Intracranial complications of acute sinusitis, which are substantially less common than orbital complications, are more serious, with higher morbidity and mortality than those involving the orbit. Intracranial complications should be suspected in the patient who presents with a very severe headache, photophobia, seizures, or other focal neurologic findings. Intracranial complications include subdural empyema, epidural empyema, venous thrombosis, brain abscess, and meningitis.[29] Typically, patients with intracranial complications of acute bacterial sinusitis are previously healthy adolescent males with frontal sinusitis.[33,34]

There have been no head-to-head comparisons of the diagnostic accuracy of contrast-enhanced CT scanning to MRI with contrast in the evaluation of orbital and intracranial complications of sinusitis in children. In general, the contrast-enhanced CT scan has been the preferred imaging study when complications of sinusitis are suspected.[35,36] However, there are documented cases in which a contrast-enhanced CT scan has not revealed the abnormality responsible for the clinical presentation and the MRI with contrast has, especially for intracranial complications and rarely for orbital complications.[37,38] Accordingly, the most recent appropriateness criteria from the American College of Radiology endorse both MRI with contrast and contrast-enhanced CT as complementary examinations when evaluating potential complications of sinusitis.[35] The availability and speed of obtaining the contrast-enhanced CT are desirable; however, there is increasing concern regarding exposure to radiation. The MRI, although very sensitive, takes longer than the contrast-enhanced CT and often requires sedation in young children (which carries its own risks). In older children and adolescents who may not require sedation, MRI with contrast, if available, may be preferred when intracranial complications are likely. Furthermore, MRI with contrast should be performed when there is persistent clinical concern or incomplete information has been provided by the contrast-enhanced CT scan.

Key Action Statement 3

Initial Management of Acute Bacterial Sinusitis

3A: "Severe onset and worsening course" acute bacterial sinusitis. The clinician should prescribe antibiotic therapy for acute bacterial sinusitis in children with severe onset or worsening course (signs, symptoms, or both) (Evidence Quality: B; Strong Recommendation).

KAS Profile 3A

Aggregate evidence quality: B; randomized controlled trials with limitations.	
Benefit	Increase clinical cures, shorten illness duration, and may prevent suppurative complications in a high-risk patient population.
Harm	Adverse effects of antibiotics.
Cost	Direct cost of therapy.
Benefits-harm assessment	Preponderance of benefit.
Value judgments	Concern for morbidity and possible complications if untreated.
Role of patient preference	Limited.
Intentional vagueness	None.
Exclusions	None.
Strength	Strong recommendation.

3B: "Persistent illness." The clinician should either prescribe antibiotic therapy OR offer additional outpatient observation for 3 days to children with persistent illness (nasal discharge of any quality or cough or both for at least 10 days without evidence of improvement) (Evidence Quality: B; Recommendation).

The purpose of this section is to offer guidance on initial management of persistent illness sinusitis by helping clinicians choose between the following 2 strategies:

1. Antibiotic therapy, defined as initial treatment of acute bacterial sinusitis with antibiotics, with the intent of starting antibiotic therapy as soon as possible after the encounter.
2. Additional outpatient observation, defined as initial management of acute bacterial sinusitis limited to continued observation for 3 days, with commencement of antibiotic therapy if either the child does not improve clinically within several days of diagnosis or if there is clinical worsening of the child's condition at any time.

KAS Profile 3B

Aggregate evidence quality: B; randomized controlled trials with limitations.	
Benefit	Antibiotics increase the chance of improvement or cure at 10 to 14 days (number needed to treat, 3–5); additional observation may avoid the use of antibiotics with attendant cost and adverse effects.
Harm	Antibiotics have adverse effects (number needed to harm, 3) and may increase bacterial resistance. Observation may prolong illness and delay start of needed antibiotic therapy.
Cost	Direct cost of antibiotics as well as cost of adverse reactions; indirect costs of delayed recovery when observation is used.
Benefits-harm assessment	Preponderance of benefit (because both antibiotic therapy and additional observation with rescue antibiotic, if needed, are appropriate management).
Value judgments	Role for additional brief observation period for selected children with persistent illness sinusitis, similar to what is recommended for acute otitis media, despite the lack of randomized trials specifically comparing additional observation with immediate antibiotic therapy and longer duration of illness before presentation.
Role of patient preference	Substantial role in shared decision-making that should incorporate illness severity, child's quality of life, and caregiver values and concerns.
Intentional vagueness	None.
Exclusions	Children who are excluded from randomized clinical trials of acute bacterial sinusitis, as defined in the text.
Strength	Recommendation.

In contrast to the 2001 AAP guideline,[5] which recommended antibiotic therapy for all children diagnosed with acute bacterial sinusitis, this guideline allows for additional observation of children presenting with persistent illness (nasal discharge of any quality or daytime cough or both for at least 10 days without evidence of improvement). In both guidelines, however, children presenting with severe or worsening illness (which was not defined explicitly in the 2001 guideline[5]) are to receive antibiotic therapy. The rationale for this approach (Table 2) is discussed below.

Antibiotic Therapy for Acute Bacterial Sinusitis

In the United States, antibiotics are prescribed for 82% of children with acute sinusitis.[39] The rationale for antibiotic therapy of acute bacterial sinusitis is based on the recovery of bacteria in high density ($\geq 10^4$ colony-forming units/mL) in 70% of maxillary sinus aspirates obtained from children with a clinical syndrome characterized by persistent nasal discharge, daytime cough, or both.[16,40] Children who present with severe-onset acute bacterial sinusitis are presumed to have bacterial infection, because a temperature of at least 39°C/102.2°F coexisting for at least 3 consecutive days with purulent nasal discharge is not consistent with the well-documented pattern of acute viral URI. Similarly, children with worsening-course acute bacterial sinusitis have a clinical course that is also not consistent with the steady improvement that characterizes an uncomplicated viral URI.[9,10]

Three RCTs have compared antibiotic therapy with placebo for the initial management of acute bacterial sinusitis in children. Two trials by Wald et al[4,41] found an increase in cure or improvement after antibiotic therapy compared with placebo with a number needed to treat of 3 to 5 children. Most children in these studies had persistent acute bacterial sinusitis, but children with severe or worsening illness were also included. Conversely, Garbutt et al,[42] who studied only children with persistent acute bacterial sinusitis, found no difference in outcomes for antibiotic versus placebo. Another RCT by Kristo et al,[43] often cited as showing no benefit from antibiotics for acute bacterial sinusitis, will not be considered further because of methodologic flaws, including weak entry criteria and inadequate dosing of antibiotic treatment.

The guideline recommends antibiotic therapy for severe or worsening acute bacterial sinusitis because of the benefits revealed in RCTs[4,41] and a theoretically higher risk of suppurative complications than for children who present with persistent symptoms. Orbital and intracranial complications of acute bacterial sinusitis have not been observed in RCTs, even when placebo was administered; however, sample sizes have inadequate power to preclude an increased risk. This risk, however, has caused some investigators to exclude children with severe acute bacterial sinusitis from trial entry.[42]

Additional Observation for Persistent Onset Acute Bacterial Sinusitis

The guideline recommends either antibiotic therapy or an additional brief period of observation as initial management strategies for children with persistent acute bacterial sinusitis because, although there are benefits to antibiotic therapy (number needed to treat, 3–5), some children improve on their own, and the risk of suppurative complications is low.[4,41] Symptoms of persistent acute bacterial sinusitis may be mild and have varying effects on a given child's quality of life, ranging from slight (mild cough, nasal discharge) to significant (sleep disturbance, behavioral changes, school or child care absenteeism). The benefits of antibiotic therapy in some trials[4,41] must also be balanced against an increased risk of adverse events (number need to harm, 3), most often self-limited diarrhea, but also including occasional rash.[4]

Choosing between antibiotic therapy or additional observation for initial management of persistent illness sinusitis presents an opportunity for shared decision-making with families (Table 2). Factors that might influence this decision include symptom severity, the child's quality of life, recent antibiotic use, previous experience or outcomes with acute bacterial sinusitis, cost of antibiotics, ease of administration, caregiver concerns about potential adverse effects of antibiotics, persistence of respiratory symptoms, or development of complications. Values and preferences expressed by the caregiver should be taken into consideration (Table 3).

Children with persistent acute bacterial sinusitis who received antibiotic therapy in the previous 4 weeks, those with concurrent bacterial infection (eg, pneumonia, suppurative cervical adenitis, group A streptococcal pharyngitis, or acute otitis media), those with actual or suspected complications of acute bacterial sinusitis, or those with underlying conditions should generally be managed with antibiotic therapy. The latter group includes children with asthma, cystic fibrosis, immunodeficiency, previous sinus surgery, or anatomic abnormalities of the upper respiratory tract.

Limiting antibiotic use in children with persistent acute bacterial sinusitis who may improve on their own reduces common antibiotic-related adverse events, such as diarrhea, diaper dermatitis, and skin rash. The most recent RCT of acute bacterial sinusitis in children[4] found adverse events of 44% with antibiotic and 14% with placebo.

Limiting antibiotics may also reduce the prevalence of resistant bacterial pathogens. Although this is always a desirable goal, no increase in resistant bacterial species was observed within the group of children treated with a single course of antimicrobial agents (compared with those receiving placebo) in 2 recent large studies of antibiotic versus placebo for children with acute otitis media.[44,45]

Key Action Statement 4

Clinicians should prescribe amoxicillin with or without clavulanate as first-line treatment when a decision has been made to initiate antibiotic treatment of acute bacterial sinusitis (Evidence Quality: B; Recommendation).

KAS Profile 4

Aggregate evidence quality: B; randomized controlled trials with limitations.

Benefit	Increase clinical cures with narrowest spectrum drug; stepwise increase in broadening spectrum as risk factors for resistance increase.
Harm	Adverse effects of antibiotics including development of hypersensitivity.
Cost	Direct cost of antibiotic therapy.
Benefits-harm assessment	Preponderance of benefit.
Value judgments	Concerns for not encouraging resistance if possible.
Role of patient preference	Potential for shared decision-making that should incorporate the caregiver's experiences and values.
Intentional vagueness	None.
Exclusions	May include allergy or intolerance.
Strength	Recommendation.

TABLE 2 Recommendations for Initial Use of Antibiotics for Acute Bacterial Sinusitis

Clinical Presentation	Severe Acute Bacterial Sinusitis[a]	Worsening Acute Bacterial Sinusitis[b]	Persistent Acute Bacterial Sinusitis[c]
Uncomplicated acute bacterial sinusitis without coexisting illness	Antibiotic therapy	Antibiotic therapy	Antibiotic therapy or additional observation for 3 days[d]
Acute bacterial sinusitis with orbital or intracranial complications	Antibiotic therapy	Antibiotic therapy	Antibiotic therapy
Acute bacterial sinusitis with coexisting acute otitis media, pneumonia, adenitis, or streptococcal pharyngitis	Antibiotic therapy	Antibiotic therapy	Antibiotic therapy

[a] Defined as temperature ≥39°C and purulent (thick, colored, and opaque) nasal discharge present concurrently for at least 3 consecutive days.
[b] Defined as nasal discharge or daytime cough with sudden worsening of symptoms (manifested by new-onset fever ≥38°C/100.4°F or substantial increase in nasal discharge or cough) after having experienced transient improvement of symptoms.
[c] Defined as nasal discharge (of any quality), daytime cough (which may be worse at night), or both, persisting for >10 days without improvement.
[d] Opportunity for shared decision-making with the child's family; if observation is offered, a mechanism must be in place to ensure follow-up and begin antibiotics if the child worsens at any time or fails to improve within 3 days of observation.

The purpose of this key action statement is to guide the selection of antimicrobial therapy once the diagnosis of acute bacterial sinusitis has been made. The microbiology of acute bacterial sinusitis was determined nearly 30 years ago through direct maxillary sinus aspiration in children with compatible signs and symptoms. The major bacterial pathogens recovered at that time were *Streptococcus pneumoniae* in approximately 30% of children and nontypeable *Haemophilus influenzae* and *Moraxella catarrhalis* in approximately 20% each.[16,40] Aspirates from the remaining 25% to 30% of children were sterile.

Maxillary sinus aspiration is rarely performed at the present time unless the course of the infection is unusually prolonged or severe. Although some authorities have recommended obtaining cultures from the middle meatus to determine the cause of a maxillary sinus infection, there are no data in children with acute bacterial sinusitis that have compared such cultures with cultures of a maxillary sinus aspirate. Furthermore, there are data indicating that the middle meatus in healthy children is commonly colonized with *S pneumoniae, H influenzae*, and *M catarrhalis*.[46]

Recent estimates of the microbiology of acute sinusitis have, of necessity, been based primarily on that of acute otitis media (AOM), a condition with relatively easy access to infective fluid through performance of tympanocentesis and one with a similar pathogenesis to acute bacterial sinusitis.[47,48] The 3 most common bacterial pathogens recovered from the middle ear fluid of children with AOM are the same as those that have been associated with acute bacterial sinusitis: *S pneumoniae*, nontypeable *H influenzae,* and *M catarrhalis*.[49] The proportion of each has varied from study to study depending on criteria used for diagnosis of AOM, patient characteristics, and bacteriologic techniques. Recommendations since the year 2000 for the routine use in infants of 7-valent and, more recently, 13-valent pneumococcal conjugate vaccine (PCV-13) have been associated with a decrease in recovery of *S pneumoniae* from ear fluid of children with AOM and a relative increase in the incidence of infections attributable to *H influenzae*.[50] Thus, on the basis of the proportions of bacteria found in middle ear infections, it is estimated that *S pneumoniae* and *H influenzae* are currently each responsible for approximately 30% of cases of acute bacterial sinusitis in children, and *M catarrhalis* is responsible for approximately 10%. These percentages are contingent on the assumption that approximately one-quarter of aspirates of maxillary sinusitis would still be sterile, as reported in earlier studies. *Staphylococcus aureus* is rarely isolated from sinus aspirates in children with acute bacterial sinusitis, and with the exception of acute maxillary sinusitis associated with infections of dental origin,[51] respiratory anaerobes are also rarely recovered.[40,52] Although *S aureus* is a very infrequent cause of acute bacterial sinusitis in children, it is a significant pathogen in the orbital and intracranial complications of sinusitis. The reasons for this discrepancy are unknown.

Antimicrobial susceptibility patterns for *S pneumoniae* vary considerably from community to community. Isolates obtained from surveillance centers nationwide indicate that, at the present time, 10% to 15% of upper respiratory tract isolates of *S pneumoniae* are nonsusceptible to penicillin[53,54]; however, values for penicillin nonsusceptibility as high as 50% to 60% have been reported in some areas.[55,56] Of the organisms that are resistant, approximately half are highly resistant to penicillin and the remaining half are intermediate in resistance. [53,54,56–59] Between 10% and 42% of *H influenzae*[56–59] and close to 100% of *M catarrhalis* are likely to be β-lactamase positive and nonsusceptible to amoxicillin. Because of dramatic geographic variability in the prevalence of β-lactamase–positive *H influenzae*, it is extremely desirable for the practitioner to be familiar with local patterns of susceptibility. Risk factors for the presence of organisms

likely to be resistant to amoxicillin include attendance at child care, receipt of antimicrobial treatment within the previous 30 days, and age younger than 2 years.[50,55,60]

Amoxicillin remains the antimicrobial agent of choice for first-line treatment of uncomplicated acute bacterial sinusitis in situations in which antimicrobial resistance is not suspected. This recommendation is based on amoxicillin's effectiveness, safety, acceptable taste, low cost, and relatively narrow microbiologic spectrum. For children aged 2 years or older with uncomplicated acute bacterial sinusitis that is mild to moderate in degree of severity who do not attend child care and who have not been treated with an antimicrobial agent within the last 4 weeks, amoxicillin is recommended at a standard dose of 45 mg/kg per day in 2 divided doses. In communities with a high prevalence of nonsusceptible *S pneumoniae* (>10%, including intermediate- and high-level resistance), treatment may be initiated at 80 to 90 mg/kg per day in 2 divided doses, with a maximum of 2 g per dose.[55] This high-dose amoxicillin therapy is likely to achieve sinus fluid concentrations that are adequate to overcome the resistance of *S pneumoniae,* which is attributable to alteration in penicillin-binding proteins on the basis of data derived from patients with AOM.[61] If, within the next several years after licensure of PCV-13, a continuing decrease in isolates of *S pneumoniae* (including a decrease in isolates of nonsusceptible *S pneumoniae)* and an increase in β-lactamase–producing *H influenzae* are observed, standard-dose amoxicillin-clavulanate (45 mg/kg per day) may be most appropriate.

Patients presenting with moderate to severe illness as well as those younger than 2 years, attending child care, or who have recently been treated with an antimicrobial may receive high-dose amoxicillin-clavulanate (80–90 mg/kg per day of the amoxicillin component with 6.4 mg/kg per day of clavulanate in 2 divided doses with a maximum of 2 g per dose). The potassium clavulanate levels are adequate to inhibit all β-lactamase–producing *H influenzae* and *M catarrhalis*.[56,59]

A single 50-mg/kg dose of ceftriaxone, given either intravenously or intramuscularly, can be used for children who are vomiting, unable to tolerate oral medication, or unlikely to be adherent to the initial doses of antibiotic.[62–64] The 3 major bacterial pathogens involved in acute bacterial sinusitis are susceptible to ceftriaxone in 95% to 100% of cases.[56,58,59] If clinical improvement is observed at 24 hours, an oral antibiotic can be substituted to complete the course of therapy. Children who are still significantly febrile or symptomatic at 24 hours may require additional parenteral doses before switching to oral therapy.

The treatment of patients with presumed allergy to penicillin has been controversial. However, recent publications indicate that the risk of a serious allergic reaction to second- and third-generation cephalosporins in patients with penicillin or amoxicillin allergy appears to be almost nil and no greater than the risk among patients without such allergy.[65–67] Thus, patients allergic to amoxicillin with a non–type 1 (late or delayed, >72 hours) hypersensitivity reaction can safely be treated with cefdinir, cefuroxime, or cefpodoxime.[66–68] Patients with a history of a serious type 1 immediate or accelerated (anaphylactoid) reaction to amoxicillin can also safely be treated with cefdinir, cefuroxime, or cefpodoxime. In both circumstances, clinicians may wish to determine individual tolerance by referral to an allergist for penicillin and/or cephalosporin skin-testing before initiation of therapy.[66–68] The susceptibility of *S pneumoniae* to cefdinir, cefpodoxime, and cefuroxime varies from 60% to 75%,[56–59] and the susceptibility of *H influenzae* to these agents varies from 85% to 100%.[56,58] In young children (<2 years) with a serious type 1 hypersensitivity to penicillin and moderate or more severe sinusitis, it may be prudent to use a combination of clindamycin (or linezolid) and cefixime to achieve the most comprehensive coverage against both resistant *S pneumoniae* and *H influenzae*. Linezolid has excellent activity against all *S pneumoniae*, including penicillin-resistant strains, but lacks activity against *H influenzae* and *M catarrhalis*. Alternatively, a quinolone, such as levofloxacin, which has a high level of activity against both *S pneumoniae* and *H influenzae*, may be prescribed.[57,58] Although the use of quinolones is usually restricted because of concerns for toxicity, cost, and emerging resistance, their use in this circumstance can be justified.

Pneumococcal and *H influenzae* surveillance studies have indicated that resistance of these organisms to trimethoprim-sulfamethoxazole and azithromycin is sufficient to preclude their use for treatment of acute bacterial sinusitis in patients with penicillin hypersensitivity.[56,58,59,69]

The optimal duration of antimicrobial therapy for patients with acute bacterial sinusitis has not received systematic study. Recommendations based on clinical observations have varied widely, from 10 to 28 days of treatment. An alternative suggestion has been made that antibiotic therapy be continued for 7 days after the patient becomes free of signs and symptoms.[5] This strategy has the advantage of individualizing the treatment of each patient, results in a minimum course of 10 days, and

avoids prolonged antimicrobial therapy in patients who are asymptomatic and therefore unlikely to adhere to the full course of treatment.[5]

Patients who are acutely ill and appear toxic when first seen (see below) can be managed with 1 of 2 options. Consultation can be requested from an otolaryngologist for consideration of maxillary sinus aspiration (with appropriate analgesia/anesthesia) to obtain a sample of sinus secretions for Gram stain, culture, and susceptibility testing so that antimicrobial therapy can be adjusted precisely. Alternatively, inpatient therapy can be initiated with intravenous cefotaxime or ceftriaxone, with referral to an otolaryngologist if the patient's condition worsens or fails to show improvement within 48 hours. If a complication is suspected, management will differ depending on the site and severity.

A recent guideline was published by the Infectious Diseases Society of America for acute bacterial rhinosinusitis in children and adults.[70] Their recommendation for initial empirical antimicrobial therapy for acute bacterial sinusitis in children was amoxicillin-clavulanate based on the concern that there is an increasing prevalence of *H influenzae* as a cause of sinusitis since introduction of the pneumococcal conjugate vaccines and an increasing prevalence of β-lactamase production among these strains. In contrast, this guideline from the AAP allows either amoxicillin or amoxicillin-clavulanate as first-line empirical therapy and is therefore inclusive of the Infectious Diseases Society of America's recommendation. Unfortunately, there are scant data available regarding the precise microbiology of acute bacterial sinusitis in the post–PCV-13 era. Prospective surveillance of nasopharyngeal cultures may be helpful in completely aligning these recommendations in the future.

Key Action Statement 5A

Clinicians should reassess initial management if there is either a caregiver report of worsening (progression of initial signs/symptoms or appearance of new signs/symptoms) OR failure to improve (lack of reduction in all presenting signs/symptoms) within 72 hours of initial management (Evidence Quality: C; Recommendation).

KAS Profile 5A

Aggregate evidence quality: C; observational studies	
Benefits	Identification of patients who may have been misdiagnosed, those at risk of complications, and those who require a change in management.
Harm	Delay of up to 72 hours in changing therapy if patient fails to improve.
Cost	Additional provider and caregiver time and resources.
Benefits-harm assessment	Preponderance of benefit.
Value judgments	Use of 72 hours to assess progress may result in excessive classification as treatment failures if premature; emphasis on importance of worsening illness in defining treatment failures.
Role of patient preferences	Caregivers determine whether the severity of the patient's illness justifies the report to clinician of the patient's worsening or failure to improve.
Intentional vagueness	None.
Exclusions	Patients with severe illness, poor general health, complicated sinusitis, immune deficiency, previous sinus surgery, or coexisting bacterial illness.
Strength	Recommendation.

The purpose of this key action statement is to ensure that patients with acute bacterial sinusitis who fail to improve symptomatically after initial management are reassessed to be certain that they have been correctly diagnosed and to consider initiation of alternate therapy to hasten resolution of symptoms and avoid complications. "Worsening" is defined as progression of presenting signs or symptoms of acute bacterial sinusitis or onset of new signs or symptoms. "Failure to improve" is lack of reduction in presenting signs or symptoms of acute bacterial sinusitis by 72 hours after diagnosis and initial management; patients with persistent but improving symptoms do not meet this definition.

The rationale for using 72 hours as the time to assess treatment failure for acute bacterial sinusitis is based on clinical outcomes in RCTs. Wald et al[41] found that 18 of 35 patients (51%) receiving placebo demonstrated symptomatic improvement within 3 days of initiation of treatment; only an additional 3 patients receiving placebo (9%) improved between days 3 and 10. In the same study, 48 of 58 patients (83%) receiving antibiotics were cured or improved within 3 days; at 10 days, the overall rate of improvement was 79%, suggesting that no additional patients improved between days 3 and 10. In a more recent study, 17 of 19 children who ultimately failed initial therapy with either antibiotic or placebo demonstrated failure to improve within 72 hours.[4] Although Garbutt et al[42] did not report the percentage of patients who improved by day 3, they did demonstrate that the majority of improvement in symptoms occurred within

the first 3 days of study entry whether they received active treatment or placebo.

Reporting of either worsening or failure to improve implies a shared responsibility between clinician and caregiver. Although the clinician should educate the caregiver regarding the anticipated reduction in symptoms within 3 days, it is incumbent on the caregiver to appropriately notify the clinician of concerns regarding worsening or failure to improve. Clinicians should emphasize the importance of reassessing those children whose symptoms are worsening whether or not antibiotic therapy was prescribed. Reassessment may be indicated before the 72-hour process by which such reporting occurs should be discussed at the time the initial management strategy is determined.

Key Action Statement 5B

If the diagnosis of acute bacterial sinusitis is confirmed in a child with worsening symptoms or failure to improve in 72 hours, then clinicians may change the antibiotic therapy for the child initially managed with antibiotic OR initiate antibiotic treatment of the child initially managed with observation (Evidence Quality: D; Option based on expert opinion, case reports, and reasoning from first principles).

KAS Profile 5B

Aggregate evidence quality: D; expert opinion and reasoning from first principles.	
Benefit	Prevention of complications, administration of effective therapy.
Harm	Adverse effects of secondary antibiotic therapy.
Cost	Direct cost of medications, often substantial for second-line agents.
Benefits-harm assessment	Preponderance of benefit.
Value judgments	Clinician must determine whether cost and adverse effects associated with change in antibiotic is justified given the severity of illness.
Role of patient preferences	Limited in patients whose symptoms are severe or worsening, but caregivers of mildly affected children who are failing to improve may reasonably defer change in antibiotic.
Intentional vagueness	None.
Exclusions	None.
Strength	Option.

mark if the patient is substantially worse, because it may indicate the development of complications or a need for parenteral therapy. Conversely, in some cases, caregivers may think that symptoms are not severe enough to justify a change to an antibiotic with a less desirable safety profile or even the time, effort, and resources required for reassessment. Accordingly, the circumstances under which caregivers report back to the clinician and the corresponds to the patient's pattern of illness, as defined in Key Action Statement 1. If caregivers report worsening of symptoms at any time in a patient for whom observation was the initial intervention, the clinician should begin treatment as discussed in Key Action Statement 4. For patients whose symptoms are mild and who have failed to improve but have not worsened, initiation of antimicrobial agents or continued observation (for up to 3 days) is reasonable.

The purpose of this key action statement is to ensure optimal antimicrobial treatment of children with acute bacterial sinusitis whose symptoms worsen or fail to respond to the initial intervention to prevent complications and reduce symptom severity and duration (see Table 4).

Clinicians who are notified by a caregiver that a child's symptoms are worsening or failing to improve should confirm that the clinical diagnosis of acute bacterial sinusitis

If caregivers report worsening of symptoms after 3 days in a patient initially treated with antimicrobial agents, current signs and symptoms should be reviewed to determine whether acute bacterial sinusitis is still the best diagnosis. If sinusitis is still the best diagnosis, infection with drug-resistant bacteria is probable, and an alternate antimicrobial agent may be administered. Face-to-face reevaluation of the patient is desirable. Once the decision is made to change medications, the clinician should consider the limitations of the initial antibiotic coverage, the anticipated susceptibility of residual bacterial pathogens, and the ability of antibiotics to adequately penetrate the site of infection. Cultures of sinus or nasopharyngeal secretions in patients with initial antibiotic failure have identified a large percentage of bacteria with resistance to the original antibiotic.[71,72] Furthermore, multidrug-resistant *S pneumoniae* and β-lactamase–positive *H influenzae* and *M catarrhalis* are more commonly isolated after previous antibiotic exposure.[73–78] Unfortunately, there are no studies in children that have investigated the microbiology of treatment failure in acute bacterial sinusitis or cure rates using second-line antimicrobial agents. As a result, the likelihood of adequate antibiotic coverage for resistant organisms must be

addressed by extrapolations from studies of acute otitis media in children and sinusitis in adults and by using the results of data generated in vitro. A general guide to management of the child who worsens in 72 hours is shown in Table 4.

NO RECOMMENDATION

Adjuvant Therapy

Potential adjuvant therapy for acute sinusitis might include intranasal corticosteroids, saline nasal irrigation or lavage, topical or oral decongestants, mucolytics, and topical or oral antihistamines. A recent Cochrane review on decongestants, antihistamines, and nasal irrigation for acute sinusitis in children found no appropriately designed studies to determine the effectiveness of these interventions.[79]

Intranasal Steroids

The rationale for the use of intranasal corticosteroids in acute bacterial sinusitis is that an antiinflammatory agent may reduce the swelling around the sinus ostia and encourage drainage, thereby hastening recovery. However, there are limited data on how much inflammation is present, whether the inflammation is responsive to steroids, and whether there are differences in responsivity according to age. Nonetheless, there are several RCTs in adolescents and adults, most of which do show significant differences compared with placebo or active comparator that favor intranasal steroids in the reduction of symptoms and the patient's global assessment of overall improvement.[80–85] Several studies in adults with acute bacterial sinusitis provide data supporting the use of intranasal steroids as either monotherapy or adjuvant therapy to antibiotics.[81,86] Only one study did not show efficacy.[85]

There have been 2 trials of intranasal steroids performed exclusively in children: one comparing intranasal corticosteroids versus an oral decongestant[87] and the other comparing intranasal corticosteroids with placebo.[88] These studies showed a greater rate of complete resolution[87] or greater reduction in symptoms in patients receiving the steroid preparation, although the effects were modest.[88] It is important to note that nearly all of these studies (both those reported in children and adults) suffered from substantial methodologic problems. Examples of these methodologic problems are as follows: (1) variable inclusion criteria for sinusitis, (2) mixed populations of allergic and nonallergic subjects, and (3) different outcome criteria. All of these factors make deriving a clear conclusion difficult. Furthermore, the lack of stringent criteria in selecting the subject population increases the chance that the subjects had viral URIs or even persistent allergies rather than acute bacterial sinusitis.

The intranasal steroids studied to date include budesonide, flunisolide, fluticasone, and mometasone. There is no reason to believe that one steroid would be more effective than another, provided equivalent doses are used.

Potential harm in using nasal steroids in children with acute sinusitis includes the increased cost of therapy, difficulty in effectively administering nasal sprays in young children, nasal irritation and epistaxis, and potential systemic adverse effects of steroid use. Fortunately, no clinically significant steroid adverse effects have been discovered in studies in children.[89–96]

Saline Irrigation

Saline nasal irrigation or lavage (not saline nasal spray) has been used to remove debris from the nasal cavity and temporarily reduce tissue edema (hypertonic saline) to promote drainage from the sinuses. There have been very few RCTs using saline nasal irrigation or lavage in acute sinusitis, and these have had mixed results.[97,98] The 1 study in children showed greater improvement in nasal airflow and quality of life as well as a better rate of improvement in total symptom score when compared with placebo in patients treated with antibiotics and decongestants.[98] There are 2 Cochrane reviews published on the use of saline nasal irrigation in acute sinusitis in adults that showed variable results. One review published in 2007[99] concluded that it is a beneficial adjunct, but the other, published in 2010,[100] concluded that most trials were too small or contained too high a risk of bias to be confident about benefits.

Nasal Decongestants, Mucolytics, and Antihistamines

Data are insufficient to make any recommendations about the use of oral or topical nasal decongestants, mucolytics, or oral or nasal spray antihistamines as adjuvant therapy for acute bacterial sinusitis in children.[79] It is the opinion of the expert panel that antihistamines should not be used for the primary indication of acute bacterial sinusitis in any child, although such therapy might be helpful in reducing typical allergic symptoms in patients with atopy who also have acute sinusitis.

OTHER RELATED CONDITIONS

Recurrence of Acute Bacterial Sinusitis

Recurrent acute bacterial sinusitis (RABS) is an uncommon occurrence in healthy children and must be distinguished from recurrent URIs, exacerbations of allergic rhinitis, and chronic sinusitis. The former is defined by episodes of bacterial infection of the paranasal sinuses lasting fewer than 30 days and separated by intervals of

TABLE 3 Parent Information Regarding Initial Management of Acute Bacterial Sinusitis

How common are sinus infections in children?	Thick, colored, or cloudy mucus from your child's nose frequently occurs with a common cold or viral infection and does not by itself mean your child has sinusitis. In fact, fewer than 1 in 15 children get a true bacterial sinus infection during or after a common cold.
How can I tell if my child has bacterial sinusitis or simply a common cold?	Most colds have a runny nose with mucus that typically starts out clear, becomes cloudy or colored, and improves by about 10 d. Some colds will also include fever (temperature >38°C [100.4°F]) for 1 to 2 days. In contrast, acute bacterial sinusitis is likely when the pattern of illness is persistent, severe, or worsening. 1. *Persistent* sinusitis is the most common type, defined as runny nose (of any quality), daytime cough (which may be worse at night), or both for at least 10 days without improvement. 2. *Severe* sinusitis is present when fever (temperature ≥39°C [102.2°F]) lasts for at least 3 days in a row and is accompanied by nasal mucus that is thick, colored, or cloudy. 3. *Worsening* sinusitis starts with a viral cold, which begins to improve but then worsens when bacteria take over and cause new-onset fever (temperature ≥38°C [100.4°F]) or a substantial increase in daytime cough or runny nose.
If my child has sinusitis, should he or she take an antibiotic?	Children with *persistent* sinusitis may be managed with either an antibiotic or with an additional brief period of observation, allowing the child up to another 3 days to fight the infection and improve on his or her own. The choice to treat or observe should be discussed with your doctor and may be based on your child's quality of life and how much of a problem the sinusitis is causing. In contrast, all children diagnosed with *severe* or *worsening* sinusitis should start antibiotic treatment to help them recover faster and more often.
Why not give all children with acute bacterial sinusitis an immediate antibiotic?	Some episodes of *persistent* sinusitis include relatively mild symptoms that may improve on their own in a few days. In addition, antibiotics can have adverse effects, which may include vomiting, diarrhea, upset stomach, skin rash, allergic reactions, yeast infections, and development of resistant bacteria (that make future infections more difficult to treat).

at least 10 days during which the patient is asymptomatic. Some experts require at least 4 episodes in a calendar year to fulfill the criteria for this condition. Chronic sinusitis is manifest as 90 or more uninterrupted days of respiratory symptoms, such as cough, nasal discharge, or nasal obstruction.

Children with RABS should be evaluated for underlying allergies, particularly allergic rhinitis; quantitative and functional immunologic defect(s), chiefly immunoglobulin A and immunoglobulin G deficiency; cystic fibrosis; gastroesophageal reflux disease; or dysmotile cilia syndrome.[101] Anatomic abnormalities obstructing one or more sinus ostia may be present. These include septal deviation, nasal polyps, or concha bullosa (pneumatization of the middle turbinate); atypical ethmoid cells with compromised drainage; a lateralized middle turbinate; and intrinsic ostiomeatal anomalies.[102] Contrast-enhanced CT, MRI, or endoscopy or all 3 should be performed for detection of obstructive conditions, particularly in children with genetic or acquired craniofacial abnormalities.

The microbiology of RABS is similar to that of isolated episodes of acute bacterial sinusitis and warrants the same treatment.[72] It should be recognized that closely spaced sequential courses of antimicrobial therapy may foster the emergence of antibiotic-resistant bacterial species as the causative agent in recurrent episodes. There are no systematically evaluated options for prevention of RABS in children. In general, the use of prolonged prophylactic antimicrobial therapy should be avoided and is not usually recommended for children with recurrent acute otitis media. However, when there are no recognizable predisposing conditions to remedy in children with RABS, prophylactic antimicrobial agents may be used for several months during the respiratory season. Enthusiasm for this strategy is tempered by concerns regarding the encouragement of bacterial resistance. Accordingly, prophylaxis should only be considered in carefully selected children whose infections have been thoroughly documented.

Influenza vaccine should be administered annually, and PCV-13 should be administered at the recommended ages for all children, including those with RABS. Intranasal steroids and nonsedating antihistamines can be helpful for children with allergic rhinitis, as can antireflux medications for those with gastroesophageal reflux disease. Children with anatomic abnormalities may require endoscopic surgery for removal of or reduction in ostiomeatal obstruction.

The pathogenesis of chronic sinusitis is poorly understood and appears to be multifactorial; however, many of the conditions associated with RABS

TABLE 4 Management of Worsening or Lack of Improvement at 72 Hours

Initial Management	Worse in 72 Hours	Lack of Improvement in 72 Hours
Observation	Initiate amoxicillin with or without clavulanate	Additional observation or initiate antibiotic based on shared decision-making
Amoxicillin	High-dose amoxicillin-clavulanate	Additional observation or high-dose amoxicillin-clavulanate based on shared decision-making
High-dose amoxicillin-clavulanate	Clindamycin[a] and cefixime OR linezolid and cefixime OR levofloxacin	Continued high-dose amoxicillin-clavulanate OR clindamycin[a] and cefixime OR linezolid and cefixime OR levofloxacin

[a] Clindamycin is recommended to cover penicillin-resistant *S pneumoniae*. Some communities have high levels of clindamycin-resistant *S pneumoniae*. In these communities, linezolid is preferred.

have also been implicated in chronic sinusitis, and it is clear that there is an overlap between the 2 syndromes.[101,102] In some cases, there may be episodes of acute bacterial sinusitis superimposed on a chronic sinusitis, warranting antimicrobial therapy to hasten resolution of the acute infection.

Complications of Acute Bacterial Sinusitis

Complications of acute bacterial sinusitis should be diagnosed when the patient develops signs or symptoms of orbital and/or central nervous system (intracranial) involvement. Rarely, complicated acute bacterial sinusitis can result in permanent blindness, other neurologic sequelae, or death if not treated promptly and appropriately. Orbital complications have been classified by Chandler et al.[32] Intracranial complications include epidural or subdural abscess, brain abscess, venous thrombosis, and meningitis.

Periorbital and intraorbital inflammation and infection are the most common complications of acute sinusitis and most often are secondary to acute ethmoiditis in otherwise healthy young children. These disorders are commonly classified in relation to the orbital septum; periorbital or preseptal inflammation involves only the eyelid, whereas postseptal (intraorbital) inflammation involves structures of the orbit. Mild cases of preseptal cellulitis (eyelid <50% closed) may be treated on an outpatient basis with appropriate oral antibiotic therapy (high-dose amoxicillin-clavulanate for comprehensive coverage) for acute bacterial sinusitis and daily follow-up until definite improvement is noted. If the patient does not improve within 24 to 48 hours or if the infection is progressive, it is appropriate to admit the patient to the hospital for antimicrobial therapy. Similarly, if proptosis, impaired visual acuity, or impaired and/or painful extraocular mobility is present on examination, the patient should be hospitalized, and a contrast-enhanced CT should be performed. Consultation with an otolaryngologist, an ophthalmologist, and an infectious disease expert is appropriate for guidance regarding the need for surgical intervention and the selection of antimicrobial agents.

Intracranial complications are most frequently encountered in previously healthy adolescent males with frontal sinusitis.[33,34] In patients with altered mental status, severe headache, or Pott's puffy tumor (osteomyelitis of the frontal bone), neurosurgical consultation should be obtained. A contrast-enhanced CT scan (preferably coronal thin cut) of the head, orbits, and sinuses is essential to confirm intracranial or intraorbital suppurative complications; in such cases, intravenous antibiotics should be started immediately. Alternatively, an MRI may also be desirable in some cases of intracranial abnormality. Appropriate antimicrobial therapy for intraorbital complications include vancomycin (to cover possible methicillin-resistant *S aureus* or penicillin-resistant *S pneumoniae*) and either ceftriaxone, ampicillin-sulbactam, or piperacillin-tazobactam.[103] Given the polymicrobial nature of sinogenic abscesses, coverage for anaerobes (ie, metronidazole) should also be considered for intraorbital complications and should be started in all cases of intracranial complications if ceftriaxone is prescribed.

Patients with small orbital, subperiosteal, or epidural abscesses and minimal ocular and neurologic abnormalities may be managed with intravenous antibiotic treatment for 24 to 48 hours while performing frequent visual and mental status checks.[104] In patients who develop progressive signs and symptoms, such as impaired visual acuity, ophthalmoplegia, elevated intraocular pressure (>20 mm), severe proptosis (>5 mm), altered mental status, headache, or vomiting, as well as those who fail to improve within 24 to 48 hours while receiving antibiotics, prompt surgical intervention and drainage of the abscess should be undertaken.[104] Antibiotics can be tailored to the results of culture and sensitivity studies when they become available.

AREAS FOR FUTURE RESEARCH

Since the publication of the original guideline in 2001, only a small number of high-quality studies of the diagnosis and treatment of acute bacterial sinusitis in children have been published.[5] Ironically, the number of published guidelines on the topic (5) exceeds the number of prospective,

placebo-controlled clinical trials of either antibiotics or ancillary treatments of acute bacterial sinusitis. Thus, as was the case in 2001, there are scant data on which to base recommendations. Accordingly, areas for future research include the following:

Etiology

1. Reexamine the microbiology of acute sinusitis in children in the postpneumococcal conjugate vaccine era and determine the value of using newer polymerase chain reaction–based respiratory testing to document viral, bacterial, and polymicrobial disease.
2. Correlate cultures obtained from the middle meatus of the maxillary sinus of infected children with cultures obtained from the maxillary sinus by puncture of the antrum.
3. Conduct more and larger studies to more clearly define and correlate the clinical findings with the various available diagnostic criteria of acute bacterial sinusitis (eg, sinus aspiration and treatment outcome).
4. Develop noninvasive strategies to accurately diagnose acute bacterial sinusitis in children.
5. Develop imaging technology that differentiates bacterial infection from viral infection or allergic inflammation, preferably without radiation.

Treatment

1. Determine the optimal duration of antimicrobial therapy for children with acute bacterial sinusitis.
2. Evaluate a "wait-and-see prescription" strategy for children with persistent symptom presentation of acute sinusitis.
3. Determine the optimal antimicrobial agent for children with acute bacterial sinusitis, balancing the incentives of choosing narrow-spectrum agents against the known microbiology of the disease and resistance patterns of likely pathogens.
4. Determine the causes and treatment of subacute, recurrent acute, and chronic bacterial sinusitis.
5. Determine the efficacy of prophylaxis with antimicrobial agents to prevent RABS.
6. Determine the effects of bacterial resistance among *S pneumoniae*, *H influenzae*, and *M catarrhalis* on outcome of treatment with antibiotics by the performance of randomized, double-blind, placebo-controlled studies in well-defined populations of patients.
7. Determine the role of adjuvant therapies (antihistamines, nasal corticosteroids, mucolytics, decongestants, nasal irrigation, etc) in patients with acute bacterial sinusitis by the performance of prospective, randomized clinical trials.
8. Determine whether early treatment of acute bacterial sinusitis prevents orbital or central nervous system complications.
9. Determine the role of complementary and alternative medicine strategies in patients with acute bacterial sinusitis by performing systematic, prospective, randomized clinical trials.
10. Develop new bacterial and viral vaccines to reduce the incidence of acute bacterial sinusitis.

SUBCOMMITTEE ON ACUTE SINUSITIS

Ellen R. Wald, MD, FAAP (Chair, Pediatric Infectious Disease Physician: no financial conflicts; published research related to sinusitis)
Kimberly E. Applegate, MD, MS, FAAP (Radiologist, AAP Section on Radiology: no conflicts)
Clay Bordley, MD, MPH, FAAP (Pediatric Emergency and Hospitalist Medicine physician: no conflicts)
David H. Darrow, MD, FAAP (Otolaryngologist, AAP Section on Otolaryngology–Head and Neck Surgery: no conflicts)
Mary P. Glode, MD, FAAP (Pediatric Infectious Disease Physician, AAP Committee on Infectious Disease: no conflicts)
S. Michael Marcy, MD, FAAP (General Pediatrician with Infectious Disease Expertise, AAP Section on Infectious Diseases: no conflicts)
Nader Shaikh, MD, FAAP (General Academic Pediatrician: no financial conflicts; published research related to sinusitis)
Michael J. Smith, MD, MSCE, FAAP (Epidemiologist, Pediatric Infectious Disease Physician: research funding for vaccine clinical trials from Sanofi Pasteur and Novartis)
Paul V. Williams, MD, FAAP (Allergist, AAP Section on Allergy, Asthma, and Immunology: no conflicts)
Stuart T. Weinberg, MD, FAAP (PPI Informatician, General Academic Pediatrician: no conflicts)
Carrie E. Nelson, MD, MS (Family Physician, American Academy of Family Physicians: employed by McKesson Health Solutions)
Richard M. Rosenfeld, MD, MPH, FAAP (Otolaryngologist, AAP Section on Otolaryngology–Head and Neck Surgery, American Academy of Otolaryngology–Head and Neck Surgery: no financial conflicts; published research related to sinusitis)

CONSULTANT

Richard N. Shiffman, MD, FAAP (Informatician, Guideline Methodologist, General Academic Pediatrician: no conflicts)

Sinusitis Clinical Practice Guideline Quick Reference Tools

- Action Statement Summary
  — Clinical Practice Guideline for the Diagnosis and Management of Acute Bacterial Sinusitis in Children Aged 1 to 18 Years
- *ICD-10-CM* Coding Quick Reference for Sinusitis
- AAP Patient Education Handout
  — *Sinusitis and Your Child*

Action Statement Summary

Clinical Practice Guideline for the Diagnosis and Management of Acute Bacterial Sinusitis in Children Aged 1 to 18 Years

Key Action Statement 1

Clinicians should make a presumptive diagnosis of acute bacterial sinusitis when a child with an acute URI presents with the following:

- Persistent illness, ie, nasal discharge (of any quality) or daytime cough or both lasting more than 10 days without improvement;

OR

- Worsening course, ie, worsening or new onset of nasal discharge, daytime cough, or fever after initial improvement;

OR

- Severe onset, ie, concurrent fever (temperature ≥39°C/102.2°F) and purulent nasal discharge for at least 3 consecutive days (Evidence Quality: B; Recommendation).

Key Action Statement 2A

Clinicians should not obtain imaging studies (plain films, contrast-enhanced computed tomography [CT], MRI, or ultrasonography) to distinguish acute bacterial sinusitis from viral URI (Evidence Quality: B; Strong Recommendation).

Key Action Statement 2B

Clinicians should obtain a contrast-enhanced CT scan of the paranasal sinuses and/or an MRI with contrast whenever a child is suspected of having orbital or central nervous system complications of acute bacterial sinusitis (Evidence Quality: B; Strong Recommendation).

Key Action Statement 3

Initial Management of Acute Bacterial Sinusitis

3A: "Severe onset and worsening course" acute bacterial sinusitis. The clinician should prescribe antibiotic therapy for acute bacterial sinusitis in children with severe onset or worsening course (signs, symptoms, or both) (Evidence Quality: B; Strong Recommendation).

3B: "Persistent illness." The clinician should either prescribe antibiotic therapy OR offer additional outpatient observation for 3 days to children with persistent illness (nasal discharge of any quality or cough or both for at least 10 days without evidence of improvement) (Evidence Quality: B; Recommendation).

Key Action Statement 4

Clinicians should prescribe amoxicillin with or without clavulanate as first-line treatment when a decision has been made to initiate antibiotic treatment of acute bacterial sinusitis (Evidence Quality: B; Recommendation).

Key Action Statement 5A

Clinicians should reassess initial management if there is either a caregiver report of worsening (progression of initial signs/symptoms or appearance of new signs/symptoms) OR failure to improve (lack of reduction in all presenting signs/symptoms) within 72 hours of initial management (Evidence Quality: C; Recommendation).

Key Action Statement 5B

If the diagnosis of acute bacterial sinusitis is confirmed in a child with worsening symptoms or failure to improve in 72 hours, then clinicians may change the antibiotic therapy for the child initially managed with antibiotic OR initiate antibiotic treatment of the child initially managed with observation (Evidence Quality: D; Option based on expert opinion, case reports, and reasoning from first principles).

Sinusitis and Your Child

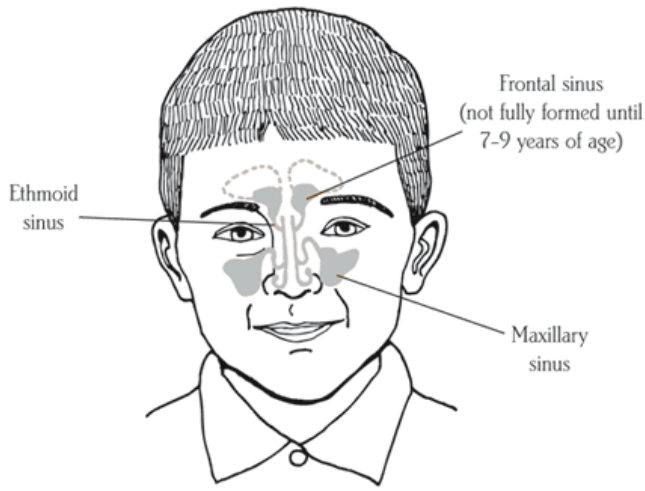
Sinusitis is an inflammation of the lining of the nose and sinuses. It is a very common infection in children.

Viral sinusitis usually accompanies a cold. Allergic sinusitis may accompany allergies such as hay fever. Bacterial sinusitis is a secondary infection caused by the trapping of bacteria in the sinuses during the course of a cold or allergy.

Fluid inside the sinuses

When your child has a viral cold or hay fever, the linings of the nose and sinus cavities swell up and produce more fluid than usual. This is why the nose gets congested and is "runny" during a cold.

Most of the time the swelling disappears by itself as the cold or allergy goes away. However, if the swelling does not go away, the openings that normally allow the sinuses to drain into the back of the nose get blocked and the sinuses fill with fluid. Because the sinuses are blocked and cannot drain properly, bacteria are trapped inside and grow there, causing a secondary infection. Although nose blowing and sniffing may be natural responses to this blockage, when excessive they can make the situation worse by pushing bacteria from the back of the nose into the sinuses.



The linings of the sinuses and the nose always produce some fluid (secretions). This fluid keeps the nose and sinus cavities from becoming too dry and adds moisture to the air that you breathe.

Is it a cold or bacterial sinusitis?

It is often difficult to tell if an illness is just a viral cold or if it is complicated by a bacterial infection of the sinuses.

Generally viral colds have the following characteristics:

- Colds usually last only 5 to 10 days.
- Colds typically start with clear, watery nasal discharge. After a day or 2, it is normal for the nasal discharge to become thicker and white, yellow, or green. After several days, the discharge becomes clear again and dries.
- Colds include a daytime cough that often gets worse at night.
- If a fever is present, it is usually at the beginning of the cold and is generally low grade, lasting for 1 or 2 days.
- Cold symptoms usually peak in severity at 3 or 5 days, then improve and disappear over the next 7 to 10 days.

Signs and symptoms that your child may have bacterial sinusitis include:

- Cold symptoms (nasal discharge, daytime cough, or both) lasting more than 10 days *without improving*
- Thick yellow nasal discharge *and* a fever for at least 3 or 4 days in a row
- A severe headache behind or around the eyes that gets worse when bending over
- Swelling and dark circles around the eyes, especially in the morning
- Persistent bad breath along with cold symptoms (However, this also could be from a sore throat or a sign that your child is not brushing his teeth!)

In very rare cases, a bacterial sinus infection may spread to the eye or the central nervous system (the brain). If your child has the following symptoms, call your pediatrician immediately:

- Swelling and/or redness around the eyes, not just in the morning but all day
- Severe headache and/or pain in the back of the neck
- Persistent vomiting
- Sensitivity to light
- Increasing irritability

Diagnosing bacterial sinusitis

It may be difficult to tell a sinus infection from an uncomplicated cold, especially in the first few days of the illness. Your pediatrician will most likely be able to tell if your child has bacterial sinusitis after examining your child and hearing about the progression of symptoms. In older children, when the diagnosis is uncertain, your pediatrician may order computed tomographic (CT) scans to confirm the diagnosis.

Treating bacterial sinusitis

If your child has bacterial sinusitis, your pediatrician may prescribe an antibiotic for at least 10 days. Once your child is on the medication, symptoms should start to go away over the next 2 to 3 days—the nasal discharge will clear and the cough will improve. *Even though your child may seem better, continue to give the antibiotics for the prescribed length of time. Ending the medications too early could cause the infection to return.*

When a diagnosis of sinusitis is made in children with cold symptoms lasting more than 10 days without improving, some doctors may choose to continue observation for another few days. If your child's symptoms worsen during this time or do not improve after 3 days, antibiotics should be started.

If your child's symptoms show no improvement 2 to 3 days after starting the antibiotics, talk with your pediatrician. Your child might need a different medication or need to be re-examined.

Treating related symptoms of bacterial sinusitis

Headache or sinus pain. To treat headache or sinus pain, try placing a warm washcloth on your child's face for a few minutes at a time. Pain medications such as acetaminophen or ibuprofen may also help. (However, do not give your child aspirin. It has been associated with a rare but potentially fatal disease called Reye syndrome.)

Nasal congestion. If the secretions in your child's nose are especially thick, your pediatrician may recommend that you help drain them with saline nose drops. These are available without a prescription or can be made at home by adding 1/4 teaspoon of table salt to an 8-ounce cup of water. Unless advised by your pediatrician, do not use nose drops that contain medications because they can be absorbed in amounts that can cause side effects.

Placing a cool-mist humidifier in your child's room may help keep your child more comfortable. Clean and dry the humidifier daily to prevent bacteria or mold from growing in it (follow the instructions that came with the humidifier). Hot water vaporizers are not recommended because they can cause scalds or burns.

Remember

If your child has symptoms of a bacterial sinus infection, see your pediatrician. Your pediatrician can properly diagnose and treat the infection and recommend ways to help alleviate the discomfort from some of the symptoms.

From your doctor

Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome

- *Clinical Practice Guideline*

CLINICAL PRACTICE GUIDELINE

Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome

abstract

FREE

OBJECTIVES: This revised clinical practice guideline, intended for use by primary care clinicians, provides recommendations for the diagnosis and management of the obstructive sleep apnea syndrome (OSAS) in children and adolescents. This practice guideline focuses on uncomplicated childhood OSAS, that is, OSAS associated with adenotonsillar hypertrophy and/or obesity in an otherwise healthy child who is being treated in the primary care setting.

METHODS: Of 3166 articles from 1999–2010, 350 provided relevant data. Most articles were level II–IV. The resulting evidence report was used to formulate recommendations.

RESULTS AND CONCLUSIONS: The following recommendations are made. (1) All children/adolescents should be screened for snoring. (2) Polysomnography should be performed in children/adolescents with snoring and symptoms/signs of OSAS; if polysomnography is not available, then alternative diagnostic tests or referral to a specialist for more extensive evaluation may be considered. (3) Adenotonsillectomy is recommended as the first-line treatment of patients with adenotonsillar hypertrophy. (4) High-risk patients should be monitored as inpatients postoperatively. (5) Patients should be reevaluated postoperatively to determine whether further treatment is required. Objective testing should be performed in patients who are high risk or have persistent symptoms/signs of OSAS after therapy. (6) Continuous positive airway pressure is recommended as treatment if adenotonsillectomy is not performed or if OSAS persists postoperatively. (7) Weight loss is recommended in addition to other therapy in patients who are overweight or obese. (8) Intranasal corticosteroids are an option for children with mild OSAS in whom adenotonsillectomy is contraindicated or for mild postoperative OSAS. *Pediatrics* 2012;130:576–584

CPAP—continuous positive airway pressure
OSAS—obstructive sleep apnea syndrome

INTRODUCTION

Obstructive sleep apnea syndrome (OSAS) is a common condition in childhood and can result in severe complications if left untreated. In 2002, the American Academy of Pediatrics (AAP) published a practice guideline for the diagnosis and management of childhood OSAS.[1] Since that time, there has been a considerable increase in publications and research on the topic; thus, the guidelines have been revised.

www.pediatrics.org/cgi/doi/10.1542/peds.2012-1671

doi:10.1542/peds.2012-1671

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

The purposes of this revised clinical practice guideline are to (1) increase the recognition of OSAS by primary care clinicians to minimize delay in diagnosis and avoid serious sequelae of OSAS; (2) evaluate diagnostic techniques; (3) describe treatment options; (4) provide guidelines for follow-up; and (5) discuss areas requiring further research. The recommendations in this statement do not indicate an exclusive course of treatment. Variations, taking into account individual circumstances, may be appropriate.

