through minor incisions, with the assistance of video camera technology. Patients report experiencing less pain, quicker recovery, and less scarring than with traditional ostomy surgery.

Indications for Ostomies

Ostomies may be permanent or temporary, and ostomy surgery is performed in all age groups, ranging from neonates to older adults. Reasons for needing an ostomy include congenital anomalies (e.g., imperforate anus, Hirschsprung

disease), inflammatory bowel disease (i.e., ulcerative colitis and Crohn's disease), familial polyposis, cancer, radiation damage, pressure injuries, trauma, and any other conditions necessitating diversion of the urinary or fecal stream.²⁻⁴ The type of ostomy depends on the underlying disorder or condition being treated.

The two most common disorders leading to *ileostomy* surgery are (1) ulcerative colitis, which affects the large intestine and rectum, and (2) Crohn's disease, which may involve any part of the gastrointestinal (GI) tract. Other conditions that may result in need for an ileostomy are traumatic injury, cancer, familial polyposis, and necrotizing enterocolitis.

The most common reasons for *colostomy* surgery are (1) cancer of the colon or rectum, (2) diverticulitis, and (3) traumatic injury. Other indications are obstruction of the colon or rectum, genetic malformation, radiation colitis, and fecal incontinence. In some cases, a temporary colostomy may be placed to protect areas of the colon that have been surgically repaired. Healing of diseased or damaged bowel may take several weeks, months, or years, but eventually the colon and the rectum are reconnected and bowel continuity is restored. [Figure 22-1](#) shows the location of various types of colostomies.

Figure 22–1 Anatomic drawing of the lower digestive and urinary tracts depicting location and permanence of colostomies. (Source: Adapted with permission from *Am J Nurs.* 1977;77:443.)

Urinary diversions, or *urostomies*, are created to correct bladder dysfunction or to restore functionality after bladder loss, which can be secondary to cancer, neurogenic bladder, genetic malformation, or interstitial cystitis.

Types of Ostomies

The three basic types of ostomies are (1) ileostomy, (2) colostomy (the most common type), and (3) urostomy (see [Color Plates](#), photographs 6A–I). Each type has several variations, depending on the location of the stoma, the reason for the surgical procedure, or whether the procedure will maintain urinary or fecal continence.

Ileostomy

An ileostomy is surgically created by bringing a portion of the ileum through the abdominal wall (see [Color Plates](#), photograph 6A). Initially, the discharge is liquid, but as the ileum adapts, it assumes some of the absorptive functions of the colon and the discharge may become semisoft. The discharge is continuous and contains digestive enzymes that may irritate the peristomal skin.

Several types of continent ileostomies have been devised (see [Color Plates](#), photograph 6B). Typically, an internal pouch is created from the ileum, and an intussusception (a slipping of a length of intestine within an adjacent portion) of the bowel is used to create a “nipple” that renders the patient continent for stool and flatus. The pouch is periodically emptied by inserting a catheter through the nipple, which is attached to the skin usually in the right lower abdominal quadrant, into the pouch. At first, the pouch holds approximately 75 mL, but it stretches with use, so that at 6 months postoperatively, it may hold 600–800 mL and can be drained 3–5 times daily. Patients do not need to wear an external pouching system, but they often use a gauze pad or stoma cap over the opening.

The restorative proctocolectomy (S pouch or J pouch, named for the resulting

anatomic configuration) with ileoanal reservoir spares the rectum in patients with ulcerative colitis or familial polyposis. The colon is removed and the diseased mucosa is stripped from the rectum, and an internal pouch is created from the ileum. The distal end of the small intestine is stapled or hand sewn to the remaining rectal tissue. The sphincter is preserved, and ostomy pouching systems are unnecessary. However, a patient undergoing this procedure may have a temporary stoma (for approximately 3–6 months) placed to protect the healing pouch. After ileoanal reservoir surgery, bowel movements will be more frequent, and the patient may experience perianal skin irritation.

Colostomy

A colostomy is created by bringing a portion of the colon through the abdominal wall. The discharge may be semisoft, paste-like, or formed, depending on the portion of bowel used ([Figure 22-1](#)).

Ascending colostomies are uncommon. The ascending colon is retained, but the rest of the large bowel is removed or bypassed (see [Color Plates](#), photograph 6C). The stoma usually is placed on the right side of the abdomen. The discharge is similar to that with an ileostomy—semisoft—and a pouch must be worn at all times.

The *transverse* colon is the site of most temporary colostomies ([Figure 22-1](#)). A loop of the transverse colon is lifted through the abdominal incision, and a rod or bridge (which is removed within 1–2 weeks) is placed under the loop to give it support while the stoma heals. The discharge usually is semiliquid or very soft and contains digestive enzymes.

Loop colostomies have one large opening but two tracts (see [Color Plates](#), photograph 6D). The proximal tract discharges fecal material, and the distal tract secretes small amounts of mucus. A pouching system must be worn at all times. A person with a loop colostomy also may pass a minimal amount of stool or mucus through the rectum as a normal occurrence.

For a *double-barrel transverse* colostomy, the bowel is completely divided by bringing both the proximal end and the distal end through the abdominal wall and then suturing them to the skin (see [Color Plates](#), photograph 6E). The distal stoma also may be called the mucous fistula.

Descending and *sigmoid* colostomies are fairly common; generally the stoma

is placed on the left side of the abdomen (see [Color Plates](#), photograph 6F). The fecal discharge has a paste-like consistency and at times may consist of formed stool. This type of colostomy may be regulated by irrigation; therefore, a pouching system may or may not be needed. However, many patients prefer a pouch to irrigation. Not everyone with a descending or sigmoid colostomy is a good candidate for irrigation or prefers irrigation. Factors to consider in making the decision to irrigate include the presence or absence of stomal complications and the patient's normal stooling pattern, psychomotor ability, and willingness to commit the time required to properly irrigate the ostomy.

Urinary Diversions

Urinary diversion surgery creates an alternative route for discharge of urine through an opening in the abdominal wall. Urinary stomas should function immediately after surgery. The broad term for a urinary diversion is *urostomy*.

The *ileal conduit* is the most common type of urinary diversion (see [Color Plates](#), photograph 6G). After the bladder is removed, ileal or colon conduits are created by implanting the ureters into an isolated loop of bowel; one end of the bowel loop is sutured, and the distal end is brought to the surface of the abdomen. The stoma looks similar to an ileostomy or colostomy stoma. A pouching system must be worn continuously. Mucous shreds will be present in the urine when the small intestine or the large intestine is used to create the diversion (see [Color Plates](#), photograph 6H). Because the ileum is used to create an ileal conduit, some people incorrectly refer to the ileal conduit as an ileostomy. Clarification of the type of effluent (stool or urine) will help in selecting the correct type of pouch.

In a *ureterostomy*, one or both ureters are detached from the bladder and brought to the outside of the abdominal wall, where a stoma is created. This procedure is used less frequently because the ureters tend to narrow unless they have been dilated permanently because of previous disease (see [Color Plates](#), photograph 6I).

A *cystostomy* is performed when blockage or narrowing of the urethra occurs. Urine is diverted from the bladder to the abdominal wall. A pouch must be worn continuously. An infant with a cystostomy may wear diapers instead of a pouch.

The *continent urinary diversion* is available for selected patients, but its use requires that certain criteria be met. An Indiana pouch is a type of continent urostomy in which a reservoir is created from part of the cecum and ileum, with a portion of the ileum brought through the abdominal wall to create a stoma. The ureters are attached to the cecum pouch. The remaining ileum is reattached to the colon for normal digestive flow. The ileocecal valve is left intact and becomes part of the continence mechanism, preventing urine from exiting the pouch. The internal pouch is emptied by inserting a catheter into the stoma to drain the urine. Patients usually follow a strict schedule for catheterizing the stoma often enough to avoid leakage. The new pouch may hold up to 600 mL of urine. An external pouching system is not necessary. Most patients wear a gauze pad or stoma cap.

The *orthotopic neobladder* is a rebuilt bladder. The small intestine is used to create a pouch, and the pouch is then attached to the native urethra. This procedure allows patients to void using the urethra, but voiding relies on use of the abdominal muscles to empty the neobladder.

Algorithm: Selection of Ostomy Pouching System

Figure 22–2 Selection of ostomy pouching system. Key: WOC = Wound, ostomy, and continence.

Management of Ostomies

Management Goals

The ideal pouching system should maintain a seal for a predictable amount of time (average wear time is 3–4 days) and protect the peristomal skin. All pouches are odor proof and are available with a variety of features such as opaque versus clear, drainable versus closed-end, and so on. The pouching system collects the stoma output until it is convenient for the person with the ostomy to empty or remove the pouch. The goal is to have no leakage (with a secure seal) and to maintain the peristomal skin. If the peristomal skin becomes irritated, achieving a good seal on the pouching system is very difficult, potentially resulting in leakage and pain around the stoma, with consequent distress to the patient.

The ostomy industry is highly specialized and rapidly changing as researchers and manufacturers try to improve designs, resulting in a wide range of choices. Pouch selection is based upon the type of stoma, its location on the abdomen, the peristomal skin contours, and the patient's self-management abilities.

General Management Approach

Patients and/or their caregivers should be taught self-care skills to manage the ostomy, including (1) sizing the stoma, (2) cutting a skin barrier to fit the stoma (or selecting a precut pouch or barrier), (3) cleaning the peristomal skin, (4) choosing and using accessory products, (5) applying the pouch, (6) removing the pouch, and (7) emptying the pouch.

Patients are most likely to achieve optimal outcomes if the pouching system is properly fitted ([Figure 22–2](#)) and if the stoma is cared for appropriately. In interactions with persons with an ostomy, the health care provider should always be aware of the sensitive nature of the topic and ensure that privacy is respected during all encounters. Lack of a comfortable environment in which to discuss problems, concerns, and alternatives may induce patients to avoid such discussions, with less-than-optimal outcomes. Follow-up assessment and care may be accomplished through a telephone call or scheduled appointment or during the patient's routine pharmacy visits to purchase supplies or medications.

As noted, the pouching system should remain in place for a predictable period of time, usually at least 3 days. Frequent changes of the pouching system may signal a potential problem. In many cases, patients may be referred to an appropriate primary care provider or a wound, ostomy, and continence (WOC) nurse specialist for follow-up evaluation and treatment of problems identified by the initial health care provider. Problems such as inability to maintain a pouch seal for a predictable amount of time or development of a peristomal hernia, stenosis, prolapse, retraction, or peristomal skin injury warrant referral.

The presence of an ostomy and its location in the GI or urinary system should always be noted in the patient's profile, to minimize medication-related risks. It is helpful to maintain a record of current and past ostomy products with order numbers that the patient has used and any problems that the patient has experienced. This information can be helpful in making future recommendations or to assist in problem solving.

Types of Ostomy Pouching Systems

A large variety of pouching systems are available, and the choice of a pouching system will depend upon the size and shape of the stoma, the location of the stoma opening, the type of effluent from the stoma (urine, pasty or liquid stool), the contours of the peristomal skin, and patient preferences and abilities.

The components of a pouching system include a skin barrier, which provides the skin protection and adhesive seal, and the pouch. and are available in a one- or two-piece system (Figure 22–3). With a one-piece system, the skin barrier and the pouch are nondetachable from each other; with a two-piece system, the skin barrier is separate from the pouch, and the pouch is attached to the skin barrier by an adhesive or flange coupling system.

Figure 22–3 Sample ostomy appliances: A: Coloplast SenSura Mio urostomy pouch; B: Coloplast SenSura Mio drainable pouch; C: Coloplast SenSura Mio closed-end pouch; D–F: Hollister New Image two-piece pouching system with Lock’n Roll closure, flange and pouch views, respectively. (Source: A–C reprinted with permission from Coloplast, Minneapolis, MN; D–F reprinted with permission from Hollister Incorporated, Libertyville, IL.)

Both one- and two-piece pouching systems are available in drainable, closed-end, and urostomy styles. Drainable pouches allow the user to open the end of the pouch to empty the contents into the toilet. A closed-end system requires the wearer to remove and discard the pouch when about 3/4 full. Closed-end systems can be used by patients who have one or two formed bowel movements within 24 hours, or who routinely irrigate the ostomy to remove output. Most insurers will reimburse the user for two closed-end pouches per day. Urostomy systems allow easy emptying throughout the day through a valve at the bottom of the pouch. At night, most urostomy patients connect their pouch to dependent drainage, to prevent overfilling of the pouch.

Fit and Application

The fit of the pouching system is critical to ensure peristomal skin protection and a secure seal. The stoma is measured at the skin stoma junction to ensure that all of the skin is protected. If the stoma is round, the opening in the pouching system also will need to be round; if the stoma shape is other than round, the opening should be cut (or in some cases molded) to the typically oval shape.

The shape of the skin barrier also is a decision point for choosing a pouching system. Skin barriers are available in flat or convex. When the patient is fitted for a skin barrier, the area around the stoma is assessed in sitting, standing, and reclining positions; in each position, the skin barrier should be a mirror image of the peristomal skin contours. If the area around the stoma is flat in all positions, the skin barrier chosen will be flat; if the area around the stoma is concave, the skin barrier of choice will be convex. Another consideration in choosing the shape of the skin barrier is the protrusion of the stoma: If the stoma does not have adequate protrusion above the skin, a convex barrier may help achieve a secure seal, as the convexity can help apply light pressure to allow the stoma to protrude into the pouching system.

Pouch options include clear versus opaque, length (in a range of 7–16 inches), various types of closures, presence or absence of a gas filter, and drainable versus nondrainable (closed-end). The choice of pouch depends upon patient preference (with recognition that the skin barrier is the portion of the pouching system that provides security and peristomal skin protection) and may be dictated by the volume of stoma output (the shorter the pouch length, the more often it may need to be emptied), requirement for visibility of the

stoma effluent to determine when or whether to empty/change the pouch, and level of daily activity of the person with the ostomy.

Directly after surgery, a cut-to-fit pouch maybe used until the stoma heals, because the stoma will shrink as the postoperative edema lessens.

Immediately after surgery, the patient is learning self-care and moving toward adjustment. On becoming more comfortable with how to manage the stoma, the person will participate in making choices about the best pouching system. A WOC nurse is an excellent source of assistance in custom-fitting pouching systems.

Wear Time

Wear time for the pouching system is determined by the integrity of the skin barrier. The skin barrier is constructed from a material called a *hydrocolloid*. The hydrocolloid softens in the presence of moisture. As softening occurs, less functional adhesive is available to secure the seal. A person with a high liquid output or very moist skin (as from heavy perspiration) may find that the skin barrier must be changed in 3–4 days. A person with solid to semisolid stool may be able to wear the skin barrier longer than 4 days. Patients are taught to inspect the back of the skin barrier upon removal. On observation, if the opening in the skin barrier is significantly larger than it was on application, this may be a sign that erosion of the seal has occurred, which could allow the stoma effluent to make contact with the skin, with consequent leakage and skin irritation. Although activities such as swimming or playing tennis may decrease the wear time of the pouch, this decreased time should not discourage participation in physical activities. More recently developed pouch adhesives can effectively keep the system in place during these activities.

Product Selection Guidelines

The selection of products should be customized to achieve best care for the patient's stoma and peristomal area. For instance, some systems require manipulation that a patient with arthritis may not be able to perform. Patients may have other special needs, such as those related to visual impairment or, conversely, to expectations for participation in high levels of physical activity in water sports. Ostomy Accessories

Belts

Some pouching systems have belt tabs, which allow attachment of a belt for additional support. Indications for the use of a belt may be a convex flange, as the belt can help to press the adhesive to the skin; high activity level (e.g., running), for which the belt will provide better adherence; and personal preference. Some patients may find that wearing a belt for just a few hours after pouch application helps to enhance the seal, decreasing the risk of subsequent leakage.

Skin Barrier Rings, Powder, Paste, Barrier Strips

Skin barrier rings, powder, paste, and barrier strips are accessories that can be used to enhance the pouching system seal and manage peristomal skin complications ([Table 22-2](#)). Skin barrier rings can be used to provide a seal around the stoma in patients with a fecal stoma and increase wear time. Skin barrier powder is a hydrocolloid that can dry moist peristomal skin, support healing, and enhance the seal in problematic situations involving denuded peristomal skin. Skin barrier powder is applied to the irritated skin and gently rubbed in, and the excess is brushed off. Leaving loose powder on the skin may interfere with the pouching system adhesive seal. A liquid skin barrier can be used to seal the powder. Skin barrier paste (again a hydrocolloid) can be used to fill a crease on the peristomal skin or to caulk the inner opening of the skin barrier on the pouching system, to secure the seal. Skin barrier strips can be placed on the outer seal, to secure the edges of the pouch.

Table 22-2 Ostomy Products With Selected Manufacturer Examples

Product	Example(s) of Manufacturer Products With Purpose/Use
Pouch deodorant	Hollister Adapt Lubricating Deodorant, Brava Lubricating Deodorant
	<i>Also facilitates emptying of pouch by providing lubrication in the pouch.</i>
	Hollister M9 Drops
	<i>Placed in pouch to neutralize odor.</i>
Liquid skin barrier	ConvaTec Sting Free Barrier Wipes, Smith and Nephew No Sting Barrier Wipes
	<i>Place on skin for protection or to seal skin barrier powder.</i>
Barrier rings	Coloplast Brava Protective Seals, Eakin Cohesive Seals, Hollister Adapt rings
	<i>Hydrocolloid rings stretched to fit around stoma for peristomal skin protection.</i>
Adhesive remover	Sensicare Sting Free Remover wipes, Adapt Universal Remover wipes
	<i>Removes residual adhesive from peristomal skin, facilitates pouch removal.</i>
Adhesive releaser	Sensicare Sting Free Adhesive Spray Releaser, Adapt Medical Adhesive Remover Spray
	<i>Used to release the pouch seal from the skin.</i>
Skin barrier paste	Stomahesive Paste, Brava Paste
	<i>Used to caulk edge of skin barrier also to fill in uneven areas.</i>
Skin barrier powder	Brava Ostomy Powder, Adapt Powder
	<i>Used to dry an injured skin surface.</i>
Barrier strips	Brava Elastic Barrier Strips, Adapt Barrier Extenders
	<i>Used to secure outer seal of pouching system.</i>
Osto-EZ-Vent	<i>Quickly and easily releases gas buildup in ostomy pouches.</i>
Hernia support	Brava Ostomy Support Belt, NuHope Hernia Support Belt, Security Hernia/

Product	Example(s) of Manufacturer Products With Purpose/Use
belts	Ostomy Support Belt
	<i>Provides support of peristomal hernia.</i>

Absorbent Gel Packets and Flakes

Absorbent gel packets and flakes placed in the pouch (e.g., Ileosorb, Par-Sorb) dissolve as the pouch fills, turning the liquid effluent into a gel. The use of these products can reduce noise caused by sloshing of stomal fluids, control odor, avert development of peristomal skin irritation, and prevent leakage, especially at night while the patient sleeps.

Cleansing and Special Skin Care Products

Cleansing of the stoma and surrounding skin is best done with plain water. If soap is used, it should be rinsed off thoroughly, and the skin should be dried before a new pouching system is applied. Use of moisturizers and products containing lanolin, petrolatum, or oils should be avoided because they prevent the pouching system from adhering to the skin.

Adhesive Removers and Releasers

The seal of the pouching system is created from hydrocolloids, and with erosion over time, hydrocolloid remnants can build up on the skin. Excessive adhesive on the skin also can prevent a good seal, and many people with an ostomy use nongreasy (usually silicone-based) adhesive removers to clean the peristomal skin. Adhesive releasers in spray or wipe form can be used to remove the pouch from the skin to prevent medical related adhesive skin damage.

Irrigation Kits

Irrigation is a method that can be used to maintain control of output in patients with colostomies. Irrigation is similar to performing an enema at the site of the stoma. The patient who has a left-sided (sigmoid or descending) stoma with no other bowel disease may be a candidate for irrigation. Because the goal of this management approach is no release of fecal material between

irrigation procedures, only patients with semisolid stools are candidates for irrigation. Using an irrigation kit (a bag with tubing that features a soft rubber cone), approximately 1000 mL of lukewarm tap water is instilled into the bowel through the cone inserted in the stoma. The bowel expands, causing peristalsis, with subsequent elimination of waste through the stoma.

Frequency of irrigation depends on the patient's normal bowel habits. The recommended approach is to irrigate at the same time every day and eventually to irrigate every other day. Establishing the irrigation regimen takes approximately 6 weeks. After achieving good control, the patient may wear a security pouch (in case stool or gas is discharged between irrigations). Elimination by irrigation is not necessary for health; it is merely one method of colostomy management. Patients who choose this procedure should be instructed in technique by a WOC nurse or their primary care provider.

Deodorizers

All pouching systems are odor proof; however, if the person with an ostomy notes odor even with the end of the pouch closed, the source of the odor may be leakage under the pouch seal. However, emptying a fecal pouch also will release odor from the effluent, and an important management concern for many people with an ostomy is to reduce this odor. Any of a variety of in-pouch deodorants, typically drops, can be placed into the pouch via the bottom. Most such products work by neutralizing the odor of the stool. When the pouch is emptied, the deodorant is also emptied, so more deodorant must be placed afterward. DevKo external tablets also may be placed into the pouch to decrease odor. Derifil internal deodorant tablets (active ingredient is 100 mg chlorophyllin copper complex sodium) may also be used. Of note, the purpose of such deodorizers is only to lessen odor during pouch emptying; no odor should be detectable when the pouch is on and adequately sealed.

Changes in Diet

Diet does not generally play an important role in ostomy management. Most patients can eat their usual diet, including all of the foods they ate before surgery if they chew everything well. A diet low in fiber is advisable for the first 6 weeks after surgery, however, to allow the intestine to heal and the swelling to resolve. The usual diet can be resumed after that time.

The effects of various foods on ostomy output are summarized in [Table 22–3](#). Patients with a urostomy may want to avoid foods that cause urine odor. Patients with colostomies, especially those who irrigate, should avoid foods that can cause loose stools. (This problem varies among individual patients.) Because they have no control over passage of gas, patients with a fecal ostomy may prefer to reduce their intake of gas-forming foods. Products such as alpha-D-galactosidase may be used to limit gas formation (see [Chapter 14](#)). Patients with ileostomies are more prone to intestinal obstruction from high-fiber foods eaten in large quantities or eaten exclusive of other foods ([Table 22–4](#)).^{5,6} Thoroughly chewing high-fiber foods and eating them in small amounts and with other types of food will help prevent food blockage. The patient should be instructed on how to manage a food blockage. [Table 22–5](#) lists signs and symptoms of blockage; [Table 22–6](#) summarizes its management.

Table 22–3 Effects of Foods on Stoma Output
Foods That Thicken Stool
Applesauce; bananas; bread; buttermilk; cheese; marshmallows; milk; pasta, boiled; peanut butter, creamy; potatoes; pretzels; rice; tapioca; toast; yogurt
Foods That Loosen Stool
Beer and other alcoholic beverages; chocolate; dried or string beans; fried foods; greasy foods; highly spiced foods; leafy green vegetables (lettuce, broccoli, spinach); prune or grape juice; raw fruits (except bananas); raw vegetables, fruit juices, milk
Foods That May Cause Stool Odor
Asparagus; beans; cabbage family vegetables (cabbage, Brussels sprouts, broccoli, cauliflower); cheese; eggs; fish; garlic; onions; some spices; turnips
Foods That May Cause Urine Odor
Asparagus; seafood; some spices
Foods That Combat Urine Odor
Buttermilk; cranberry juice; yogurt
Foods That Cause Gas
Beans (dried, string, or baked); apples; beer; cabbage family vegetables (cabbage, Brussels sprouts,

broccoli, cauliflower, kale); carbonated beverages; corn; cucumbers; dairy products; mushrooms; onions; peas; radishes; spinach; spicy foods

Foods That Color Stool

Beets; berries; chocolate; fats; fish; meat (large amounts of red meat); milk; red gelatin; vegetables; popsicles; licorice

Partial Obstruction	Complete Obstruction
Watery output with foul odor	Absence of output (urine and fecal)
Cramping abdominal pain	Severe cramping pain
Abdominal distention (possible)	Abdominal distention
Stomal swelling (possible)	Stomal swelling
Nausea and vomiting (possible)	Nausea and vomiting
	Decreased pulse rate

Source: References 5 and 6.

Table 22-6 Conservative Management of Food Blockage

1. Sit in warm tub bath to relax abdominal muscles.
2. Massage the peristomal area while in the knee-to-chest position to attempt dislodgement of fibrous mass.
3. If stoma is swollen, remove pouch and replace with a pouch that has a larger stoma opening.
4. If able to tolerate fluids (i.e., not vomiting) and passing stool, increase intake of fluid and electrolytes, but avoid solid foods. Drink 1 glass of liquid each time pouch is emptied. Juices such as grape juice exert a mild cathartic effect.
5. If vomiting, not passing stool, or both, do not take liquids or solid food orally and seek medical attention.
6. Notify a primary care provider or wound, ostomy, and continence nurse if any of the following is noted:
 - Stool output stops (indicating complete blockage).
 - Conservative measures (listed above) fail to resolve symptoms.
 - Signs of partial obstruction persist ([Table 22-5](#)).
 - Inability to tolerate fluids or replacement fluids and electrolytes becomes evident.
 - Signs and symptoms of fluid and electrolyte imbalance ([Table 22-7](#)) develop.

Source: Reference 5.

Complications of Ostomies

Persons with ostomies may experience both psychological and physical complications. The health care provider should be prepared to address these complications or to refer patients to their primary care provider or to a WOC nurse. These nurse specialists often are based in hospitals, clinics, or home health care agencies. The United Ostomy Associations of America is an organization that provides peer support for patients. Before surgery, patients should receive a thorough explanation that describes what procedure will be performed, what to expect during the postsurgical recovery period, and what pouching and supplies will be used and the proposed stoma site marking.

Psychological Complications

Some patients anticipating ostomy surgery fear that they will not be able to continue their former job, participate in sports, perform sexually, or have children. These patients need reassurance that an ostomy rarely impairs the ability to carry out such activities. Contacting the local United Ostomy Associations of America is of utmost importance in assisting with the rehabilitation of these patients; both providers and patients are encouraged to utilize the support of this organization. Patients also may wish to find a local WOC nurse. Before and after ostomy surgery, appropriate education and counseling on ostomy care will provide needed information and support. Literature is available from all of the major ostomy product manufacturers, the United Ostomy Associations of America, and the American College of Surgeons. If postoperatively the patient would benefit from contacting a mental health specialist, a referral to a clinician with experience in living with an ostomy is recommended.

Physiologic Complications

The major physiologic consequence of a GI ostomy is fluid and electrolyte imbalance. Such disturbances are most problematic in patients with a liquid or semisoft stoma discharge, such as with ileostomy and ascending or transverse colostomy. Patients with these types of ostomies must maintain adequate fluid intake to compensate for loss of the absorptive function of the colon and for absence of ileocecal valve function. Patients with ileostomies lose approximately 500–1000 mL of fluid daily through the stoma, whereas those with a normally functioning colon lose 100–200 mL daily.³ During common illnesses, patients with ileostomies, especially infants, are particularly vulnerable to fluid and electrolyte imbalance caused by vomiting and diarrhea.

Caregivers and patients should be educated about common signs and symptoms of a fluid and electrolyte imbalance ([Table 22–7](#)).^{5,6}

Table 22–7 Signs and Symptoms of Fluid and Electrolyte Imbalance	
Adults	Infants
Increased thirst	Depressed fontanel
Dry mouth and mucous membranes	Lethargy
Orthostatic hypotension	Sunken eyes
Decreased urine volume	Weak cry
Increased urine concentration (dark in color)	Decreased frequency of wet diapers
Sunken eyes	Increased urine concentration (dark in color)
Extreme weakness	
Flaccid muscles	
Diminished reflexes	
Muscle cramps (abdominal and leg)	
Lethargy	
Tingling or cramping in feet and hands	
Confusion	
Nausea and vomiting	
Shortness of breath	

Source: References 5 and 6.

Because the GI tract is the site of nutrient absorption, some patients with ostomies may experience deficiencies owing to postsurgical changes in gut anatomy. For example, iron and vitamins D₂ and D₃ are absorbed in the small intestine; riboflavin is absorbed in the upper GI tract; vitamin B₁₂ is absorbed in

the terminal ileum; phytonadione is absorbed in the proximal small intestine; menadione is absorbed in the distal small intestine; and calcium, pyridoxine, pantothenic acid, biotin, choline, inositol, carnitine, vitamins C and E, and thiamine (vitamin B₁) are absorbed in various sites within the intestinal tract (specific sites have not been identified). Vitamin A deficiency may be seen in persons with disease of the terminal ileum (e.g., Crohn's disease).

Hypophosphatemia and hypomagnesemia are seen in people with calcium deficiency caused by malabsorption. In addition, copper deficiency, which interferes with the absorption of iron, has been reported in patients who have undergone intestinal bypass surgery. Folic acid absorption requires interaction with enzymes present in the upper part of the jejunum; therefore, absorption of folic acid takes place predominantly in the proximal part of the small intestine.⁷⁻⁹

The effect of ostomy surgery on absorption of vitamins and minerals has not been well studied; however, patients with ileostomies or colostomies should be monitored for signs and symptoms of deficiencies.

Patients with a urostomy, an ileostomy, or an ascending colostomy require adequate daily intake of fluid to prevent the precipitation of crystals or kidney stones in the urine. In addition, they may be at increased risk for gallbladder stone formation. Patients with a urostomy should adjust their diet to produce acidic urine, thereby reducing the risk of infection and crystal formation around the stoma. Cranberry products have been studied in the prevention of recurrent urinary tract infections. However, sufficient evidence to support its use in all patient populations is conflicting across various studies.¹⁰⁻¹³

Considerations in evaluating these studies include patient population, product used (especially the percentage of the active ingredient), drug-drug interactions, recurrent infections versus prophylaxis, and trial methodology.

Systemic Complications

Constipation is caused by the regular use of opioid-containing analgesics or may be a result of the patient's eating habits (e.g., insufficient dietary fiber, fluid intake). Constipation may be a problem in patients with descending and sigmoid colostomies. Treatment depends on the cause and may include dietary changes or medication adjustment. Patients experiencing problems with constipation should be encouraged to avoid the foods listed in [Table 22-3](#) that can thicken the stool.^{5,6}

Certain foods can cause diarrhea in ostomy patients ([Table 22–3](#)).^{5,6} Gut pathology (e.g., ulcerative colitis, Crohn’s disease, *Clostridioides difficile* colitis), or obstruction caused by a food bolus also can cause diarrhea. Medications, influenza, and food poisoning are other potential causes. Diarrhea is a special problem in patients with ileostomies and ascending colostomies because the associated bowel changes cause impaired fluid and electrolyte reabsorption. Patients with chronically loose stools may wish to use an absorptive agent (e.g., Ileosorb, Par-Sorb) designed for placement in the pouch. Absorptive agents do not correct the problem; they merely assist in coping with the problem. Increased nonfermentable fiber (e.g., Metamucil, Citrucel) may be used to help correct diarrhea in patients with a colon. Antidiarrheals (e.g., loperamide, diphenoxylate plus atropine) can slow transit time and decrease output. Of note, an unexpected high or decreased output or no output in a patient with an ileostomy may reflect a partial small-bowel obstruction. In such instances, the patient needs to seek emergency medical attention.

Intestinal gas is another potential problem that may be related to food. Eliminating foods that cause gas formation from the diet may be adequate to correct the problem ([Table 22–3](#)). Oral simethicone to reduce gas production or use of pouches with gas filters may be helpful. Odor is not normal except when the pouching system is changed or emptied. Otherwise, odor may be an indication of poor hygiene, leakage, or failure to properly connect the pouch to the skin barrier. The health care provider should review proper care and connection of the pouching system with patients who are concerned about odor. Oral deodorants that will act in the digestive system to eliminate odors from digested foods are discussed in the earlier section on deodorizers.