This practice guideline focuses on uncomplicated childhood OSAS—that is, the OSAS associated with adenotonsillar hypertrophy and/or obesity in an otherwise healthy child who is being treated in the primary care setting. This guideline specifically excludes infants younger than 1 year of age, patients with central apnea or hypoventilation syndromes, and patients with OSAS associated with other medical disorders, including but not limited to Down syndrome, craniofacial anomalies, neuromuscular disease (including cerebral palsy), chronic lung disease, sickle cell disease, metabolic disease, or laryngomalacia. These important patient populations are too complex to discuss within the scope of this article and require consultation with a pediatric subspecialist.

Additional information providing justification for the key action statements and a detailed review of the literature are provided in the accompanying technical report available online.[2]

METHODS OF GUIDELINE DEVELOPMENT

Details of the methods of guideline development are included in the accompanying technical report.[2] The AAP selected a subcommittee composed of pediatricians and other experts in the fields of sleep medicine, pulmonology, and otolaryngology, as well as experts from epidemiology and pediatric practice to develop an evidence base of literature on this topic. The committee included liaison members from the AAP Section on Otolaryngology-Head and Neck Surgery, American Thoracic Society, American Academy of Sleep Medicine, American College of Chest Physicians, and the National Sleep Foundation. Committee members signed forms disclosing conflicts of interest.

An automated search of the literature on childhood OSAS from 1999 to 2008 was performed by using 5 scientific literature search engines.[2] The medical subject heading terms that were used in all fields were snoring, apnea, sleep-disordered breathing, sleep-related breathing disorders, upper airway resistance, polysomnography, sleep study, adenoidectomy, tonsillectomy, continuous positive airway pressure, obesity, adiposity, hypopnea, hypoventilation, cognition, behavior, and neuropsychology. Reviews, case reports, letters to the editor, and abstracts were not included. Non–English-language articles, animal studies, and studies relating to infants younger than 1 year and to special populations (eg, children with craniofacial anomalies or sickle cell disease) were excluded. In several steps, a total of 3166 hits was reduced to 350 articles, which underwent detailed review.[2] Committee members selectively updated this literature search for articles published from 2008 to 2011 specific to guideline categories. Details of the literature grading system are available in the accompanying technical report.

Since publication of the previous guidelines, there has been an improvement in the quality of OSAS studies in the literature; however, there remain few randomized, blinded, controlled studies. Most studies were questionnaire or polysomnography based. Many studies used standard definitions for pediatric polysomnography scoring, but the interpretation of polysomnography (eg, the apnea hypopnea index [AHI] criterion used for diagnosis or to determine treatment) varied widely. The guideline notes the quality of evidence for each key action statement. Additional details are available in the technical report.

The evidence-based approach to guideline development requires that the evidence in support of each key action statement be identified, appraised, and summarized and that an explicit link between evidence and recommendations be defined. Evidence-based recommendations reflect the quality of evidence and the balance of benefit and harm that is anticipated when the recommendation is followed. The AAP policy statement, "Classifying Recommendations for Clinical Practice Guidelines,"[3] was followed in designating levels of recommendation (see Fig 1 and Table 1).

DEFINITION

This guideline defines OSAS in children as a "disorder of breathing during sleep characterized by prolonged partial upper airway obstruction and/or intermittent complete obstruction (obstructive apnea) that disrupts normal ventilation during sleep and normal sleep patterns,"[4] accompanied by symptoms or signs, as listed in Table 2. Prevalence rates based on level I and II studies range from 1.2% to 5.7%.[5–7] Symptoms include habitual snoring (often with intermittent pauses, snorts, or gasps), disturbed sleep, and daytime neurobehavioral problems. Daytime sleepiness may occur, but is uncommon in young children. OSAS is associated with neurocognitive impairment, behavioral problems, failure to thrive, hypertension, cardiac dysfunction, and systemic inflammation. Risk factors include adenotonsillar hypertrophy, obesity, craniofacial anomalies, and neuromuscular disorders. Only the first 2 risk factors are

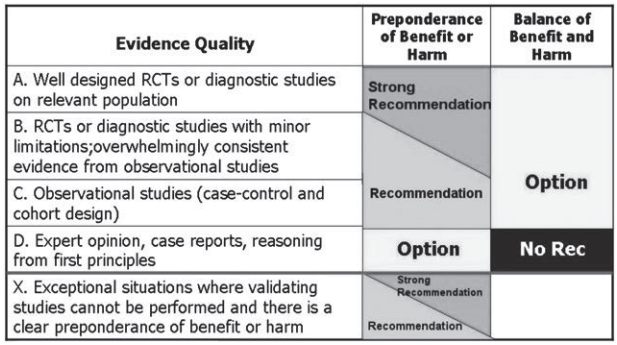

FIGURE 1

Evidence quality. Integrating evidence quality appraisal with an assessment of the anticipated balance between benefits and harms if a policy is carried out leads to designation of a policy as a strong recommendation, recommendation, option, or no recommendation. RCT, randomized controlled trial; Rec, recommendation.

discussed in this guideline. In this guideline, obesity is defined as a BMI >95th percentile for age and gender.[8]

KEY ACTION STATEMENTS

Key Action Statement 1: Screening for OSAS

As part of routine health maintenance visits, clinicians should inquire whether the child or adolescent snores. If the answer is affirmative or if a child or adolescent presents with signs or symptoms of OSAS (Table 2), clinicians should perform a more focused evaluation. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Evidence Profile KAS 1

- Aggregate evidence quality: B
- Benefit: Early identification of OSAS is desirable, because it is a high-prevalence condition, and identification and treatment can result in alleviation of current symptoms, improved quality of life, prevention of sequelae, education of parents, and decreased health care utilization.
- Harm: Provider time, patient and parent time.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: Panelists believe that identification of a serious medical condition outweighs the time expenditure necessary for screening.
- Role of patient preferences: None.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Recommendation.

Almost all children with OSAS snore,[9–11] although caregivers frequently do not volunteer this information at medical visits.[12] Thus, asking about snoring at each health maintenance visit (as well as at other appropriate times, such as when evaluating for tonsillitis) is a sensitive, albeit nonspecific, screening measure that is quick and easy to perform. Snoring is common in children and adolescents; however, OSAS is less common. Therefore, an affirmative answer should be followed by a detailed history and examination to determine whether further evaluation for OSAS is needed (Table 2); this clinical evaluation alone

TABLE 1 Definitions and Recommendation Implications

Statement	Definition	Implication
Strong recommendation	A strong recommendation in favor of a particular action is made when the anticipated benefits of the recommended intervention clearly exceed the harms (as a strong recommendation against an action is made when the anticipated harms clearly exceed the benefits) and the quality of the supporting evidence is excellent. In some clearly identified circumstances, strong recommendations may be made when high-quality evidence is impossible to obtain and the anticipated benefits strongly outweigh the harms.	Clinicians should follow a strong recommendation unless a clear and compelling rationale for an alternative approach is present.
Recommendation	A recommendation in favor of a particular action is made when the anticipated benefits exceed the harms but the quality of evidence is not as strong. Again, in some clearly identified circumstances, recommendations may be made when high-quality evidence is impossible to obtain but the anticipated benefits outweigh the harms.	It would be prudent for clinicians to follow a recommendation, but they should remain alert to new information and sensitive to patient preferences.
Option	Options define courses that may be taken when either the quality of evidence is suspect or carefully performed studies have shown little clear advantage to one approach over another.	Clinicians should consider the option in their decision-making, and patient preference may have a substantial role.
No recommendation	No recommendation indicates that there is a lack of pertinent published evidence and that the anticipated balance of benefits and harms is presently unclear.	Clinicians should be alert to new published evidence that clarifies the balance of benefit versus harm.

TABLE 2 Symptoms and Signs of OSAS

History
Frequent snoring (≥3 nights/wk)
Labored breathing during sleep
Gasps/snorting noises/observed episodes of apnea
Sleep enuresis (especially secondary enuresis)[a]
Sleeping in a seated position or with the neck hyperextended
Cyanosis
Headaches on awakening
Daytime sleepiness
Attention-deficit/hyperactivity disorder
Learning problems
Physical examination
Underweight or overweight
Tonsillar hypertrophy
Adenoidal facies
Micrognathia/retrognathia
High-arched palate
Failure to thrive
Hypertension

[a] Enuresis after at least 6 mo of continence.

does not establish the diagnosis (see technical report). Occasional snoring, for example, with an upper respiratory tract infection, is less of a concern than snoring that occurs at least 3 times a week and is associated with any of the symptoms or signs listed in Table 2.

Key Action Statement 2A: Polysomnography

If a child or adolescent snores on a regular basis and has any of the complaints or findings shown in Table 2, clinicians should either (1) obtain a polysomnogram (Evidence Quality A, Key Action strength: Recommendation) OR (2) refer the patient to a sleep specialist or otolaryngologist for a more extensive evaluation (Evidence quality D, Key Action strength: Option). (Evidence Quality: Grade A for polysomnography; Grade D for specialist referral, Recommendation Strength: Recommendation.)

Evidence Profile KAS 2A: Polysomnography

- Aggregate evidence quality: A
- Benefits: Establish diagnosis and determine severity of OSAS.
- Harm: Expense, time, anxiety/discomfort.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: Panelists weighed the value of establishing a diagnosis as more important than the minor potential harms listed.
- Role of patient preferences: Small because of preponderance of evidence that polysomnography is the most accurate way to make a diagnosis.
- Exclusions: See Key Action Statement 2B regarding lack of availability.
- Intentional vagueness: None.
- Strength: Recommendation.

Evidence Profile KAS 2A: Referral

- Aggregate evidence quality: D
- Benefits: Subspecialist may be better able to establish diagnosis and determine severity of OSAS.
- Harm: Expense, time, anxiety/discomfort.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: Panelists weighed the value of establishing a diagnosis as more important than the minor potential harms listed.
- Role of patient preferences: Large.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Option.

Although history and physical examination are useful to screen patients and determine which patients need further investigation for OSAS, the sensitivity and specificity of the history and physical examination are poor (see accompanying technical report). Physical examination when the child is awake may be normal, and the size of the tonsils cannot be used to predict the presence of OSAS in an individual child. Thus, objective testing is required. The gold standard test is overnight, attended, in-laboratory polysomnography (sleep study). This is a noninvasive test involving the measurement of a number of physiologic functions overnight, typically including EEG; pulse oximetry; oronasal airflow, abdominal and chest wall movements, partial pressure of carbon dioxide (P_{CO_2}); and video recording.[13] Specific pediatric measuring and scoring criteria should be used.[13] Polysomnography will demonstrate the presence or absence of OSAS. Polysomnography also demonstrates the severity of OSAS, which is helpful in planning treatment and in postoperative short- and long-term management.

Key Action Statement 2B: Alternative Testing

If polysomnography is not available, then clinicians may order alternative diagnostic tests, such as nocturnal video recording, nocturnal oximetry, daytime nap polysomnography, or ambulatory polysomnography. (Evidence Quality: Grade C, Recommendation Strength: Option.)

Evidence Profile KAS 2B

- Aggregate evidence quality: C
- Benefit: Varying positive and negative predictive values for establishing diagnosis.
- Harm: False-negative and false-positive results may underestimate or overestimate severity, expense, time, anxiety/discomfort.
- Benefits-harms assessment: Equilibrium of benefits and harms.
- Value judgments: Opinion of the panel that some objective testing is better than none. Pragmatic decision based on current shortage of pediatric polysomnography facilities (this may change over time).
- Role of patient preferences: Small, if choices are limited by availability;

families may choose to travel to centers where more extensive facilities are available.

- Exclusions: None.
- Intentional vagueness: None.
- Strength: Option.

Although polysomnography is the gold standard for diagnosis of OSAS, there is a shortage of sleep laboratories with pediatric expertise. Hence, polysomnography may not be readily available in certain regions of the country. Alternative diagnostic tests have been shown to have weaker positive and negative predictive values than polysomnography, but nevertheless, objective testing is preferable to clinical evaluation alone. If an alternative test fails to demonstrate OSAS in a patient with a high pretest probability, full polysomnography should be sought.

Key Action Statement 3: Adenotonsillectomy

If a child is determined to have OSAS, has a clinical examination consistent with adenotonsillar hypertrophy, and does not have a contraindication to surgery (see Table 3), the clinician should recommend adenotonsillectomy as the first line of treatment. If the child has OSAS but does not have adenotonsillar hypertrophy, other treatment should be considered (see Key Action Statement 6). Clinical judgment is required to determine the benefits of adenotonsillectomy compared with other treatments in obese children with varying degrees of adenotonsillar hypertrophy. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Evidence Profile KAS 3

- Aggregate evidence quality: B
- Benefit: Improve OSAS and accompanying symptoms and sequelae.
- Harm: Pain, anxiety, dehydration, anesthetic complications, hemorrhage, infection, postoperative respiratory difficulties, velopharyngeal incompetence, nasopharyngeal stenosis, death.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: The panel sees the benefits of treating OSAS as more beneficial than the low risk of serious consequences.
- Role of patient preferences: Low; continuous positive airway pressure (CPAP) is an option but involves prolonged, long-term treatment as compared with a single, relatively low-risk surgical procedure.
- Exclusions: See Table 3.
- Intentional vagueness: None.
- Strength: Recommendation.

Adenotonsillectomy is very effective in treating OSAS. Adenoidectomy or tonsillectomy alone may not be sufficient, because residual lymphoid tissue may contribute to persistent obstruction. In otherwise healthy children with adenotonsillar hypertrophy, adenotonsillectomy is associated with improvements in symptoms and sequelae of OSAS. Postoperative polysomnography typically shows a major decrease in the number of obstructive events, although some obstructions may still be present. Although obese children may have less satisfactory results, many will be adequately treated with adenotonsillectomy; however, further research is needed to determine which obese children are most likely to benefit from surgery. In this population, the benefits of a 1-time surgical procedure, with a small but real risk of complications, need to be weighed against long-term treatment with CPAP, which is associated with discomfort, disruption of family lifestyle, and risks of poor adherence. Potential complications of adenotonsillectomy are shown in Table 4. Although serious complications (including death) may occur, the rate of these complications is low, and the risks of complications need to be weighed against the consequences of untreated OSAS. In general, a 1-time only procedure with a relatively low morbidity is preferable to lifelong treatment with CPAP; furthermore, the efficacy of CPAP is limited by generally suboptimal adherence. Other treatment options, such as anti-inflammatory medications, weight loss, or tracheostomy, are less effective, are difficult to achieve, or have higher morbidity, respectively.

TABLE 3 Contraindications for Adenotonsillectomy

Absolute contraindications
No adenotonsillar tissue (tissue has been surgically removed)
Relative contraindications
Very small tonsils/adenoid
Morbid obesity and small tonsils/adenoid
Bleeding disorder refractory to treatment
Submucus cleft palate
Other medical conditions making patient medically unstable for surgery

Key Action Statement 4: High-Risk Patients Undergoing Adenotonsillectomy

Clinicians should monitor high-risk patients (Table 5) undergoing adenotonsillectomy as inpatients postoperatively. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

TABLE 4 Risks of Adenotonsillectomy

Minor
Pain
Dehydration attributable to postoperative nausea/vomiting and poor oral intake
Major
Anesthetic complications
Acute upper airway obstruction during induction or emergence from anesthesia
Postoperative respiratory compromise
Hemorrhage
Velopharyngeal incompetence
Nasopharyngeal stenosis
Death

TABLE 5 Risk Factors for Postoperative Respiratory Complications in Children With OSAS Undergoing Adenotonsillectomy

Younger than 3 y of age
Severe OSAS on polysomnography[a]
Cardiac complications of OSAS
Failure to thrive
Obesity
Craniofacial anomalies[b]
Neuromuscular disorders[b]
Current respiratory infection

[a] It is difficult to provide exact polysomnographic criteria for severity, because these criteria will vary depending on the age of the child; additional comorbidities, such as obesity, asthma, or cardiac complications of OSAS; and other polysomnographic criteria that have not been evaluated in the literature, such as the level of hypercapnia and the frequency of desaturation (as compared with lowest oxygen saturation). Nevertheless, on the basis of published studies (primarily Level III, see Technical Report), it is recommended that all patients with a lowest oxygen saturation <80% (either on preoperative polysomnography or during observation in the recovery room postoperatively) or an AHI ≥24/h be observed as inpatients postoperatively as they are at increased risk for postoperative respiratory compromise. Additionally, on the basis of expert consensus, it is recommended that patients with significant hypercapnia on polysomnography (peak P_{CO_2} ≥60 mm Hg) be admitted postoperatively. The committee noted that that most published studies were retrospective and not comprehensive, and therefore these recommendations may change if higher-level studies are published. Clinicians may decide to admit patients with less severe polysomnographic abnormalities based on a constellation of risk factors (age, comorbidities, and additional polysomnographic factors) for a particular individual.

[b] Not discussed in these guidelines.

Evidence Profile KAS 4

- Aggregate evidence quality: B
- Benefit: Effectively manage severe respiratory compromise and avoid death.
- Harm: Expense, time, anxiety.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: The panel believes that early recognition of any serious adverse events is critically important.
- Role of patient preferences: Minimal; this is an important safety issue.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Recommendation.

Patients with OSAS may develop respiratory complications, such as worsening of OSAS or pulmonary edema, in the immediate postoperative period. Death attributable to respiratory complications in the immediate postoperative period has been reported in patients with severe OSAS. Identified risk factors are shown in Table 5. High-risk patients should undergo surgery in a center capable of treating complex pediatric patients. They should be hospitalized overnight for close monitoring postoperatively. Children with an acute respiratory infection on the day of surgery, as documented by fever, cough, and/or wheezing, are at increased risk of postoperative complications and, therefore, should be rescheduled or monitored closely postoperatively. Clinicians should decide on an individual basis whether these patients should be rescheduled, taking into consideration the severity of OSAS in the particular patient and keeping in mind that many children with adenotonsillar hypertrophy have chronic rhinorrhea and nasal congestion, even in the absence of viral infections.

Key Action Statement 5: Reevaluation

Clinicians should clinically reassess all patients with OSAS for persisting signs and symptoms after therapy to determine whether further treatment is required. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Evidence Profile KAS 5A

- Aggregate evidence quality: B
- Benefit: Determine effects of treatment.
- Harm: Expense, time.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: Data show that a significant proportion of children continue to have abnormalities postoperatively; therefore, the panel determined that the benefits of follow-up outweigh the minor inconveniences.
- Role of patient preferences: Minimal; follow-up is good clinical practice.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Recommendation.

Clinicians should reassess OSAS-related symptoms and signs (Table 2) after 6 to 8 weeks of therapy to determine whether further evaluation and treatment are indicated. Objective data regarding the timing of the postoperative evaluation are not available. Most clinicians recommend reevaluation 6 to 8 weeks after treatment to allow for healing of the operative site and to allow time for upper airway, cardiac, and central nervous system recovery. Patients who remain symptomatic should undergo objective testing (see Key Action Statement 2) or be referred to a sleep specialist for further evaluation.

Key Action Statement 5B: Reevaluation of High-Risk Patients

Clinicians should reevaluate high-risk patients for persistent OSAS after adenotonsillectomy, including those who had a significantly abnormal baseline polysomnogram, have sequelae of OSAS, are obese, or remain symptomatic after treatment, with an objective test (see Key Action Statement 2) or refer such patients to a sleep specialist. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Evidence Profile KAS 5B

- Aggregate evidence quality: B
- Benefit: Determine effects of treatment.
- Harm: Expense, time, anxiety/discomfort.
- Benefits-harms assessment: Preponderance of benefit over harm.

- Value judgments: Given the panel's concerns about the consequences of OSAS and the frequency of postoperative persistence in high-risk groups, the panel believes that the follow-up costs are outweighed by benefits of recognition of persistent OSAS. A minority of panelists believed that all children with OSAS should have follow-up polysomnography because of the high prevalence of persistent postoperative abnormalities on polysomnography, but most panelists believed that persistent polysomnographic abnormalities in uncomplicated children with mild OSAS were usually mild in patients who were asymptomatic after surgery.
- Role of patient preferences: Minimal. Further evaluation is needed to determine the need for further treatment.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Recommendation.

Numerous studies have shown that a large proportion of children at high risk continue to have some degree of OSAS postoperatively[10,13,14]; thus, objective evidence is required to determine whether further treatment is necessary.

Key Action Statement 6: CPAP

Clinicians should refer patients for CPAP management if symptoms/signs (Table 2) or objective evidence of OSAS persists after adenotonsillectomy or if adenotonsillectomy is not performed. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Evidence Profile KAS 6

- Aggregate evidence quality: B
- Benefit: Improve OSAS and accompanying symptoms and sequelae.
- Harm: Expense, time, anxiety; parental sleep disruption; nasal and skin adverse effects; possible midface remodeling; extremely rare serious pressure-related complications, such as pneumothorax; poor adherence.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: Panelists believe that CPAP is the most effective treatment of OSAS that persists postoperatively and that the benefits of treatment outweigh the adverse effects. Other treatments (eg, rapid maxillary expansion) may be effective in specially selected patients.
- Role of patient preferences: Other treatments may be effective in specially selected patients.
- Exclusions: Rare patients at increased risk of severe pressure complications.
- Intentional vagueness: None.
- Policy level: Recommendation.

CPAP therapy is delivered by using an electronic device that delivers air at positive pressure via a nasal mask, leading to mechanical stenting of the airway and improved functional residual capacity in the lungs. There is no clear advantage of using bilevel pressure over CPAP.[15] CPAP should be managed by an experienced and skilled clinician with expertise in its use in children. CPAP pressure requirements vary among individuals and change over time; thus, CPAP must be titrated in the sleep laboratory before prescribing the device and periodically readjusted thereafter. Behavioral modification therapy may be required, especially for young children or those with developmental delays. Objective monitoring of adherence, by using the equipment software, is important. If adherence is suboptimal, the clinician should institute measures to improve adherence (such as behavioral modification, or treating side effects of CPAP) and institute alternative treatments if these measures are ineffective.

Key Action Statement 7: Weight Loss

Clinicians should recommend weight loss in addition to other therapy if a child/adolescent with OSAS is overweight or obese. (Evidence Quality: Grade C, Recommendation Strength: Recommendation.)

Evidence Profile KAS 7

- Aggregate evidence quality: C
- Benefit: Improve OSAS and accompanying symptoms and sequelae; non–OSAS-related benefits of weight loss.
- Harm: Hard to achieve and maintain weight loss.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: The panel agreed that weight loss is beneficial for both OSAS and other health issues, but clinical experience suggests that weight loss is difficult to achieve and maintain, and even effective weight loss regimens take time; therefore, additional treatment is required in the interim.
- Role of patient preferences: Strong role for patient and family preference regarding nutrition and exercise.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Recommendation.

Weight loss has been shown to improve OSAS,[16,17] although the degree of weight loss required has not been determined. Because weight loss is a slow and unreliable process, other treatment modalities (such as adenotonsillectomy or CPAP therapy) should be instituted until sufficient weight loss has been achieved and maintained.

Key Action Statement 8: Intranasal Corticosteroids

Clinicians may prescribe topical intranasal corticosteroids for children with mild OSAS in whom adenotonsillectomy is contraindicated or for children with mild postoperative OSAS. (Evidence Quality: Grade B, Recommendation Strength: Option.)

Evidence Profile KAS 8

- Aggregate evidence quality: B
- Benefit: Improves mild OSAS and accompanying symptoms and sequelae.
- Harm: Some subjects may not have an adequate response. It is not known whether therapeutic effect persists long-term; therefore, long-term observation is required. Low risk of steroid-related adverse effects.
- Benefits-harms assessment: Preponderance of benefit over harm.
- Value judgments: The panel agreed that intranasal steroids provide a less invasive treatment than surgery or CPAP and, therefore, may be preferred in some cases despite lower efficacy and lack of data on long-term efficacy.
- Role of patient preferences: Moderate role for patient and family preference if OSAS is mild.
- Exclusions: None.
- Intentional vagueness: None.
- Strength: Option.

Mild OSAS is defined, for this indication, as an AHI <5 per hour, on the basis of studies on intranasal corticosteroids described in the accompanying technical report.[2] Several studies have shown that the use of intranasal steroids decreases the degree of OSAS; however, although OSAS improves, residual OSAS may remain. Furthermore, there is individual variability in response to treatment, and long-term studies have not been performed to determine the duration of improvement. Therefore, nasal steroids are not recommended as a first-line therapy. The response to treatment should be measured objectively after a course of treatment of approximately 6 weeks. Because the long-term effect of this treatment is unknown, the clinician should continue to observe the patient for symptoms of recurrence and adverse effects of corticosteroids.

AREAS FOR FUTURE RESEARCH

A detailed list of research recommendations is provided in the accompanying technical report.[2] There is a great need for further research into the prevalence of OSAS, sequelae of OSAS, best treatment methods, and the role of obesity. In particular, well-controlled, blinded studies, including randomized controlled trials of treatment, are needed to determine the best care for children and adolescents with OSAS.

SUBCOMMITTEE ON OBSTRUCTIVE SLEEP APNEA SYNDROME*

Carole L. Marcus, MBBCh, Chairperson (Sleep Medicine, Pediatric Pulmonologist; Liaison, American Academy of Sleep Medicine; Research Support from Philips Respironics; Affiliated with an academic sleep center; Published research related to OSAS)

Lee J. Brooks, MD (Sleep Medicine, Pediatric Pulmonologist; Liaison, American College of Chest Physicians; No financial conflicts; Affiliated with an academic sleep center; Published research related to OSAS)

Sally Davidson Ward, MD (Sleep Medicine, Pediatric Pulmonologist; No financial conflicts; Affiliated with an academic sleep center; Published research related to OSAS)

Sleep Apnea Clinical Practice Guideline Quick Reference Tools

- Action Statement Summary
  — Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome
- *ICD-10-CM* Coding Quick Reference for Sleep Apnea
- AAP Patient Education Handout
  — *Sleep Apnea and Your Child*

Action Statement Summary

Diagnosis and Management of Childhood Obstructive Sleep Apnea Syndrome

Key Action Statement 1: Screening for OSAS

As part of routine health maintenance visits, clinicians should inquire whether the child or adolescent snores. If the answer is affirmative or if a child or adolescent presents with signs or symptoms of OSAS (Table 2), clinicians should perform a more focused evaluation. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 2A: Polysomnography

If a child or adolescent snores on a regular basis and has any of the complaints or findings shown in Table 2, clinicians should either (1) obtain a polysomnogram (Evidence Quality A, Key Action strength: Recommendation) OR (2) refer the patient to a sleep specialist or otolaryngologist for a more extensive evaluation (Evidence quality D, Key Action strength: Option). (Evidence Quality: Grade A for polysomnography; Grade D for specialist referral, Recommendation Strength: Recommendation.)

Key Action Statement 2B: Alternative Testing

If polysomnography is not available, then clinicians may order alternative diagnostic tests, such as nocturnal video recording, nocturnal oximetry, daytime nap polysomnography, or ambulatory polysomnography. (Evidence Quality: Grade C, Recommendation Strength: Option.)

Key Action Statement 3: Adenotonsillectomy

If a child is determined to have OSAS, has a clinical examination consistent with adenotonsillar hypertrophy, and does not have a contraindication to surgery (see Table 3), the clinician should recommend adenotonsillectomy as the first line of treatment. If the child has OSAS but does not have adenotonsillar hypertrophy, other treatment should be considered (see Key Action Statement 6). Clinical judgment is required to determine the benefits of adenotonsillectomy compared with other treatments in obese children with varying degrees of adenotonsillar hypertrophy. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 4: High-Risk Patients Undergoing Adenotonsillectomy

Clinicians should monitor high-risk patients (Table 5) undergoing adenotonsillectomy as inpatients postoperatively. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 5: Reevaluation

Clinicians should clinically reassess all patients with OSAS for persisting signs and symptoms after therapy to determine whether further treatment is required. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 5B: Reevaluation of High-Risk Patients

Clinicians should reevaluate high-risk patients for persistent OSAS after adenotonsillectomy, including those who had a significantly abnormal baseline polysomnogram, have sequelae of OSAS, are obese, or remain symptomatic after treatment, with an objective test (see Key Action Statement 2) or refer such patients to a sleep specialist. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 6: CPAP

Clinicians should refer patients for CPAP management if symptoms/signs (Table 2) or objective evidence of OSAS persists after adenotonsillectomy or if adenotonsillectomy is not performed. (Evidence Quality: Grade B, Recommendation Strength: Recommendation.)

Key Action Statement 7: Weight Loss

Clinicians should recommend weight loss in addition to other therapy if a child/adolescent with OSAS is overweight or obese. (Evidence Quality: Grade C, Recommendation Strength: Recommendation.)

Key Action Statement 8: Intranasal Corticosteroids

Clinicians may prescribe topical intranasal corticosteroids for children with mild OSAS in whom adenotonsillectomy is contraindicated or for children with mild postoperative OSAS. (Evidence Quality: Grade B, Recommendation Strength: Option.)

Coding Quick Reference for Sleep Apnea

Sleep Apnea and Your Child

Does your child snore a lot? Does he sleep restlessly? Does he have difficulty breathing, or does he gasp or choke, while he sleeps?

If your child has these symptoms, he may have a condition known as sleep apnea.

Sleep apnea is a common problem that affects an estimated 2% of all children, including many who are undiagnosed.

If not treated, sleep apnea can lead to a variety of problems. These include heart, behavior, learning, and growth problems.

How do I know if my child has sleep apnea?

Symptoms of sleep apnea include

- Frequent snoring
- Problems breathing during the night
- Sleepiness during the day
- Difficulty paying attention
- Behavior problems

If you notice any of these symptoms, let your pediatrician know as soon as possible. Your pediatrician may recommend an overnight sleep study called a *polysomnogram.* Overnight polysomnograms are conducted at hospitals and major medical centers. During the study, medical staff will watch your child sleep. Several sensors will be attached to your child to monitor breathing, oxygenation, and brain waves. An electroencephalogram (EEG) is a test that measures brain waves.

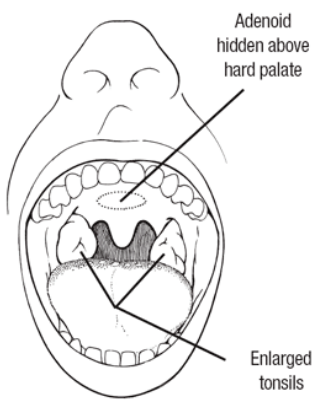
The results of the study will show whether your child suffers from sleep apnea. Other specialists, such as pediatric pulmonologists, otolaryngologists, neurologists, and pediatricians with specialty training in sleep disorders, may help your pediatrician make the diagnosis.

What causes sleep apnea?

Many children with sleep apnea have larger tonsils and adenoids.

Tonsils are the round, reddish masses on each side of your child's throat. They help fight infections in the body. You can only see the adenoid with an x-ray or special mirror. It lies in the space between the nose and throat.

Large tonsils and adenoid may block a child's airway while she sleeps. This causes her to snore and wake up often during the night. However, not every child with large tonsils and adenoid has sleep apnea. A sleep study can tell your doctor whether your child has sleep apnea or if she is simply snoring.



Children born with other medical conditions, such as Down syndrome, cerebral palsy, or craniofacial (skull and face) abnormalities, are at higher risk for sleep apnea. Overweight children are also more likely to suffer from sleep apnea.

How is sleep apnea treated?

The most common way to treat sleep apnea is to remove your child's tonsils and adenoid. This surgery is called a tonsillectomy and adenoidectomy. It is highly effective in treating sleep apnea.

Another effective treatment is nasal continuous positive airway pressure (CPAP), which requires the child to wear a mask while he sleeps. The mask delivers steady air pressure through the child's nose, allowing him to breathe comfortably. Continuous positive airway pressure is usually used in children who do not improve after tonsillectomy and adenoidectomy, or who are not candidates for tonsillectomy and adenoidectomy.

Children who may need additional treatment include children who are overweight or suffering from another complicating condition. Overweight children will improve if they lose weight, but may need to use CPAP until the weight is lost.

Remember

A good night's sleep is important to good health. If your child suffers from the symptoms of sleep apnea, talk with your pediatrician. A proper diagnosis and treatment can mean restful nights and restful days for your child and your family.

From your doctor

CLINICAL PRACTICE GUIDELINE

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Clinical Practice Guideline: Evaluation and Management of Well-Appearing Febrile Infants 8 to 60 Days Old

Robert H. Pantell, MD, FAAP,[a] Kenneth B. Roberts, MD, FAAP,[b] William G. Adams, MD, FAAP,[c] Benard P. Dreyer, MD, FAAP,[d] Nathan Kuppermann, MD, MPH, FAAP, FACEP,[e] Sean T. O'Leary, MD, MPH, FAAP,[f] Kymika Okechukwu, MPA,[g] Charles R. Woods Jr, MD, MS, FAAP[h] SUBCOMMITTEE ON FEBRILE INFANTS

This guideline addresses the evaluation and management of well-appearing, term infants, 8 to 60 days of age, with fever ≥38.0°C. Exclusions are noted. After a commissioned evidence-based review by the Agency for Healthcare Research and Quality, an additional extensive and ongoing review of the literature, and supplemental data from published, peer-reviewed studies provided by active investigators, 21 key action statements were derived. For each key action statement, the quality of evidence and benefit-harm relationship were assessed and graded to determine the strength of recommendations. When appropriate, parents' values and preferences should be incorporated as part of shared decision-making. For diagnostic testing, the committee has attempted to develop numbers needed to test, and for antimicrobial administration, the committee provided numbers needed to treat. Three algorithms summarize the recommendations for infants 8 to 21 days of age, 22 to 28 days of age, and 29 to 60 days of age. The recommendations in this guideline do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.

BACKGROUND

Efforts to develop an evidence-based approach to the evaluation and management of young febrile infants have spanned more than 4 decades.[1] In the 1970s, concerns arose about the emergence and rapid progression of group B *Streptococcus* (GBS) infection in neonates, whose clinical appearance and preliminary laboratory evaluations did not always reflect the presence of serious disease.[2] Such concerns led to extensive evaluations, hospitalizations, and antimicrobial treatment of all febrile infants younger than 60 days,[3] with many institutions extending complete sepsis workups to 90 days. However, the seminal

1983 study by De Angelis et al[4] highlighted the iatrogenic complications that accompany hospitalizing young, febrile infants and provided an impetus for developing clinical strategies that would be more selective for hospitalizations. Today, the consequences of medical errors during hospitalizations are well known.[5–7]

In the 1980s and 1990s, there were numerous efforts to develop and validate clinical prediction models for detecting serious bacterial illness (SBI).[8–15] Efforts were hampered by the heterogeneity of the definition of SBI. Some studies included clinically obvious infections such as cellulitis. Others included pneumonia, which may be viral or bacterial; many included bacterial gastroenteritis in infants with diarrhea. All included urinary tract infection (UTI), bacteremia, and bacterial meningitis, but UTI is so much more common than the other infections that it distorts models attempting to identify all causes.

These prediction models involved a combination of clinical and laboratory test parameters that were based on a priori criteria and were not derived from the primary data. Each variable was defined arbitrarily, such as age groupings in weeks or months and integers ending in zero, for which there is no real physiologic or biological basis. For example, the variable that defined an abnormal white blood cell (WBC) count as <5000 per mm^3 or $>15\,000$ per mm^3 was not statistically derived but established in advance as an indicator and tested in combination with other predictor variables.

Recommendations emerged that generally relied on clinical appearance, age, urinalysis, WBC count (and/or absolute neutrophil count [ANC], band count, and/or immature to total neutrophil ratio), and cerebrospinal fluid (CSF) analysis (except for the Rochester criteria, which did not require CSF).[10] All had somewhat similar sensitivities and specificities as well as predictive values. The models were promulgated because of moderately high sensitivities (90% to 95%) and high negative predictive values (NPVs) (97%–99%). The high NPVs were expected because of the uncommon occurrence of the most serious infections, which, along with modest specificities (20% to 40%), also explained the relatively low positive predictive values.

A major shift occurred in the mid-1980s when Powell et al in Rochester accepted the inability to predict who was at high risk and attempted instead to predict who was at low risk, even in the first month of life.[10,14] A pattern emerged in which it was recommended that all infants in the youngest group (<29 days of age) should receive extensive evaluations, hospitalization, and empirical antimicrobial treatment, and infants 29 to 90 days of age could be managed with presumptive intramuscular ceftriaxone as outpatients with pending blood, urine, and CSF culture results.[15]

In time, other groups used techniques to develop clinical prediction rules that rely on gathered data to derive and define the best, most precise, and parsimonious set of variables that predict a defined outcome that can be translated into recommendations.[16–18] Still another approach was the sequential approach of established clinical and laboratory criteria.[19,20] Despite these substantial efforts, there has been ongoing evidence that community and emergency physicians do not routinely follow these recommendations in real-world settings.[17,21–27] Clinical outcomes have not been shown to suffer despite nonadherence to contemporaneous standards of care.

Differing approaches to the management of very young febrile infants indicated the need for a guideline that is current, evidence-based, and developed by a national professional society or organization with broad representation. This led the American Academy of Pediatrics (AAP) to embark on developing this guideline with the assistance of an evidence review commissioned by the Agency for Healthcare Research and Quality (AHRQ).[26]

Attention has been given to the following present-day considerations:

1. Changing Bacteriology

Since the 1980s, the epidemiology of bacterial infections in neonates and infants has changed as a result of many factors, including prenatal GBS screening and incorporation of immunization against *Streptococcus pneumoniae.* Furthermore, improvements in food safety may have resulted in a decrease in the incidence of disease caused by *Listeria monocytogenes* in this age group. Recent studies demonstrate that *Esherichia coli* is now the most common organism to cause bacteremia, while GBS remains the most common cause of meningitis in most studies.[25,27–31] Infections with *L monocytogenes* are now rare in the United States.[32,33] The shift from Gram-positive to Gram-negative predominance has implications for the choice of tests, interpretation of values for decision-making, and the selection of antimicrobial drugs. Using the decision models of the 1980s today can lead to misclassification of bacterial meningitis in 23.3% to 32.1% of cases.[34]

2. Cost of Unnecessary Care

Studies indicate significant variation in care and consequently considerable differences in costs.[17,22–24] Differential access, delays, language barriers, and fragmented care can also be costly to infants, families, and the health care system. A substantial basis for practice variability among clinicians is attributable to differences in infants' clinical presentations and severities of illness. However, more than 50% of the variability has been unexplained.[35] Beyond unnecessary hospitalizations, and financial and social costs, there are also potential harms from hospital-acquired infections and iatrogenesis in prolonged hospitalizations.

Costs are justified on the basis of the magnitude of the benefit and/or reduction of potential harms. In studies of prediction models, instances of missed invasive bacterial infections (IBI) in well-appearing low-risk infants are uncommon. For infants not managed according to existing clinical prediction models, there are also uncommon misses reported in the literature. These factors suggested there is an opportunity to "safely do less."[36]

3. Advances in Testing

Inflammatory Markers

The WBC, ANC, and band count, combined with clinical appearance and urinalysis, have been the foundation of earlier clinical prediction models. With *E coli* replacing GBS as the most common bacterial pathogen in this age group, these markers are no longer as useful. C-reactive protein (CRP), an inflammatory marker (IM) produced by the liver in response to infections and numerous other conditions, is now available for point-of-care testing.[37] Procalcitonin, expressed mainly by thyroid C cells, is produced rapidly in response to infection and other tissue injuries. It is more specific for bacterial infections than other IMs and rises more quickly to abnormal values. Procalcitonin has emerged as the most accurate IM for risk stratification available, although not currently available at many sites in the United States with timely results on a 24/7 basis.[38,39] (See additional discussion in KAS 10)

Pathogen Identification

There have been improvements allowing more accurate screening for invasive infections and more rapid and precise identification of bacterial, viral, and fungal pathogens. Automated blood culture systems can now identify most bacterial pathogens in <24 hours. Most recently, nested multiplex polymerase chain reaction (PCR) testing of positive blood cultures can identify bacterial pathogens and antimicrobial resistance genes in approximately 1 hour.[40–42] Similarly, multiplex meningoencephalitis panels can provide results on CSF for 14 potential CSF pathogens in 1 hour.[43]

Viral Testing

The development of rapid viral PCR and multiplex respiratory viral testing has led to identifying emerging agents, such as parechovirus, and prompted analyses of their effect on risk stratification of young febrile infants.[44–53] Although the presence of documented respiratory viral infections decreases the risk of IBIs in febrile infants (see Inclusion Criteria 5, Positive viral test), it remains unclear how a positive viral test result should influence further laboratory evaluation and management, especially in the first month of life. In addition, it is unclear whether a positive viral test result will either obviate or shorten hospitalization. Researchers in a study analyzing data before the widespread availability of multiplex viral testing (2000–2012) did not find a difference in length of stay between febrile infants with or without positive viral test results.[54] More work is needed, and this is included as an important question in Future Research.

Emerging Technologies

The area of genomic diagnostics for IBIs is still in its relative infancy, including both genomic identification of viral and bacterial genetic material as well as identifying host genomic responses to viral or bacterial infections. Both need further work to see how these technologies compare in accuracy and timing to routine diagnostic techniques. But progress is being made for RNA transcriptional profiling[55] and next-generation sequencing of microbial cell-free DNA.[56]

4. Opportunities to Improve the Care of Hospitalized Infants

Advances in testing and clinical strategies can speed discharge. Data indicate that including evidence-based strategies in care process models can improve infant outcomes.[57] Hospital environments can be stressful for parents but can be restructured to support maternal/child bonding and breastfeeding.[58] See further discussion in KAS 6.

5. Evolving Research Strategies

Although early studies largely emanated from single-site inner-city emergency departments (EDs), recent investigations conducted by large, geographically widespread research networks and integrated regional health care systems have developed more generalizable evidence.[17–20,22,25,57] Advances in data storage and analysis as well as adoption of statistical procedures[59] for developing clinical prediction rules offer

advantages compared with earlier efforts. Collaborative efforts of primary care practices, EDs, hospitals, and integrated health systems are creating larger and more refined data sets. With personalized medicine, enabled by these large data sets and evolving modeling techniques capable of analyzing infants on dozens of variables, the committee anticipates that in the future we will see "one child, one guideline."

This guideline, grounded in continually expanding evidence and including new technologies, should, for today's clinicians, form the foundation on which a more nuanced and precise approach can be used to develop an optimal strategy for evaluating and managing each febrile infant. The committee encourages use of the 3 age-based algorithms in Figs 1–3 as a guide to arriving at the best approach. Approaches may differ somewhat depending on many perinatal or neonatal factors, clinician's experience, parents' abilities and values, nature of relationship with the infant's family, characteristics of the clinical setting, and ability to obtain timely laboratory results, among others.

EVIDENCE FOR AGE-BASED RISK STRATIFICATION

Ongoing research has challenged classifying all infants younger than

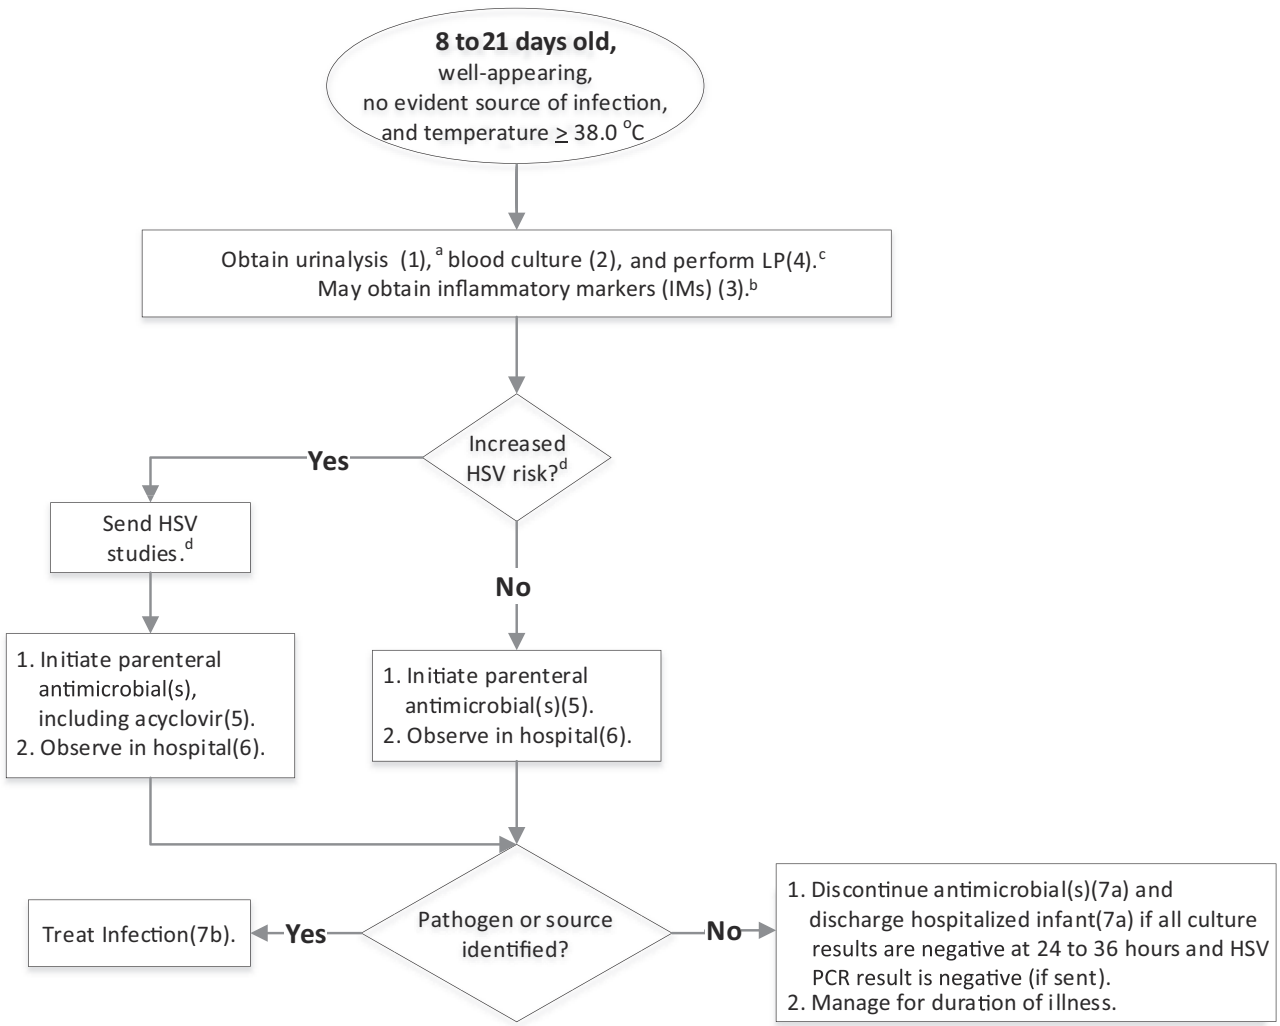

FIGURE 1 Algorithm for 8- to 21-day-old infants. [a] KAS references are shown in parentheses. [b] Laboratory values of inflammation are considered elevated at the following levels: (1) procalcitonin >0.5 ng/mL, (2) CRP >20 mg/L, and (3) ANC >4000, >5200 per mm^3 (see text). Although we recommend all infants in this age group have a complete sepsis workup, receive parenteral antimicrobial agents, and be monitored in a hospital, knowing IM results can potentially guide ongoing clinical decisions. [c] Send CSF for cell count, Gram stain, glucose, protein, bacterial culture, and enterovirus PCR (if available) if pleocytosis is present and during periods of increased local enterovirus prevalence. [d] HSV should be considered when there is a maternal history of genital HSV lesions or fevers from 48 hours before to 48 hours after delivery and in infants with vesicles, seizures, hypothermia, mucous membrane ulcers, CSF pleocytosis in the absence of a positive Gram stain result, leukopenia, thrombocytopenia, or elevated alanine aminotransferase levels. For further discussion, see the current *Red Book*. Recommended HSV studies are CSF PCR; HSV surface swabs of the mouth, nasopharynx, conjunctivae, and anus for an HSV culture (if available) or PCR assay; alanine aminotransferase; and blood PCR.

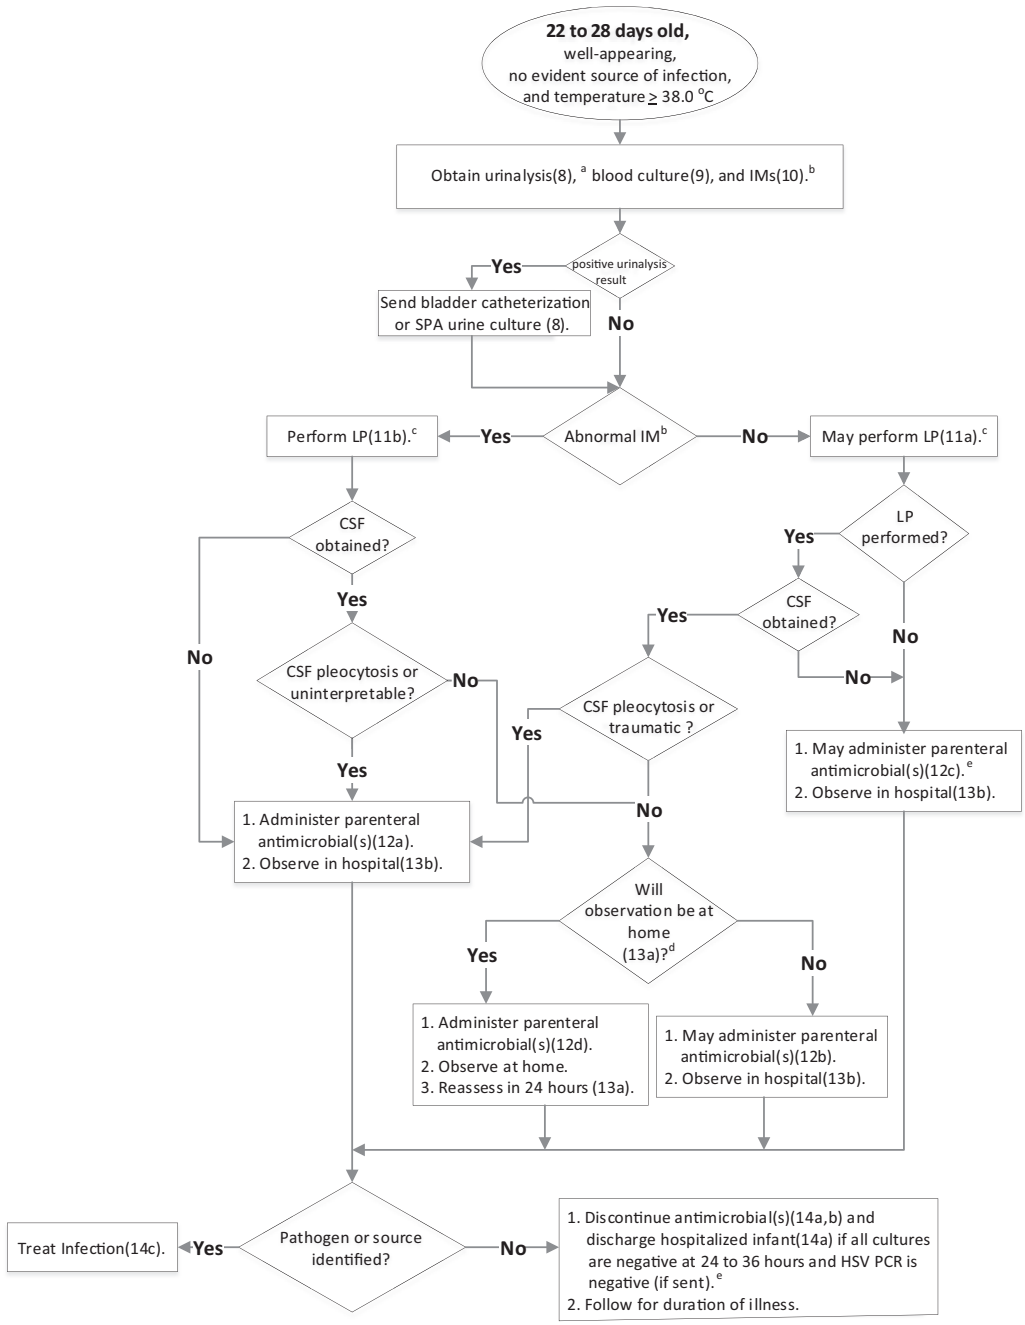

FIGURE 2 Algorithm for 22- to 28-day-old infants. [a] KAS references are shown in parentheses. [b] If available, procalcitonin should be obtained along with ANC or CRP. If procalcitonin is unavailable, both ANC and CRP should be obtained, and a temperature >38.5°C is considered abnormal. IMs are considered abnormal at the following levels: (1) temperature >38.5°C, (2) procalcitonin >0.5 ng/mL, (3) CRP >20 mg/L, and (4) ANC >4000, >5200 per mm^3 (see text). [c] LP is recommended before administration of antimicrobial agents because interpreting CSF after the administration of antimicrobial agents is difficult. However, the risk of meningitis in 22- to 28-day-old infants is lower than that in infants <22 days old in several studies. Therefore, in some circumstances, clinicians may elect to defer an LP and initiate antimicrobial agents, recognizing the potential risk of partially treated meningitis. Send CSF for cell count, Gram stain, glucose, protein, bacterial culture, and enterovirus PCR (if available) if pleocytosis is present and during periods of increased enterovirus prevalence. HSV can occur in this age group. HSV should be considered in infants with vesicles, seizures, hypothermia, mucous membrane ulcers, CSF pleocytosis in the absence of a positive Gram stain result, leukopenia, thrombocytopenia, or elevated alanine aminotransferase levels. For further discussion, see the current *Red Book*. Recommended HSV studies: CSF PCR; HSV surface swabs of mouth, nasopharynx, conjunctivae, and anus for HSV culture (if available) or PCR assay; alanine aminotransferase; and blood PCR. [d] Infant may be managed at home if parent and clinician agree that the following are present: reliable phone and transportation, parent willingness to observe and communicate changes in condition, and agreement to the infant being reevaluated in 24 hours. [e] If CSF is positive for enterovirus, clinicians may withhold or discontinue antimicrobial agents and discharge at 24 hours, provided they meet other criteria for observation at home.

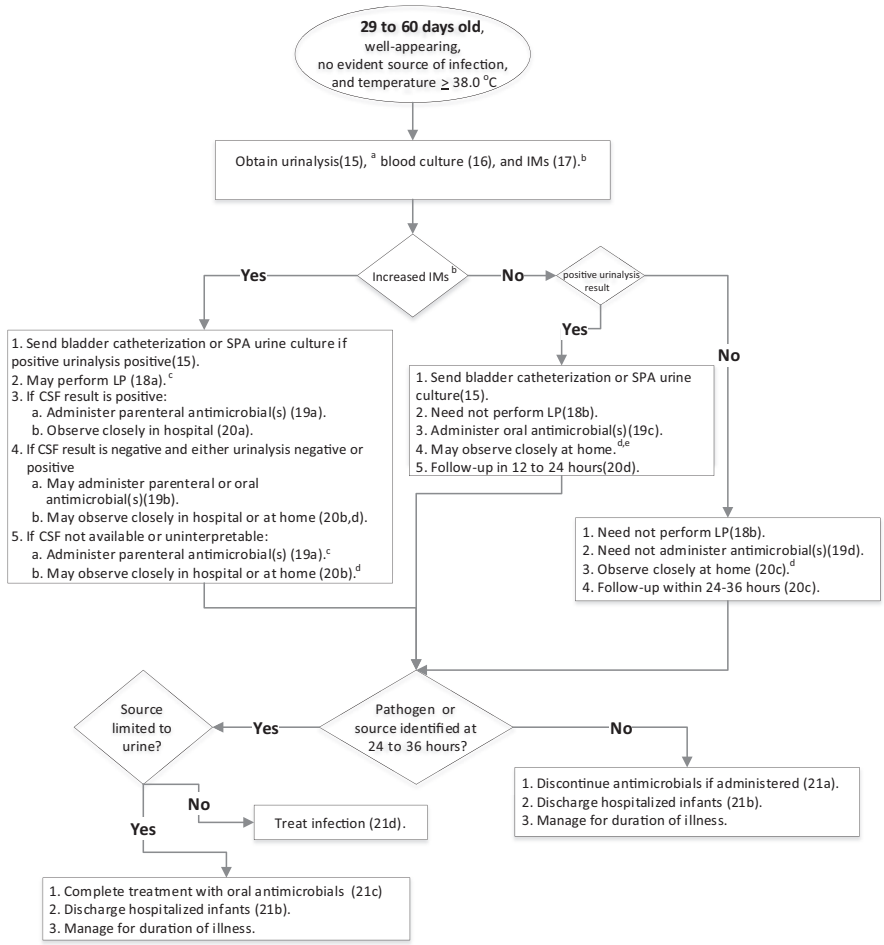

FIGURE 3 Algorithm for 29- to 60-day-old infants. [a] KAS references are shown in parentheses. [b] If available, procalcitonin should be obtained along with ANC or CRP. If procalcitonin is unavailable, both ANC and CRP should be obtained, and a temperature >38.5°C is considered abnormal. IMs are considered abnormal at the following levels: (1) temperature >38.5°C, (2) procalcitonin >0.5 ng/mL, (3) CRP >20 mg/L, (4) ANC >4000, >5200 per mm^3 (see text). [c] Send CSF for cell count, Gram stain, glucose, protein, bacterial culture, and enterovirus PCR (if available) if CSF pleocytosis is present and during periods of increased local enterovirus prevalence. Although uncommon in this age group, HSV should be considered when there is a maternal history of genital HSV lesions and in infants with vesicles, seizures, hypothermia, mucous membrane ulcers, CSF pleocytosis in the absence of a positive Gram stain result, leukopenia, thrombocytopenia, or elevated alanine aminotransferase levels. For further discussion, see the current *Red Book*. Recommended HSV studies are CSF PCR; HSV surface swabs of mouth, nasopharynx, conjunctivae, and anus for HSV culture (if available) or PCR assay; alanine aminotransferase; and blood PCR. If CSF is unobtainable or uninterpretable, there are insufficient data to make a specific recommendation. Options include the following: observe without treatment for a period of time and, depending on infant clinical condition, repeat LP and/or laboratory markers; begin empirical antimicrobial agents and reassess in 24 hours on the basis of infant response and results of blood culture; if CSF is bloody or antimicrobial agents have previously been started, analysis by multiplex PCR can add additional information; consult with local a pediatric infectious disease specialist. [d] Infant may be managed at home if parent and clinician agree that the following are present: reliable phone and transportation, parent willingness to observe and communicate changes in condition, and agreement to the infant being reevaluated in 24 hours. [e] Most 29- to 60-day-old infants with negative IM and urinalysis results may be observed at home. However, hospital observation is an option for infants when there are barriers to follow-up.

29 days as high risk. The Pediatric Research in Office Settings (PROS) study indicated that when combined with other variables, infants >25 days of age were at low risk for IBIs, 0.4%.[17] Subsequently, the European Collaborative Group developed and validated the step-by-step approach with a combination of clinical and laboratory variables that included 22- to 28-day-old infants, capable of identifying infants at low risk for IBIs, ranging from 0.2% to 0.7%.[19,20] A recent scoring system methodologically derived by Aronson et al identified age >21 days to be useful in identifying low-risk infants.[60] In a prospective study of 4778 infants from the Pediatric Emergency Care Applied Research Network (PECARN), there was a significantly lower rate of bacteremia in the fourth week (1.6%) compared with weeks 2 (5.3%) and 3 (3.3%) and no difference from weeks 5 and 6

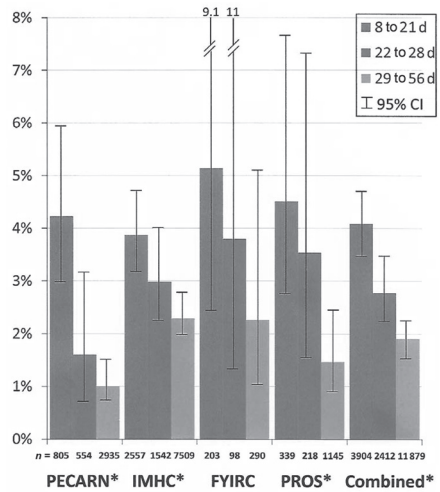

FIGURE 4 Rate of bacteremia by age groupings. * χ^2 for trend: $P < .001$. Note that the 95% CIs in the combined group do not overlap. Data were adapted from reference 61; from reference 94, with detail provided by C.L.B. (personal communication, 2020); from reference 24, with detail provided by Paul Aronson (personal communication, 2020); and from reference 17, with detail provided by Matthew Pantell (personal communication, 2020). FYIRC, Febrile Young Infants Research Collaborative; IMHC, University of Utah/Intermountain Healthcare.

($P = .76$).[61] A prospective national surveillance study in England analyzed 22 075 episodes of IBI from 2010–2017.[62] This population-based analysis documented a dramatic decrease in IBI after the first week of life, followed by a continuous stepwise decrease in population incidence over the next 8 weeks. The decline in bacteremia prevalence by age for regional and national studies is portrayed in Fig 4.

Because risk of IBI has extensively been documented to steadily decline over the first few months, any day or week cutoff is arbitrary and subject to interpretation depending on a clinician's or a parent's risk aversion or tolerance. These data form the basis for the committee developing a separate algorithm for infants 22 to 28 days of age.

CHALLENGES

A number of unique challenges confronted the development of an evidence-based approach to the febrile infant.

1. The initial challenge was to decide whether to include infants in the first week of life. The committee decided early on that infants in the first week of life are sufficiently different in rates and types of illness, including early-onset bacterial infection, that they should be excluded from this guideline.
2. Many published studies used SBI as an outcome measure. Because SBI is not a single clinical entity, analyses fell short of identifying the risks for specific infections. UTI is so much more common than the other bacterial infections that it can distort the accuracy of a prediction model to detect bacteremia or bacterial meningitis. This guideline addresses evidence for bacterial meningitis and bacteremia separately from UTIs; the committee strongly discourages further use of the term "SBI."
3. Meningitis, the most serious bacterial infection responsible for infants' fevers, is uncommon. Accumulating a large enough sample size to be able to accurately predict infrequent infections is a major research challenge; an even larger sample size is required to address the morbidity and long-term consequences accompanying meningitis.
4. As the epidemiology of bacterial species responsible for infections is continually changing, a prediction model or rule developed today will not necessarily be valid in the future. Species types and resistance patterns also vary geographically.
5. Existing clinical prediction models as well as prediction rules often rely on "clinical appearance," well versus ill, a subjective assessment.[8–17,19,20] Despite an elegant process of development, the Yale Observational Score,[8] a formal scoring system for illness appearance, has not proven to be useful in this age group.[63,64] The accuracy of clinician assessment is likely related to experience. Unfortunately, there is no measure or adequate definition for what constitutes "experienced," or of "well appearing." Researchers in large studies have often treated clinical appearance as binary: well appearing or not, or ill appearing or not. When offered 3 categories, however, both senior residents[65] and experienced pediatricians[17] classified a quarter of the young febrile infants they encountered in an intermediate category, acknowledgment that the distinction between "well" and "ill" is not always clear-cut. The distinction is likely to be most difficult before the emergence of the social smile, which enables the infant to "respond to social overtures," a key element in the Yale Observational Score.[8] Clinicians differ in a variety of ways including knowledge, clinical experience with febrile infants, and in the time available to evaluate and monitor infants. The committee acknowledges that some clinicians may have different levels of experience and

confidence in determining well appearance compared with experienced pediatricians.
6. Clinicians work in different settings with a range of familiarity with their patients and families, access to medical records, and abilities to follow-up with patients in a timely fashion.
7. Clinicians have variable access to newer diagnostic tests and timely results, particularly procalcitonin.
8. Families possess a spectrum of knowledge and skills to continuously observe and assess infants discharged from the hospital. Multiple factors may affect a timely return visit. There has been considerable interest focused on shared decision-making for young febrile infants,[66–70] including a recent mobile device app to help clinicians communicate with parents.[71]

For purposes of this guideline, the committee believes that at a minimum, families should be provided with information about the risks and benefits of all procedures, including invasive procedures such as a lumbar puncture (LP) and a bladder catheterization. An opportunity for questions and dialogue between the family and care team should be provided. Families' decisions about their infant will be made in the context of their previous experiences with the health system, their personal beliefs and values, and knowledge and understanding of their child's condition and diagnostic and treatment options and outcomes.

The decision to actively monitor an infant at home or in the hospital requires a collaborative discussion between the family and the care team. The discussion should be centered on the best interest of the child, taking into account the family's and the care team's assessment of the multiple factors of risk and risk tolerance, experience and comfort of monitoring an ill infant, and ease and accessibility of transportation. Academic medical centers and children's hospitals generally provide high-quality observation for ill infants, as do many community hospitals with dedicated pediatrics units. Many hospitals do not have nurses and staff with experience and skills caring for young infants, however. In the current health care system, insurance status and coverage may further affect the family's and care team's decision on location of monitoring.

RISK TOLERANCE: A NUMBER IS NOT A DECISION

Even with the availability of valid and reliable data, thoughtful investigators and clinicians will have different thresholds for recommending diagnostic tests and therapeutic interventions. The committee believes understanding risk tolerance is of fundamental importance to guideline interpretation. In a straightforward case of a febrile infant having CSF pleocytosis with a predominance of polymorphonuclear leukocytes and a positive Gram stain result, the committee would expect clinicians to unanimously agree the infant be hospitalized and receive immediate antimicrobial treatment. Similarly, on the basis of prevalences cited in KAS 1, 8, and 15, a risk for UTI can be estimated at 10%, which translates to a recommendation to perform 10 urinalyses to detect a single UTI, or a number needed to test of 10. This is an example in which agreement to perform a urinalysis is expected. However, challenges frequently occur. For example, if clinical and laboratory evaluations suggest the likelihood of bacteremia is 1:100 (number needed to treat = 100) or a risk of bacterial meningitis at 1:1000 (number needed to test = 1000), is it worth 100 doses of antibiotics to treat a single case of bacteremia while awaiting blood culture results? Should the committee recommend performing the number of LPs required to obtain 1000 samples of interpretable CSF to prevent a delay in recognizing and treating a single case of bacterial meningitis? Responses to these questions depend on how much risk is considered tolerable. The challenge in guideline development was succinctly stated as, "Thus, evidence alone never speaks for itself or conveys the truth because it always requires interpretation."[72] In the committee's discussions, responses to the above questions and similar issues varied among and within the specialty groups constituting the committee and reviewers.

Differences in risk tolerance also exist between parents and physicians and may exist among family members. A clinician may estimate that an infant's risk of meningitis is 1% and an LP is indicated, whereas a parent may have a higher threshold for consenting to the procedure. These differences, along with other parent beliefs and values, provide further challenges in an effort to share decision-making in an acute setting.

CONSENSUS RECOMMENDATIONS

The recommendations in this guideline reflect universal agreement or a strong consensus among committee members. In the one situation when there was majority but not consensus agreement, additional committee members were appointed and added; subsequently, consensus was achieved. The major reason for disagreement was varying levels of risk tolerance among committee members. For these recommendations, a more detailed

explanation of the uncertainties involved and attempts to derive numbers needed to test and numbers needed to treat are provided in the specific Key Action Statements.

METHODOLOGY

The working group consisted of representatives from epidemiology; general pediatrics; pediatric subspecialties, including emergency medicine, infectious diseases, and hospital medicine; and family medicine. Individuals with expertise in guideline development, algorithm creation, and quality improvement were also included. During the development of this guideline, all members had access to the AHRQ evidence review,[26] the additional analyses by the committee epidemiologist (C.R.W. Jr.) as well as others, copies of all published literature cited in these reports, and the opportunity to participate in 4 meetings convened at the AAP and on conference calls. The authoring group relied on data and analyses from the following: (1) a formal analysis and systematic review of published articles from the United States and selected international countries that was conducted by an Evidence-Based Practice Center under contract to AHRQ; (2) a supplemental review and analyses were performed by the epidemiologist assigned to the committee; (3) consistent with a previous AAP guideline[73] if literature gaps existed, data were solicited and received from authors of previously published, peer-reviewed articles who performed additional analyses from their investigations: Kaiser Permanente Northern California; Intermountain Healthcare; the AAP PROS network; the Febrile Young Infant Research Collaborative (FYIRC); Boston Children's Hospital; The European Collaborative Group; Cruces University Hospital, Barakaldo,

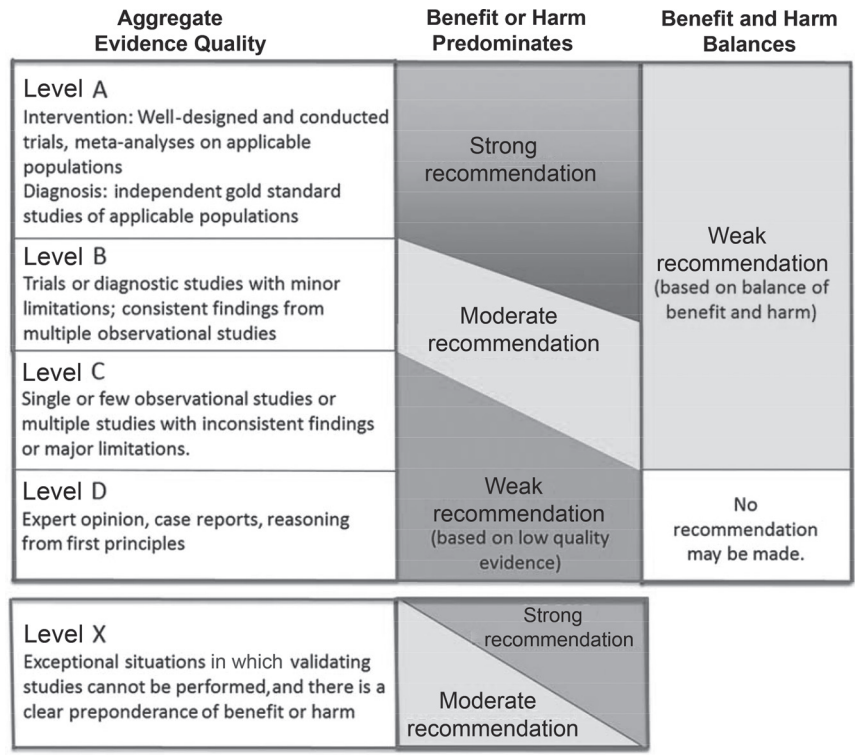

FIGURE 5 AAP rating of evidence and recommendations.

Spain; and the PECARN; and (4) committee members with active research and data collection projects provided ongoing study reports. Ongoing data analyses from these works in progress are consistent with cited references and support the recommendations.

Finally, after the formulation of a set of recommendations, there was further consideration by AAP Sections and Committees, external organizations, physician reviewers, and parents, as well as focus groups of pediatricians from general pediatrics, pediatric hospital medicine, pediatric emergency medicine, pediatric critical care, and pediatric infectious diseases (see Acknowledgments for review groups).

The committee's focus was to develop a guideline to improve the diagnosis and treatment of UTIs, bacteremia, and meningitis. Sometimes the term "SBI" is used because it was the only outcome measure reported in many investigations. In some analyses, bacteremia and bacterial meningitis are combined as IBIs because of the nature of those infections compared with UTIs.

Recommendations are contained in the algorithms for infants 8 to 21 days of age, 22 to 28 days of age, and 29 to 60 days of age and are expounded in the accompanying Key Action Statements. For each recommendation, the quality of available evidence on which the recommendation is based is rated, and the strength of each recommendation is provided (Fig 5). Risks and benefits also are indicated, and assessments of their balance are provided.

In accordance with recent suggestions by the National Academy of Medicine, the committee attempted transparency by occasionally commenting on value judgments.[74] A clinical decision

involves more than just knowing a specific risk. The decision about what action is appropriate with a given risk depends on the experience, value judgments, and risk tolerance and aversion of the interpreting clinician. To the extent possible, it is appropriate to incorporate parents' values and preferences in shared decision-making.

As noted above and consistent with all AAP clinical practice guidelines, each recommendation represents a consensus of the committee, although not necessarily universal agreement.

POPULATION ADDRESSED

This guideline addresses febrile infants who are well appearing. Infants appearing moderately or severely ill are at higher risk for IBIs and are NOT addressed in the guideline. Because of the difficulties assessing well appearance discussed previously in Challenges, we recommend that when clinicians are uncertain as to whether an infant is well appearing, this guideline should not be applied.

For eligibility, this guideline addresses febrile infants who (1) are well appearing, (2) have documented rectal temperatures of ≥38.0°C or 100.4°F at home in the past 24 hours or determined in a clinical setting, (3) had a gestation between ≥37 and <42 weeks, and (4) are 8 to 60 days of age and at home after discharge from a newborn nursery or born at home.

The following merit additional consideration specific to their condition and are intended to be excluded from the algorithms:

1. Preterm infants (<37 weeks' gestation).
2. Infants younger than 2 weeks of age whose perinatal courses were complicated by maternal fever, infection, and/or antimicrobial use.
3. Febrile infants with high suspicion of herpes simplex virus (HSV) infection (eg, vesicles).
4. Infants with a focal bacterial infection (eg, cellulitis, omphalitis, septic arthritis, osteomyelitis). These infections should be managed according to accepted standards.
5. Infants with clinical bronchiolitis, with or without positive test results for respiratory syncytial virus (RSV). A review by Ralston et al of 11 studies of bronchiolitis found no cases of meningitis, and researchers in 8 studies reported no cases of bacteremia.[51]
6. Infants with documented or suspected immune compromise.
7. Infants whose neonatal course was complicated by surgery or infection.
8. Infants with congenital or chromosomal abnormalities.
9. Medically fragile infants requiring some form of technology or ongoing therapeutic intervention to sustain life.
10. Infants who have received immunizations within the last 48 hours. The incidence of postimmunization fevers ≥38.0°C is estimated to be >40% within the first 48 hours.[75]

Infants with the following may be included:

1. Respiratory symptoms: the presence of upper respiratory tract infection symptoms or other respiratory symptoms not diagnostic of bronchiolitis should not exclude infants from inclusion in the pathway.
2. Diarrhea: infants suspected of having diarrhea caused by treatable bacterial pathogens should have stool specimens tested. If studies for bacteria are negative, infants may then enter the decision tree pathway. Loose stools do not exclude infants from the pathway.
3. Otitis media: diagnosing infants with presumed otitis media does not preclude their entry into the pathway.
4. Current or recent use of antimicrobial agents in infants older than 2 weeks of age requires individualized interpretation for febrile infants who enter the pathway.
5. Positive viral test results: the availability of rapid respiratory molecular testing for a variety of viruses is increasing, outpacing the availability of evidence for how such testing should be used.

The 2014 Cochrane review that included older infants and children did not recommend respiratory viral testing in the ED.[52] In evaluating the implications of a positive viral respiratory test result, numerous studies have documented lowering of IBI risk in subsets of patients. However, no prospective study has yet provided convincing data on whether a positive viral test result sufficiently reduces the IBI risk to change decision-making, after considering other historical, clinical, and available markers of inflammation.

In a 2004 study, Byington et al evaluated whether a positive respiratory viral test result lowered the risk of IBI in 1385 infants 1 to 90 days of age.[76] Viruses were detected in 35%, and the bacteremia risk in the viral-positive infants was 1%, significantly lower than the 2.7% in viral-negative infants. When positive viral test results were combined with the Rochester classification, there was no reduction in risk for infants already classified as low risk. Rochester high-risk group infants with positive viral test results had a similar prevalence of bacteremia as low-risk infants.

Emerging data from several large studies address viral testing in young febrile infants stratified by age. Infants <28 days of age with a positive viral test result have a risk of IBI from 1.1% to 2.1%.[44–50,76] One

TABLE 1 Summary of Key Action Statements

	Evidence Quality; Strength of Recommendation
Infants 8 to 21 d of age (KASs 1-7): Clinicians . . .	
KAS 1: Should obtain urine specimen by catheterization or suprapubic aspiration (SPA) of bladder for urinalysis and, if urinalysis result is positive, for culture.	Grade: A; Strong Recommendation
KAS 2: Should obtain a blood culture.	Grade: A; Strong Recommendation
KAS 3: May assess IMs.	Grade: B; Weak Recommendation
KAS 4: Should obtain CSF for analysis (WBC count, protein, glucose, Gram stain) and culture for bacteria. See notes for viral testing.	Grade: A; Strong Recommendation
KAS 5: Should initiate parenteral antimicrobial therapy.	Grade: A; Strong Recommendation
KAS 6: Should actively monitor infants while awaiting results of bacterial cultures in a hospital setting with nurses and staff experienced in the care of neonates/young infants.	Grade: B; Moderate Recommendation
KAS 7a: Should discontinue parenteral antimicrobial agents and discharge hospitalized patients when all of the following criteria are met: (1) culture results are negative for 24–36 h or only positive for contaminants; (2) the infant continues to appear clinically well or is improving (eg, fever, feeding); (3) there are no other reasons for hospitalization.	Grade: B; Strong Recommendation
KAS 7b: Should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment.	Grade: A; Strong Recommendation
Infants 22 to 28 d of age (KASs 8–4): Clinicians . . .	
KAS 8: Should obtain urine specimen by catheterization or SPA of bladder for urinalysis and, if urinalysis result is positive, for culture.	Grade: A; Strong Recommendation
OR Should obtain urine specimen by bag, spontaneous void, or stimulated void for urinalysis and, if urinalysis result is positive, obtain a catheterization or SPA specimen for culture.	Grade: A Strong Recommendation
KAS 9: Should obtain a blood culture.	Grade: A; Strong Recommendation
KAS 10: Should assess IMs.	Grade: B; Strong Recommendation
KAS 11a: Clinicians may obtain a CSF analysis on infants 22–28 d of age even if all of the following criteria are met: (1) urinalysis result is negative or positive; (2) no IM obtained is abnormal; (3) blood and urine cultures have been obtained; (4) infant is hospitalized.	Grade: B; Moderate Recommendation
KAS 11b. Should obtain CSF for analysis (WBC count, protein, glucose, Gram stain), and bacterial culture if any IM obtained is abnormal.	Grade: C; Moderate Recommendation
KAS 12a. Should administer parenteral antimicrobial therapy in a hospital if either of the following apply: (1) CSF analysis suggests bacterial meningitis; (2) urinalysis result is positive.	Grade: A; Strong Recommendation
KAS 12b. May administer parenteral antimicrobial therapy in a hospital if ALL of the following apply: (1) CSF analysis is normal; (2) urinalysis is normal; (3) Any IM obtained is abnormal.	Grade: B; Moderate Recommendation
KAS 12c. May administer parenteral antimicrobial therapy to hospitalized infants even if ALL of the following are met: (1) urinalysis is normal; (2) no IM obtained is abnormal; (3) CSF analysis is normal or enterovirus-positive.	Grade: B; Weak Recommendation
KAS 12d: Should administer parenteral antimicrobial therapy for infants who will be managed at home even if ALL of the following are met: (1) urinalysis is normal; (2) No IM obtained is abnormal; (3) CSF analysis is normal.	Grade: C; Moderate Recommendation
KAS 13a: May manage infants at home if all of the following criteria are met: (1) Urinalysis is normal; (2) No IM obtained is abnormal. (3) CSF analysis is normal or enterovirus-positive. (4) Verbal teaching and written instructions have been provided for monitoring throughout the period of time at home. (5) Follow-up plans for reevaluation in 24 h have been developed and are in place. (6) Plans have been developed and are in place in case of change in clinical status, including means of communication between family and providers and access to emergency medical care.	Grade: B; Moderate Recommendation
KAS 13b: Should hospitalize infants in a facility with nurses and staff experienced in the care of neonates/young infants when CSF is not obtained or is uninterpretable.	Grade: B; Weak Recommendation
KAS 14a: Should discontinue antimicrobial agents and discharge hospitalized infants after 24 to 36 h of negative culture results if the following are met: (1) the infant is clinically well or improving (eg, fever, feeding); (2) there are no other reasons for hospitalization; (3) there is no other infection requiring treatment (eg, otitis media).	Grade: B; Strong Recommendation
KAS 14b: Should discontinue antimicrobial agents on infants managed at home when all of the following criteria are met: (1) infant is clinically well or improving (eg, fever, feeding) at time of reassessment; (2) all culture results are negative at 24–36 h; (3) there is no other infection requiring treatment (eg, otitis media).	Grade: B; Strong Recommendation
KAS 14c: Should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment.	Grade: A; Strong Recommendation
Infants 29 to 60 d of age (KASs 15-21): Clinicians . . .	
KAS 15: Should obtain urine specimen by bag, spontaneous void, or stimulated void for urinalysis and, if urinalysis result is positive, obtain a catheterization or SPA specimen for culture.	Grade: A; Strong Recommendation
or Should obtain urine specimen by catheterization or SPA of bladder for urinalysis and, if result is positive, for culture.	Grade: A; Strong Recommendation

TABLE 1 Continued

	Evidence Quality; Strength of Recommendation
KAS 16: Should obtain a blood culture.	Grade: B; Moderate Recommendation
KAS 17: Should assess IMs.	Grade: B; Moderate Recommendation
KAS 18a: May obtain CSF for analysis (WBC count, differential, protein, glucose, Gram stain), culture for bacteria, and test for enterovirus when CSF pleocytosis is detected or during enterovirus season if any IM is abnormal.	Grade: C; Weak Recommendation
KAS 18b: Need not obtain CSF for analysis and culture if all IMs obtained are normal.	Grade: B; Moderate Recommendation
KAS 19a: Should use parenteral antimicrobial therapy if CSF analysis suggests bacterial meningitis.	Grade: A; Strong Recommendation
KAS 19b: May use parenteral antimicrobial therapy if both of the following apply: (1) CSF analysis (if CSF obtained) is normal; (2) any IM obtained is abnormal.	Grade: B; Moderate Recommendation
KAS 19c: Should initiate oral antimicrobial therapy if all of the following apply: (1) CSF analysis (if CSF obtained) is normal; (2) urinalysis result is positive; (3) no IM obtained is abnormal.	Grade: B; Strong Recommendation
KAS 19d: Need not use antimicrobial therapy while awaiting bacterial culture results if all of the following are met: (1) CSF analysis, if CSF obtained, is normal or enterovirus-positive; (2) urinalysis result is negative; (3) no IM obtained is abnormal.	Grade: B; Moderate Recommendation
KAS 20a: Should hospitalize infants in a unit with nurses and staff experienced in the care of 29- to 60-d-old infants if CSF analysis, if CSF obtained, is abnormal.	Grade: A; Strong recommendation
KAS 20b: May hospitalize infants in a unit with nurses and staff experienced in the care of 29- to 60-d-old infants if any IM obtained is abnormal.	Grade: B; Moderate recommendation
KAS 20c: Should manage patients at home if all of the following criteria are met: (1) CSF analysis, if CSF obtained, is normal; (2) urinalysis result is negative; (3) all IMs obtained are normal; (4) appropriate parental education has been provided; (5) follow-up plans for reevaluation in 24 h have been developed and are in place (6) plans have been developed and are in place in case of change in clinical status, including means of communication between family and providers and access to emergency medical care.	Grade: B; Moderate Recommendation
KAS 20d: May manage infants without antimicrobial treatment at home without having obtained interpretable CSF if all of the following are met: (1) urinalysis result is negative; (2) all IMs obtained are normal; (3) parents can return promptly if there is a change in infant condition and agree to follow-up in 24 to 36 h. Infants monitored at home should be reassessed in the following 24 h.	Grade: B; Moderate Recommendation
KAS 21a. Should discontinue antimicrobial agents when all of the following are met: (1) all bacterial culture results are negative at 24–36 h; (2) infant is clinically well or improving (eg, fever, feeding); (3) there is no other infection requiring treatment (eg, otitis media).	Grade: B; Strong Recommendation
KAS 21b: Should discharge hospitalized patients with positive urine culture (UTI) results if all of the following are met: (1) blood culture result is negative; (2) result of CSF culture, if obtained, is negative; (3) infant is clinically well or improving (eg, fever, feeding); (4) there are no other reasons for hospitalization.	Grade: B; Strong Recommendation
KAS 21c: Should discontinue parenteral antibiotics (if started) and begin or continue oral antimicrobial for infants with UTIs managed at home when all of the following are met: (1) urine culture result is positive; (2) all other bacterial culture results are negative at 24–36 h; (3) infant is clinically well or improving (eg, fever, feeding).	Grade: B; Strong Recommendation
KAS 21d: Should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment.	Grade: A; Strong Recommendation

study found statistically significant reductions in the prevalence of IBI when compared with viral-negative infants.[50] Other studies revealed lower rates of IBI but not statistically significantly lower.[44,47,48] In a prospective PECARN study for infants <28 days of age, bacteremia was detected in 1.1% and meningitis in 0.8% of infants with detected viral infections.[48] The risks of IBI in viral-positive infants <28 days of age are sufficiently high to warrant similar testing and treatment as viral-negative infants.

For infants 29 to 60 days of age, the bacteremia rate was significantly lower in viral-positive infants compared with viral-negative infants (0.6% vs 1.8%).[48] Another recent study of 29- to 90-day old infants detected bacteremia in 3.7% of viral-negative infants, whereas those with rhinovirus infections had a prevalence of 1.4% and a reduced relative risk of 0.52 (95% confidence interval [CI], 0.34–0.81).[50] There are situations in which viral testing may augment the recommended evaluation and management of febrile infants 29 days and older, such as during RSV, bronchiolitis,[51] or influenza seasonal outbreaks. In these situations, individual tests for RSV or influenza can each be obtained at <3% the cost of a multiplex respiratory viral panel, according to the latest charges listed in *Current Procedural Terminology*; the cost of multiplex testing in other countries has been reported to be substantially lower. In

KAS 1: Clinicians should obtain urine specimen by catheterization or SPA of bladder for urinalysis and, if urinalysis result is positive, for culture. Evidence Quality: A; Strong Recommendation

Benefits	Identification of UTIs Basing culture on urinalysis results reduces likelihood of false-positive result attributable to contamination or misdiagnosis of asymptomatic bacteriuria.
Risks, harm, cost	Requiring positive urinalysis result may miss some true UTIs. Obtaining culture if negative urinalysis result may result in falsely positive culture attributable to contamination or misdiagnosis of asymptomatic bacteriuria leading to inaccurate documentation of a first UTI (which may prompt unnecessary imaging should a UTI occur subsequently). Discomfort of catheterization or SPA. Parent anxiety.
Benefit–harm assessment	Preponderance of benefit based on high rate of UTI.
Shared decision-making	Parents opposed to catheterization should be offered a choice of SPA and informed about the higher rate of ambiguous/false-positive culture results obtained from bagged or voided specimens.[77,78]
Key references	73, 77–93

summary, although viral testing should not affect entrance into the recommended pathway, for infants >28 days of age, it can be considered in individualizing evaluation and management decisions.

Summary of KASs for Evaluation and Management of Well-Appearing Febrile Infants: 8 to 21, 22 to 28, and 29 to 60 Days of Age (Table 1)

WELL-APPEARING 8- TO 21-DAY-OLD INFANTS

Diagnostic Evaluation

The following recommendations and options are for febrile (temperature ≥38.0°C), well-appearing, term infants 8 to 21 days of age without risk factors identified in the exclusion criteria.

KAS 1: Clinicians should obtain urine specimen by catheterization or SPA of bladder for urinalysis and, if urinalysis result is positive, for culture. Evidence Quality: A; Strong Recommendation

A positive urinalysis result for purposes of this guideline is defined as the presence of any leukocyte esterase (LE) on dipstick, >5 WBCs per high-powered field (hpf) in centrifuged urine, or >10 WBCs/mm^3 in uncentrifuged urine on microscopic urinalysis using a hemocytometer.

Urinalysis: Of the estimated 10% of febrile infants with UTIs, 94% have urinalysis positive for leukocyte esterase (LE) (95% CI, 91%– to 97%).[80] The sensitivity is even higher for UTI associated with bacteremia (97.6% and 100% in 2 studies).[80,86] Therefore, for 1000 infants, ∼approximately 94 to 98 infants with UTIs will be detected by a positive urinalysis result, and 2 to 6 may be "missed." It is unclear whether a "miss" represents a UTI, asymptomatic bacteriuria, or contamination. Consequently, if a urinalysis result is negative, an estimated 200 to 500 catheterizations or suprapubic aspirations (SPAs) followed by cultures would be required to detect 1 additional infant with bacteriuria, and that infant might have asymptomatic bacteriuria or contamination rather than a true UTI.

Culture: In the AAP clinical practice guideline on UTI from 2011, reaffirmed in 2016, addressing infants 2 to 24 months of age, the diagnosis of UTI was made on the basis of pyuria and at least 50 000 colony-forming units (cfu) per mL of a single uropathogenic organism in an appropriately collected specimen of urine.[73] Recent studies indicate it

KAS 2: Clinicians should obtain a blood culture. Evidence Quality: A; Strong Recommendation

Benefits	Identification of bacteremia: 3.9% to 5.1% of all febrile infants in this age group[17,24,61,94]; 15% to 20% of infants younger than 28 d with UTI.[91,93,94] Identification of organism (and sensitivities) for directed antimicrobial treatment. Early detection and treatment may prevent progression of infection.
Risks, harm, cost	False-positive results: Most positive blood cultures in febrile infants are attributable to contaminants (63% to 88%),[25,27,30] potentially leading to unnecessary use of antimicrobial agents, further or repeat testing, and prolonged hospitalization. Discomfort of venipuncture. Costs can be substantial depending on further testing, treatment, and hospitalization after a false-positive culture result.
Benefit–harm assessment	Preponderance of benefit.
Shared decision-making	Parents can be made aware that testing is based on the high likelihood of bacteremia, especially in infants with a positive urinalysis result. Parents can be informed of potential challenges that may be encountered in distinguishing pathogens from contaminants as part of explaining the evaluation process.
Key references	27,61,93

KAS 3: Clinicians may assess IMs. Evidence Quality: B; Weak Recommendation

Benefits	For infants with negative urinalysis and negative CSF analysis results, abnormal IM results may influence decisions regarding when to discontinue antimicrobial therapy and hospitalization in infants with negative culture results.
Risks, harm, cost	False-negative results, underestimating risk of bacteremia or bacterial meningitis with normal IMs.[16,27,39] False-positive results, overestimating the risk of bacteremia or bacterial meningitis. Adds additional, marginal cost as it is recommended all infants in this age group will be hospitalized.
Benefit–harm assessment	Balance of benefit and harm.
Key references	18–20, 39, 60, 107

A detailed discussion of IMs follows KAS 10.[95–105]

is reasonable to extend the recommendation of the AAP UTI guideline to infants addressed here,[77–80,85–89] although 10 000 colony-forming units/mL is now an acceptable threshold for diagnosing UTI from catheterized urine specimens when pyuria and fever are also present.[80,89] This new level also circumvents the problem of interpreting data from laboratories not reporting gradations from 10 000 to 100 000. Positive urine culture results obtained in the absence of an abnormal urinalysis indicating inflammation are likely to represent asymptomatic bacteriuria or contamination.

Culture of urine specimens not collected by catheterization or SPA is not recommended because of an unacceptable rate of false-positive results attributable to contamination of such specimens.[77,78] An initial urine specimen obtained by catheter or SPA obviates the delay and need for a second specimen by catheter or SPA following after a positive result from a bag urine. The sensitivity and specificity of urinalysis parameters for UTI from bagged specimens are somewhat less than those of catheterized specimens.[77,78]

For physicians with experience, SPA is effective, provides the "cleanest" specimen, and saves time; complications are rare.[81] In some situations, such as phimosis or labial adhesions, SPA may be required[73]; a training video is available online.[82]

KAS 4: Clinicians should obtain CSF for analysis (WBC count, protein, glucose, Gram stain), and culture for bacteria. See notes for viral testing. Evidence Quality: A; Strong Recommendation

Benefits	Early detection of bacterial meningitis. The prevalence of meningitis is 0.5%–1.3% in this age group.[24,94] Detection of CSF pleocytosis or elevated protein attributable to HSV infection. Early treatment may decrease neurologic morbidity. Identification of pathogen from CSF to target type and duration of antimicrobial treatment. A normal CSF analysis helps in the decision whether to discharge infants at 24 to 36 h. Avoids unnecessarily prolonged antimicrobial therapy if CSF was obtained after antimicrobial agents started and diagnosis of meningitis is uncertain.
Risks, harm, cost	Discomfort for infant. Potential for transient respiratory compromise during positioning for LP. Traumatic LPs yielding uninterpretable CSFs have been documented to prolong length of stay for hospitalized infants. False-positive CSF culture results[27,106,107] prolonging hospitalization. Substantial cost if hospitalizing because of ambiguous CSF or prolonged hospitalization for bacterial contaminant. Parental anxiety.
Benefit–harm assessment	Preponderance of benefit.
Shared decision-making	Parents must consent to this procedure. If, for whatever reason, a parent is resistant or unwilling to consent to an LP, the risk of meningitis, the evidence quality, benefit/harm assessment, and value judgments should be communicated to the parent to foster informed decision-making. The potential need for a future LP, depending on further clinical information and progress, is an important part of the discussion. These discussions should be documented.
Key references	66–70, 108, 111, 137

KAS 2: Clinicians should obtain a blood culture. Evidence Quality: A; Strong Recommendation

KAS 3: Clinicians may assess IMs. Evidence Quality: B; Weak Recommendation

Because it is recommended that all 8- to 21-day-old infants be hospitalized and treated, IMs are not required for these initial decisions. However, some clinicians consider them useful in decision-making about later management, such as whether to discontinue antimicrobial agents at 24 or 36 hours while awaiting final results of bacterial cultures.

KAS 4: Clinicians should obtain CSF for analysis (WBC count, protein, glucose, Gram stain), and culture for bacteria. See notes for viral testing. Evidence Quality: A; Strong Recommendation.

CSF with pleocytosis or from infants with HSV risk factors should be evaluated for HSV.[116,117] Population-based rates of HSV in neonates range from 2 to 5 per 100 000, with 15% having fever as the only symptom.[108–116] Although rare in well-appearing infants, prompt recognition and treatment of HSV in infants, especially those younger than 21 days with other risk factors, is essential. In addition to the presence of vesicles and/or seizures, infants should be

considered at increased risk of HSV if any of the following are present: CSF pleocytosis with a negative Gram stain, leukopenia, thrombocytopenia, hypothermia, mucous membrane ulcers, or maternal history of genital HSV lesions or fever from 48 hours before to 48 hours after delivery. If liver function tests were obtained, an elevated alanine aminotransferase (ALT) also indicates a higher risk of HSV. For further details of evaluation and management of HSV, see the AAP *Red Book*.[111]

Enterovirus (EV) PCR testing should be performed on CSF with pleocytosis and during months when there is a seasonal increase in enterovirus, regardless of pleocytosis. Rapid detection of enterovirus, along with HSV and an emerging viral cause of meningitis, human parechovirus (HPeV), can be accomplished with meningoencephalitis multiplex PCR panels identifying 14 pathogens.[43,118,119] When available in a timely fashion, multiplex PCR testing can enhance clinical decision-making.

Pleocytosis is detected overall in 8.8% of CSF analyses; the rate is higher in summer (17%) because of enterovirus.[117] The likelihood of bacterial meningitis in the presence of enterovirus in the CSF is low.[120] Therefore, the detection of CSF enterovirus can eliminate the need for further interventions.[121,122] Newer tests provide rapid identification of enterovirus.[123,124] CSF pleocytosis is often detected in febrile infants with

KAS 5: Clinicians should initiate parenteral antimicrobial therapy. Evidence Quality: A; Strong Recommendation

Benefits	Anticipated reduction in morbidity and mortality from bacterial infections.
Risks, harm, cost	Adverse drug reactions including anaphylaxis (rare). Complications related to intravenous lines including infiltration, infection, nerve compression (in ankle). Potential disruption of evolving microbiome. Development of antimicrobial resistance.
Benefit–harm assessment	Preponderance of benefit.
Key references	15, 17–20, 25, 27, 30, 145

UTIs who do not have bacterial, enterovirus or HSV meningitis.[126–128] These panels can give rapid results but should only be used as an addition to bacterial cultures. There are still relatively limited data on young infants so precise test accuracy is still uncertain, and there have been reports of both false-positive and false-negative results; *Listeria* is not in the panel.[118,119]

An LP is not always successful. The rate of failure and/or traumatic LP in infants younger than 90 days is 20% to 50%; the rate of unsuccessful or dry LP is 25% to 40%; the rate of bloody LP is 10% to 30%.[106,130–132] Ultrasonography may assist in obtaining CSF.[133] When using a bedside ultrasound landmark-guided technique, success in obtaining CSF on the first LP attempt was 58% compared with 31% without ultrasonography. Using ultrasonography resulted in a 75% success rate after 3 attempts.[135]

There is also a significant rate of nonpathogenic bacteria cultured from CSF. In a multisite study with 410 positive CSF bacterial culture results in infants <90 days of age, researchers found only 13% were pathogens and the rest were contaminants.[107] Authors of another study from Kaiser Permanente Northern California found only 22% of CSF isolates from infants <90 days to be pathogens.[27] Authors in a study of febrile infants in the second month of life found that 40 of 41 positive culture results were caused by contaminants.[106]

The CSF from a traumatic LP should be cultured and can be tested for HSV if indicated. In general, correction (or ratios) for red blood cells (RBCs) in CSF is discouraged because of lack of validating studies. It is reasonable to interpret CSF WBC counts at face value in CSF specimens with up to 10 000 RBCs per mm^3 (Table 2).[133]

INITIAL TREATMENT

The antimicrobial agents in Table 3 are recommended for initial empirical therapy and should be modified following results of cultures and sensitivities.

TABLE 2 CSF Values in Febrile Infants Without Evidence of UTI, IBI, HSV, Enterovirus, or Traumatic CSF

	Age, d	*n*	Mean	Median	Range
WBCs per mm^3	1–28	278	6.1	5.0	0–18
	29–60	318	3.1	3.0	0–8.5
Protein mg/dL	1–28	278	75.4	73.0	15.8–131.0
	29–60	318	58.9	54.0	5.5–105.5
Glucose	1–28	278	45.3	46.0	30.0–61.0
Glucose	29–60	318	48.0	48.0	20.6–65.5
RBCs per mm^3	1–28	278	95.5	5.5	0–236
RBCs per mm^3	29–60	318	75.5	2.0	0–64.5

Statistical outliers were removed. Other studies reveal slightly different ranges. Local laboratory tests may provide slightly different upper limits of normal. Adapted from Byington CL, Kendrick J, Sheng X. Normative cerebrospinal fluid profiles in febrile infants. *J Pediatr*. 2011;158(1):130–134.

KAS 6: Clinicians should actively monitor infants while awaiting results of bacterial cultures in a hospital setting with nurses and staff experienced in the care of neonates and young infants. Evidence Quality: B; Moderate Recommendation

Benefits	Hospitalization allows ongoing monitoring for a change in clinical status and the ability to change management and/or expeditiously transfer to a more intensively monitored unit if required. Relieves parents of monitoring responsibility and may reduce anxiety. Provides ability to administer intravenous antimicrobial agents.
Risks, harm, cost	Hospitalization increases risk of hospital-acquired infections. Increased risk of iatrogenic events related to intravenous catheters. Parental anxiety about infant's condition and financial strain. Stress to mothers because of breastfeeding challenges and separation from other children. Substantial cost.
Benefit–harm assessment	Preponderance of benefit.
Shared decision-making	Although monitoring in a hospital is recommended, parents have the right to refuse. Risks and consequences of IBI and of hospitalization should be discussed. In the event parents choose to return home, parents should understand criteria for returning to the hospital discussed in KAS 13.
Key references	57, 68–70, 136

KAS 5: Clinicians should initiate parenteral antimicrobial therapy. Evidence Quality: A; Strong Recommendation

The recommendation to treat all infants 8 to 21 d of age is based on the prevalence of IBIs being highest in this age category (Fig 4) and ~2% (number needed to treat 50) even in infants with negative urinalysis and or IMs. The preponderance of evidence indicates that infants with viral infections have a risk of IBI of ~1% or a number needed to treat of 100. See above discussion.

Overall, for studies since the year 2000 in infants <90 days of age, Gram-negative organisms have been responsible for the majority of infections (60% to 80%). *E coli* has been the most common pathogen detected, with a prevalence of 70% to 90% of UTIs, 30% to 60% of bacteremia infections, and 15% to 30% of bacterial meningitis.[17,26,31,39,61,94] The prevalence of GBS infection in the first week of life has declined because of prenatal screening and peripartum antimicrobial prophylaxis but is still encountered in >20% of febrile infants with bacteremia after the first week. In a 2013 series, GBS was the most common pathogen in the second month[30] and was the most common cause of meningitis in the 2019 Reducing Variability in the Infant Sepsis Evaluation study.[31] *L monocytogenes* is rarely encountered.[29–33]

Enteroviral testing of CSF has been shown to shorten length of stay and duration of antimicrobial use.[120,137] It is helpful if available within a time period that will assist clinical decision-making. In general, if CSF is positive for enterovirus, antimicrobial agents should be discontinued (or withheld), because concomitant enteroviral and bacterial meningitis is rare. However, in some cases of enterovirus meningitis or meningoencephalitis, CSF may reveal a significant pleocytosis with a neutrophil predominance. In such cases, or in cases in which there is otherwise reason to suspect a concomitant bacterial infection, such as abnormal IMs, it is reasonable to continue antimicrobial agents until CSF and blood cultures are negative for 24 to 36 hours.

In communities with circulation of *E coli* strains that produce extended-spectrum β-lactamases, gentamicin should be used instead of ceftazidime for treatment of suspected bacteremia or sepsis, and meropenem should be used

KAS 7a: Clinicians should discontinue parenteral antimicrobial agents and discharge hospitalized patients when all of the following criteria are met: (1) culture results are negative for 24–36 h or only positive for contaminants; (2) the infant continues to appear clinically well or is improving (eg, fever, feeding); and (3) there are no other reasons for hospitalization. Evidence Quality: B; Strong Recommendation

Benefits	Discontinuing antimicrobial agents minimizes risk of adverse treatment consequence. Reduces impact on microbiome. Contributes to antimicrobial stewardship. Discharge minimizes exposure to nosocomial infections and iatrogenic exposures. Limits family disruption. Reduces cost of illness episode.
Risks, harm, cost	Inadequate duration of therapy with antimicrobial (if treated) for bacterial pathogen not identified before discontinuation. Potential clinical deterioration at home if inadequate treatment of pathogen not detected before discharge.
Benefit–harm assessment	Preponderance of benefit.
Shared decision-making	Parents should be made aware of the low risk of undetected pathogens after 24 to 36 h and be able to return in a timely fashion for: Change in general appearance particularly a dusky color, or respiratory or other distress; Behavior change, including lethargy, irritability, inconsolable crying, difficulty in consoling or comforting, or other evidence of distress; Difficulty feeding; Vomiting; Decreased urine output.
Key references	57, 107, 138–144

KAS 7b: Clinicians should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment. Evidence Quality: A; Strong Recommendation

Benefits	Treats infection. Reduces likelihood of morbidity. Contributes to antimicrobial stewardship.
Risks, harm, cost	Adverse reaction to antimicrobial. Interferes with infant's evolving microbiome. Accelerates emergence of antimicrobial resistance.
Benefit–harm assessment	Preponderance of benefit.
Key references	145

instead of ceftazidime when bacterial meningitis is suspected. Use of fourth- and fifth-generation cephalosporins may also be considered with expert consultation.

Cephalosporins do not provide adequate coverage for *Listeria* or enterococci. Ampicillin generally should be used as part of empirical therapy when these microbes are suspected.

FURTHER MANAGEMENT AND MONITORING

KAS 6: Clinicians should actively monitor infants while awaiting results of bacterial cultures in a hospital setting with nurses and staff experienced in the care of neonates and young infants. Evidence Quality: B; Moderate Recommendation

The committee recommends that, to improve the care of hospitalized infants, efforts should be directed at optimizing the environment to support maternal/child bonding and breastfeeding. This can be accomplished through the following effective measures: allow parents to room-in with the infant; encourage the continuation of breastfeeding and provide lactation support including access to breast pumps for nursing mothers; provide timely communication with families about the results and interpretation of testing and expected consequences of having a diagnosis of UTI, bacteremia, and/or bacterial meningitis on the basis of ongoing results; provide timely communication with the infant's primary care provider.

KAS 7a: Clinicians should discontinue parenteral antimicrobial agents and discharge hospitalized patients when all of the following criteria are met:

1. **culture results are negative for 24 to 36 hours or only positive for contaminants;**
2. **the infant continues to appear clinically well or is improving (eg, fever, feeding); and**
3. **there are no other reasons for hospitalization.**

Evidence Quality: B; Strong Recommendation

Although infants whose CSF is positive for enterovirus may be observed without antimicrobial agents, they should remain in a hospital setting for a minimum of 24 h because of the small risk of progression to enteroviral sepsis, which generally only occurs in infants <21 d of age.

Discontinuation of antimicrobial agents and discharge at 36 hours can potentially result in a lapse of treatment of a slow-growing pathogen and readmission, but this has seldom been reported. Automated blood culture techniques and multiplex PCR detection have reduced the time to identify pathogens.[40–42] Time to positivity of blood culture is dependent on the type and concentration of bacterial organism. Between 4% and 17.6% of pathogens take >24 hours to grow; less than 5% take >36 hours.[138–144] Compared with ill-appearing infants, infants not appearing ill are less likely to have pathogens identified in <24 hours (85.0% vs 92.9%). Pathogens vary in median times to positivity: GBS takes 9.3–14.3 hours[138–140,143]; *E coli* takes 11.3–13.6 hours[138,140,143]; and *S aureus* takes 18.5–19.9 hours.[138–140,143] For *E coli*, the most common organism identified, 24% take longer than 24 hours to grow, whereas only 5.9% of GBS grow after 24 hours.[138]

KAS 8: Clinicians should obtain urine specimen by catheterization or SPA of bladder for urinalysis and, if urinalysis result is positive, for culture, or should obtain urine specimen by bag, spontaneous void, or stimulated void for urinalysis and, if urinalysis is positive, obtain a catheterization or SPA specimen for culture. Evidence Quality: A; Strong Recommendation

Benefits	Identification of UTIs.
Risks, harm, cost	Falsely positive culture result (contamination) or misdiagnosis of asymptomatic bacteriuria leading to unnecessary and potentially harmful treatment and inaccurate documentation of a first UTI (which may prompt unnecessary imaging should a UTI occur subsequently). Discomfort of catheterization or SPA. Parent anxiety.
Benefit–harm assessment	Preponderance of benefit.
Role of parent preferences	Parents opposed to catheterization should be offered a choice of SPA and informed about the higher rate of ambiguous or false-positive culture results obtained from bagged or voided specimens.[77,78] A false-positive urine culture result can potentially prolong antimicrobial administration and duration of hospitalization.
Key references	73, 77, 93

For detailed discussion, see KAS 1.

KAS 9: Clinicians should obtain blood culture. Evidence Quality: A; Strong Recommendation

Benefits	Identification of bacteremia: 1.6% to 5% of all febrile infants in this age group[17,24,61,94]; 7.5% to 10% of infants with UTI.[10,26,91–93] Identification of organism (and sensitivities) for targeted antimicrobial treatment. Early detection and treatment may prevent progression of infection.
Risks, harm, cost	False-positive results: most positive blood cultures in febrile infants are attributable to contaminants,[23,27,30] potentially leading to unnecessary use of antimicrobial agents, further or repeat testing, and prolonged hospitalization. Discomfort of venipuncture. Costs can be substantial depending on further testing, treatment, and/or hospitalization after a false-positive culture result.
Benefit–harm assessment	Preponderance of benefit.
Key references	27, 30, 61

Nonpathogens generally take longer than 24 hours to grow in culture media. Approximately 25% of nonpathogens grow in the first 24 hours.[138] Antimicrobials can be stopped at 24 hours if a pure growth of a nonpathogen is identified. When available, multiplex PCR is capable of detecting many bacterial pathogens and antimicrobial resistance from a positive culture medium in an hour.[40–43]

KAS 7b: Clinicians should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment. Evidence Quality: A; Strong Recommendation

WELL-APPEARING 22- TO 28-DAY-OLD INFANTS

The following recommendations and options are for febrile (temperature >38.0°C), well-appearing, term infants 22 to 28 days old without risk factors identified in the exclusion criteria.

The evidence indicates the risk of bacteremia and bacterial meningitis is lower in infants 22 to 28 days of age than in infants 8 to 21 days of age. However, they continue to be at higher risk than older infants, leading us to separate this group as discussed above in the section on "Evidence for Age-based Risk Stratification."

Diagnostic Evaluation

KAS 8: Clinicians should obtain urine specimen by catheterization or SPA of bladder for urinalysis and, if urinalysis result is positive, for culture, or should obtain urine specimen by bag, spontaneous void, or stimulated void for urinalysis and, if urinalysis is positive, obtain a catheterization or SPA specimen for culture. Evidence Quality: A; Strong Recommendation

KAS 9: Clinicians should obtain blood culture. Evidence Quality: A; Strong Recommendation

KAS 10: Clinicians should assess IMs. Evidence Quality: B; Strong Recommendation

IMs have been included in every strategy proposed to address febrile infants. No single IM, in isolation, is reliable for risk stratification. Further study will allow ongoing accumulation of evidence and more precise values for these markers. The committee anticipates modification and refinement as efforts to improve the care of febrile infants continue.