Peristomal Skin Complications

Peristomal skin complications are defined as skin inflammation, injury, or damage that occurs within the 3–4 inches of skin surface surrounding the stoma or that involves the skin covered by the adhesive portion of the pouching system (barrier and tape).¹⁴ The most common cause of peristomal skin complications is peristomal moisture-associated damage, often resulting from exposure of the skin to stoma effluent. Peristomal skin complications are reported to be as high as 77%.^{15,16}

Skin irritation around the stoma can result from prolonged contact with stoma effluent. Ostomy pouching systems and accessories also can irritate skin as a

consequence of poor fit or the irritative nature of materials used in their composition. The peristomal skin may look “weepy” or erythematous, with papules and macules evident. Several peristomal skin assessment tools are available for both clinician and patient: The Ostomy Skin Tool (OST) ¹⁷ and the Peristomal Skin Assessment Guide¹⁸ are two tools for the clinician, and the Consumer Peristomal Skin Assessment Tool¹⁹ is for the person with an ostomy.

Peristomal moisture-associated skin damage is the most commonly reported skin complication for the patient with a urinary or fecal diversion. Peristomal moisture-associated skin damage is defined as inflammation and erosion of the skin adjacent to the stoma associated with exposure of the effluent such as urine or stool.²⁰ The injured area appears red, with superficial skin loss, and the changes observed can mirror the pattern of exposure of the skin to the stoma output. Management of the injured skin includes identification and correction of the contributing factors, which may include the opening in the skin barrier differs from the size or shape of the stoma, the shape of the pouching system does not match that of the peristomal area, prolonged wear time, or user error. Once the etiologic condition has been determined and corrected, a skin barrier powder may be applied to the peristomal skin before the pouch is applied (see earlier).

Allergic contact dermatitis is characterized by burning, pruritus (itching), blisters, and red or denuded skin. This complication usually results from an allergic reaction to the pouching system or an accessory. The area of involvement usually matches the contour of the product causing the reaction. A patch test will identify the allergen in patients who have a history of allergy or of reaction to adhesive tape, eczema, or psoriasis, as well as in those who have very fair skin. Management includes identifying and removing the allergen. It may take some time for the redness to dissipate, and a topical corticosteroid spray can be used to decrease the inflammation. For persons at risk for such reactions, “patch testing” a variety of products is an option to determine if they will be tolerated without problems.

Pseudoverrucous lesions (encrustations) may develop in patients with urinary diversions because of the alkalinity of the urine. With continuous contact of this abnormal urine with the skin, an alkaline dermatitis will result, manifested as thickening of the affected skin with gray discoloration due to deposition of alkaline crystals. The first step in management is to prevent any urine contact with the skin, so a new pouching system, a refitting of the skin barrier opening,

or a decrease in the wear time may be needed. A cloth soaked with a solution of one-third white vinegar to two-thirds water should be applied to the involved area for 5–10 minutes at pouch change to help to dissolve the crystals. Definitive treatment for alkaline dermatitis is acidification of the urine. Patients should avoid alkaline ash foods, such as citrus fruits and juices; paradoxically, these foods are acidic when consumed but generate an alkaline output. Increasing fluid intake to 2–3 quarts daily also may reduce alkalinity. Acidifying the urine with cranberry juice or pills may be considered as well.

Mechanical injury may result from a variety of causes; most common are medical adhesive–related skin injuries and pressure injuries. Medical adhesive–related skin injuries occur on removal of the pouching system. The area of injury is located specifically beneath the adhesive portion of the pouching system; the injury lesion, which is moist and typically painful, manifests as a partial thickness skin loss. Some cases are preventable such as with gentle adhesive removal (by the push-pull method) or the use of an adhesive releaser or remover. The injured skin can be treated with skin barrier powder to provide a dry surface to heal the skin. If the affected area is extensive, a thin hydrocolloid dressing can be used until healing occurs. Pressure injuries can develop in the peristomal area and manifest as full or partial thickness lesions in an area under pressure from the pouching system, such as a convex skin barrier or the inappropriate use of a belt. Treatment for the pressure injury begins with identifying the part of the pouching system causing the prolonged pressure, with appropriate modifications to correct the problem, followed by specific measures to help heal the injury, such as application of a thin hydrocolloid or superficial skin barrier powder.

Folliculitis, an inflammation of the hair follicles, is characterized by redness at the base of the hair follicles around the stoma. Aggressive removal of any adhesive from the skin can traumatically remove hairs, resulting in irritation and infection. Using a clipper to remove hair in the peristomal area may help prevent folliculitis. Because folliculitis is related to an overgrowth of staphylococci on the skin, the use of an antibacterial wash should be considered; in some advanced cases, use of an oral antibiotic may be considered.

Fungal infection/candidiasis can develop in the peristomal area in patients who are on antibiotics, are immunosuppressed, have diabetes, or are undergoing chemotherapy. Candidiasis manifests with pruritus and

maculopapular rash with satellite lesions. The moisture associated with the rash can interfere with the pouch seal causing leakage. Treatment of the condition is with the use of the powdered antifungal agent nystatin. As with skin barrier powder, the powder can be liberally applied to the affected area and rubbed in, and the excess brushed off. Once the area clears, the powder is no longer necessary.

Stoma Complications

Stoma stenosis is narrowing or contraction of the stomal tissue at the skin or fascial level. Causes are thought to be related to postoperative ischemia, active disease such as Crohn's disease, or excessive scar formation. Management of mild stenosis may include a low-residue diet and use of stool softeners. For severe stoma stenosis, stoma revision should be considered.

Peristomal hernia is a defect in the abdominal wall that allows the intestine to bulge into the peristomal area and is one of the most common ostomy complications. Several risk factors for development of a peristomal hernia have been suggested: creation of a large fascial opening, placing the stoma lateral to the rectus sheath, obesity, and malnutrition. The patient may complain of a bulge when standing or sitting, pain, pouching difficulties, leakage, and peristomal skin irritation. Modification of the pouching system to a more flexible system to fit over and around the peristomal bulge may help with the pouch seal. An ostomy support belt or binder may be used to provide comfort and reduce the bulge. The patient should be referred to a WOC nurse for a plan of care. Surgery may be required if pain at the site increases, the degree of herniation worsens, or signs of stoma obstruction develop.

Fistula is an abnormal opening between two internal organs, or from inside the body extending through the skin. Enterocutaneous fistulas (abnormal passages between the intestine and skin) can occur in patients with or without an ostomy. This complication is most often a manifestation of Crohn's disease, advancing cancer, abscess formation, radiation damage, and traumatic injury. If a fistula exhibits excessive drainage, an ostomy pouching system may be applied to contain the effluent, which otherwise can induce skin damage with denudation.

Prolapse is a telescoping of the intestine through the stoma. This pathoanatomic problem is thought to result for a number of reasons: too-large

opening in the abdominal wall, inadequate surgical fixation of the bowel to the abdominal wall, or poorly developed fascial support. The danger of prolapse is in the resulting decrease in blood supply to the bowel present outside the abdominal cavity. The enlarged stomal protrusion is more susceptible to damage from the pouching system and is frightening to the patient. Treatment usually is conservative. The prolapse may be reduced by having the patient lie supine and applying continuous pressure on the most distal part of the stoma. Placement of cold packs on the stomal area may reduce the associated edema, facilitating reduction of the prolapse. Once reduction is obtained, use of a rigid pouching system should be avoided because of the risk of strangulation of the stomal tissue. The patient should apply a flexible pouch with a resized opening while lying flat. Surgical correction may be required if the stomal tissue becomes purple or ecchymotic or if the prolapse persists.

Retraction is the disappearance of stoma tissue to below skin level. Causes include tension on the stoma from a variety of reasons such as a short mesentery, thickened abdominal wall, obesity, and stomal necrosis. If the retraction is not severe, use of a convex pouching system and a belt may be adequate. In other cases, surgical correction may be required.

Medication Considerations With Ostomies

An understanding of the absorption characteristics of medications is important to optimize their effectiveness in patients with ostomies. Both prescription and nonprescription medications should be reviewed to ascertain the best formulation for each patient. Potential drug interactions and adverse effects of special concern in patients with ostomies also should be addressed in the drug therapy plan. [Table 22–8](#) lists some general drug management principles for patients with colostomies, ileostomies, and urostomies.^{21,22}

Table 22–8 General Drug Management Principles With Ostomies

Type of Ostomy	General Management
Ileostomy, colostomy	Avoid sustained-release, extended-release, and enteric-coated medications or those that contain a wax matrix. Liquid, crushable, and chewable preparations are preferred.
Ileostomy, colostomy	Do not crush medications before first consulting an appropriate health care provider.

Type of Ostomy	General Management
Ileostomy, colostomy	Check pouch for undissolved tablets to monitor drug absorption.
Ileostomy, colostomy, urostomy	Review medication plans for potential drug interactions and/or adverse effects.
Ileostomy, colostomy, urostomy	Alert patients to medication-induced color changes in urine and/or stool.

Source: References 21 and 22.

Medication Absorption With Ostomies

The upper portion of the small intestine is the major absorptive site for many medications. However, many drugs rely on an intact colon for absorption.²¹ Changes in GI anatomy after ostomy surgery will therefore affect the body's handling of certain drugs, in different formulations.

Formulation Characteristics and Absorption With Ostomies

Drug absorption in the presence of an ostomy is well known to be affected by product formulation, among multiple factors (Table 22–8). Patients with ostomies should be instructed to check the pouch for undissolved tablets or tablet fragments whenever they take solid oral medications. If the absorptive areas of the intestine have been altered, coated or sustained-release preparations may pass through the intestinal tract without being absorbed, potentiating drug failure.²² Some medications also are contained within a wax matrix (e.g., Slow K) from which the active drug leaches as the tablet moves through the GI tract.

Specific Drug Classes Associated With Adverse Effects Including Malabsorption in Patients With Ostomies

In addition to the noted challenges with drug absorption, [Table 22–9](#) lists a broad selection of medications with the potential to cause adverse effects, which vary with different dosage forms.^{23–34} Presented here is an overview of such effects with commonly used drugs in patients with ostomies.

Table 22–9 Potential Effects of Selected Prescription Drugs in Patients With Ostomies

Drug Class	Type of Ostomy	Potential Effects
Histamine type 1 (H ₁) receptor antagonists	Ileostomy, colostomy, urostomy	No problems have been reported with use of cetirizine, loratadine, or fexofenadine.
Anti-inflammatory agents	Ileostomy	NSAIDs are associated with GI irritation and bleeding. Use only with caution in patients with history of GI ulceration or bleeding and in those with inflammatory bowel disease (COX-2 inhibitors may have lower risk profile).
		No problems have been reported with Celecoxib.
Opiates	Colostomy	Tramadol's opiate agonist activity can cause constipation, by a similar mechanism for opiates such as oxycodone.
		Liquids, IR products, or patches are preferred to avoid erratic absorption associated with ER products.
Selective serotonin reuptake inhibitors	Ileostomy	No problems have been reported with use of sertraline, citalopram, or fluoxetine.
		Hyponatremia and diarrhea have been reported with paroxetine, necessitating close monitoring of fluid and electrolyte status.
Antipsychotics	Colostomy, ileal conduit	Constipation has been reported with use of olanzapine and clozapine and can occur with all anticholinergic drug regimens.
		Reported delayed lithium toxicity necessitates close monitoring of serum levels in patients with ileal conduits.
Antidiabetic	Ileostomy	Possible dose-related GI effects are related to variable

Drug Class	Type of Ostomy	Potential Effects
agents		absorption of metformin, a weak base primarily absorbed in the small intestine. Some patients have experienced increased stoma output, necessitating a change in their antidiabetic regimen.
		No problems have been reported with other antidiabetic agents.
Anticonvulsants	Ileostomy	Erratic absorption has been reported with enteric-coated and SR products.
		Use of liquids or IR products is generally recommended.
Antilipidemics	Ileostomy, colostomy, urostomy	No problems have been reported with use of HMG-CoA reductase inhibitors.
Cardiac/ antihypertensive drugs	Ileostomy	Fluid and electrolyte abnormalities are common with use of diuretics.
		Careful monitoring is recommended during use of ACE inhibitors.
		Hyperkalemia may be a particular problem.
GI medications	Ileostomy, colostomy	Diarrhea is associated with use of all PPIs, necessitating careful monitoring of fluid and electrolyte status.
		No problems have been reported with use of H2RAs.
		Avoid laxatives in patients with ileostomies owing to risk of severe fluid and electrolyte disturbances.
Antimicrobial agents	Ileostomy, urostomy, colostomy	Altered normal bowel flora and diarrhea related to broad-spectrum antibiotics can be a significant problem for patients with ileostomies.
		High doses of ciprofloxacin are associated with alkaline urine; if they are used, urinary acidification to avoid bacterial overgrowth in urostomy patients requires close monitoring.
Other drugs	End-jejunostomy, ileostomy	Some reports of drug failure are associated with malabsorption of warfarin in patients with short-bowel syndrome.

Drug Class	Type of Ostomy	Potential Effects
		Adequate length of functionally intact proximal small bowel is important in cyclosporine dosing; if liquid formulation or IV administration is required, more frequent monitoring is recommended.
		Variable volume of distribution and increased clearance of gentamicin have been reported in patients with ileostomies, possibly necessitating more frequent monitoring.
		Highly variable bioavailability of digoxin (dependent on length of remaining bowel) requires monitoring for drug failure.

Key: ACE = Angiotensin-converting enzyme; COX-2 = cyclooxygenase-2; ER = extended-release; GI = gastrointestinal; HMG-CoA = hydroxymethylglutaryl coenzyme A; H2RAs = histamine type 2 receptor antagonists; IR = immediate-release; IV = intravenous; NSAID = nonsteroidal anti-inflammatory drug; PPI = proton pump inhibitor; SR = sustained-release.

Source: References 23–34.

Antibiotics

In general, antibiotics may alter the normal flora of the intestinal tract, causing diarrhea or predisposing the patient to development of fungal infection of the skin surrounding the stoma.

Sulfa Drugs

Use of sulfa drugs in patients with ostomies warrants attention to hydration status, because crystallization in the kidney occurs more often in the setting of fluid imbalance. To minimize this problem, an increase in fluid intake is indicated.

Diuretics

Diuretics can increase the amount of fluids and electrolytes lost through urostomies. Their use in patients with ileostomies presents a challenge because fluid losses initially are often difficult to manage. Caution is therefore

warranted with use of medications in this drug class. Frequent monitoring of fluid balance and serum electrolytes is required.

Laxatives

Because of the risk of electrolyte imbalance and dehydration, ileostomy patients should never use laxatives unless these agents have been prescribed by their primary care provider. Patients with colostomies may use laxatives, but only under close supervision. If constipation is an issue, the primary care provider may recommend a stool softener.

Antacids

Products that contain calcium may promote stone formation in patients with urostomies. Magnesium-based products can cause diarrhea in patients with ileostomies. Conversely, in patients with problems of constipation, the use of aluminum-based antacids should be avoided because of their specific association with this problem.

Opioid-Containing Products

Opioid-containing products, such as oxycodone, codeine, and morphine, decrease gastrointestinal motility, potentially causing constipation. With the high addiction potential of opioid medications and the national efforts to curb dependence on these agents, health care providers are encouraged to recommend nonopiate agents for pain management, such as acetaminophen, whenever possible. With use of opioid-containing medications, a stool softener, may be prescribed by the patient's primary care provider because of the risk of constipation.

Additional Medication-Related Issues With Ostomies

Urine and Stool Discoloration

Some medications can cause color changes in the urine and/or feces, which will be noticed more often with ostomy management. The discoloration can be unsettling to an uninformed patient, leading to unnecessary anxiety. [Table 22–10](#) lists common medications that cause such color changes.^{35–37} The

health care provider should discuss these possible changes with the patient in developing the drug therapy plan.

Table 22-10 Selected Drugs That Discolor Feces and Urine

Drugs That Discolor Feces			
Black	Fluorouracil	Blue	Orange-Brown
Acetazolamide	Hydralazine	Chloramphenicol	Rifabutin
Aluminum hydroxide	Iodide-containing drugs	Manganese dioxide	Pink-Red
Aminophylline	Iron	Methylene blue	Anticoagulants ^a
Amphetamine	Levodopa	Gray	Aspirin
Amphotericin B ^a	Melphalan	Colchicine	Barium
Anticoagulants ^a	Methotrexate	Green	Cefdinir ^b
Aspirin ^a	Nitrates	Indomethacin	Clofazimine
Barium	Nonsteroidal anti-inflammatory drugs ^a	Iron	Nonsteroidal anti-inflammatory drugs ^a
Bismuth	Phenylephrine	Medroxyprogesterone	Tetracycline syrup
Chloramphenicol	Potassium salts ^a	Green-Gray	White or Speckled
Chlorpropamide	Procarbazine		
Cholestyramine	Sulfonamides	Oral antibiotics	Aluminum hydroxide
Corticosteroids	Tetracycline	Orange-Red	Barium
Cyclophosphamide	Thallium	Phenazopyridine	Oral antibiotics
Cytarabine	Theophylline	Rifampin	Yellow or Yellow-Green
Ethacrynic acid	Thiotepa ^a	Rifapentine	Senna
Drugs That Discolor Urine			
Black	Dark	Purplish Red	Yellow
Ferrous salts	Aminosalicylic acid	Chlorzoxazone	Aloe

Phenacetin	Chloroquine	Red	Riboflavin
Senna	Metronidazole	Carbidopa/levodopa	Tolcapone
Blue or Green	Nitrofurantoin	Daunorubicin	Sulfasalazine
Amitriptyline	Phenacetin	Dimethylsulfoxide	Vitamin B ₁₂
Cimetidine (injection)	Primaquine	Doxorubicin	Yellow-Brown
Flutamide	Orange	Idarubicin	Cascara
Indomethacin	Chlorzoxazone	Red-Brown	Nitrofurantoin
Magnesium salicylate	Dantrolene	Aloe	Primaquine
Methocarbamol	Entacapone	Levodopa	Senna
Methylene blue	Warfarin	Phenytoin	Sulfonamides
Mitoxantrone	Orange-Red	Quinine	Yellow-Orange
Promethazine (injection)	Phenazopyridine	Warfarin	Sulfasalazine
Propofol (injection)	Rifampin	Violet	Vitamin A
Triamterene	Pink-Red	Senna	Yellow-Pink
	Phenothiazines		Cascara
	Phenytoin		Aspirin

^a Discoloration may be caused by bleeding.

^b Discoloration caused by nonabsorbable complex between cefdinir or metabolites and iron in the GI tract.

Key: GI = Gastrointestinal.

Source: References 35–37.

Dietary Supplements

Herbal products are not regulated by the U.S. Food and Drug Administration (FDA) because they are considered dietary supplements. Moreover, not all ingredients contained in a product are listed on the label. Herbal supplements can interact with medications and may cause a variety of adverse effects. Patients with ostomies who desire to use herbal agents should do so only under medical supervision.

Assessment of Patients With Ostomies: A Case-Based Approach

In most cases, ostomy surgery necessitates the use of a pouching system designed to collect the waste material normally eliminated through the bowel or bladder. Because the specific circumstances dictating the need for an ostomy and the resultant surgical outcomes are highly variable, one patient may function well with use of a particular type of pouch or accessory, whereas another may develop problems with the same products. Moreover, the patient's needs may change over time. A pouching system or accessory that previously produced ideal outcomes may no longer be appropriate because of changes in body contour caused by aging, pregnancy, weight gain or loss, or concurrent medical conditions. As the rate of obesity continues to rise, so do the challenges for health care providers in supporting the special needs of people with ostomies, for whom weight changes and obesity bring added complexity to management.

Patients scheduled for ostomy surgery often are apprehensive about how the operation will proceed, how they will manage the ostomy postoperatively, and how they will be perceived by others. Both pre- and postoperatively, the person's self-image typically is threatened, with a detrimental effect on self-esteem. Therefore, special efforts should be made during the assessment to ensure privacy, to establish a trusting relationship, and to bolster the patient's confidence in subsequent self-management.

Cases 22–1 and 22–2 illustrate assessment of two different patients with established ostomies.

Case 22–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	The patient's stoma-related symptoms began during the summer when she was at the beach and perspired a lot.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	She has experienced pruritus (itching) and rash underneath her ileostomy appliance for the past week, and now the affected skin is becoming denuded and "weepy." Her pouch has started to leak more often. She usually wears this pouching system for 3–4 days, but now she can keep it on for only 24 hours.
c. Description of the patient's efforts to relieve the symptoms	The patient applied pectin-based powder before appliance changes, but her symptoms have not resolved.
d. Patient's identity	Alexis Jones
e. Patient's age, gender, height, and weight	32 years, female, 5 ft 6 in., 130 lb
f. Patient's occupation	Web designer
g. Patient's dietary habits	MNT diet for diabetes
h. Patient's sleep habits	n/a
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Diabetes:</i> Glucophage 500 mg twice daily <i>Asthma:</i> Flovent 220 mg 2 puffs twice daily, albuterol 2 puffs every 6 hours as needed

j. Why was the stoma created, what type of stoma, and how often is the pouch emptied, what is the consistency of the stool?	Ms. Jones underwent proctocolectomy with creation of an ileostomy 2 years ago for management of severe medically unresponsive ulcerative colitis.
k. Allergies	Aspirin
l. History of other adverse reactions to medications	None
m. Other (describe) -----	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	Since the summer, Ms. Jones has developed a rash and itching. The rash appears to be caused by moisture. The patient's diabetes is a related factor.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Refer Ms. Jones to a WOC nurse. (2) Recommend application of nystatin powder to the affected area with each pouch change. (3) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Suggest that Ms. Jones contact the WOC nurse or other health care provider who manages her ostomy care, to obtain a prescription for nystatin powder. Advise that she should describe the rash, timing of onset, and her symptoms.

6. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“Seeing a WOC nurse or your regular ostomy care provider is very important to treat this situation.”
Implement	
7. When providing a recommendation that the patient contact a health care provider to suggest the use of nystatin powder, convey accurate information to the patient or caregiver.	“Wash peristomal skin using your usual routine. Apply nystatin powder sparingly and rub into the peristomal skin. Dust off the excess powder. A protective barrier wipe, such as 3M No Sting Skin Prep, may be applied to enhance the pouch seal. Apply the pouch. Use the nystatin powder with each pouch change until 1 week after the rash has resolved. Avoid washing the stoma with soap, especially antibacterial soap. If the rash and itching continue, consult a WOC nurse or your primary care provider.”

Key: MNT = Medical nutrition therapy; n/a = not applicable; WOC = wound, ostomy, and continence.

Case 22–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient’s symptoms and medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	Patient has experienced leakage from his colostomy pouching system in the past few weeks. He has noticed redness, denuded skin, and a bulge around the stoma. Pain described as a burning sensation at the site also is distressing for the

	patient.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	Since his surgery 1 year ago, the patient has gained 20 pounds. He usually changes his pouch twice a week, but now he has to change it every day and continues to have leakage and peristomal redness.
c. Description of the patient's efforts to relieve the symptoms	Patient applied skin barrier powder and skin sealant to protect his skin, but he continues to have skin irritation and leakage.
d. Patient's identity	Kevin Smith
e. Patient's age, gender, height, and weight	60 years, male, 5 ft 11 in., 175 lb
f. Patient's occupation	Retired engineer
g. Patient's dietary habits	High-fiber diet with junk food
h. Patient's sleep habits	n/a
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>Allergic rhinitis:</i> Nasonex 2 spray in each nostril once daily or 1 spray in each nostril once daily
j. Why was the stoma created, what type of stoma and how often is the pouch emptied, what is the consistency of the stool?	Mr. Smith was diagnosed with rectal cancer 2 years ago, which was treated with preoperative irradiation and chemotherapy and then abdominal perineal resection with creation of a sigmoid colostomy. He has one stool per day that is semiformal. Lately he has noted crampy abdominal pain just before the stool discharges from the stoma.
k. Allergies	Latex
l. History of other adverse reactions to medications	None
m. Other (describe) -----	Mr. Smith has been nervous about family issues and has been constantly eating, which has increased his weight.
Assess	
2. Differentiate patient's	Leakage, pain, and denuded skin around his stoma are the

signs/symptoms, and correctly identify the patient's primary problem(s).	result of local changes including development of abdominal creases with weight gain and documented peristomal hernia.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required and share this information with the patient or caregiver.	Options include (1) Refer Mr. Smith to a WOC nurse for further assessment and treatment. (2) Recommend use of a skin barrier powder to improve the condition of the peristomal skin, followed by application of a skin sealant. (3) Recommend use of a barrier ring with pouching system. Mr. Smith should be fitted with a hernia belt, which will provide support. (4) Refer Mr. Smith to the website: http://psag-consumer.wocn.org/#home. that can help him to identify and plan care for the peristomal skin issues. (5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Assessment of the stoma and skin indicates that a barrier ring and appropriate pouch are needed, as well as a hernia belt for support. Upon further discussion, Mr. Smith says he prefers a one-piece pouch with belt over a two-piece pouch.
6. Describe the recommended therapeutic approach to the patient or caregiver.	"In addition to ostomy care, you will need a belt for support of the hernia. Treat skin around the stoma with a skin barrier powder, such as Stomahesive powder, and a skin sealant, such as 3M No Sting Skin Prep, before applying the pouch with barrier ring. Change the pouching system every 2 days until the peristomal skin is free of pain and is no longer denuded; then resume pouch changes twice a week."

7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	<i>Physiologic issues:</i> “Pouch leakage and denuded skin will decrease with proper follow-up with a WOC nurse or other ostomy care provider to modify your pouching technique. The bulge will be less prominent with support from a hernia support belt.” <i>Psychologic issues:</i> “Contact the local chapter of the United Ostomy Associations of America for peer support to help you improve your self-esteem and body image.” (See Table 22-1 .)
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	See Figure 22-3 and Table 22-2 for proper pouching technique and appropriate skin accessories.
b. Maximum number of days the therapy should be employed	“Change the pouch twice a week.”
c. Product administration procedures	“Wash peristomal skin as usual. Apply thin layer of powder. Rub powder into skin and dust off any excess. Apply liquid skin barrier before applying the pouch with barrier ring.”
d. Expected time to onset of relief	“With proper skin care and use of a hernia belt for support, leakage and skin injury should decrease. You will notice a decrease in the burning sensation.”
e. Degree of relief that can be reasonably expected	“You should notice a decreased intensity of symptoms within 24 to 48 hours.”
f. Most common adverse effects	“Some ostomates have had an allergic reaction to the powder or pouch adhesive.”
g. Adverse effects that warrant medical intervention should they occur	“Consult a WOC nurse if burning, stinging, or local irritation occurs.”
h. Patient options in the	“Consult a WOC nurse or your primary care provider if leakage

event that condition worsens or persists	or burning continues after 1 week of treatment.”
i. Specific nondrug measures	“Change the pouch every 2 days until peristomal skin is clear.”
j. Solicit follow-up questions from the patient or caregiver.	“What happens if I can't lose weight, I develop more creases, and my stoma retracts more?”
Answer the patient's or caregiver's questions.	“Consult a WOC nurse. You may need another type of pouching system. In addition, because weight gain may lead to obesity, which carries significant health risks beyond ostomy-related problems, you should consult a nutritionist for a proper diet program.”
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Ask Mr. Smith to call you at the next pouch change to ensure that no further leakage has occurred and that the affected skin has improved. If the leakage continues, have the patient call the WOC nurse.

Key: n/a = Not applicable; WOC = wound, ostomy, and continence.

Patient Counseling for Ostomy Care

The pharmaceutical care needs of a patient with an ostomy include selection of the appropriate supplies and procurement and use of ostomy supplies. Monitoring the ostomy self-management regimen and counseling the patient and family on special needs (e.g., skin care, diet, fluid intake, drug therapy) are other important components of ostomy care.

Counseling of the person with an ostomy should be done in a sensitive and caring manner. A common postsurgical issue is disturbance in the person's self-image, with consequent damage to self-esteem; therefore, in assisting patients with ostomy needs, special care must be taken to avoid verbal or

facial expressions that might convey negative feelings regarding the necessary maintenance procedures. Peer support can be especially helpful for the ostomate population. Patients should be provided with contact information for local and national ostomy associations and a list of product manufacturers that can supply information about product use ([Table 22–1](#)). Further assistance can be obtained from a WOC nurse in the patient’s geographic area (www.wocn.org). The following self-help books also should be recommended to patients with ostomies:

- Barrie B. *Second Act*. New York, NY: Scribner; 1997.
- Benirschke R. *Alive & Kicking*. San Diego, CA: Rolf Benirschke Enterprises; 1999.
- Benirschke R. *Embracing Life*. San Diego, CA: Rolf Benirschke Enterprises; 2009.
- Benirschke R. *Great Comebacks*. San Diego, CA: Rolf Benirschke Enterprises; 2002.
- Elsagher B. *I’d Like to Buy a Bowel Please! Ostomy A to Z*. Andover, MN: Expert Publishing; 2006.
- Elsagher B. *If the Battle Is Over Why Am I Still in Uniform? Humor as a Survival Tactic to Combat Cancer*. Andover, MN: Expert Publishing; 2005.
- Kupfer B, Foley-Bolch K, Kasouf MF, et al. *Yes We Can*. Worcester, MA: Chandler House Press; 2000.
- Ruggieri P. *Colon & Rectal Cancer. A Patient’s Guide to Treatment*. Omaha, NE: Addicus Books; 2001.
- Taylor J. *Pretty Girl Blues*. PGB Publishing; 2013. Available at: <http://www.prettygirlblues.com/PurchasePGB.html>.

The person with an ostomy must adapt to many challenges in everyday life. Supporting the patient’s involvement in the various aspects of self-care and in the development of health care plans will help to alleviate much of the fear and anxiety often associated with living with an ostomy. Expression of any problems and concerns should be encouraged so that the patient’s ability to achieve self-treatment objectives can be better assessed. Health care providers or managers also should consider patients’ special needs for conditions unrelated to the ostomy. The box “Patient Education for Ostomy Care” lists specific information to provide in patient counseling.

Patient Education for Ostomy Care

The objectives of self-care for ostomies are (1) to understand how the stoma functions and to maintain an effective ostomy management regimen; (2) to identify and implement proper techniques for use of the pouching system and accessories, and to avoid complications that result from improper use; and (3) to reduce the risk of other types of complications. For most patients, carefully following the product instructions and the self-care measures listed here will help to ensure optimal therapeutic outcomes.

Pouching System Selection and Use

- Use only the type of pouching system recommended for your type of ostomy.
- If your system no longer fits well, consult your WOC nurse or primary care provider before changing to a different type of pouching system.
- Do not consider skin irritation to be inevitable; identify the cause and correct it, and treat the irritation as soon as it occurs.
- If possible, identify the cause for leakage around the pouching system and correct the problem immediately. Consider using the Peristomal Skin Assessment Guide, available online (<http://psag-consumer.wocn.org/#home>). Consult your WOC nurse or primary care provider if you cannot determine the cause.
- Establish a routine for ostomy care. Keep the routine simple; use as few accessories as possible.
- Order more supplies when you have four changes left.

Effects of Medication Use

- Sustained- or extended-release medicines may undergo erratic absorption because of the altered postsurgical anatomy, which makes their effect unpredictable. These medications should be used with caution. Coated medications, as well as sustained- or extended-release medications, should not be crushed or chewed.
- Use caution when taking antibiotics and diuretics. Antibiotics can cause diarrhea or promote development of fungal infections of the skin around the stoma. Diuretics can cause dehydration or

electrolyte imbalance in people with ileostomies.

- Use caution when taking laxatives, antidiarrheals, or other medications that alter gastrointestinal motility. Laxatives can increase fecal output in people with ileostomies, whereas antidiarrheals decrease the fecal output.
- Know which medications will discolor the urine or feces ([Table 22–10](#)).

When to Seek Medical Attention

- Consult your WOC nurse or primary care provider about using nonprescription medications to treat diarrhea or constipation. Seek medical attention for the problem after you experience no improvement with 1 week of self-treatment.
 - See your WOC nurse if you experience any of the following complications:
 - Depression and anxiety
 - Abdominal pain
 - Narrowing of the stoma
 - A bulge near the stoma
 - Protrusion of the bowel through the stoma
 - Retraction of stoma below the skin
 - Excessive bleeding from or around the stoma (more than a teaspoon)
 - Pain on touching the skin around the stoma or applying the pouching system
 - Overgrowth of the skin around the stoma
 - Ostomy Care

Key Points for Ostomy Care

- Patients with ostomies may experience both psychological and physical complications after ostomy surgery. Specific issues should be addressed, with referral as needed to a primary care provider, a WOC nurse, and/or the United Ostomy Associations of

America.