- Temperature >38.5°C: A sign of inflammation, fever is the most readily available marker of infection. Surprisingly, it was not included in early studies of decision models,[10–15] but there has been ongoing and recent work on the value of fever elevation in predicting IBI.[16,17,48,57,60,95,96,147] It emerged as an important predictor in studies using recursive partitioning analysis to derive threshold fever values for prediction rules.[16,17] In the PROS Network study of 3066 infants with 63 cases of IBI, a temperature >38.5°C, when combined with ill appearance and age <25 days, had a sensitivity of 93.7% and NPV of 99.6%.[17] A temperature ≥38.5°C at any point during the ED stay placed infants at higher risk in a study of 207 cases of IBI in well-appearing febrile infants ≤60 days seen in the EDs of 11 children's hospitals in the Febrile Young Infant Research Collaborative.[60] Researchers in a PECARN analysis addressing SBI documented an increased in adjusted odds ratio of 1.8 for each 1°C increase >38.0.[48] Also, a temperature <38.5°C is used in

KAS 10: Clinicians should assess IMs. Evidence Quality: B; Strong Recommendation

Benefits	For infants with negative urinalysis and/or pending urine results and/or blood and/or CSF cultures, IMs may influence the decision whether to initiate antimicrobial agents. For an infant with a negative urinalysis result and pending blood culture result, the absence of abnormal IMs may contribute to the decision of whether to perform LPs in infants 22 to 28 d of age. In the presence of a negative CSF analysis or bloody or failed LP, normal IMs may influence decisions regarding hospitalization, initiation of antimicrobial agents, and duration of treatment.
Risks, harm, cost	False-negative results, underestimating risk of bacteremia or bacterial meningitis with normal IMs. False-positive results, overestimating the risk of bacteremia and bacterial meningitis (see discussion below).
Benefit–harm assessment	Preponderance of benefit.
Key references	13–16, 18–20, 37–39, 60, 97–105, 146

For purposes of this guideline, IMs are considered abnormal at the following levels: temperature >38.5°C, ANC >4000, 5200 per mm^3, CRP >20 mg/L, procalcitonin >0.5 ng/mL.

Intermountain Healthcare's Care Process Model to distinguish whether there is a need for further testing in infants older than 28 days who test positive for RSV.[57] Recently, by adding a temperature >38.5°C as an additional high-risk criterion to the Rochester criteria in 7- to 28-day-old infants, the Roseville Protocol documented a sensitivity of 96.7%.[147] Therefore, moderately elevated temperatures are useful in predicting IBI and can immediately suggest how extensive an evaluation may be appropriate. However, as an independent predictor, 30% of febrile infants with IBI have maximum documented fevers of ≤38.5.[96] Temperature elevation is a useful predictor of IBI when combined with other clinical features, and laboratory-based IMs can improve the sensitivity for detecting IBI.

- Elevated WBC count and its components: These tests are widely available, but with an evolving epidemiology of IBI and availability of newer tests, their usefulness in predicting IBIs is changing. The arbitrary thresholds (WBC count >15 000 per mm^3, ANC >10 000 per mm^3, band count >1500 per mm^3, immature to total neutrophil ratio >0.2) that define "abnormal" have been used in numerous studies of predictive models.[10–15,19,20] These studies all used WBC count components in combination with other infant characteristics such as well appearance, or urinalysis results, to identify low-risk infants. Researchers who analyzed WBC count and/or ANC as independent predictors of IBI[16,39,103,104] have documented that as a stand-alone screen, neither is sufficiently sensitive nor specific, although ANC is substantially better than the WBC count. Researchers in an ED study of 5279 infants <90 days of age identified 68 infants with IBIs.[16] Using a derived multivariable prediction rule with recursive partitioning analysis, they found that there were 14 misclassified cases of bacteremia and 1 case of bacterial meningitis. Of these 15 infants, 9 had "normal" WBC counts (5000–15 000/mm^3). This study indicates that a normal WBC count is not reassuring.[16] In a French study of 2047 febrile infants seen in 15 pediatric EDs, the area under the curve (AUC) for WBC count was 0.48 compared with 0.61 for ANC.[39] In the PROS study, an abnormal WBC count (<5000/mm^3, >15 000/mm^3) was significant in a multivariate analysis with an adjusted odds ratio of 3.62 (95% CI, 2.13–6.15) and slightly increased the AUC of a non–laboratory-based model from 0.767 to 0.803. The committee does not recommend use of abnormal WBC count for risk stratification.
- ANC: >4000,[18] >5200[60] cells per mm^3. Although arbitrary values of ANC continue to be included in decision models, researchers in 2 studies methodologically derived optimal cutoffs. The subcommittee presents both values (>4000, >5200), reflecting the current state of the evidence.

1. In a prospective study of 1821 febrile infants with 30 cases of IBI younger than 60 days, the PECARN group used recursive partitioning to derive optimal thresholds for detecting IBI. This study found that an ANC of >4090 per mm^3, when combined with an abnormal urinalysis and a procalcitonin of greater than 1.7 ng/mL, detected 29 of 30 cases, 96.7% (95% CI, 83.3%–99.4%) with a specificity of 61.5%.[18] No case of meningitis was missed.
2. The Febrile Young Infant Research Collaborative study did not include procalcitonin but methodologically derived an ANC ≥5185 per mm^3 as part of a scoring system to identify IBIs retrospectively. The sensitivity of its scoring system for 207 cases of IBIs was 98.8% (95% CI, 95.7%–99.9%) but had a specificity of 31.3%; none of the 26 cases of bacterial meningitis was missed.[60]

The step-by-step method proposed by the European Collaborative of 11 EDs[19,20] selected a higher ANC threshold (10 000) for its model and detected 81 of 87 infants with IBIs. No cases of bacterial meningitis were missed; the sensitivity for IBIs was 92% (95% CI, 85.0%–97.2%), lower than the 2 American studies. The only prospective office-based study, using recursive partitioning, did not identify ANC as a predictor for the 63 cases of IBIs.[17]

ANC is helpful but not as accurate as newer IMs.[16] In a subset analysis of 46 infants 8 to 60 days of age with bacterial meningitis, blood ANC ranged from 600 to 24 500, with a median of 4700; 39% had ANCs <4000 and 80% had ANCs <10 000.[17,20] As used in a PECARN analysis, an ANC of <4090 combined with a negative urinalysis result had a sensitivity of 76.6% (95% CI, 0.59%–0.88%); addition of procalcitonin was required to achieve the high sensitivity of its decision rule for IBI.[18] Because of availability, timeliness, and these data, an elevated ANC is a useful IM when combined with other clinical and laboratory predictors.

Although several studies have identified ANC cutoffs for infants at low risk of IBI,[18–20,60] counts <1000 should raise concerns for sepsis in the youngest infants.

- CRP (≥20 mg/L): In studies addressing laboratory markers, CRP has been shown to be more accurate than WBC count or ANC in detecting

KAS 11a: Clinicians may obtain a CSF analysis on infants 22 to 28 days of age even if all of the following criteria are met: (1) urinalysis result is negative or positive; (2) no IM obtained is abnormal; (3) blood and urine cultures have been obtained; and (4) infant is hospitalized. Evidence Quality: B; Moderate Recommendation

Benefits of testing	Early detection of bacterial meningitis.
	Detection of CSF pleocytosis or elevated protein attributable to HSV infection.
	Early treatment may decrease neurologic morbidity.
	Identification of pathogen from CSF to target type and duration of antimicrobial treatment.
	A normal CSF analysis helps in the decision whether to discharge infants at 24–36 h.
	Avoids unnecessarily prolonged antimicrobial therapy if CSF was obtained after antimicrobial agents started and diagnosis of meningitis is uncertain. This situation may occur if a blood culture grows a pathogen in 24 h and clinical circumstances suggest an LP is indicated.
Benefits of not testing	Avoids consequences of LP: discomfort or harm.
	Avoids further medical interventions because of false-positive results from CSF pleocytosis or bacterial contaminants.
	Avoids unnecessary or prolonged hospitalizations because of false-positive culture results.
	Avoids cost of procedure and unnecessary hospitalization.
	Avoids transient respiratory compromise resulting from positioning.
Risk, harm, cost of testing	Discomfort for infant.
	Potential for transient respiratory compromise during positioning for LP.
	Traumatic LPs yielding uninterpretable CSFs have been documented to prolong length of stay for hospitalized infants.[132]
	Unnecessary prolongation of hospitalization from false-positive bacterial culture result.
	Substantial cost if hospitalizing because of ambiguous CSF or prolonged hospitalization for bacterial contaminant.
	Parental anxiety.
Risks, harm, cost of not testing	In otherwise low-risk infants, delayed recognition of bacterial meningitis with increased risk of morbidity.
	Prolonged treatment if delay in obtaining CSF raises concern for partially treated meningitis.
Benefit–harm assessment	Benefit in specified situations.
Shared decision-making	Parents must provide consent for this procedure. An option by the committee to not obtain CSF for analysis is based on a consensus regarding the rate and risks of meningitis and benefit–harm assessment. Parents should be sufficiently informed to participate in this decision.
Key references	17–20, 22, 60, 106, 148

Because the prevalence of bacterial meningitis, along with the prevalence of bacteremia, declines in 22- to 28-d-old infants, the committee's tolerance for this risk resulted in a recommendation that differs from the one for 8- to 21-d-old infants.

bacteremia and meningitis.[39,101,102] As independent predictors of IBIs, the AUC for CRP was documented as 0.77 compared with 0.61 for ANC,[39] with another study producing values of 0.75 and 0.65, respectively.[146] In the absence of procalcitonin and in combination with other clinical predictors, a CRP ≥20 mg/L has identified infants at higher risk.[19,20,101] It generally can be determined in a timely fashion and has recently become available as a point-of-care test.[37]

- Procalcitonin (>0.5 ng/mL): Serum procalcitonin, as an independent predictor of bacterial infections, has better test characteristics than other laboratory markers of inflammation. In a prospective study of 15 French EDs, Milcent et al[39] identified 21 infants 7 to 90 days of age with IBIs. The AUC for procalcitonin, CRP, ANC, and WBC count were documented to be 0.91, 0.77, 0.61, and 0.48, respectively. In this study, a procalcitonin value of 0.3 ng/mL best demarcated low- and high-risk infants and in multivariate analysis was the only independent predictor of IBIs. These findings were replicated in a recent ED study from Spain[146] with 38 infants <60 days of age with IBIs. The AUC for procalcitonin, CRP, and ANC was 0.82, 0.75, and 0.65, respectively. The value of procalcitonin when used in combination with other clinical and laboratory findings is becoming clear.[18–20,38,97–105] Using a procalcitonin level of >0.5 ng/mL, along with other clinical variables, was useful in identifying a low-risk group (0.7%) for IBIs in infants >21 days but an unacceptably low sensitivity of 44% for younger infants.[100] The PECARN study, described above, demonstrated a sensitivity of 96.7% by adding an elevated procalcitonin (1.7 ng/mL) to leukocyturia and ANC >4090 mm^3. Changing the procalcitonin level to 0.5 ng/mL (and the ANC to 4000 mm^3) only minimally decreased rule specificity, so it is advocated by the PECARN investigators as a safer and easier-to-apply cutoff. Procalcitonin is the earliest IM to increase but may still be negative in febrile infants,[18] including those evaluated in the first hours after onset of fever.[146] Although it is currently the best IM available, it should not be used alone for decision-making; 20% of febrile infants with bacterial meningitis had procalcitonin <0.5 ng/mL.[20]

The committee recommends procalcitonin in all age groups. Procalcitonin testing is not yet routinely available in many institutions in the United States. If procalcitonin is unavailable or results are not reported in a timely fashion, the committee recommends using a fever of >38.5°C in combination with other IMs for purposes of risk stratification.

KAS 11a: Clinicians may obtain a CSF analysis on infants 22 to 28 days of age even if all of the following criteria are met:

1. **urinalysis result is negative or positive;**
2. **no IM obtained is abnormal;**

KAS 11b: Clinicians should obtain CSF for analysis (WBC count, protein, glucose, Gram stain) and bacterial culture if any IM obtained Is abnormal. Evidence Quality: C; Moderate Recommendation

Benefits	Early detection of bacterial meningitis. The prevalence of bacterial meningitis in this age group is 0.4% to 0.6%. [24,94] Detection of CSF pleocytosis or elevated protein attributable to HSV infection. Early treatment may lead to decreased neurologic morbidity. Identification of pathogen from CSF to target type and duration of antimicrobial treatment. Avoids unnecessarily prolonged antimicrobial therapy if CSF was obtained after antimicrobial agents started and diagnosis of meningitis is uncertain.
Risks, harm, cost	Discomfort for infant. Potential for transient respiratory compromise during positioning for LP. Traumatic LPs have been documented to prolong length of stay for hospitalized infants. Unnecessary prolongation of hospitalization from false-positive bacterial culture result. Substantial cost if hospitalizing because of ambiguous CSF or prolonged hospitalization for bacterial contaminant. Parental anxiety.
Benefit–harm assessment	Preponderance of benefit for infants with specified risk factors if CSF obtained.
Role of patient preferences	Parents must provide consent for this procedure. KAS 4 extensively discusses rates and consequences of unsuccessful LPs, uninterpretable CSFs, and false-positive bacterial culture rates. If, for whatever reason, a parent is resistant or unwilling to consent to an LP, risk of meningitis, the evidence quality, and benefit/harm assessment should be communicated to the parent to foster informed decision-making. The potential need for a future LP, depending on further clinical information and progress, is an important part of the discussion. These discussions should be documented.

For detailed discussion, including viral testing, see KAS 4.

3. **blood and urine cultures have been obtained; and**
4. **infant is hospitalized.**

Evidence Quality: B; Moderate Recommendation

There are insufficient data to estimate the probability of meningitis in this age group if only 1 IM is abnormal or if only a urinalysis result is positive. Almost all current decision rules and models rely on a combination of at least 2 IMs and a urinalysis to define risk.

Recent studies from primary care and EDs document LPs in infants <28 days of age being performed in 60% to 82% of evaluations. There is wide regional variation ranging from 10.7% to 31.3% of infants going without an LP.[23,24,148] With recent data, Kaiser Northern California documents 39% of 7- to 28-day-old infants with fever did not undergo LP. Infants evaluated in the ED were 5 times more likely to have an LP than those evaluated in the office.[22] There were no reported cases of delayed recognition of bacterial meningitis in settings in which LPs were not universally performed.

In infants <28 days of age, none of the 21 cases of bacterial meningitis in the PROS, PECARN, and step-by-step studies were missed (sensitivity 100%; CI, 84%–100%). Using a bacterial meningitis prevalence in 22- to 28-day-old infants of 0.39[22] or 0.46[94] or ~1 in 200 to 250 and the lower end of the sensitivity CI (84%) suggests 1250 to 1560 interpretable CSF samples would be required to detect each additional case of bacterial meningitis (number needed to test = 1250–1560). Without procalcitonin, these studies detected 14 of 14 cases of bacterial meningitis (95% CI, 80%–100%), indicating a number needed to test of 1000 to 1250.

Researchers in a few studies have addressed a positive urinalysis result or UTI as a risk factor for meningitis. Data for 22- to 28-day-old infants are limited, as are data for UTI without abnormal IMs. For infants 7 to 30 days of age in the Reducing Variability in the Infant Sepsis Evaluation study of 1281 infants with positive urinalysis results who had an LP performed, 0.8% were treated for bacterial meningitis.[149] This was similar to the 1.0% of the 4644 infants with negative results on the urinalysis. The data also indicated that none of the 98 infants with positive urinalysis results did not have an LP ultimately had meningitis detected. Similarly, in an outpatient study of 100 infants with UTI <30 days of age, researchers found no cases of meningitis.[150] However, in both of these studies, the lower limits of the CI indicates up to 4% could be missed.

KAS 12a: Clinicians should administer parenteral antimicrobial therapy in a hospital if either of the following apply: (1) CSF analysis suggests bacterial meningitis; or (2) urinalysis result is positive. Evidence Quality: A; Strong Recommendation

Benefits	If diagnostic testing indicates the fever is attributable to UTI or bacterial meningitis, the infection would be treated promptly. Anticipated reduction in morbidity or mortality.
Risks, harm, cost	Adverse drug reactions including anaphylaxis (rare). Complications related to intravenous lines including infiltration, infection, nerve compression (in ankle). Potential disruption of evolving microbiome. Development of antimicrobial resistance.
Benefit–harm assessment	Preponderance of benefit.
Key references	3, 57, 145

KAS 12b: Clinicians may administer parenteral antimicrobial therapy in a hospital if all of the following apply: (1) CSF analysis is normal; (2) urinalysis is normal; and (3) any IM obtained is abnormal. Evidence Quality: B; Moderate Recommendation

Benefits	An abnormal IM indicates a risk of bacteremia >5%, a threshold sufficiently high to recommend empirical treatment. Anticipated reduction in morbidity and mortality.
Risks, harm, cost	Adverse drug reactions including anaphylaxis (rare). Complications related to intravenous lines including infiltration, infection, nerve compression (in ankle). Potential disruption of evolving microbiome. Development of antimicrobial resistance.
Benefit–harm assessment	Preponderance of benefit.
Key references	3, 57, 145

KAS 11b: Clinicians should obtain csf for analysis (WBC count, protein, glucose, Gram stain) and bacterial culture if any IM obtained is abnormal. Evidence Quality: C; Moderate Recommendation

See note on KAS11a.

INITIAL TREATMENT

The antimicrobial agents in Table 3 are recommended for initial empirical therapy and should be modified following results of cultures and sensitivities.

KAS 12a: Clinicians should administer parenteral antimicrobial therapy in a hospital if either of the following apply:

1. **CSF analysis suggests bacterial meningitis; or**
2. **urinalysis result is positive.**

Evidence Quality: A; Strong Recommendation

KAS 12b: Clinicians may administer parenteral antimicrobial therapy in a hospital if all of the following apply:

1. **CSF analysis is normal;**
2. **urinalysis is normal; and**
3. **any IM obtained is abnormal.**

Evidence Quality: B; Moderate Recommendation

KAS 12c: Clinicians may administer parenteral therapy to hospitalized infants even if all of the following are met:

1. **urinalysis is normal;**
2. **no IM obtained is abnormal; and**
3. **CSF analysis is normal or enterovirus-positive.**

Evidence Quality: B; Weak Recommendation

Recent evidence documents the sensitivity of LE for UTI of 94% (95% CI, 91%–97%),[79] even higher in UTI associated with bacteremia (97.6% and 100% in 2 studies)[80,86]; an NPV of 99% also supports a low likelihood of UTI.[78,85–89] There are insufficient data to estimate precisely the risk of bacterial meningitis with normal CSF analysis, but, based on the scarcity of cases in the literature, the risk appears to be quite low. However, as current prediction rules fail to

TABLE 3 Initial Empirical Antibacterial Therapy for Well-Appearing Febrile Infants 7 to 60 Days Old

Suspected Source of Infection	8–21 d Old	22–28 d Old	29–60 d Old
UTI[a]	Ampicillin IV or IM (150 mg/kg per d divided every 8 h) and either ceftazidime IV or IM (150 mg/kg per d divided every 8 h) or gentamicin IV or IM (4 mg/kg per dose every 24 h)	Ceftriaxone IV or IM (50 mg/kg per dose every 24 h)	Ceftriaxone IV or IM (50 mg/kg/dose every 24 h). Oral medications for infants older than 28 d.[b] Cephalexin 50–100 mg/kg per d in 4 doses or cefixime 8 mg/kg per d in 1 dose
No focus identified[c]	Ampicillin IV or IM (150 mg/kg per d divided every 8 h) and either ceftazidime IV or IM (150 mg/kg per d divided every 8 h) or gentamicin IV or IM (4 mg/kg per dose every 24 h)[d]	Ceftriaxone IV or IM (50 mg/kg per dose every 24 h)	Ceftriaxone IV or IM (50 mg/kg/dose every 24 h)
Bacterial meningitis[e]	Ampicillin IV or IM (300 mg/kg per d divided every 6 h) and ceftazidime IV or IM (150 mg/kg per d divided every 8 h)	Ampicillin IV or IM (300 mg/kg per d divided every 6 h) and ceftazidime IV or IM (150 mg/kg per d divided every 8 h)	Ceftriaxone IV (100 mg/kg or d once daily or divided every 12 h) or Ceftazidime IV (150 mg/kg or d divided every 8 h) and vancomycin[f] IV (60 mg/kg or d divided every 8 h)

Use of a local antibiogram, if available, can guide choices. Note: If a focus of infection such as pneumonia, cellulitis, gastroenteritis, or musculoskeletal infection is identified, different regimens that cover typical microbial pathogens for the site of infection should be administered. IM, intramuscular; IV, intravenous. Adapted from Bradley JS, Nelson JD, Barnett ED, et al, eds. *2019 Nelson's Pediatric Antimicrobial Therapy.* 25th ed. Itasca, IL: American Academy of Pediatrics; 2019; and Kimberlin DW, Brady MT, Jackson MA, Long SS, eds. *Red Book: 2018 Report of the Committee on Infectious Diseases.* 31st ed. Itasca, IL: American Academy of Pediatrics; 2018.

[a] On the basis of urinalysis results.

[b] AAP Subcommittee on Urinary Tract Infection.[73]

[c] For example, possible bacteremia. For 22 to 28 day old infants, providers may decide that observation without initiation of therapy is appropriate after risk versus benefit discussion with the infant's parents or caregivers.

[d] Gentamicin may provide clinical benefit because of synergy with ampicillin against GBS and enterococcal species.

[e] On the basis of CSF analysis results. Some experts will add gentamicin or another aminoglycoside to this regimen, particularly if the CSF Gram stain reveals Gram-negative organisms.

[f] Vancomycin is part of empirical therapy because of the possibility of resistant *S pneumoniae*. It should be stopped if an organism other than *S pneumoniae* is identified, even if susceptibilities are still pending.

KAS 12c: Clinicians may administer parenteral therapy to hospitalized infants even if all of the following are met: (1) urinalysis is normal; (2) no IM obtained is abnormal; and (3) CSF analysis is normal or enterovirus-positive. Evidence Quality: B; Weak Recommendation

Benefits	Of treating: If etiology of fever is bacteremia, the infection would be treated promptly. Anticipated reduction in morbidity and mortality. Of not treating: No adverse drug reactions. No complication of intramuscular administration. No disruption of infant's evolving microbiome. Delayed development of antimicrobial resistance.
Risks, harm, cost	Of treating: Adverse drug reactions including anaphylaxis (rare). Complication of intramuscular administration. Potential disruption of evolving microbiome. Development of antimicrobial resistance. Of not treating: If etiology of fever is bacteremia not suspected by risk stratification, the infection could potentially progress. Potential increase in morbidity or mortality.
Benefit–harm assessment	Balanced.
Key references	3, 57, 145

detect about 3% to 8% of bacteremia cases, antimicrobial agents may be administered.[18,20]

KAS 12d: Clinicians should use parenteral antimicrobial therapy for infants who will be managed at home even if all of the following are met:

1. **urinalysis is normal;**
2. **no IM obtained is abnormal; and**
3. **CSF analysis is normal.**

Evidence Quality: C; Moderate Recommendation

If all IMs are normal and urinalysis and CSF analysis do not suggest infection, the risk of bacteremia is between 1% and 2% (number needed to treat 50–100).

KAS 13a: Clinicians may manage infants at home if all of the following criteria are met:

1. **urinalysis is normal;**
2. **no IM obtained is abnormal;**
3. **CSF analysis is normal or enterovirus-positive;**
4. **verbal teaching and written instructions have been provided for monitoring throughout the period of time at home for the following:**
   - **change in general appearance, particularly a dusky color, or respiratory or other distress;**
   - **behavior change, including lethargy, irritability, inconsolable crying, difficulty in consoling/comforting, or other evidence of distress;**
   - **difficulty feeding;**
   - **vomiting; and**
   - **decreased urine output;**
5. **follow-up plans for reevaluation in 24 hours have been developed and are in place; and**
6. **plans have been developed and are in place in case of change in clinical status, including means of communication between family and providers and access to emergency medical care.**

Evidence Quality: B; Moderate Recommendation

Value judgments: The committee values careful infant monitoring provided by hospital staff skilled in the care of neonates and young infants. In some situations, infants may not be hospitalized because of lack of access to a local hospital unit able to care for young infants (in which case referral to a regional hospital is an acceptable alternative) or other circumstances. In primary care settings, in which close follow-up is possible, more than 30% of low-risk infants are managed at home after initial evaluation.[17,22] For infants seen in EDs, 15% to 30% are not hospitalized.[23,24] In these studies, the subsequent admission rate is 1% to 2%; delays in treating bacterial infections have been rare. Several recent studies suggest otherwise low-risk infants in the absence of CSF data may be of sufficiently low risk to safely be managed at home after initial evaluation.[18,20]

For infants discharged from the hospital after initial evaluation, phone or other telecommunication contact should be attempted and documented at appropriate intervals after returning home. Infants should be scheduled for repeat clinical evaluation within the next 24 hours or sooner, if deemed appropriate. If at 24 hours, the parents report no clinical worsening and all culture results are negative, a phone

KAS 12d: Clinicians should use parenteral antimicrobial therapy for infants who will be managed at home even if all of the following are met: (1) urinalysis is normal; (2) no IM obtained is abnormal; and (3) CSF analysis is normal. Evidence Quality: C; Moderate Recommendation

Benefits	If etiology of fever is bacteremia, the infection would be treated promptly without the delay involved in returning to hospital. Anticipated reduction in morbidity and mortality.
Risks, harm, cost	Adverse drug reactions including anaphylaxis (rare). Complication of intramuscular administration. Potential disruption of evolving microbiome. Development of antimicrobial resistance.
Benefit–harm assessment	Preponderance of benefit.
Key references	3, 57, 145

KAS 13a: Clinicians may manage infants at home if all of the following criteria are met: (1) urinalysis is normal; (2) no IM obtained is abnormal; (3) CSF analysis is normal or enterovirus-positive; (4) verbal teaching and written instructions have been provided for monitoring throughout the period of time at home; (5) follow-up plans for reevaluation in 24 h have been developed and are in place; and (6) plans have been developed and are in place in case of change in clinical status, including means of communication between family and providers and access to emergency medical care. Evidence Quality: B; Moderate Recommendation

Benefits	Potential reduction of family disruption and stress. Improved circumstances for breastfeeding. Decreased risk of iatrogenic consequences of hospitalization. Eliminates risk of hospital-acquired infection. Less costly.
Risks, harm, cost	Delayed response if there is a clinical change potentially indicating infection progression. Potential increase in parental anxiety and fatigue. Dependent on parental ability to judge clinical change in a newborn infant.
Benefit–harm assessment	Preponderance of benefit in low-risk infants if discharge criteria are met.
Shared decision-making	For low-risk infants, the decision whether to hospitalize or not should be made after physicians provide estimates of the risks of underlying IBIs and benefits of home versus hospital monitoring. Parents and physicians have different values for clinical outcomes in young febrile infants. It has been documented that parents place greater value on short-term benefits such as avoiding pain, discomfort, and errors in diagnostic testing while physicians gave greater wt to avoiding short- and long-term morbidity.[66,67] These and other inherent value differences should be considered when engaging in discussions. Also, individual parents and physicians have different tolerances for risk.[66–71]
Key references	17, 22–24

The benefit/harm ratio of hospitalizing depends, in large part, on reducing the risk of sending home an infant with undiagnosed, untreated meningitis. In KAS 11b, the committee estimated the risk of meningitis going undetected and can estimate that 1200 to 1500 febrile infants would require hospitalization to avoid 1 infant going home with undetected bacterial meningitis. The benefit/harm assessment is also dependent on the quality of observation and monitoring in each hospital compared with parents' abilities to recognize any worsening of illness and return promptly.

conversation may be sufficient for follow-up. Transportation difficulty is a contributor to health inequity. Given the importance of the ability to return for changes in clinical status and further evaluations we recommend institutions consider travel vouchers (taxi or ride-share) for families with transportation insecurity. Telemedicine is increasingly being used for follow-up visits and may be appropriate in some situations.

If the reevaluation will be performed at another location or by a different clinical evaluator, it is recommended that the site for medical reevaluation be arranged in advance and clinician-to-clinician communication be direct. Clear written and documented instructions should be given to parents as to the time and place of the return visit.

KAS 13b: Clinicians should hospitalize infants in a facility with nurses and staff experienced in the care of neonates/young infants when CSF is not obtained or is uninterpretable. Evidence Quality: B; Weak Recommendation

FURTHER MANAGEMENT AND MONITORING

KAS 14a: Clinicians should discontinue antimicrobial agents and discharge hospitalized infants after 24 to 36 hours of negative culture results if the following are met:

1. **the infant is clinically well or improving (eg, fever, feeding);**
2. **there are no other reasons for hospitalization; and**
3. **there is no other infection requiring treatment (eg, otitis media).**

Evidence Quality: B; Strong Recommendation

In the most recent large studies, bacterial pathogens were not detected by 24 h in 15% to 18% and longer than 36 h in 5% to 7%; for CSF, the respective times were 11% to 18% and 6% to 15%.[138,139] Growth by 24 h occurred in a lower proportion of well-appearing infants with bacteremia (85%) compared with ill-appearing infants (93%).[138]

KAS 14b: Clinicians should discontinue antimicrobial agents on infants managed at home when all of the following criteria are met:

1. **infant is clinically well or improving (eg, fever, feeding) at time of reassessment;**
2. **all cultures are negative at 24 to 36 hours; and**
3. **there is no other infection requiring treatment (eg, otitis media).**

Evidence Quality: B; Strong Recommendation

KAS 14c: Clinicians should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment. Evidence Quality: A; Strong Recommendation

WELL-APPEARING 29- TO 60-DAY-OLD-INFANTS

Diagnostic Evaluation

The following recommendations and options are for febrile (temperature >38.0°C), well-appearing, term infants 29 to 60 days of age without risk factors identified in the exclusion criteria.

KAS 13b: Clinicians should hospitalize infants in a facility with nurses and staff experienced in the care of neonates/young infants when CSF is not obtained or is uninterpretable. Evidence Quality: B; Weak Recommendation

Benefits	Opportunity for observation by skilled, experienced staff and ability to administer treatment promptly if condition worsens.
Risks, harm, cost	Hospitalization increases risk of hospital-acquired infections. Increased risk of iatrogenic events related to intravenous catheters. Parental anxiety about infant's condition and financial strain. Stress to mothers because of breastfeeding challenges and separation from other children. Substantial cost.
Benefit–harm assessment	Balanced.
Shared decision-making	In 13a, criteria for an infant to be managed at home include normal CSF analysis. For clinicians and parents, having jointly decided on an LP, a result with inadequate or confusing CSF analysis presents a dilemma. Risks should be reviewed, and parents should understand the assessment of benefit- harm. Likelihood of missing meningitis with a variety of decision rules and models is discussed in KAS 10. For uninterpretable CSF, an ME panel may assist decision-making.
Key references	3, 57, 151

KAS 15: Clinicians should obtain urine specimen by bag, spontaneous void, or stimulated void for urinalysis and, if urinalysis result is positive, obtain a catheterization or SPA specimen for culture, or obtain urine specimen by catheterization or SPA of bladder for urinalysis and, if result is positive, for culture. Evidence Quality A; Strong Recommendation

Circumcised boys have a likelihood of UTI <1% and may be exempted from this recommendation.

Although the sensitivity of LE is not 100%, the rate of positive urine culture results without an abnormal urinalysis is roughly the same as the rate of asymptomatic bacteriuria and contamination. Moreover, renal scarring appears to be mediated by host WBCs rather than the presence of bacteria.

In one high-volume ED, limiting catheterizations to children with positive urine screen results from bag specimens reduced catheterization rates by more than half (63%–<30%) without increasing length of time in the facility or missing any UTIs.[85] Use of bladder-stimulation techniques[84] is more time-efficient than urine bag collection.[83] In newborn infants, bladder and lumbar stimulation was highly successful in facilitating midstream urine collection in a median time of 45 seconds.[90] Specimens obtained by methods other than catheterization or SPA are not suitable for culture because of a high contamination rate.[77,78]

KAS 14a: Clinicians should discontinue antimicrobial agents and discharge hospitalized infants after 24 to 36 hours of negative culture results if the following are met: (1) the infant is clinically well or improving (eg, fever, feeding); (2) there are no other reasons for hospitalization; and (3) there is no other infection requiring treatment (eg, otitis media). Evidence Quality: B; Strong Recommendation

Benefits	Minimizes exposure to hospital-acquired infections and iatrogenic exposures. Limits family disruption. Reduces cost of illness episode.
Risks, harm, cost	Inadequate duration of therapy with antimicrobial for bacterial pathogen not identified before discontinuation at 24 h (5%–18%) or 36 h (<5%).
Benefit–harm assessment	Preponderance of benefit.
Key references	57, 138–144

KAS 16: Clinicians should obtain a blood culture. Evidence Quality: B; Moderate Recommendation

The prevalence of bacteremia is lower than in the younger groups of infants but still high enough to warrant a blood culture (see Fig 4).

KAS 17: Clinicians should assess IMs. Evidence Quality: B; Moderate Recommendation

For detailed discussion of IMs, see KAS 10.

KAS 18a: Clinicians may obtain CSF for analysis (WBC count, differential, protein, glucose, Gram stain), culture for bacteria, and test for enterovirus when CSF pleocytosis is detected or during enterovirus season if any IM obtained is abnormal. Evidence Quality: C; Weak Recommendation

There is substantial evidence IMs are predictive of IBI including bacterial meningitis.[10–14,16,18–20] For this age group, the number of meningitis cases in published studies is still relatively small, 64 cases in 25 917 febrile infants (0.25%). Data are unavailable comparing prevalence in IM-positive versus IM-negative infants, but decision rules and models that include IMs have sensitivities greater than 90%. In KAS 10, the committee provided data indicating that individual IMs are seldom sensitive or specific for detecting bacteremia or meningitis. However, individual values that are exceedingly high or low or finding several abnormal IMs should be considered in decision-making, because they, in all likelihood, increase the risk of bacterial meningitis.

KAS 14b: Clinicians should discontinue antimicrobial agents on infants managed at home when all of the following criteria are met: (1) infant is clinically well or improving (eg, fever, feeding) at time of reassessment; (2) all cultures are negative at 24 to 36 hours; and (3) there is no other infection requiring treatment (eg, otitis media). Evidence Quality: B; Strong Recommendation

Benefits	Minimizes risk of adverse treatment consequences. Reduces impact on microbiome. Contributes to antimicrobial stewardship.
Risks, harm, cost	Inadequate duration of therapy with antimicrobial for bacterial pathogen not identified before discontinuation at 24 h (5%–18%) or 36 h (<5%).
Benefit–harm assessment	Preponderance of benefit.
Key references	138–144

KAS 18b: Clinicians need not obtain CSF for analysis and culture if all IMs obtained are normal. Evidence Quality: B; Moderate Recommendation

The committee supports not performing an LP in well-appearing infants meeting the specified criteria. For an estimated prevalence of meningitis in 29- to 60-d-old infants of 0.25% and using a prediction rule or model with a sensitivity of 90%, the chance of missing a case of meningitis would be 0.025%. Therefore, 4000 successful LPs would be required to avoid a delay in the detection of 1 case of bacterial meningitis.

If no IM is abnormal, the committee does not include a positive urinalysis result as an indicator for performing an LP.

INITIAL TREATMENT

The antimicrobial agents in Table 3 are recommended for initial empirical therapy and should be modified following results of cultures and sensitivities.

KAS 19a: Clinicians should use parenteral antimicrobial therapy if CSF analysis suggests bacterial meningitis. Evidence Quality: A; Strong Recommendation

If CSF is not available or is uninterpretable, clinicians should use parenteral antimicrobial agents.

KAS 19b: Clinicians may use parenteral antimicrobial therapy if both of the following apply:

1. **CSF analysis (if CSF obtained) is normal; and**
2. **any IM obtained is abnormal.**

Evidence Quality: B; Moderate Recommendation

If CSF is positive for enterovirus, clinicians may discontinue (or withhold) antimicrobial agents as long as there are no other factors suggesting a bacterial infection, including abnormal IMs.

KAS 14c: Clinicians should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment. Evidence Quality: A; Strong Recommendation

Benefits	Inhibits further growth of bacterial pathogen. Cures infection. Reduces likelihood of morbidity. Contributes to antimicrobial stewardship.
Risks, harm, cost	Adverse reaction to antimicrobial. Interferes with infant's evolving microbiome. Accelerates emergence of antimicrobial resistance.
Benefit–harm assessment	Preponderance of benefit.
Key references	145

KAS 19c: Clinicians should initiate oral antimicrobial therapy if all of the following apply:

1. **CSF analysis (if CSF obtained) is normal;**
2. **urinalysis result is positive; and**
3. **no IM obtained is abnormal.**

Evidence Quality: B; Strong Recommendation

KAS 19d: Clinicians need not use antimicrobial therapy while awaiting bacterial culture results if all of the following are met:

1. **CSF analysis, if CSF obtained, is normal or enterovirus-positive;**
2. **urinalysis is negative; and**
3. **no IM obtained is abnormal.**

Evidence Quality: B; Moderate Recommendation

The risk for well-appearing infants with these negative findings having bacteremia is 0.1% for infants 29 to 60 days of age,[18] with a CI upper limit that indicates the number needed to test is >300. Recent evidence documents the sensitivity of LE for UTI of 94% (95% CI, 91%–97%),[80] even higher in UTI associated with bacteremia (97.6% and 100%) in 2 studies[80,86]; an NPV of 99% also supports a low likelihood of UTI.[38–40] There are insufficient data to estimate precisely the risk of bacterial meningitis with normal CSF analysis, but, based on the scarcity of cases in the literature, the risk appears to be quite low.

Value Judgments: There were different thresholds, within the committee, for treating with antimicrobial agents. The potential benefits are highlighted above. The overall sense of the committee was to administer antimicrobial agents if the number needed to test for bacteremia is 100 or less: that is, willing to treat as many as 100 infants with parenteral antimicrobial agents to avoid delaying treatment in 1 infant with

KAS 15: Clinicians should obtain urine specimen by bag, spontaneous void, or stimulated void for urinalysis and, if urinalysis result is positive, obtain a catheterization or SPA specimen for culture, or obtain urine specimen by catheterization or SPA of bladder for urinalysis and, if result is positive, for culture. Evidence Quality A; Strong Recommendation

Benefits	Identification of UTIs. A positive urinalysis result prompts initiation of empirical antimicrobial therapy. A positive urine culture result for pathogenic bacteria directs appropriate antimicrobial treatment. A negative urinalysis result signifies a low likelihood of a UTI and obviates catheterization or SPA (if not already performed).
Risks, harm, cost	Falsely positive culture result (contamination) or misdiagnosis of asymptomatic bacteriuria leading to unnecessary and potentially harmful treatment and inaccurate documentation of a first UTI (which may prompt unnecessary imaging should a UTI occur subsequently). Discomfort of catheterization or SPA. Parent anxiety.
Benefit–harm assessment	Preponderance of benefit.
Shared decision-making	Because nearly 90% of febrile infants will not have UTIs, obtaining a screening specimen through noninvasive methods is appropriate. Voided methods can be offered with explanations of a potential time delay and need for a second urine sample obtained by catheterization and/or SPA if initial urine screen result is positive. Parents opposed to catheterization should be offered a choice of SPA and informed about the higher rate of ambiguous or false-positive culture results obtained from bagged or voided specimens.[77] A false-positive urine culture result can potentially prolong antimicrobial administration.
Key references	73, 77–93

KAS 16: Clinicians should obtain a blood culture. Evidence Quality: B; Moderate Recommendation

Benefits	Identification of bacteremia: 1.1%–2.2% of all febrile infants in this age group[17,22,24,61,94] and 5%–10% in infants with UTI.[17,26,91–93,152,153] Identification of organism (and sensitivities) for directed antimicrobial treatment. Early detection and treatment may prevent progression of infection.
Risks, harm, cost	False-positive results: Most positive blood cultures in febrile infants are attributable to contaminants[25,27,28,30] potentially leading to unnecessary use of antimicrobial agents, further or repeat testing, and prolonged hospitalization. Discomfort of venipuncture. Costs can be substantial depending on further testing, treatment, and hospitalization after a false-positive culture result.
Benefit–harm assessment	Preponderance of benefit.
Role of patient preferences	Parents should understand that testing is based on the high likelihood of bacteremia, especially in infants with positive urinalysis result. Parents can be informed of potential challenges that may be encountered in distinguishing pathogens from contaminants as part of explaining the evaluation process.
Key references	22, 24, 30, 61

bacteremia. The committee recognizes that parents and practitioners have different levels of risk aversion and thresholds for treatment that should be incorporated into decision-making.

KAS 20a: Clinicians should hospitalize infants in a unit with nurses and staff experienced in the care of 29- to 60-day-old infants if CSF analysis, if CSF obtained, is abnormal. Evidence Quality: A; Strong Recommendation

KAS 20b: Clinicians may hospitalize infants in a unit with nurses and staff experienced in the care of 29- to 60-day-old-infants if any IM obtained is abnormal. Evidence Quality: B; Moderate Recommendation

In a PECARN substudy of 29- to 60-d-old infants, an ANC $>$ 4000 per mm^3 and/or procalcitonin $>$0.5 ng/mL had a bacteremia prevalence of 3.2%; the prevalence if these IMs were negative was 0.2%.[18]

KAS 20c: Clinicians should manage patients at home if all of the following criteria are met:

1. **CSF analysis, if CSF obtained, is normal;**
2. **urinalysis is negative;**
3. **all IMs obtained are normal;**
4. **appropriate parental education has been provided;**
5. **follow-up plans for reevaluation in 24 hours have been developed and are in place; and**
6. **plans have been developed and are in place in case of change in clinical status, including means of communication between family and providers and access to emergency medical care.**

Evidence Quality: B; Moderate Recommendation

Value judgments: The low risk of bacteremia and meningitis in infants without positive IMs can potentially reduce hospitalizations without compromising infant safety.

KAS 17: Clinicians should assess IMs. Evidence Quality: B; Moderate Recommendation

Benefits	For infants with negative urinalysis and/or pending urine and/or blood cultures, IMs may influence the decision whether to perform an LP, initiate antimicrobial agents, or hospitalize. For an infant with a negative urinalysis and pending blood culture, the absence of abnormal IMs may contribute to the decision of whether to send the infant home without antimicrobial agents.
Risks, harm, cost	False-negative results, underestimating risk of bacteremia and bacterial meningitis.[23,39] False-positive results, overestimating the risk of bacteremia or bacterial meningitis.
Benefit–harm assessment	Preponderance of benefit.
Key references	13–16, 18–20, 37–39, 60, 97–105, 146

KAS 20d: Clinicians may manage infants without antimicrobial treatment at home without having obtained interpretable CSF if all of the following are met:

1. **urinalysis is negative;**
2. **all IMs obtained are normal; and**
3. **parents can return promptly if there is a change in infant condition and agree to follow-up in 24 to 36 hours. Infants monitored at home should be reassessed in the following 24 hours.**

Evidence Quality: B; Moderate Recommendation

Value judgments: The low risk of bacteremia and meningitis in infants without positive IMs can potentially reduce hospitalizations without compromising infant safety.

KAS 18a: Clinicians may obtain CSF for analysis (WBC count, differential, protein, glucose, Gram stain), culture for bacteria, and test for enterovirus when CSF pleocytosis is detected or during enterovirus season if any IM obtained is abnormal. Evidence Quality: C; Weak Recommendation

Benefits	The prevalence of meningitis in this age group is 0.12–0.32.[17,22,24,61,94] Early detection of meningitis. Early treatment may lead to decreased neurologic morbidity. Identification of pathogen from CSF to target type and duration of antimicrobial treatment. Avoids unnecessarily prolonged antimicrobial therapy if CSF was obtained after antimicrobial agents started and diagnosis of meningitis is uncertain.
Risks, harm, cost	Discomfort for infant. Potential for transient respiratory compromise during positioning for LP. Traumatic LPs have been documented to prolong length of stay for hospitalized infants. Unnecessary prolongation of hospitalization from false-positive bacterial culture result. Substantial cost if hospitalizing because of ambiguous CSF or prolonged hospitalization for bacterial contaminant. Parental anxiety.
Benefit–harm assessment	Preponderance of benefit if CSF obtained.
Shared decision-making	Because parents must consent for this procedure, shared decision-making is required and their risk tolerances a consideration. KAS 4 extensively discusses rates and consequences of unsuccessful LPs, uninterpretable CSF analysis, and false-positive bacterial culture rates. If, for whatever reason, a parent is resistant or unwilling to consent to an LP, risk of meningitis, the evidence quality, benefit/harm assessment, and value judgments should be communicated to the parent to foster informed decision-making. The potential need for a future LP, depending on further clinical information and progress, is an important part of the discussion. These discussions should be documented.
Key references	17, 22, 24, 106, 132, 148

FURTHER MANAGEMENT AND MONITORING

KAS 21a: Clinicians should discontinue antimicrobial agents when all of the following are met:

1. **all bacterial cultures are negative at 24 to 36 hours;**
2. **infant is clinically well or improving (eg, fever, feeding); and**
3. **there is no other infection requiring treatment (eg, otitis media).**

Evidence Quality: B; Strong Recommendation

KAS 21b: Clinicians should discharge hospitalized patients with positive urine culture results (UTI) if all of the following are met:

1. **blood culture is negative;**
2. **CSF culture, if CSF obtained, is negative;**
3. **infant is clinically well or improving (eg, fever, feeding); and**
4. **there are no other reasons for hospitalization.**

Evidence Quality: B; Strong Recommendation

KAS 21c: Clinicians should discontinue parenteral antibiotics (if started) and begin or continue oral antimicrobial for infants with UTIs managed at home when all of the following are met:

1. **urine culture result is positive;**
2. **all other bacterial culture results are negative at 24 to 36 hours; and**
3. **infant is clinically well or improving (eg, fever, feeding).**

Evidence Quality: B; Strong Recommendation

KAS 18b: Clinicians need not obtain CSF for analysis and culture if all IMs obtained are normal. Evidence Quality: B; Moderate Recommendation

Benefits	Avoids unnecessary costs and discomfort of testing in low-risk infant.
Risks, harm, cost	Potential missed opportunity for early detection of developing meningitis.
Benefit–harm assessment	Preponderance of benefit.
Role of parent preferences	Parents should understand the benefit/harm assessment underlying this decision.
Key references	17, 22, 24, 106, 148

KAS 21d: Clinicians should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment. Evidence Quality: A; Strong Recommendation

FUTURE RESEARCH

Many of the unanswered questions faced in the committee's review emanated from the challenges of conducting prospective research in clinical settings with a relatively uncommon symptom. Fever in this age group has an incidence rate of 14 per 1000 term, previously healthy births per year.[22] Although >10% of febrile infants will have UTIs, the likelihood of more IBIs is much less, with bacteremia detected in <2% of febrile infants and bacterial meningitis in <0.5%. Negative outcomes, such as permanent renal damage and organ damage or death, from sepsis are rare. Permanent neurologic sequelae from bacterial meningitis occur in variable rates depending on the severity of the infection, onset of treatment, and organism. Therefore, although use of administrative databases has recently provided important information, large, prospective studies will be required to answer a number of the following questions to further refine clinical recommendations for preventing negative outcomes.

KAS 19a: Clinicians should use parenteral antimicrobial therapy if CSF analysis suggests bacterial meningitis. Evidence Quality: A; Strong Recommendation

Benefits	Anticipated reduction in morbidity and mortality from bacterial meningitis.
Risks, harm, cost	Adverse drug reactions including anaphylaxis (rare). Complications related to intravenous lines including infiltration, infection, nerve compression (in ankle). Potential disruption of evolving microbiome. Development of antimicrobial resistance.
Benefit–harm assessment	Preponderance of benefit.
Key references	107, 145

KAS 19b: Clinicians may use parenteral antimicrobial therapy if both of the following apply: (1) CSF analysis (if CSF obtained) is normal; and (2) any IM obtained is abnormal. Evidence Quality: B; Moderate Recommendation

Benefits	Anticipated reduction in morbidity and mortality if infant has bacteremia. The risk of bacteremia is 1.1%–2.1% of all febrile infants in this age group.[17,22,24,94] Identification of organism (and sensitivities) for directed antimicrobial treatment. Early detection and treatment may prevent progression of infection.
Risks, harm, cost	Adverse drug reactions including anaphylaxis (rare). Complications related to intravenous lines including infiltration, infection, nerve compression (in ankle). Potential disruption of evolving microbiome. Development of antimicrobial resistance.
Benefit–harm assessment	Preponderance of benefit.
Key references	17, 22, 145

All of the following pertain to well appearing febrile infants 8 to 60 days of age.

1. Because analyzing data for SBI has obscured understanding of optimal approaches to detect and manage individual infections, the term "SBI" should be retired and the incidence of the following infections determined separately: a. bacterial meningitis; b. bacteremia; and c. UTI.
2. The incidence of each individual infection can then be used to identify the most appropriate age groupings expressed in days rather than the arbitrary ones currently in use (weeks, months). The age groupings used in this guideline are primarily based on data gathered by week of age, as set a priori; although expressed here in days corresponding to those weeks, age groupings in the future should be derived from day-by-day data, which may generate different age groupings from the ones used here.
3. What is the morbidity and mortality of each infection for each age group?
4. What is the current epidemiology of each infection for each age group?
5. What is the best predictive rule for each infection?
6. What is the optimal initial choice and route of antimicrobial agents?
7. What is the optimal duration of therapy?
8. What are the predictors for bacteremia and for bacterial meningitis in a patient with a positive urinalysis result?
9. When does bacteremia matter in an infant with a UTI? Should

KAS 19c: Clinicians should initiate oral antimicrobial therapy if all of the following apply: (1) CSF analysis (if CSF obtained) is normal; (2) urinalysis result is positive; and (3) no IM obtained is abnormal. Evidence Quality: B; Strong Recommendation

Benefits	Inhibits further growth of bacterial pathogen. Reduces likelihood of morbidity.
Risks, harm, cost	Antimicrobial reactions and altering microbiome.
Benefit–harm assessment	Preponderance of benefit.
Key references	155

bacteremia affect treatment duration?

10. In what ways do patients referred to EDs differ from patients initially seeking care in EDs and from patients seen in community practices, and should management differ accordingly?
11. What will be the impact of newer biomarkers and of genomic and other "omic" testing?
12. How should results of multiplex viral testing be incorporated into prediction models for IBI?
13. What is the best way to individualize care? Most guidelines seek to maximize care for the vast majority of patients while allowing for individualized judgments to incorporate certain circumstances. However, most guidelines sort on a small number of variables while most patients present with a vast number of relevant factors. Collaborative efforts that generate consistently acquired patient characteristics have an opportunity, using newer statistical techniques, to match a patient with a presenting symptom to others who most closely resemble the patient's own background and clinical features. In this way, it would be possible to create an individualized guideline for each patient or "one patient, one guideline."
14. Research to individualize care must include patient factors, including better understanding of the role of patient preferences, decision-making, perceptions of risk and vulnerability, satisfaction, and understanding of care.
15. What is the most effective way to provide ongoing monitoring and follow-up? The role of telehealth and differing systems of care approaches should be explored.
16. For low-risk infants, what impact will this guideline have on reducing the use of antimicrobial agents, decreasing invasive diagnostic testing, decreasing hospitalizations, and shortening hospital lengths of stay?
17. What is the impact of individual social determinants of health on risk of IBI, diagnostic testing, management, morbidity and

KAS 19d: Clinicians need not use antimicrobial therapy while awaiting bacterial culture results if all of the following are met: (1) CSF analysis, if CSF obtained, is normal or enterovirus-positive; (2) urinalysis is negative; and (3) no IM obtained is abnormal. Evidence Quality: B; Moderate Recommendation

Benefits	Reduced risk of adverse reaction to antimicrobial agents/ anaphylaxis. Minimize disruption in developing microbiome. Small cost savings.
Risks, harm, cost	Delay in treatment of UTI, bacteremia, or bacterial meningitis with potential disease progression and increased morbidity.
Benefit–harm assessment	This is a benefit for infants receiving close and active observation, as previously discussed.
Key references	17–20, 36

KAS 20a: Clinicians should hospitalize infants in a unit with nurses and staff experienced in the care of 29- to 60-day-old infants if CSF analysis, if CSF obtained, is abnormal. Evidence Quality: A; Strong Recommendation

Benefits	An infant with a positive CSF analysis requires hospitalization for treatment and monitoring. Having the infant immediately available facilitates antimicrobial changes when culture and sensitivity results are reported, particularly if the organism is not sensitive to antimicrobial agents being administered.
Risks, harm, cost	Hospitalization increases risk of hospital-acquired infections. Increased risk of iatrogenic events related to intravenous catheters. Parental anxiety about infant's condition and financial strain. Stress to mothers because of breastfeeding challenges and separation from other children. Substantial cost.
Benefit–harm assessment	Preponderance of benefit.
Key references	57

KAS 20b: Clinicians may hospitalize infants in a unit with nurses and staff experienced in the care of 29- to 60-day-old-infants if any IM obtained is abnormal. Evidence Quality: B; Moderate Recommendation

Benefits	The risk of bacteremia is increased if an IM is abnormal.
Risks, harm, cost	Hospitalization increases risk of hospital-acquired infections. Increased risk of iatrogenic events related to intravenous catheters. Parental anxiety about infant's condition and financial strain. Stress to mothers because of breastfeeding challenges and separation from other children. Substantial cost.
Shared decision-making	For low-risk infants, the decision whether to hospitalize or not should be made after physicians provide estimates of the risks of underlying IBIs and benefits of home versus hospital monitoring. Parents and physicians have different values for clinical outcomes in young febrile infants.[67–73] These inherent value differences should be considered when engaging in discussions. Also, individual parents and physicians have different tolerances for risk.
Benefit–harm assessment	Preponderance of benefit.
Key references	4, 17, 22, 24, 58

KAS 20c: Clinicians should manage patients at home if all of the following criteria are met: (1) CSF analysis, if CSF obtained, is normal; (2) urinalysis is negative; (3) all IMs obtained are normal; (4) appropriate parental education has been provided; (5) follow-up plans for reevaluation in 24 hours have been developed and are in place; and (6) plans have been developed and are in place in case of change in clinical status, including means of communication between family and providers and access to emergency medical care. Evidence Quality: B; Moderate Recommendation

Benefits	Active monitoring for infants at increased risk of bacteremia.
Risks, harm, cost	Delay in recognizing changing clinical course warranting further evaluation. Potential increase in parental anxiety.
Benefit–harm assessment	Preponderance of benefit. This is an important consideration for infants when close and active observation is available at home.
Shared decision-making	For low-risk infants, the decision whether to hospitalize or not should be made after physicians provide estimates of the risks of underlying IBIs and benefits of home versus hospital monitoring. Parents and physicians have different values for clinical outcomes in young febrile infants.
Key references	4, 10, 14, 15, 17–21, 36

KAS 20d: Clinicians may manage infants without antimicrobial treatment at home without having obtained interpretable CSF if all of the following are met: (1) urinalysis is negative; (2) all IMs obtained are normal; and (3) parents can return promptly if there is a change in infant condition and agree to follow-up in 24 to 36 hours. Infants monitored at home should be reassessed in the following 24 hours. Evidence Quality: B; Moderate Recommendation

Benefits	Minimize disruption to family attachment and maternal breastfeeding. Substantial cost savings. Reduced risk of iatrogenic events and hospital borne infections.
Risks, harm, cost	Delay in recognizing changing clinical course warranting further evaluation. Potential increase in parental anxiety.
Benefit–harm assessment	Preponderance of benefit.
Key references	4, 10, 14, 15, 17–20, 36

KAS 21a: Clinicians should discontinue antimicrobial agents when all of the following are met: (1) all bacterial cultures are negative at 24 to 36 hours; (2) infant is clinically well or improving (eg, fever, feeding); and (3) there is no other infection requiring treatment (eg, otitis media). Evidence Quality: B; Strong Recommendation

Benefits	Limits costs, disruption to microbiome, adverse reaction.
Risks, harm, cost	Potential inadequate treatment of bacteremia if pathogen grows after 24 h: 5%–15%; after 36 h: <5%.
Benefit–harm assessment	Preponderance of benefit.
Key references	57, 92, 138–144

KAS 21b: Clinicians should discharge hospitalized patients with positive urine culture results (UTI) if all of the following are met: (1) blood culture is negative; (2) CSF culture, if CSF obtained, is negative; (3) infant is clinically well or improving (eg, fever, feeding); and (4) there are no other reasons for hospitalization. Evidence Quality: B; Strong Recommendation

Benefits	Limits costs, exposure to hospital-acquired infections, family disruption.
Risks, harm, cost	Potential clinical deterioration if pathogen grows from blood after discharge.
Benefit–harm assessment	Preponderance of benefit.
Key references	153–155

KAS 21c: Clinicians should discontinue parenteral antibiotics (if started) and begin or continue oral antimicrobial for infants with UTIs managed at home when all of the following are met: (1) urine culture result is positive; (2) all other bacterial culture results are negative at 24 to 36 hours; and (3) infant is clinically well or improving (eg, fever, feeding). Evidence Quality: B; Strong Recommendation

Benefits	Ensures adequacy of treatment. Reduced discomfort from parenteral administration. Reduced risk of intravenous infiltration. Reduced disruption to family.
Risks, harm, cost	Potential inadequate treatment of bacteremia if pathogen grows after 24 h: 5%–15%; after 36 h: <5%.
Benefit/harm assessment	Preponderance of benefit.
Key references	138–144, 155

KAS 21d: Clinicians should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment. Evidence Quality: A; Strong Recommendation

Benefits	Inhibits further growth of bacterial pathogen. Cures infection. Reduces likelihood of morbidity. Contributes to antimicrobial stewardship.
Risks, harm, cost	Adverse reaction to antimicrobial. Interferes with infant's evolving microbiome. Accelerates emergence of antimicrobial resistance.
Benefit–harm assessment	Preponderance of benefit.
Key references	145, 155

mortality, discharge planning, and follow-up?