- The objectives of self-care for an ostomy are to understand how the stoma functions, to maintain an effective ostomy management regimen, to identify and implement optimal techniques for use of the pouching system and accessories, to avoid complications that result from improper use, and to reduce the risks of other complications.
- Patients should be advised about the effects of food on stomal output and the need to monitor for signs and symptoms of dehydration.
- The selection of an appropriate pouching system depends on the patient's stoma and body contour, manual dexterity, and type of ostomy.
- The ideal ostomy pouching system should provide a predictable wear time and protect the peristomal skin. The health care provider can assist the patient in achieving these outcomes.
- Patients should be counseled on the effects of medications:
 - Use of liquid, crushable, or chewable medications is preferable.
 - Coated or sustained-release medications require caution with use, because if the GI tract has been shortened or its function otherwise altered, full absorption may not occur.
- Caution is warranted with use of antibiotics and diuretics. Antibiotics can cause diarrhea or promote fungal infections of the skin around the stoma. Diuretics can cause dehydration or electrolyte imbalance in patients with ileostomies.
- Laxatives, antidiarrheals, and other medications that alter GI motility should be used with caution. Laxatives can increase fecal output in patients with ileostomies, whereas antidiarrheals decrease the fecal output.

Chapter 23: Essential and Conditionally Essential Nutrients

Authors: Mary M. Bridgeman, Carol J. Rollins

Vitamin and mineral supplements represent one of the largest and most widely used nonprescription product categories in the United States. More than one third of Americans take a daily multivitamin/mineral (MVM) supplement; sales accounted for one sixth of all dietary supplement sales and 40% of all purchases for vitamin and mineral supplements in 2014.¹ Annual U.S. sales data for all dietary supplements in 2014 were estimated at \$36.7 billion, including \$14.3 billion for all vitamin- and mineral-containing supplements, with an estimated \$5.7 billion specifically for MVMs.¹ Use of MVM supplements has additionally increased over the past 25 years.^{2,3} Nutrition experts agree that foods are the preferred source of vitamins and minerals and that most people can easily meet their daily requirements by eating a balanced diet, although experts agree less about the extent to which the U.S. population consumes such a diet. The lack of overt symptoms of nutritional deficiency in this country supports the position that for most Americans, dietary sources provide adequate amounts of vitamins and minerals; however, the likelihood that subclinical deficiencies may contribute to chronic diseases is receiving increasing attention. Similarly, concerns have emerged that the presence of comorbid conditions and use of certain chronic medications may precipitate nutritional deficits, either by preventing adequate intake or absorption of essential nutrients (i.e., those the human body cannot make) or by creating a situation in which nutrients that are not usually essential (because of adequate endogenous production) now become essential—that is, “conditionally essential” nutrients. These concerns emphasize the importance of encouraging the selection of nutrient-dense foods throughout the life cycle and recognition of the need to recommend appropriate nutritional supplementation for persons at risk for deficiency.

According to the Dietary Supplement Health and Education Act (DSHEA) of 1994, dietary supplements, including vitamins, minerals, and MVM preparations, are not drugs and thus are not intended to prevent, cure, diagnose, treat, or mitigate disease. Health-conscious consumers, however, often seek nutritional supplements as a means of prevention and self-treatment for myriad actual or perceived health ailments; commonly cited

reasons for use are to maintain overall health and to improve health status.⁴ Marketing claims and natural product enthusiasts encourage these self-care behaviors by promoting use of nutrient supplementation, often in doses well above established tolerable upper limits.⁵ In any case, the issues of benefit versus harm from the use of nutritional supplements and the necessity of supplementation in a nutrient-replete person remain unresolved. Regular use of supplements can help in meeting recommended dietary requirements; with this approach, however, a potential risk is that some users will exceed the tolerable upper intake levels of specific nutrients.⁵ Currently, no or only limited evidence supports the use of supplements for cancer prevention; in fact, some data suggest *increased* cancer risk with intake of certain nutrients at higher doses for prolonged periods of time.^{6,7} Furthermore, the National Institutes of Health–sponsored State-of-the-Science Conference concluded that the available evidence is insufficient to support routine use of MVM supplements for primary prevention of chronic diseases.⁸

Beyond the risk of toxicity, one of the greatest dangers of “food fads,” use of multiple supplements, and “mega-dosing” with single vitamins is that such practices may be embraced as a replacement for sound medical care. The lure of marketing or the desire to self-treat may attract desperate or uninformed patients who have serious illnesses, placing them at greater risk because of the associated delay in seeking appropriate medical attention. Furthermore, drug–nutrient interactions can be significant, yet they often are overlooked as part of the patient’s medical history. For these reasons, health care providers should be aware of the potential use of various nutrient supplements, as well as their associated benefits and risks.

Epidemiology and Etiology of Nutritional Deficiencies

Although overt nutrient deficiency is rare in the United States, the prevalence of subclinical deficiencies is unknown. Specific patient populations may be at higher risk for deficient nutrient intakes because of pathophysiologic, physiologic, metabolic, behavioral, or economic factors, summarized in [Table 23–1](#).^{9,10} Beyond providing energy, protein, and other dietary essentials for day-to-day function (i.e., macronutrients), foods contain numerous other compounds that are important for health maintenance and disease prevention

(i.e., micronutrients), and health care providers can be instrumental in educating patients on choices of nutrient-dense food before vitamin and/or mineral supplementation is recommended. (See [Chapter 24](#) for further discussion of dietary components.)

Table 23–1 Factors Contributing to Nutritional Deficiency

- Inadequate dietary intake resulting from substance abuse, poverty, eating disorders, dementia, or restrictive diets
- Consumption of energy-dense but nutrient-poor foods
- Poor dentition, swallowing difficulty, or xerostomia
- Loss of taste, smell, or sight perception
- Decreased absorption resulting from malabsorptive conditions and/or surgical resection or disease of the intestine (e.g., cystic fibrosis, short bowel syndrome, Roux-en-Y gastric bypass, gastric hypochlorhydria, chronic diarrhea, inflammatory bowel disease)
- Inability to buy or prepare meals because of tremor, fatigue, or arthritic pain
- Anorexia caused by reduced physical activity, social isolation, pain, disease, or depression
- Lack of knowledge about balanced nutrition
- Increased losses, as with hemodialysis therapy
- Inadequate synthesis
- Abnormal metabolism, as with alcoholism or certain genetic polymorphisms
- Increased metabolic requirements resulting from severe injury, infection, trauma, pregnancy, or prolonged physical exercise
- Medications affecting judgment, coordination, memory, appetite, nutrient absorption, gastric pH, or gastrointestinal tract function

Pathophysiology of Nutritional Deficiencies

A comprehensive discussion of the pathophysiology of vitamin and mineral deficiencies is outside the scope of this chapter. The reader is referred to standard medical and nutrition textbooks for such information.

Clinical Presentation of Nutritional Deficiencies

A vitamin deficiency may evolve in several stages, and clinical signs may appear only after development of prolonged and significant deficiency ([Table 23–2](#)).¹⁰ Attributing clinical signs and symptoms to a single nutrient deficiency

is difficult, because in the setting of insufficiency, such manifestations may overlap, reflecting inadequacies of multiple nutrients. Signs and symptoms of specific vitamin and mineral deficiencies are reviewed for the individual micronutrients discussed later in the chapter.

Table 23–2 Stages in Evolution of Vitamin Deficiency

1. Inadequate nutrient delivery, synthesis, or absorption
2. Depletion of nutrient stores
3. Biochemical changes
4. Physical manifestations of deficiency
5. Frank morbidity and death

With its global scope of effect, poor nutrition increases the overall risks of chronic disease, infection, and complications associated with reproduction, acute illness, surgery, and chemotherapy. For the pediatric population, growth, development, and learning may be compromised. For adults, poor nutrition over a lifetime can exacerbate the aging process, causing earlier morbidity and death. Balanced nutrition (with varied food choices providing adequate protein and appropriate calories, vitamins, and minerals) is essential for health through all stages of the life cycle.

Nutrient Supplementation: Principles and Terminology

Vitamin and mineral supplements should be used as *adjuncts* to a balanced diet, not as substitutes for nutritious food. Although nutritional supplements can be obtained without a prescription and typically are self-prescribed, they are complex agents with specific indications. Medical assessment should precede their use, especially with popularized regimens of daily intakes that exceed recommended amounts for a specific nutrient. Furthermore, vitamins and minerals often are better absorbed from food sources than from supplements—a point that should be highlighted for persons seeking to purchase such supplements. Health care providers may refer patients to a registered dietitian for personalized counseling on diet modification as well as

nutritional supplementation.

Nutritional supplement use is intended to prevent nutritional deficiencies, replenish compromised nutrient stores, or maintain the present nutritional status. Nonprescription nutritional supplements are not intended for self-treatment for vitamin deficiencies.

In the United States, *Dietary Reference Intakes* (DRIs), nutrient reference standards, are established by the National Academies of Science, Engineering, and Medicine. These standards are intended to guide good nutrition by addressing the adequacy of the food supply, establishing principles and guidelines for adequate dietary intake, and providing authoritative judgment on the relationships among food intake, nutrition, and health. DRI is the general term for a set of reference values used to evaluate nutrient intakes of healthy people, outlined in [Table 23–3](#). Values vary according to the subject's age and sex and include

Table 23–3 Dietary Reference Intake (DRI) Components: Terminology and Definitions			
Component	Name	Definition	Comments
DRI ^a	Dietary Reference Intake	An assembly of 7 reference standards developed under the National Academies of Sciences, Engineering, and Medicine for planning and assessing diets relative to nutrient intake in apparently healthy people	Information presented in this table is divided into 22 categories ("groups") defined by sex and life stage (age). The reference standards are established by consensus committees.
EAR	Estimated Average Requirement	Amount of a nutrient per day that is expected to meet the requirement of 50% of healthy persons in the group	Based on a specific indicator of adequacy for the nutrient and a thorough review of the literature.
RDA	Recommended Dietary Allowance	Amount of a nutrient per day that is expected to meet the nutrient requirements for maintenance of good health in healthy persons	Based on normal distribution within an EAR; meets requirements for 97%–98% of healthy persons in the specified group.

Component	Name	Definition	Comments
		within the group; set at 2 standard deviations above the EAR	
AI	Adequate Intake	Average daily intake of a nutrient for persons in the group who appear to be healthy and maintaining a defined criterion of adequacy Inadequate scientific data, due either to lack of studies or inherent uncertainty, to establish an EAR with confidence for that nutrient	Based on experimentally derived intake levels or observations of mean nutrient intakes by the group. Mean intake is used for healthy breastfed infants; believed to meet requirements for the other groups.
UL	Tolerable Upper Intake Level	Highest usual intake of a nutrient that may be consumed daily without risk of adverse effects in healthy persons within the group Established for 19 nutrients based on current literature: vitamins A, D, E, and C, plus folate, niacin, pyridoxine (B ₆), choline, iron, calcium, magnesium, and phosphorus	Risk is assessed on toxicology data for most nutrients.
CDRR	Chronic Disease Risk Reduction Intake	Recommendation for a specific nutrient or other food substance to mitigate or reduce the risk of chronic disease based on an appropriate chronic disease endpoint A CDRR has been established only for sodium in adults 19 years and older: reduce intakes if above 2300 mg daily	A recent addition to DRIs; guiding principles for determining CDRRs were published in 2017. ^b Endpoints related to chronic disease were used to establish AIs for sodium, potassium, fluoride, and total fiber, and EARs for calcium and vitamin D; however, these are not the same as CDRR.

Component	Name	Definition	Comments
AMDR	Acceptable Macronutrient Distribution Range	Range of usual intakes for a macronutrient that provides adequate intakes of essential nutrients and is related to reduced risk of chronic disease	Expressed as a percentage of total energy intake. The reader is referred to standard nutrition textbooks for information about AMDRs; they are not discussed in this book.
EER	Estimated Energy Requirement	Energy intake calculated using weight, height, physiologic state (e.g., pregnancy, lactation), and degree of energy expenditure that is estimated to maintain energy balance or normal growth (pediatrics)	The reader is referred to standard nutrition textbooks for information about EERs; they are not discussed in this book.

^a Links to DRI-associated tables can be found at: <http://www.nationalacademies.org/hmd/Activities/Nutrition/SummaryDRIs/DRI-Tables.aspx> and http://www.nationalacademies.org/hmd/~media/Files/Report%20Files/2019/DRI-Tables-2019/6_DRIValues_Summary.pdf?la=en.

^b Guiding Principles for Developing Dietary Reference Intakes Based on Chronic Disease is available at: <https://www.nap.edu/download/24828> (doi: 10.17226/24828).

- *Recommended Dietary Allowance (RDA)*: average daily level of intake sufficient to meet the nutrient requirements of nearly all healthy people
- *Adequate Intake (AI)*: established when evidence is insufficient to develop an RDA and is set at a level assumed to ensure nutritional adequacy
- *Tolerable Upper Intake Level (UL)*: maximum daily intake unlikely to cause adverse health effects

If the patient's diet is not providing micronutrients in the amounts required for normal growth and function, supplementation with vitamins and minerals may be appropriate, in the absence of any underlying pathology or contraindication. A once-daily MVM formulation providing no more than 100% of the DRIs should suffice in most cases. Patient counseling should emphasize

that for healthy people, no specific benefit is derived from supplementing nutrients in doses above the DRI; in addition, ULs for daily use should not be exceeded without medical supervision.

Another consideration in use of nutritional supplements is the potential disparity between a product's actual content and its labeled content. Such labeling inaccuracies are not uncommon, because despite U.S. regulations requiring that the actual content of a vitamin or mineral supplement be equal to or greater than the amount stated on the product label (to account for shelf life losses and differences between manufacturer product batches), dietary supplements are not assessed for compliance or standardization by any government agency.¹¹ Unlike prescription drugs, dietary supplements do not require proof of safety or efficacy before being marketed, although standards for manufacturing, packaging, and labeling have been established by the U.S. Food and Drug Administration (FDA). Additionally, third party and independent verification programs also exist, such as the United States Pharmacopoeia–Dietary Supplement Verification Program (USP-DSVP) and those from NSF International and the Natural Products Association, among others. Availability of products bearing such seals indicating validation of adherence to good manufacturing practices creates an opportunity for the pharmacist to educate patients on product selection standards and quality.¹²

Patients should be reminded that the best method for avoiding nutritional deficiencies is to consume a balanced diet each day that includes foods from sources high in several essential nutrients. To guide consumers in selecting a balanced diet while allowing for individual preferences, the U.S. Department of Health and Human Services and the U.S. Department of Agriculture together release the reference *Dietary Guidelines for Americans* every 5 years. The 2015–2020 Guidelines are current until replaced by *Dietary Guidelines for Americans, 2020–2025*.¹³ In these guidelines, consumers are advised to regularly choose a variety of nutrient-dense foods in moderate portion sizes, as exemplified in the *MyPlate* diagram (Figure 23–1). Each food group represented on *MyPlate* provides a significant source of essential nutrients. For example, the dairy group is a major source of calcium, and the fruit and vegetable groups are sources of fiber and the primary sources of antioxidant vitamins. By selecting a variety of foods within the various groups and eating the appropriate number of servings from each food group daily, consumers can “balance” the diet for adequate intake of essential and conditionally essential nutrients. *MyPlate* is an evidence-based tool that is both user-friendly and

comprehensive for assessing the need for nutrient supplementation. When performing a nutritional assessment and determining the need for multivitamin supplementation, the health care provider should inquire about the patient's intake from these food groups.¹³

Figure 23–1 Basic food groups as shown on the MyPlate diagram. (Source: Image from www.choosemyplate.gov.)

Although high doses of specific vitamins and minerals are reported to be of therapeutic benefit for certain conditions, megavitamin enthusiasts' claims have not been confirmed objectively. To the contrary, as noted earlier, some clinical trials have suggested potential harm from supplementation originally claimed to be beneficial. These results are described within the individual micronutrient sections.

Vitamins and minerals that have therapeutic value in the treatment of medical conditions (e.g., niacin therapy for hyperlipidemia) are being used as drugs rather than as supplements for disease prevention or health maintenance. Deficiency states require medical management. Furthermore, in many cases, prolonged ingestion of *megadoses*—doses in excess of daily routine recommended intake values—of vitamin and mineral supplements has not been evaluated in large-scale clinical trials for safety and efficacy. Some vitamins (e.g., vitamin A, niacin, pyridoxine) and minerals (e.g., iron, fluoride) are known to have toxic effects at high doses. Therefore, patients should be cautioned against initiating high-dose self-medication with any nutrient without proper medical supervision.

Vitamins

Vitamins are nutrients that cannot be synthesized in the body in sufficient quantities and must be obtained through the diet. With conditionally essential nutrients such as L-arginine, L-carnitine, taurine, and coenzyme Q10, endogenous production is adequate in most circumstances, but certain disorders (e.g., cardiovascular disease) can be associated with impaired biosynthesis. Under these conditions, conditionally essential nutrients may then become essential nutrients, comparable to vitamins, necessitating dietary intake to meet requirements. Vitamins are used as both dietary supplements and therapeutic agents to treat deficiencies or other pathologic

conditions.

As previously noted, DRI reference values are developed by the National Academies of Science, Engineering, and Medicine (Tables 23–4 and 23–5).^{14,15} Adjustment may be necessary with strenuous physical activity, the presence of disease, or compromise of absorption site integrity by disease or resection.

Figure 23–2 summarizes sites of nutrient absorption, although some nutrients can be absorbed at other sites particularly when absorption at the primary site is compromised. As nutritional supplements, vitamins usually are dosed at 50%–150% of DRI values. Practitioners should advise caution for use of high-dose supplements (>200% of the DRI) without medical supervision. Identified ULs are listed in Table 23–6. As therapeutic agents, vitamins should be recommended only for specific evidence-based medical indications.

Figure 23–2 Major sites of nutrient absorption. The site of absorption may be influenced by transit time through the GI tract and by disease or surgical procedures that alter GI function or anatomy. Key: FA = Fatty acids (lipids); GI = gastrointestinal; HCl = hydrochloric acid; RYGB = Roux-en-Y gastric bypass; SCFA = short-chain fatty acids.

Table 23–4 Dietary Reference Intakes (DRIs): Recommended Dietary Allowances and Adequate Intakes—Vitamins Food and Nutrition Board, Institute of Medicine—National Academies of Sciences, Engineering, and Medicine							
Life Stage Group	Vitamin A (mcg/day) ^a	Vitamin C (mg/day)	Vitamin D (mcg/day) ^{b,c}	Vitamin E (mg/day) ^d	Vitamin K (mcg/day)	Thiamine (mg/day)	Riboflavin (mg/day)

Note: This table (taken from the DRI reports; see www.nap.edu) presents recommended dietary allowances (RDAs) in **bold type** and adequate intakes (AIs) in ordinary type followed by an asterisk (*). An *RDA* is the average daily dietary intake

those who are older than 50 years to meet the folate intake by consuming foods fortified with folic acid, it is recommended that all women capable of becoming pregnant take folate 400 mcg daily from supplements or fortified foods in addition to intake of food folate. In view of evidence linking maternal folate intake with neural tube defects in the fetus, it is recommended that all women capable of becoming pregnant take folate 400 mcg daily from supplements or fortified foods in addition to intake of food folate from a varied diet until their pregnancy is confirmed and they enter prenatal care, which ordinarily occurs after the end of the periconceptional period—the critical time for formation of the neural tube. It is assumed that women will continue consuming 400 mcg from supplements or fortified food until their pregnancy is confirmed and they enter prenatal care, which ordinarily occurs after the end of the periconceptional period.

Note: This table (taken from the DRI reports; see www.nap.edu) presents recommended dietary allowances (RDAs) in **bold type** and adequate intakes (AIs) in ordinary type followed by an asterisk (*). An RDA is the average daily dietary intake level sufficient to meet the nutrient requirements of nearly all (97%–98%) healthy subjects in a group. It is calculated from an Estimated Average Requirement (EAR). If sufficient scientific evidence is not available to establish an EAR, allowing calculation of an RDA, an AI is usually developed. For healthy breastfed infants, an AI is the mean intake. The AI for other life stage and gender groups is believed to cover the needs of all persons in the groups, but lack of data or uncertainty in the data prevents being able to specify with confidence the percentage of persons covered by this intake. Intakes for Vitamin C, Vitamin E, Selenium, and Carotenoids (2000); and Dietary Reference Intakes for Vitamin A, Vitamin K, Arsenic, Boron, Chromium, Copper, Iodine, Iron, Manganese, Molybdenum, Nickel, Silicon, Vanadium, and Zinc (2001); Dietary Reference Intakes for Water, Potassium, Sodium, Chloride, and Sulfate (2005); Dietary Reference Intakes for Calcium and Vitamin D (2011); and Dietary Reference Intakes for Sodium and Potassium (2019). FDA has published a less comprehensive set of values to be used for food and dietary supplement labeling.¹⁶ For nutrient intakes for adults older than 18 years, values are listed as a percentage of daily values (%DV) for a 2000-calorie diet. The vitamin or mineral supplement label includes a box with the heading “Supplement Facts.” In addition to information on serving size and servings per container, the label lists all required nutrients that are present in the dietary supplement in significant amounts and the %DV, if a reference value has been established. It also lists all other dietary ingredients present in the product (including botanicals and amino acids) for which no %DV has been established. The %DV is based on DRI values for adults and for children 4 years of age and older, unless the product is designed for children younger than 4 years or for women who are pregnant or lactating.

Frequently, “natural” vitamin products are supplemented with synthetic vitamins. For example, because the amount of vitamin C present in rose hips (the fleshy fruits of a rose) is relatively small, synthetic vitamin C, which lacks the mass of vegetable matter, is added to allow product formulation as a tablet of convenient size. However, this addition may not be noted on the label, and the price of the partially natural product is often considerably higher than that for the completely synthetic—but equally effective—product. Patients should be informed that the body cannot distinguish between a vitamin molecule derived from a synthetic source and one derived from a natural source, and that most synthetic vitamins are the biochemical equivalent of the more expensive “natural” vitamins.

Fat-Soluble Vitamins

Two broad categories of vitamins exist: fat-soluble and water-soluble. Vitamins A, D, E, and K are fat-soluble vitamins. They are soluble in lipids and usually are absorbed into the lymphatic system before passing into the general circulation. Their absorption is facilitated by bile. These vitamins are stored in body tissues, so ingestion of excessive quantities may lead to toxicity. Fat-soluble vitamins, in general, come from similar dietary sources, including dietary fats and oils, milk products, and egg yolks (Table 23–7).^{13,17} Deficiencies occur when fat intake is limited or fat absorption is compromised. Diseases and conditions that may be associated with malabsorption of fat-soluble vitamins include celiac disease, cystic fibrosis, obstructive jaundice, hepatic cirrhosis, physiologic–anatomic changes secondary to bariatric surgical procedures, and short bowel syndrome. Deficiencies also may be precipitated

by drugs that affect lipid absorption, such as cholestyramine, which binds bile acids, thereby hindering lipid emulsification; orlistat, which inhibits gastric and pancreatic lipases in the intestinal lumen; and mineral oil, which is not absorbed and therefore increases fecal loss of fat-soluble vitamins. Potential drug–nutrient interactions are listed in [Table 23–8](#). The manufacturer recommends a daily multivitamin supplement for those taking orlistat; [Chapter 27](#) provides a more comprehensive discussion of the use of orlistat for weight loss.

Table 23–7 Food Sources Rich in Selected Nutrients

Vitamin	Food Sources
Fat-Soluble Vitamins	
Vitamin A	Liver, milk fat, egg yolk, yellow and dark green leafy vegetables, apricots, cantaloupe, peaches, carrots
Vitamin D	Vitamin D-supplemented milk, egg yolk, liver, salmon, tuna, sardines
Vitamin E	Wheat germ, vegetable oils, margarine, green leafy vegetables, milk fat, egg yolks, nuts
Vitamin K	Liver, vegetable oil, spinach, kale, cabbage, cauliflower
Water-Soluble Vitamins	
Vitamin C	Green and red peppers, broccoli, spinach, tomatoes, potatoes, strawberries, citrus fruit, kiwi
Vitamin B ₁₂	Liver, meat, poultry, oysters, clams, dairy products
Folate	Liver, lean beef, wheat, whole-grain cereals, eggs, fish, dry beans, lentils, green leafy vegetables, folate-supplemented cereals and grains
Niacin	Lean meats, fish, liver, poultry, grains, eggs, peanuts, milk, legumes
Pantothenic acid	Eggs, kidney, liver, salmon, yeast, some present in all foods
Vitamin B ₆	Meats, cereals, lentils, legumes, nuts, egg yolk, milk
Riboflavin	Meats, poultry, fish, dairy products, green leafy vegetables, enriched cereals and breads, eggs
Thiamin	Legumes, whole-grain and enriched cereals and breads, wheat germ, pork, beef

Vitamin	Food Sources
Biotin	Liver, egg yolk, mushrooms, peanuts, milk, most vegetables, bananas, yeast
I-Carnitine	Dairy products, meat
Choline	Egg yolk, cereal, fish, meats
Minerals	
Calcium	Dairy products, sardines, clams, oysters, turnip greens, mustard greens
Iron	Liver, meat, egg yolk, legumes, whole or enriched grains, dark green vegetables, shrimp
Magnesium	Whole-grain cereals, tofu, nuts, legumes, green vegetables
Phosphorus	Milk, meat, poultry, fish, seeds, nuts, egg yolk
Chromium	Liver, fish, clams, meats, whole-grain cereals, milk, corn oil
Cobalt	Organ meats, oysters, clams, poultry, milk, cream, cheese
Copper	Liver, shellfish, whole grains, cherries, legumes, poultry, oysters, chocolate
Manganese	Vegetables, fruits, nuts, legumes, whole-grain cereals
Molybdenum	Legumes, cereals, dark green leafy vegetables, organ meats, milk
Selenium	Meat, grains, onions, milk
Silicon	Cereal products, root vegetables
Vanadium	Shellfish, mushrooms, parsley, dill seed, black pepper
Zinc	Oysters, shellfish, liver, beef, lamb, pork, legumes, milk, wheat bran

Table 23–8 Micronutrient–Drug and Micronutrient–Micronutrient Interactions

Micronutrient	Interacting Drug/ Micronutrient	Effect	Precautionary Measure(s)
Vitamins			

Micronutrient	Interacting Drug/ Micronutrient	Effect	Precautionary Measure(s)
Vitamins A, E (large doses)	Warfarin	Increased anticoagulation and risk of bleeding	Take only in recommended U.S. DRI amounts.
Vitamins A, E, D, K, C	Cholestyramine, colestipol, orlistat, or mineral oil	Decreased vitamin absorption	Avoid prolonged use of cholestyramine, colestipol, orlistat, or mineral oil.
Vitamin D	Phenytoin, carbamazepine, barbiturates	Increased metabolism of vitamin D	Ensure adequate dietary intake of vitamin D.
	Corticosteroids	May impair metabolism of vitamin D	Ensure adequate dietary intake of vitamin D.
Vitamin K	Broad-spectrum antibiotics (long-term therapy)	Vitamin K deficiency induced by decreased gut flora	Ensure adequate dietary intake of vitamin K.
	Warfarin	Decreased anticoagulation	Keep daily intake of vitamin K consistent.
	Vitamin E (large doses)	Antagonizes function of vitamin K	Avoid chronic supplementation with high-dose vitamin E.
	Vitamin A (large doses)	May interfere with vitamin K absorption	Avoid chronic supplementation with high-dose vitamin A.
Vitamin B ₁₂	Metformin, colchicine, anticonvulsants, ascorbic acid supplements, gastric acid-lowering agents (proton pump inhibitors, H ₂ RAs), tetracyclines, and long-term use of antibiotics	Potential decreased absorption of cyanocobalamin	Clinical significance is unknown.
Folic acid	Phenytoin and possibly other related	Possible inhibition of folic acid absorption, leading to	Monitor for megaloblastic anemia.

Micronutrient	Interacting Drug/ Micronutrient	Effect	Precautionary Measure(s)
	anticonvulsants (chronic use)	megaloblastic anemia; with subsequent increased folic acid supplementation, potential for decreased serum phenytoin levels and difficulty with seizure control	Consult with neurologist regarding supplementation, if possible. Patient should report use of any dietary supplement to their neurologist.
	Trimethoprim	Weak folic acid antagonism; decreased activity/ effectiveness; rare occurrence of megaloblastic anemia in patients with preexisting low folic acid level	Monitor for megaloblastic anemia.
	Pyrimethamine (large doses)	Possible megaloblastic anemia	Monitor for megaloblastic anemia.
	Methotrexate	Folic acid antagonism; decreased activity/ effectiveness	Monitor use of folic acid in patients on maintenance regimens for psoriasis or rheumatoid arthritis.
	Sulfasalazine	Decreased folic acid absorption when these agents are administered together	Separate dosing of these agents.
Niacin	Oral hypoglycemic agents; sulfinpyrazone and probenecid	Decreased hypoglycemic effects; possible inhibited uricosuric effects	Monitor blood glucose with regular finger sticks.
Vitamin B ₆	Isoniazid	Pyridoxine antagonism, manifested as perioral numbness resulting from peripheral neuropathy	Routinely take 50 mg daily of pyridoxine hydrochloride with isoniazid, or 10 mg of pyridoxine for each 100 mg of isoniazid.
	Phenobarbital and phenytoin	Decreased serum drug levels	Consider monitoring levels in patients

Micronutrient	Interacting Drug/ Micronutrient	Effect	Precautionary Measure(s)
			taking high-dose pyridoxine.
	Levodopa	Levodopa antagonism; decreased effectiveness	Avoid supplemental pyridoxine or, if possible, substitute levodopa/carbidopa for levodopa.
Minerals			
Calcium	Iron, zinc, magnesium	Inhibited nutrient absorption caused by high calcium intake	Separate dosing by at least 2 hours.
	Corticosteroids	Inhibited calcium absorption from gut; increased bone fractures and osteoporosis	Consider calcium supplementation.
	Aluminum-containing antacids, phosphates, cholestyramine	Decreased calcium absorption	Separate dosing by at least 2 hours.
	H2RAs, proton pump inhibitors	Decreased absorption of calcium carbonate, which requires an acidic environment	Consider calcium citrate supplementation.
	Levothyroxine	Reduced drug absorption	Separate dosing by 4 hours.
	Tetracyclines, fluoroquinolones	Decreased antibiotic absorption	Separate dosing by 2 hours.before or 6 hours.after ingestion of the antibiotic.
	Phenytoin, carbamazepine, phenobarbital	Decreased calcium absorption by increasing metabolism of vitamin D	Consider calcium and vitamin D supplementation.
Magnesium	Tetracyclines, fluoroquinolones	Decreased antibiotic absorption	Separate dosing by 2 hours.before or 6 hours.after ingestion of the antibiotic.

Micronutrient	Interacting Drug/ Micronutrient	Effect	Precautionary Measure(s)
	Levothyroxine	Reduced drug absorption	Separate dosing by 4 hours.
Phosphorus	Sucralfate or antacids containing magnesium, calcium, or aluminum	Decreased absorption of phosphorus	Ensure adequate intake of dietary phosphorus.
Iron	Antacids	Decreased iron solubility and absorption	Separate dosing by at least 2 hours.
	Tetracyclines, fluoroquinolones	Decreased antibiotic and iron absorption	If concurrent administration is medically necessary, take tetracycline or fluoroquinolone 2 hours before or 6 hours after taking iron.
	Levothyroxine	Decreased drug absorption	Separate dosing by 4 hours.
Trace Elements			
Copper	Zinc, high-dose vitamin C	Copper antagonism	Micronutrients may compete for absorption and utilization; ensure supplements are administered in balanced doses, or monitor for signs of deficiency.
Fluoride	Magnesium, aluminum, calcium	Decreased effect and absorption of fluoride	Separate supplementation by at least 2 hours.
Iodine (potassium iodide)	Lithium salts	Possible additive hypothyroid effects	Monitor thyroid function tests.
Zinc	Copper	Possible decreased copper levels	High-dose, prolonged zinc supplementation

Micronutrient	Interacting Drug/ Micronutrient	Effect	Precautionary Measure(s)
			may require copper supplementation.
	Tetracyclines, fluoroquinolones	Possible decreased antibiotic absorption	Separate dosing by 2 hours.before or 6 hours.after ingestion of the antibiotic.

Key: DRI = Dietary Reference Intake; H2RA = histamine type 2 receptor antagonist.

Vitamin A

The designation *vitamin A* refers to a large group of compounds that includes the retinoids (e.g., retinol) and the carotenoids (e.g., alpha-carotene, beta-carotene). Biochemical changes occur in some of these compounds during absorption in the intestine to form active vitamin A. Certain other compounds (e.g., the carotenoids, lutein, lycopene) are not converted to active vitamin A but have other health-promoting properties. These compounds can be found in dark green vegetables and red, orange, or deep yellow vegetables and fruits.

In healthy adults, more than 90% of the body's supply of vitamin A is stored in the liver. Because of this generous reserve, the risk of deficiency during short-term periods of inadequate intake or fat malabsorption is minimal. Infants and young children, by contrast, are more susceptible to vitamin A deficiency because they have not established the necessary reserves.

Function. Vitamin A is essential for normal growth and reproduction, normal skeletal and tooth development, and proper functioning of most organs of the body (notably, the specialized functions of the eye involving the conjunctiva, retina, and cornea). Vitamin A is thus indicated for preventing and treating manifestations of vitamin A deficiency, such as xerophthalmia (dry eye) and nyctalopia (night blindness). Synthesis of the glycoproteins necessary to maintain normal epithelial cell mucous secretions also requires vitamin A. This mucosal barrier is vital to the body's defense against bacterial infections in the upper respiratory system.

Deficiency. Vitamin A deficiency is rare in well-nourished populations.

However, an estimated 250,000–500,000 children worldwide develop blindness each year because of vitamin A deficiency.¹⁸ Conditions such as celiac or Crohn’s disease, pancreatic disorders, cancer, tuberculosis, pneumonia, and prostate disease, as well as therapy with corticosteroids, may lead to excessive excretion of vitamin A. Fat malabsorption may impair vitamin A absorption; in the United States, vitamin A deficiency occurs more often from diseases of fat malabsorption than from malnutrition.

One of the earliest symptoms of vitamin A deficiency is night blindness.¹⁸ Other characteristic clinical findings include follicular hyperkeratosis, loss of appetite, impaired taste and smell, and disturbance of equilibrium. Some of these abnormalities may be masked by those associated with concurrent deficiencies of other nutrients. The drying and hyperkeratinization of the skin caused by the disruption of vitamin A–dependent epithelial integrity predispose patients to infections.

Dosing and Daily Requirements. Vitamin A is indicated for use in the treatment and prevention of vitamin A deficiency.¹⁹ The patient’s estimated dietary intake of vitamin A is needed to determine a nontoxic dose for supplementation.

The DRI values for vitamin A are measured in micrograms as retinol activity equivalents (RAEs), for which dosing considerations are summarized in [Table 23–9](#).¹⁴ The Food and Nutrition Board recommends use of RAEs as a way to determine the amounts of carotenoids absorbed, as well as their degree of conversion to vitamin A in the body. RAEs replace the former designation of retinol equivalents (REs) used to calculate total vitamin A values from various dietary sources.

Table 23–9 Retinol Activity Equivalent Dosing Considerations	
1 retinol activity equivalent (RAE)	= 1 retinol equivalent (RE) ^a
	= 1 mcg retinol
	= 12 mcg beta-carotene
	= 24 mcg alpha-carotene
	= 24 mcg beta-cryptoxanthin
	= 3.33 IU vitamin A activity from retinol

	= 10 IU vitamin A activity from beta-carotene

^a The RAE unit has replaced the RE unit.

The DRI values for vitamin A are listed in [Table 23–4](#).¹⁴ The UL of 3 mg vitamin A daily in adults has been established on the basis of congenital birth defect risks and liver abnormalities associated with vitamin A toxicity.¹⁴ Evidence suggests high-dose vitamin A intake, even that below the established UL, may be associated with an increased risk of bone fractures.²⁰

Clearly, if the health care provider determines that vitamin A supplementation is appropriate, a nonprescription multivitamin containing no more than the DRI value of vitamin A can be recommended for self-care until the patient can be fully evaluated; under medical supervision, doses may be considerably higher.¹⁴ Preferably, a significant percentage of total vitamin A content should be contributed by beta-carotene, which is not associated with the risk of fractures or vitamin A toxicity. Beta-carotene's better safety profile may be related to limitations in its absorption and conversion to retinol.²⁰ However, the increased cancer risk associated with beta-carotene supplementation in both smokers and former smokers should be kept in mind (see under "Safety Considerations," next). High-dose vitamin A or beta-carotene therapy should never be undertaken without close medical supervision.

Safety Considerations. Because vitamin A is stored in the body, high doses can lead to a toxic syndrome known as hypervitaminosis A. The potential for development of this condition increases as patients consume multiple sources containing vitamin A: a multivitamin for eye health, another for cancer prevention, and potentially two more for treatment of skin disorders and wound healing. Long-term administration of vitamin A is unlikely to cause toxicity with doses less than 10,000 IU per day of retinol or equivalents; however, the risk for toxicity may increase in patients with chronic renal or liver disease, and in persons with low body weight, protein malnutrition, excessive alcohol consumption, or vitamin C deficiency.¹⁹ Headache is a predominant symptom and may be accompanied by diplopia (double vision), nausea, vomiting, vertigo, fatigue, or drowsiness. Treatment consists of discontinuing vitamin A supplementation, which should result in complete recovery.

Although beta-carotene toxicity is not likely, consuming large amounts of carrots in the daily diet may result in carotenemia, which can produce a yellow skin hue. Pregnant women or women of childbearing age should avoid vitamin A doses above the DRI, and the total vitamin A content of all dietary supplements and fortified foods consumed regularly should be carefully evaluated because of the teratogenic risk with excess vitamin A intake. For this reason, women of childbearing age should be reminded not to take other dietary supplements when a prescription prenatal vitamin is dispensed.

The potential role of vitamin A as a cancer-preventing antioxidant prompted two large randomized controlled trials to evaluate supplementation in current or former smokers at risk for development of lung cancer. In these trials, either no benefit with supplementation or a greater risk of lung cancer, cardiovascular disease, or death in those receiving supplementation was identified.^{21,22} Such trials confirm that vitamin supplementation cannot confer the same health benefits as those provided by a diet rich in fruits and vegetables.

Vitamin D (Calciferol)

A number of chemical compounds are associated with vitamin D activity. Cholecalciferol (vitamin D₃) is the naturally occurring form of vitamin D that is synthesized in the skin from endogenous or dietary cholesterol on exposure to ultraviolet radiation (sunlight). Ergocalciferol (vitamin D₂), which is used as a food additive, differs only slightly in structure from cholecalciferol. Metabolic activation of vitamin D requires hydroxylation by both the liver and the kidneys. The metabolite 25-hydroxycholecalciferol (calcidiol) is formed by the liver and then hydroxylated by the kidneys to its active form, 1,25-dihydroxycholecalciferol (calcitriol). Therefore, either renal or hepatic dysfunction may result in clinical manifestations of vitamin D deficiency, including hypocalcemia unresponsive to nonprescription vitamin D supplementation. Affected patients require a hydroxylated vitamin D preparation available only by prescription.

Function. Vitamin D, which has properties of both a hormone and a vitamin, is necessary for the proper formation of bone and for mineral homeostasis. It is closely involved with the activity of parathyroid hormone, phosphate, and calcitonin in maintaining homeostasis of serum calcium levels. Adequate vitamin D intake and supplementation in conjunction with sufficient intake of

calcium, not vitamin D alone, may reduce the risk of bone fractures and falls in postmenopausal women with osteoporosis when dosed according to clinical evidence.^{23,24} Other nonskeletal effects (e.g., reduced overall mortality, decreased risk for diabetes and cancer, lower rates of correlation with multiple sclerosis and allergies and asthma) have been evaluated in controlled clinical trials, with variable results.²⁵ Observational data have suggested that vitamin D deficiency may be associated with increased risk of cardiovascular diseases, including hypertension, coronary artery disease, and cardiomyopathy.²⁶ A recent meta-analysis of prospective randomized clinical data, however, suggests that supplementation with vitamin D does not confer cardiovascular disease protection or benefit.²⁷ Furthermore, high-dose vitamin D supplementation in a prospective, multicenter placebo-controlled study, the Vitamin D and Omega-3 Trial (VITAL), with patients randomly assigned to receive high-dose vitamin D (2000 IU per day, $n = 12,927$) or placebo ($n = 12,944$), did not reduce the risk of major cardiovascular events or rates of invasive cancer types, including breast, prostate, and colorectal cancer.²⁸ Caution against excess supplementation is warranted because some people may be at inherently greater risk for breast, esophageal, prostate, and pancreatic cancers.²⁵ Additional controlled trials are needed to confirm the health benefits, risks, and role of vitamin D supplementation for specific patient populations. Furthermore, as data on vitamin D supplementation and the role of serum level monitoring continue to accrue, dosing recommendations for prescription-only vitamin D formulations may be considerably higher when based on serum monitoring.

Deficiency. Vitamin D deficiency may result from inadequate intake; gastrointestinal (GI) diseases (e.g., hepatobiliary disease, malabsorption, chronic pancreatitis); chronic renal failure; inadequate sunlight exposure or dark skin pigmentation; hereditary disorders of vitamin D metabolism; obesity or gastric bypass therapy; or long-term therapy with antiepileptic medications (e.g., phenytoin, carbamazepine, primidone). In older patients, aging skin may not synthesize vitamin D efficiently, and the converting process that takes place in the liver and kidneys also may be compromised. The altered physiologic actions—in addition to reduced sun exposure, absorption, and dietary intake of vitamin D typical for this age group—leave older adults at increased risk for vitamin D deficiency.

The signs and symptoms of vitamin D deficiency are reflected as calcium abnormalities, specifically those involved with bone formation. Vitamin D

deficiency also has been associated with muscle weakness, an increased risk of falls, an increased risk of cardiovascular disease and certain cancers, and psychiatric disorders.²⁸ Of note, however, an “association” does not indicate causation, so the significance of such reported correlations remains unclear.

The classic vitamin D deficiency state is rickets, affecting children; osteoporosis with increased risk of fractures also occurs in adults. Vitamin D increases calcium and phosphate absorption from the small intestine, mobilizes calcium from bone, permits normal bone mineralization, improves renal reabsorption of calcium, and maintains serum calcium and phosphorus levels. As serum calcium levels fall, compensatory mechanisms (e.g., increased secretion of parathyroid hormone) become activated in an attempt to restore serum calcium homeostasis. Long-term increases in parathyroid hormone secretion ultimately lead to secondary hyperparathyroidism. If physiologic mechanisms fail to make the appropriate adjustments in calcium and phosphorus levels, demineralization of bone ensues to maintain essential plasma calcium levels. During growth, the demineralization process leads to a failure of bone matrix mineralization, widening of the epiphyseal plate from weight load on softened bone structures, and deformity of joints. In adults, such demineralization may lead to severe osteomalacia.

The incidence of rickets in the United States is low, but the condition is still seen. Rickets is most likely to occur in children who abstain from milk and in infants breastfed by mothers who receive an inadequate intake of vitamin D.

Dosing and Daily Requirements. Most people obtain the RDA or AI for vitamin D from dietary sources and from exposure to sunlight ([Table 23–4](#)). People who are regularly exposed to sunlight generally will have no dietary requirement for vitamin D. However, substantial segments of the U.S. population receive limited sunlight exposure, especially during the winter months. Regular use of broad-spectrum sunscreen is widely encouraged to prevent skin cancer, but that protection theoretically limits vitamin D synthesis in the skin and may warrant consideration of vitamin D intake from dietary sources; recent evidence has questioned the extent of the effect of sunscreen on influencing vitamin D synthesis. Milk and milk products are the major sources of dietary vitamin D in the United States, because milk is routinely supplemented with 100 IU (2.5 mcg) of vitamin D per cup.

Vitamin D is indicated for the treatment of hypocalcemia and hypophosphatemia associated with hypoparathyroidism. Prescription vitamin

D analogues (e.g., calcitriol) are approved for the treatment of secondary hyperparathyroidism in patients with chronic renal failure.¹⁹

If the health care provider determines that vitamin D supplementation is appropriate because of poor dietary intake or inadequate exposure to sunlight, a multivitamin supplement containing cholecalciferol (vitamin D₃) 15–20 mcg (600–800 IU) taken daily may be recommended. Some evidence suggests that vitamin D intake of up to 25 mcg (1000 IU) daily may have health benefits. The current UL for vitamin D is 100 mcg (4000 IU) daily, although this value may be increased in the future.¹⁴ Data gathered from the recent upswing in use of prescription-only high-dose (50,000 IU weekly) vitamin D supplements suggest that such doses are safe and necessary to achieve adequate serum concentrations. However, these high doses should not be recommended for self-care.

Safety Considerations. Taking more than the UL of vitamin D daily may lead to adverse effects, including anorexia, hypercalcemia, soft tissue calcification, kidney stones, renal failure, and increased risk of certain types of cancer.^{14,15} Patients receiving doses above the UL (e.g., those who have rickets or low serum concentrations) should be under medical supervision and closely monitored for these adverse effects.

Vitamin E (Tocopherol)

The term *vitamin E* refers to the tocopherols and the tocotrienols, compounds that occur naturally in plants.

Function. Vitamin E functions primarily as an antioxidant, protecting cellular membranes from oxidative damage or destruction. This process may be aided by selenium and vitamin C. Vitamin E also may have a role in heme biosynthesis, steroid metabolism, and collagen formation.

Vitamin E supplements, often combined with other antioxidants, have been promoted for treatment of numerous diseases (e.g., atherosclerosis, diabetes, cancer, Parkinson's disease, Alzheimer's disease). These recommendations often are based on observational studies in which regular intake of fruits and vegetables rich in antioxidants has shown beneficial effects on health maintenance and prevention of disease. However, clinical trials have suggested a lack of benefit with vitamin E supplementation in reducing the risks of multiple conditions, including cardiovascular events or mortality,

stroke, cancer, diabetes, and Alzheimer's disease.^{29–31} On the contrary, antioxidant supplementation that includes vitamin E may be associated with an increased risk of congestive heart failure in certain populations, increased risk of hemorrhagic stroke in adults, and an increased risk of fetal loss when given to prevent preeclampsia.^{31–33}

For both patients and providers, it is essential to recognize that vitamin supplementation is not necessarily benign and has not shown benefit over a well-balanced diet, especially with dosing in excess of the DRI.

Deficiency. Vitamin E deficiency is extremely rare but may occur in two patient populations: premature infants of very low birth weight and patients with disorders of fat malabsorption. For example, neurologic abnormalities responsive to supplemental vitamin E have been reported in some patients with biliary disease and cystic fibrosis. Vitamin E deficiency also has been associated with symptoms of peripheral neuropathy, intermittent claudication, muscle weakness, and hemolytic anemia.

Dosing and Daily Requirements. The RDA for vitamin E is reported as milligrams of alpha-tocopherol. One mg is equivalent to 1.49 international units (IU) of the natural vitamin or 2.22 IU of the synthetic form.¹⁴

The average diet supplies approximately 3–15 mg daily of vitamin E, so large doses in excess of the DRI are not necessary unless the patient is experiencing fat malabsorption. The FDA-approved use of vitamin E is for prevention and treatment of hemolytic anemia associated with deficiency.¹⁹

Vitamin E requirements may vary in proportion to the amount of polyunsaturated fatty acids in the diet. The polyunsaturated fatty acid content of the U.S. diet has increased, and the plant oils responsible for the increase are rich in tocopherol. The lack of evidence for deficiency at the present intake supports the current adult RDA of 15 mg daily; the UL for vitamin E is 1000 mg daily.¹⁴

Safety Considerations. Potential risks associated with vitamin E supplementation are described in the “Function” section.

Vitamin K

Phytonadione (vitamin K₁) is present in many vegetables. Menaquinone

(vitamin K₂) is a product of colonic bacterial metabolism. Menadione (vitamin K₃) is a synthetic compound that is 2–3 times more potent than the natural form of vitamin K.

Function. Vitamin K has important roles in normal physiology. It promotes the synthesis of clotting factors II, VII, IX, and X in the liver and also activates these factors, along with the anticoagulation proteins C and S. The clotting factors remain inactive in the liver in the presence of warfarin or in the absence of vitamin K. When vitamin K is administered, normal activity of the clotting factors resumes. Vitamin K also is necessary for the activation of osteocalcin, which plays a role in bone mineralization and the prevention of osteoporosis.³⁴

Deficiency. The DRI value for vitamin K is 90–120 mcg daily for adults, depending on age and gender.¹⁴ The normal gut flora synthesizes enough menaquinone to supply a significant part of the body's requirement for vitamin K. Therefore, the prevalence of deficiency among healthy, well-nourished persons is low. Interference with bile production or secretion may contribute to vitamin K deficiency, because vitamin K absorption in the small intestine requires bile. Malabsorption syndromes and bowel resections may lead to decreased vitamin K absorption. Liver disease also may cause symptoms of vitamin K deficiency if hepatic production of the prothrombin clotting factor is decreased. Other potential causes of deficiency include intestinal disease or resection and chronic, broad-spectrum antibiotic therapy. Deficiency may be evidenced by unusual bleeding and demonstrated by an elevated international normalized ratio (INR). Comparisons of lower and higher dietary intakes of vitamin K indicate increased risk of osteoporotic fractures with lower intake; however, well-designed trials are needed to confirm this association.³⁴

Dosing and Daily Requirements. The DRI values for vitamin K are listed in [Table 23–4](#); a UL for vitamin K has not been established.¹⁴ Vitamin K₁ (phytonadione) is approved for use in neonates at birth (1 dose of 1 mg) to prevent hemorrhage. This dose is necessary because placental transport of vitamin K is low, and the neonate has yet to acquire the intestinal microflora responsible for producing the vitamin. Other approved uses include the prevention and treatment of hypoprothrombinemia caused by drug-induced deficiency and the treatment of hemorrhage.¹⁹

Consistent dietary intake of vitamin K (70–140 mcg daily) does not usually interfere with warfarin anticoagulant activity. However, sudden changes in the

dietary or supplemental intake of vitamin K can significantly alter the patient's INR.

Safety Considerations. Even in large amounts over an extended period, vitamin K does not produce toxic manifestations. However, the vitamin K content of MVM products should be evaluated for anyone receiving warfarin for anticoagulation.

Water-Soluble Vitamins

Vitamin C, the B-complex vitamins (riboflavin, thiamine, B₆, B₁₂, niacin, pantothenic acid, biotin, folic acid), and the vitamin-like compound choline are classified as water-soluble vitamins. These vitamins generally are not stored in the body, and excess quantities tend to be excreted in the urine. Therefore, daily intake of these vitamins is desirable for optimal health. Thiamine, riboflavin, niacin, vitamin B₆, and pantothenic acid are involved in cellular energy production and utilization, and they may support synthesis of amino acids, fatty acids, cholesterol, steroids, and glucose.³⁵ Biotin may support fat and carbohydrate metabolism, whereas folate, vitamin B₆, vitamin B₁₂, choline, and riboflavin are involved with homocysteine metabolism; folate also is a critical cofactor in deoxyribonucleic acid (DNA) synthesis. All B-complex vitamins come from similar dietary sources ([Table 23-7](#)), so persons presenting with signs and symptoms of deficiency in one of the B-complex vitamins also may be at risk for deficiency in others. A listing of select drug–micronutrient interactions with the water-soluble vitamins is included in [Table 23-8](#).

Vitamin C (Ascorbic Acid)

Vitamin C is the most easily destroyed of all of the vitamins because of its sensitivity to heat, oxygen, and alkaline environments. It is a relatively simple compound with powerful antioxidant activity that serves to protect the capillary basement membrane. Vitamin C has been called the “fresh food” vitamin; most of the daily vitamin C intake is derived from vegetables and fruit sources.

Function. Vitamin C is necessary for the biosynthesis of hydroxyproline, a precursor of collagen, osteoid, and dentin. This vitamin also assists in the absorption of nonheme iron from food by reducing the ferric iron in the stomach to ferrous iron. However, use of vitamin C supplementation with iron

generally is not necessary for patients with normal gastric acidity who are taking adequate doses of iron.

Large doses of vitamin C (500–1000 mg daily) have been promoted to prevent and treat the common cold. Of note, such claims are largely unsupported by well-designed controlled clinical studies.^{18,36} Consumption of 5 servings or more of fruits and vegetables daily (≥ 200 mg vitamin C) has been associated with a lower incidence of cancer, heart disease, stroke, and certain eye diseases.³⁷ However, currently available data are inadequate to support vitamin C supplementation above the DRI for the prevention or treatment of these chronic conditions.³⁶

Deficiency. Characteristics of vitamin C deficiency include fatigue, capillary hemorrhages and petechiae, swollen hemorrhagic gums, and bone changes. Deficiency also may impair wound healing. Profound dietary deficiency eventually can lead to development of scurvy, with widespread capillary hemorrhaging and a weakening of collagenous structures.

Scurvy is rare in the United States because it develops only with chronically inadequate consumption of vitamin C. Infants who are fed artificial formulas without vitamin supplements may develop symptoms of scurvy. In adults, however, scurvy occurs after 3–5 months of a diet free of vitamin C.

Dosing and Daily Requirements. Health care providers are rarely confronted with patients with overt signs and symptoms of vitamin C deficiency. Only 10 mg daily of vitamin C prevents scurvy; a normal diet containing fresh fruits and vegetables contains many times this amount. The DRI values for vitamin C are listed in [Table 23–4](#). Supplementation of 100–125 mg daily has been recommended for smokers, because higher daily ascorbic acid losses were observed in such patients.³⁶ The UL for vitamin C is 2 g daily.¹⁴

Most adult multivitamin supplements contain 60–100 mg of vitamin C, an appropriate amount to consume if supplementation is required. A daily dose greater than 400 mg is rarely indicated, and excess intake is excreted in the urine. In patients with a severe vitamin C deficiency, as evidenced by clinical signs of scurvy, 100–300 mg daily of vitamin C for at least 2 weeks is recommended to replenish body stores.¹⁹ Infants who do not have vitamin C supplements in their formula should receive 40–50 mg daily; infants who are breastfed by well-nourished mothers will receive a sufficient amount. If a supplement is warranted for an adult, the health care provider may

recommend a multivitamin product containing 60–200 mg of vitamin C to be taken once a day. Vitamin C is indicated for use in the prevention and treatment of scurvy and to acidify the urine.¹⁹

Safety Considerations. With a clinical presentation indicative of vitamin C deficiency, the relative risks and benefits of ascorbic acid therapy should be considered in each case. A short-term trial of ascorbic acid with medical supervision may be warranted to promote wound healing in potentially deficient patients. Megadoses, however, may cause nausea, stomach cramps, diarrhea, and nephrolithiasis. Ascorbic acid toxicity also can lead to hemolysis in patients deficient in glucose 6-phosphate dehydrogenase. Rebound scurvy has occurred in infants whose mothers took megadoses of vitamin C during pregnancy. Vitamin C in doses of 1 g daily with 400 IU of vitamin E resulted in an increased risk of fetal loss or perinatal death when this regimen was given for prenatal supplementation.³³ Patients with diabetes mellitus, recurrent renal calculi, or renal dysfunction also should avoid prolonged use of high-dose vitamin C supplementation.

Vitamin B₁₂ (Cyanocobalamin)

Vitamin B₁₂, the most complex vitamin molecule, exists in several forms, all of which contain the element cobalt. The term *vitamin B₁₂* refers to all cobalamins that have vitamin activity in humans. Cyanocobalamin, the common pharmaceutical form of the vitamin, is the most stable of the cobalamins.

Function. Vitamin B₁₂ is active in all cells, especially those in the bone marrow, the central nervous system (CNS), and the GI tract. It also is involved in fat, protein, and carbohydrate metabolism. A cobalamin coenzyme functions in the synthesis of DNA and in the synthesis and transfer of single-carbon units (e.g., the methyl group in the synthesis of methionine and choline). Vitamin B₁₂ participates in methylation reactions and cell division, usually in concert with folic acid. Vitamin B₁₂ is necessary for the metabolism of folates; therefore, folate deficiency may be observed in concert with vitamin B₁₂ deficiency. Vitamin B₁₂ also is necessary for the metabolism of lipids and the formation of myelin.

Vitamin B₁₂ has been studied in relation to elevated levels of homocysteine, an amino acid that requires vitamins B₁₂, B₆, and folate as cofactors for

metabolism. Hyperhomocysteinemia has been identified as an independent risk factor for cardiovascular disease. Supplementation with folate, vitamin B₆, and vitamin B₁₂ has been shown to reduce plasma homocysteine levels. However, this apparent benefit has not been proved to lower the risk of major coronary or major vascular events in persons at increased risk for cardiovascular disease.³⁸

Deficiency. Vitamin B₁₂ is found almost exclusively in animal protein; healthy people without dietary restriction rarely experience vitamin B₁₂ deficiency. The body stores enough vitamin B₁₂ in the liver that a deficiency would take approximately 3 years to develop. Vitamin B₁₂ deficiency may be caused by poor absorption or utilization of, increased requirement for, or enhanced excretion of this vitamin. Absorption is a complex process, with about 99% of gut absorption occurring via active mechanisms (Figure 23–3). In patients with conditions that affect absorption (e.g., those with ileal diseases or who have undergone intestinal resection or gastrectomy), the reabsorption phase of the enterohepatic cycle is affected, and deficiency may result. Patients older than 50 years of age are at increased risk for vitamin B₁₂ deficiency secondary to reduced gastric acidity and the consequent decrease in release of food-bound vitamin B₁₂. Reduced intestinal motility, achlorhydria, and use of gastric acid-lowering agents in this patient population contribute to bacterial overgrowth in the small intestine, resulting in more microorganisms utilizing available vitamin B₁₂.³⁹ In addition, atrophic gastritis, a condition that affects 10%–30% of older adults, can result in macrocytic anemia owing to inadequate release of vitamin B₁₂ from foods or to inadequate production of gastric intrinsic factor (pernicious anemia). For these reasons, vitamin B₁₂ supplementation from either fortified foods or a dietary supplement is recommended for this age group, as the synthetic vitamin B₁₂ found in these formulations does not require stomach acid to ensure adequate absorption.

Figure 23–3 Vitamin B12 homeostasis. Key: CoB = Cobalamin; HC = haptocorrin; HCl = hydrochloride; IF = intrinsic factor; TC = transcobalamin.

A variety of medication classes may contribute to the development of vitamin B₁₂ deficiency, including proton pump inhibitors, histamine type 2 (H₂) receptor antagonists (H₂RAs), and metformin, among others. Development of vitamin B₁₂ deficiency has been reported after as little as 3 months of metformin therapy.^{40,41}

Vegetarians who do not consume any animal products (including infants breastfed by vegetarian mothers) also are at risk for developing vitamin B₁₂ deficiency. Vitamin B₁₂ supplementation should be encouraged for these patients.

Vitamin B₁₂ is necessary for the maintenance of myelin, and deficiency states are associated with many neurologic signs and symptoms (e.g., paresthesia, peripheral neuropathy, unsteadiness, poor muscular coordination, mental confusion, agitation, hallucinations, overt psychosis). Other manifestations of vitamin B₁₂ deficiency mimic those of folate deficiency and are manifested in organ systems with rapidly duplicating cells. Effects on the hematopoietic system result in macrocytic anemia, whereas GI effects include glossitis and epithelial changes occurring along the entire digestive tract.

Health care providers should caution patients that accurate diagnosis of a suspected anemia requires laboratory assessment of the complete blood cell profile with differential count and potentially other laboratory parameters. Anemia resulting from a folic acid deficiency should be treated with folic acid; pernicious anemia and vitamin B₁₂ deficiency should be treated with vitamin B₁₂; and iron-deficiency anemia should be treated with iron. Use of an antianemia preparation that contains multiple hematinic factors should be avoided without appropriate laboratory evaluation.

Dosing and Daily Requirements. The DRI values for vitamin B₁₂ are listed in [Table 23–4](#); a UL has not been established for vitamin B₁₂.¹⁴ Oral forms can be used if the deficiency is caused by inadequate intake. For most deficiencies caused by malabsorption, high-dose oral supplementation is appropriate because the small percentage of a high dose absorbed by passive mechanisms (not requiring intrinsic factor and binding of vitamin B₁₂ in the terminal ileum) can meet requirements; intramuscular or deep subcutaneous administration is seldom required. Vitamin B₁₂ is approved for use in the treatment of pernicious anemia and vitamin B₁₂ deficiency. Other approved uses include supplementation during periods of increased requirements (e.g., pregnancy, thyrotoxicosis, hemorrhage, malignancy, liver disease, kidney disease).¹⁹ Patients who have undergone bariatric surgery (e.g., gastric bypass, gastric sleeve resection) require lifelong vitamin B₁₂ supplementation to prevent deficiency, as do patients who have undergone resection of the terminal ileum.

Hydroxocobalamin, a prescription-only product equal in hematopoietic effect

to cyanocobalamin, may be appropriate for some patients. It is more extensively bound to proteins at the site of injection and in plasma, making renal excretion slower and prolonging the duration of action.

Safety Considerations. Excessive doses have not resulted in toxicity; however, nondeficient patients taking large quantities of the vitamin have reported no benefit.

Folic Acid (Pteroylglutamic Acid, Folate)

Function. Folate is essential for cell division, DNA production, and brain and spinal cord development. It also is used in the metabolism of various amino acids. *Folic acid* refers to the synthetic version of this vitamin found in nutritional supplements and in fortified foods; *folate* refers to the naturally occurring form found only in food sources.

Folates are present in a wide variety of food sources and are heat-labile; the folic acid content of food depends on how the food is processed. Many commercially prepared carbohydrate foods (e.g., breads, pasta) are fortified with folic acid. Folic acid, whether contained in a nutritional supplement or consumed through dietary sources, is not biologically active and must undergo in vivo enzymatic conversion to the usable form (Figure 23–4).⁴² A significant percentage of the general population may have a genetic polymorphism of methylenetetrahydrofolate reductase (MTHFR) that results in inadequate enzyme activity and inability to convert folic acid to its active form.⁴³ This genetic variance has major implications for pregnant women, because folic acid supplementation in patients with this polymorphism is not effective at reducing the risk of neural tube defects in their offspring.⁴² Other genetic defects in folate metabolism may lead to abnormalities in homocysteine metabolism (leading to elevated homocysteine levels), which have been associated with neural tube defects.⁴⁴ Folate deficiency is closely linked with deficiency of other water-soluble vitamins. Furthermore, low plasma concentrations of folate, vitamin B₆, and vitamin B₁₂ have been associated with elevated concentrations of homocysteine, which may increase the risk of cardiovascular disease. Folate supplementation may reduce elevated serum homocysteine concentrations, although this effect has not translated into improved cardiovascular outcomes.⁴¹

Figure 23–4 Folate activation pathway.

Deficiency. The requirements for folic acid are related to metabolic rate and cell turnover, and increased amounts of folic acid are needed during pregnancy, lactation, and infancy. Infection, hemolytic anemia, blood loss (in which red blood cell production must be increased to replenish blood supply), and hypermetabolic states (e.g., hyperthyroidism) also increase folic acid requirements. Because folic acid deficiency in pregnancy has been associated with an increased risk of neural tube defects in the infant, supplementation for all women of childbearing age is recommended.

Causes of folic acid deficiency include alcoholism, malabsorption, food faddism, and liver disease. Iatrogenic causes are associated with administration of certain medications, including dihydrofolate reductase inhibitors (e.g., methotrexate, trimethoprim), anticonvulsants, and sulfasalazine.¹⁹

Deficiency of folic acid results in impaired cell division and protein synthesis. Signs and symptoms of folic acid deficiency include sore mouth, diarrhea, and CNS symptoms (e.g., irritability, forgetfulness). The most common laboratory-identified feature of folic acid deficiency is megaloblastic anemia (characterized by large erythroblasts circulating in the blood).

Because vitamin B₁₂ is essential for the metabolism of folates, a megaloblastic anemia responsive to folic acid administration is a feature of vitamin B₁₂ deficiency. Folic acid given without vitamin B₁₂ to patients with inadequate intrinsic factor (pernicious anemia) or vitamin B₁₂ deficiency would correct the anemia but would not stop the damage to the CNS (characterized by lack of coordination, impaired sense of position, and various behavioral disturbances). Because folic acid can mask the signs—but not the progression—of vitamin B₁₂ deficiency, patients should receive an appropriate medical evaluation for the cause of anemia rather than an empirical vitamin supplement.