As a first step, questions 1, 2, and 5 could be partially answered by an effort to combine existing data sets from the large clinical and research groups publishing in this area. There are also international networks with similar foci on febrile infants. Although this would be challenging, it would still provide the shortest time to obtain the most accurate current assessment of risks.

It is clear that both the bacteriology and the technology involved in risk stratification and organism identification are evolving. Future research would benefit from a collaborative effort among researchers to define a common data set, with uniform definitions of elements and agreements to combine data for specific analyses. This effort could also lead to a model to answer question 10. As for question 12, it is now both methodologically and technologically feasible for a clinician to be able to enter a number of demographic, clinical, and laboratory data for a febrile infant and get the best estimate of risk for that patient.

ACKNOWLEDGMENTS

The committee acknowledges the generosity of individuals who graciously performed additional analyses from their published data sets and wisdom for this endeavor: Paul Aronson, MD, for the Febrile Young Infant Research Collaborative; Richard Bachur, MD (Division of Emergency Medicine, Boston Children's Hospital); Carrie Byington, MD (University of Utah and Intermountain Healthcare); Borja Gomez, MD (Pediatric Emergency Department, Cruces University Hospital); Tara Greenhow, MD (Kaiser Permanente Northern California); Nate Kuppermann, MD, MPH (PECARN); and Matthew Pantell, MD, MS (PROS). We also thank Eric Biondi, MD, for leading a series of focus groups of primary care and subspecialty pediatricians who scrutinized the guideline and provided feedback on implementation. We especially recognize Borja Gomez, MD (Pediatric Emergency Department, Cruces University Hospital). In a truly collegial fashion, he regularly ran subanalyses for us on his previously published data that helped us fill in many gaps and provide a more refined set of recommendations. The following groups provided feedback and suggestions that were incorporated during the process of development: AAP committees: Committee on Fetus and Newborn, Committee on Hospital Care, Committee on Infectious Diseases, Committee on Medical Liability and Risk Management, Committee on Pediatric Emergency Medicine, and Committee on Practice and Ambulatory Medicine; AAP council(s): Council on Quality Improvement and Patient Safety; AAP sections: Section on Administration and Practice Management, Section on Critical Care, Section on Emergency Medicine, Section on Epidemiology, Public Health, and Evidence, Section on Hospital Medicine, and Section on Infectious Diseases; other AAP groups: Family Partnerships Network, PROS, Quality Improvement Innovation Networks; and external groups: American Academy of Family Physicians, American College of Emergency Physicians, and Pediatric Infectious Diseases Society.

ABBREVIATIONS

AAP: American Academy of Pediatrics
AHRQ: Agency for Healthcare Research and Quality
ANC: absolute neutrophil count
AUC: area under the curve
CI: confidence interval
CRP: C-reactive protein
CSF: cerebrospinal fluid
ED: emergency department
GBS: group B *Streptococcus*
HSV: herpes simplex virus
IBI: invasive bacterial infection
IM: inflammatory marker
KAS: key action statement
LE: leukocyte esterase
LP: lumbar puncture
NPV: negative predictive value
PCR: polymerase chain reaction
PECARN: Pediatric Emergency Care Applied Research Network
PROS: Pediatric Research in Office Settings
RBC: red blood cell
RSV: respiratory syncytial virus
SBI: serious bacterial illness
SPA: suprapubic aspiration
UTI: urinary tract infection
WBC: white blood cell

FINANCIAL DISCLOSURE: The authors have indicated they have no financial relationships relevant to this article to disclose.

FUNDING: No external funding.

POTENTIAL CONFLICT OF INTEREST: Dr Byington is affiliated with BioFire and IDbyDNA. Dr Woods is affiliated with UpToDate. Dr Munoz-Rivas is affiliated with UpToDate, Moderna, and Pfizer; the other authors have indicated they have no potential conflicts of interest to disclose.

Well-Appearing Febrile Infants Clinical Practice Guideline Quick Reference Tools

- Action Statement Summary
  — Evaluation and Management of Well-Appearing Febrile Infants 8 to 60 Days Old
- *ICD-10-CM* Coding Quick Reference for Well-Appearing Febrile Infants

Action Statement Summary

Evaluation and Management of Well-Appearing Febrile Infants 8 to 60 Days Old

Infants 8 to 21 d of age (Key Action Statements 1–7): Clinicians…

Key Action Statement 1

Should obtain urine specimen by catheterization or suprapubic aspiration (SPA) of bladder for urinalysis and, if urinalysis result is positive, for culture. (Grade: A; Strong Recommendation)

Key Action Statement 2

Should obtain a blood culture. (Grade: A; Strong Recommendation)

Key Action Statement 3

May assess inflammatory markers (IMs). (Grade: B; Weak Recommendation)

Key Action Statement 4

Should obtain cerebrospinal fluid (CSF) for analysis (white blood cell [WBC], protein, glucose, Gram stain) and culture for bacteria. See notes for viral testing. (Grade: A; Strong Recommendation)

Key Action Statement 5

Should initiate parenteral antimicrobial therapy. (Grade: A; Strong Recommendation)

Key Action Statement 6

Should actively monitor infants while awaiting results of bacterial cultures in a hospital setting with nurses and staff experienced in the care of neonates/young infants. (Grade: B; Moderate Recommendation)

Key Action Statement 7a

Should discontinue parenteral antimicrobial agents and discharge hospitalized patients when all of the following criteria are met: (1) culture results are negative for 24–36 h or only positive for contaminants; (2) the infant continues to appear clinically well or is improving (eg, fever, feeding); (3) there are no other reasons for hospitalization. (Grade: B; Strong Recommendation)

Key Action Statement 7b

Should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment. (Grade: A; Strong Recommendation)

Infants 22 to 28 d of age (KASs 8–14): Clinicians…
Key Action Statement 8

Should obtain urine specimen by catheterization or SPA of bladder for urinalysis and, if urinalysis result is positive, for culture. (Grade: A; Strong Recommendation)

OR

Should obtain urine specimen by bag, spontaneous void, or stimulated void for urinalysis and, if urinalysis result is positive, obtain a catheterization or SPA specimen for culture. (Grade: A; Strong Recommendation)

Key Action Statement 9

Should obtain a blood culture. (Grade: A; Strong Recommendation)

Key Action Statement 10

Should assess IMs. (Grade: B; Strong Recommendation)

Key Action Statement 11a

May obtain a CSF analysis on infants 22–28 d of age even if all of the following criteria are met: (1) urinalysis result is negative or positive; (2) no IM obtained is abnormal; (3) blood and urine cultures have been obtained; (4) infant is hospitalized. (Grade: C; Moderate Recommendation)

Key Action Statement 11b

Should obtain CSF for analysis (WBC, protein, glucose, Gram stain), and bacterial culture if any IM obtained is positive. (Grade: B; Moderate Recommendation)

Key Action Statement 12a

Should administer parenteral antimicrobial therapy in a hospital if either of the following apply: (1) CSF analysis suggests bacterial meningitis; (2) urinalysis result is positive. (Grade: A; Strong Recommendation)

Key Action Statement 12b

May administer parenteral antimicrobial therapy in a hospital if ALL of the following apply: (1) CSF analysis is normal; (2) urinalysis is normal; (3) any IM obtained is abnormal. (Grade: B; Moderate Recommendation)

Key Action Statement 12c

May administer parenteral antimicrobial therapy to hospitalized infants even if ALL of the following are met: (1) urinalysis is normal; (2) no IM obtained is abnormal; (3) CSF analysis is normal or enterovirus-positive. (Grade: B; Weak Recommendation)

Key Action Statement 12d

Should administer parenteral antimicrobial therapy for infants who will be managed at home even if ALL of the following are met: (1) urinalysis is normal; (2) no IM obtained is abnormal; (3) CSF analysis is normal. (Grade: C; Moderate Recommendation)

Key Action Statement 13a

May manage infants at home if all of the following criteria are met: (1) urinalysis is normal; (2) no IM obtained is abnormal. (3) CSF analysis is normal or enterovirus-positive. (4) verbal teaching and written instructions have been provided for monitoring throughout the period of time at home. (5) follow-up plans for reevaluation in 24 h have been developed and are in place. (6) plans have been developed and are in place in case of change in clinical status, including means of communication between family and providers and access to emergency medical care. (Grade: B; Moderate Recommendation)

Key Action Statement 13b

Should hospitalize infants in a facility with nurses and staff experienced in the care of neonates/young infants when CSF is not obtained or is uninterpretable. (Grade: B; Weak Recommendation)

Key Action Statement 14a

Should discontinue antimicrobial agents and discharge hospitalized infants after 24 to 36 h of negative culture results if both of the following are met: (1) the infant is clinically well or improving (eg, fever, feeding); (2) there are no other reasons for hospitalization. (Grade: B; Strong Recommendation)

Key Action Statement 14b

Should discontinue antimicrobial agents on infants managed at home when all of the following criteria are met: (1) infant is clinically well or improving (eg, fever, feeding) at time of reassessment; (2) all culture results are negative at 24–36 h; (3) there is no other infection requiring treatment (eg, otitis media). (Grade: B; Strong Recommendation)

Key Action Statement 14c

Should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment. (Grade: A; Strong Recommendation)

Infants 29 to 60 d of age (KASs 15–21): Clinicians…
Key Action Statement 15

Should obtain urine specimen by bag, spontaneous void, or stimulated void for urinalysis and, if urinalysis result is positive, obtain a catheterization or SPA specimen for culture. (Grade: A; Strong Recommendation)

OR

Should obtain urine specimen by catheterization or SPA of bladder for urinalysis and, if result is positive, for culture. (Grade: A; Strong Recommendation)

Key Action Statement 16

Should obtain a blood culture. (Grade: B; Moderate Recommendation)

Key Action Statement 17

Should assess IMs. (Grade: B; Moderate Recommendation)

Key Action Statement 18a

May obtain CSF for analysis (WBC, differential, protein, glucose, Gram stain), culture for bacteria, and test for enterovirus when CSF pleocytosis is detected or during enterovirus season if any IM is abnormal. (Grade: C; Weak Recommendation)

Key Action Statement 18b

Need not obtain CSF for analysis and culture if all IMs obtained are normal. (Grade: B; Moderate Recommendation)

Key Action Statement 19a

Should use parenteral antimicrobial therapy if CSF analysis suggests bacterial meningitis. (Grade: A; Strong Recommendation)

Key Action Statement 19b

May use parenteral antimicrobial therapy if both of the following apply: (1) CSF analysis (if CSF obtained) is normal; (2) any IM obtained is abnormal. (Grade: B; Moderate Recommendation)

Key Action Statement 19c

Should initiate oral antimicrobial therapy if all of the following apply: (1) CSF analysis (if CSF obtained) is normal; (2) urinalysis result is positive; (3) no IM obtained is abnormal. (Grade: B; Strong Recommendation)

Key Action Statement 19d

Need not use antimicrobial therapy while awaiting bacterial culture results if all of the following are met: (1) CSF analysis, if obtained, or normal or enterovirus-positive; (2) urinalysis result is negative; (3) no IM obtained is abnormal. (Grade: B; Moderate Recommendation)

Key Action Statement 20a

Should hospitalize infants in a unit with nurses and staff experienced in the care of 29- to 60-d-old infants if CSF analysis, if obtained, is abnormal. (Grade: A; Strong Recommendation)

Key Action Statement 20b

May hospitalize infants in a unit with nurses and staff experienced in the care of 29- to 60-d-old infants if any IM obtained is abnormal. (Grade: B; Moderate Recommendation)

Key Action Statement 20c

Should manage patients at home if all of the following criteria are met: (1) CSF analysis, if CSF obtained, is normal; (2) urinalysis result is negative; (3) all IMs obtained are normal; (4) appropriate parental education has been provided; (5) follow-up plans for reevaluation in 24 h have been developed and are in place; (6) plans have been developed and are in place in case of change in clinical status, including means of communication between family and providers and access to emergency medical care. (Grade: B; Moderate Recommendation)

Key Action Statement 20d

May manage infants without antimicrobial treatment at home without having obtained interpretable CSF if all of the following are met: (1) urinalysis result is negative; (2) all IMs obtained are normal; (3) parents can return promptly if there is a change in infant condition and agree to follow-up in 24 to 36 h. Infants monitored at home should be reassessed in the following 24 h. (Grade: B; Moderate Recommendation)

Key Action Statement 20e

Need not treat with antimicrobial therapy if all of the following apply: (1) CSF analysis (if CSF obtained) is normal; (2) urinalysis result is negative; (3) no IM obtained is abnormal. (Grade: C; Moderate Recommendation)

Key Action Statement 21a

Should discontinue antimicrobial agents when all of the following are met: (1) all bacterial culture results are negative at 24–36 h; (2) infant is clinically well or improving (eg, fever, feeding); (3) there is no other infection requiring treatment (eg, otitis media). (Grade: B; Strong Recommendation)

Key Action Statement 21b

Should discharge hospitalized patients with positive urine culture results if all of the following are met: (1) blood culture result is negative; (2) result of CSF culture, if obtained, is negative; (3) infant is clinically well or improving (eg, fever, feeding); (4) there are no other reasons for hospitalization. (Grade: B; Strong Recommendation)

Key Action Statement 21c

Should discontinue parenteral antibiotics (if started) and begin or continue oral antimicrobial for infants with urinary tract infections managed at home when all of the following are met: (1) urine culture result is positive; (2) all other bacterial culture results are negative at 24–36 h; (3) infant is clinically well or improving (eg, fever, feeding). (Grade: B; Strong Recommendation)

Key Action Statement 21d

Should treat infants' positive bacterial pathogens in urine, blood, or CSF with targeted antimicrobial therapy for the duration of time consistent with the nature of the disease, responsible organism, and response of the infant to treatment. (Grade: A; Strong Recommendation)

Coding Quick Reference for Well-Appearing Febrile Infants
ICD-10-CM
P81.9 Disturbance of temperature regulation of newborn, unspecified (Fever of newborn NOS)
R50.9 Fever, unspecified (fever of unknown origin)

SECTION 2

Endorsed Clinical Practice Guidelines

The American Academy of Pediatrics endorses and accepts as its policy the following guidelines from other organizations.

CARDIOVASCULAR HEALTH

Expert Panel on Integrated Guidelines for Cardiovascular Health and Risk Reduction in Children and Adolescents: Summary Report

National Heart, Lung, and Blood Institute

INTRODUCTION (EXCERPT). Atherosclerotic cardiovascular disease (CVD) remains the leading cause of death in North Americans, but manifest disease in childhood and adolescence is rare. By contrast, risk factors and risk behaviors that accelerate the development of atherosclerosis begin in childhood, and there is increasing evidence that risk reduction delays progression toward clinical disease. In response, the former director of the National Heart, Lung, and Blood Institute (NHLBI), Dr Elizabeth Nabel, initiated development of cardiovascular health guidelines for pediatric care providers based on a formal evidence review of the science with an integrated format addressing all the major cardiovascular risk factors simultaneously. An expert panel was appointed to develop the guidelines in the fall of 2006. (10/12)

CEREBRAL PALSY

Diagnostic Assessment of the Child With Cerebral Palsy

Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

ABSTRACT. ***Objective.*** The Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society develop practice parameters as strategies for patient management based on analysis of evidence. For this parameter the authors reviewed available evidence on the assessment of a child suspected of having cerebral palsy (CP), a nonprogressive disorder of posture or movement due to a lesion of the developing brain.

Methods. Relevant literature was reviewed, abstracted, and classified. Recommendations were based on a four-tiered scheme of evidence classification.

Results. CP is a common problem, occurring in about 2 to 2.5 per 1,000 live births. In order to establish that a brain abnormality exists in children with CP that may, in turn, suggest an etiology and prognosis, neuroimaging is recommended with MRI preferred to CT (Level A). Metabolic and genetic studies should not be routinely obtained in the evaluation of the child with CP (Level B). If the clinical history or findings on neuroimaging do not determine a specific structural abnormality or if there are additional and atypical features in the history or clinical examination, metabolic and genetic testing should be considered (Level C). Detection of a brain malformation in a child with CP warrants consideration of an underlying genetic or metabolic etiology. Because the incidence of cerebral infarction is high in children with hemiplegic CP, diagnostic testing for coagulation disorders should be considered (Level B). However, there is insufficient evidence at present to be precise as to what studies should be ordered. An EEG is not recommended unless there are features suggestive of epilepsy or a specific epileptic syndrome (Level A). Because children with CP may have associated deficits of mental retardation, ophthalmologic and hearing impairments, speech and language disorders, and oral-motor dysfunction, screening for these conditions should be part of the initial assessment (Level A).

Conclusions. Neuroimaging results in children with CP are commonly abnormal and may help determine the etiology. Screening for associated conditions is warranted as part of the initial evaluation. (3/04, reaffirmed 7/07, 11/13)

CERUMEN IMPACTION

Cerumen Impaction

American Academy of Otolaryngology—Head and Neck Surgery Foundation

ABSTRACT. This update of the 2008 American Academy of Otolaryngology—Head and Neck Surgery Foundation cerumen impaction clinical practice guideline provides evidence-based recommendations on managing cerumen impaction. Cerumen impaction is defined as an accumulation of cerumen that causes symptoms, prevents assessment of the ear, or both. Changes from the prior guideline include

- a consumer added to the development group;
- new evidence (3 guidelines, 5 systematic reviews, and 6 randomized controlled trials);
- enhanced information on patient education and counseling;
- a new algorithm to clarify action statement relationships;
- expanded action statement profiles to explicitly state quality improvement opportunities, confidence in the evidence, intentional vagueness, and differences of opinion;
- an enhanced external review process to include public comment and journal peer review; and
- new key action statements on managing cerumen impaction that focus on primary prevention, contraindicated intervention, and referral and coordination of care. (1/17)

CONGENITAL MUSCULAR DYSTROPHY

Evidence-based Guideline Summary: Evaluation, Diagnosis, and Management of Congenital Muscular Dystrophy. Report of the Guideline Development Subcommittee of the American Academy of Neurology and the Practice Issues Review Panel of the American Association of Neuromuscular & Electrodiagnostic Medicine

American Academy of Neurology and American Association of Neuromuscular & Electrodiagnostic Medicine

ABSTRACT. ***Objective.*** To delineate optimal diagnostic and therapeutic approaches to congenital muscular dystrophy (CMD) through a systematic review and analysis of the currently available literature.

Methods. Relevant, peer-reviewed research articles were identified using a literature search of the MEDLINE, EMBASE, and Scopus databases. Diagnostic and therapeutic data from these articles were extracted and analyzed in accordance with the American Academy of Neurology classification of evidence schemes for diagnostic, prognostic, and therapeutic studies. Recommendations were linked to the strength of the evidence, other related literature, and general principles of care.

Results. The geographic and ethnic backgrounds, clinical features, brain imaging studies, muscle imaging studies, and muscle biopsies of children with suspected CMD help predict subtype-specific diagnoses. Genetic testing can confirm some subtype-specific diagnoses, but not all causative genes for CMD have been described. Seizures and respiratory complications occur in specific subtypes. There is insufficient evidence to determine the efficacy of various treatment interventions to optimize respiratory, orthopedic, and nutritional outcomes, and more data are needed regarding complications.

Recommendations. Multidisciplinary care by experienced teams is important for diagnosing and promoting the health of children with CMD. Accurate assessment of clinical presentations and genetic data will help in identifying the correct subtype-specific diagnosis in many cases. Multiorgan system complications occur frequently; surveillance and prompt interventions are likely to be beneficial for affected children. More research is needed to fill gaps in knowledge regarding this category of muscular dystrophies. (3/15, reaffirmed 7/18, 9/21)

DEPRESSION

Guidelines for Adolescent Depression in Primary Care (GLAD-PC): Part I. Practice Preparation, Identification, Assessment, and Initial Management

Rachel A. Zuckerbrot, MD; Amy Cheung, MD; Peter S. Jensen, MD; Ruth E.K. Stein, MD; Danielle Laraque, MD; and GLAD-PC Steering Group

ABSTRACT. ***Objectives***. To update clinical practice guidelines to assist primary care (PC) clinicians in the management of adolescent depression. This part of the updated guidelines is used to address practice preparation, identification, assessment, and initial management of adolescent depression in PC settings.

Methods. By using a combination of evidence- and consensus-based methodologies, guidelines were developed by an expert steering committee in 2 phases as informed by (1) current scientific evidence (published and unpublished) and (2) draft revision and iteration among the steering committee, which included experts, clinicians, and youth and families with lived experience.

Results. Guidelines were updated for youth aged 10 to 21 years and correspond to initial phases of adolescent depression management in PC, including the identification of at-risk youth, assessment and diagnosis, and initial management. The strength of each recommendation and its evidence base are summarized. The practice preparation, identification, assessment, and initial management section of the guidelines include recommendations for (1) the preparation of the PC practice for improved care of adolescents with depression; (2) annual universal screening of youth 12 and over at health maintenance visits; (3) the identification of depression in youth who are at high risk; (4) systematic assessment procedures by using reliable depression scales, patient and caregiver interviews, and *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* criteria; (5) patient and family psychoeducation; (6) the establishment of relevant links in the community; and (7) the establishment of a safety plan.

Conclusions. This part of the guidelines is intended to assist PC clinicians in the identification and initial management of adolescents with depression in an era of great clinical need and shortage of mental health specialists, but they cannot replace clinical judgment; these guidelines are not meant to be the sole source of guidance for depression management in adolescents. Additional research that addresses the identification and initial management of youth with depression in PC is needed, including empirical testing of these guidelines. (2/18)

Guidelines for Adolescent Depression in Primary Care (GLAD-PC): Part II. Treatment and Ongoing Management

Amy H. Cheung, MD; Rachel A. Zuckerbrot, MD; Peter S. Jensen, MD; Danielle Laraque, MD; Ruth E.K. Stein, MD; and GLAD-PC Steering Group

ABSTRACT. ***Objectives***. To update clinical practice guidelines to assist primary care (PC) in the screening and assessment of depression. In this second part of the updated guidelines, we address treatment and ongoing management of adolescent depression in the PC setting.

Methods. By using a combination of evidence- and consensus-based methodologies, the guidelines were updated in 2 phases as informed by (1) current scientific evidence (published and unpublished) and (2) revision and iteration among the steering committee, including youth and families with lived experience.

Results. These updated guidelines are targeted for youth aged 10 to 21 years and offer recommendations for the management of adolescent depression in PC, including (1) active monitoring of mildly depressed youth, (2) treatment with evidence-based medication and psychotherapeutic approaches in cases of moderate and/or severe depression, (3) close monitoring of side effects, (4) consultation and comanagement of care with mental health specialists, (5) ongoing tracking of outcomes, and (6) specific steps to be taken in instances of partial or no improvement after an initial treatment has begun. The strength of each recommendation and the grade of its evidence base are summarized.

Conclusions. The Guidelines for Adolescent Depression in Primary Care cannot replace clinical judgment, and they should not be the sole source of guidance for adolescent depression management. Nonetheless, the guidelines may assist PC clinicians in the management of depressed adolescents in an era of great clinical need and a shortage of mental health specialists. Additional research concerning the management of depressed youth in PC is needed, including the usability, feasibility, and sustainability of guidelines, and determination of the extent to which the guidelines actually improve outcomes of depressed youth. (2/18)

DUCHENNE MUSCULAR DYSTROPHY

Practice Guideline Update Summary: Corticosteroid Treatment of Duchenne Muscular Dystrophy

David Gloss, MD, MPH&TM; Richard T. Moxley III, MD; Stephen Ashwal, MD; and Maryam Oskoui, MD, for the American Academy of Neurology Guideline Development Subcommittee

ABSTRACT. ***Objective.*** To update the 2005 American Academy of Neurology (AAN) guideline on corticosteroid treatment of Duchenne muscular dystrophy (DMD).

Methods. We systematically reviewed the literature from January 2004 to July 2014 using the AAN classification scheme for therapeutic articles and predicated recommendations on the strength of the evidence.

Results. Thirty-four studies met inclusion criteria.

Recommendations. In children with DMD, prednisone should be offered for improving strength (Level B) and pulmonary function (Level B). Prednisone may be offered for improving timed motor function (Level C), reducing the need for scoliosis surgery (Level C), and delaying cardiomyopathy onset by 18 years of age (Level C). Deflazacort may be offered for improving strength and timed motor function and delaying age at loss of ambulation by 1.4–2.5 years (Level C). Deflazacort may be offered for improving pulmonary function, reducing the need for scoliosis surgery, delaying cardiomyopathy onset, and increasing survival at 5–15 years of follow-up (Level C for each). Deflazacort and prednisone may be equivalent in improving motor function (Level C). Prednisone may be associated with greater weight gain in the first years of treatment than deflazacort (Level C). Deflazacort may be associated with a greater risk of cataracts than prednisone (Level C). The preferred dosing regimen of prednisone is 0.75 mg/kg/d (Level B). Over 12 months, prednisone 10 mg/kg/weekend is equally effective (Level B), with no long-term data available. Prednisone 0.75 mg/kg/d is associated with significant risk of weight gain, hirsutism, and cushingoid appearance (Level B). *Neurology*® 2016;86:465–472 (2/16, reaffirmed 1/19)

DYSPLASIA OF THE HIP

Guideline on Detection and Nonoperative Management of Pediatric Developmental Dysplasia of the Hip in Infants up to Six Months of Age: Evidence-based Clinical Practice Guideline

American Academy of Orthopaedic Surgeons

OVERVIEW. This clinical practice guideline is based upon a systematic review of published articles related to the detection and early management of hip instability and dysplasia in typically developing children less than 6 months of age. This guideline provides practice recommendations for the early screening and detection of hip instability and dysplasia and also highlights gaps in the published literature that should stimulate additional research. This guideline is intended towards appropriately

trained practitioners involved in the early examination and assessment of typically developing children for hip instability and dysplasia. (9/14)

FOOD ALLERGY

Guidelines for the Diagnosis and Management of Food Allergy in the United States: Report of the NIAID-Sponsored Expert Panel

National Institute of Allergy and Infectious Diseases

ABSTRACT. Food allergy is an important public health problem that affects children and adults and may be increasing in prevalence. Despite the risk of severe allergic reactions and even death, there is no current treatment for food allergy: the disease can only be managed by allergen avoidance or treatment of symptoms. The diagnosis and management of food allergy also may vary from one clinical practice setting to another. Finally, because patients frequently confuse nonallergic food reactions, such as food intolerance, with food allergies, there is an unfounded belief among the public that food allergy prevalence is higher than it truly is. In response to these concerns, the National Institute of Allergy and Infectious Diseases, working with 34 professional organizations, federal agencies, and patient advocacy groups, led the development of clinical guidelines for the diagnosis and management of food allergy. These Guidelines are intended for use by a wide variety of health care professionals, including family practice physicians, clinical specialists, and nurse practitioners. The Guidelines include a consensus definition for food allergy, discuss comorbid conditions often associated with food allergy, and focus on both IgE-mediated and non-IgE-mediated reactions to food. Topics addressed include the epidemiology, natural history, diagnosis, and management of food allergy, as well as the management of severe symptoms and anaphylaxis. These Guidelines provide 43 concise clinical recommendations and additional guidance on points of current controversy in patient management. They also identify gaps in the current scientific knowledge to be addressed through future research. (12/10)

HEMORRHAGE

An Evidence-based Prehospital Guideline for External Hemorrhage Control

American College of Surgeons Committee on Trauma

ABSTRACT. This report describes the development of an evidence-based guideline for external hemorrhage control in the prehospital setting. This project included a systematic review of the literature regarding the use of tourniquets and hemostatic agents for management of life-threatening extremity and junctional hemorrhage. Using the GRADE methodology to define the key clinical questions, an expert panel then reviewed the results of the literature review, established the quality of the evidence and made recommendations for EMS care. A clinical care guideline is proposed for adoption by EMS systems. (3/14)

HIV

Guidelines for the Prevention and Treatment of Opportunistic Infections in HIV-Exposed and HIV-Infected Children

US Department of Health and Human Services

SUMMARY. This report updates the last version of the Guidelines for the Prevention and Treatment of Opportunistic Infections (OIs) in HIV-Exposed and HIV-Infected Children, published in 2009. These guidelines are intended for use by clinicians and other health-care workers providing medical care for HIV-exposed and HIV-infected children in the United States. The guidelines discuss opportunistic pathogens that occur in the United States and ones that might be acquired during international travel, such as malaria. Topic areas covered for each OI include a brief description of the epidemiology, clinical presentation, and diagnosis of the OI in children; prevention of exposure; prevention of first episode of disease; discontinuation of primary prophylaxis after immune reconstitution; treatment of disease; monitoring for adverse effects during treatment, including immune reconstitution inflammatory syndrome (IRIS); management of treatment failure; prevention of disease recurrence; and discontinuation of secondary prophylaxis after immune reconstitution. A separate document providing recommendations for prevention and treatment of OIs among HIV-infected adults and post-pubertal adolescents (*Guidelines for the Prevention and Treatment of Opportunistic Infections in HIV-Infected Adults and Adolescents*) was prepared by a panel of adult HIV and infectious disease specialists (see http://aidsinfo.nih.gov/guidelines).

These guidelines were developed by a panel of specialists in pediatric HIV infection and infectious diseases (the Panel on Opportunistic Infections in HIV-Exposed and HIV-Infected Children) from the U.S. government and academic institutions. For each OI, one or more pediatric specialists with subject-matter expertise reviewed the literature for new information since the last guidelines were published and then proposed revised recommendations for review by the full Panel. After these reviews and discussions, the guidelines underwent further revision, with review and approval by the Panel, and final endorsement by the National Institutes of Health (NIH), Centers for Disease Control and Prevention (CDC), the HIV Medicine Association (HIVMA) of the Infectious Diseases Society of America (IDSA), the Pediatric Infectious Disease Society (PIDS), and the American Academy of Pediatrics (AAP). So that readers can ascertain how best to apply the recommendations in their practice environments, the recommendations are rated by a letter that indicates the strength of the recommendation, a Roman numeral that indicates the quality of the evidence supporting the recommendation, and where applicable, a * notation that signifies a hybrid of higher-quality adult study evidence and consistent but lower-quality pediatric study evidence.

More detailed methodologic considerations are listed in Appendix 1 (Important Guidelines Considerations), including a description of the make-up and organizational structure of the Panel, definition of financial disclosure and management of conflict of interest, funding sources for the guidelines, methods of collecting and synthesizing evidence and formulating recommendations, public commentary, and plans for updating the guidelines. The names and financial disclosures for each of the Panel members are listed in Appendices 2 and 3, respectively.

An important mode of childhood acquisition of OIs and HIV infection is from infected mothers. HIV-infected women may be more likely to have coinfections with opportunistic pathogens (e.g., hepatitis C) and more likely than women who are not HIV-infected to transmit these infections to their infants. In addition, HIV-infected women or HIV-infected family members coinfected with certain opportunistic pathogens may be more likely to transmit these infections horizontally to their children, resulting in increased likelihood of primary acquisition of such infections in young children. Furthermore, transplacental transfer of antibodies that protect infants against serious infections may be lower in HIV-infected women than in women who are HIV-uninfected. Therefore, infections with opportunistic pathogens may affect not just HIV-infected infants but also HIV-exposed, uninfected infants. These guidelines for treating OIs in children, therefore, consider treatment of infections in all children—HIV-infected and HIV-uninfected—born to HIV-infected women.

In addition, HIV infection increasingly is seen in adolescents with perinatal infection who are now surviving into their teens and in youth with behaviorally acquired HIV infection. Guidelines for postpubertal adolescents can be found in the adult OI guidelines, but drug pharmacokinetics (PK) and response to treatment may

differ in younger prepubertal or pubertal adolescents. Therefore, these guidelines also apply to treatment of HIV-infected youth who have not yet completed pubertal development.

Major changes in the guidelines from the previous version in 2009 include:

- Greater emphasis on the importance of antiretroviral therapy (ART) for prevention and treatment of OIs, especially those OIs for which no specific therapy exists;
- Increased information about diagnosis and management of IRIS;
- Information about managing ART in children with OIs, including potential drug-drug interactions;
- Updated immunization recommendations for HIV-exposed and HIV-infected children, including pneumococcal, human papillomavirus, meningococcal, and rotavirus vaccines;
- Addition of sections on influenza, giardiasis, and isosporiasis;
- Elimination of sections on aspergillosis, bartonellosis, and HHV-6 and HHV-7 infections; and
- Updated recommendations on discontinuation of OI prophylaxis after immune reconstitution in children.

The most important recommendations are highlighted in boxed major recommendations preceding each section, and a table of dosing recommendations appears at the end of each section. The guidelines conclude with summary tables that display dosing recommendations for all of the conditions, drug toxicities and drug interactions, and 2 figures describing immunization recommendations for children aged 0 to 6 years and 7 to 18 years.

The terminology for describing use of antiretroviral (ARV) drugs for treatment of HIV infection has been standardized to ensure consistency within the sections of these guidelines and with the *Guidelines for the Use of Antiretroviral Agents in Pediatric HIV Infection.* Combination antiretroviral therapy (cART) indicates use of multiple (generally 3 or more) ARV drugs as part of an HIV treatment regimen that is designed to achieve virologic suppression; highly active antiretroviral therapy (HAART), synonymous with cART, is no longer used and has been replaced by cART; the term ART has been used when referring to use of ARV drugs for HIV treatment more generally, including (mostly historical) use of one- or two-agent ARV regimens that do not meet criteria for cART.

Because treatment of OIs is an evolving science, and availability of new agents or clinical data on existing agents may change therapeutic options and preferences, these recommendations will be periodically updated and will be available at http://AIDSinfo.nih.gov. (11/13, updated 11/18, 3/21)

INFANTILE SPASMS

Evidence-based Guideline Update: Medical Treatment of Infantile Spasms

American Academy of Neurology and Child Neurology Society

ABSTRACT. ***Objective.*** To update the 2004 American Academy of Neurology/Child Neurology Society practice parameter on treatment of infantile spasms in children.

Methods. MEDLINE and EMBASE were searched from 2002 to 2011 and searches of reference lists of retrieved articles were performed. Sixty-eight articles were selected for detailed review; 26 were included in the analysis. Recommendations were based on a 4-tiered classification scheme combining pre-2002 evidence and more recent evidence.

Results. There is insufficient evidence to determine whether other forms of corticosteroids are as effective as adrenocorticotropic hormone (ACTH) for short-term treatment of infantile spasms. However, low-dose ACTH is probably as effective as high-dose ACTH. ACTH is more effective than vigabatrin (VGB) for short-term treatment of children with infantile spasms (excluding those with tuberous sclerosis complex). There is insufficient evidence to show that other agents and combination therapy are effective for short-term treatment of infantile spasms. Short lag time to treatment leads to better long-term developmental outcome. Successful short-term treatment of cryptogenic infantile spasms with ACTH or prednisolone leads to better long-term developmental outcome than treatment with VGB.

Recommendations. Low-dose ACTH should be considered for treatment of infantile spasms. ACTH or VGB may be useful for short-term treatment of infantile spasms, with ACTH considered preferentially over VGB. Hormonal therapy (ACTH or prednisolone) may be considered for use in preference to VGB in infants with cryptogenic infantile spasms, to possibly improve developmental outcome. A shorter lag time to treatment of infantile spasms with either hormonal therapy or VGB possibly improves long-term developmental outcomes. (6/12, reaffirmed 1/18, 5/21)

MEDULLARY THYROID CARCINOMA

Revised American Thyroid Association Guidelines for the Management of Medullary Thyroid Carcinoma

American Thyroid Association Guidelines Task Force on Medullary Thyroid Carcinoma

ABSTRACT. ***Introduction.*** The American Thyroid Association appointed a Task Force of experts to revise the original Medullary Thyroid Carcinoma: Management Guidelines of the American Thyroid Association.

Methods. The Task Force identified relevant articles using a systematic PubMed search, supplemented with additional published materials, and then created evidence-based recommendations, which were set in categories using criteria adapted from the United States Preventive Services Task Force Agency for Healthcare Research and Quality. The original guidelines provided abundant source material and an excellent organizational structure that served as the basis for the current revised document.

Results. The revised guidelines are focused primarily on the diagnosis and treatment of patients with sporadic medullary thyroid carcinoma (MTC) and hereditary MTC.

Conclusions. The Task Force developed 67 evidence-based recommendations to assist clinicians in the care of patients with MTC. The Task Force considers the recommendations to represent current, rational, and optimal medical practice. (6/15)

MIGRAINE HEADACHE

Practice Guideline Update: Acute Treatment of Migraine in Children and Adolescents. Report of the Guideline Development, Dissemination, and Implementation Subcommittee of the American Academy of Neurology and the American Headache Society

Maryam Oskoui, MD, MSc; Tamara Pringsheim, MD; Yolanda Holler-Managan, MD; Sonja Potrebic, MD, PhD; Lori Billinghurst, MD, MSc; David Gloss, MD; Andrew D. Hershey, MD, PhD; Nicole Licking, DO; Michael Sowell, MD; M. Cristina Victorio, MD; Elaine M. Gersz; Emily Leininger; Heather Zanitsch; Marcy Yonker, MD; and Kenneth Mack, MD, PhD

ABSTRACT. ***Objective.*** To provide evidence-based recommendations for the acute symptomatic treatment of children and adolescents with migraine.

Methods. We performed a systematic review of the literature and rated risk of bias of included studies according to the American Academy of Neurology classification of evidence criteria. A multidisciplinary panel developed practice recommendations, integrating findings from the systematic review and following an

Institute of Medicine–compliant process to ensure transparency and patient engagement. Recommendations were supported by structured rationales, integrating evidence from the systematic review, related evidence, principles of care, and inferences from evidence.

Results. There is evidence to support the efficacy of the use of ibuprofen, acetaminophen (in children and adolescents), and triptans (mainly in adolescents) for the relief of migraine pain, although confidence in the evidence varies between agents. There is high confidence in the evidence that adolescents receiving oral sumatriptan/naproxen and zolmitriptan nasal spray are more likely to be headache-free at 2 hours than those receiving placebo. No acute treatments were effective for migraine-related nausea or vomiting; some triptans were effective for migraine-related phonophobia and photophobia.

Recommendations. Recommendations for the treatment of acute migraine in children and adolescents focus on the importance of early treatment, choosing the route of administration best suited to the characteristics of the individual migraine attack, and providing counseling on lifestyle factors that can exacerbate migraine, including trigger avoidance and medication overuse. (8/19)

Practice Guideline Update: Pharmacologic Treatment for Pediatric Migraine Prevention. Report of the Guideline Development, Dissemination, and Implementation Subcommittee of the American Academy of Neurology and the American Headache Society

Maryam Oskoui, MD, MSc; Tamara Pringsheim, MD; Lori Billinghurst, MD; Sonja Potrebic, MD, PhD; Elaine M. Gersz; David Gloss, MD, MPH&TM; Yolanda Holler-Managan, MD; Emily Leininger; Nicole Licking, DO; Kenneth Mack, MD, PhD; Scott W. Powers, PhD, ABPP; Michael Sowell, MD; M. Cristina Victorio, MD; Marcy Yonker; Heather Zanitsch; and Andrew D. Hershey, MD, PhD

ABSTRACT. ***Objective.*** To provide updated evidence-based recommendations for migraine prevention using pharmacologic treatment with or without cognitive behavioral therapy in the pediatric population.

Methods. The authors systematically reviewed literature from January 2003 to August 2017 and developed practice recommendations using the American Academy of Neurology 2011 process, as amended.

Results. Fifteen Class I–III studies on migraine prevention in children and adolescents met inclusion criteria. There is insufficient evidence to determine if children and adolescents receiving divalproex, onabotulinumtoxinA, amitriptyline, nimodipine, or flunarizine are more or less likely than those receiving placebo to have a reduction in headache frequency. Children with migraine receiving propranolol are possibly more likely than those receiving placebo to have an at least 50% reduction in headache frequency. Children and adolescents receiving topiramate and cinnarizine are probably more likely than those receiving placebo to have a decrease in headache frequency. Children with migraine receiving amitriptyline plus cognitive behavioral therapy are more likely than those receiving amitriptyline plus headache education to have a reduction in headache frequency.

Recommendations. The majority of randomized controlled trials studying the efficacy of preventive medications for pediatric migraine fail to demonstrate superiority to placebo. Recommendations for the prevention of migraine in children include counseling on lifestyle and behavioral factors that influence headache frequency and assessment and management of comorbid disorders associated with headache persistence. Clinicians should engage in shared decision-making with patients and caregivers regarding the use of preventive treatments for migraine, including discussion of the limitations in the evidence to support pharmacologic treatments. (8/19)

NOSEBLEED (EPISTAXIS)

Clinical Practice Guideline: Nosebleed (Epistaxis)

David E. Tunkel, MD; Samantha Anne, MD, MS; Spencer C. Payne, MD; Stacey L. Ishman, MD, MPH; Richard M. Rosenfeld, MD, MPH, MBA; Peter J. Abramson, MD; Jacqueline D. Alikhaani; Margo McKenna Benoit, MD; Rachel S. Bercovitz, MD, MS; Michael D. Brown, MD, MSc; Boris Chernobilsky, MD; David A. Feldstein, MD; Jesse M. Hackell, MD; Eric H. Holbrook, MD; Sarah M. Holdsworth, MSN, APRN; Kenneth W. Lin, MD, MPH; Meredith Merz Lind, MD; David M. Poetker, MD, MA; Charles A. Riley, MD; John S. Schneider, MD, MA; Michael D. Seidman, MD; Venu Vadlamudi, MD; Tulio A. Valdez, MD; Lorraine C. Nnacheta, MPH, DrPH; Taskin M. Monjur

ABSTRACT. **Objective.** Nosebleed, also known as epistaxis, is a common problem that occurs at some point in at least 60% of people in the United States. While the majority of nosebleeds are limited in severity and duration, about 6% of people who experience nosebleeds will seek medical attention. For the purposes of this guideline, we define the target patient with a nosebleed as a patient with bleeding from the nostril, nasal cavity, or nasopharynx that is sufficient to warrant medical advice or care. This includes bleeding that is severe, persistent, and/or recurrent, as well as bleeding that impacts a patient's quality of life. Interventions for nosebleeds range from self-treatment and home remedies to more intensive procedural interventions in medical offices, emergency departments, hospitals, and operating rooms. Epistaxis has been estimated to account for 0.5% of all emergency department visits and up to one-third of all otolaryngology-related emergency department encounters. Inpatient hospitalization for aggressive treatment of severe nosebleeds has been reported in 0.2% of patients with nosebleeds.

Purpose. The primary purpose of this multidisciplinary guideline is to identify quality improvement opportunities in the management of nosebleeds and to create clear and actionable recommendations to implement these opportunities in clinical practice. Specific goals of this guideline are to promote best practices, reduce unjustified variations in care of patients with nosebleeds, improve health outcomes, and minimize the potential harms of nosebleeds or interventions to treat nosebleeds.

The target patient for the guideline is any individual aged ≥3 years with a nosebleed or history of nosebleed who needs medical treatment or seeks medical advice. The target audience of this guideline is clinicians who evaluate and treat patients with nosebleed. This includes primary care providers such as family medicine physicians, internists, pediatricians, physician assistants, and nurse practitioners. It also includes specialists such as emergency medicine providers, otolaryngologists, interventional radiologists/neuroradiologists and neurointerventionalists, hematologists, and cardiologists. The setting for this guideline includes any site of evaluation and treatment for a patient with nosebleed, including ambulatory medical sites, the emergency department, the inpatient hospital, and even remote outpatient encounters with phone calls and telemedicine. Outcomes to be considered for patients with nosebleed include control of acute bleeding, prevention of recurrent episodes of nasal bleeding, complications of treatment modalities, and accuracy of diagnostic measures.

This guideline addresses the diagnosis, treatment, and prevention of nosebleed. It focuses on nosebleeds that commonly present to clinicians via phone calls, office visits, and emergency room encounters. This guideline discusses first-line treatments such as nasal compression, application of vasoconstrictors, nasal packing, and nasal cautery. It also addresses more complex epistaxis management, which includes the use of endoscopic arterial

ligation and interventional radiology procedures. Management options for 2 special groups of patients—patients with hereditary hemorrhagic telangiectasia syndrome and patients taking medications that inhibit coagulation and/or platelet function—are included in this guideline.

This guideline is intended to focus on evidence-based quality improvement opportunities judged most important by the guideline development group. It is not intended to be a comprehensive, general guide for managing patients with nosebleed. In this context, the purpose is to define useful actions for clinicians, generalists, and specialists from a variety of disciplines to improve quality of care. Conversely, the statements in this guideline are not intended to limit or restrict care provided by clinicians based on their experience and assessment of individual patients. (1/20)

PALLIATIVE CARE

Clinical Practice Guidelines for Quality Palliative Care, 4th Edition
National Consensus Project for Quality Palliative Care (2018)

POSITIONAL PLAGIOCEPHALY

Systematic Review and Evidence-based Guidelines for the Management of Patients With Positional Plagiocephaly
Congress of Neurologic Surgeons

ABSTRACT. *Background.* Positional plagiocephaly is a common problem seen by pediatricians, pediatric neurologists, and pediatric neurosurgeons. Currently, there are no evidence-based guidelines on the management of positional plagiocephaly. The topics addressed in subsequent chapters of this guideline include: diagnosis, repositioning, physical therapy, and orthotic devices.

Objective. To evaluate topics relevant to the diagnosis and management of patients with positional plagiocephaly. The rigorous systematic process in which this guideline was created is presented in this chapter.

Methods. This guideline was prepared by the Plagiocephaly Guideline Task Force, a multidisciplinary team comprised of physician volunteers (clinical experts), medical librarians, and clinical guidelines specialists. The task force conducted a series of systematic literature searches of the National Library of Medicine and the Cochrane Library, according to standard protocols described below, for each topic addressed in subsequent chapters of this guideline.

Results. The systematic literature searches returned 396 abstracts relative to the 4 main topics addressed in this guideline. The results were analyzed and are described in detail in each subsequent chapter included in this guideline.

Conclusion. Evidence-based guidelines for the management of infants with positional plagiocephaly will help practitioners manage this common disorder. (11/16)

RHINOPLASTY

Improving Nasal Form and Function after Rhinoplasty
American Academy of Otolaryngology—Head and Neck Surgery Foundation

ABSTRACT. Rhinoplasty, a surgical procedure that alters the shape or appearance of the nose while preserving or enhancing the nasal airway, ranks among the most commonly performed cosmetic procedures in the United States, with >200,000 procedures reported in 2014. While it is difficult to calculate the exact economic burden incurred by rhinoplasty patients following surgery with or without complications, the average rhinoplasty procedure typically exceeds $4000. The costs incurred due to complications, infections, or revision surgery may include the cost of long-term antibiotics, hospitalization, or lost revenue from hours/days of missed work. The resultant psychological impact of rhinoplasty can also be significant. Furthermore, the health care burden from psychological pressures of nasal deformities/aesthetic shortcomings, surgical infections, surgical pain, side effects from antibiotics, and nasal packing materials must also be considered for these patients. Prior to this guideline, limited literature existed on standard care considerations for pre- and postsurgical management and for standard surgical practice to ensure optimal outcomes for patients undergoing rhinoplasty. The impetus for this guideline is to utilize current evidence-based medicine practices and data to build unanimity regarding the peri- and postoperative strategies to maximize patient safety and to optimize surgical results for patients. (2/17)

SEIZURE

Treatment of the Child With a First Unprovoked Seizure
Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

ABSTRACT. The Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society develop practice parameters as strategies for patient management based on analysis of evidence regarding risks and benefits. This parameter reviews published literature relevant to the decision to begin treatment after a child or adolescent experiences a first unprovoked seizure and presents evidence-based practice recommendations. Reasons why treatment may be considered are discussed. Evidence is reviewed concerning risk of recurrence as well as effect of treatment on prevention of recurrence and development of chronic epilepsy. Studies of side effects of anticonvulsants commonly used to treat seizures in children are also reviewed. Relevant articles are classified according to the Quality Standards Subcommittee classification scheme. Treatment after a first unprovoked seizure appears to decrease the risk of a second seizure, but there are few data from studies involving only children. There appears to be no benefit of treatment with regard to the prognosis for long-term seizure remission. Antiepileptic drugs (AED) carry risks of side effects that are particularly important in children. The decision as to whether or not to treat children and adolescents who have experienced a first unprovoked seizure must be based on a risk–benefit assessment that weighs the risk of having another seizure against the risk of chronic AED therapy. The decision should be individualized and take into account both medical issues and patient and family preference. (1/03, reaffirmed 7/06, 7/10, 7/13, 1/16, 10/18, 9/21)

SEPTIC SHOCK AND SEPSIS-ASSOCIATED ORGAN DYSFUNCTION

Surviving Sepsis Campaign International Guidelines for the Management of Septic Shock and Sepsis-Associated Organ Dysfunction in Children
Scott L. Weiss, MD, MSCE, FCCM (Co-Vice Chair); Mark J. Peters, MD, PhD (Co-Vice Chair); Waleed Alhazzani, MD, MSc, FRCPC (Methodology Chair); Michael S. D. Agus, MD, FCCM, FAAP; Heidi R. Wong, MD; Jerry J. Zimmerman, MD, PhD, FCCM; Niranjan Kissoon, MB BS, MCCM, FRCP(C), FAAP, FACPE (Co-Chair); and Pierre Tissieres, MD, DSc (Co-Chair)

ABSTRACT. ***Objectives.*** To develop evidence-based recommendations for clinicians caring for children (including infants, school-aged children, and adolescents) with septic shock and other sepsis-associated organ dysfunction.

Design. A panel of 49 international experts, representing 12 international organizations, as well as three methodologists and three public members was convened. Panel members assembled at key international meetings (for those panel members attending the conference), and a stand-alone meeting was held for all panel members in November 2018. A formal conflict-of-interest policy was developed at the onset of the process and enforced throughout. Teleconferences and electronic-based discussion among the chairs, co-chairs, methodologists, and group heads, as well as within subgroups, served as an integral part of the guideline development process.

Methods. The panel consisted of six subgroups: recognition and management of infection, hemodynamics and resuscitation, ventilation, endocrine and metabolic therapies, adjunctive therapies, and research priorities. We conducted a systematic review for each Population, Intervention, Control, and Outcomes question to identify the best available evidence, statistically summarized the evidence, and then assessed the quality of evidence using the Grading of Recommendations Assessment, Development, and Evaluation approach. We used the evidence-to-decision framework to formulate recommendations as strong or weak, or as a best practice statement. In addition, "in our practice" statements were included when evidence was inconclusive to issue a recommendation, but the panel felt that some guidance based on practice patterns may be appropriate.

Results. The panel provided 77 statements on the management and resuscitation of children with septic shock and other sepsis-associated organ dysfunction. Overall, six were strong recommendations, 52 were weak recommendations, and nine were best-practice statements. For 13 questions, no recommendations could be made; but, for 10 of these, "in our practice" statements were provided. In addition, 49 research priorities were identified.

Conclusions. A large cohort of international experts was able to achieve consensus regarding many recommendations for the best care of children with sepsis, acknowledging that most aspects of care had relatively low quality of evidence resulting in the frequent issuance of weak recommendations. Despite this challenge, these recommendations regarding the management of children with septic shock and other sepsis-associated organ dysfunction provide a foundation for consistent care to improve outcomes and inform future research. (2/20)

STATUS EPILEPTICUS

Diagnostic Assessment of the Child With Status Epilepticus (An Evidence-based Review)

Quality Standards Subcommittee of the American Academy of Neurology and the Practice Committee of the Child Neurology Society

ABSTRACT. ***Objective.*** To review evidence on the assessment of the child with status epilepticus (SE).

Methods. Relevant literature were reviewed, abstracted, and classified. When data were missing, a minimum diagnostic yield was calculated. Recommendations were based on a four-tiered scheme of evidence classification.

Results. Laboratory studies (Na^{++} or other electrolytes, Ca^{++}, glucose) were abnormal in approximately 6% and are generally ordered as routine practice. When blood or spinal fluid cultures were done on these children, blood cultures were abnormal in at least 2.5% and a CNS infection was found in at least 12.8%. When antiepileptic drug (AED) levels were ordered in known epileptic children already taking AEDs, the levels were low in 32%. A total of 3.6% of children had evidence of ingestion. When studies for inborn errors of metabolism were done, an abnormality was found in 4.2%. Epileptiform abnormalities occurred in 43% of EEGs of children with SE and helped determine the nature and location of precipitating electroconvulsive events (8% generalized, 16% focal, and 19% both). Abnormalities on neuroimaging studies that may explain the etiology of SE were found in at least 8% of children.

Recommendations. Although common clinical practice is that blood cultures and lumbar puncture are obtained if there is a clinical suspicion of a systemic or CNS infection, there are insufficient data to support or refute recommendations as to whether blood cultures or lumbar puncture should be done on a routine basis in children in whom there is no clinical suspicion of a systemic or CNS infection (Level U). AED levels should be considered when a child with treated epilepsy develops SE (Level B). Toxicology studies and metabolic studies for inborn errors of metabolism may be considered in children with SE when there are clinical indicators for concern or when the initial evaluation reveals no etiology (Level C). An EEG may be considered in a child with SE as it may be helpful in determining whether there are focal or generalized epileptiform abnormalities that may guide further testing for the etiology of SE, when there is a suspicion of pseudostatus epilepticus (nonepileptic SE), or nonconvulsive SE, and may guide treatment (Level C). Neuroimaging may be considered after the child with SE has been stabilized if there are clinical indications or if the etiology is unknown (Level C). There is insufficient evidence to support or refute routine neuroimaging in a child presenting with SE (Level U). (11/06, Reaffirmed 7/10, 7/13, 7/16, 1/19)

TELEHEALTH

Operating Procedures for Pediatric Telehealth

American Telemedicine Association

INTRODUCTION. Children represent one of our most vulnerable populations, and, as such, require special considerations when participating in telehealth encounters. Some services provided to adult patients by telehealth may not be easily adapted to or appropriate for pediatric patients due to physical factors (patient size), legal factors (consent, confidentiality), the ability to communicate and provide a history, developmental stage, unique pediatric conditions, and age-specific differences in both normal and disease states (AHRQ, n.d.; Alverson, 2008). These operating procedures for pediatric telehealth aim to improve the overall telehealth experience for pediatric patients, providers, and patient families. Telehealth holds particular promise in facilitating the management and coordination of care for medically

complex children and those with chronic conditions, such as asthma, chronic lung disease, autism, diabetes, and behavioral health conditions.