Dosing and Daily Requirements. The DRI values for folic acid are listed in [Table 23–4](#). Folic acid is approved for use in the treatment of megaloblastic anemias caused by folate deficiency. Folic acid also is approved for prevention of neural tube defects in infants of folate-deficient mothers.¹⁹

All women of childbearing age should consume synthetic folic acid at a dose of 400 mcg daily from fortified foods and/or dietary supplementation, in addition to the folate obtained from food sources.¹⁴

Persons known to have a polymorphism in MTHFR should receive a prescription vitamin containing biologically active derivatives of folic acid, available in forms such as l-methylfolate, 5-methyltetrahydrofolate calcium salt, and (6S)-5-methyltetrahydrofolate glucosamine salt.⁴²

The supplemental dose of folic acid for correction of a deficiency in adults usually is 1 mg daily, particularly if the deficiency occurs with conditions that may increase the folate requirement or suppress red blood cell formation (e.g., pregnancy, other hypermetabolic states, alcoholism, hemolytic anemia). Doses larger than the UL of 1 mg daily are rarely necessary, except in some life-threatening hematologic diseases; the Centers for Disease Control and Prevention (CDC) has recommended a 4 mg/dose of folic acid for women with a previous pregnancy affected by a neural tube defect. Maintenance therapy for deficiencies may be stopped after 1–4 months if the diet contains at least one fresh fruit or vegetable daily. For chronic malabsorption diseases, folic acid treatment may be lifelong, and parenteral doses may be required.

Safety Considerations. Folic acid toxicity is virtually nonexistent because of its water solubility and rapid excretion. Doses up to 15 mg daily have been given without toxic effect. The UL is set to minimize the risk of masking vitamin B₁₂ deficiency. Several drugs, when taken chronically, may increase the need for folic acid ([Table 23–8](#)).

Niacin (Nicotinic Acid)

The physiologically active form of niacin is niacinamide. Niacin and niacinamide are constituents of the coenzymes nicotinamide adenine dinucleotide (NAD) and nicotinamide adenine dinucleotide phosphate (NADP).

Function. The niacin coenzymes are electron transfer agents; that is, they accept or donate hydrogen in the aerobic respiration of all body cells. Niacin is a unique vitamin in that humans can synthesize it from dietary tryptophan, with about 60 mg of tryptophan equivalent to 1 mg of niacin. Most people receive about 50% of their niacin requirement from tryptophan-containing proteins and the rest as preformed niacin or niacinamide.

Deficiency. The classic and only described niacin deficiency state is pellagra. Pellagra is rare, developing most often in alcoholics, poorly nourished persons of advanced age, and people on diets that severely restrict sources of niacin. It also may occur in geographic areas in which large quantities of corn are

consumed, as some of the niacin found in corn is bound to undigestible constituents, making it unavailable for absorption. Other causes of pellagra include isoniazid therapy and decreased tryptophan conversion, as in Hartnup disease and with carcinoid tumors.

Clinical features of niacin deficiency include the “three Ds” of dermatitis, diarrhea, and dementia, often accompanied by neuropathy, glossitis (manifested as a beefy red tongue), stomatitis, and proctitis. Patients exhibit a characteristic rash, with well-demarcated lesions of hard, cracked skin and blackish pigmentation that is crusty and scaly. Lesions occur primarily on sun-exposed areas, including dorsal surfaces of the hands, arms, and feet as well as the neck (Casal necklace) and face. Secondary infections may occur in such lesions. The entire GI tract is generally affected, with atrophy of its epithelium. Inflammation of the small intestine may be associated with episodes of occult bleeding and/or diarrhea.

Dosing and Daily Requirements. The DRI values for niacin are listed in [Table 23–4](#). The recommended UL for this vitamin in adults is 35 mg daily.¹⁴

Niacin requirements are increased after a severe injury, infection, or burn, or in the setting of acute illness, substantially increased caloric expenditure or decreased dietary caloric intake, or low tryptophan intake (e.g., a low-protein diet, high intake of corn as a staple in the diet). Both niacin and niacinamide are FDA-approved for the prevention and treatment of pellagra. Niacin, but not niacinamide, also is approved for adjunctive treatment of hyperlipidemia and hypercholesterolemia.¹⁹

Niacin or niacinamide, 150–500 mg daily in divided doses, is used to treat pellagra. Daily dosages of 1–2 g in 3 divided doses, up to 8 g daily, of niacin (*not* niacinamide), are used to treat hypercholesterolemia and hyperlipidemia. Niacin increases beneficial high-density lipoprotein cholesterol and decreases concentrations of potentially harmful triglycerides, total cholesterol, and low-density lipoprotein cholesterol by mechanisms unrelated to its function as an essential micronutrient. However, such high-dose niacin therapy should not be undertaken as a self-care measure; close medical supervision is required because of potentially serious associated drug-induced toxicity, primarily hepatic toxicity.

Safety Considerations. Niacinamide is associated with little toxicity; conversely, niacin toxicity can involve GI symptoms (e.g., nausea, vomiting, diarrhea),

hepatotoxicity, skin lesions, tachycardia, and hypertension. Patients should be forewarned that therapeutic doses of niacin may cause flushing and a sensation of warmth, especially around the face, neck, and ears. This reaction, which is prevalent upon initiation of therapy, may be diminished with aspirin 325 mg or ibuprofen 200 mg taken 30–60 minutes before the niacin dose, in the absence of any contraindications. Alternatively, the extended-release formulation may cause less flushing but carries a greater risk of gastric and hepatic adverse effects. Itching or tingling and headache also may occur with niacin supplementation. These effects usually will subside or decrease in intensity within 2 weeks of continued therapy. If niacin causes GI upset, it should be taken with meals; slow titration to therapeutic dosage also may reduce the risk of such adverse effects.

Because of the adverse GI effects, high doses of niacin are contraindicated in patients with gastritis or peptic ulcer disease. Niacin can provoke the release of histamine, so its use in patients with asthma should be undertaken with caution. Niacin also may impair liver function, disturb glucose tolerance, and cause hyperuricemia. Patients prescribed therapeutic doses of this nutrient must be monitored regularly for potential adverse effects.

Vitamin B₆ (Pyridoxine)

The water-soluble vitamin B₆ exists in three forms: pyridoxine (vitamin B₆), pyridoxal, and pyridoxamine. Although all three forms are equally effective in nutrition, pyridoxine hydrochloride is the form most often used in vitamin formulations.

Function. Vitamin B₆ serves as a cofactor for more than 60 enzymes, including decarboxylases, synthetases, transaminases, and hydroxylases. It is important in heme production and in the metabolism of homocysteine. As previously stated, hyperhomocysteinemia is a potential risk factor for cardiovascular disease, and it has been shown to respond particularly to folic acid supplementation but also to vitamin B₆. Whether the impact of these nutrients on homocysteine levels results in improved clinical outcomes has yet to be determined.³⁷ Limited data support a role for vitamin B₆ in the treatment of migraine headache and nausea of pregnancy; however, use of vitamin B₆ in these conditions generally is undertaken as part of an overall plan under medical supervision rather than as a sole self-care approach. Vitamin B₆ also has been suggested as a potential agent for treatment of carpal tunnel

syndrome, premenstrual syndrome (PMS), and depression; clinical research evidence supporting its use for these ailments, however, is inadequate.⁴⁵

Dietary Sources. See [Table 23–7](#). Cooking destroys some vitamin B₆.

Deficiency. Causes of vitamin B₆ deficiency include alcoholism, severe diarrhea, food faddism, malabsorptive syndromes, drugs (isoniazid and penicillamine), and genetic diseases (cystathioninuria and xanthurenic aciduria).

Manifestations of severe vitamin B₆ deficiency in infants include irritability and convulsive disorders. Medical referral of the affected child is indicated, and treatment with vitamin B₆ hydrochloride generally normalizes the electroencephalogram and resolves clinical symptoms. Symptoms and signs in adults whose diets are deficient in vitamin B₆ or who are taking a vitamin B₆ antagonist drug are difficult to distinguish from those of niacin and riboflavin deficiencies. Clinical findings may include pellagra-like dermatitis; oral lesions; peripheral neuropathy; scaliness around the nose, mouth, and eyes; and dulling of mentation. Serious deficiency signs and symptoms include convulsions, peripheral neuritis, and sideroblastic anemia, marked by inability of the bone marrow to produce normal red blood cells, with consequent iron accumulation in the mitochondria of erythroid precursors.

Dosing and Daily Requirements. DRI values for vitamin B₆ are listed in [Table 23–4](#). The FDA-approved use of this vitamin is for treatment of vitamin B₆ deficiency, including drug-induced deficiency as seen with isoniazid.¹⁹ Daily doses up to 250 mg of vitamin B₆ have been used in the treatment of hyperhomocysteinemia.³⁸ However, the UL for this vitamin is 100 mg daily for adults.¹⁴

Treatment of sideroblastic anemia requires 50–200 mg daily of pyridoxine hydrochloride to aid production of hemoglobin and erythrocytes. Several vitamin B₆–dependent inborn errors of metabolism have been shown to respond to large doses of vitamin B₆.

Safety Considerations. Vitamin B₆ may be toxic in high doses. A severe sensory neuropathy similar to that observed with the deficiency state has been reported when gram quantities were taken to relieve symptoms of PMS. Similar symptoms have been reported in women taking doses as small as 50 mg daily for PMS. Recovery occurred slowly upon withdrawal of vitamin B₆.

High daily doses of vitamin B₆ (200–600 mg) inhibit prolactin. Prenatal vitamins, which contain 1–10 mg per dosage unit, do not appear to have a significant antiprolactin effect.

Thiamine (Vitamin B₁)

Thiamine is a water-soluble, B-complex vitamin available in oral tablet and injectable dosage forms.

Function. Thiamine's active form, thiamine pyrophosphate (formerly known as cocarboxylase), plays a vital role in the oxidative decarboxylation of pyruvic acid; in the formation of acetyl coenzyme A (CoA), which enters the Krebs cycle; and in other important biochemical conversion cycles. Thiamine is necessary for myocardial function, nerve cell function, and carbohydrate metabolism. The amount of thiamine required increases with increased carbohydrate consumption.

Dietary Sources. Dietary sources highest in thiamine are listed in [Table 23–7](#). The thiamine content of food can be destroyed by heat, oxidation, and an alkaline environment, but the vitamin is stable through frozen storage.

Deficiency. The primary causes of thiamine deficiency are inadequate diet, alcoholism, malabsorptive syndromes, prolonged diarrhea, chronic furosemide therapy, increased requirements (e.g., pregnancy), and food faddism.

Thiamine deficiency in the United States is found primarily in chronic alcohol abusers. Not only is their diet often nutritionally deficient, but alcohol ingestion also impairs thiamine absorption and transport across the intestine and increases the rate of thiamine diphosphate destruction. Thiamine deficiency, also known as beriberi, may manifest with neuromuscular signs and symptoms such as peripheral neuritis, weakness, and Wernicke's encephalopathy. Cardiac dysfunction also may result, possibly accompanied by edema, tachycardia on minimal exertion, enlarged heart, and electrocardiographic abnormalities.

Dosing and Daily Requirements. The DRI values for thiamine are listed in [Table 23–4](#). Symptomatic patients are preferably treated with intravenous thiamine, owing to poor bioavailability of oral thiamine. However, long-term oral supplementation may be recommended for patients at continued risk of deficiency, including alcohol abusers and persons receiving high-dose

furosemide therapy. The FDA-approved use of thiamine is for the treatment of thiamine deficiency.¹⁹

Safety Considerations. The kidney easily clears excessive thiamine intake, and oral doses of 500 mg have been found to be nontoxic.

Potential Drug–Nutrient Interactions. Diuretics increase the urinary excretion of thiamine. Therefore, patients on chronic diuretic therapy (e.g., those with congestive heart failure or hypertension) may be at risk for subclinical thiamine deficiency and associated cardiovascular complications.

Supplementation with 100% of the DRI for this vitamin is a reasonable approach to management.⁴⁶

Pantothenic Acid, Riboflavin (Vitamin B₂), and Biotin (Vitamin H)

Other water-soluble B-complex vitamins include pantothenic acid, riboflavin, and biotin. All of these nutrients serve a variety of roles in the metabolism and conversion of carbohydrate and other macronutrients into sources of energy for numerous metabolic processes.

Functions. Pantothenic acid is a cofactor for multiple biological reactions necessary for energy synthesis. Pantothenic acid is a precursor of CoA, which is active in many biological reactions and plays a primary role in cholesterol, steroid, and fatty acid synthesis. Pantothenic acid is important for acetylation reactions and the formation of citric acid for the Krebs cycle, and it is crucial in the intraneuronal synthesis of acetylcholine. This nutrient also is important in gluconeogenesis; synthesis and degradation of fatty acids; synthesis of sterols, steroid hormones, and porphyrins; and the release of energy from carbohydrates.

Riboflavin is a water-soluble vitamin essential for cellular growth and maintenance of vision and the integrity of mucous membranes, skin, nails, and hair. Riboflavin is a constituent of two important coenzymes: flavin adenine dinucleotide and flavin mononucleotide. It has roles in numerous oxidation and reduction reactions, including the cytochrome P450 reductase enzyme system involved in drug metabolism.

Biotin is necessary for various metabolic functions, including carbohydrate, fat, and amino acid metabolism; several biotin-dependent enzymes are known to

exist.

Deficiency. Because pantothenic acid, riboflavin, and biotin are contained in many foods, deficiency states are rare and hard to detect. In malabsorption syndromes, it is difficult to distinguish manifestations of pantothenic acid deficiency from those of other nutrient deficiencies. Signs and symptoms of pantothenic acid deficiency include somnolence, fatigue, cardiovascular instability, abdominal pain, and paresthesia of hands and/or feet followed by hyperreflexia and muscular weakness in the legs. Administration of pharmacologic doses of pantothenic acid reverses these symptoms and has even been used to eliminate burning feet syndrome.

As with pantothenic acid, riboflavin deficiency, although rare, may be caused by inadequate intake, alcoholism, or malabsorptive syndromes. Deficiency of this vitamin may occur in association with other B-complex vitamin deficiency states (e.g., pellagra) or during pregnancy. Early signs of riboflavin deficiency may involve ocular symptoms, as the eyes become light-sensitive and easily fatigued. Other ocular manifestations may include development of blurred vision; itching, watering, and sore eyes; and corneal vascularization, resulting in a bloodshot appearance to the eye. Clinical findings with more advanced deficiency include stomatitis, seborrheic dermatitis, and magenta tongue.

Biotin deficiency states are rare but appear to result in signs and symptoms of nausea, vomiting, lassitude, muscle pain, anorexia, anemia, and depression. Dermatitis, a grayish color of the skin, and glossitis may be among the physical findings; hypercholesterolemia and cardiac abnormalities also may occur. Biotin deficiency in humans can be caused by ingesting a large number of raw egg whites, which contain avidin, a protein that binds biotin, thereby preventing its absorption. Persons in a rapid weight-loss program with intense caloric restriction and those with chronic malabsorption should receive supplementation, generally as part of an MVM supplement.

Dosing and Daily Requirements. AI and DRI values for these vitamins are listed in [Table 23–4](#); no UL has been established for pantothenic acid.¹⁴ The need for riboflavin appears to increase during periods of increased cell growth, such as during pregnancy and with wound healing. Absorption is enhanced when riboflavin is taken with food. The FDA-approved use of riboflavin is in the prevention and treatment of riboflavin deficiency.¹⁹ No UL has been determined for this vitamin.

Safety Considerations. Pantothenic acid, riboflavin, and biotin generally are considered nontoxic, even in large doses. The use of riboflavin typically causes a yellow-orange fluorescence or discoloration of the urine. Patients who report this effect should be reassured that this color change is normal. No known toxic concentration is associated with pantothenic acid, riboflavin, or biotin. Adverse effects have not been reported with biotin therapy; however, FDA has issued a warning regarding use of high-dose biotin supplementation, commonly found in supplements marketed for supporting hair and nail health, with certain laboratory assays yielding falsely elevated or falsely low results, depending on the test used.

Vitamin-like Compounds: Pseudovitamins

Vitamin-like compounds, or pseudovitamins, are substances that have a chemical structure very similar to that of vitamins but lack the usual physiologic or biochemical actions. That is, they are not essential for specific body functions of growth, maintenance, and reproduction. Examples of vitamin-like compounds are choline, lipoic acid, and inositol; of these substances, choline is reviewed here.

Choline

Choline is contained in most living cells and in foods. It usually is present in the form of phosphatidylcholine, commonly known as lecithin, and in several other phospholipids found in cell membranes. Intestinal mucosal cells and pancreatic secretions contain enzymes capable of splitting phospholipids to release choline. Choline also is found in sphingomyelin and is highly concentrated in nervous tissue.

Choline is available in food sources, either as choline or lecithin, and also is synthesized in the body. Therefore, choline most likely is not a vitamin. Food sources are listed in [Table 23-7](#); [Table 23-4](#) lists DRI values. An average diet furnishes ample choline daily. The recommended UL for choline is 3.5 g daily.¹⁴

Function. Choline, a precursor in the biosynthesis of acetylcholine, is an important donor of methyl groups used in the biochemical formation of other substances in vivo. Furthermore, choline and inositol are considered to be lipotropic agents (i.e., agents involved in the mobilization of lipids). Both choline and inositol have been used to treat fatty liver and abnormal fat

metabolism, but efficacy has not been established for either compound.

Deficiency. A deficiency state has not been identified in humans, possibly because choline is readily available in the diet and is synthesized in the body.

Safety Considerations. The administration of large doses of lecithin has been associated with sweating, GI distress, vomiting, and diarrhea.

Minerals

Minerals constitute about 4% of body weight, being found in a diverse array of organic compounds in the body—such as phosphorus in phosphoproteins and phospholipids, iron in hemoglobin, and iodine as a precursor for thyroxine. These elements function as constituents of many enzymes, hormones, vitamins, and inorganic compounds (e.g., sodium chloride, potassium chloride, calcium, phosphorus) that are present as free ions. Various body tissues contain differing amounts of specific minerals. For example, bone has a high content of calcium, phosphorus, and magnesium, whereas soft tissue has a high quantity of potassium. Minerals are involved in regulating cell membrane permeability, osmotic pressure, and acid–base and water balance. In addition, certain ions act as the mediators of action potential conduction and neurotransmitter action.

A well-balanced diet is required to maintain proper mineral balance. Optimal mineral intake values for humans are still imprecise; only AIs are available for trace element minerals such as chromium, fluoride, and manganese. [Table 23–5](#) lists the DRIs for select elements and minerals, and [Table 23–7](#) includes dietary sources of the minerals discussed in this chapter. Possible adverse effects of long-term ingestion of high-dose mineral supplements are often unknown, and high doses of one mineral can decrease the bioavailability of other minerals and vitamins. Pharmacists and other health care providers should be aware of select drug–nutrient interactions and mineral deficiencies that may be precipitated by certain medications ([Table 23–8](#)).

Principal Minerals in Health and Nutrition

Calcium

The most abundant cation in the body is calcium (about 1200 g).

Approximately 99% of body calcium is present in the skeleton; the remaining 1% is present in extracellular fluid, intracellular structures, and cell membranes. Calcium is a major component of bones and teeth. The calcium content in bone is continuously undergoing a process of resorption and formation. With advancing age, the resorption process comes to predominate over bone building, and a decrease in calcium absorption efficiency results in a gradual loss of bone density, leading to osteoporosis. This effect can be minimized with optimal calcium and vitamin D intake throughout the life cycle and regular participation in weight-bearing exercise; the benefit of these measures should be emphasized in patient counseling.

Function. Calcium activates a number of enzymes and is required for acetylcholine synthesis. Calcium increases cell membrane permeability, aids in vitamin B₁₂ absorption, regulates muscle contraction and relaxation, and catalyzes several steps in the activation of plasma clotting factors. Calcium also is necessary for the functional integrity of many cells, especially those of the neuromuscular and cardiovascular system.

Dietary Sources. Teenagers experiencing rapid growth and bone maturation need to consume adequate calcium, readily available in dairy products (especially milk), or as a nutritional supplement. Most adults can easily meet calcium RDAs by incorporating dairy products into the regular diet. Each 8-ounce serving of nonfat milk contains about 300 mg of calcium. As an alternative, calcium supplements usually are well tolerated in daily doses of less than 2 g. [Table 23–10](#) lists selected calcium supplements.

Table 23–10 Selected Nonprescription Calcium Supplements	
Trade Name	Primary Ingredient(s) With Amount Per Serving
Caltrate 600+D Tablets	Elemental calcium 600 mg (as carbonate); vitamin D 200–800 IU (depending on formulation)
Citracal Maximum+D3 Caplets	Elemental calcium 630 mg (as citrate); vitamin D 500 IU
Regular Strength Chewable Tablets	Elemental calcium 500 mg (as carbonate)
Viactiv Calcium plus D Soft Chews	Elemental calcium 500 mg (as carbonate); vitamin D 500 IU; vitamin K 40 mcg

The health care provider should evaluate the patient's dietary intake of calcium (including calcium-fortified foods) before recommending daily calcium supplementation. Calcium fortification is an option with various nontraditional sources (e.g., juices, breads, breakfast bars). To optimize calcium absorption, patients should avoid co-ingestion with bran, whole-grain cereals, or high-oxalate foods (e.g., cocoa, soybeans, spinach); with use of a supplement, a product co-formulated with vitamin D may be recommended if vitamin D intake from other sources is inadequate.

Deficiency. Decreased calcium concentrations may have profound and diverse consequences, including convulsions, tetany, behavioral and personality disorders, mental and growth retardation, and bone deformities (the most common being rickets in children and osteomalacia in adults). Changes that occur in osteomalacia include softening of bones, rheumatic-type pain in the bones of the legs and lower back, general weakness with difficulty walking, and spontaneous fractures. Common causes of hypocalcemia and associated skeletal disorders include malabsorptive syndromes; hypoparathyroidism; vitamin D deficiency; renal failure with impaired activation of vitamin D; long-term anticonvulsant therapy (with increased breakdown of vitamin D); and decreased dietary intake of calcium, particularly during periods of growth, pregnancy, and lactation, and among people of advanced age.

Dosing and Daily Requirements. Oral calcium supplements are approved for use in the treatment and prevention of calcium deficiency. Other FDA-approved uses include treatment of acid indigestion and hyperphosphatemia associated with end-stage renal disease.¹⁹ The recommended UL for calcium is 2–3 g daily for patients older than 1 year.¹⁵

Recommendations for calcium intake are based on elemental calcium content, not the calcium salt. Because labels can be misleading, health care providers should be familiar with the many salt forms and the different percentages of calcium in each, including carbonate (40%), citrate (21%), lactate (13%), gluconate (9%), and phosphate salts (23%–39%).⁴⁷ Calcium carbonate and calcium phosphate salts are insoluble in water and should be taken with meals to enhance absorption, which is optimal at low pH. Patients requiring supplementation who have achlorhydria or who are on chronic therapy with histamine type 2 receptor antagonists or proton pump inhibitors may benefit most from taking one of the water-soluble salt formulations (e.g.,

calcium citrate), which are absorbed more readily in basic environments.

The small intestine controls calcium absorption. Patients ingesting relatively low amounts of calcium absorb proportionately more calcium than those with adequate intake; patients taking large amounts of calcium, as in supplementation, excrete more as fecal calcium. Optimal absorption occurs with individual doses of 500 mg or less; therefore, patients taking more than 500 mg of supplemental calcium should be encouraged to take calcium in divided doses.¹⁵ In conjunction with adequate calcium and vitamin D intake, weight-bearing exercise is essential in maintaining bone mass.

Safety Considerations. Calcium in doses greater than 3 g daily can be harmful. Large amounts taken as dietary supplements or antacids can lead to accumulation of high levels of calcium in the urine with formation of renal stones, which can result in permanent renal damage. Development of hypercalcemia is possible (particularly in patients taking concomitant high-dose vitamin D preparations); this condition is associated with anorexia, nausea, vomiting, constipation, and polyuria. Increased deposition of calcium in soft tissue also can occur with hypercalcemia. The U.S. Preventive Services Task Force (USPSTF) is more conservative regarding calcium intake and recommends that daily calcium intake not exceed 1000 mg.⁴⁸ USPSTF's recommendation is based on recognition of insufficient evidence to determine whether calcium supplementation can reduce fractures in community-dwelling adults and on concerns that high-dose supplementation may increase the risk of adverse effects.

The relationship between dietary and supplemental calcium intake and potentially increased risk of cardiovascular disease has caused much controversy and uncertainty in the medical community over the past several years. A prospective study showed that supplemental calcium intake at a dose greater than 1000 mg daily was associated with an increased risk of death from heart disease in men.⁴⁹ Supplemental calcium intake at any dose in women, on the other hand, was not found to correlate with increased risk of cardiovascular disease, heart disease, or cerebrovascular event-related death in this trial. Moreover, dietary calcium intake was found to be unrelated to increased risk of cardiovascular death in either men or women, underscoring the importance of dietary calcium intake over supplemental calcium use. The study was conducted in 388,229 men and women ages 50–71 years and was designed to evaluate the effects of both dietary and supplemental calcium

intake on mortality rates for cardiovascular disease, heart disease, and stroke. Results from a post hoc analysis of the Women's Health Initiative dataset also identified no increase in risk for myocardial infarction, coronary heart disease, total heart disease, stroke, or overall cardiovascular disease in postmenopausal women receiving 1000 mg daily elemental calcium carbonate plus 400 IU daily of vitamin D₃.⁵⁰ Clearly, more information is necessary to further elucidate the correlations between calcium supplementation and cardiovascular disease risk. For patients considering calcium supplementation, a complete dietary and lifestyle evaluation is indicated to determine the possible risks and benefits of supplementation with this mineral.

Calcium intake also has been suggested to influence risk of prostate cancer. In fact, three trials have found an increased risk for prostate cancer with calcium intakes greater than 1500 mg daily from either supplements or dietary sources.⁵¹ Recommending calcium intakes closer to the DRI/RDA for men at risk for prostate cancer is reasonable until further evidence clarifies this association.

Health care providers should counsel patients about the potential for constipation associated with calcium supplementation and the importance of adequate hydration, dietary fiber, and physical activity in preventing this adverse effect.

Iron

Iron is widely available in the U.S. diet. Iron absorption from the intestinal tract is controlled by the body's need for iron, conditions in the intestinal lumen, the food source of iron, and other components of the meal (e.g., the meal's vitamin C content).

Function. Iron plays an important role in oxygen and electron transport. In the body, iron is either functional or stored ([Figure 23–5](#)).

Figure 23–5 Iron distribution in the body.

Dietary Sources. Dietary iron is available in two forms: heme and nonheme iron. Heme iron is found in meats and is reasonably well absorbed. Nonheme iron (e.g., that found in enriched grains and dark green vegetables) constitutes most of the dietary iron but is poorly absorbed. Published values of iron

content in foods are therefore misleading, because the amount absorbed depends on the nature of the iron. Although various specific ways to calculate the iron absorption from a given meal have been devised, the available iron content of foods often is estimated by assuming that about 10% of the total iron (heme plus nonheme) is absorbed if no iron deficiency is present. In the iron-deficient state, iron absorption improves to as much as 20% from an average diet. However, this estimate is not valid in the absence of heme iron. Less iron is absorbed from vegetarian diets.

Ingested nonheme iron (which is mostly in the form of ferric hydroxide) is solubilized in gastric juice to ferric chloride, then reduced to the ferrous form, and finally chelated to substances such as ascorbic acid, sugars, and amino acids. Chelates have a low molecular weight and can be solubilized and absorbed before they reach the alkaline medium of the distal small intestine, where precipitation may occur. When released at the spleen, liver, bone marrow, intestinal mucosa, and other iron storage sites, the iron is combined with apoferritin to form ferritin or hemosiderin (Figure 23–5). As needed, ferritin is released into the plasma, where it is oxidized to the ferric state and bound to a beta globulin to form transferrin. Iron is used in all cells of the body; however, most of it is incorporated into the hemoglobin of red blood cells.

Deficiency. The major mechanism of iron loss is blood loss (e.g., hemorrhagic loss, menstruation). Iron also is lost from the body with the sloughing of skin cells and GI mucosal cells, and by excretion in urine, sweat, and feces. Excess iron loss may result in iron deficiency. Early manifestations of iron deficiency are subtle, with vague symptoms. Although pallor and easy fatigability may be associated with iron deficiency, they can be attributed to other causes and are nonspecific findings. Other signs and symptoms of iron-deficiency anemia include split or “spoon-shaped” nails, sore tongue, angular stomatitis, and dyspnea on exertion. Coldness and numbness of the extremities also may be reported. Hypochromic microcytosis, as evidenced by a decreased mean corpuscular volume and low hemoglobin concentration (decreased mean corpuscular hemoglobin concentration), characterizes iron deficiency on laboratory assessment.

Iron-deficiency anemia constitutes a widespread clinical problem and is the most common form of anemia in the United States. Although it causes few deaths, it does contribute to poor health and suboptimal performance. Iron deficiency may result from inadequate intake (e.g., inadequate diet,

malabsorption) or from increased demands (e.g., pregnancy and lactation, growth, blood loss, treatment with erythropoiesis-stimulating agents). Because normal iron losses through the urine, feces, and skin are minimal, and because the major fraction of total body iron is efficiently stored and conserved (recycled), iron deficiency caused by poor diet or malabsorption develops very slowly over the course of several months.

Despite fortification of flour and public health efforts at education regarding proper nutrition, iron deficiency remains a common problem, especially during the following four life periods:

Childhood (younger than 2 years): Children may not obtain adequate iron because of the low iron content of cow's milk.

- Adolescence: In addition to blood loss with menstruation, adolescent girls are experiencing rapid physical growth, which entails an expanding red cell mass and the need for iron in myoglobin.
- Pregnancy and postpartum period: Women face the expanding blood volume of pregnancy, the demands of the fetus and placenta, and the blood loss of childbirth.
- Older adulthood: Persons of advanced age (i.e., 65 years or older) often consume inadequate dietary iron, exhibit compromised absorption secondary to achlorhydria, and experience an increased incidence of GI tract blood loss resulting from malignancy, gastric ulceration, or use of nonsteroidal anti-inflammatory drugs (NSAIDs). However, the prevalence of elevated iron stores may be significantly greater than the prevalence of iron deficiency in this age group. Therefore, in the absence of a confirmed diagnosis of iron-deficiency anemia, routine supplementation is not recommended for this age group.

Supplemental iron may be warranted for women with heavy or prolonged menstrual blood loss or for persons who frequently donate blood. Iron also may be indicated during recovery from disease- and injury-associated blood loss (e.g., with peptic ulcer disease, esophageal varices, cancer, or traumatic injury such as that incurred in motor vehicle crashes). In addition, infants being fed human milk may need supplemental iron beginning at 4–6 months of age if iron-rich foods are not introduced into the diet ([Chapter 26](#) discusses pediatric nutrition).

Chronic use of drugs such as salicylates or other NSAIDs, corticosteroids, or

anticoagulants may cause drug-induced blood loss. This effect may be the result of direct irritation of the gastric mucosa or the tendency of such drugs to cause increased bleeding. Iron supplementation should be used cautiously, if at all, in patients at high risk for GI bleeding.

Dosing and Daily Requirements. Because of the GI adverse effects associated with oral iron supplementation, the UL for elemental iron has been set at 45 mg daily for adults.¹⁴ Oral iron supplements are indicated for the prevention and treatment of iron-deficiency anemia.¹⁹

When iron supplementation is appropriate, the provider needs to evaluate which iron product is best. The choice should be based on how well the iron preparation is absorbed and tolerated and the amount of elemental iron per dose, as well as product price. Because ferrous salts are absorbed 3 times more efficiently than ferric salts, an iron product of the ferrous group usually is appropriate. Ferrous sulfate is the standard against which other iron salts are compared.

Ferrous sulfate contains 20% elemental iron, or about 65 mg in a 325 mg tablet. In patients with iron deficiency, 20% of the elemental iron (approximately 12 mg) may be absorbed. Maximum incorporation of iron into red blood cells and replacement of stores are supported with a regimen of 36–48 mg of elemental iron daily; thus, the traditional therapeutic dose for treating iron deficiency is 2–4 tablets containing 325 mg ferrous sulfate daily for 3 months. Clinical trials also have investigated the efficacy of once-daily and alternate-day dosing strategies; results suggest that these strategies may be equally efficacious or that one is better tolerated than the other in some instances. Inadequate response or worsening of symptoms during iron supplementation indicates that the patient should consult an appropriate health care provider. In cases of severe or chronic iron deficiency, when serious medical conditions have been ruled out, continuous maintenance doses of 3–4 tablets containing 325 mg ferrous sulfate daily for 3–6 months should normalize hemoglobin and replace iron stores (in the absence of ongoing losses from GI bleeding or another cause).