Through the use of telehealth, providers can provide appointment flexibility, increase access, promote continuity of care, and improve quality, either as a part of or as a complement to care delivered through the patient-centered medical home (PCMH). Whether telehealth services are delivered through the PCMH or as a complement to it, telehealth providers **should** routinely communicate with a patient's primary care provider and any relevant specialists regarding a telehealth encounter. Telehealth providers **shall** have a standard mechanism in place to share secure documentation of the encounter with the PCMH (AAP, 2015) in a timely manner.

These operating procedures do reference general telehealth operating principles that apply beyond pediatrics and that warrant particular emphasis, but they are not meant to serve as a comprehensive stand-alone guide to the development and operation of a telemedicine service. ATA has developed and published core standards for telehealth operations that provide overarching guidance for clinical, technical and administrative standards (ATA, 2014a). The Pediatric Operating Procedures complement existing professional organization guidance from the American Academy of Pediatrics, the American Psychological Association, the American Association of Family Physicians and the Society of Adolescent Health and Medicine. THYROID NODULES AND DIFFERENTIATED THYROID CANCER

Management Guidelines for Children With Thyroid Nodules and Differentiated Thyroid Cancer

American Thyroid Association Guidelines Task Force on Pediatric Thyroid Cancer

ABSTRACT. ***Background.*** Previous guidelines for the management of thyroid nodules and cancers were geared toward adults. Compared with thyroid neoplasms in adults, however, those in the pediatric population exhibit differences in pathophysiology, clinical presentation, and long-term outcomes. Furthermore, therapy that may be recommended for an adult may not be appropriate for a child who is at low risk for death but at higher risk for long-term harm from overly aggressive treatment. For these reasons, unique guidelines for children and adolescents with thyroid tumors are needed.

Methods. A task force commissioned by the American Thyroid Association (ATA) developed a series of clinically relevant questions pertaining to the management of children with thyroid nodules and differentiated thyroid cancer (DTC). Using an extensive literature search, primarily focused on studies that included subjects ≤18 years of age, the task force identified and reviewed relevant articles through April 2014. Recommendations were made based upon scientific evidence and expert opinion and were graded using a modified schema from the United States Preventive Services Task Force.

Results. These inaugural guidelines provide recommendations for the evaluation and management of thyroid nodules in children and adolescents, including the role and interpretation of ultrasound, fine-needle aspiration cytology, and the management of benign nodules. Recommendations for the evaluation, treatment, and follow-up of children and adolescents with DTC are outlined and include preoperative staging, surgical management, postoperative staging, the role of radioactive iodine therapy, and goals for thyrotropin suppression. Management algorithms are proposed and separate recommendations for papillary and follicular thyroid cancers are provided.

Conclusions. In response to our charge as an independent task force appointed by the ATA, we developed recommendations based on scientific evidence and expert opinion for the management of thyroid nodules and DTC in children and adolescents. In our opinion, these represent the current optimal care for children and adolescents with these conditions. (7/15)

TOBACCO USE

Treating Tobacco Use and Dependence: 2008 Update

US Department of Health and Human Services

ABSTRACT. *Treating Tobacco Use and Dependence: 2008 Update,* a Public Health Service-sponsored Clinical Practice Guideline, is a product of the Tobacco Use and Dependence Guideline Panel ("the Panel"), consortium representatives, consultants, and staff. These 37 individuals were charged with the responsibility of identifying effective, experimentally validated tobacco dependence treatments and practices. The updated Guideline was sponsored by a consortium of eight Federal Government and nonprofit organizations: the Agency for Healthcare Research and Quality (AHRQ); Centers for Disease Control and Prevention (CDC); National Cancer Institute (NCI); National Heart, Lung, and Blood Institute (NHLBI); National Institute on Drug Abuse (NIDA); American Legacy Foundation; Robert Wood Johnson Foundation (RWJF); and University of Wisconsin School of Medicine and Public Health's Center for Tobacco Research and Intervention (UW-CTRI). This Guideline is an updated version of the 2000 *Treating Tobacco Use and Dependence: Clinical Practice Guideline* that was sponsored by the U.S. Public Health Service, U. S. Department of Health and Human Services.

An impetus for this Guideline update was the expanding literature on tobacco dependence and its treatment. The original 1996 Guideline was based on some 3,000 articles on tobacco treatment published between 1975 and 1994. The 2000 Guideline entailed the collection and screening of an additional 3,000 articles published between 1995 and 1999. The 2008 Guideline update screened an additional 2,700 articles; thus, the present Guideline update reflects the distillation of a literature base of more than 8,700 research articles. Of course, this body of research was further reviewed to identify a much smaller group of articles that served as the basis for focused Guideline data analyses and review.

This Guideline contains strategies and recommendations designed to assist clinicians; tobacco dependence treatment specialists; and health care administrators, insurers, and purchasers in delivering and supporting effective treatments for tobacco use and dependence. The recommendations were made as a result of a systematic review and meta-analysis of 11 specific topics identified by the Panel (proactive quitlines; combining counseling and medication relative to either counseling or medication alone; varenicline; various medication combinations; long-term medications; cessation interventions for individuals with low socioeconomic status/limited formal education; cessation interventions for adolescent smokers; cessation interventions for pregnant smokers; cessation interventions for individuals with psychiatric disorders, including substance use disorders; providing cessation interventions as a health benefit; and systems interventions, including provider training and the combination of training and systems interventions). The strength of evidence that served as the basis for each recommendation is indicated clearly in the Guideline update. A draft of the Guideline update was peer reviewed prior to publication, and the input of 81 external reviewers was considered by the Panel prior to preparing the final document. In addition, the public had an opportunity to comment through a *Federal Register* review process. The key recommendations of the updated Guideline, *Treating Tobacco Use and Dependence: 2008 Update,* based on the literature review and expert Panel opinion, are as follows:

Ten Key Guideline Recommendations

The overarching goal of these recommendations is that clinicians strongly recommend the use of effective tobacco dependence counseling and medication treatments to their patients who use tobacco, and that health systems, insurers, and purchasers assist clinicians in making such effective treatments available.

1. Tobacco dependence is a chronic disease that often requires repeated intervention and multiple attempts to quit. Effective treatments exist, however, that can significantly increase rates of long-term abstinence.
2. It is essential that clinicians and health care delivery systems consistently identify and document tobacco use status and treat every tobacco user seen in a health care setting.
3. Tobacco dependence treatments are effective across a broad range of populations. Clinicians should encourage every patient willing to make a quit attempt to use the counseling treatments and medications recommended in this Guideline.
4. Brief tobacco dependence treatment is effective. Clinicians should offer every patient who uses tobacco at least the brief treatments shown to be effective in this Guideline.
5. Individual, group, and telephone counseling are effective, and their effectiveness increases with treatment intensity. Two components of counseling are especially effective, and clinicians should use these when counseling patients making a quit attempt:
   - Practical counseling (problem solving/skills training)
   - Social support delivered as part of treatment
6. Numerous effective medications are available for tobacco dependence, and clinicians should encourage their use by all patients attempting to quit smoking—except when medically contraindicated or with specific populations for which there is insufficient evidence of effectiveness (i.e., pregnant women, smokeless tobacco users, light smokers, and adolescents).
   - Seven first-line medications (5 nicotine and 2 non-nicotine) reliably increase long-term smoking abstinence rates:
     – Bupropion SR
     – Nicotine gum
     – Nicotine inhaler
     – Nicotine lozenge
     – Nicotine nasal spray
     – Nicotine patch
     – Varenicline
     – Clinicians also should consider the use of certain combinations of medications identified as effective in this Guideline.
7. Counseling and medication are effective when used by themselves for treating tobacco dependence. The combination of counseling and medication, however, is more effective than either alone. Thus, clinicians should encourage all individuals making a quit attempt to use both counseling and medication.
8. Telephone quitline counseling is effective with diverse populations and has broad reach. Therefore, both clinicians and health care delivery systems should ensure patient access to quitlines and promote quitline use.
9. If a tobacco user currently is unwilling to make a quit attempt, clinicians should use the motivational treatments shown in this Guideline to be effective in increasing future quit attempts.
10. Tobacco dependence treatments are both clinically effective and highly cost-effective relative to interventions for other clinical disorders. Providing coverage for these treatments increases quit rates. Insurers and purchasers should ensure that all insurance plans include the counseling and medication identified as effective in this Guideline as covered benefits.

The updated Guideline is divided into seven chapters that provide an overview, including methods (Chapter 1); information on the assessment of tobacco use (Chapter 2); clinical interventions, both for patients willing and unwilling to make a quit attempt at this time (Chapter 3); intensive interventions (Chapter 4); systems interventions for health care administrators, insurers, and purchasers (Chapter 5); the scientific evidence supporting the Guideline recommendations (Chapter 6); and information relevant to specific populations and other topics (Chapter 7).

A comparison of the findings of the updated Guideline with the 2000 Guideline reveals the considerable progress made in tobacco research over the brief period separating these two publications. Tobacco dependence increasingly is recognized as a chronic disease, one that typically requires ongoing assessment and repeated intervention. In addition, the updated Guideline offers the clinician many more effective treatment strategies than were identified in the original Guideline. There now are seven different first-line effective agents in the smoking cessation pharmacopoeia, allowing the clinician and patient many different medication options. In addition, recent evidence provides even stronger support for counseling (both when used alone and with other treatments) as an effective tobacco cessation strategy; counseling adds to the effectiveness of tobacco cessation medications, quitline counseling is an effective intervention with a broad reach, and counseling increases tobacco cessation among adolescent smokers.

Finally, there is increasing evidence that the success of any tobacco dependence treatment strategy cannot be divorced from the health care system in which it is embedded. The updated Guideline contains new evidence that health care policies significantly affect the likelihood that smokers will receive effective tobacco dependence treatment and successfully stop tobacco use. For instance, making tobacco dependence treatment a covered benefit of insurance plans increases the likelihood that a tobacco user will receive treatment and quit successfully. Data strongly indicate that effective tobacco interventions require coordinated interventions. Just as the clinician must intervene with his or her patient, so must the health care administrator, insurer, and purchaser foster and support tobacco intervention as an integral element of health care delivery. Health care administrators and insurers should ensure that clinicians have the training and support to deliver consistent, effective intervention to tobacco users.

One important conclusion of this Guideline update is that the most effective way to move clinicians to intervene is to provide them with information regarding multiple effective treatment options and to ensure that they have ample institutional support to use these options. Joint actions by clinicians, administrators, insurers, and purchasers can encourage a culture of health care in which failure to intervene with a tobacco user is inconsistent with standards of care. TURNER SYNDROME

Clinical Practice Guidelines for the Care of Girls and Women With Turner Syndrome: Proceedings From the 2016 Cincinnati International Turner Syndrome Meeting

Claus H. Gravholt; Niels H. Andersen; Gerard S. Conway; Olaf M. Dekkers; Mitchell E. Geffner; Karen O. Klein; Angela E. Lin; Nelly Mauras; Charmian A. Quigley; Karen Rubin; David E. Sandberg; Theo C. J. Sas; Michael Silberbach; Viveca Söderström-Anttila; Kirstine Stochholm; Janielle A. van Alfen-van derVelden;

Joachim Woelfle; and Philippe F. Backeljauw (on behalf of the International Turner Syndrome Consensus Group)

ABSTRACT. Turner syndrome affects 25–50 per 100,000 females and can involve multiple organs through all stages of life, necessitating multidisciplinary approach to care. Previous guidelines have highlighted this, but numerous important advances have been noted recently. These advances cover all specialty fields involved in the care of girls and women with TS. This paper is based on an international effort that started with exploratory meetings in 2014 in both Europe and the USA, and culminated with a Consensus Meeting held in Cincinnati, Ohio, USA in July 2016. Prior to this meeting, five groups each addressed important areas in TS care: 1) diagnostic and genetic issues, 2) growth and development during childhood and adolescence, 3) congenital and acquired cardiovascular disease, 4) transition and adult care, and 5) other comorbidities and neurocognitive issues. These groups produced proposals for the present guidelines. Additionally, four pertinent questions were submitted for formal GRADE (Grading of Recommendations, Assessment, Development and Evaluation) evaluation with a separate systematic review of the literature. These four questions related to the efficacy and most optimal treatment of short stature, infertility, hypertension, and hormonal replacement therapy. The guidelines project was initiated by the European Society of Endocrinology and the Pediatric Endocrine Society, in collaboration with the European Society for Paediatric Endocrinology, the Endocrine Society, the European Society of Human Reproduction and Embryology, the American Heart Association, the Society for Endocrinology, and the European Society of Cardiology. The guideline has been formally endorsed by the European Society of Endocrinology, the Pediatric Endocrine Society, the European Society for Paediatric Endocrinology, the European Society of Human Reproduction and Embryology and the Endocrine Society. Advocacy groups appointed representatives who participated in pre-meeting discussions and in the consensus meeting. (9/17)

SECTION 3

2021 Policies

From the American Academy of Pediatrics

- *Policy Statements*
  ORGANIZATIONAL PRINCIPLES TO GUIDE AND DEFINE THE CHILD HEALTH CARE SYSTEM AND TO IMPROVE THE HEALTH OF ALL CHILDREN

- *Clinical Reports*
  GUIDANCE FOR THE CLINICIAN IN RENDERING PEDIATRIC CARE

- *Technical Reports*
  BACKGROUND INFORMATION TO SUPPORT AMERICAN ACADEMY OF PEDIATRICS POLICY

Includes policy statements, clinical reports, and technical reports published between January 1, 2021, and December 31, 2021

INTRODUCTION

This section of ***Pediatric Clinical Practice Guidelines & Policies: A Compendium of Evidence-based Research for Pediatric Practice*** is composed of policy statements, clinical reports, and technical reports issued by the American Academy of Pediatrics (AAP) and is designed as a quick reference tool for AAP members, AAP staff, and other interested parties. Section 3 includes the full text of all AAP policies published in 2021. Section 4 is a compilation of all active AAP policies (through December 31, 2021) arranged alphabetically, with abstracts where applicable. A subject index is also available. These materials should help answer questions that arise about the AAP position on child health care issues. **However, remember that AAP policy statements, clinical reports, and technical reports do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate.**

Policy statements have been written by AAP committees, councils, sections, or task forces and approved by the AAP Board of Directors. Most of these statements have appeared previously in ***Pediatrics*** or ***AAP News***.

This section does not contain all AAP policies. It does not include

- Press releases.
- Motions and resolutions that were approved by the Board of Directors. These can be found in the Board of Directors' minutes.
- Policies in manuals, pamphlets, booklets, or other AAP publications. These items can be ordered through the AAP. To order, visit http://shop.aap.org/books or call 866/843-2271.
- Testimony before Congress or government agencies.

All policy statements, clinical reports, and technical reports from the American Academy of Pediatrics automatically expire 5 years after publication unless reaffirmed, revised, or retired at or before that time. Please check the American Academy of Pediatrics website at www.aap.org for up-to-date reaffirmations, revisions, and retirements.

The 2021 Recommendations for Preventive Pediatric Health Care (Periodicity Schedule) has been approved by the American Academy of Pediatrics (AAP) and represents a consensus of the AAP and the Bright Futures Periodicity Schedule Workgroup. Each child and family is unique; therefore, these recommendations are designed for the care of children who are receiving competent parenting, have no manifestations of any important health problems, and are growing and developing in a satisfactory fashion. Developmental, psychosocial, and chronic disease issues for children and adolescents may require frequent counseling and treatment visits separate from preventive care visits. Additional visits also may become necessary if circumstances suggest variations from normal.

The AAP continues to emphasize the great importance of continuity of care in comprehensive health supervision and the need to avoid fragmentation of care.[1]

The Periodicity Schedule will not be published in *Pediatrics*. Readers are referred to the AAP website (www.aap.org/periodicityschedule) for the most recent version of the Periodicity Schedule and the full set of footnotes. This process will ensure that health care professionals have the most current recommendations. The Periodicity Schedule will be reviewed and revised annually to reflect current recommendations.

Following are the changes made to the Periodicity Schedule since it was last published in March 2020.

DEVELOPMENTAL

- Footnote 11 has been updated to read, "Screening should occur per 'Promoting Optimal Development: Identifying Infants and Young Children with Developmental Disorders Through Developmental Surveillance and Screening' (https://pediatrics.aappublications.org/content/145/1/e20193449)."

AUTISM SPECTRUM DISORDER

- Footnote 12 has been updated to read, "Screening should occur per 'Identification, Evaluation, and Management of Children With Autism Spectrum Disorder' (https://pediatrics.aappublications.org/content/145/1/e20193447)."

HEPATITIS C VIRUS INFECTION

Screening for hepatitis C virus (HCV) infection has been added to occur at least once between the ages of 18 and 79 years (to be consistent with recommendations of the US Preventive Services Task Force [USPSTF] and Centers for Disease Control and Prevention [CDC]).

- Footnote 31 has been added to read, "All individuals should be screened for hepatitis C virus (HCV) infection according to the USPSTF (https://www.uspreventiveservicestaskforce.org/uspstf/recommendation/hepatitis-c-screening) and CDC recommendations (https://www.cdc.gov/mmwr/volumes/69/rr/rr6902a1.htm) at least once between the ages of 18 and 79. Those at increased risk of HCV infection, including those who are persons with past or current injection drug use, should be tested for HCV infection and reassessed annually."

Access to Optimal Emergency Care for Children

Kathleen M. Brown, MD, FAAP, FACEP,[a] Alice D. Ackerman, MD, MBA, FAAP,[b] Timothy K. Ruttan, MD, FACEP, FAAP,[c] Sally K. Snow, RN, BSN, CPEN, FAEN,[d] COMMITTEE ON PEDIATRIC EMERGENCY MEDICINE; AMERICAN COLLEGE OF EMERGENCY PHYSICIANS, PEDIATRIC EMERGENCY MEDICINE COMMITTEE; EMERGENCY NURSES ASSOCIATION, PEDIATRIC COMMITTEE, 2018–2019

Every year, millions of pediatric patients seek emergency care. Significant barriers limit access to optimal emergency services for large numbers of children. The American Academy of Pediatrics, American College of Emergency Physicians, and Emergency Nurses Association have a strong commitment to identifying these barriers, working to overcome them, and encouraging, through education and system changes, improved access to emergency care for all children.

AAP COMMITTEE ON PEDIATRIC EMERGENCY MEDICINE; AMERICAN COLLEGE OF EMERGENCY PHYSICIANS, PEDIATRIC EMERGENCY MEDICINE COMMITTEE; EMERGENCY NURSES ASSOCIATION, PEDIATRIC COMMITTEE, 2018–2019. Access to Optimal Emergency Care for Children. *Pediatrics.* 2021;147(5): e2021050787

All children deserve access to optimal (safe and high-quality) emergency care. Given the inherent vulnerabilities of children and potential lifelong consequences of poorly treated health conditions, access to optimal emergency health care is particularly important. In the United States, emergency departments (EDs) serve as the national safety net for individuals unable to find care elsewhere as well as a resource during public health emergencies and disasters through the provision of comprehensive acute care 24 hours a day and 7 days a week. Vulnerable populations who rely more heavily on the ED for services are disproportionally affected when this safety net is weakened or fails, and this needs to be addressed to ensure optimal care for all Americans. A significant portion of annual ED visits are by children younger than 18 years. Recent national data reveal that children account for approximately 20% of all ED visits, which represents more than 27 million total ED visits in the United States.[1] The vast majority of these visits take place outside of pediatric medical centers and children's hospitals.[2]

The American Academy of Pediatrics (AAP), American College of Emergency Physicians (ACEP), and Emergency Nurses Association (ENA) have previously endorsed policy statements advocating for improved access to emergency care.[3–5] Despite these statements and calls for action by other groups,[6] access to optimal emergency care remains limited for many children in the United States. The 2014 ACEP "Report Card on Emergency Medicine" examined access to emergency care for patients of

all ages on a state-by-state basis, and it found that few states have adequate policies and resources to deliver an acceptable level of emergency care access. The overall nationwide grade of D− was unchanged since the last report card was issued in 2009, reflecting a lack of improvement in emergency care access, despite recent efforts at health care reform.[7]

PROBLEMS THAT RESTRICT ACCESS TO CARE

Children and their families face barriers to optimal emergency care at many key points of access. These include the following.

1. Public and Professional Awareness of Available Resources and Systems of Care

Deficits remain in the awareness and perceptions of the public and health care professionals regarding the emergency care system and how best to access emergency care when needed. These include:

- lack of a consensus on what should drive entry into the emergency care system and appropriate points of access for patients;
- underuse of emergency medical services (EMS) in emergencies because of a misconception by some caregivers that they can reach EDs faster on their own;
- limited access to a medical home for patients and poor coordination of 2-way communication between emergency physicians, nurse practitioners or physician assistants, and the primary care provider;[8]
- misconception that urgent care centers provide comprehensive emergency services;
- lack of knowledge of the inconsistent readiness of EDs to care for children of all ages;[2]
- language and health literacy barriers to understanding the appropriate use of less emergent sources of care, such as urgent clinic appointments or urgent care centers; and
- poor access to timely primary care appointments among vulnerable patients, especially children who have public insurance, have language barriers, are members of racial and ethnic minorities, and/or live in underserved areas.[9,10]

2. Entry Into the Emergency Care System

Many factors may limit a family's ability to access the emergency care system for their child. These include:

- lack of universal access to enhanced or basic 911 services and wireless 911 service for cellular phones, with continued reliance in some areas on local 10-digit emergency telephone numbers;[11]
- language barriers that can impede the use of 911 services in many locales;
- limited transportation resources to access emergency care outside of the 911 system;
- long transportation times, especially in rural environments;[12]
- concern for financial consequences of activating the 911 system and incurring bills that may not be adequately covered by all insurance types;
- concerns on the part of families of ill or injured children regarding immigration issues, social service agency intervention, and other legal or financial concerns that might arise once care has been accessed; and
- excessive demand on the emergency care system because of inappropriate use of 911 systems by patients who do require them. This limits the availability of such services and can potentially delay a more urgent transport.

3. Availability of Optimal Pediatric Prehospital Care

The Institute of Medicine (now the National Academy of Medicine)[6] and others have outlined some of the deficiencies in pediatric prehospital care, including:

- variability in pediatric readiness between urban, suburban, and rural prehospital care systems as well as discrepancies in readiness between high-volume pediatric facilities and their low-volume (fewer than 10 pediatric patients per day) counterparts;
- lack of comprehensive pediatric training, experience, competency assessment, and ongoing quality improvement for prehospital EMS and interfacility transport professionals;
- limited scientific evidence on which to base protocols or procedures for prehospital care of children;
- limited high-quality and specific evidence-based guidelines for care efficacy and safety within all levels of EMS for children; and
- lack of validated quality metrics and paucity of quality improvement efforts in pediatric prehospital care.

4. Availability of Optimal Emergency Care for Children

- Underserved areas and populations.
  - Impact of closing hospital EDs: The closure of EDs and hospitals that disproportionately serve disadvantaged populations has impacted both rural areas and underserved urban areas, with differential impacts in each type of region.[13]
  - Critical access hospitals: The federal government has historically supported rural hospitals. In 1997, the Centers for Medicare and Medicaid Services created the Critical Access Hospital Program, through which Congress, through the Balanced Budget Act of 1997, designated several small rural hospitals as critical access facilities, recognizing that

their small size limited their scope of service.[14] Such hospitals received extra federal funding to focus on critical medical services. Often, these facilities have low volumes in general and in particular have low pediatric volumes, which limits experience in pediatric care and creates a challenge for skill retention. Moreover, changes in health care reimbursement models have led to struggles for rural hospitals, leading to many closures and decreased services in some instances. From 2010 to 2016, 75 rural hospitals in the United States closed or ceased operations, prompting new concerns about access to essential services in rural communities.[15,16]

  - Development of expanded medical services: Accelerated trends toward retail medical clinics, urgent care clinics, and freestanding EDs, in addition to expansion of existing facilities, disproportionately benefit areas with a higher socioeconomic status, which has the potential to create further disparities in access to care in underserved areas.[17]

- ED crowding: Long ED wait times for pediatric patients can discourage families from seeking timely care for emergency situations. In addition, crowded EDs create a challenging and rushed environment that is less child friendly and fails to address the specific needs of each pediatric patient.[18] Long wait times and crowding in EDs is particularly difficult for children with special health care needs, including those with physical and intellectual disabilities or mental and behavioral health concerns. Crowding has been associated with decreased safety, timeliness, and effectiveness of emergency care in children.[19–24]
- Readiness of EDs for pediatric patients: Data from the 2013 National Pediatric Readiness Project (NPRP) noted that pediatric preparedness had improved since 2003, with the national median assessment score increasing from 55 to 69 of 100 points.[2] Despite this improvement, many gaps in pediatric readiness remain, particularly in EDs with a low volume of pediatric patients. In the 2013 assessment, at least 15% of EDs lacked at least 1 specific piece of recommended equipment, 81% reported barriers to implementing guidelines for pediatric emergency care, only 47% included pediatric-specific components to their disaster plans, and fewer than one-half included children in disaster drills.[2] Further study of 1 state (California) determined that the presence of a pediatric emergency care coordinator and the inclusion of pediatric-specific elements in the ED quality improvement plan were associated with improved scores on the NPRP. However, in the same state, only about one-half of the hospitals had a person designated as a pediatric emergency care coordinator, and fewer than one-half had a quality improvement plan that included at least 1 pediatric-specific metric.[25]
- Quality of care (evidence-based practice and quality improvement): Despite significant growth in high-quality pediatric emergency care research, a relative paucity of data to support evidence-based care for childhood emergencies remains. In addition, a significant delay between the creation of evidence and its translation into practice in the ED further challenges knowledge translation and dissemination.[26,27]
- Access to pediatric medical subspecialists, pediatric surgical specialists, and mental health professionals: Significant geographic variation exists in access to pediatric subspecialty care, with children in rural areas disproportionately affected by poor access to subspecialists and longer transport times to centers that provide specialty care, including care for behavioral and mental health emergencies.[28,29] This lack of access limits the ability to provide emergency and ongoing care for children closer to their homes and places a larger burden on families requiring specialty care in addressing complications from ongoing disease processes and treatments.[30–32] Moreover, regardless of their insurance, patients may experience challenges with accessing specialty care and navigating networks of care.[33] Telemedicine has been proposed as a potential solution to this problem and has received significant attention because of coronavirus disease 2019, with improvement in access and a reduction in previously described implementation barriers.[34]

5. Financial Considerations

Limited and often inadequate payment for primary care for many children decreases both the availability of primary care and the ability to provide unscheduled visits in the primary care office setting. Children covered by Medicaid or the Children's Health Insurance Program visit the ED more frequently than both those with private insurance and those who are uninsured. However, reasons for the visit differed among population groups. When asked about their child's last visit to the ED, respondents for children who had Medicaid or Children's Health Insurance Program were more likely

than those with private coverage to report that their usual medical home was not open or they did not have another place to obtain care. In contrast, respondents for certain categories of privately insured children were more likely to report they last visited the ED because the family's primary care provider told them to go or they perceived that the condition was too serious to be treated by primary care.[35] In a recent study, researchers demonstrated that office-based primary care pediatricians increased their Medicaid participation after the payment increases, in large part by increasing their Medicaid panel percentage.[36]

Other financial concerns include:

- A failure by payers to use the "prudent-layperson" standard for definition of emergency care, which creates financial hardships after a care episode and can discourage future timely emergency visits.
- An increased number of insurance plans with high deductibles may discourage families from seeking emergency care when needed. Increasing regulatory and managed care initiatives related to emergency access for children that often require complex and time-consuming telephone calls and documentation to ensure appropriate payment for care.
- Managed care protocols designed to reduce the use of emergency facilities provide variable levels of appropriate alternatives for care.
- Increasing numbers of "narrow networks" (in which, in exchange for paying lower insurance premiums, the plan restricts the number and type of physicians, nurse practitioners, or physician assistants whose services are covered) can limit access to EDs in children's hospitals and to subspecialty services, which delays access to timely care and can result in poor health outcomes.

Improving Access to Emergency Care for Children

The emergency care environment remains challenging for pediatric patients, as outlined in this report, but efforts have been ongoing in recent years to improve access to optimal pediatric emergency care. Professional organizations such as the ACEP, the AAP, and the ENA, along with government agencies such as the Emergency Medical Services for Children (EMSC) program of the Health Resources and Services Administration, have worked to increase the information available to lay people as well as medical professionals. Enhanced and next-generation 911 systems are steadily improving the ease and reliability of calls for help and enable prehospital professionals to respond appropriately and efficiently. An increased focus on prehospital care and pediatric readiness in the ED setting through EMSC programs, the NPRP, and state-based pediatric readiness recognition programs in hospitals has increased both awareness and the ability to address pediatric emergencies at all stages of care.

Although inherent challenges remain, an increased focus on pediatric emergency research through networks, such as the Pediatric Emergency Care Applied Research Network, has helped to advance the evidence base, increase awareness, and promote efforts to address the need for more information.[37–39] In addition, pediatric emergency medical education continues to expand through increasing numbers of fellowships, residency training that includes dedicated pediatric emergency education, and ongoing targeted continuing medical education training. Pediatric nursing residency training programs and certification in pediatric emergency nursing contribute positively to patient satisfaction and nurse retention.[40]

Despite these recent efforts to improve access to emergency care, access to optimal emergency care for children can and should be improved. The ACEP, the AAP, and the ENA believe that every child in need should have access to quality pediatric emergency health care in the appropriate setting. Efforts must be made at local, state, and federal levels to improve prompt and appropriate access to pediatric emergency health care, including dental, behavioral, and mental health emergencies for all children, regardless of socioeconomic status, ethnic origin, language, immigration status, type of insurance, geographic location, or health status.

RECOMMENDATIONS

I. Improving Entry Into the Emergency Care System

The ACEP, the AAP, and the ENA recommend the following.

A. Pediatricians, emergency physicians, emergency nurses, health care systems and their professional organizations should work with stakeholders within their communities to improve public and health care professional's awareness of available resources and systems of care by:
   1. improving transparency of pediatric systems of care within communities, including educating families and caregivers about the urgent and emergency care resources in their community;
   2. developing and disseminating knowledge and resources to increase public, health professional, and government awareness about the magnitude of the problem of access to emergency medical care for children;
   3. improving awareness, use, and dissemination of

comprehensive resources available through the EMSC program;

4. encouraging collaborative efforts by emergency physicians, nurse practitioners and physician assistants, and primary care providers to identify an appropriate medical home for every child;
5. increasing access to a medical home by expansion of after-hours and/or improved coordination with after-hours or urgent care clinics with the medical home for ambulatory sensitive conditions to improve timely and appropriate care;[8]
6. encouraging the use of the emergency information form published by the AAP and ACEP[41] (this form is particularly helpful for children with medical complexity);[42] and
7. developing electronic versions of the emergency information form with health information exchange for easy access.

B. Federal governmental agencies should provide ongoing funding support for future resource development, education, research, and quality outcomes measurement by the EMSC program, as recommended in the 2006 Institute of Medicine report.

C. State and federal governmental agencies should work with EMS systems and health care organizations to improve entry into the emergency care system by:

1. improving all 911 systems to facilitate communication with non–English speaking families;
2. continuing to broaden enhanced and next-generation 911 systems to more locations in the United States to allow wireless services via cellular phones as well as voice-over Internet protocols, text messaging, and video transfer; and
3. improving collaboration and connectivity between schools, child care facilities, mental health professionals, medical homes, and local EMS systems to facilitate easy access into the EMS system.

II. Improving Pediatric Prehospital Care

The ACEP, the AAP, and the ENA recommend the following:

A. State and federal governmental agencies should work with EMS systems to ensure optimal prehospital care for children by:

1. funding, supporting, and promoting the further development and improvement of EMS for children at the federal, state, and local levels;
2. insuring the inclusion of children's needs in all funded efforts to improve prehospital care (eg, EMS education, EMS quality metrics [National EMS Quality Alliance (NEMSQA)], prehospital evidence-based guideline consortium); and
3. encouraging state EMS systems, local EMS agencies, and hospitals to incorporate children in disaster planning and response.[43]

B. EMS physicians and agency leaders should work with pediatricians, emergency physicians, emergency nurses, their professional organizations, and other stakeholders within their communities to ensure availability of optimal prehospital care for children by promoting improved readiness for pediatric patients, as outlined in the joint policy statement "Pediatric Readiness in Emergency Medical Services Systems."[44]

III. Improving Emergency Department Care for Children and Adolescents

The ACEP, the AAP, and the ENA recommend the following:

A. Pediatricians, emergency physicians, emergency nurses, health care systems, and professional organizations should work with stakeholders within their communities to ensure availability of optimal emergency care for children by

1. promoting improved readiness and a minimal standard for readiness in all EDs, as outlined in the joint policy statement "Pediatric Readiness in the Emergency Department;"[45]
2. developing quality metrics and quality improvement efforts for ED care of pediatric patients;
3. encouraging the availability of and access to existing pediatric medical subspecialists, pediatric surgical specialists, and mental health professionals who have special skills and expertise that are required for optimal care of critically ill and injured children;
4. encouraging the expansion of training programs to ensure future availability of adequate numbers of pediatric surgical and medical subspecialists necessary to provide specialized pediatric emergency care;
5. supporting the development of nurse practitioners and physician assistants with particular training and expertise in pediatric emergency care, with the goal to expand access to emergency care, with appropriate levels of supervision based on jurisdictional regulations;
6. promoting the development, dissemination, and

implementation of evidence-based guidelines and other strategies to improve diagnostic accuracy, therapeutic effectiveness, and minimization of unwanted variation in care;

7. continuing to explore new and innovative methods of pediatric medical subspecialist care, such as telemedicine, to aid medical professionals in settings of limited resources; and
8. promoting the development of guidelines and education to the approach of children with behavioral and emotional difficulties (intellectual disabilities, autism spectrum disorder, and mental health disorders) for both prehospital and emergency care.[46]

B. State and federal governmental agencies, health care systems, and professional organizations should work with stakeholders within their communities to ensure the availability of optimal emergency care for children by

1. promoting maintenance of ED facilities and work to prevent the closing of hospitals that provide critical services in underserved communities;
2. encouraging all EDs and facilities that provide urgent care for children to establish transfer agreements and protocols with facilities with higher levels of pediatric care resources to promote timely access to specialty pediatric emergency care and subspecialty tertiary care for critically ill and injured children;[47]
3. developing state or regional programs to recognize facilities that have demonstrated pediatric readiness;[48,49]
4. developing funding sources, multidisciplinary support, and enhanced research efforts directed at all aspects of pediatric emergency care, including health equity, to provide the evidence for standards for effective and safe patient care; and
5. promoting the inclusion of pediatric expertise into comprehensive psychiatric emergency programs, when these are available in a community.

C. State and federal governmental agencies, health care systems, and professional organizations should work with payers to overcome financial barriers to the provision of optimal emergency care for children by:

1. encouraging managed care organizations to accept the prudent-layperson definition of an emergency and provide payment for services mandated by the Emergency Medical Treatment and Active Labor Act (42 USC §1395dd);
2. improving payment for pediatric care, by using a value-based model that encourages the achievement of a pediatric-relevant cost to benefit ratio, especially valuing efforts that lead to prevention or better control of long-standing problems, recognizing that the most effective intervention may not be the one with the lowest cost but still represents the optimal choice;
3. providing appropriate payment levels at all episodes of care to facilitate unscheduled primary care visits and reduce the burden on the emergency care system;
4. providing payment for telemedicine to optimize the delivery of care for services that can be delivered via telemedicine;
5. expanding coverage for the expanse of language-translation services required to provide emergency care;
6. expanding networks of care to allow patient access to specialty care and children's hospitals when indicated for patients and reducing barriers to care for patients within networks of care; and
7. improving transparency of coverage for emergency care and eliminate the retrospective denial of payments for any reasons, including for chronic conditions or out-of-network emergency care.

Ambient Air Pollution: Health Hazards to Children

Heather L. Brumberg, MD, MPH, FAAP,[a] Catherine J. Karr, MD, PhD, FAAP,[b] COUNCIL ON ENVIRONMENTAL HEALTH

Ambient air pollution is produced by sources including vehicular traffic, coal-fired power plants, hydraulic fracturing, agricultural production, and forest fires. It consists of primary pollutants generated by combustion and secondary pollutants formed in the atmosphere from precursor gases. Air pollution causes and exacerbates climate change, and climate change worsens health effects of air pollution. Infants and children are uniquely sensitive to air pollution, because their organs are developing and they have higher air per body weight intake. Health effects linked to air pollution include not only exacerbations of respiratory diseases but also reduced lung function development and increased asthma incidence. Additional outcomes of concern include preterm birth, low birth weight, neurodevelopmental disorders, IQ loss, pediatric cancers, and increased risks for adult chronic diseases. These effects are mediated by oxidative stress, chronic inflammation, endocrine disruption, and genetic and epigenetic mechanisms across the life span. Natural experiments demonstrate that with initiatives such as increased use of public transportation, both air quality and community health improve. Similarly, the Clean Air Act has improved air quality, although exposure inequities persist. Other effective strategies for reducing air pollution include ending reliance on coal, oil, and gas; regulating industrial emissions; reducing exposure with attention to proximity of residences, schools, and child care facilities to traffic; and a greater awareness of the Air Quality Index. This policy reviews both short- and long-term health consequences of ambient air pollution, especially in relation to developmental exposures. It examines individual, community, and legislative strategies to mitigate air pollution.

INTRODUCTION

Air pollution exposures are widespread, and children are uniquely vulnerable. Since publication of the 2004 American Academy of Pediatrics policy statement on ambient air pollutants,[1] the evidence for child health impacts has expanded considerably. Current levels of air pollutants are associated with many of the most important pediatric morbidities, including asthma incidence and prevalence, adverse birth outcomes,

behavioral and cognitive development, and pediatric cancers, as well as with increased risk for a range of chronic diseases in adult life.[2–6]

Common sources of air pollution include emissions from traffic, coal-fired power plants, poorly ventilated wood-burning stoves or boilers, and forest fires. Toxicants in these emissions can influence the morphologic and functional development of organ systems from the fetal period to early, middle, and late childhood.[7] In addition, children receive higher doses because of their faster breathing rate and proportionately greater air intake per kilogram of body weight compared with adults.[8]

This policy statement focuses on short- and long-term health effects of key air pollutants that originate outdoors. These pollutants may enter buildings (and vehicles) through open doors and windows, ventilation systems, and cracks in structures, adding to the burden of indoor-derived air pollutants. Studies addressing regulated individual contaminants as well as mixtures or sources (traffic-related air pollution [TRAP], diesel particles, animal agricultural emissions, hydraulic fracking, wood burning) are included. Several other air contaminants are not included but have been addressed in other comprehensive reviews or other American Academy of Pediatrics policy statements (eg, tobacco smoke, mercury, asbestos, etc).[9–12]

EXPOSURE TO OUTDOOR AIR POLLUTANTS

The US Environmental Protection Agency (EPA) sets air quality standards for 6 criteria air pollutants (Table 1).[13] These are periodically updated and include primary standards to protect sensitive populations, including children. The EPA also monitors outdoor concentrations of 187 air toxics known or suspected to cause cancer or other serious health effects, such as birth defects; these are referred to as hazardous air pollutants. Examples include benzene, formaldehyde, polycyclic aromatic hydrocarbons (PAHs), and metals, such as chromium.[14]

States (or local agencies delegated by the state) have the primary authority to ensure compliance. These state and local air agencies, as well as the local public health agencies, are knowledgeable and can provide information about local and regional concerns.

Regulatory monitoring of criteria air pollutants indicates overall improvement in ambient air concentrations (Fig 1).[14] National mean levels of the 6 criteria air pollutants have fallen by 70% across the United States since passage of the Clean Air Act in 1970.[15] However, in 2016, 62% of children resided in a county with exceedance of at least 1 standard.[14] Despite these overall improvements, important socioeconomic and racial disparities in exposure continue to be observed in the trend data. Compared with non-Hispanic white individuals, Asian American or Pacific Islander, Black non-Hispanic, and Hispanic individuals were more likely to reside in counties unable to meet the air quality standards for particulate matter 2.5 μm or less in diameter ($PM_{2.5}$) and ozone.[14] Children living in poverty were more likely to reside in census tract areas above the benchmark for 1 in 10 000 cancer risk from hazardous air pollutants compared with those living in households at or above the poverty level.[14] Irrespective of poverty status, a higher percentage of children who identify as Black or Asian American live in census tracts where noncancer health-based benchmarks are exceeded.[14] Of note, the trend in levels of $PM_{2.5}$ shows a slight increase in the United States since 2015, the first recorded deterioration in national air quality in nearly a half century.[16]

Community air quality may reflect mobile (eg, on- and off-road vehicles) and point sources, including industrial facilities (such as coal-fired power plants and electricity-generating plants), dry-cleaning shops, restaurants (especially those using wood-fire ovens), metal plating facilities, residential wood burning, barbeques, etc, as well as seasonal variability and meteorology. Combustion contributes many primary pollutants (carbon monoxide [CO], nitrogen oxide [NO_x], particulate matter [PM], and volatile organic compounds [VOCs]). Combustion processes may also lead to secondary pollutants (ozone, nitrate, or sulfate aerosols) formed in the atmosphere from precursor gases.

TRAP is ubiquitous. These emissions include primary particles representing particulate matter 10

TABLE 1 Six EPA Criteria Pollutants With National Ambient Air Quality Standards

Pollutants	Standard
CO	9 ppm over 8 h, 35 ppm over 1 h
Lead	0.15 μg/m^3 over 3 mo
NO_2	100 ppb over 1 h; 53 ppb annual average
PM, including $PM_{2.5}$ and PM_{10}	$PM_{2.5}$: 35 μg/m^3 over 24 h; 12 μg/m^3 annual average PM_{10}: 150 μg/m^3 over 24 h
SO_2	75 ppb over 1 h
Ozone	0.070 ppm over 8 h

Permissible levels of the 6 criteria air pollutants (primary standards based on public health protection). These enforceable standards are reevaluated periodically by the EPA. Standards noted are based on information from the EPA National Ambient Air Quality Standards Table. (Available at: https://www.epa.gov/criteria-air-pollutants/naaqs-table. Accessed February 4, 2019.)

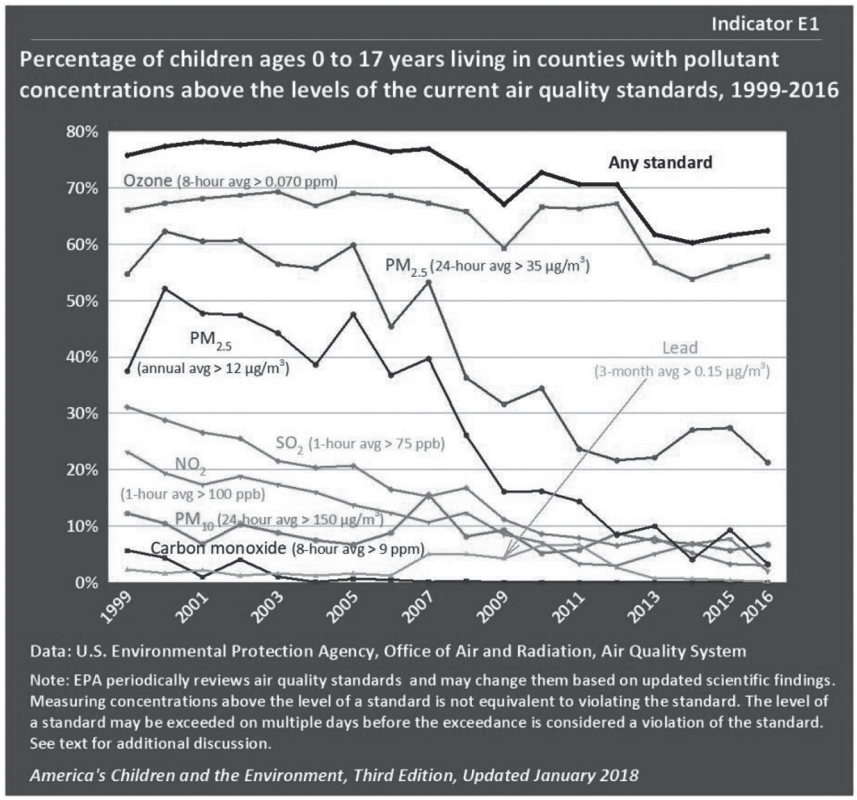

FIGURE 1
Percentage of children aged 0 to 17 years living in counties with pollutant concentrations above the levels of the current air quality standards, 1999–2016. avg, average. (Reprinted with permission from US Environmental Protection Agency. ACE: environments and contaminants - criteria air pollutants. Available at: https://www.epa.gov/ace/ace-environments-and-contaminants-criteria-air-pollutants. Accessed February 4, 2019.)

μm or less in diameter (PM_{10}), $PM_{2.5}$, and ultrafine PM (<100 nm), which are formed during combustion of fuels and comprise insoluble carbonaceous material (referred to as elemental carbon or black carbon), along with other toxic components, such as metals and PAHs. Diesel particles contain mostly ultrafine PM enriched in black carbon and PAHs as well as VOCs, such as formaldehyde. Resuspended road dust, tire wear, and brake wear represent noncombustion sources of traffic-related PM. In addition, secondary particles may be formed in the atmosphere post emission and include PM in the nanoparticle size range.[17]

An emerging source of concern is fossil fuel extraction by hydraulic fracturing, or "fracking." Water containing proprietary chemicals under high pressure is forced underground to crack deep shale layers and release trapped gas.[18,19] The volume of natural gas derived from fracking doubled in the United States from 2000 to 2011 and continues to increase.[19] The wellhead, controlled burns (flaring), water storage pits and tanks, sand operations, and diesel-powered equipment and trucks contribute VOCs, PAHs, and criteria air pollutants, such as NO_x and $PM_{2.5}$.[20,21]

Biomass combustion is an important source of air pollutants, such as PM. Globally, cooking- and heating-related emissions from solid fuel use are significant (eg, wood, charcoal, dung, crop waste). Large health initiatives for alternative fuels and improved cook stoves are targeting high pollution observed in middle- and low-income countries.[22] In some communities in North America, wood burning for heat and intentional burning of agricultural waste are important regional contributors to regional air quality.[23]

In agricultural communities, significant emissions from industrial-scale animal operations, such as poultry, swine, dairy, or beef, may result from the decomposition of animal waste or application of waste in liquid form as fertilizer. This includes gases and odorous vapors, including ammonia, hydrogen sulfide, and PM, that may contain endotoxin and other bioaerosols.[24]

Air pollution and climate change are closely linked, and the contribution of climate change to air quality is of concern. Climate change has increased the size and frequency of wildfires in North America, and ground-level ozone formation from precursor gases is enhanced in the presence of increasing temperatures.[25] Climate change influences the distribution, quantity, and quality of aeroallergens as well as ozone levels. Among those with allergic disease and asthma, global climate change is estimated to worsen disease, lead to more symptom days, and reduce quality of life.[26]

Air pollution is experienced by populations as a mixture containing components with various toxicological properties. Several common pathophysiological pathways have been identified as important mechanisms of how air pollution may affect health, including oxidative stress, inflammation, endocrine disruption, genetics, and epigenetics (Fig 2). The effects of air pollution occur at each stage of the life course and may cross generations via epigenetic and genetic factors. The delineation of mechanisms is complicated by the fact that different

pathways may trigger one another, such as oxidative stress causing inflammation or DNA damage.[27,28] PM and PAHs have been associated with increased histone acetylation and DNA methylation, respectively.[29,30] Supporting the role of environmental exposures on epigenetic modifications is the association of exposure to air pollution and increased methylation of the *FOXP3* locus from T regulatory lymphocytes, changes known to increase asthma morbidity.[30,31]

The subsequent morbidities arising from these pathways in childhood are reviewed in the following sections. The emphasis is on human epidemiological data, much of which are observational. Observational studies of air pollution and regulation of air pollutants are based on causal inferences from observational data with consideration of confounders and application of epidemiological criteria for causality (eg, dose response, biological plausibility, and consistency of evidence).

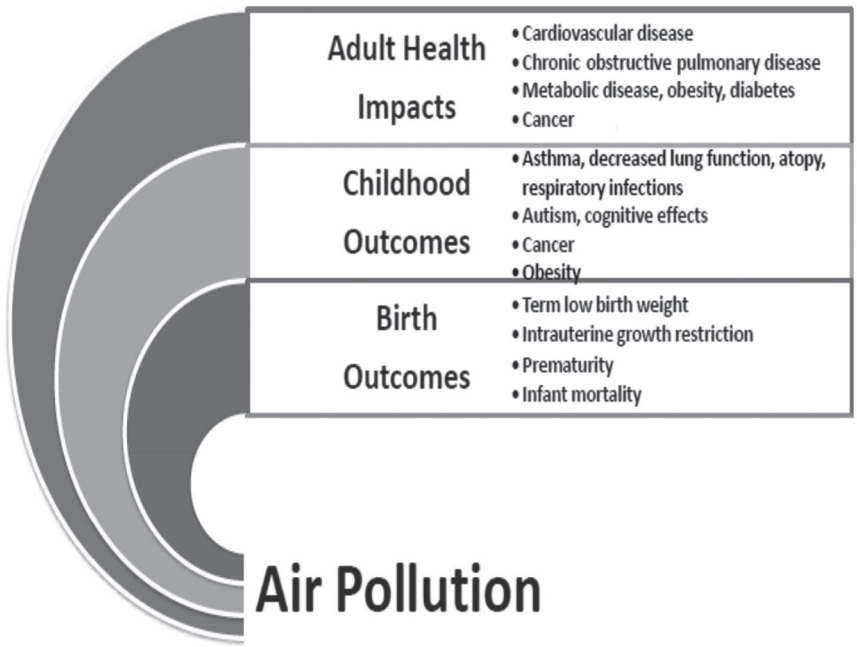

FIGURE 2
Mechanisms and key morbidities of concern for air pollution exposure across the life course and subsequent generations. Key mechanistic pathways include the following: Systemic or pulmonary inflammation, oxidative stress, immune modulation, endocrine disruption, genetic, and epigenetic effects.

BIRTH OUTCOMES

Multiple studies, many systematic reviews, and a few pooled analyses are available and have supported associations between ambient air pollution exposure during pregnancy and adverse birth outcomes. In most studies, researchers have examined effects on fetal growth (as term low birth weight or small for gestational age) and preterm birth.[2,32–36] In a pooled analysis comprising multiple studies and examination of multiple pollutants, birth weight decrements of approximately 10 to 30 g and odds ratios of 1.05 to 1.10 for low birth weight and of 1.04 to 1.06 for preterm birth were observed in relation to representative concentrations of higher CO, nitrogen dioxide (NO_2), PM_{10}, and $PM_{2.5}$.[2]

For context, van der Zee et al[37] sought to translate ambient air pollution effect sizes to a more familiar air contaminant sharing many constituents, environmental tobacco smoke. The risk of low birth weight associated with a 10 μg/m^3 increase in NO_2 or $PM_{2.5}$ was estimated to be equivalent to the effect of maternal passive smoking of 1.3 ± 0.7 or 3.8 ± 2.3 cigarettes, respectively. The public health impact is significant, with an estimated 3.3% of 2010 preterm births in the United States attributable to airborne PM exposure at a cost of more than $5 billion dollars in medical care and lost economic productivity.[38]

Limitations to this evidence base include an inadequate understanding of specific windows of vulnerability (eg, trimester or more refined time points) during pregnancy. Current findings are heterogeneous regarding specific trimester effects.[39,40] Methodologic challenges include accuracy of gestational age measurements, which may be measured by last menstrual period rather than by early ultrasonography.[39]

Data on other pregnancy and birth outcomes are fewer but accumulating. Maternal air pollution exposure and hypertensive disorders in pregnancy have been systematically reviewed, and most studies support an association.[41,42] This association provides a mechanistic link to intrauterine growth restriction, perinatal and neonatal mortality, preterm birth, and associated prematurity-related neonatal diseases, all highly associated with maternal hypertensive disorders. In addition, several studies report associations between airborne particulate exposures and increased risk of postneonatal death from respiratory causes.[33,43–47] Exposures to airborne sulfur dioxide (SO_2)[43] and CO[42] have also been associated with postneonatal mortality. There are conflicting data on associations between ambient air pollution and sudden infant death

syndrome.[43,45,46,48] There have also been mixed results regarding a possible association between ambient air pollution and risk of stillbirth.[49–55]

Thus, the evidence reveals that components of air pollution and proximity to traffic reduce birth weight and increase the risk for low birth weight at term, being small for gestational age, and preterm birth. Firm conclusions about congenital anomalies and air pollution are hampered by fewer available studies and inconsistent findings. Increased risk of congenital heart anomalies has been noted most consistently.[56–58] Emerging data suggest that exposures to fracking may increase risk of certain adverse birth outcomes, including congenital anomalies, preterm birth, and being small for gestational age.[59–61] Additional evidence needs to be amassed to understand the role of air pollution in infant mortality, stillbirth, sudden infant death syndrome, and congenital anomalies.

NEURODEVELOPMENT

Mechanistic data, large well-designed cohort studies, and systematic reviews of multiple studies support mounting concern for effects of air pollution, largely TRAP, on the developing central nervous system.[3,62–66] Recent systematic reviews of the epidemiological studies suggest evidence is currently strongest for pre- or postnatal PAH exposure to decrease neurocognitive function and for $PM_{2.5}$ to increase the risk of autism spectrum disorder.[63,65,67] There are also several studies revealing associations of autism spectrum disorder with NO_2.[62,67] Studies in which researchers examine the association of air pollutant exposures with attention-deficit/hyperactivity disorder risk are fewer and have inconsistent results.[62,63]

Interestingly, reduction in PAH pollution after the closure of a coal-fired power plant in China was reported to resolve previously observed decrements in motor and overall developmental quotients in area children, thus suggesting positive public health effects may be possible with improved community air quality.[68]

Studies of possible associations between neurocognitive development and postnatal exposures to air pollution include a focus on school-based exposures. These studies demonstrate adverse effects of pollution on measures of academic success and neurobehavioral development.[69–71] Growth in cognitive development assessed by repeat assessments has also been shown to be adversely affected by traffic-related air contaminant exposures at school.[71]

Overall, despite heterogeneity in exposure assessments and outcome metrics, the current literature suggests that exposure to ambient air pollutants and TRAP in early life, particularly during pregnancy, likely plays a role in the genesis of neurodevelopmental disorders in children. Exposures postnatally may also affect the trajectory of normal neurodevelopment. Continued attention to robust characterization of exposures across the pediatric life course and assessment of neurodevelopmental health and functional growth throughout childhood are needed to more adequately assess risks and protective factors.