Table 23–11 lists comparison data on various iron salts.⁵² Ferrous salts may be given in combination with ascorbic acid to improve iron absorption. If necessary, the health care provider can encourage taking iron with fruit or juice high in ascorbic acid or with a vitamin C supplement. Combination products with iron and ascorbic acid also are available, but these products can

be expensive, and the dose of vitamin C often is inadequate to support absorption. Chemicals that may decrease iron absorption include phosphates in eggs and milk, carbonates, oxalates, tannins, and phytates in cereals.

Table 23–11 Common Nonprescription Oral Iron Formulations

Iron Formulation	Typical Dose	Percent Elemental Iron	Comparison Data
Ferrous sulfate	325 mg/ tablet	20% (65 mg/ tablet)	The gold standard for supplementation; available in multiple dosage forms; extensive history of use; proven effective; and economical.
			Delayed-release and enteric-coated products may improve tolerability, but iron absorption may be reduced.
Ferrous fumarate	60 mg/ tablet	33% (20 mg/ tablet)	No advantage over ferrous sulfate; however, may be better tolerated by some patients.
Ferrous gluconate	225 mg/ tablet	12% (27 mg/ tablet)	No advantage over ferrous sulfate; however, may be better tolerated by some patients.

Source: [Reference 52](#).

SAFETY Considerations. All iron products tend to irritate the GI mucosa and may produce nausea, abdominal pain, constipation, and (less frequently) diarrhea. These adverse effects may be minimized by reducing the dose or by giving iron with meals; however, co-ingestion of food may decrease the amount of iron absorbed by as much as 50%. The initial recommendation should be to take the iron supplement on an empty stomach; if GI adverse effects occur, the patient should be instructed to change this routine and take the iron with food.

A frequent adverse effect of iron therapy is constipation. This association has prompted the formulation of iron products that also contain a stool softener (e.g., docusate). During iron therapy, stools commonly have a black, tarry appearance because of the presence of unabsorbed iron in the feces.

Unfortunately, this finding also may indicate GI blood loss and a serious medical problem. Medical evaluation is indicated if an underlying GI condition is suspected, or if a history of GI disease exists. If the stool does not darken somewhat during iron therapy, however, the iron product may not have disintegrated properly or released the iron.

Iron must be dispensed and stored in a child-resistant container. Accidental poisonings with iron occur most often in children, who are attracted to the sugar-coated, colored tablets or who may accidentally overdose on chewable multivitamins containing iron. Such poisoning is considered a medical emergency, and any accidental ingestion of iron should be referred for evaluation by an appropriate health care provider, or to a poison control center. The clinical outcome depends on the speed and adequacy of treatment.

Symptoms and signs of acute iron poisoning include abdominal pain, vomiting, diarrhea, electrolyte imbalances, and shock. In later stages, cardiovascular collapse may occur, especially if the underlying cause has not been properly recognized and treated as a medical emergency. Treatment for iron toxicity may begin immediately at home after consultation with a poison control center or local emergency department.

Magnesium

Magnesium is essential for all living cells. It is the second most plentiful cation of intracellular fluids and the fourth most abundant cation in the body. About 2000 mEq magnesium is present in an average 70-kg adult, with about 50% of this amount in the bone, about 45% as an intracellular cation, and about 1%–5% in the extracellular fluid.

Function. Magnesium is required for normal bone structure formation and the proper function of more than 300 enzymes, including those involved with adenosine triphosphate (ATP)–dependent phosphorylation, protein synthesis, and carbohydrate metabolism. Extracellular magnesium is critical to both the maintenance of nerve and muscle electrical potentials and the transmission of impulses across neuromuscular junctions.

Magnesium tends to mimic calcium in its effects on the CNS and skeletal muscle. Magnesium deficiency blunts the normal response of the parathyroid glands to hypocalcemia. Accordingly, tetany, caused by a lack of calcium, cannot be corrected with calcium unless hypomagnesemia also is corrected.

Similarly, magnesium deficiency impairs the transport of potassium into cells; therefore, hypokalemia cannot be corrected in the presence of magnesium deficiency.

Dietary Sources. People who consume fresh foods regularly should not develop magnesium deficiency because all unprocessed foods contain magnesium (albeit in widely varying amounts). Processing (during which the germ and outer layers of cereal grains are removed) results in significant loss of available magnesium.

Deficiency. Deficiency states usually are caused by GI or renal losses. Examples of etiologic disorders and conditions are malabsorptive syndromes, acute or chronic diarrhea, steatorrhea, and drug-induced magnesium wasting in the urine, as seen with alcohol abuse, diuretic therapy, long-term use of proton pump inhibitors, calcineurin inhibitors (e.g., cyclosporine, tacrolimus), and nephrotoxins (e.g., amphotericin B). Signs and symptoms of magnesium deficiency may include neuromuscular irritability, increased CNS stimulation, delirium, and convulsions.

Dosing and Daily Requirements. Oral magnesium supplements are indicated for use in the treatment and prevention of hypomagnesemia.¹⁹ The recommended UL for magnesium is 350 mg daily for older children and adults.¹⁴

Safety Considerations. No evidence is available to suggest that oral intake of magnesium is harmful to persons with normal renal function, although diarrhea may occur with large doses. Hypermagnesemia can develop with overzealous use of magnesium sulfate (Epsom salts) or magnesium hydroxide (milk of magnesia) as a laxative, or with use of magnesium-containing antacids in patients with severe renal failure. Hypermagnesemia is associated with diminished deep tendon reflexes and variable degrees of muscle weakness, lethargy, and sedation. Progression to stupor and coma, especially at high serum concentrations, may occur. Cardiovascular manifestations may include hypotension and dysrhythmia.

Phosphorus

Phosphorus is present throughout the body, but approximately 85% of the body's store is located in bone. Phosphorus is present in nearly all foods, especially protein-rich foods and cereal grains ([Table 23–7](#)).

Function. Phosphorus is essential for many metabolic processes. It serves as an integral structural component of the bone matrix as calcium phosphate, and it is a functional component of phospholipids, carbohydrates, nucleoproteins, and high-energy nucleotides. Plasma phosphate levels are under the tight biologic control of parathyroid hormone, calcitonin, and vitamin D. DNA and RNA structures contain sugar–phosphate linkages. Cell membranes contain phospholipids, which regulate the transport of solutes into and out of the cell. Many metabolic processes depend on phosphorylation. The adenosine diphosphate (ADP)–ATP system (which provides a mechanism for the storage and release of energy for use in all of the body’s metabolic processes) involves phosphorus compounds. Additionally, an important buffer system of the body consists of inorganic phosphates.

Calcium and phosphorus have a reciprocal relationship. Both minerals are regulated partially by parathyroid hormone. Secretion of parathyroid hormone stimulates an increase in serum calcium levels through increased bone resorption, gut absorption, and reabsorption in renal tubules. Parathyroid hormone also causes a decrease in the reabsorption of phosphate by the kidney. Therefore, when serum calcium is high, serum phosphate generally is low, and vice versa.

Deficiency. Because nearly all foods contain phosphorus, deficiency states usually do not occur unless induced. For example, patients taking aluminum hydroxide as an antacid for prolonged periods may exhibit hypophosphatemia, characterized by weakness, anorexia, malaise, pain, and bone loss. Aluminum binds dietary phosphorus, forming insoluble and poorly absorbed complexes.

Dosing and Daily Requirements. The FDA-approved use for phosphorus is to alleviate signs and symptoms of deficiency.¹⁹ The recommended UL for phosphorus is 4 g daily for older children and most adults.¹⁴

Safety Considerations. GI adverse effects (e.g., diarrhea, stomach pain) have been reported with oral supplementation of phosphate salts.

Trace Elements

Trace elements, which are present in minute quantities in plant and animal tissue, are considered essential for numerous physiologic processes. Zinc and manganese are trace elements. A subset of trace elements, the “ultratrace” elements, has an estimated dietary requirement of less than 1 mg daily.

Essential ultratrace minerals include arsenic, boron, cobalt, copper, chromium, iodine, molybdenum, nickel, selenium, and silicon. Lithium and vanadium possibly are essential minerals, but further study is required to determine this status. Bromine, cadmium, fluorine, lead, and tin are not considered essential. The trace and ultratrace element content of foods typically reflects the availability of such elements in the soil in which the food was grown. One of the best defenses against deficiencies is to consume foods from a variety of geographically diverse regions.

Presented next is a review of the trace elements copper, fluoride, iodine, and zinc. These particular trace elements may need to be supplemented in patients with specialty needs. The reader is referred to more comprehensive references for detailed description of the functions, daily requirements, and safety concerns specific to other trace and ultratrace elements not included in this discussion. [Tables 23–5](#) and [23–6](#) provide a summary of DRIs and ULs for select trace elements, and [Table 23–7](#) lists food sources of these nutrients.

Copper

Copper ions exist in two states: the cuprous ion and the cupric ion (a potent oxidizing agent). Copper is similar to zinc in that it forms complexes with a number of the same chelating agents. Virtually all tissues of the body contain copper, but concentrations are highest in the liver, brain, heart, and kidney.

Function. Copper is essential for the proper structure and function of the CNS, and it plays a major role in iron metabolism. Ceruloplasmin, one of the copper metalloenzymes, is especially important in converting absorbed ferrous iron to transported ferric iron. Other copper-containing enzymes are cytochrome oxidase, dopamine beta-hydroxylase, and superoxide dismutase.

Deficiency. Copper deficiency is uncommon in humans, with a few notable exceptions. Deficiencies have been observed in premature infants; in severely malnourished infants fed milk-based, low-copper diets; after Roux-en-Y gastric bypass in persons who do not consume a supplement; and in patients receiving parenteral nutrition with inadequate copper.

One of the prominent features of copper deficiency is neurologic symptoms with gait disturbances, particularly impaired proprioception and vibration sense. Other associated clinical findings include ataxia, myelopathy, optic neuritis, polyneuropathy, and demyelination. In deficiency states, iron

absorption is impaired, typically resulting in hypochromic anemia, and spontaneous rupture of major vessels also may be observed.

Dosing and Daily Requirements. For protection against possible hepatotoxicity, the recommended UL for copper is 10 mg daily for adults.¹⁴

Safety Considerations. Wilson's disease is an inborn error of metabolism resulting in copper retention, which leads to CNS, kidney, and liver damage. Affected persons must avoid all copper supplementation. Acute symptoms and signs of copper toxicity include nausea, vomiting, diarrhea, hemolysis, convulsions, and GI bleeding. Symptoms respond to treatment with penicillamine.

Supplementation also should be avoided in patients with severe hepatic dysfunction or cholestasis, as biliary clearance of copper may be compromised.

Fluoride

Available therapeutic forms of fluoride include sodium fluoride, acidulated phosphate fluoride, and stannous fluoride. Sodium fluoride contains about 45% fluoride ion, whereas stannous fluoride contains about 24% fluoride ion.

Function. Fluoride occurs normally in bones and tooth enamel as a calcium salt. Intake of small amounts has been shown to reduce tooth decay markedly, presumably by making the enamel more resistant to the erosive action of acids produced by bacteria in the oral cavity.

Dietary Sources. Fluoride is present in soil and water, but the content varies widely from region to region. Most municipal water supplies are fluoridated to achieve 1 part per million (ppm) of fluoride, a level that has been shown to be safe and to reduce the prevalence of dental caries in children by nearly 50%. Estimates of fluoride intake from food, beverages, and water vary greatly, depending on the presence of fluoridated drinking water.

Deficiency. Fluoride deficiency states in humans, other than potential dental decay, have not been described.

Dosing and Daily Requirements. The recommended UL for this trace element is 10 mg daily for older children and adults.¹⁴

Fluoride is approved by FDA for use in the prevention of dental caries.¹⁹

Fluoride is a normal constituent of the diet in that it occurs in soils, water supplies, plants, and animals. All sources of fluoride should be evaluated before supplementation is recommended for children whose home water supply is low in fluoride. Children may obtain fluoride from other water sources (e.g., day care facility, school) or in other beverages that may contain various amounts of fluoride (e.g., soft drinks, juices, bottled water).⁵³

Sodium fluoride is available by prescription as oral tablets and solutions, topical solutions, and gels, as well as in combination products. Nonprescription topical rinses containing fluoride 0.01%–0.02% (e.g., sodium fluoride) and gels containing 0.4% stannous fluoride (e.g., Gel-Kam) are rinsed or brushed onto the teeth to reduce sensitivity and prevent dental cavities.

Safety Considerations. Excessive fluoride can be toxic. Acute toxicity should not result from the low levels present in drinking water but may occur with administration of excessive doses of fluoride supplements. Because acute toxicity affects the GI system and the CNS, it can be life-threatening. Symptoms and signs include salivation, GI distress, muscle weakness, tremors, and (rarely) seizures. Because fluoride binds calcium, symptoms of calcium deficiency (including tetany) also may be seen. Eventually, respiratory and cardiac failure may occur. All accidental ingestions of fluoride in children warrant referral for evaluation by a knowledgeable health care provider or poison control center, as fluoride intoxication may be fatal. Treatment includes precipitation of the fluoride by using gastric lavage with calcium hydroxide 0.15% solution, intravenous administration of dextrose and saline for hydration, and an appropriate calcium regimen to prevent tetany.

Chronic fluoride toxicity is manifested as changes in the structure of bones and teeth. Tooth enamel, if still under development, acquires a mottled appearance consisting of white, patchy plaques along with pitting brown stains. Prolonged ingestion of water that contains greater than 2 ppm of fluoride has resulted in a significant incidence of mottling. Extremely large doses (e.g., 20–80 mg daily) have resulted in chalky, brittle bones that tend to fracture easily, a condition known as crippling skeletal fluorosis.

Iodine

The thyroid gland contains about one third of the iodine in the body, stored in

the form of a complex glycoprotein, thyroglobulin. The only known function of thyroglobulin is to provide thyroxine and triiodothyronine, hormones that regulate the metabolic rate of cells, thereby influencing physical and mental growth, nervous and muscle tissue function, circulatory activity, and nutrient utilization.

Function. Iodine is an essential micronutrient required to synthesize thyroxine and triiodothyronine. High concentrations of iodine inhibit the release of these hormones.

Dietary Sources. The primary dietary source of iodine is iodized salt, which contains 1 part of sodium or potassium iodide per 10,000 parts (0.01%) of salt. A dose approximating 95 mcg of iodine can be obtained from about one-fourth teaspoon of salt (1.25 g). In the United States, most of the table salt products sold are iodized; however, salt used in food processing and for institutional use is not. Additional dietary sources of iodine include saltwater fish and shellfish. Produce also may be a source of iodine; the iodine content of produce reflects that of the soil in which it was grown.

Deficiency. A moderate iodine deficiency can lead to thyroid hypertrophy, resulting in goiter; severe deficiency results in hypothyroidism. The consumption of foods from diverse locations and the addition of iodide to table salt have essentially eliminated goiter as a health problem in the United States.

Dosing and Daily Requirements. Because of the fortification of salt, the iodine content of typical diets in the United States is still well above the DRI values for adults ([Table 23–4](#)). Iodine supplements are unwarranted for most people. Potassium iodide is available as a tablet, syrup, and solution, and it is included in various combination products.

Safety Considerations. Some people are allergic to iodine or organic preparations containing iodine, with development of a rash on ingestion. Symptoms of chronic iodism (iodine intoxication) may include an unpleasant taste and burning in the mouth or throat, along with sensitivity of the teeth or soreness of the gums. Other manifestations may include increased salivation, sneezing, eye irritation, and eyelid swelling. In addition, prolonged use of iodine supplementation can result in hypothyroidism.¹⁸ A UL of 1.1 mg daily in adults has been recommended.¹⁴

Zinc

Zinc is an integral component of at least 70 metalloenzymes, including carbonic anhydrase, lactate dehydrogenase, alkaline phosphatase, carboxypeptidase, aminopeptidase, and alcohol dehydrogenase.

Function. Zinc is a cofactor in the synthesis of DNA and RNA. It is involved in the mobilization of vitamin A from the liver and in the enhancement of follicle-stimulating hormone and luteinizing hormone. Zinc is essential for normal cellular immune functions, spermatogenesis, and normal testicular function. It also is important in the stabilization of membrane structure.

The divalent ion is most commonly found and used in the body. Zinc has a relatively rapid turnover rate. The balance between zinc absorption from the small intestine and excretion through feces is efficiently regulated by the body. Vegetarians may require higher amounts of zinc, because diets high in fiber and phytates hinder zinc absorption.

Dietary Sources. Most dietary zinc (about 70%) is derived from animal products ([Table 23-7](#)).

Deficiency. Zinc deficiency is not widespread in the United States. Marginally low zinc values have been associated with birth defects, growth retardation in children, and slow wound healing in adults. Additional manifestations of deficiency include immunologic abnormalities, impaired taste and smell, delayed sexual maturation, hypogonadism, hypospermia, and dermatitis.

Malabsorptive syndromes, infection, major surgery, alcoholism, pregnancy, lactation, and high-fiber diets rich in phytates predispose affected persons to zinc deficiency. Zinc depletion is relatively rare but may be seen in patients on long-term parenteral nutrition and in patients with GI tract abnormalities (e.g., fistulas or prolonged, severe diarrhea).

Zinc deficiency adversely affects DNA, RNA, carbohydrate, and protein catabolism. Iron supplements decrease zinc absorption just as zinc supplements decrease iron absorption, probably through competition for the same transport system. If both minerals are taken with a meal, the adverse interaction is less pronounced. In patients with impaired wound healing, zinc supplementation may be marginally beneficial.

Dosing and Daily Requirements. Typical Western diets supply 10–15 mg of zinc per day. Because only 10%–40% of zinc is absorbed from the GI tract, ingestion of zinc sulfate 220 mg (50 mg of elemental zinc) will supply 5–20 mg of zinc. Treatment of suspected deficiencies usually involves short-term administration of elemental zinc. Patients with large GI losses through fistulas or ostomies, or in stool with metabolic or other disorders, require larger supplemental doses of zinc. At doses above 40 mg elemental zinc per day, copper deficiency may be induced. Therefore, the UL for elemental zinc is 40 mg daily in adults if therapy with zinc is going to be long term.¹⁴ Absorption may be reduced when zinc supplements are taken with foods high in calcium or phosphorus.

Zinc has been evaluated in numerous studies as a potential agent for treatment of the common cold. However, zinc formulations and doses have varied, and trial results have been conflicting. To date, the accumulated evidence is insufficient to recommend zinc supplementation for the treatment or prevention of the common cold.⁵⁴

Safety Considerations. Zinc is most effective taken 1 hour before or 2 hours after meals, but if GI upset occurs, administration with food may minimize these effects. Zinc also is toxic; however, the emetic effect that occurs after consumption of large amounts may minimize problems with accidental overdose. Reported signs and symptoms of zinc toxicity in humans include vomiting, dehydration, poor muscle coordination, dizziness, and abdominal pain.

Nutritional Considerations in Special Patient Populations

A number of patient populations have specific dietary and supplementation counseling needs, as previously mentioned. Pediatric patients, including children and adolescents, may be at greatest risk for developing nutrient deficiency; however, these patients also may be least likely to use supplements. The pharmacist must be prepared to address concerns related to dietary insufficiency from parents and caregivers of “picky eaters” or of children with chronic diseases. Similarly, pregnancy and lactation, as conditions that represent increased metabolic demands, require the pharmacist to be prepared to educate and reinforce the importance of folic acid and other nutrients in discussions related to perinatal and preconception health throughout pregnancy and lactation. Postoperative patients who have

undergone procedures such as Roux-en-Y gastric bypass or pancreaticoduodenectomy (the Whipple procedure) may additionally require evaluation of the affected absorptive area, which may influence the recommendation to pursue maintenance supplementation of numerous nutrients. Finally, older adults, often with multiple medical conditions and taking an array of medications, may be at increased risk for nutrient deficiencies, necessitating the pharmacist's expertise in navigating appropriate selection and use of supplementation.

Multivitamin and Multimineral Supplements

Multivitamin and multimineral supplements, as previously described, are not intended to supplant a healthy, balanced diet but rather are best used to augment dietary sources and support general health. Specific nutrients of concern for inadequate intake (shortfall nutrients) recognized by the *Dietary Guidelines for Americans 2015–2020* include vitamins A, D, E, and C and folate, calcium, magnesium, and potassium, with iron also a concern in adolescent and premenopausal females. Of these nutrients, calcium, vitamin D, and potassium are of particular concern, in view of direct evidence of adverse health effects associated with inadequate daily intake and deficiency.¹³ However, MVM supplements do not target these or any other specific nutrients; rather, they provide a broad range of micronutrients. In evaluating the use of an MVM product for a particular patient, the health care provider should consider recommending a preparation that contains the basic and essential vitamins and minerals, including the following: vitamins C, B₁ (thiamine), B₂ (riboflavin), B₃ (niacin), B₆ (pyridoxine), B₉ (folic acid), B₅ (pantothenic acid), A, E, D₂ or D₃ (cholecalciferol), and K, as well as biotin, potassium, iodine, selenium, borate, zinc, calcium, magnesium, manganese, molybdenum, and beta carotene.

Owing to availability of a multitude of different nonprescription multivitamin products, further consideration of the patient's age and gender is warranted to ensure selection of a formulation that is most likely to meet individual nutritional needs. Most multivitamins formulated for women ages 18–50 years contain increased amounts of iron and folic acid to combat anemia related to menstrual blood loss and to prevent neural tube defects in the infant, respectively. Multivitamins formulated for men younger than 50 generally contain higher amounts of certain vitamins and less iron. Finally, senior multivitamins formulated for persons older than age 50 may contain more

calcium and certain B vitamins (e.g., B₆, B₁₂) but do not contain iron. Patients should be reminded to refer to the product labeling for directions for use and not to exceed the recommended intake.

For patients with questions about biochemical function, DRI values, food sources, signs and symptoms of deficiency, drug–nutrient interactions, and additional information on specific vitamins, minerals, or other dietary supplements, an excellent resource is the National Institutes of Health Office of Dietary Supplements Vitamin and Mineral Supplement Fact Sheets (with versions for both consumers and health care professionals), available at <https://ods.od.nih.gov/factsheets/list-VitaminsMinerals/>.

Assessment of Nutritional Adequacy: A Case-Based Approach

Assessing a person's nutritional status is difficult in the ambulatory environment. Clinical impressions often are erroneous, because the stages between well-nourished and poorly nourished states are not readily evident. However, guidelines may help provide a more objective assessment of nutritional status. The health care provider will need good observational skills, familiarity with questions most likely to yield helpful information (see Cases 23–1 and 23–2 for examples of questions), and knowledge of which population groups tend to be at risk for particular deficiencies. By asking key questions, the provider may detect cultural, physical, environmental, and social conditions that suggest inadequate vitamin intake. The more specific the information obtained from the patient, the more helpful the provider can be in determining the need for nutritional supplementation. Questions about the absence of different food types in the diet and about previous treatment of similar symptoms also may be important.

Although most nutritional assessment measures are beyond the scope of routine pharmacy practice, clinical observation can reveal various markers of the patient's physical status. For example, appearance of the fingernails may signal presence of malnutrition as a lack of luster to the nail surfaces and darkening at the upper ends. The texture, amount, and other characteristics of hair also may be indicators of nutritional status. The eyes (particularly the conjunctiva) may be affected in vitamin A and iron deficiencies, with ocular

manifestations including xerophthalmia, night blindness, and blurred vision. The mouth may show stomatitis, glossitis, or hypertrophic or pale gums with vitamin B deficiencies. Poor dentition may limit the foods that can be consumed by the affected person, thereby compromising intake from certain food groups such as protein. Visible goiter, poor skin color and texture, obesity or thinness relative to body habitus, and the presence of edema also may indicate malnutrition. The pharmacist should be familiar with overt but nonspecific symptoms of vitamin and mineral deficiencies for which prompt referral to an appropriate health care provider may be crucial. Additionally, it is important to recognize patients at risk for nutritional deficiency or those with increased metabolic demands (e.g., older adults, chronic alcohol abusers, pregnant and lactating women), who typically require further medical evaluation.

Checking the patient's medication history is important because of the potential for drug–micronutrient interactions ([Table 23–8](#)). Any clinical manifestations suggestive of a serious illness warrant referral to a primary care provider. Just as nutritional deficiencies may lead to disease, disease may lead to nutritional deficiencies. Patients may present with one or more deficiencies, which may be very difficult to identify. Rarely in the United States do health care providers encounter patients with severe deficiencies resulting in conditions such as scurvy, pellagra, or beriberi. Milder forms of malnutrition, however, are not uncommon.

Cases 23–1 and 23–2 provide examples of the assessment of two different patients with nutritional inadequacy.

Case 23–1

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and medical history,	

including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A patient comes to the pharmacy counter inquiring about the use of various vitamins to help prevent cancer, because a close friend was recently diagnosed with colon cancer. He indicates that he currently does not use any vitamin, mineral, or dietary supplements.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	n/a
c. Description of the patient's efforts to relieve the symptoms	n/a
d. Patient's identity	Patrick Rodriguez
e. Patient's age, gender, height, and weight	64 years, male, 5 ft 9 in., 170 lb
f. Patient's occupation	High school teacher; divorced
g. Patient's dietary habits	Eats alone most of the time: typically cereal, soymilk, and juice for breakfast; soup or sandwich for lunch; easy meals for dinner (e.g., frozen dinners with protein, starch, vegetable). Often meets a few friends to have lunch and watch sports on Saturday and/or Sunday.
h. Patient's sleep habits	n/a
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>History of high blood pressure:</i> hydrochlorothiazide/lisinopril 12.5/20 mg, 1 tablet every morning
	<i>Occasional muscle aches:</i> acetaminophen 325 mg as needed
j. Allergies	Penicillin, cefazolin

k. History of other adverse reactions to medications	n/a
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	The patient's age and dietary habits may warrant consideration of a multivitamin supplement. However, no evidence to date supports the use of multivitamins to completely negate cancer risk.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Assess the patient's perceived need for the nutrient supplements. (2) Evaluate dietary intake from food groups, encouraging at least 5 servings of produce, 3 servings of low-fat dairy products (inquire about tolerance first; he uses soymilk for breakfast), 2 servings of protein, and 6 servings of whole-grain food sources daily. (3) Discuss which nutrients may need supplementation based on the patient's patterns of dietary intake, age, and special requirements. (4) Discuss the lack of data on and potential for harm associated with megadoses of vitamins.(5) Take no action.
Plan	
5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Regular intake of a well-balanced diet that includes fruit, vegetables, whole grains, and low-fat dairy and lean protein sources is recommended for patients with high blood pressure. A multivitamin/mineral supplement that includes vitamin B ₁₂ and a balance of other nutrients would be reasonable for Mr. Rodriguez, who prefers simple, easy meals. He also should be evaluated for adequate calcium and vitamin D intake, especially if he does not consume any dairy products.

6. Describe the recommended therapeutic approach to the patient or caregiver.	“A nutrient-rich diet has been shown to be beneficial in the prevention of many diseases, including hypertension and cancer. You can achieve this diet by (1) adding a fruit or a vegetable to your midday meal or as a snack, (2) choosing whole-grain breads and cereals, and (3) looking for healthy frozen meals and soups, as opposed to those with high levels of hidden fat and salt.”
	“A daily multivitamin/multimineral supplement would ensure you are meeting daily nutritional needs, but an ‘over 50’ product designed for people in your age group would be best. These products tend to have lower iron as well as higher amounts of vitamin B₁₂. If you are not regularly consuming dairy products, calcium and vitamin D supplementation should be considered. Check your intake of these nutrients from supplemented products, such as some orange juice brands, and discuss having your serum vitamin D concentration evaluated with your regular health care provider.”
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	“There is no evidence that vitamin supplements, in the absence of deficiency, can completely reduce cancer risk. When selecting a multivitamin, be sure to compare the level of supplementation of each nutrient, including calcium and vitamin D, with its DRI value on the product label. Additional supplementation in excess of the DRI is often unnecessary unless specifically recommended by your regular health care provider.”
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	
a. Appropriate dose and frequency of administration	“Consider a daily USP-approved senior multivitamin/multimineral supplement that contains no more than 100% of DRIs for the various nutrients.”
b. Maximum number of days the therapy	n/a

should be employed	
c. Product administration procedures	"You may take your multivitamin with your current medications in the morning. However, check with your pharmacist about taking your vitamin with any newly prescribed medications."
Solicit follow-up questions from the patient or caregiver.	"What about antioxidant vitamins? Do they prevent cancer?"
Answer the patient's or caregiver's questions.	"Data from well-designed studies do not support antioxidant supplementation for the prevention or treatment of cancer. In fact, some evidence suggests potential harm from supplementation of vitamins A, E, and C, and also selenium and other nutrients, in relation to cancer risk. Therefore, dosing of these nutrients above the DRI cannot be recommended at this time."
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mr. Rodriguez in 1 week to inquire about his compliance with multivitamin recommendations and dietary modification. If necessary, reinforce the recommendations.

Key: DRI = Dietary Reference Intake; n/a = not applicable; UL = upper intake level; USP = United States Pharmacopeia.

Case 23–2

Relevant Evaluation Criteria	Scenario/Model Outcome
Collect	
1. Gather essential information about the patient's symptoms and	

medical history, including	
a. Description of symptom(s) (i.e., nature, onset, duration, severity, associated symptoms)	A patient approaches the pharmacy counter seeking a recommendation for bone health support. She reports that her friend recently fell and broke her hip. She wants to start a calcium/vitamin D supplement because she has read that such supplements can reduce fracture risk.
b. Description of any factors that seem to precipitate, exacerbate, and/or relieve the patient's symptom(s)	n/a
c. Description of the patient's efforts to relieve the symptoms	n/a
d. Patient's identity	Anna Noble
e. Patient's age, gender, height, and weight	72 years, female, 5 ft 3 in., 100 lb
f. Patient's occupation	Retired microbiologist
g. Patient's dietary habits	Tea with milk for breakfast; crackers and cheese for lunch when it is hot outside, soup if the weather is cold; easy-to-prepare microwavable meals for dinner
h. Patient's sleep habits	n/a
i. Concurrent medical conditions, prescription and nonprescription medications, and dietary supplements	<i>High blood pressure: enalapril 2.5 mg 1 tablet daily AM</i>
	<i>Gastroesophageal reflux disease: esomeprazole 20 mg 1 tablet daily</i>

	AM
	<i>Insomnia:</i> zolpidem 5 mg as needed at bedtime
	Family history of hypertension, macular degeneration, and osteoporosis
j. Allergies	NKA
k. History of other adverse reactions to medications	None
Assess	
2. Differentiate patient's signs/symptoms, and correctly identify the patient's primary problem(s).	According to recent warnings, use of chronic acid-suppressive medications can reduce dietary calcium uptake with potentially increased fracture risk. Furthermore, in view of Mrs. Noble's family history of osteoporosis and her small body size, she may need further medical evaluation.
3. Identify exclusions for self-treatment.	None
4. Formulate a comprehensive list of therapeutic alternatives for the primary problem to determine whether referral to a health care provider is required, and share this information with the patient or caregiver.	Options include (1) Focus on potential drug-nutrient interactions in counseling about need for calcium supplementation. (2) Discuss the role of balanced nutrition as the ideal route of taking vitamins and minerals. Identify nutritional needs unique to this patient and micronutrients for which supplementation may be recommended. (3) Refer Mrs. Noble for medical evaluation, including serum vitamin D concentration, and osteoporosis screening. In view of her age, body habitus, family history of osteoporosis, and chronic use of acid-suppressive therapy, she may be at increased risk for osteoporosis and bone fracture. (4) Take no action.
Plan	

5. Select an optimal therapeutic alternative to address the patient's problem, taking into account patient preferences.	Assess the patient's perceived need for nutrient supplements. Evaluate dietary intake from food groups, encouraging at least 5 servings of produce, 3 servings of low-fat dairy products, 2 servings of protein, and 6 servings of whole-grain food sources daily.
6. Describe the recommended therapeutic approach to the patient or caregiver.	Discuss the vitamin and mineral content of the various supplements and compare the total intake with each nutrient's DRI.
	"For a woman of your age, daily intake of 1200 mg of calcium and 800 IU of vitamin D is indicated. Speak with your regular health care provider about your potential risk for osteoporosis and fracture."
7. Explain to the patient or caregiver the rationale for selecting the recommended therapeutic approach from the considered therapeutic alternatives.	"Calcium and vitamin D supplementation alone may not be adequate to reduce your risk of fracture from a fall if you have underlying osteoporosis. Also, chronic use of omeprazole may further increase this risk, which complicates management. Calcium absorption from both dietary and supplement forms may be affected by stomach acid production; acid-suppressing medications such as esomeprazole may cause impaired calcium absorption. Alternative forms of calcium are available for supplementation; however, you should ask your regular health care provider whether you should continue use of acid-suppressive therapy."
Implement	
8. When recommending self-care with nonprescription medications and/or nondrug therapy, convey accurate information to the patient or caregiver.	Criterion does not apply in this case.
Follow-up: Monitor and Evaluate	
9. Assess patient outcome.	Contact Mrs. Noble in 1 week to inquire about her compliance with your multivitamin recommendations and dietary modifications. If

	necessary, reinforce these recommendations. Also inquire about follow-up with her primary care provider and the need to schedule testing for serum vitamin D concentration.

Key: DRI = Dietary Reference Intake; n/a = not applicable; NKA = no known allergies.

Patient Education for Nutritional Deficiencies

The objective of self-treatment is to prevent nutritional deficiencies or to maintain present nutritional status. For most patients, carefully following product instructions and the self-care measures listed here will help ensure optimal therapeutic outcomes.

Vitamins, Minerals, and Trace Elements

- To ensure proper nutrition, eat a varied diet as recommended in MyPlate ([Figure 23–1](#)). Vitamin supplements are not a substitute for a well-balanced diet.
- Carefully read labels on all vitamin and mineral preparations before taking them. Note the amounts of vitamins and minerals required to meet DRI values.
- Do not take doses of vitamins and minerals higher than the recommended DRIs. High doses of vitamins or minerals may be dangerous and should not be taken indiscriminately.
- Take vitamin and mineral supplements with meals if you experience gastrointestinal symptoms.
- Women of childbearing age should take 400 mcg of supplemental folic acid in addition to maintaining a well-balanced diet. This regimen has been shown to reduce the risk of neural tube defects in the fetus.
- Be aware that iron supplements or vitamins with iron may turn the

stool black. This discoloration is not a cause for alarm, unless it is associated with other signs and symptoms consistent with a gastrointestinal bleed.

- As with any medicine, store vitamin and combination vitamin/mineral supplements out of the reach of children, especially if the product contains iron. Teach children that vitamins are drugs and potential poisons and therefore cannot be taken indiscriminately.
- Be aware that therapeutic use of niacin-containing products (but not niacinamide) may cause a flushing, itching, or tingling sensation, which should decrease in intensity with continued therapy. Taking an aspirin or other nonsteroidal anti-inflammatory drug 30–60 minutes before taking niacin may help decrease these effects.
- Do not self-medicate if you suspect a vitamin deficiency; consult an appropriate health care provider instead.

Patient Counseling for Nutrient Supplementation

The public often is exposed to exaggerated and fraudulent claims concerning vitamin products. Health care providers should keep informed about such issues in the medical and pharmaceutical literature and should not support or appear to support claims until they are substantiated by reliable clinical studies. Patients inquiring about such claims should be educated regarding potential risks with nontraditional use of vitamins.

Patients purchasing a nonprescription liquid dietary supplement should be instructed on its proper use and storage, including dilution and preparation techniques. In addition, patient counseling should include information on possible adverse effects (e.g., diarrhea, constipation).

The box “Patient Education for Nutritional Deficiencies” lists specific information to provide in patient counseling. The consumer also can be directed to websites and sources for printed literature that provide evidence-

based recommendations for vitamin and mineral supplementation, such as those listed in the “References” section for this chapter. Referral to a registered dietitian (RD) or registered dietitian nutritionist (RDN) should be considered for patients with evidence of nutritional deficiencies.

Evaluation of Patient Outcomes for Nutritional Adequacy

Nutritional therapy should involve a diet that is based on *MyPlate* and possibly the use of nutritional supplements. The health care provider should advise patients to return 30 days after implementing nutritional therapy (or sooner if symptoms worsen). Patients whose symptoms have worsened should be referred to a primary care provider. Patients who have experienced symptomatic improvement while taking nutritional supplements should nevertheless be encouraged to eat a healthful diet and not to rely on supplements as the primary source for vitamins and minerals.

Key Points for Nutritional Adequacy

- The benefits of a varied, balanced diet in terms of health maintenance and disease prevention have been demonstrated repeatedly. However, the same benefits have not been observed when suboptimal dietary intake is augmented with vitamin and mineral supplementation.
- To assess variety in food choices, the patient’s typical food pattern can be compared with *MyPlate* recommendations. Patients may be referred to an RD or RDN for personalized and more complete counseling on diet modification and nutritional supplementation.
- Overt vitamin or mineral deficiencies are rare in the United States; however, subclinical deficiencies may be contributing to chronic disease.
- The need, if any, for vitamin, mineral, or MVM supplementation should be based on the provider’s assessment of the patient’s

dietary intake, metabolic requirements, absorptive capability, and potential drug–micronutrient interactions. However, supplementation should rarely exceed 100% of the DRI. Clinical trials continue to reveal unanticipated health risks with megadoses of various micronutrients.

Chapter 24: Functional and Meal Replacement Foods

Authors: Caitlyn Pepe, Carol J. Rollins

Foods serve many purposes in our lives. Foremost is their role in survival: Foods provide us with sustenance to maintain metabolism and be physically active. Scientific research suggests that foods also affect health and wellness in specific ways, and consumers are aware of these findings. In a 2013 survey of 1005 adults selected to reflect the American population, 90% believed that health benefits other than basic nutrition are associated with certain foods.¹ Americans also report making changes to improve the healthfulness of their diet; in a 2019 survey, 23% reported actively pursuing foods or a particular diet for health benefits.² Eating more fruits and vegetables, seeking healthier protein sources, consuming more foods that contain whole grains, and maintaining a better and healthier diet overall are among the changes reported. Decisions about purchasing foods and beverages are influenced by healthfulness (62%) slightly more than convenience (57%). The perception of healthfulness depends on a number of factors, including nutrition knowledge, claims or information about health benefits of a food, attitudes and beliefs regarding health and susceptibility to disease, and trust of the information source.³ Regardless of other influences, taste (86%) continues to dominate purchasing decisions, followed by price (68%).²

Lack of time to plan and prepare meals leads health-conscious consumers to seek convenient methods to optimize nutrition for wellness and health promotion, including purchase of high-quality prepared foods and other fast yet healthy alternatives to traditional “sit-down” meals. In addition, more people who have conditions or impairments that affect their ability to obtain adequate nutrients through a regular diet are living independently, and they may seek convenient methods to supplement or replace conventional meals.

The U.S. Food and Drug Administration (FDA) is charged with regulating drugs, dietary supplements, and foods (see [Chapter 4](#)). In this context, *foods* are substances used “primarily for taste, aroma, or nutritive value.”⁴ Specific FDA regulations pertain to food safety and labeling. For all regulated foods, manufacturers are required to provide assurance in advance (premarket) that ingredients are safe, and any labeling claims must be substantiated, truthful,

and not misleading. Particular forms or uses of foods, such as infant formulas (see [Chapter 26](#)) and medical foods, are required to meet additional criteria to ensure the safety of somewhat vulnerable groups.

Although dietitians are the recognized food and nutrition experts, all health care providers should be aware of the role that foods may play in an overall plan to improve or maintain health, especially foods that have benefits beyond their basic nutrients or that help patients reach nutrient goals when healthy meals are not readily available or cannot be ingested. (See [Chapter 23](#) for discussion of vitamins, minerals and nutritional balance.) This chapter provides an overview of two main types of foods: (1) foods used for their potential health benefits—those with specific *functional* effects—and (2) foods intended as *replacements* for regular meals.

Functional Foods

A broad definition of *functional foods* (FF) is as providing “health benefits beyond those of basic nutrition.” This definition encompasses unmodified whole foods (fruits, vegetables, whole-grain products) and designer foods such as purple carrots.^{4,5} A somewhat narrower definition used by the International Life Sciences Institute restricts FF to “unmodified foods with naturally occurring bioactive components.”⁵ Examples are tomatoes, for their lycopene content, and soybeans, which provide isoflavones. The Institute of Medicine (IOM) Food and Nutrition Board restricts the definition of FF to “those foods in which the concentration of one or more ingredients has been altered to enhance the food’s contribution to a healthful diet.”^{4,5} This definition includes foods enriched or fortified with nutrients, phytochemicals, or botanical products, such as orange juice with added calcium. Elements isolated from nontraditional food sources and added to traditional foods, such as stanol esters added to margarine-type spreads, also fit this definition of FF. From this standpoint in current biomedical paradigms, plant-based foods are considered functional because of the synergy in dietary phytochemicals.^{6,7}

As defined by FDA, FF blur the distinction between drugs and foods, much as dietary supplements did until 1994, when the Dietary Supplement Health and Education Act (DSHEA) established a distinct regulatory scheme for dietary supplements.⁴ The term *functional food* is not officially sanctioned by FDA, and no legal definition or regulatory category for FF has been established. A

specific FF may be regulated as a drug or in one of several subcategories of food, depending on its intended use and labeling.^{4,5} Estimates of the global market for FF vary widely depending on the source; \$153.6 billion annually for 2019 was estimated by one source, with a projection of \$260.4 billion per year by the end of 2025.⁸ Contemporary U.S. health care reforms that mandate preventive care and emergence of the field of nutrition economics will likely fuel the growth of FF as their role in dietary recommendations and public health policy, including as a primary care option, increases.⁷

Health care providers should be familiar with FF to fully evaluate their patients' diets in relation to preventive and proactive lifestyle changes that modify risks for chronic diseases. In addition, as a trusted source of information, health care providers may influence patients' acceptance of foods with health benefits.³ Making evidence-based decisions related to the use of FF can be difficult, however, because few randomized controlled trials have been conducted, and because in many studies, only a small number of subjects are enrolled. Epidemiologic studies generally rely on recall of food intake, which obscures true associations between selected food components and disease risk. If researchers are to translate the epidemiology of dietary patterns into clinical interventions, they need a detailed look at specific diets from certain geographic regions with low and very low incidence rates for the major chronic diseases, along with detailed quantification and qualification of dietary phytochemical content.⁹ Interactions between dietary components also must be considered as contributing to beneficial effects of specific foods and dietary patterns.¹⁰ Other factors to consider include the use of biomarkers and the nutrigenomic and epigenomic effects of dietary phytochemicals in whole foods as bioactive food components in individuals.¹¹ The fact that a large number of compounds can arise from a basic chemical structure (e.g., a flavonoid) to produce distinctive effects further complicates the task of identifying active compounds within foods, because different foods within a given category (e.g., citrus) may not lead to the same outcome relative to health or disease mitigation.¹² This daunting complexity makes it challenging to design and conduct clinical trials aimed at prevention of disease. Isolating the food component and administering it as a dietary supplement rather than as an FF, in keeping with many clinical studies, would simplify study design and reduce interactions among food components. Unfortunately, available data do not support this approach, because multiple-constituent dietary phytochemicals in the matrix of plant-based whole foods appear to be safer and more effective than single and multiple-constituent high-dose dietary

supplements.^{6,10,13,14} Associations between FF or bioactive food components and health maintenance or disease prevention usually show a relative risk (RR) of <2.¹⁵ In a traditional medical toxicology model, in which exposures generally involve large doses of a single component, an RR of <2 is considered weak. By contrast, nutritional exposures are broad-based and involve small doses of multiple-component mixtures within whole foods consumed over a prolonged period. An RR of 1.5 should be ranked as “strong” for such exposures. In view of the limitations of available data and the potential for complex interactions among FF and bioactive food components, lifestyle factors, and genetics, the evaluation of FF requires examination of the totality of evidence, including that from biologic models and multiple types of research (preclinical, epidemiologic, clinical, translational).¹⁵ Dietary phytochemical patterns in whole foods and functional dietary patterns have become leading areas for FF science and functional nutrition in current research programs; these patterns will become more important in future research as understanding of these areas evolves.^{6,15} To compare findings or combine results for analysis, researchers must include preparation methods and sources of FF (whole food, isolated component, dietary supplement) in study reports.

Categories of Foods Classified as Functional Foods

FF typically fit into one of five categories on the basis of statutory definitions and regulatory guidelines for health claims on food labels:

1. Foods associated with health claims recognized by FDA
2. Foods that carry structure or function claims
3. Foods for special dietary use
4. Medical foods
5. Certain conventional foods that may be of traditional or cultural significance

A basic understanding of these categories, with recognition of those for which medical supervision is required, is essential for health care providers to optimize clinical care.

All labeling claims require FDA approval; however, the required level of

supporting scientific evidence varies depending on the category under which FF are marketed (e.g., a greater level of supporting science is required for medical foods than for structure–function claims).

Foods With Health Claims

Health claims characterize the relationship between a substance (food, food component, dietary ingredient, dietary supplement) and a disease or health-related condition.^{4,5,16} (See [Chapters 50](#) and [51](#) for discussion of dietary supplements.) Only claims about reduction of disease risk are allowed; no claim about “diagnosis, cure, mitigation, or treatment of disease” can be made. Three types of health claims can be made for conventional foods: authorized, authoritative, and qualified. Each type of claim is associated with specific levels of supportive data and specified labeling criteria. *Authorized* health claims require publication of an FDA regulation after an extensive review of the scientific literature, along with significant scientific agreement that the food/nutrient and disease relationship is well established. Of the health claims allowed for foods, authorized claims undergo the most thorough FDA review. The exact wording of the claim statement is not specified, but the statement appearing on the food label must meet specific criteria.

Statements for authorized health claims cannot quantify the degree of risk reduction, and the term *may* or *might* must be used to qualify the relationship between a food or dietary component and a disease. The label must state that the disease or health-related condition depends on many factors, implying that diet is not the only consideration in disease management. It also must indicate that the benefit related to a disease or health-related condition is part of a total dietary pattern; thus, the need for an overall healthy diet is reinforced. No health claims are permitted for foods containing more than 13 g of fat, 4 g of saturated fat, 60 mg of cholesterol, or 480 mg of sodium per reference amount customarily consumed (RACC); up to double these amounts are allowed for main dishes and meal products.^{16,17} The RACC typically is 1 serving as defined on the product label. Health claims cannot be indicated for children younger than 2 years. [Table 24–1](#) lists authorized and authoritative health claims, requirements for foods listing these health claims, and sample statements that might be used on a food label.^{4,5,16,17}

Table 24–1 Authorized and Authoritative Health Claims

Health Claim	Requirements for Foods	Sample Claim Statement(s) Containing Required Components	Selected Foods Meeting Claim Requirements
Authorized Health Claims			
Calcium–osteoporosis [Calcium and vitamin D– osteoporosis]	High in calcium [high in calcium and vitamin D] Bioavailable Phosphorus content no more than calcium content	Adequate calcium throughout life, as part of a well-balanced diet, may reduce the risk of osteoporosis. Adequate calcium and vitamin D, as part of a well-balanced diet along with physical activity, may reduce the risk of osteoporosis.	Milk Orange juice with added calcium
Sodium–hypertension	Low sodium	Diets low in sodium may reduce the risk of high blood pressure, a disease associated with many factors.	Fruits and vegetables, canned or frozen with no added salt, fresh
Dietary fat–cancer	Low fat “Extra lean” fish and game meat	Development of cancer depends on many factors. A diet low in total fat may reduce the risk of some cancers. <i>(Cannot specify types of fats or fatty acids that may be related to risk of cancer.)</i>	Fruits and vegetables, fresh, frozen, or canned Most cereals Nonfat and low-fat milk and dairy products
Dietary saturated fat and cholesterol–risk of coronary heart disease	Low saturated fat Low cholesterol Low fat “Extra lean” fish and game meat	While many factors affect heart disease, diets low in saturated fat and cholesterol may reduce the risk of this disease.	Fruits and vegetables, fresh, frozen, or canned Most cereals Nonfat and low-fat milk and dairy products
Fiber-containing grain products, fruits, and vegetables–cancer	Grain product, fruit, or vegetable containing	Low-fat diets rich in fiber-containing grain products, fruits, and vegetables may reduce the risk of some types of cancer, a	Fruits and vegetables, fresh, frozen, or canned

Health Claim	Requirements for Foods	Sample Claim Statement(s) Containing Required Components	Selected Foods Meeting Claim Requirements
	dietary fiber Low fat Good source of dietary fiber without fortification	disease associated with many factors. <i>(Cannot specify types of dietary fiber that may be related to risk of cancer.)</i>	Whole-grain breads, cereals, and pasta Brown rice
Fruits, vegetables, and grain products that contain fiber, particularly soluble fiber—risk of coronary heart disease	Fruit, vegetable, or grain product containing fiber Low saturated fat Low cholesterol Low fat Minimum of 0.6 g soluble fiber per RACC without fortification Soluble fiber content provided on the label	Diets low in saturated fat and cholesterol and rich in fruits, vegetables, and grain products that contain some types of dietary fiber, particularly soluble fiber, may reduce the risk of heart disease, a disease associated with many factors.	Fruits and vegetables, fresh, frozen, or canned Whole-grain breads, cereals, and pasta Brown rice
Fruits and vegetables— cancer	Fruit or vegetable Low fat Good source of vitamin A or C, or dietary fiber without fortification	Low-fat diets rich in fruits and vegetables (foods that are low in fat and may contain dietary fiber, vitamin A, or vitamin C) may reduce the risk of some types of cancer, a disease associated with many factors. <i>[X food is high in vitamin A, vitamin C, and/or is a good source of fiber.]</i>	Broccoli Berries Green beans Carrots Cantaloupe Citrus fruits Most dark green leafy vegetables
Folate—neural tube defects	Contains at least 40 mcg folate per serving Foods in conventional form that are a	Healthful diets with adequate folate may reduce a woman's risk of having a child with a brain or spinal cord defect.	Most dark green leafy vegetables (see Chapter 23)

Health Claim	Requirements for Foods	Sample Claim Statement(s) Containing Required Components	Selected Foods Meeting Claim Requirements
	good source without fortification Contains not more than the RDI for vitamin A as retinol, or preformed vitamin A or D Amount of folate must be in the nutrition label		
Dietary noncarcinogenic carbohydrate sweeteners– dental caries	Sugar-free Eligible substances listed in 21 CFR 101.80; examples: xylitol, sorbitol, mannitol, maltitol, isomalt, isomalulose, lactol, hydrogenated starch hydrolysates, hydrogenated glucose syrups, erythritol, D-tagatose, and sucralose Does not lower plaque pH below 5.7 when fermentable carbohydrate is present	Frequent between-meal consumption of foods high in sugars and starches promotes tooth decay. The sugar alcohols in [<i>name of food</i>] do not promote tooth decay. Short claim for small packages: Does not promote tooth decay.	Many “dietetic” sugar-free products marketed for people with diabetes Many low-calorie products marketed for weight loss

Health Claim	Requirements for Foods	Sample Claim Statement(s) Containing Required Components	Selected Foods Meeting Claim Requirements
Soluble fiber from certain foods—risk of coronary heart disease	Low saturated fat Low cholesterol Low fat Includes one or more: (1) an eligible source of whole oat or barley with ≥ 0.75 g soluble fiber per RACC, (2) Oatrim containing ≥ 0.75 g beta-glucan per RACC, (3) psyllium husk containing ≥ 1.7 g soluble fiber per RACC Amount of soluble fiber per RACC must be declared in the nutrition label	Soluble fiber from foods such as [<i>name of soluble fiber source (optional—name of food product)</i>], as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [<i>name of food product</i>] supplies [<i>x</i>] g of the [<i>necessary daily dietary intake for the benefit</i>] soluble fiber from [<i>name of soluble fiber source</i>] necessary per day to have this effect. <i>Note:</i> Foods with a psyllium seed husk health claim must also bear a statement on the label concerning the need to consume adequate fluids and that it should not be taken by those with difficulty swallowing.	Rolled oats, oatmeal Whole oats cold cereals Whole oat flour Oat bran Barley (whole grain, dry milled barley) Cereals with added psyllium
Soy protein—risk of coronary heart disease ^a	Contains ≥ 6.25 g soy protein per RACC Low saturated fat Low cholesterol Low fat, unless fat is from whole soybeans (no added fat)	<i>Example 1:</i> Foods containing 25 g of soy protein a day, as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [<i>name of food</i>] supplies [<i>x</i>] g of soy protein. <i>Example 2:</i> Diets low in saturated fat and cholesterol that include 25 g of soy protein a day may reduce the risk of heart disease. One serving of [<i>name of food</i>] provides [<i>x</i>] g of soy protein.	
Plant sterol/stanol	Spreads and	<i>Example 1:</i> Foods containing at	Margarine

Health Claim	Requirements for Foods	Sample Claim Statement(s) Containing Required Components	Selected Foods Meeting Claim Requirements
esters—risk of coronary heart disease	salad dressings must contain ≥ 0.65 g plant sterol esters per RACC Spreads, salad dressings, and snack bars must contain ≥ 1.7 g plant stanol esters per RACC Low saturated fat Low cholesterol	least 0.65 g per serving of plant sterol esters, eaten twice a day with meals for a total intake of at least 1.3 g, as part of a diet low in saturated fat and cholesterol, may reduce the risk of heart disease. A serving of [<i>name of food</i>] supplies [x] g of vegetable oil sterol esters. <i>Example 2:</i> Diets low in saturated fat and cholesterol that include 2 servings of foods that provide a daily total of at least 3.4 g of plant vegetable oil stanol esters in two meals may reduce the risk of heart disease. A serving of [<i>name of food</i>] supplies [x] g of plant vegetable oil stanol esters. <i>Note:</i> Spreads and salad dressings with >13 g fat per 50 g of product must include a statement “See nutrition information for fat content.”	spreads with added sterol/stanol esters Orange juice with added sterol/stanol esters Nonfat milk with added sterol/stanol esters
Authoritative Health Claims ^b			
Whole-grain foods—risk of heart disease and certain cancers (Docket No. 199P-2209)	Must contain $\geq 51\%$ whole-grain ingredients by weight per RACC Low fat Must meet specified dietary fiber content: 3 g/RACC of 55 g 2.8 g/RACC of 50 g 2.5 g/RACC of 45 g 1.7 g/RACC of 35 g	Diets rich in whole-grain foods and other plant foods and low in total fat, saturated fat, and cholesterol may reduce the risk of heart disease and some types of cancer.	Low-fat whole-grain breads and cereals Whole-grain cereals and pasta Brown rice

Health Claim	Requirements for Foods	Sample Claim Statement(s) Containing Required Components	Selected Foods Meeting Claim Requirements
Whole-grain foods with moderate fat content—risk of heart disease (Docket No. 03Q-0547)	Same as above (Docket No. 199P-2209), except “low fat” is omitted	Diets rich in whole-grain foods and other plant foods and low in total fat, saturated fat, and cholesterol may help reduce the risk of heart disease.	Moderate-fat whole-grain breads and cereals
Potassium—risk of high blood pressure and stroke (Docket No. 2000Q-1582)	Good source of potassium Low sodium Low total fat Low saturated fat Low cholesterol	Diets containing foods that are a good source of potassium and that are low in sodium may reduce the risk of high blood pressure and stroke.	Many fruits and vegetables
Fluoridated water—reduced risk of dental caries (Docket No. 2006Q-0418)	Total fluoride > 0.6-1 mg/L Bottled water must meet standards of identity and quality (21 CFR 165.110) Excludes bottled water for infants	Drinking fluoridated water may reduce the risk of dental caries [or tooth decay].	Bottled water containing fluoride
Saturated fat, cholesterol, and trans fat—reduced risk of heart disease (Docket No. 2006Q-0458)	Low saturated fat Low cholesterol Quantity of trans fat on label and <0.5 g trans fat per RACC Total fat <6.5 g	Diets low in saturated fat and cholesterol, and as low as possible in trans fat, may reduce the risk of heart disease.	Fruits and vegetables, fresh, frozen, or canned Most cereals Nonfat and low-fat milk and dairy products
Substitution of saturated fat in the diet with unsaturated fatty acids—reduced risk of heart disease (Docket No.	Low fat Low cholesterol	Replacing saturated fat with similar amounts of unsaturated fats may reduce the risk of heart disease. To achieve this benefit, total daily calories should not increase.	Baked goods using polyunsaturated oils rather than butter or hydrogenated

Health Claim	Requirements for Foods	Sample Claim Statement(s) Containing Required Components	Selected Foods Meeting Claim Requirements
2007Q-0192)			oils

^a Soy protein content of foods is available from the Agricultural Research Service, U.S. Department of Agriculture (USDA). Nutrient Data Laboratory [database online]. [Search for “standard reference.”] Available at: <http://www.nal.usda.gov/fnic/foodcomp/search>. Accessed June 18, 2019. *Note:* “In the *Federal Register* of October 31, 2017, FDA published a proposed rule to revoke our regulation authorizing the use of health claims on the relationship between soy protein and coronary heart disease on the label or in the labeling of foods. We proposed this action based on our review of the totality of publicly available scientific evidence currently available and our tentative conclusion that such evidence does not support our previous determination that there is significant scientific agreement among qualified experts for a health claim regarding the relationship between soy protein and reduced risk of coronary heart disease.”¹⁶ A final statement has not been published on the proposed rule to revoke this claim.

^b Wording in the sample claim statement for authoritative claims is required by the U.S. Food and Drug Administration.

Key: CFR = Code of Federal Regulations; RACC = reference amount customarily consumed (usually 1 serving as listed on label); RDI = recommended dietary intake.

Source: References 4 and 16–19.

The manufacturer can make certain health claims for foods, food components, or dietary ingredients (but not dietary supplements) by notifying FDA after the agency receives a statement from an authoritative scientific body of the U.S. government vested with responsibility to protect public health or to conduct research related to human nutrition; this type of health claim is called an *authoritative* claim.^{4,16} The National Institutes of Health, the Centers for Disease Control and Prevention, and the National Academy of Sciences, Engineering, and Medicine are sources for authoritative claims. Significant scientific evidence supports such health claims, although FDA itself does not complete an extensive review of the data. Authoritative health claims currently recognized by FDA and required wording for the claims statement are listed in

Table 24–1.^{4,16,17}

The third type of health claim is a qualified claim. *Qualified* health claims are appropriate for use when evidence of health benefits of a food, food component, or dietary supplement is still emerging; scientific research supporting the claim tends to be limited or preliminary; and the “significant scientific agreement” level of evidence required for authorized and authoritative health claims cannot be met. **Table 24–2** lists qualified claims and specific “qualifying” terms required by FDA to indicate that evidence for the claim is limited.^{4,5,18–20} Labeling guidance issued by FDA for qualified health claims intermixes information regarding labeling of dietary supplements and conventional foods.¹⁹ **Chapter 50** provides further discussion of qualified health claims and labeling.

Table 24–2 Qualified Health Claims for Conventional Foods^a			
Food/Nutrient^b	Correlated Disease/Condition	Level of Evidence	Comments^c
Omega-3 fatty acids: EPA and DHA (Docket No. 2003Q-0401, 09/08/2004)	CHD	Supportive but not conclusive research	Total fat, saturated fat, cholesterol, and sodium maximum limits apply. Fish sources may not exceed 16 g total fat per RACC unless a statement “See nutrition information for total fat content” is included with the health claim.
EPA and DHA (Docket No. FDA-2014-Q-1146, 06/19/2019)	Blood pressure in the general population	Inconsistent and inconclusive evidence	Consuming EPA and DHA combined may reduce blood pressure and reduce the risk of hypertension, a risk factor for CHD (coronary heart disease). One serving of [<i>name of the food or dietary supplement</i>] provides [x] g of EPA and DHA.
Walnuts (Docket No. 2002P-029, 03/09/2004)	Heart disease	Supportive but not conclusive research	1.5 ounces of whole or chopped walnuts per day
Nuts (Docket No. 2002P-0505, 07/14/2003)	Heart disease	Supportive but not conclusive research	Limited to almonds, hazelnuts, peanuts, pecans, some pine nuts, pistachio nuts, walnuts; 1.5 ounces per day. Nut-containing products must contain >11 g acceptable nuts and <13 g total fat.

Food/Nutrient^b	Correlated Disease/ Condition	Level of Evidence	Comments^c
Monounsaturated fat from olive oil (Docket No. 2003Q-0559, 11/01/2004)	CHD	Limited and not conclusive evidence	Suggested intake of about 2 tablespoons (23 g) daily; replaces a similar amount of saturated fat and does not increase the total number of calories.
Unsaturated fatty acids from canola oil (Docket No. 2006Q-0091, 10/06/2006)	CHD	Limited and not conclusive evidence	Suggested intake of about 1.5 tablespoons (19 g) daily; replaces a similar amount of saturated fat and does not increase the total number of calories.
Corn oil and corn oil-containing products (Docket No. 2006P-0243, 03/26/2007)	Heart disease	Very limited and preliminary evidence	Suggested intake of about 1 tablespoon (16 g) daily; replaces a similar amount of saturated fat and does not increase the total number of calories.
Oleic acid in edible oils (Docket No. FDA-2017-Q-0807, 11/19/2018)	CHD	Supportive but not conclusive scientific evidence	Suggested intake of about 1½ tablespoons (20 g) of oils containing high levels of oleic acid; oleic acid-containing oils should replace fats and oils higher in saturated fat and not increase the total number of calories per day. One serving of [x] oil provides [x] g of oleic acid (which is [x] g of monounsaturated fatty acid).
Soybean oil (Docket No. FDA-2016-Q-0995, 07/31/2017)	CHD	Supportive but not conclusive scientific evidence	Intake of about 1½ tablespoons (20.5 g) daily of soybean oil; soybean oil should replace saturated fat and not increase the total number of calories per day. One serving of this product contains [x] g of soybean oil.
Macadamia nuts (Docket No. FDA-2015-Q-4850, 07/24/2017)	CHD	Supportive but not conclusive research	Eating 1.5 ounces daily of macadamia nuts, as part of a diet low in saturated fat and cholesterol and not resulting in increased intake of saturated fat or calories, may reduce the risk of coronary heart disease. See nutrition information for fat [and calorie] content.
100% whey protein partially hydrolyzed infant	Atopic dermatitis	Very little to little scientific	In healthy infant, not exclusively breastfed, with family history of allergy, fed the formula from birth to 4 months, claim is for reduced

Food/Nutrient^b	Correlated Disease/ Condition	Level of Evidence	Comments^c
formula (Docket No. FDA-2009-Q-0301, 05/24/2011)		evidence, uncertain	atopic dermatitis up to 3 years of age.
Ground peanuts (Docket No. FDA-2016-Q-0274, 09/07/2017)	Peanut allergy	Evidence limited to a single study	For most infants with severe eczema and/or egg allergy who are already eating solid foods, introducing foods containing ground peanuts between 4 and 10 months of age and continuing consumption may reduce the risk of developing peanut allergy by 5 years of age. Must contain the following statement in bold print: If your infant has severe eczema and/or egg allergy, check with your infant's health care provider before feeding foods containing ground peanuts.
Green tea (Docket No. 2004-Q-0427, 02/24/2011)	Cancer	May reduce risk, but very little scientific evidence	Breast cancer and prostate cancer studies were evaluated.
Tomatoes, tomato sauce (Docket No. 2004-Q-0201, 11/08/2005)	Prostate, ovarian, gastric, and pancreatic cancers	Unlikely, uncertain, or little scientific evidence	Studies are few, with major design limitations and conflicting results. Recommended amount for health benefit is ½-1 cup/week for prostate cancer, twice weekly for ovarian cancer.
Psyllium husk (Docket No. FDA-2013-Q-0167, 06/24/2014)	Diabetes	Very little scientific evidence	Claim for reduced risk of diabetesPsyllium husk must not be present in trivial amounts, although FDA does not specify a minimum amount; psyllium husk must be >95% pure to minimize potential allergenicity.
High-amylose maize starch (Docket Number FDA2015-Q-2352, 12/12/2016)	Diabetes type 2	Limited scientific evidence	The starch contains type 2-resistant starch, a type of fiber.

^a Includes only claims related to conventional foods.