CHILDHOOD AND ADULT RESPIRATORY ILLNESS

The primary exposure pathway for air pollutants is inhalation, and thus, the respiratory tract represents a sensitive and key target for health effects. The adverse consequences of air pollution on the respiratory system have been recognized for decades, and the particular vulnerability of children is well established.

PM, NO_x, ozone, and measures of traffic are most frequently implicated in studies of respiratory compromise. Traffic is a primary source of NO_x in most settings. For children living in urban areas, TRAP is often the most significant air pollution exposure source. For children residing in areas with significant animal agriculture, emerging data suggest emissions from large animal-feeding operations (eg, ammonia, hydrogen sulfide, and PM) may influence respiratory health, including pediatric asthma.[72–74]

Children with asthma are highly vulnerable to the respiratory effects of air pollutants. Ozone, NO_x, PM, and TRAP have been consistently associated with reduced asthma control manifested as increased symptoms, such as wheezing, rescue medication use, and decreased lung function, as well as increased use of medical services and school absences.[17,75] In addition, 2 of the most common infectious disease problems of early childhood, bronchiolitis and otitis media, have been linked with ambient air pollution.[76,77] Air pollution may adversely affect individuals with cystic fibrosis by increasing the risk of pulmonary exacerbations and related antibiotic use as well as by increasing the risk for a decline in lung function.[78,79]

There is a rapidly developing evidence base supporting the role of early-life exposures (including exposures in utero) in the development of asthma and allergic disease in childhood and in reduced lung function. In multiple large cohort studies in a variety of locations in Europe and North America, authors have investigated early-life exposure to NO_x, PM, and/or measures of traffic and found consistent associations with increased risk of development and exacerbation of

asthma.[4] This reflects exposure based on home residence as well as exposure based on school proximity to roads with a high density of traffic.[80,81] Similarly, several studies have reported associations between measures of air pollution exposure and lung function impairment in children.[82,83] Long-term decrements in lung function growth have been demonstrated for pediatric cohorts both with and without asthma. In a systematic review of this body of evidence, the authors concluded that there is strong support for adverse effects on lung function growth in childhood and adolescence.[84] The evidence base includes natural experimental studies that reveal improvements in lung function growth associated with relocation of children to less polluted residential settings or secular trends in air quality improvement, highlighting the potential public health impact of interventions to improve air quality.[85]

In addition to asthma, other atopic conditions (eczema, allergic rhinitis) have been associated with exposure to TRAP.[86] In addition to epidemiological studies, experimental data from studies of animals, in vitro systems, and human volunteers provide evidence of diesel exhaust particle induction of airway inflammatory reaction and enhancement of immunologic response to allergens.[87] In the Canadian Healthy Infant Longitudinal Development (CHILD) prospective birth cohort study, exposure to NO_2 during the first year of life (derived from a traffic-focused land use model) was positively associated with atopy at 1 year of age; exposure during pregnancy was not significantly associated.[88] A recent meta-analysis revealed no association of TRAP with sensitization to indoor allergens; however, PM was associated with sensitization to outdoor allergens, such as pollen and grass.[89]

In summary, ambient air pollution is responsible for a significant public health burden of respiratory disorders in children, including not only asthma and cystic fibrosis exacerbations but also the development of asthma and allergic disease as well as impaired lung functional development. These consistent findings support ongoing efforts and targeted interventions to reduce air pollution exposures among pregnant women and children in various locations (eg, home, school, and while commuting).

LONG-TERM HEALTH EFFECTS

Cancer

Ambient air pollution and some of its constituents have been identified as human carcinogens that are specifically associated with increased risk of childhood leukemia. In 2013, the International Agency for Research on Cancer separately classified (1) outdoor air pollution and (2) PM, an important component of outdoor air pollution, as known human carcinogens,[90] in addition to diesel and gasoline engine exhausts and some nitroarenes, which were designated in 2014.[91] Authors of recent meta-analyses found a significant increase in risk of childhood leukemia associated with proximity of traffic and petrol stations to residence in the postnatal period. Increased risk of leukemia was not, however, associated with the same exposures in the prenatal period.[5,92] The specific pollutants NO_2 and benzene have been associated with childhood leukemia.[92] Links between air pollution and other childhood cancers have been difficult to assess in meta-analyses because of the paucity of studies.[5] Given emerging evidence regarding the association between postnatal exposure to TRAP and childhood cancers, ongoing research is merited to confirm these findings and examine other types of childhood cancers in relation to traffic proximity and specific pollutants.

Obesity

The relationship between childhood obesity and environment is multifactorial and complex. The effects of air pollution may be direct, through toxicological properties of particulate pollutants, or indirect, through, for example, avoidance of physical activity in areas of high traffic density because of safety concerns.[93–95] Although the body of literature is small, several well-designed prospective studies have begun to describe this multidimensional relationship between TRAP and childhood obesity and emphasize the need for further studies to help clarify this relationship.

Antecedents of Adult Cardiovascular Disease

PM is a well-established risk factor for cardiovascular disease and mortality in adults,[6,96] but data on childhood exposure to ambient air pollution and subsequent cardiovascular disease risk in adulthood are few. Prehypertension (3 measurements above the 90th percentile for age) in youth and adolescents is associated with PM, noise pollution, and secondhand tobacco smoke exposure.[97] There is also a small emerging literature suggesting a potential link between childhood exposure to PM and development of short-term elevated blood pressure.[98,99] Future longitudinal studies are needed to identify critical windows of exposure and whether elevated blood pressure attributed to air pollution in childhood persists into adulthood.

Modifiers of Health Effects

The ultimate toxicity of air pollution on individual children and populations is modified by developmental processes (timing of exposure during sensitive windows of development) and cofactors,

including other toxicant exposures and genetic polymorphisms. An ongoing emphasis of air pollution research in the area of developmental origins of health and disease will be useful in understanding the early life-course vulnerabilities and potential effects into adulthood[100] (Fig 2). In addition, many studies are identifying potentiating effects of coexposure to social stressors.[101–104] Genetic polymorphisms in several oxidative stress genes (*GSTM1*, *GSTP1*, and *NQO1*) and inflammation genes (*TNF*) have been associated with differences in toxic effects of ozone and PM.[105,106] Future genome-wide association studies and whole-genome sequencing may be more helpful in understanding the mechanisms of health outcomes related to air pollution exposure.[29]

There is emerging literature examining antioxidant properties of vitamins C, D, and E mitigating air pollution oxidative effects, but human data are few.[107] In a clinical trial of children in Mexico City, investigators observed that genetically vulnerable children (those with severe asthma with the *GSTM1* deletion in the area coding for glutathione transferase enzyme, which protects against oxidative stress) revealed less severe ozone-related decreases in forced expiratory flow when supplemented with antioxidant vitamins C and E.[108]

PREVENTION OF EXPOSURE AND EFFECTS

Several natural experiments have demonstrated that reducing community air contaminants can lead to improved health outcomes. In the landmark study of 6 US cities, longitudinal decreases in $PM_{2.5}$ resulted in significant decreases in mortality.[109] Childhood asthma exacerbations were significantly reduced during the 1996 Olympics in Atlanta, Georgia, when initiatives surrounding the games included increased public transportation and telecommuting, which resulted in significantly less air pollution.[110] In Beijing, China, when reduced air pollution measures for the 2008 Olympics occurred, birth weights averaged 23 g higher.[111]

Regulatory protections under the Clean Air Act and the National Ambient Air Quality Standards have helped reduce the percentages of children living in areas with concentrations above the annual standard of $PM_{2.5}$ (from 37.5% to 3.3%), the 8-hour ozone standard (from 66.1% to 57.8%), the 1-hour SO_2 standard (from 31.1% to 3.0%), and the 1-hour NO_2 standard (from 23.2% to 2%) from 1999 to 2016.[14] Major ongoing contributors to air pollution, besides power plants and industrial fossil fuel combustion, include increasing urban populations and motor vehicles on the roads and deforestation that decreases plant use of CO_2.[17,25] Some strategies to address the growing motor vehicle fleet includes maintaining emissions standards, anticipation and planning of transportation efficiencies to match needs, availability of clean fuels (including electric), and requirements for inspections and vehicle maintenance.[17] Furthermore, catalytic converter use has reduced ambient air pollution (ie, ozone, mobile air toxics, and $PM_{2.5}$).[17] Interestingly, when school buses in select Washington State communities used clear air technologies, participating elementary school students had both better lung function and less school absenteeism.[112]

Other ways to decrease exposure would be to adjust behavior on the basis of degree of ambient air pollution. The Air Quality Index (AQI), calculated by the EPA on the basis of daily ambient concentrations of National Ambient Air Quality Standards and then grouped and color coded to 6 categories ranging from good (green) to hazardous (maroon), provides a tool for this.[113] On the basis of local air quality at any particular time, individuals may make decisions to reduce time spent in exertional activities outside or elect to do indoor activities. Although much of the general public may not recognize the AQI implications, the AQI would be a powerful tool for physicians to help patients alter behavior as needed if better awareness could be achieved.[114,115] In addition to the AQI, policies limiting proximity of schools, child care facilities, and residences to traffic corridors, as well as anti-idling policies at schools, could reduce exposure in vulnerable populations in areas where they spend significant time.[115] These strategies are important because many US children attend schools in high-traffic areas or encounter diesel school buses with exposure to traffic-related pollutants.[17,112,116]

The EPA has reviewed costs and benefits of air quality regulation since 1997, and their first retrospective assessment demonstrated a mean benefit savings of $22.2 trillion, including health, quality of life, and agricultural benefits, versus a cost of regulation and compliance of $523 billion.[117] Most recently, in 2011 an EPA prospective analysis of the years 1990–2020, a $2 trillion benefit and $65 billion in costs were calculated.[117]

CONCLUSIONS

Ambient air pollution is increasingly recognized as a preventable risk factor for a spectrum of pediatric health concerns. Not only do health effects manifest as exacerbations of chronic diseases (eg, asthma) but air pollution also appears to be associated with the development of major pediatric diseases, including adverse birth outcomes, abnormal lung and neurodevelopment, and pediatric cancer, as well as obesity and cardiovascular disease risk.

Proposed mechanisms involve immune, inflammatory, and oxidative pathways as well as gene-environment interactions and epigenetic changes combined with sociodemographic cofactors. Exposure and resultant health effects may be ameliorated most effectively through policy changes to reduce exposure across the life course. In addition, education around modifiable behaviors may contribute to exposure and toxicity reduction. Evidence demonstrates that children and adults are exposed to potential environmental toxicants from distant as well as proximal sources. This mandates preventive action at the level of state, national, and international policy development, regulation, and enforcement. Although inequalities of exposure to children in certain neighborhoods from local sources of pollution occur, children everywhere experience heightened risk. Continued efforts to unravel the complexity of combined exposures, exposure timing, moderators of effect, and key sources will serve to further focus the most effective policies and approaches for exposure prevention.

RECOMMENDATIONS

1. Pediatric Practice

a. Recognize air quality concerns and resources in your practice area and for individual patients.

b. Serve as a role model and practice model in reducing contributions to poor air quality by using and promoting active transport (eg, walking, cycling) and alternative transportation to gasoline-powered motor vehicles.

c. Use the AQI as a tool in helping educate families of potential protective behaviors. The AQI may be the most useful in especially vulnerable patients with medical risk factors, such as preexisting asthma. Additional information, clinical scenarios, and patient education tools may be found through the EPA Web site at https://www.epa.gov/pmcourse/learn-about-particle-pollution-and-your-patients-health-course.

d. Serve as a source of expertise in your community on the vulnerability of children to air pollution and the importance of primary prevention.

2. Research

a. Evaluate programs and policies designed to reduce exposure to ambient and infiltrated air pollution for effectiveness and health economic analyses.

b. Increase monitoring and health impact assessment in areas with historically less emphasis or enhanced vulnerability (areas with animal agricultural production, child care facilities, and low-income communities).

c. Develop reliable biomarkers of exposure to key traffic constituents and biomass sources.

d. Enhance understanding of genetic and nongenetic modifiers of air pollution effects.

e. Elucidate effects of exposure to mixtures of air pollutants and modifying influences of nonchemical stressors, genetic factors, and nutrition.

3. Regulation and Policy

a. Continue to uphold and strengthen the Clean Air Act, which has demonstrated success in reducing air pollution from mobile and stationary sources.

b. Advocate for reversing rollbacks of emission limits for coal, gas, and oil industries.

c. Ensure consideration of pediatric and fetal stages of the life course in all program and regulatory standard reviews related to ambient air contaminants.

d. Promote school and child care facility siting policies that reduce exposure to traffic-derived air contaminants or other influential proximal sources.

e. Incorporate active transport and air pollution exposure reduction considerations into land use planning.

f. Promote lower-emission technology and approaches for transit.

g. Review regulatory approaches for addressing increasing evidence of community health effects from air contaminants derived from animal-feeding operations.

h. Advocate for 100% renewable energy.

i. Require all states to have emissions standards and vehicle inspections to enforce these standards.

j. Ensure adequate federal and state governmental allocation of resources:

   i. To optimize effective enforcement of current and future regulations of air pollutants.

   ii. To incentivize curtailing of polluting industries.

   iii. To facilitate adoption of lower-emission technology.

The Council on Environmental Health extends thanks to Kembra L. Howdeshell, PhD (National Institute of Environmental Health Sciences), for providing technical assistance and critical review of the draft scientific report.

ABBREVIATIONS

AQI: Air Quality Index
CO: carbon monoxide
EPA: US Environmental Protection Agency
NO_2: nitrogen dioxide
NO_x: nitrogen oxide
PAH: polycyclic aromatic hydrocarbon
PM: particulate matter
$PM_{2.5}$: particulate matter $\leq$2.5 μm in diameter
PM_{10}: particulate matter $\leq$10 μm in diameter
SO_2: sulfur dioxide
TRAP: traffic-related air pollution
VOC: volatile organic compound

FUNDING: No external funding.

POTENTIAL CONFLICT OF INTEREST: The authors have indicated they have no potential conflicts of interest to disclose.

Antibiotic Stewardship in Pediatrics

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Antibiotic Stewardship in Pediatrics

Jeffrey S. Gerber, MD, PhD, FAAP,[a] Mary Anne Jackson, MD, FAAP,[b] Pranita D. Tamma, MD, MHS,[c] Theoklis E. Zaoutis, MD, FAAP,[a]
COMMITTEE ON INFECTIOUS DISEASES, PEDIATRIC INFECTIOUS DISEASES SOCIETY

Antibiotic overuse contributes to antibiotic resistance, which is a threat to public health. Antibiotic stewardship is a practice dedicated to prescribing antibiotics only when necessary and, when antibiotics are considered necessary, promoting use of the appropriate agent(s), dose, duration, and route of therapy to optimize clinical outcomes while minimizing the unintended consequences of antibiotic use. Because there are differences in common infectious conditions, drug-specific considerations, and the evidence surrounding treatment recommendations (eg, first-line therapy, duration of therapy) between children and adults, this statement provides specific guidance for the pediatric population. This policy statement discusses the rationale for inpatient and outpatient antibiotic stewardship programs; essential personnel, infrastructure, and activities required; approaches to evaluating their effectiveness; and gaps in knowledge that require further investigation. Key guidance for both inpatient and outpatient antibiotic stewardship programs are provided.

REVIEW OF EVIDENCE

Overview

Antibiotics are the most common class of medications prescribed to children.[1] Although antibiotic therapy has saved countless lives, their overuse can cause harm. Antibiotic exposure can lead to antibiotic resistance, *Clostridioides difficile* infections (CDIs), and other drug-related adverse events, such as end-organ toxicities, diarrhea, rashes, cytopenia, and anaphylaxis. The Centers for Disease Control and Prevention (CDC) estimates that antibiotic-resistant microbes cause nearly 3 million infections and 35 000 deaths each year in the United States.[2] Antibiotics are frequently used in both pediatric inpatient and outpatient settings, with a significant proportion of antibiotic use considered unnecessary.[3] Antibiotic stewardship is a practice dedicated to using antibiotics only when necessary and, when antibiotics are deemed necessary, to targeting the spectrum of activity and using the appropriate dose, route, and duration of therapy to optimize clinical outcomes while minimizing the

undesirable consequences of antibiotic use.[4] A growing body of evidence demonstrates that antibiotic stewardship programs (ASPs) reduce antibiotic overuse while improving patient outcomes. Consistent with the CDC, the Infectious Diseases Society of America, the Society for Healthcare Epidemiology of America, and the Pediatric Infectious Diseases Society, the American Academy of Pediatrics endorse the development and implementation of ASPs across pediatric health care settings.

This policy statement discusses the rationale for inpatient and outpatient ASPs; essential personnel, infrastructure, and activities required; approaches to evaluating their effectiveness; and gaps in knowledge that require further investigation.

The Role of ASPs

Strategies to address antimicrobial use and the emergence of antimicrobial-resistant pathogens, including formulary management and restriction, have been used for more than 4 decades, but results of such interventions were variable. Briceland et al[5] published the first evidence showing the positive effects from the use of a formal program with an infectious disease physician and pharmacist audit and feedback in 1988, and thereafter, there have been increasing efforts to customize and apply such stewardship strategies at hospitals throughout the United States. In a consensus statement by the Infectious Diseases Society of America, the Society for Healthcare Epidemiology of America, and the Pediatric Infectious Diseases Society, antibiotic stewardship has been defined as "coordinated interventions designed to improve and measure the appropriate use of [antibiotic] agents by promoting the selection of the optimal [antibiotic] drug regimen including dosing, duration of therapy, and route of administration."[6] Although most of the evidence base for antibiotic stewardship has focused on the acute care setting, the CDC has published core elements of antibiotic stewardship for acute care (including small and critical access hospitals), long-term care, and ambulatory care settings.[7]

Unintended Consequences of Antibiotic Use in Children

Although numerous antibiotics have been developed since the discovery of penicillin, they have been closely followed by the development of increasingly complex mechanisms of antibiotic resistance by bacterial pathogens as these agents have been introduced into clinical practice.[8] The increase in multidrug-resistant infections has outpaced the development of novel antibiotics capable of treating them.[9] Although not addressed in this document, the use of antibiotics in animal agriculture also contributes to antibiotic resistance.[10]

Adverse consequences associated with antibiotic use extend beyond the development of resistance in targeted organisms. As seen from evaluation of pediatric data from the National Electronic Injury Surveillance System in the United States between 2011 and 2015, antibiotic-associated adverse drug events accounted for almost 50% of emergency department visits for adverse events from systemic medications.[11] CDI is another potential consequence of antibiotic use. In a large surveillance study, 71% of CDI cases in children were community associated and generally developed after exposure to antibiotics prescribed during ambulatory encounters for otitis media, sinus infections, or acute respiratory tract infections (ARTIs).[12] Researchers in more recent investigations have explored the effect of antibiotic exposure on the intestinal microbiome. Data suggest the potential for antibiotic exposures, especially when frequent and occurring early in life, to promote intestinal dysbiosis and possible effects on the development of conditions such as juvenile idiopathic arthritis, inflammatory bowel disease, asthma, and diabetes.[13–15]

Inpatient ASPs

Stewardship programs dedicated to a variety of pediatric patient populations are becoming increasingly prevalent in the United States. A 2011 survey of 38 freestanding children's hospitals reported that 42% had established ASPs and an additional 37% were in the process of implementing programs.[16] In 2014, the CDC compiled a checklist of "Core Elements of Hospital Antibiotic Stewardship Programs" that included the following: support from leadership for the ASP, including appropriate financial support; an identified physician leader for the ASP; a pharmacist coleader; support from other relevant stakeholders (ie, microbiology laboratory personnel, infection prevention team members, information technology staff, and nursing and other allied health professionals, among others); specific interventions to improve antibiotic use (eg, prior approval, postprescription review with feedback, etc); pharmacy-driven interventions (eg, dose optimization, therapeutic drug monitoring, automatic conversion of intravenous to oral antibiotic therapy, etc); recommendations for the diagnosis and treatment of specific syndromes (eg, community-acquired pneumonia, urinary tract infections, etc); monitoring antibiotic prescribing and resistance patterns and regularly reporting findings to health care workers; and educating health care workers about resistance and optimal prescribing.[16] In January 2017, The Joint Commission (TJC) Antimicrobial Stewardship Standard went into effect, further emphasizing the need for all acute care facilities to have ASPs.[17] The Pediatric Antibiotic Stewardship Program Toolkit

developed by the American Academy of Pediatrics and the Pediatric Infectious Diseases Society offers guidance more specific to the pediatric population.[18] For hospitals with both adult and pediatric patients, inclusion of a pediatric infectious diseases physician and/or pharmacist as members of the ASP is recommended.

The core team members of ASPs include physician and pharmacist leaders, according to both the CDC Core Elements[16] and TJC Antimicrobial Stewardship Standard.[17] Dedicated financial support to these leaders is critical to enable the success of stewardship programs.[19] Ideally, both physicians and pharmacists will have an infectious diseases fellowship or postgraduate year 2 infectious diseases residency training, respectively, to ensure comprehensive knowledge of the diagnosis and management of infectious diseases.[20] In resource-limited settings, ASPs may be led by physicians and/or pharmacists without formal infectious diseases training; however, an ASP team member with pediatric expertise is required. Although team members are encouraged to develop program goals together, unique roles for the physician leader include underscoring to other clinicians how the overarching goals of the ASP are to optimize patient outcomes and prevent unnecessary harm to patients and to function as a bridge to hospital executive leadership. Pharmacists typically conduct the majority of routine interventions and often lead efforts to compile and validate antibiotic use data. The pharmacist also functions as a liaison between providers and both the department of pharmacy and the therapeutic standards committee to encourage agreement between stewardship and pharmacy goals.

Close relationships between stewardship leaders and hospital leaders can further the goals of the stewardship program.[16,17] Along with financial resources, executives can facilitate the involvement of stewardship leaders in strategic high-level meetings and connect the stewardship team to institution-wide stakeholders who can help further disseminate concepts of stewardship.

Both the CDC Core Elements and TJC Antimicrobial Stewardship Standard highlight the importance of monitoring antibiotic use and antibiotic resistance.[16,17] A data analyst can support the stewardship program by compiling relevant antibiotic use and microbiological data that can periodically be fed back to hospital administration and clinicians and identify necessary interventions led by the ASP. Moreover, the data analyst can lead efforts to report institutional data to the CDC National Healthcare Safety Network Antimicrobial Use and Resistance Module.[16]

Nurses are valuable partners in antibiotic stewardship efforts and can be actively integrated into stewardship interventions.[21] Bedside nurses provide continuity of care to patients and can be vital in ensuring that goals of care are carried over and readdressed on a daily basis.[22] Furthermore, nurses can assist with alleviating patient and guardian concerns about antibiotic use (or a perceived but appropriate "lack" of antibiotic use). Additional guidance on specific examples of how valuable nurses can be to stewardship efforts are available.[21,23] Additionally, the stewardship team may consider working closely with the clinical microbiology laboratory to assist with antibiogram development (ie, a periodic report summarizing the susceptibility activity of a bacteria to a variety of antibiotics), help inform selective reporting of antibiotic susceptibility results, and improve the selection and implementation of rapid diagnostic tests. The stewardship team can also function as a conduit between the microbiology laboratory and clinician by educating providers about appropriate culture specimen collection and testing criteria as well as interpretation of the antibiogram and rapid diagnostic test results.[24] Finally, stewardship teams can work with the infection prevention team as the infection prevention team compiles data on hospital-wide resistant organism trends and *C difficile* laboratory-infectious disease events (a metric standardly collected by many US hospitals on a quarterly basis and reported to the CDC) that can be informative in guiding stewardship interventions.

Stewardship Strategies in the Inpatient Setting

Local Guidelines

The development and dissemination of institutional guidelines for diagnosing and treating common infectious syndromes is a key function of stewardship programs. Guidelines provide evidence-based and standardized diagnostic and treatment recommendations based on local data and promote adherence to the use of formulary drugs. Inpatient antibiotic guidelines can be developed to target common indications for antibiotic use, such as community-acquired pneumonia, urinary tract infections, hospital- and ventilator-associated pneumonia, skin and soft tissue infections, intraabdominal infections, and neonatal and pediatric sepsis. These indications represent the majority of antibiotic use in most institutions.[25] Inpatient guidelines can discuss appropriate clinical criteria suggestive of bacterial infections, diagnostic testing (including imaging studies when needed), specific empirical and targeted therapy (including dosing and options for severe drug allergies), and appropriate durations of therapy. Each guideline can be developed with input from each of the relevant

specialties and include medical, pharmacy, and nursing representatives. Ensuring guidelines are available at the point of care (eg, intranet, patient unit handbooks, pocket cards, apps, etc) increases the likelihood that clinicians will easily access them when necessary. Finally, periodic reviews and updates of local guidelines by the stewardship team will maintain their relevance as new evidence emerges.

Prior Approval Versus Postprescription Review With Feedback

Stewardship programs should determine their approach to interventions on the basis of available resources.[26] Direct, face-to-face interactions such as "handshake stewardship" is always favored when possible, because they foster a collaborative relationship between the stewardship team and clinicians, but they can be labor intensive.[27] Although telephone calls or notes in the medical record will never be substitutes for human interactions, they can play an important role in promoting evidence-based antibiotic use and may be more feasible for many programs. Stewardship programs may want to consider prior approval, postprescription review with feedback, or a combination of the 2 approaches to encourage judicious antibiotic use.[26] Prior approval generally consists of a phone call to the stewardship team for select anti-infectives justifying the use of the agent before it is dispensed by pharmacy. This approach can reduce unnecessary antibiotic initiation, optimize the selection of empirical antibiotics, provide information on optimal culture techniques, and encourage infectious diseases consultations when necessary. Drawbacks of this approach include its focus on specific restricted agents, potential to disrupt front-line clinician workflow, potential delays in antibiotic administration for sepsis, and an inability to address downstream antibiotic use, such as intravenous to oral conversion or duration of therapy.

Postprescription review with feedback generally occurs 48 to 72 hours after antibiotics are initiated, when more clinical data are available to make recommendations. Advantages to this approach include greater flexibility in the timing of interventions and the ability to address targeted therapy decisions. An important limitation with this approach is that recommendations are generally optional because most stewardship programs are not able to enforce mandatory discontinuation of antibiotics. Additionally, postprescription review generally does not affect the first 2 to 3 days of antibiotic therapy, which often constitute a large portion of inpatient antibiotic use. A hybrid approach including a component of prior approval and postprescription review is often the most effective.[28]

Syndrome-Specific Stewardship

Syndrome-specific interventions target specific disease processes such as community-acquired pneumonia[29] or skin and soft tissue infections.[30] It also includes perioperative prophylaxis recommendations or surgical conditions such as the management of appendicitis.[31–33] Perioperative prophylaxis remains an important target because approximately 40% of all antibiotics in the inpatient setting are administered to surgical patients.[34] Syndrome-specific stewardship is generally operationalized through the development of local guidelines and targeted educational interventions around the syndrome.[29] Benefits include engagement of front-line clinicians and facilitation of sustained practices. Additionally, syndrome-specific stewardship can address both empirical and targeted prescribing and is generally viewed as a measure toward optimizing "patient safety" or "quality improvement," rather than as an approach involving less-attractive restrictive interventions. Disadvantages include incomplete capture of all cases of a specific condition, particularly if a culture result is not the usual trigger (eg, community-acquired pneumonia); challenges obtaining consensus approaches among various stakeholders; and the inability to target antibiotic use that occurs without clear indications. When developing specific treatment recommendations in local guidelines for specific syndromes, clear criteria for determination of penicillin allergies and when penicillin allergy testing might be necessary can be helpful.

Rapid Diagnostic Tests

Diagnostic test implementation provides a unique opportunity for stewardship teams to educate providers in real time and to inform prescribing practices.[24] Rapid diagnostics can facilitate antibiotic de-escalation (eg, switching from vancomycin to oxacillin for methicillin-susceptible *Staphylococcus aureus* bacteremia), broadening therapy when necessary (eg, switching from vancomycin to daptomycin for vancomycin-resistant *Enterococcus faecium* bacteremia), stopping therapy (eg, discontinuing vancomycin for a single positive culture for coagulase-negative *Staphylococcus* bacteremia), or in some cases, identifying a viral etiology that may reduce the likelihood of a bacterial pathogen. Before implementing a new test, the stewardship team may want to develop and disseminate a guidance document for prescribers on how to interpret results of the new test. Moreover, the team can develop language to include in the electronic health record that is concise, relevant, and understandable to clinicians. The main disadvantage of interventions around implementation of rapid diagnostic tests is that the impact is generally limited to a small number of

patients (eg, patients with bloodstream or respiratory tract infections). Furthermore, these tests can be costly and sometimes resource intensive. Stewardship programs may also struggle with ensuring prescriber "buy-in" if the test does not have negative or positive predictive values approaching 100%.

Outpatient ASPs

The vast majority of antibiotic prescribing occurs in the outpatient setting.[35] One in 5 pediatric ambulatory visits result in an antibiotic prescription, accounting for nearly 50 million antibiotic prescriptions annually in the United States, at least half of which are considered inappropriate.[36] ARTIs account for more than two-thirds of antibiotic prescriptions for children, at least one-third of which are unnecessary.[37] Although most outpatient pediatric antibiotic prescriptions come from primary care encounters, subspecialty practices, emergency departments, urgent care clinics, retail clinics, and dentists' offices are also important settings for outpatient antibiotic stewardship.

As with inpatient stewardship, effective outpatient stewardship requires strong leadership. Ideally, a single clinician leader with expertise in antibiotic use in the outpatient setting is identified. If the practice is part of a larger organization (eg, health care network), commitment from administrators, such as salary support and providing the authority to implement change, is important. Last, the ability to track and report antibiotic prescribing and, ideally, clinical outcomes data is critical for measuring the impact of interventions (and potentially as a tool for influencing appropriate antibiotic use). The Antimicrobial Stewardship Standard of TJC for the outpatient setting went into effect in January 2020.[38]

Stewardship Strategies in the Outpatient Setting

Standard antibiotic stewardship approaches recommended for the hospital setting, such as prior approval and real time, postprescription review with feedback, are not practical in the ambulatory setting. However, a variety of stewardship strategies have been successfully implemented in outpatient practices, and their effects on antibiotic prescribing and clinical outcomes have been reviewed.[39,40] These include, but are not limited to, clinical decision support, clinician and/or patient education (eg, watchful waiting for acute otitis media, when appropriate), and audit with feedback of antibiotic prescribing. Implementation of a systematic approach to follow up negative culture results and discontinue antibiotics that were initiated on the basis of initial signs and symptoms can also reduce exposure to antibiotics. It is common for there to be a system to notify the patient and families of positive results in cases in which an antibiotic was not prescribed; however, it is important to also have a comparable process for discontinuing antibiotics when final results are negative. Because communication between the clinician and patient and/or caregiver can influence the decision to prescribe an antibiotic, communication training is another potential strategy.[41] Consideration of the sociobehavioral aspects and context of the encounter during which antibiotic prescribing might occur have also been shown to be important levers for improving practice.[42,43] Furthermore, educating parents about the natural course of viral and bacterial infections can foster an understanding of expectations (eg, prolonged cough for viral pharyngitis). The emergency department remains a hybrid in which elements of both inpatient and outpatient stewardship generally need to be merged to optimize antibiotic prescribing for both patients discharged from the hospital and for those who will ultimately be hospitalized.

Unnecessary Prescribing

Clinical encounters in which antibiotics could be avoided altogether can be a primary target for outpatient stewardship. Examples include antibiotic prescribing for nonspecific upper respiratory infection, bronchiolitis, acute bronchitis, asthma exacerbation, or conjunctivitis. When considering the epidemiology of bacterial infections presenting in the ambulatory setting requiring antibiotics, it has been conservatively estimated that antibiotic prescribing could be safely reduced by 30%.[37]

Diagnosis Stewardship

Just as antibiotic prescribing rates vary across providers and practices, rates of diagnosis of the most common childhood infections have been shown to vary substantially.[44] Thus, "diagnostic stewardship" can be considered as a means to reduce prescribing. Examples include reserving antibiotic treatment of pharyngitis for children with a positive group A streptococcal test result and only testing children with a suggestive clinical syndrome, requiring characteristic findings identified by pneumatic otoscopy and clinical signs of middle ear infection to confirm and treat acute otitis media, demonstrating pyuria in conjunction with signs and symptoms suggestive of a urinary tract infection and to distinguish asymptomatic bacteriuria from true infection, and confirming severe, progressive, or prolonged and unrelenting symptoms for the diagnosis and treatment of acute bacterial sinusitis.

Antibiotic Choice

Even when antibiotics are indicated, outpatient stewardship interventions can improve patient care. Broad-spectrum second-line antibiotics are prescribed as often as first-line

recommended narrow-spectrum agents for ARTIs.[36] This practice can lead to avoidable adverse drug events and antibiotic resistance and can increase overall health care costs without clinical benefit over narrow-spectrum agents.[45] In some cases, these nonrecommended antibiotics are less likely to cover the most likely offending pathogen, such as oral cephalosporins or azithromycin for pneumococcus, the prime target for acute otitis media, sinusitis, and pneumonia.

Duration and Route of Therapy

Even when the right drug and dose are prescribed, the duration of therapy is an important stewardship target. Many infections treated for 10 or 14 days will respond to shorter antibiotic courses, including most uncomplicated skin and soft tissue infections, pneumonia, and urinary tract infections.[46] The use of outpatient parenteral antibiotic therapy can be limited to conditions for which oral therapy is known to be less effective.[47,48] A large proportion of outpatient parenteral antibiotic therapy for children is unnecessary, and use of peripherally inserted central catheters is associated with a high rate of adverse events in children.[49–51]

Challenges to implementing antibiotic stewardship in the outpatient setting include finding resources to support a program, identifying a clinician leader who has the time and interest to commit to engaging outpatient clinicians in a quality improvement initiative, obtaining data to identify high-impact targets and track process improvement and clinical outcomes, and sustaining improvement over time.

Measuring the Success of ASPs

Process Measures

When evaluating ASPs, outcomes are frequently categorized into those that are related to process outcomes (eg, antibiotic use) or to clinical outcomes (eg, length of hospital stay). This distinction is debatable, because process outcomes, with all of their downstream effects, are themselves arguably a clinically relevant outcome. Antibiotic usage outcomes generally examine changes in antibiotic use practices after the implementation of stewardship interventions. It is always preferred to use data reporting antibiotics dispensed from the pharmacy or administered to patients rather than purchasing data when measuring antibiotic use because the former more accurately assesses antibiotic exposure. Published data from pediatric ASPs have consistently demonstrated that these programs can effectively decrease antibiotic use.[52–57] These findings were summarized in a systematic review including 9 studies reporting outcomes from US pediatric ASPs.[58]

In the past, defined daily doses per 1000 patient-days was widely accepted as an antibiotic stewardship process outcome in the inpatient setting but has largely been replaced in the United States by days of therapy (DOTs) per 1000 patient-days. As opposed to defined daily doses, DOTs have the advantage of not being affected by variations in dosing and, therefore, are more representative of pediatric prescribing practices in which dosing can vary greatly between age groups. DOTs account for the number of different antibiotics (but not doses) administered each day. For example, if a child receives cefepime, gentamicin, and vancomycin on a hospital day, this would contribute 3 DOTs. Limitations of this metric include the lack of accounting for antibiotics prescribed at the time of hospital discharge, which make it sensitive to changes in the mean hospital length of stay,[59,60] and its inability to discriminate between antibiotic spectrum of activity (eg, a day of ceftriaxone and metronidazole would count as 2 DOTs, whereas a day of meropenem would count as 1 DOT).

Metrics that can be considered in outpatient settings include the number of antibiotic prescriptions per monthly patient-visits, proportions of all visits or sick visits leading to antibiotics, and proportions of visits for particular diagnoses leading to antibiotics. However, because of inherent differences in the acuity of patients visiting urgent care centers versus primary care clinics and challenges with providing close follow-up of patients in urgent care settings, comparisons between antibiotic use across these practices can be problematic.

In the current medical landscape, in which payment requirements are becoming increasingly stringent, cost-saving strategies are of particular interest to health care administrators. Several investigators have found implementation of pediatric ASPs to be associated with reduced antibiotic-related expenditures.[52,61] This is particularly true in the initial years after implementation but has also been shown to be sustainable.[53] Although cost savings are appealing to administrators and regulatory bodies and therefore improve resource allocation and "buy-in," focusing on clinical outcomes is more likely to influence clinician antibiotic prescribing behavior.

Clinical Outcomes Measures

Clinical outcomes are more challenging to measure than antibiotic use, because they are more resource intensive to collect; may be rare (eg, death), so may not provide sufficient statistical power when evaluated in the context of ASP interventions; and are potentially attributable to multiple other non–stewardship-related interventions. Although improvement in clinical outcomes after optimization of antibiotic therapy is ideal, a reduction in antibiotic use without worsening clinical outcomes is also acceptable. Examples of clinical outcomes to consider include CDI, antibiotic resistance, antibiotic-

associated adverse drug events, length of stay, hospital readmission, and mortality.

CDI is a common adverse event associated with antibiotic use that has been well-studied in the adult population but less so in children. The most common standardized CDI metric is CDI cases per 10 000 hospitalizations. Reductions in rates of CDI with stewardship programs have been identified in adult populations[38,62–64] but have not been observed in children, in part because the incidence of CDI is lower in children compared with adults, and *C difficile* has a high likelihood of being a colonizer (rather than a pathogen) in young children, making it challenging to adequately power a study to demonstrate a difference in CDI rates.

Decreasing rates of antibiotic resistance is an important goal of a stewardship program; however, similar to CDI rates, they are difficult to demonstrate, mostly because there are numerous alternate pathways by which the development and spread of antibiotic resistance occur, including lapses in infection prevention practices, outpatient antibiotic use, and mixing of patient populations from outside institutions. In addition, resistance is a dynamic process and may take months to years to emerge. A reduction in antibiotic resistance attributable to pediatric stewardship programs has not been the subject of extensive evaluation, and when it has been assessed, results have been conflicting.[57,65–67] These findings are similar to what has been observed with adult ASPs.[68–70]

Hospital length of stay is frequently studied as a metric in health care interventions, although less often for ASPs. In one children's hospital in which postprescription review and feedback was used, hospital length of stay was reduced by approximately 1 day, and 30-day readmission was reduced by 3%.[71] Although decreasing length of stay is an important goal of health care institutions, it is inherently multifactorial and, thus, not ideal as a primary outcome of ASPs.

Decreased mortality is difficult to associate with ASP interventions, because it is a relatively rare outcome in children in general and because excessive antibiotic use is unlikely to meaningfully affect survival. Mortality has not been shown to be a feasible outcome of stewardship programs in either children or adults, and its use as a primary outcome is discouraged.

Gaps in Knowledge

Although the field of antibiotic stewardship has made considerable advancements over the past decade, notable knowledge gaps remain.[21] Some gaps in knowledge for antibiotic stewardship to highlight include (1) effective adaptation of the organizational structure and interventions established for the acute care setting to ambulatory and long-term care settings, (2) understanding the cultural and adaptive influences of antibiotic prescribing, (3) understanding how best to incorporate nursing into stewardship efforts and fostering an environment in which nursing contribution is actively encouraged, (4) defining the optimal treatment of common bacterial infections specific to the pediatric population (eg, comparisons of different drug regimens, durations of therapy, parenteral versus oral therapy, and optimal dosing strategies) to improve the evidence base for stewardship recommendations, (5) developing and validating metrics that consider the potential harm of antibiotics and weigh the risks versus the benefits (ie, an antibiotic-associated harm score), (6) establishment of risk-adjusted antibiotic use benchmarking approaches, (7) approaches to effectively teaching clinicians to become "self-stewards," and (8) incorporating the patient and family perspective and shared decision-making into stewardship.

RECOMMENDATIONS

1. The American Academy of Pediatrics and the Pediatric Infectious Diseases Society recommend establishing ASPs to improve antibiotic prescribing.
2. ASPs governing antibiotic use for children should include specialists with pediatric expertise.
3. Inpatient ASPs are ideally composed of a medical director and a clinical pharmacist(s), both with expertise in pediatric infectious diseases and/or antibiotic stewardship.
4. Inpatient ASPs can use clinical guidelines, prior approval, and postprescription review and feedback as core interventions.
5. Inpatient ASPs can include pharmacy-driven interventions such as dose optimization, therapeutic drug monitoring, automatic conversion of intravenous to oral antibiotic therapy, or dose adjustments in cases of organ dysfunction.
6. Inpatient ASPs can consider auditing, analyzing, and reporting local unit-specific antibiotic prescribing data periodically to relevant stakeholders.
7. Outpatient primary care practices, urgent care clinics, and emergency departments could consider establishing standardized approaches for antibiotic prescribing including clinical guidelines and/or decision support.
8. Outpatient stewardship can focus on judicious use of antibiotics for ARTIs, including avoidance of antibiotic prescribing for undifferentiated upper respiratory tract infection, bronchiolitis, acute bronchitis, and nonstreptococcal pharyngitis; refraining from prescribing antibiotics for urinary

tract infections in the absence of a urinalysis and urine culture; and judicious diagnosis of acute otitis media, acute sinusitis, and group A streptococcal pharyngitis.

9. Outpatient stewardship efforts can emphasize use of the narrowest-spectrum antibiotics for the shortest duration of therapy that will adequately treat bacterial infections.

Biologics for Asthma and Allergic Skin Diseases in Children

Heather Hoch De Keyser, MD, MSCS, FAAP,[a] Bradley Chipps, MD, FAAP,[b] Chitra Dinakar, MD, FAAP,[c,d]
SECTION ON ALLERGY AND IMMUNOLOGY and SECTION ON PEDIATRIC PULMONOLOGY AND SLEEP MEDICINE

An estimated 7 million children in the United States have asthma, which causes a significant health care burden and affects quality of life. The minority of these children have asthma that does not respond to Global Initiative for Asthma steps 4 and 5 care, and biological medications are recommended at this level in the 2019 Global Initiative for Asthma recommendations. In addition, biologics have been introduced into the care of children with allergic skin diseases. Omalizumab and mepolizumab are approved for children as young as 6 years, and benralizumab and dupilumab are approved for people aged ≥12 years. Reslizumab is approved only for people aged ≥18 years. These monoclonal antibodies may be added for appropriate patients when asthma or allergic skin diseases are not well controlled. Pediatricians and pediatric subspecialists should work together and be aware of the benefits and risks of these medications for their patients, as well as the practical implications of providing these options for their patients. This clinical report serves as an evaluation of the current literature on these types of medications in the treatment of children with asthma and allergic skin disease.

ASTHMA

Asthma may not be controlled in 38% of affected children, and biological medications may be prescribed if appropriate, other pharmacologic treatment, treatment of comorbidities, and verification of medication adherence does not lead to an acceptable level of control.[1] The minority of these children have asthma that does not respond to Global Initiative for Asthma (GINA) steps 4 and 5 care, and biological medications are recommended at this level in the 2019 GINA recommendations.[2] It is important to first confirm the diagnosis of asthma and to verify adherence to and appropriate technique for using an inhaler before embarking on biological therapy. Limited numbers of clinical trials include children, resulting in minimal current information on biological use in the pediatric population. The exception is the oldest biological therapy, omalizumab,

which has a more significant amount of data on use in children. Increasing numbers and types of biological therapies have become available to this population, however, and the niche for each product will be better defined as its role in asthma care evolves. Pediatricians and pediatric subspecialists should be aware of the current range of biological medications available to children with severe asthma. In addition, general pediatricians should monitor patients for evidence of poor response to traditional therapies and consider referring to pediatric subspecialists for evaluation of eligibility for these types of medications. Finally, those who administer this type of care for children with asthma should be aware of the potential for anaphylaxis for many biologics, especially omalizumab and reslizumab, and be prepared to treat and evaluate anaphylaxis and other potential treatment-related adverse effects. The American Academy of Pediatrics policy statement "Preparation for Emergencies in the Offices of Pediatricians and Pediatric Primary Care Providers" is a helpful reference in the preparation for such emergencies.[3] The purpose of this clinical report is to review the available literature for these types of medications in children.

ASTHMA MEDICATIONS

Anti–Immunoglobulin E Therapy

Omalizumab was approved by the US Food and Drug Administration (FDA) in 2003. It is a subcutaneously administered humanized anti–immunoglobulin E (IgE) antibody that is licensed for the treatment of patients aged >6 years with moderate to severe asthma who have a positive skin test result to a perennial allergen and whose IgE is between 30 and 1300 IU for people aged 6 to 12 years and between 30 and 700 IU for those aged ≥12 years.[1,4,5]

In 2001, Milgrom et al evaluated children aged 6 to 12 years with moderate to severe asthma in a double-blind, randomized, placebo-controlled trial.[6] The participants had asthma that was well controlled for 3 months by using inhaled corticosteroids (ICSs) (168–420 μg beclomethasone equivalent) and had a forced expiratory volume in the first second of expiration (FEV_1) of greater than 60% predicted. The primary outcome was ICS reduction. After 28 weeks of omalizumab therapy, the ICS dose was reduced, as tolerated, and the percentage of patients in whom ICS reduction occurred was 100% with omalizumab versus 66.7% of the placebo group patients. Fewer participants had asthma exacerbations during the steroid reduction phase in the omalizumab group versus placebo (18.2% versus 38.5%). The proportion of the participants who had ICS completely withdrawn in the omalizumab group was 55% and in the placebo group was 39%. Withdrawal of ICS did not compromise asthma control. Physician-rated global evaluation of treatment effectiveness was excellent or good in the omalizumab group at 44% and 32.7% in the placebo group.

Lanier et al conducted a 52-week trial in participants aged 6 to 12 years with moderate to severe, persistent asthma that was uncontrolled on greater than 200 μg of fluticasone or equivalent and who had a history of severe exacerbation within the previous 2 years of therapy.[7] Participants were randomly assigned 2:1 to receive omalizumab or placebo, and there was a 24-week, fixed inhaled-steroid phase followed by a 28-week, adjustable ICS steroid phase. From the baseline period to week 24 (fixed phase), there was a 31% reduction in exacerbations (defined as worsening of symptoms requiring doubling of baseline ICS dose and/or systemic steroids) in the omalizumab group versus placebo and a 43% reduction in exacerbations over the entire study time frame (52 weeks) with omalizumab versus placebo. The global evaluation of treatment effectiveness was also rated excellent or good by 79% in the omalizumab group and 56% in the placebo group.

Third and fourth studies were conducted by the Inner-City Asthma Consortium.[8,9] In these studies, researchers enrolled, predominantly, children from low-income families and people of color. The first of these included participants 6 to 20 years of age with persistent allergic asthma for greater than 1 year, at least 1 positive skin-prick test result for perennial allergens, weight between 20 and 150 kg, and serum IgE concentration 30 to 1300 IU/mL, per the omalizumab-insert dosing table.[8] Participants were randomly assigned to receive omalizumab or placebo, in addition to standard care during a 60-week treatment period. The mean age was approximately 11 years. The percentage of children with one or more exacerbation during the study period was 48.8% with placebo and 30.3% in the omalizumab group. In addition, seasonal analysis of exacerbations revealed that omalizumab reduced the spring and fall spikes in asthma exacerbations. The mean ICS dose in the omalizumab group was 663 μg per day versus 771 μg per day in the placebo group. This study underscored the efficacy of omalizumab in children from low-income families and people of color.

In a companion study, researchers enrolled participants aged 6 to 17 years who met package-insert criteria for omalizumab and who had uncontrolled asthma, defined as an ICS dose of greater than 200 μg

of fluticasone a day and more than 1 exacerbation in the last year.[9] Those receiving 500 μg twice a day of fluticasone or equivalent (treatment step 5 from the National Asthma Education and Prevention Program Expert Panel Report) were randomly assigned 3:1 to receive omalizumab or placebo, and participants receiving less than 500 μg per day of fluticasone or equivalent were randomly assigned 3:3:1 to receive omalizumab plus inhaled placebo, ICS boost plus injected placebo, or guideline-based care with injected placebo and inhaled placebo. The 90-day treatment period commenced 4 to 6 weeks before the start of the school year. There was a reduction in fall exacerbations with omalizumab, with 11.3% of participants in the omalizumab group having exacerbations, compared with 21% in the placebo group. The effect was even higher in those with more than 1 exacerbation during the run-in phase; the fall exacerbation rate was 6.4% for omalizumab and 36.3% for those in all placebo groups.

In a French, real-world study, researchers enrolled participants aged 6 to 18 years with severe allergic asthma who were partially or poorly controlled by GINA guidelines with a mean ICS dose of 703 μg fluticasone equivalent per day[10] and evaluated outcomes at baseline and after initiation of omalizumab add-on treatment. In week 52 versus baseline, control improved to good control (by GINA guidelines) in 67% of participants. Exacerbations were reduced by 72% and hospitalizations were reduced by 89% in the first year of therapy. FEV_1 increased by 4.9%, and there was a 30% reduction in mean ICS dose.

Omalizumab is indicated for allergic asthma and currently approved for people as young as 6 years. Injection dosing is based on IgE concentration and body weight, with injections administered either every 2 or every 4 weeks.[5] The cost is substantial. According to the 2018 Institute for Clinical and Economic Review report on biological therapies for asthma, the per-unit manufacturer net price of omalizumab is $802.64, with per-patient costs varying significantly depending on the dosage needed as well as provider and payer, with an average net adult cost per year of $28 895.[11] In addition, anaphylaxis is a risk with this medication; the patient should be under medical observation for anaphylaxis after every injection,[5] and epinephrine autoinjectors should be prescribed for use at home in the case of delayed anaphylaxis.[12] Safety outcomes were primarily studied in patients older than 12 years but have shown an incidence of postmarketing anaphylactic reactions of 0.2% in treated patients,[13,14] leading to a black box warning on anaphylaxis.[15] Initial pooled data from phase I through III clinical trials revealed a numeric imbalance in the number of malignancies in patients treated with omalizumab versus placebo; however, in further pooled analysis of 67 phase I through IV clinical trials, including 4254 patients who received omalizumab treatment, researchers found no significant association between malignancy and omalizumab treatment in the overall group, although specific conclusions in the pediatric subgroup were not possible because of small sample size.[16] The FDA recognizes the following most common adverse events for omalizumab for asthma: "[adults and adolescents >12 years] arthralgia, pain (general), leg pain, fatigue, dizziness, fracture, arm pain, pruritus, dermatitis, and earache; [pediatric patients 6 to <12 years of age] nasopharyngitis, headache, pyrexia, upper abdominal pain, pharyngitis streptococcal, otitis media, viral gastroenteritis, arthropod bites, and epistaxis." In addition, the FDA cautions not to use omalizumab for acute asthma symptoms, not to abruptly discontinue corticosteroids, and to monitor for signs of serum sickness, eosinophilia, vasculitic rashes, worsening pulmonary symptoms, cardiac complications, or neuropathy.[5]

Omalizumab has been shown to generate improved asthma control, reduce incidence and frequency of exacerbations, reduce health care use for severe exacerbations, have corticosteroid-sparing effects, and ultimately result in improved quality of life for qualifying patients with moderate and severe persistent asthma.

Anti–Interleukin 5 Therapy

Interleukin 5 (IL-5) is a cytokine involved in eosinophil activation, which makes it a key target for therapeutic intervention in eosinophil-driven diseases, including asthma. There have been multiple anti–IL-5 antibodies under development in recent years. The therapeutics described have been studied in populations of people with asthma as young as 6 years, although importantly, data on children have not been reported separately.

Mepolizumab

Mepolizumab is a fully humanized anti–IL-5 antibody, currently approved in the United States for the add-on maintenance treatment of severe asthma.[17] Mepolizumab binds to IL-5, blocking its interaction with the IL-5 receptor on the surface of eosinophils, obstructing its actions at that level.[18] The best response is observed in patients with eosinophil concentrations >300 cells/μL.

The first key study to evaluate the efficacy of mepolizumab was the DREAM study (Dose Ranging

Efficacy And Safety With Mepolizumab in Severe Asthma), a multicenter, randomized, placebo-controlled trial.[19] In this trial, researchers enrolled 621 participants with a history of recurrent severe asthma exacerbations and signs of eosinophilic inflammation. Although children aged 12 to 17 years were eligible for enrollment, demographics suggest that no pediatric participants were enrolled.[20] The investigators found the rate of clinically significant exacerbations was significantly reduced in the mepolizumab groups (2.40 per participant per year in the placebo group, 1.24 per participant per year in the low-dose mepolizumab group [75 mg, intravenous (IV)], 1.46 in the medium-dose group [250 mg, IV], and 1.15 in the high-dose group [750 mg, IV]). All mepolizumab-treated groups also had reduced circulating blood eosinophils and sputum eosinophils. One post hoc analysis of the DREAM trial data also showed that treatment response was unaffected by season or atopy.[21]

After the DREAM trial, there were 2 additional studies in which researchers evaluated the efficacy of mepolizumab in adults and adolescents. The Mepolizumab as Adjunctive Therapy in Patients with Severe Asthma (MENSA) study, in which researchers enrolled 576 participants aged 12 to 82 years (only 25 patients in age range 12–17 years[22]), revealed a 47% reduction in exacerbation rates in those receiving IV mepolizumab and a 53% reduction in those receiving subcutaneous injections.[23] In addition, there was a reduction in exacerbations necessitating an emergency department visit or hospitalization (32% in the IV mepolizumab group and 61% in the subcutaneous mepolizumab group). There was an increase in FEV_1 in both mepolizumab-treated groups, as well as improvements in markers of asthma control.

In the Steroid Reduction with Mepolizumab Study (SIRIUS) study, researchers sought to evaluate the steroid-sparing effect of mepolizumab in people with severe eosinophilic asthma (enrolling 135 participants, 16–74 years of age) and found a 50% reduction in steroids from baseline in the treatment group, with no reduction in the placebo group.[24] Along with the reduction in steroid dosing, there was a reduction in exacerbations in the mepolizumab group by 32%, and a reduction in asthma symptoms. Importantly, the SIRIUS study did not report the number of pediatric participants; however, the mean age of both the placebo and mepolizumab groups was 50 years. Both the SIRIUS and MENSA studies revealed no significant safety concerns with mepolizumab.