^b FDA docket number is given first, followed by the date of enforcement or discretion letter.

^c Includes certain requirements for the claim.

Key: CHD = Coronary heart disease; DHA = docosahexaenoic acid; EPA = eicosapentaenoic acid.

Source: References [4](#), [5](#), [16](#), [18](#), [20](#), and [27](#).

Foods With Structure–Function Claims

Structure–function claims indicate the effect that consuming the product has on a body structure or function. These claims commonly are associated with dietary supplements but also can appear on food labels. Structure–function claims differ from health claims in that FDA validation or authorization is not required before their use; however, prior notification of FDA regarding the claim is required. In addition, structure–function claims cannot make reference regarding reduced risk of disease, because such a reference would place the product under regulation as a drug.^{4,5,16,21} For example, a probiotic yogurt marketed as for the prevention or treatment of diarrhea is considered a drug; however, if the label instead claims to “improve digestion,” this is considered an acceptable structure–function claim. Other examples of structure–function claims are statements that the product builds strong bones, supports the immune system, improves memory, maintains intestinal flora, improves strength, or promotes urinary tract health. Foods carrying a structure–function claim are considered FF; they are not considered dietary supplements when they are represented as a conventional food. For instance, margarine-type spreads with added stanol esters constitute a food, and the stanol ester is considered a food additive. However, dietary supplements in food form (drinks and bars) that are labeled and marketed as dietary supplements are regulated as dietary supplements (see [Chapter 50](#)). Distinguishing FF from dietary supplements, therefore, can be confusing.

Foods for Special Dietary Use

Foods for special dietary use, as defined by FDA, include foods used to supply particular dietary needs, or to supplement or fortify the usual diet, and marketed as such; they do not meet general dietary needs.^{4,16} Particular dietary needs may be related to the presence of physical, physiologic, pathologic, or other conditions, such as disease, convalescence, pregnancy, lactation, underweight, overweight, infancy, or the need for sodium restriction. Foods intended for use as the only nutrient source in the diet and those intended to supplement the diet by increasing total intake of a specific ingredient (vitamin, mineral, or other nutrient) also are considered to meet a particular dietary need. These foods are subject to general labeling requirements for foods, and medical supervision of their use is not required. By some definitions, foods for special dietary use are considered FF; however, this approach to marketing FF is seen in the food supply much less frequently than is structure–function labeling.

Medical Foods

Medical foods were first defined in the *Federal Register* in 1973; they were represented by an infant formula for patients with phenylketonuria, which had previously been regulated as a drug.⁴ The Orphan Drug Act Amendments of 1988 also define medical foods and require that specific criteria be met before their use and distribution. These foods are to be recommended or prescribed by a physician and used under continued medical supervision; however, they are not prescription-only products in the same manner as for prescription drugs, because they can be sold without a physician's written order. Medical foods do not occur naturally; rather, they are specially formulated and processed to meet *distinctive nutritional requirements* related to the disease or condition for which they are intended.⁴ Distinctive requirements for a select medicinal component in the food (or the food product as a whole) must be established by previous medical evaluation on the basis of recognized scientific principles. Regulations do not prohibit products from being in tablet or capsule form, and some products in these forms, especially vitamin–mineral products, marketed as medical foods may better meet the FDA definition of dietary supplements. Health care providers should be able to distinguish between true medical foods that require ongoing physician supervision and products that can be safely used for “nutritional self-care” by the public. (See

the “Medical Foods and Meal Replacement Foods” section later in the chapter for further discussion of medical foods.)

Conventional Foods

Conventional foods that do not fit into any of the preceding four categories also can be classified as FF. Research on conventional FF comes from contemporary medical ethnobiology and ethnopharmacy, with the foundation being ethnic or traditional foods associated with health benefits in various cultures and supported by epidemiologic studies. For example, long-standing systems of traditional FF use in Asia are linked epidemiologically to some of the lowest cancer rates in the world and to very low incidence of other chronic diseases.^{22,23} The strength of evidence supporting a functional role for such foods is typically weak–moderate, and clinical trials tend to be lacking; therefore, even a qualified health claim often cannot be supported at this time.⁵ However, other foods are known to contain specific compounds for which molecular functional nutrition and pharmacology studies have been conducted. Studies of dietary phytochemicals and fish oils have revealed a variety of specific phytochemicals and marine zoochemicals (e.g., epigallocatechin-3-gallate [EGCG], resveratrol, curcumin, eicosapentaenoic acid [EPA], docosahexaenoic acid [DHA]) that modulate several molecular targets at the same time and can serve collectively as agents for chronic disease prevention and health preservation.^{14,24–26} Table 24–3 provides examples of conventional foods and the components likely responsible for their role as FF, and Table 24–4 lists examples of functional components and typical food sources.^{5,7,10–12,15,27–30}

Table 24–3 Examples of Conventional Foods Classified as Functional Foods			
Food	Functional Component(s)	Potential Health Benefit(s)	Comments
Apples	Flavonols, phenols, proanthocyanidins, soluble fiber (pectin)	Decreased risk of certain types of cancer; improved glucose and cholesterol concentrations; may contribute to maintenance of heart health	Recommend 1 apple daily, but quantity for health benefit is not defined.

Food	Functional Component(s)	Potential Health Benefit(s)	Comments
Bananas, ripe	Prebiotics, FOS	Decreased hypertension and hypercholesterolemia	Weak evidence exists for 3–10 g daily.
Berries; cherries	Anthocyanidins	Antioxidant functions; may contribute to healthy immune system	Recommend ½–1 cup daily, but amount for health benefit is not defined.
Cinnamon	Proanthocyanidins	May contribute to maintenance of urinary tract and heart health	Weak evidence exists; amount for health benefit is not well researched.
Citrus fruits	Ascorbic acid, zeaxanthin, limonene	Decreased risk of AMD ^a ; decreased cancer risk	Weak–moderate evidence exists for AMD ^a with 6 mg daily as lutein; rodent studies involved limonene and cancer.
Cocoa, chocolate	Flavonols	Antioxidant functions, decreased risk of coronary heart disease	Dark chocolate appears to be most effective.
Corn	Lutein, zeaxanthin, free stanols/sterols	Decreased risk of AMD ^a ; may decrease risk of CHD	Weak–moderate evidence exists for 6 mg daily as lutein; health claim pertains to stanol/sterol esters added to foods.
Cranberry juice ^b	Proanthocyanidins	Decreased UTI from decreased adherence of bacteria to cell walls; may also prevent adhesion of plaque-forming bacteria in the mouth	Moderate evidence exists for 300 mL daily to decrease UTI (58% reduction in bacteriuria in 150 elderly women in the first randomized controlled trial [JAMA. 1994 Mar 9; 271(10):751–4.1994]).
Cruciferous vegetables: broccoli,	Glucosinolates, indoles, isothiocyanates (sulforaphane),	Decreased risk of certain types of cancer	Weak–moderate evidence exists for >½ cup daily.

Food	Functional Component(s)	Potential Health Benefit(s)	Comments
brussels sprouts, cauliflower, cabbage	organosulfur compounds, thiols		
Dairy products, including some cheese	Conjugated linoleic acid	Decreased risk of breast cancer; possible role in improved body composition	Weak evidence exists for breast cancer link; animal studies suggest role in decreased body fat; necessary amount for health effects is not determined.
Dairy products, fermented (acidophilus milk, buttermilk, kefir, yogurt)	Probiotic organisms (lactobacilli, bifidobacteria)	Maintenance of GI tract health; decreased colon cancer risk; decreased cholesterol	See Chapter 20 for discussion of probiotics.
Eggs (yolk)	Lutein, zeaxanthin	Decreased risk of AMD ^a	Weak-moderate evidence exists for 6 mg daily as lutein.
Eggs, enriched with DHA	DHA	Decreased risk of CHD; increased HDL cholesterol	Chickens are fed fish oils or algae as a source of DHA.
Fatty fish (wild salmon, herring)	Omega-3 fatty acids	Decreased triglycerides and risk of heart disease, including fatal and nonfatal MI	Recommend 2 meals/week containing fatty fish; supportive but not conclusive evidence exists, per qualified health claim.
Flax	Phytoestrogens (lignans), alpha-linolenic acid	Decreased risk of CHD by decreasing cholesterol and platelet aggregation; weak estrogenic activity may decrease hormone-related cancers; maintenance of a healthy immune system;	Weak evidence exists for CHD association; very weak evidence exists for reduced cancer risk; amounts necessary for health benefit from flax are not defined.

Food	Functional Component(s)	Potential Health Benefit(s)	Comments
		alpha-linolenic acid may contribute to maintenance of visual function.	
Garlic	Organosulfur compounds, thiols	Decreased total and LDL cholesterol; may decrease the risk of gastric cancer; promotes healthy immune function	Weak-moderate evidence exists for approximately 1 fresh clove daily for cholesterol reduction; epidemiologic evidence for decreased cancer risk is equivocal; considerable variation exists in the amount of active compounds for available products.
Grapes, red and black	Anthocyanidins, phenolic compounds	Antioxidant functions; decreased CV risk	Epidemiologic evidence suggests inverse association with CV disease risk.
Grape juice	Resveratrol	Decreased risk of MI caused by decreased platelet aggregation	Moderate-strong evidence exists for 8-16 ounces daily.
Greens: spinach, kale, collards	Lutein, zeaxanthin	Decreased risk of AMD ^a	Weak-moderate evidence exists for 6 mg daily as lutein.
Jerusalem artichoke	Prebiotics, FOS	Decreased hypertension; decreased hypercholesterolemia	Weak evidence exists for 3-10 g daily.
Meat (beef, lamb, turkey) and milk	Conjugated linoleic acid	Antitumor effect proposed; possible role in improved body composition	Suppressed cancer cell growth in rat studies; animal studies suggest role in decreased body fat; necessary amount for health effects undetermined.
Onions,	Organosulfur compounds,	Decreased total and LDL	Weak-moderate

Food	Functional Component(s)	Potential Health Benefit(s)	Comments
leeks, scallions	thiols	cholesterol	evidence exists.
Onion powder	Prebiotics, FOS	Decreased hypertension; decreased hypercholesterolemia	Weak evidence exists for 3-10 g daily.
Rye	Phytoestrogens (lignans)	May contribute to maintenance of heart health and healthy immune system	Amounts necessary for health benefit from rye are not defined.
Tea, black	Polyphenols, flavonoids	Decreased risk of CHD	Evidence is not conclusive.
Tea, green	Catechins (epigallocatechin-3-gallate, epigallocatechin, epicatechin-3-gallate, epicatechin)	Decreased risk of certain types of cancer; improved CV health; weight control	Qualified health claim evaluation concluded green tea (not specifically catechins) is highly unlikely to reduce risk for cancer; evidence for prevention of CV disease and obesity is weak (intake estimates of >4 cups daily).
Tomatoes and processed tomato products	Lycopene	Antioxidant that efficiently decreases singlet oxygen in biologic systems; possible decreased risk of certain cancers (prostate) and MI	Evidence based on inverse associations of tissue lycopene and cancers or MI is weak; qualified health claim evaluation concluded that it is unlikely or uncertain that tomatoes or sauce (not specifically lycopene) reduces risks.
Tree nuts	Monounsaturated fatty acids, vitamin E	Decreased risk of CHD	Moderate evidence exists for 1-2 ounces daily; some nuts have qualified health claim.

^a See [Chapter 28](#) for discussion of AMD and its treatment with eye supplements.

^b In response to a health claim petition linking consumption of cranberry products to reduced risk of recurrent UTIs in healthy women, FDA issued three wording options for the qualified claim for cranberry juice beverages and for the qualified claim for the 500 mg cranberry DS. The full enforcement discretion letter that includes this information and other criteria that must be met is available at https://www.fda.gov/media/140304/download?utm_campaign=CFSANCU_CranberryQHC_07%2F21%2F2020.

Key: AMD = Age-related macular degeneration; CHD = coronary heart disease; CV = cardiovascular; DHA = docosahexaenoic acid; DS = dietary supplement; FOS = fructooligosaccharides; GI = gastrointestinal; HDL = high-density lipoprotein; LDL = low-density lipoprotein; MI = myocardial infarction; UTI = urinary tract infection.

Table 24–4 Examples of Functional Flavonoid Components in Conventional Foods

Functional Component (Subclass of Flavonoids)	Dietary Phytochemicals	Food Sources	Potential Health Benefit(s)
Anthocyanins	Cyanidin Delphinidin Malvidin	Red, blue, and purple berries and grapes; cherries; potatoes; purple sweet potatoes; blue corn; rhubarb; plums	Augment cellular antioxidant defenses; may contribute to maintenance of brain function
Flavones	Hesperetin Naringenin	Citrus fruits and juices	Neutralize free radicals, which may damage cells; augment cellular antioxidant defenses
Flavonols	Isorhamnetin Kaempferol Myricetin Quercetin	Apples, berries, broccoli, kale, tea, onions (scallions, yellow onions; onions have highest flavonol content)	Neutralize free radicals, which may damage cells; augment cellular antioxidant defenses
Flavanols (monomers)	Catechin Epicatechin Epigallocatechin ECGEGCG	Teas (green and white), chocolate, grapes, berries, apples	May contribute to maintenance of heart health

Functional Component (Subclass of Flavonoids)	Dietary Phytochemicals	Food Sources	Potential Health Benefit(s)
Flavanols (polymers)	Proanthocyanidins Theaflavins Thearubigins	Teas (oolong and black), chocolate, apples, berries, red grapes	May contribute to maintenance of heart health and urinary tract health

Key: ECG = Epicatechin-3-gallate; EGCG = epigallocatechin-3-gallate.

Protective Effects of Functional Foods

Functional Foods and Biomarkers: Epigenomics and Chemoprevention

The disposition of dietary phytochemicals is similar to that of drugs and xenobiotics to the extent that the phytochemicals can be studied with respect to their individual pharmacokinetics and pharmacodynamics.³⁰

Pharmacokinetic studies suggest that variations in disease risk or preventive efficacy of certain dietary phytochemicals may be at least partially related to genetic polymorphisms in metabolism that result in altered enzyme activity; thus, the same phytochemical may have different pharmacodynamic effects in different patients. It is unclear if genetic polymorphisms contribute to the beneficial effects associated with fiber, prebiotics, and probiotics, or whether these effects have a greater association with changes that alter the environment within the gastrointestinal (GI) tract and thereby affect the types of organisms that thrive in the GI tract. It is possible that phytochemicals, fibers, and prebiotics interact with the genetic polymorphisms or with the genetics, in general, of the probiotic organisms to induce the benefits associated with these FF components. (See [Chapter 20](#) for discussion of probiotics.) Because of such complexities, common biomarkers used to monitor a condition or health risk may be inadequate to establish a link between a phytochemical, fiber, prebiotic, or probiotic and each component's

clinical end point. IOM developed a framework for the qualification of risk biomarkers that recommends evaluation of the relationship between the clinical end point and the risk biomarker, as well as evidence that the intervention affecting the risk biomarker is concomitantly linked to the clinical end point.^{22,30} Linking biomarkers for health and disease to *epigenomics* (defined as heritable changes in gene expression that occur without a change in DNA sequence)²⁶ is a major challenge in FF research.¹¹

Fiber

Fiber is a component of FF that has been widely studied for associations with potential health benefits. *Fiber* consists of dietary components that humans cannot digest, including plant cell walls; nonstarch polysaccharides from seaweed, microorganisms, or seed husks (psyllium); resistant starches; and nondigestible oligosaccharides.³¹ The terms *dietary fiber* and *functional fiber* are related to dietary reference intakes (see [Chapter 23](#)) and distinguish between sources of fiber.^{31,32} However, because of the heterogeneous composition of these substances, dietary fiber has no chemical definition, and until 2016, FDA regulations had no established definition for its use.³³ Based on the IOM definition, *total fiber* is the sum of dietary and functional fiber.³¹ In its amendment to food labeling regulations, FDA determined that “total fiber” should be used on food labels, rather than listing dietary fiber and functional fiber separately. *Dietary fiber* is defined by IOM as “nondigestible carbohydrates and lignin that are naturally occurring (intrinsic and intact) in plants”; FDA added “and insoluble carbohydrates (with 3 or more monomeric units)” to its definition.^{31,33} Per the IOM definition, *functional fiber* is “isolated nondigestible carbohydrates that have beneficial physiologic effects in humans, including fiber extracted or modified from plants or animal sources”; FDA also included “synthetic non-digestible carbohydrates (with 3 or more monomeric units)” in the regulation. Through a rigorous science review, FDA identified isolated or synthetic nondigestible carbohydrates that were determined to have health benefits and to meet the agency’s new definition of fiber, provided a document with data used to determine fibers that did not meet the new definition, and published guidance regarding information that should be submitted for a scientific evaluation to prove that other purified or isolated fibers meet the agency’s definition of fiber.^{34–36}

FDA evaluated the literature for 26 fiber types that were determined to not meet the agency’s definition of fiber.³⁵ The final report included background

information and various physiologic effects reported for the fibers, such as effects on blood cholesterol, blood glucose, laxation or bowel function, and mineral absorption. Only 7 of these fibers were deemed to meet FDA requirements for fiber and were listed in the Code of Federal Regulations.³⁴ Two of the fibers, beta-glucan soluble fiber and psyllium husk, already had in place authorized health claims related to the risk of coronary heart disease.^{16,34} A general authorized health claim exists for fruits, vegetables, and grain products that contain fiber, particularly soluble fiber, for reducing risk of coronary heart disease. The other recognized fibers included cellulose, guar gum, pectin, locust bean gum, and hydroxypropylmethylcellulose. A general authorized health claim also has been presented for benefit of fiber-containing grain products, fruits, and vegetables in reducing cancer risk.¹⁶ Numerous products currently considered fiber by many manufacturers were not included in the FDA rule, leading to submission of a large number of comments (i.e., informed complaints) to the agency and a suggestion that the current guidance on fiber requires major revision.³⁷ At this time, however, more rigorous research will be required to have such “fibers” added to the list of FDA-recognized fibers. Research should include the effects of extracting fiber from cell walls, because the effects of such extracted fiber may differ from those of in situ fiber owing to altered chemical and physical properties. Viscosity and fermentability were not included in FDA’s definition for fiber, although these factors may have important correlates with health effects.^{38,39} The terms *soluble fiber* and *insoluble fiber*, as used in this discussion, remain pervasive in both professional and nonprofessional literature. FDA regulations require listing the number of grams of dietary fiber (denoting soluble or insoluble fiber is voluntary) on the nutrition label if a claim for fiber is included on the product.³⁴

Recommended and Actual Intake

As published by IOM, adequate intakes (AIs) for total fiber are in the range of 21–38 g daily, with amounts for women and older people being lower than those for men and younger people.³² (See [Chapter 23](#) for general information on AIs.) Values for AIs are based on usual caloric intake in each age group and a baseline of 14 g of dietary fiber per 1000 calories, which appears to be the amount needed to promote heart health.^{31,40} Unfortunately, actual mean fiber intake is only about 15–17 g daily for women and 17–20 g daily for men; progress toward meeting the goals has been minimal over the past 2 decades.^{41,42}

Soluble and Insoluble Fibers

Soluble fibers typically undergo substantial degradation and fermentation in the colon; negligible degradation and fermentation occur with most insoluble fibers. [Table 24–5](#) outlines food components, food sources, and functional fiber sources typically associated with soluble and insoluble fibers. The food sources listed are good to excellent sources of fiber based on tests previously accepted for identifying fiber content⁴²; however, not all fibers listed in the table are recognized in the newer FDA regulations for nutrient labeling.¹⁷

Table 24–5 Components and Sources of Soluble and Insoluble Fiber ^a		
Component	Sources	
	Soluble Fiber	Insoluble Fiber
Food component	Pectins, gums, mucilages, algal substances, some hemicellulose	Cellulose, lignin, most hemicellulose
Food sources with ≥2.5 g of total fiber per serving ^b	Cereals: oat bran (uncooked, ²/₃ cup), oatmeal (cooked, 1 cup) Fruits: apples and pears with skin on, oranges (1 medium), figs and prunes (3 small) Vegetables: broccoli, carrots, cauliflower, corn, kale and other greens, dark green or loose leaf lettuce, peas, squash, zucchini (cooked, ³/₄–1 cup)	Bran and whole-grain (corn, rye, wheat) products: bran cereals (dry cereal, ¹/₃–1 cup), brown rice (cooked, 1 cup), whole wheat bread (2 slices) Dried beans: lima, kidney, pinto, white (cooked, ¹/₄–¹/₂ cup)Dried peas: green, split (cooked, ¹/₄–¹/₂ cup)
Functional fiber sources	Beet fiber, FOS, guar gum (galactomannan, Benefiber), inulin, karaya gum, konjac mannan (glucomannan), locust bean gum, pectin, psyllium (ispaghula seed husk)	Calcium polycarbophil, methylcellulose, powdered cellulose, soy polysaccharide (also has significant soluble fiber effects)

^a Not all fibers listed in the table are recognized by the U.S. Food and Drug Administration in regulations for nutrient labeling.

^b Serving size shown in parentheses. The food sources listed are good (2.5–4.9 g of fiber per serving) to excellent (5 g or more of fiber per serving) sources of total dietary fiber and are listed under the fiber type that exemplifies their predominant health effects.

Key: FOS = Fructooligosaccharides.

Source: Adapted from [References 31, 34, and 42](#).

Methods of Increasing Fiber Intake

Table 24–6 lists suggestions for increasing fiber content in the diet. Caution is advised with the use of fiber-containing products in patients with poor GI motility or underlying GI dysfunction, including narcotic-associated dysmotility. Inadequate fluid intake also may contribute to GI distress from a high-fiber diet. It is advisable to gradually increase fiber, because a sudden increase can cause bloating, gas, and, occasionally, diarrhea. A reasonable approach is to add 1–2 servings of foods that are abundant in fiber (**Table 24–5**) to the diet every few days until the goal for fiber intake is reached. Reading ingredient labels is essential to evaluate adequacy of fiber content, especially for breads and cereals, in which a *whole* grain should be the first ingredient listed.

Table 24–6 Methods for Increasing Fiber in the Diet

- Eat breads containing “wheat berries,” whole wheat flour, or other whole grains as the first ingredient on the label. These products should replace breads from refined flours that do not include whole grains.
- Replace part of refined (non-whole-grain) cereals with whole-grain cereal for persons who prefer refined cereals; or mix very-high-fiber cereals into a favorite brand of cereal.
- Eat oatmeal as a hot breakfast cereal, or select a cold cereal with oats or whole grain as the primary ingredient.
- Sprinkle bran on cereal, yogurt, or other foods.
- Eat brown rice, whole wheat pasta, and whole-grain crackers rather than white rice and products from refined grains.
- Add fruit to breakfast cereals, breads, yogurt, and salads.
- Select recipes that use whole-grain flours, and/or add rolled oats to baked goods.
- Select recipes for baked goods that include apples, applesauce, carrots, pumpkin, or other fruits or vegetables as a significant ingredient.
- Add kidney, garbanzo, navy, or other beans to salads and soups, including canned soups. Rinse and drain canned beans to reduce components prone to cause intestinal gas.
- Serve fruit and/or vegetable salads with picnic lunches instead of potato chips.
- Serve canned beans (black, kidney, white, baked) as an alternative protein source.
- Eat fresh or dried fruit for snacks and desserts; frozen and canned fruits (in juice) also can be used.

- Use a low-fat refried bean dip or hummus with whole wheat baked tortilla chips for snacks.
- Eat fruits and vegetables, including potatoes, with the skin on.
- Select snack or meal replacement bars containing at least 2.5 g of fiber per serving.
- Include “finger food” vegetables (carrots, celery, cauliflower pieces, broccoli florets) in lunch boxes and as snacks.
- For children, make animal or other fun shapes from vegetable pieces.
- Eat nuts and/or seeds for snacks, or add to mixed dishes, salads, breads, and cereals.

Benefits of Fiber

The generally accepted benefits of fiber are laxation effects, normalization of blood lipid concentrations, and attenuation of blood glucose response.^{5,36,38,42} These benefits are the accepted measures of efficacy that are required for label claims of fiber content in Canada and the United States.^{32,33} Other benefits of fiber, such as weight control, have been suggested in humans; however, results of relevant studies are limited and conflicting.

Laxation

Stool characteristics associated with *laxation*, or improved bowel function, include increased stool bulk, weight, and water content; decreased stool transit time and normalization of stool frequency to once daily; reduced symptoms of constipation; and an overall improvement in ease of defecation. Epidemiologic studies strongly support the positive role of fiber from whole grains, fruits, and vegetables in laxation. Insoluble fiber has been associated most frequently with improved laxation, although evidence also indicates some soluble fibers have similar effects. The role of functional fibers in laxation is well accepted, and adequate scientific evidence exists to support FDA approval of some fibers as nonprescription bulking agents for treatment of *occasional* constipation, as discussed in [Chapter 15](#). Studies supporting the efficacy of bulk-forming fibers in *chronic* constipation tend to be of intermediate to low quality, and results are mixed.

Normalization of Blood Lipid Concentrations

Data on reduced risk of coronary heart disease (CHD) with intake of certain fibers are sufficient to support an FDA-authorized health claim ([Table 24–1](#)).^{4,5,16} Multiple epidemiologic studies have reported a reduced risk of CHD or cardiovascular disease (CVD) with high dietary fiber intake and/or fiber-rich

foods. The relationship appears to hold over many years and across ethnic groups. **Table 24–7** summarizes data related to risk of CHD from several large, well-designed prospective epidemiologic studies with longer-term follow-up and pooled data studies.^{40,43–49}

Table 24–7 Summary of Selected Studies Related to Fiber and Risk of Coronary Heart Disease (CHD) and Improved Glucose Control

Study Name and Population Characteristics^a	Follow-up Time (Years)	Results/Conclusions
Pooled data, cohort studies; total of 672,408 men and women in 18 studies ⁴³ ; ages 25–99 years		<i>CHD</i> : RR 0.93 (7% decrease) for all CHD events and 0.83 (17% decrease) for CHD (CHD-related) mortality; RR 0.92 for all CHD events and RR 0.76 for CHD mortality for each 10 g daily increment of total dietary fiber. Inverse relationship between intake of dietary fiber from cereal sources and fruits and risk of CHD; intake of dietary fiber from cereal sources only and CHD mortality; soluble and insoluble fiber intake and risk of CHD/CHD mortality.
Nurses' Health and Health Professionals Follow-up Studies ⁴⁴ ; prospective cohort design; 2258 women and 1840 men; ages 30–75 years	22–32	<i>CVD</i> : HR 0.75 for all-cause mortality after MI for highest fifth quintile fiber intake; stronger association for cereal fiber, with HR 0.73 for all-cause mortality and HR 0.72 for CVD mortality; with increased fiber intake from before to after MI, HR 0.69 for all-cause mortality
Pooled data, cohort studies ⁴⁵ ; total of 2,254,632 men and women in 22 studies; ages 16–79 years	6–22	<i>CVD/CHD</i> : RR 0.91 (9% decrease) for CVD and CHD for each 7 g daily increment of total dietary fiber; inverse relationship between intake of insoluble fiber and fiber from cereal and vegetable sources and risk of CHD/CVD; inverse relationship between fruit fiber intake and risk of CVD
Pooled data, prospective cohort studies ⁴⁶ ; total of 3,600,126 men and women in 15 studies; ages 20–85 years	5.9–40	<i>CVD/CHD</i> : RR 0.77 for CVD mortality and 0.76 for CHD mortality; RR 0.91 for CVD mortality and RR 0.89 for CHD mortality for each 10 g daily increment of total dietary fiber

Study Name and Population Characteristics ^a	Follow-up Time (Years)	Results/Conclusions
		High intake of dietary fiber of 29.6 g daily reduced CVD mortality by 23%, and 23.2 g daily reduced CHD mortality by 24%, compared with low intake of 14 g daily and 12.5 g daily.
PREDIMED Study ⁴⁷ : observational cohort design; 7216 men and women; ages 55–75 years	5.9	CVD: HR 0.59 (41% lower risk) in highest quintile of fiber intake of median 35 g daily, compared with lowest quintile of median 17 g daily; inverse relationship between baseline fiber intake and fruit consumption and CVD-related mortality
		Subjects who increased their fruit consumption to >210 g daily had 41% lower all-cause mortality. Participants were free of CVD at baseline.
Cardiovascular Health Study, fiber intake analysis ⁴⁰ : cohort design; 3588 men and women; ages ≥65 years (average 72 at baseline)	8.6	CHD/CVD: Cereal fiber intake was inversely associated with incident CVD. HR 0.79 (21% lower risk) in highest quintile of fiber intake versus lowest quintile. The difference was seen with about 4.6 g fiber daily (2 slices whole-grain bread). Lower risk predominantly seen with fiber in dark bread (whole-wheat, rye, pumpernickel). Fruit and vegetable fiber intake was not associated with incident CVD. Participants were free of known CVD at baseline.
NIH-AARP Diet and Health Study ⁴⁸ : 367,442 men and women; ages 50–71 years	14 (5,148,760 person-years ^b)	CVD/Glucose: Fiber intake from whole grains was inversely associated with all-cause mortality and risk of death from CVD and diabetes. All-cause mortality was decreased by 17% in the highest quintile for whole grains, 1.2 oz eq daily, and 19% for highest quintile for cereal fiber, 10.22 g daily.
Pooled data, prospective cohort studies ⁴⁰ : total of 91,058 men and 245,186 women in 10 studies; ages 35–98 years	6–10	CHD: RR for all coronary events 0.86 (14% decrease) and RR 0.73 (27% decrease) for coronary death for each 10 g daily increment of total dietary fiber. For cereal fiber, RR 0.9 for all coronary events and RR 0.75 for death; for fruit fiber, RR 0.84 and 0.7; for vegetable fiber, RR 1.00 for all coronary events and death. Results were similar for men and women.
Pooled data, prospective cohort studies ⁴⁹ : 488,293 men and	10.8	Glucose: RR 0.81 (19% decrease) for type 2 DM with total dietary fiber intake. For cereal fiber, RR 0.77; for fruit fiber, RR 0.94; for insoluble fiber, RR 0.75. 34% lower risk of DM with high fiber intake of 35 g daily compared with that for the lowest quintile of

Study Name and Population Characteristics^a	Follow-up Time (Years)	Results/Conclusions
women in 17 studies		15 g daily. RR 0.94 (6% decrease) for DM per 2 g daily increment in cereal fiber intake.
Nurses' Health Studies: NHS-I and NHS-II ⁴⁰ : cohort design; total 161,737 women; NHS-I: 73,327, ages 37–64 years; NHS-II: 88,410, ages 26–46 years	12–18	<i>Glucose:</i> For each 40 g increment in whole-grain intake, multivariate analysis indicated RR for DM of 0.54 (NHS-I) and 0.64 (NHS-II). BMI accounted for 42% and 57% of the association with RR after adjustment for BMI of 0.7 and 0.83, respectively, for NHS-I and NHS-II.

^a Number of participants included in the analysis is not always the entire study population; meta-analyses may include subsets of data from more than one trial.

^b One person-year is equivalent to data for one person followed for 1 year.

Key: BMI = Body mass index; CVD = cardiovascular disease; DM = diabetes mellitus; HR = hazard ratio; MI = myocardial infarction; RR = relative risk.

The key to fiber's ability to lower cholesterol and reduce CHD risk appears to be consuming an adequate quantity of highly viscous fiber, primarily from whole-grain cereal (oats, barley, rye) and beans (legumes), or from guar gum, pectin, and psyllium. More recent data suggest that fruit fiber may have a beneficial effect relative to CHD/CVD, whereas the association with vegetable fiber is less clear.

Attenuation of Blood Glucose Response

Multiple large, well-designed prospective epidemiologic and cohort studies with longer-term follow-up have reported an association between consumption of fiber and attenuation of blood glucose response, improved

insulin response, and/or reduced risk of diabetes, as summarized in [Table 24–7](#) studies.^{40,43–49} The overall conclusion from these studies is that an inverse relationship exists between risk of diabetes and intake of dietary fiber. Intake of cereal fiber appears to be most frequently related to improved glucose control and/or reduced risk of diabetes; foods most likely to provide a positive effect include cereal grains such as oats, barley, and rye. Some legumes (beans), fruits, and vegetables, as well as guar gum and pectin, also may have a beneficial effect on glucose control. Available evidence suggests that nonviscous fibers, such as wheat bran, have little effect on glycemic control.