Secondary data analyses were conducted on the MENSA and SIRIUS trials. In one such analysis, researchers evaluated mepolizumab in subjects who had previously received omalizumab therapy. In MENSA, mepolizumab reduced exacerbations by 57% and 47% in those who had and who had not previously received omalizumab, respectively.[25] The SIRIUS trial showed reduced oral corticosteroid (OCS) rates regardless of previous omalizumab use.[25] In addition, both studies showed that asthma control and quality of life were improved regardless of omalizumab use. A secondary analysis of the DREAM and MENSA studies revealed a "close relationship between baseline blood eosinophil levels and clinical efficacy of mepolizumab," with efficacy highest in those with eosinophil concentrations of at least 150 cells/μL, with one pooled analysis showing treatment-associated exacerbation rate reductions increasing from a 26% rate reduction in those with $<$150 eosinophils/μL to a 70% rate reduction in those with $>$500 eosinophils/μL.[26] The efficacy and safety of mepolizumab in children aged 6 to 11 years have been extrapolated from the adult and adolescent trials, as well as a clinical trial (NCT no. 02377427) that showed that a dose of 40 mg, subcutaneously, every 4 weeks showed similar drug-exposure levels in children aged 6 to 11 years as the 100-mg dose used in adults and adolescents.[22]

Safety evaluations of mepolizumab have raised no significant safety concerns,[19,23,24] although long-term evaluations are ongoing. The FDA recognizes "headache, injection site reaction, back pain, and fatigue" as the most common adverse reactions, and it warns to monitor for hypersensitivity reactions, herpes zoster (consider varicella immunizations before treatment), not to use mepolizumab for the treatment of acute bronchospasm, to use caution when reducing steroids during treatment, and to treat any existing helminthic infections before therapy and monitor for further infections.[22] Mepolizumab is approved for the add-on maintenance of children and adults 6 years and older with severe asthma and an eosinophilic phenotype, but it should be noted that the most robust data are in adults.[22] The FDA-recommended dose is 100 mg, administrated subcutaneously, every 4 weeks for patients 12 years and older, and 40 mg every 4 weeks for patients aged 6 through 11 years.[22] Self-injection may be an option for patients 12 years and older.[22]

Reslizumab

Reslizumab is another anti–IL-5 agent for use in severe asthma that binds to circulating IL-5 and

downregulates the IL-5 signaling pathway.[27] In one phase III trial in 315 participants aged 12 to 75 years (15 participants aged 12–17 years), it was found to improve lung function, asthma control scores measured by the Asthma Control Questionnaire, and quality of life scores measured by the Asthma Quality of Life Questionnaire.[27] Pooled data from 2 phase III trials of reslizumab showed a reduction in asthma exacerbations compared with placebo (rate ratios 0.5 and 0.41)[28]; however, in the small group of adolescents aged 12 to 18 years studied ($N = 25$), the exacerbation rate was higher with reslizumab than with placebo.[29] Therefore, reslizumab is not currently approved for use in children younger than 18 years, and further study would be required before considering this as a treatment option in this age group. Reslizumab is dosed as an IV infusion, 3 mg/kg every 4 weeks.[29] The FDA recognizes oropharyngeal pain as the most common adverse effect,[29] although there is an anaphylaxis risk of approximately 0.3%, prompting a black box warning from the FDA and the recommendation for in-office infusions and close monitoring.[15] In addition, the FDA warns that malignancies have been seen in clinical studies, that corticosteroids should not be abruptly discontinued and should not be used for acute bronchospasm, and that patients with helminthic infections should be treated and monitored for further infection during therapy.[29]

Benralizumab

Benralizumab is the third of the anti–IL-5 monoclonal antibodies and induces a nearly complete reduction in eosinophil concentration by binding to the α chain of the IL-5 receptor on eosinophils and possibly inducing destruction by natural killer cells.[30] The first large clinical trial in which researchers evaluated benralizumab was the CALIMA study.[30] Enrolled participants were 12 to 75 years of age (total $n = 728$, with 55 participants aged 12–18 years) with severe asthma. It was found that in patients with eosinophil concentrations >300 cells/μL, benralizumab significantly reduced asthma exacerbation rate ratios relative to placebo (by 36% and 28% in the every 4-week and every 8-week dosing groups, respectively) and was well tolerated.

Similarly, in the SIROCCO study, researchers evaluated 1204 participants 12 to 75 years of age with severe asthma (53 participants aged 12–18 years) and found that in patients with eosinophil concentrations >300 cells/μL, benralizumab reduced the annual asthma exacerbation rate over 48 weeks when given every 4 or 8 weeks (by 45% and 51%, respectively) and increased prebronchodilator FEV_1 (106 mL and 159 mL, respectively).[31] The most common adverse events were worsening of asthma and nasopharyngitis and were similar between treatment groups.

Benralizumab is approved in the United States for the add-on maintenance treatment of participants with severe asthma aged 12 years and older with an eosinophilic phenotype, although long-term and pediatric-specific safety data are still needed. The FDA recognizes headache and pharyngitis as the most common adverse reactions,[32] although hypersensitivity reactions such as anaphylaxis, angioedema, and urticaria occurred in about 3% of patients.[15] The FDA warns that it should not be used for an acute exacerbation, and that providers should not abruptly stop corticosteroids and should treat preexisting helminthic infections and monitor for such infections during therapy.[32] Benralizumab is dosed as a subcutaneous injection, 30 mg every 4 weeks for the first 3 doses, followed by once every 8 weeks thereafter, but it should be noted that the most robust data are in adults.[32]

Anti–Interleukin 4 Therapies

Dupilumab

Dupilumab is an interleukin 4 (IL-4) receptor α antagonist that was recently approved in treatment of people 12 years and older who have moderate to severe asthma as add-on therapy to maintenance therapy, specifically in patients who have eosinophilic phenotype or who are OCS dependent.[33] In one key study, 210 patients with severe oral glucocorticoid-dependent asthma older than 12 years were randomly assigned to receive dupilumab or placebo.[34] Adolescent data were not reported separately; however, the average age of all participants was 51.3 years. The dupilumab group experienced a 70.1% reduction in glucocorticoid dose (compared with a 41.9% reduction in the placebo group). Despite these reductions in oral steroids, the dupilumab group had a significantly lower severe exacerbation rate (59% lower than placebo). In another recently published study, researchers enrolled 1902 people 12 years or older with uncontrolled asthma and showed an annualized exacerbation rate that was 47.7% lower with dupilumab than with placebo, and this was accompanied by a 320-mL increase in FEV_1.[35] Of note, adolescent data were not reported separately; however, the average age of study participants was 47.9 years. In participants with eosinophil concentrations >300 cells/μL, the annualized exacerbation rate was reduced even further: 65.8% lower than placebo. Injection site reactions and hypereosinophilia were more common in the dupilumab study

groups,[34,35] although long-term and pediatric-specific safety data are still needed. The FDA recognizes injection site reactions, oropharyngeal pain, and eosinophilia as the most common adverse reactions in asthma treatment,[33] although hypersensitivity reactions have been described in 0.1% to 1%, usually generalized urticaria.[15] In addition, the FDA warnings for dupilumab include not to abruptly stop corticosteroids and to treat preexisting helminthic infections and monitor for infections during treatment, to monitor for eosinophilic conditions (especially vasculitic rash, worsening pulmonary symptoms, and neuropathy), and not to use it for acute bronchospasm.[33] For asthma, the dose is 400 mg, subcutaneously, as a loading dose and then 200 mg, every 2 weeks. For OCS-dependent patients or patients with coexisting atopic dermatitis, 600 mg is the loading dose and then 300 mg every 2 weeks, and dupilumab may be self-injected.[33]

SUMMARY: BIOLOGICS IN PEDIATRIC ASTHMA

There are multiple biologics available to treat moderate to severe persistent asthma in children and adults (Table 1). Omalizumab is approved for patients 6 years and older with sensitization to at least 1 perennial allergen and serum IgE concentration between 30 and 1300 IU for patients aged 6 to 12 years and between 30 and 700 IU for those 12 years and older. Health care providers now have 18 years of experience with omalizumab. With regard to anti–IL-5 drugs, there are data for mepolizumab and benralizumab in people aged 12 to 17 years, and both drugs work indirectly on eosinophils through blocking the receptor-ligand union. These drugs are particularly helpful in participants with an eosinophilic phenotype (peripheral blood absolute eosinophil count >150 cells/μL) and are particularly helpful when the absolute eosinophil count is >300 cells/μL. These drugs are under study for the treatment of eosinophilic esophagitis, nasal polyps, and sinus disease. Dupilumab may be effective by decreasing exacerbations and improving pulmonary function tests. Dupilumab has also been approved for the treatment of chronic rhinosinusitis with nasal polyposis in adults.[33] The final answer for which biological is indicated for each individual participant type will evolve as researchers develop more information in the pediatric age range. In addition, identification of useful biomarkers and surrogate end points for use in children to predict treatment response is needed.

URTICARIA

Chronic spontaneous urticaria (chronic idiopathic urticaria) and chronic inducible urticaria (physical urticaria, such as dermatographism, or cold and/or heat-induced urticaria) are diagnosed when itchy urticarial wheals are present for more than 6 weeks.[36,37] Although more common in adults than children, chronic urticaria can be important in this age group, with a prevalence estimated at between 0.1% and 0.3% of children.[38] Chronic inducible urticaria has a specific trigger that can be identified, as opposed to chronic spontaneous urticaria, in which symptoms occur at irregular intervals. There can be multiple triggers of both syndromes. These diagnoses may lead to recalcitrant symptoms that significantly affect quality of life. Standard treatment includes second-generation, nonsedating antihistamines at up to 2 times the standard dose. Omalizumab has been shown to be effective in this disease, with response rates in all comers ranging from 52% to 90%.[39] One systematic review of 43 studies found a strong body of evidence for the efficacy of omalizumab in adults and children with treatment-refractory, chronic inducible urticaria, although they did note that there were nonresponders.[37] The adverse effect profile was similar to that observed in asthma studies. More data are needed in the treatment of children, but omalizumab appears to be a promising treatment strategy for chronic spontaneous urticaria. Omalizumab is FDA approved for chronic idiopathic urticaria in people 12 years or older who are symptomatic despite H1 antihistamine treatment.[5] When used for urticaria, omalizumab is dosed at 150 to 300 mg, subcutaneously, every 4 weeks; dosing is not based on serum IgE concentration or body weight.[25] The FDA recognizes "nausea, nasopharyngitis, sinusitis, upper respiratory tract infection, viral upper respiratory tract infection, arthralgia, headache, and cough" as the most common adverse events in the treatment of urticaria with omalizumab.[5] The other biologics previously discussed for treatment of asthma may show some promise for the treatment of chronic urticaria; however, they are still in the early stages of evaluation for efficacy[39] and have not yet been approved for use for this indication in children.

ATOPIC DERMATITIS

Atopic dermatitis is a common comorbidity in children that affects approximately 10% of the US population,[40] with onset usually before 5 years of age and with significant deleterious effects on quality of life.[41] The anti–IL-4 receptor antagonist, dupilumab, has shown promise in the treatment of atopic dermatitis in children 6 years or older. Landmark adult studies have included the SOLO1 (671 patients, 25–51 years of age) and SOLO2 (708 patients, 25–46 years of age) trials, conducted in adults 18

TABLE 1 Summary of the Biologics Currently Approved for the Treatment of Moderate to Severe Persistent Asthma With Type 2 High Phenotype

Therapy	Mechanism of Action	Indication	Dosing and Route	Adverse Effects
Omalizumab	Anti–IgE; prevents IgE from binding to its receptor on mast cells and basophils	People aged ≥6 years with moderate to severe persistent asthma, positive allergy testing, incomplete control with an ICS, and IgE 30-1300 IU/mL (United States, age 6–11 y), 30–700 IU/mL (United States, age ≥12 years), or 30–1500 IU/mL (European Union)	0.016 mg/kg per IU of IgE (in a 4-wk period) administered every 2–4 weeks subcutaneously (150–375 mg in United States; 150–600 mg in European Union)[a]	Black box warning: ∼0.1%–0.2% risk of anaphylaxis in clinical trials
Mepolizumab	Anti–IL-5; binds to IL-5 ligand; and prevents IL-5 from binding to its receptor	People aged ≥12 years with severe eosinophilic asthma unresponsive to other GINA steps 4–5 therapies. Suggested AEC ≥150–300 cells/μl	100 mg subcutaneously every 4 weeks	Rarely causes hypersensitivity reactions; can cause activation of zoster
Reslizumab	Anti–IL-5; binds to IL-5 ligand; and prevents IL-5 from binding to its receptor	People aged ≥18 years with severe eosinophilic asthma unresponsive to other GINA steps 4–5 therapies. Suggested AEC ≥400 cells/μl	Weight-based dosing of 3 mg /kg IV every 4 weeks	Black box warning: ∼0.3% risk of anaphylaxis in clinical trials
Benralizumab	Anti–IL-5; binds to IL-5 receptor α; and causes apoptosis of eosinophils and basophils	People aged ≥12 years with severe eosinophilic asthma unresponsive to other GINA steps 4–5 therapies. Suggested AEC ≥300 cells/μl	30 mg subcutaneously every 4 weeks for 3 doses; followed by every 8 weeks subsequently	Rarely causes hypersensitivity reactions
Dupilumab	Anti–IL-4R; binds to IL-4 receptor α; and blocks signaling of IL-4 and IL-13	People aged ≥12 years with severe eosinophilic asthma unresponsive to other GINA steps 4–5 therapies. Suggested AEC ≥150 cells/μl and/or FeNO level ≥25 ppb	200 or 300 mg subcutaneously every 2 weeks	Rarely causes hypersensitivity reactions; higher incidence of injection site reactions (up to 18%) and hypereosinophilia (4% to 14%)

[a]Upper limits exist for the dosing of omalizumab in patients with high IgE levels and increased weight.

years or older, which showed that over the 16-week study period, dupilumab improved scores on the Investigator's Global Assessment and Eczema Area and Severity Index and improved markers including pruritis and quality of life measures.[42] A phase IIa study with phase III open-label extension in adolescents revealed efficacy with regards to Eczema Area and Severity Index improvement over the study period.[43] Adverse effects in this study included nasopharyngitis and worsening of atopic dermatitis.[43] Overall, the safety and efficacy is similar in adolescent and adult patients,[33] although long-term safety data collection is ongoing. The FDA recognizes "injection site reactions, conjunctivitis, blepharitis, oral herpes, keratitis, eye pruritus, other herpes simplex virus infection, and dry eye" as the most common adverse reactions, and it cautions that patients should alert providers of worsening eye symptoms concerning for conjunctivitis and keratitis.[33] Dupilumab for atopic dermatitis is dosed by body weight in adolescents, with patients weighing <60 kg receiving a 400-mg initial dose and 200-mg doses every other week, and patients weighing ≥60 kg receiving a 600-mg initial dose and 300-mg doses every other week; self-injection may be considered for some patients.[33] Other emerging biological therapies in atopic dermatitis include interleukin 12 and interleukin 23 inhibitors ustekinumab, interleukin 13 inhibitors lebrikizumab and tralokinumab, interleukin 22 inhibitor fezakinumab, and oral Janus kinas inhibitor baricicitinib, as well as

TABLE 2 Key Recommendations

Key Recommendations for General Pediatricians	Key Recommendations for Pediatric Subspecialists
Evaluate adherence to medications in patients with poorly controlled atopic diseases, such as asthma, urticaria, and atopic dermatitis.	Evaluate adherence to medications in patients with poorly controlled atopic diseases, such as asthma, urticaria, and atopic dermatitis.
Refer to a pediatric subspecialist (allergist, dermatologist, or pulmonologist) for determination of whether a patient is an appropriate candidate for biological therapy, as well as for determination of which therapy best fits the patient's phenotype.	Partner with general pediatricians to identify appropriate patients for biological therapy.
Be familiar with adverse effects of biological therapy, particularly the risk of anaphylaxis with omalizumab, benralizumab, dupilumab, and reslizumab (if ever approved in the pediatric population).	Monitor for adverse effects that are particular to the particular therapy.
The home administration is approved for dupilumab, mepolizumab, and omalizumab. Further opportunities for home administration are likely in the future.	Monitor for clinical improvement in symptoms with therapy.
	Continue to work to identify new biomarkers and means to identify candidates for therapy, as well as monitor response to therapy

phosphodiesterase type 4 inhibitors, interleukin 17 inhibitors, thymic stromal lymphopoietin inhibitors, and neurokinin-1 inhibitors.[41]

CONCLUSIONS

Asthma and atopic skin conditions can be difficult to treat and lead to significant morbidity and child and family stress. Pediatricians are faced with a widening array of targeted therapies; however, the question of what therapy to choose for which patient remains an area of continued study. In many studies in biological therapies for asthma and other allergic diseases, researchers have focused on the adult population; however, drugs are becoming more and more readily available for pediatrics. In ongoing studies, researchers should focus on appropriate biomarkers (including IgE and circulating eosinophils, as well as further biomarkers yet to be determined), as well as other patient-focused factors to allow the choice of the right biological for the right patient and at the right time. In addition, further study is needed regarding the use of novel methods of administration and monitoring in resource-limited settings, such as rural areas where access to specialty care may be limited, because these medications are currently prescribed in subspecialty offices. Home administration may be possible for some biological medications (dupilumab and mepolizumab); however, assessment of the appropriate patients for such therapy, as well as monitoring adherence in these patients, will be of key importance. One of the key questions that pediatricians and pediatric subspecialists are faced with remains when to start biological therapy for continued poor asthma control versus continued focus on appropriate medication adherence. In this situation, referral to a pediatric asthma specialist may be warranted to determine when to start biological therapy and which therapy to initiate. In addition, all pediatricians should be aware of the real possibility of anaphylaxis to certain biological medications, especially omalizumab and reslizumab, although others may also have hypersensitivity reactions,[15] and be prepared to respond appropriately and immediately. Continued research is required to evaluate long-term tolerability and safety of these medications in pediatric populations, although no evidence exists for aberrations in immune function. Pediatric subspecialists, including allergists, dermatologists, and pulmonologists, are necessary and key partners in the determination of not only the appropriate children for this type of therapy but also the most appropriate therapy for each individual child. With collaboration, true personalization of medical care for these complex patients can be achieved (Table 2).

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Care of Adolescent Parents and Their Children

Makia E. Powers, MD, MPH, FAAP,[a] Jennifer Takagishi, MD, FAAP,[b] COMMITTEE ON ADOLESCENCE, COUNCIL ON EARLY CHILDHOOD

Teen pregnancy and parenting remain important public health issues in the United States and around the world. A significant proportion of teen parents reside with their families of origin, which may positively or negatively affect the family structure. Teen parents, defined as those 15 to 19 years of age, are at high risk for repeat births. Pediatricians can play an important role in the care of adolescent parents and their children. This clinical report updates a previous report on the care of adolescent parents and their children and addresses clinical management specific to this population, including updates on breastfeeding, prenatal management, and adjustments to parenthood. Challenges unique to teen parents and their children are reviewed, along with suggestions for the pediatrician on models for intervention and care.

INTRODUCTION

Adolescent parents and their children represent populations at increased risk for medical, psychological, developmental, and social problems. Pediatricians can play an integral role as the primary care provider for both adolescent parents and their children. This clinical report updates an American Academy of Pediatrics (AAP) clinical report published in 2012.[1] Although the most recent birth rate data from 2017 indicate historically low birth rates for 15- to 19-year-old adolescents and young women in the United States, the rate remains higher than in many other resource-abundant countries.[2–5]

BACKGROUND INFORMATION

Epidemiology

Birth rates among adolescents and young women 15 to 19 years of age have declined overall and for each race and ethnicity group in 2017, the year of the most recent available data.[3,4] Overall teen birth rates were 18.8 per 1000 live births and have declined 51% since 2007 and 67% since 1991, with the greatest decline among 15- to 17-year-olds.[5] American Indian or Alaskan native teenagers had the highest birth rates (32.9 per

1000), followed by Hispanic (28.9 per 1000), Black (27.5 per 1000), and white teenagers (13.2 per 1000).[4] Repeat birth rates in teen mothers have also declined from 20% in 2004 to 17% in 2016.[6] This decline is likely attributable to the increase in sexual education and/or increased contraception use among this population over the past 20 years.[7] Despite the perceptions that teen mothers have high preterm birth rates (10.3%), the highest rates of preterm births occur in women 40 years and older (14.6%). However, among teen births, mothers younger than 17 years are at increased risk of preterm delivery, of delivering low birth weight infants, and of neonatal mortality, compared with older teen mothers.[8,9]

The Pediatrician's Role

Pediatricians can shape the health of adolescent parents and their children because they are optimally trained to provide comprehensive care for infants, children, and adolescents and they understand the importance of creating a medical home for all patients, including the adolescent parent. The adolescent parent may first present to the pediatrician or adolescent specialist to seek a pregnancy test and options counseling. The AAP policy statement on options counseling provides more detailed recommendations for best practices when discussing positive pregnancy test results with newly pregnant teenagers.[10] Once the adolescent decides to continue with a pregnancy, the pediatrician can advise the pregnant adolescent to start prenatal care from an obstetrician, family physician, or other qualified health care provider.[11] It is also optimal for the pregnant adolescent to resume routine pediatric or adolescent care and initiate the care of her future child with the pediatrician with whom she has built a long-lasting relationship.

The pediatrician can play an important role in assessing the social supports of adolescent parents and linking them to proper resources, including transportation, medical insurance, housing, and accessible food.[12] It is also important for the pediatrician to understand the legal rights adolescent parents have regarding decisions for their children. Some states do not allow adolescent parents to make decisions for their children. Pediatricians can research online through the Guttmacher Institute to determine what their state's laws mandate (https://www.guttmacher.org/state-policy/explore/minors-rights-parents). Pediatricians may provide information concerning community-based options for social supports to adolescent parents, including school-based programs, community programs, and home visitation programs. There is an association between prenatal and early childhood home visitation programs and reductions in the number of subsequent pregnancies, use of governmental assistance, child abuse and neglect, and criminal behavior in adolescent mothers.[13,14] Beginning prenatally, home visitation programs can reduce risk of serious antisocial behavior and substance use by children born to adolescents during the first 15 years of life.[13,14] The Nurse-Family Partnership is an evidence-based program that pairs young first-time mothers with trained nurses beginning in early pregnancy and continuing through the child's second birthday. It is available in many communities (nursefamilypartnership.org) and is one of many community programs that can aid young mothers. Programs such as Head Start and Early Head Start are designed to address the needs of both low-income parents and children.[15] Some health insurance companies offer coordination services during prenatal care, and the provider can encourage pregnant teenagers to access these support services. Lastly, pediatricians are encouraged to begin early discussions regarding the teen parent's plan to continue and complete her education after giving birth as well as birth control options to prevent rapid repeat pregnancies.

Perceptions of Adolescent Parents

Pervasive negative stereotypes of both adolescent mothers and fathers persist, with society often viewing adolescent mothers as irresponsible, sexually promiscuous, and ambivalent about their future educational and career goals and adolescent fathers as absent from their children's lives and ambivalent toward their children.[16] Although much of the literature is focused on the negative aspects, teen fathers' involvement in the lives of teen mothers and their children can have beneficial effects, such as improved self-esteem of the mothers, decreased maternal postpartum depression, and decreased infant distress in the newborn period, in addition to positive effects on fathers.[17,18] In cases in which the pregnancy may be a result of coercion or rape, the pediatrician can identify supportive parents or partners during the prenatal and postpartum periods. In other cases, the teenager may have chosen to become a parent because they live in cultures in which it is normative behavior to have children between 16 and 18 years old. Despite the negative perceptions that may persist regarding adolescent parents, it is important to highlight positive aspects and solutions.

Adolescent parenthood can present itself in different ways, such as an adolescent mother with her female partner, an adolescent mother with the father of the infant, an adolescent mother with a male partner who is not the biological father, an adolescent mother with maternal or paternal grandparents, or the adolescent alone. It is important to acknowledge that not all people who will become pregnant identify as

female (such as transgender men) and not all people who contribute sperm that lead to pregnancy identify as men (such as transgender women). In addition, not all adolescent parents are heterosexual, and pregnancies can occur as the result of sexual contact that is consensual, coerced, related to sex work, or in the context of sexual assault. To date, however, the majority of the literature has been focused on adolescent parents who are cisgender and in heterosexual relationships. Although it is critical to continue to explore the varying landscape of adolescent parenthood, for simplicity throughout this report, the term "adolescent mother" is used to describe a young person who experienced a pregnancy and chose to parent a child, and the term "adolescent father" is used to describe a young person who has contributed to a pregnancy as a result of heterosexual sexual contact. Additionally, "partner" will be used to refer to a male or female partner of the adolescent mother. Because this clinical report aims to provide pediatricians with concrete management guidance for the care of the adolescent parent, it is important to dispute these negative stereotypes, concentrate on the positive influences that can aid in decreasing repeat teen pregnancy, and promote healthy behaviors, social supports, and longitudinal educational and career goals to improve adolescent parents' lives.

MEDICAL MANAGEMENT OF THE ADOLESCENT PARENT AND CHILD

Prenatal Management

Once the pediatrician diagnoses a pregnancy, it is important to provide a timely referral to prenatal care, ideally occurring within the first trimester. There are obstetric providers who have expertise in adolescent pregnancy and in using a medical home model. Timely entry into prenatal care can help reduce medical complications of teen pregnancy. As the mother approaches the end of the third trimester, the obstetric provider can stress the importance of the postpartum visit and give anticipatory guidance on health insurance options for the mother and infant. The teenager can then be referred back to her primary medical home after the pregnancy (whether this is back to her pediatrician or an adult or family provider). Some health care payers may provide patient navigators to assist the mother in care coordination.

Medical complications associated with adolescent pregnancy include poor maternal weight gain, anemia, and pregnancy-induced hypertension, and these complications are greatest for the youngest adolescents.[19] Poverty, lower educational level, and inadequate family support can contribute to a lack of adequate prenatal care, which may account for most negative health outcomes for both the adolescent mother and her child, including anemia, preeclampsia, poor nutrition, preterm birth, and low birth weight.[20]

The Prenatal Visit: Meet the Pediatrician

It is optimal for the pregnant teenager, the partner, and a trusted family member to schedule a prenatal visit with the pediatrician during the last trimester. The AAP *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents,* Fourth Edition, outlines the goals of this visit to include assessing family resources, community resources, and parental well-being and discussing breastfeeding decisions.[12] The AAP prenatal visit policy statement advocates that pediatricians meet with mothers during their third trimester to establish and/or reestablish care.[21] The adolescent mother may not have seen her pediatrician while she was receiving prenatal care; thus, it is important for her to reconnect with her pediatrician and establish care for herself and her infant. This policy statement discusses the importance of this visit, especially for first-time parents, single parents, and/or women with high-risk pregnancies.[21] Intent to breastfeed may drive breastfeeding initiation[22] and allow for time to attend classes and seek support. The prenatal visit is also an opportunity to meet extended family members who may be assisting in the care of the child. The pediatrician can determine the need for resources, such as child care, transportation, financial support, housing, and food. Additional support systems, including the involvement of the partner and other family members who may be assisting (ie, maternal or paternal grandparents), are important in the care of both the adolescent parents and the child.[12,21] Although this visit is ideal, we acknowledge that there may be potential barriers to scheduling these visits (ie, time constraints, insurance payment for the visit, etc). When possible, this visit can help transition the mother back to the pediatrician.

The Newborn Visit and Well-Baby Visits

The newborn and subsequent well-baby visits are opportunities for the pediatrician to evaluate the needs of the adolescent mother and other close caregivers.[21] *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents,* Fourth Edition, recommends pediatricians address family readiness, home life of the newborn infant, and routine infant care.[12] In addition to obtaining a full prenatal history and neonatal course, the pediatrician may obtain a full social history, including maternal wellness, adjustment to new parenthood, and family resources.[12] During these visits, the grandparents may be present to provide support. It is important for the pediatrician to

reinforce that the teen parent is primarily responsible for the care of the infant. The adolescent mother can give explicit permission for the pediatrician to speak with the grandparents about the infant's health care. The pediatrician may use the "meet the pediatrician visit," newborn visit, and the subsequent well-baby visits to discuss contraceptive plans and safe sleep practices, perform psychological and/or depression screening, and ask about educational plans of the mother. Dual appointments for the adolescent parent and child may assist in time constraints to address all these issues.

"Teen-tot" clinics, in which the teenage parent or parents and their children are seen by the same provider at the same appointment, have successfully cared for these families in a patient-centered approach.[23,24] Brief parenting and/or life skills interventions coupled with these medical appointments improved maternal self-esteem and decreased repeat pregnancy during a 36-month trial study.[25]

Contraception Management

Approximately 17% of births to adolescents are repeat births.[5,26] There is a significant relationship between repeat adolescent births and decreased educational achievement, increased dependence on governmental support by the adolescent mother, increased infant mortality, and low birth weight.[27] In contrast to adult women experiencing a second pregnancy, adolescents with a repeat pregnancy tend to delay prenatal care.[28] A second adolescent birth may have negative effects on the teen mother and her offspring by compounding negative socioeconomic effects and the influence of a short interpregnancy interval. The American College of Obstetricians and Gynecologists recently published recommendations for interpregnancy care, including the following: interpregnancy intervals shorter than 6 months should be avoided; family-planning counseling should be encouraged during prenatal care visits, with conversations about interest in future childbearing; women at high risk (including adolescents) should be screened for sexually transmitted infections; and the mother should be counseled on safe sex practices.[29]

Research has revealed that provision of intrauterine devices (IUDs) and implants immediately postpartum is acceptable to teenagers and reduces rapid repeat pregnancies.[30] Long-acting reversible contraceptives (LARCs) can be placed immediately after delivery of the placenta (IUD) or before hospital discharge (implants).[30] Adolescent mothers who receive IUDs are more likely to continue this form of contraception, with low risk of expulsion.[30,31] In addition, there is a reduction in repeat pregnancy rates among adolescent mothers who receive immediate postpartum (labor or delivery unit) contraceptive implants compared with those who do not.[32] Any LARC implementation before 8 weeks' postpartum is associated with decreased repeat pregnancy rates within 2 years,[33] which demonstrates the importance of LARCs in the postpartum period in reducing short-interval repeat pregnancies. The AAP policy statements on contraception for adolescents and LARCs[34,35] recommend that pediatricians have a working knowledge of the various types of contraception and be able to counsel adolescent patients on all available methods, including implants and IUDs, which are the most effective reversible methods. After the obstetric postpartum visit, the adolescent mother can choose to return to the pediatrician for primary care. If she is not on a form of birth control at that time, the pediatrician can provide contraceptive counseling to determine the mother's preferred form of contraception. She can then be referred to an obstetrician or gynecologist or adolescent health care provider if the pediatrician is not comfortable with managing her contraception needs. Pediatricians, in conjunction with obstetric and gynecologic providers, can help improve LARC use by counseling adolescent mothers on the benefit of these contraceptive methods.

Breastfeeding by Adolescent Mothers

The AAP and Centers for Disease Control and Prevention recommend that mothers exclusively breastfeed their infants for the first 6 months of life, followed by continued breastfeeding, after introducing complementary foods, until the infant is 1 year old and beyond, as desired.[36,37] Adolescent mothers who lack social support and who are at a lower socioeconomic status are less likely to breastfeed compared with older mothers.[38] Adolescent mothers who are at a higher socioeconomic status and attend prenatal classes have higher rates of exclusive breastfeeding at the time of hospital discharge.[22] Preparation before birth and early breastfeeding support are crucial to successful breastfeeding among adolescent parents.[22] Studies have shown early maternal behaviors, such as skin-to-skin contact, are associated with positive breastfeeding decisions and initiation before hospital discharge.[39] Breastfeeding education extends the duration of breastfeeding for adolescent mothers.[40,41] Breastfeeding interventions, including school-based programs, home visits, and telephone support, demonstrate that combining education and lactation counseling yields improved breastfeeding initiation, duration, or exclusivity outcomes.[42,43] Professional and peer support programs have shown promise in increasing both initiation and duration of breastfeeding but can be resource intensive.[44] Regular use of a breast pump has also been shown to help continue exclusive

breastfeeding.[45] Policies for pumping, including appropriate space and break times at school and work, should be encouraged.

Breastfeeding cessation has been related to the lack of parental knowledge of breastfeeding and pain associated with breastfeeding, often a result of improper positioning and attachment to the breast.[45] The role of the adolescent mother's partner is important because partner involvement in the adolescent mother's life is associated with an increase in breastfeeding.[46] The pediatrician can inquire about challenges related to breastfeeding and provide supportive counseling to promote breastfeeding success.

Pediatricians can encourage adolescent mothers to breastfeed their infants to improve bonding as well as the cognitive development of their children.

Adjustment to Motherhood

The transition to motherhood for adolescents can be difficult, and common themes and barriers arise in adolescent mothers of all ethnicities.[47–51] One common theme is coparenting, in which the maternal grandmother or another parent figure helps in the parenting of the child. Studies have shown the most prevalent coparenting, specifically with maternal grandmothers, can have positive effects on adolescent parenting efficacy, social competence, and academic achievement of children.[51] These results may be strongly influenced when the family of origin places high priority on positive family values.[47]

In addition to the adolescent mothers learning successful parenting techniques, such as strong communication and minimal coparenting conflict, it is important for providers to identify the adolescents' readiness for parenthood. Some adolescent mothers do not anticipate the new responsibilities, and this is reflected in their emotional readiness to parent.[50] There are screening tools to identify mothers at high risk for nonoptimal parenting and depressive symptoms, such as the Parenting Responsibility and Emotional Preparedness (PREP) screening tool.[50]

Adolescent mothers may also experience low self-esteem during pregnancy and may benefit from social supports to improve parenting efficacy.[52] The bodily changes of pregnancy may lead to poorer body image, which can lead to poor maternal attitudes and affect the ability to adjust to motherhood during pregnancy and after delivery.[48] Adolescent mothers can have difficulty accepting their pregnancy, leading them to avoid thinking about their motherhood role during pregnancy and to only intermittently incorporate thoughts of maternal identity during pregnancy.[50] Despite risk factors, teen mothers can demonstrate resilience and ability to manage their households without the risk of child maltreatment or other adverse effects on their children.[53] These findings underscore the importance of supportive families and pediatricians in helping adolescent mothers in their transition to parenthood and self-discovery of their identity as a parent.

Fatherhood

When discussing teen pregnancy, pediatricians may inadvertently overlook the role of the partner of the adolescent mother. Of all pregnancies to adolescent mothers, it is estimated that 18% to 35% of the pregnancies involve fathers younger than 20 years at the time of birth.[54] A long-standing gender bias related to male adolescents' perspectives on and attitudes toward pregnancy and pregnancy outcomes exists, as most of the research has been focused on female adolescents' perspectives of male adolescents' views. Little research specifically explores the male adolescent's views directly.[55]

Although much of the attention to adolescent parenting is focused on the mother, the adolescent father's or partner's involvement and commitment in the life of his child is important to the psychosocial development of the child.[56] The literature defines paternal involvement in terms of a father's engagement, accessibility to the child, and responsibility to the child, in other words, the amount of support from the father to his partner and child.[57]

A number of factors play a role in the father-child dynamic, including the nature of the romantic relationship with the adolescent mother during the pregnancy and after birth, paternal ability to provide and support the family, the father's level of education and socioeconomic status, the father's relationship with his family of origin, and the father's ethnic background, cultural values, and beliefs.[58] Evidence supports that fathers who remain in a romantic relationship with adolescent mothers are more involved with their children.[58] The fatherhood relationship between the male adolescent and his child or children is related to the type of relationship he had with his own father. Adolescent fathers who had high conflict with their own fathers are more likely to have signs and symptoms of depression and less engagement with their children.[59] It is important to encourage positive relationships between adolescent fathers and their children. Social workers, parenting classes, and formal parenting education can be great resources for the adolescent father.[60] Future research is needed on teen fatherhood because most of the literature on adolescent pregnancy and parenting includes only mothers. Furthermore, adolescent pregnancy prevention programs often target young girls.[61–63] The positive

contributions of adolescent fathers have not been well studied. It is important to understand the social and demographic context of adolescent fathers to provide comprehensive support for both parents.

Adolescent fathers are more likely to live in poverty, which often repeats from one generation to the next. Sons of adolescent fathers are more likely to become adolescent fathers compared with sons of older fathers.[64] In addition, substance use, early adolescent dating, school delinquency, and high physical-risk environment are significant predictors of becoming an adolescent father.[64] Research has shown that risky sexual behaviors, low educational attainment, and lack of birth control self-efficacy are associated with future fatherhood in male adolescents.[57] Young adult men who father children with adolescent mothers are also more likely to be impoverished and have lack of contraceptive knowledge.[65] It is important for adolescent fathers to be aware of contraception methods and engage in conversations with their partners to help decrease repeat pregnancies and the potential for further economic stress. Pediatricians can encourage adolescent fathers to play a central role in their children's lives. If adolescent fathers feel like their parenting role is peripheral or insignificant, they will likely not seek future advice or education around fatherhood topics.[66] Therefore, it is important for pediatricians to promote equal parenting with adolescent parents and provide community resources to assist in their developing role as parents.

Children of adolescent mothers who continue to have close ties with the child's biological father have better outcomes in employment and education, are less depressed, and are at lower risk of becoming adolescent parents themselves.[67] Fathers' engagement positively affects the psychosocial, cognitive, and behavioral outcomes of children, with evidence that cohabitation of the mother and father is associated with less externalizing behavioral problems in their children.[67] Adolescent or adult fathers who maintain active participation in the prenatal, neonatal, and immediate postpartum processes with adolescent mothers have a greater likelihood of ongoing involvement with their children.[68] Such interactions include playing with their children, giving them gifts, or feeding them but are less likely to involve diapering, bathing, and caring for the child alone. Conversely, adolescent fathers who exhibit depressive symptoms within the first year of the child's life are more likely to have depressive symptoms within the next 3 to 5 years and have lower paternal involvement.[69] Depressed fathers read to their children less frequently and are 4 times more likely to spank their children.[70] Parenting interventions can help teach such skills to adolescent fathers as well as to adolescent mothers. There are several successful adolescent parenting programs that are focused on fatherhood, but it is important for all adolescent parenting programs to engage the adolescent father in his journey of becoming a successful parent.[71]

Additional education should be focused on prevention of child abuse because risk factors for abuse include young parental age, low income, and mental health issues,[72] all of which can be observed in adolescent pregnancies. Because the alleged perpetrator of child abuse is male in the majority of cases,[73,74] this education should be aimed at including fathers.

Family Support and Management

Family factors associated with improved outcomes for the adolescent mother and her child include early child care provided by the infant's family of origin, which allows the adolescent mother to focus on positive outlooks during her journey through motherhood.[75] Adolescent mothers who experience positive health outcomes are more likely to have a positive outlook, set educational goals, and have strong social supports. It is also important for the adolescent mother to develop autonomy from her mother figure to fully adjust to her own motherhood journey.[76]

Management of Mental Health

Adolescent parents encounter multiple competing challenges, including transition to parenthood, complex living situations, and varying relationship dynamics between adolescent parents and the maternal and/or paternal grandparents.[77] A number of studies suggest that being a teen mother may be related to poorer mental health outcomes, such as mood disorders.[78] The Pregnancy Risk Assessment Monitoring System (PRAMS) reported approximately 12% of postpartum women of all ages self-reported depressive symptoms in 2012–2013.[79] Younger parental age (15–24 years) at the time of the birth of the child was associated with a higher risk of maternal depression.[79] In addition, 3% of fathers experienced postpartum depression within the first year.[80] Young fathers (15–24 years of age) with no previous history of mood disorders were more likely to experience depression compared with older fathers.[80] Parental stress during pregnancy and the postpartum period increases the risk of developing postpartum depression, and adolescent mothers with higher parenting stress and parent-child dysfunction scores have higher rates of depression.[81]

It is important for pediatricians to be aware of adolescent parents who have previous diagnoses of mental health disorders and refer them back to mental health care during the

postpartum period if they have been lost to follow-up. Research underscores the importance of detecting depression in parents, particularly younger parents, because parental depression is associated with adverse outcomes for children.[78–81] The AAP recommends integrating postpartum depression surveillance and screening at the prenatal pediatric visit and at the 1-, 2-, 4-, and 6-month well-baby visits.[21] Both the American College of Obstetricians and Gynecologists and the AAP recommend using a validated tool, but the AAP prioritizes the Edinburgh Postnatal Depression Screen (EPDS) or a 2-question screen, such as the Patient Health Questionnaire 2 (PHQ-2) or EPDS-2. Recent studies have shown the EPDS and its subscales (EPDS-7 and EPDS-2), are accurate screening tools for adolescent mothers.[21,82] Once an adolescent parent demonstrates symptoms of depression, the pediatrician can refer to or provide treatment. Prevention and treatment of postpartum depression are important in the management of adolescent parents; however, there are few studies that have shown consistent improvement in depressive symptoms.[83] Some studies have shown improvements in depressive symptoms with increased therapy use and use of a variety of care management models.[83] Further research in the area of prevention and treatment of perinatal depression in adolescent mothers is paramount for health care providers to better serve the mental health of this population.[84]

Pediatricians can also screen adolescent fathers or partners for depressive symptoms. The 2018 AAP clinical report "Incorporating Recognition and Management of Perinatal and Postpartum Depression Into Pediatric Practice" recommends screening the adolescent father or male partner at the 6-month well-baby visit with the EPDS or having the male partner fill out the screen at home and mail it back.[85] Pediatricians may find other useful mental health screening tools for primary care settings in the AAP's mental health screening and assessment tools for primary care grid (available at https://downloads.aap.org/AAP/PDF/Mental_Health_Tools_for_Pediatrics.pdf).

In addition to depression, stress exposures for both the adolescent mother and her partner may affect behavioral and health risks, such as substance use, and have implications for both the pregnant adolescent and her fetus. As with all adolescents, screening for substance use, brief intervention, and referral to treatment (SBIRT) will be even more critical for pregnant adolescents.[86,87] During the health visits, pediatricians can ascertain information about the history of substance use (including electronic cigarettes and similar devices) in the adolescent parent and any increased risk of child abuse.[10,12,88] The AAP has additional guidance regarding alcohol, tobacco, and marijuana use during pregnancy.[89–91] Pregnancy provides opportunities to assist both the mother and partner in reducing stress exposures and to support the pair to change or establish healthier behaviors.[92]

Intimate Partner Violence

The prevalence of intimate partner violence (IPV) specifically among teen mothers is 7%, compared with 2% in mothers older than 30 years.[93] Formal screening for IPV of adolescent parents during pregnancy and in the postpartum period is important. Violence during pregnancy is recognized as a serious public health concern, particularly for those of younger age (12–24 years). In the United States, approximately 27% of female and 11% of male individuals have experienced IPV during their lifetimes.[94] The National Intimate Partner and Sexual Violence Survey defines 5 types of IPV, including sexual violence, stalking, physical violence, psychological aggression, and control of reproductive and sexual health. IPV, which can include verbal abuse, assault by a partner or family member, being in a fight or being hurt, or witnessing violence, may increase during pregnancy, with 3% to 19% of pregnant women identified as victims of IPV.[95] Another form of IPV can be "contraceptive sabotage," in which a partner refuses to allow the female partner to use contraception for pregnancy prevention.[96] An adolescent mother's own exposure to violence as a child complicates and sometimes normalizes her view of IPV.[92] Specifically, there is a direct relationship between IPV and the adolescent mothers' childhood violence experiences.[97] Teen mothers may be reluctant to disclose IPV to their providers and may be more likely to stay with the abusive partner or father of the child so that the father can remain in the life of the child.[97] Children who witness IPV are more likely to experience child abuse or child mistreatment, especially children born to mothers younger than 21 years.[98,99] Pediatricians can use multiple screening tools to assess for IPV. Use of universal screening methods is suggested, preferably the use of self-administered surveys versus verbally administered assessment tools.[94] Examples of self-administered IPV surveys include the Woman Abuse Screening (WAST) Tool[100] and the Hurt, Insulted, Threatened, and Screamed (HITS) Tool.[101]

Social Determinants of Health

Newer research suggests that social determinants of health strongly influence teen pregnancy. The Centers for Disease Control and Prevention defines social determinants of health as "conditions in the places where people live, learn, work, and play that affect a wide range of health and quality-of life risks and outcomes."[102]

Poverty, a key social determinant of health, greatly affects teen mothers, fathers, and their children.[103] Within the first year of a child's life, 63% of teen mothers will receive public assistance benefits, and 52% of mothers who receive welfare will have had their first child in their teen years.[104] Poverty also influences rapid repeat pregnancies. Thus, it is ideal for prevention efforts to be expanded from the individual level to the community level, including the social, political, and economic environments in which teenagers live, work, and play. These efforts involve forging partnerships between health care programs and nontraditional groups, such as male mentorship programs and transportation services.[105] A broader focus on the communities where teenagers and their children live, rather than just a focus on individuals, may also assist in decreasing other social disadvantages for teenagers.[61]

For many teen parents and their children, poverty plays a key role in the difficult circumstances in which the children are raised. Therefore, focusing on a 2-generational approach to reducing poverty may improve outcomes for low-income families.[103] This strategy is aimed at helping both low-income children and their parents simultaneously through interventions such as job training for parents while their children attend high-quality child care programs[103] or addressing risk factors that increase the likelihood of daughters of teen mothers becoming pregnant,[62] which may decrease the continuation of this cycle. Other programs may be found at https://www.childwelfare.gov/topics/preventing/promoting/parenting/pregnant-teens/.

Other social determinants of health for adolescent mothers include high rates of residential mobility, decreased levels of financial support, and limited resources for child care support during the prenatal and postnatal periods.[63] Teen pregnancy is a high-risk period for homelessness as a result of parents kicking out the pregnant teenager or partner conflict or violence.[106] Pediatricians can inquire about housing status or safe shelter and refer the pregnant teenager to social and/or community supports if needed. Teenagers may self-report the need for financial support and job training in the early postpartum period but may have a relatively low use of community resources to meet their needs.[63] Further research is needed to determine potential barriers to adolescent parents receiving community resources.

Addressing Toxic Stressors

Adverse childhood experiences may increase lifelong risks for psychological and medical diseases, such as obesity, heart disease, diabetes, and suicidality.[107] To prevent the effects of childhood adversity, models that aim to address both adolescent parents and their children (ie, a 2-generational approach) can be used.[108] This approach includes increasing resources available to adolescent parents and their children, supporting workforce development, and raising awareness of adverse childhood experiences.[109] Directing resources toward schools and early childhood programs may help mitigate risk.[109] Identifying exposure to childhood adversity, focusing on parenting practices, and encouraging return to school may reduce the effects of adversity and promote healthy development.[109] Two types of programs have been shown to improve school completion: multiservice packages with academic and vocational support, case management, and child care provision and attendance-monitoring programs with financial support.[110]

Assessment of the effects of social disadvantage, such as housing insecurity, neighborhood violence, and racial discrimination, is important. Capitalizing on teen mothers' strengths and their families' strengths may facilitate intergenerational repair of the effects of childhood adversity on both the mother and the child.[111]

Median block income, low infant birth weight, maternal smoking, maternal childhood history of neglect, IPV perpetrated by either the mother or her partner, and maternal use of mental health services are associated with infant neglect.[112] Identifying high-risk families and intervening during the earliest months of life may prevent neglect and the subsequent effects on the child.[112] This intervention includes provision of counseling on effective, nonphysical discipline to decrease potential physical and emotional harm to the child.

Cognitive Development of Children Born to Teen Parents

Maternal support can directly affect the cognitive development of children. Children born to adolescent mothers who have low levels of emotional responsiveness and show no maternal support during playtime with their infants are at higher risk of having poorer cognitive and receptive language abilities compared with children born to adult mothers.[15] Conversely, higher levels of maternal support during infantile play may lead to greater gains in both cognitive and language abilities from infancy to age 3 years.[15] Greater resources within the family setting and lower levels of family conflict may enhance developmental gains over time.

Although children of adolescent mothers may have lower school readiness, there are modifiable factors related to higher school readiness, including maternal gains in education, maternal age of at least 18 years, lower rates of postpartum depressive symptoms, and receiving nonparental child care in infancy.[113] The following policy changes may

improve school readiness: Children should attend on-site child care centers with qualified staff while their mothers attend school, and targeted pregnancy prevention services should be provided for school-aged adolescents who have not yet attained a high school diploma.[113]

Despite studies showing concern for lowered IQ and long-term intellectual development of children of teen parents,[114] there are interventions that may improve cognitive development; specifically, interventions that were shorter in duration, conducted in smaller groups, or placed strong emphasis on the quality of parent-child interactions led to greater gains in cognitive achievement among the children.[115]

Social Development of Infants

Adverse social developmental outcomes of infants born to adolescent parents are associated with high levels of maternal depression and preterm birth.[116,117] Increased social support, including social work involvement, home visiting nursing programs, and early intervention programs, positively influences the development of infants of adolescent mothers.[117] Head Start and Early Head Start programs support early learning, including social and emotional health realms, physical health, and family well-being for low-income families.[118] Comprehensive follow-up and coordinated care services for extremely preterm infants and their adolescent mothers are important.[117] Other clinical interventions, such as those focused on coparenting relationships and conflict resolution skills between adolescent mothers and their partners, may improve the social-emotional development of children of teen mothers.[119]

Teen parents may not be prepared to handle a young child's social-emotional development, and studies suggest that teaching parents how to play with their children can improve children's vocabulary skills and emotional regulation.[120] Sit Down and Play[121] and Reach Out and Read[122] are interventions that pediatricians can integrate into their practices. Sit Down and Play teaches low-income families to make toys for their children and interact with their children in a positive fashion. Promotion of this program may involve partnerships with community resources, such as Parents as Teachers, to facilitate positive parenting behaviors through take-home play activities. The AAP clinical report on the importance of play[123] also provides advice for encouraging play for children at high risk. Reach Out and Read promotes child development through strengthened parent-child relationships, advises families on the importance of early literacy and modeling reading together, and provides a new book to children 6 months through 5 years of age during well-child visits.[122] Additional early literacy resources can be found at https://www.aap.org/en-us/literacy/Pages/Early-Literacy-Resources.aspx. Another method to encourage social-emotional development is teaching the 3 T's (tune in, take turns, and talk more) during well-child visits.[124]

Role of the Medical Community

The medical community consists of pediatricians who can have positive effects on teen parents and their children, particularly during the prenatal period. Obstetric providers care for the pregnant adolescent, and other support providers include doulas, who are lay prenatal, childbirth, and postnatal paraprofessionals. Doulas can provide emotional, physical, and social support and information during pregnancy, childbirth, and the postpartum period.[125]

The pediatrician can play an important role in mitigating some effects of teen pregnancy by encouraging early entry into prenatal care. If the adolescent mother chooses to return to her pediatrician for primary care after the postpartum obstetrical visit, the pediatrician's role can include social and financial supports, educational support, and contraception management in addition to routine adolescent care. The pediatrician may provide anticipatory guidance to strengthen a family's social supports, encouragement for a parent's adoption of positive parenting techniques, and facilitation of a child's emerging social, emotional, and language skills.[126] Resilience refers to the ability to overcome adversity built through positive experiences and learned coping skills. Primary prevention includes promoting the 7 C's of resilience: competence (knowing that you can handle a situation effectively), confidence (believing in your own abilities), connectedness (developing close ties to family and community), character (developing a solid set of morals and values to determine right from wrong and demonstrating a caring attitude toward others), contribution (realizing that the world is a better place because you are in it), coping (coping effectively with stress), and control (realizing that you can control the outcomes of your decisions).[127] The pediatrician can also link the family with supports to help promote optimism as well as encourage early learning via programs and provide information on community resources to promote emotional coaching and other positive parenting strategies.[128,129]

CONCLUSIONS

Teen parents and their children face multiple barriers to optimal development, including negative stereotypes, lack of resources, depression, poverty, lack of support, and lowered educational achievement. Pediatric health care

providers can positively influence the long-term health and lifelong trajectories for teen parents, including young fathers and mothers, and their children by creating a supportive and educational environment.

GUIDANCE FOR THE PEDIATRICIAN

1. Create a patient-centered medical home for adolescent parents and their children. Teen-tot clinics, in which both the adolescent parent or parents and their child complete appointments at the same visit, model this approach.
2. Involve partners and families in the newborn period and infancy, actively supporting their involvement in their children's care.
3. Provide a multidisciplinary and comprehensive approach to caring for parenting adolescents by using community resources, such as doulas, social services, and nurse home visitation programs.
4. Promote breastfeeding initiation and continuation among adolescent mothers by providing lactation resources and encouraging partners and maternal grandmothers to be supportive around breastfeeding.
5. Provide contraceptive counseling during the pre- and postnatal periods in partnership with obstetricians and in subsequent health supervision visits. Offer access to the full range of contraceptive services, including LARCs. Provide adolescent fathers with contraceptive counseling.
6. Use a validated screening tool for assessing postpartum depression in all adolescent parents and refer to mental health resources when indicated.
7. Screen for IPV and provide community resources to address positive responses from pregnant and parenting adolescents.
8. Emphasize the importance of completing high school and pursuing higher education or vocational training. Advocate for on-site child care in schools or training programs that can facilitate this goal.
9. Recognize all forms of parenting, including coparenting, and support the role of the adolescent father or partner.
10. Advocate for longitudinal, comprehensive solutions that are focused on primary prevention strategies to continue to decrease teen pregnancy rates. Push for funding of programs that support adolescent parents to reduce repeat pregnancies and optimize the health of both parent and child (ie, health care, food assistance, housing, and home visitation programs).
11. Promote low-cost activities with high yield in improving the social and cognitive development of young children, such as play and reading.
12. Recognize that social determinants of health, such as poverty and childhood adversity, contribute to health outcomes for adolescent parents and their children. Provide referrals to community resources to address these needs.
13. Become aware of programs in your community that support pregnant adolescents and adolescent parents.
14. Screen for substance use according to the screening, brief intervention, and referral to treatment (SBIRT) framework and refer to appropriate community resources.
15. Advocate for a 2-generational approach to improving outcomes for the dyad in areas such as poverty, education, and social-emotional development.
16. Coverage of, access to, and coordination of services among medical providers needs to be a priority for payers to assist pregnant and parenting adolescents.

Caring for American Indian and Alaska Native Children and Adolescents

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Caring for American Indian and Alaska Native Children and Adolescents

Shaquita Bell, MD, FAAP,[a,*] Jason F. Deen, MD, FAAP,[a,*] Molly Fuentes, MD, MS,[b] Kelly Moore, MD, FAAP,[c] COMMITTEE ON NATIVE AMERICAN CHILD HEALTH

American Indian and Alaska Native (AI/AN) populations have substantial health inequities, and most of their disease entities begin in childhood. In addition, AI/AN children and adolescents have excessive disease rates compared with the general pediatric population. Because of this, providers of pediatric care are in a unique position not only to attenuate disease incidence during childhood but also to improve the health status of this special population as a whole. This policy statement examines the inequitable disease burden observed in AI/AN youth, with a focus on toxic stress, mental health, and issues related to suicide and substance use disorder, risk of and exposure to injury and violence in childhood, obesity and obesity-related cardiovascular risk factors and disease, foster care, and the intersection of lesbian, gay, bisexual, transgender, queer, and Two-Spirit and AI/AN youth. Opportunities for advocacy in policy making also are presented.

INTRODUCTION

We acknowledge that this policy statement was written together on Coast Salish and Pueblo lands, both diverse, strong, and enduring communities that uphold a sacred legacy of protecting future generations. As American Indian (AI) authors and physicians ourselves, we acknowledge that we intend to represent a diverse and far-reaching group of Indigenous peoples. We humbly submit that not all aspects of caring for our communities could be captured in our article. We ask that this policy statement be used to support and advocate for improved health outcomes and the well-being of children and youth from all tribal and urban AI communities. Many solutions to the problems illustrated below can be found within these very communities.[1]

American Indian and Alaska Native (AI/AN) children and adolescents are found throughout the United States, with more now living in urban rather than rural areas.[2] Many tribal nations have their own languages, and all have rich histories, but most AI/AN people now live in metropolitan areas that may include many different tribal groups. Care for this special

population presents a unique and complex clinical opportunity for pediatricians, other providers of pediatric care, and pediatric care organizations because of the high level of documented health inequities within a sociocultural context unfamiliar to most practicing providers of pediatric care. Not only do AI/AN youth face medical access barriers, but they also have a higher prevalence of chronic stress and adverse childhood experiences (ACEs) and exposure to environmental hazards resulting in poorer health outcomes[3] when compared with the general population.[4] In addition, several other significant barriers to care deserve mention. These include conventional barriers for underresourced families, such as lack of transportation, difficulty finding child care, inability to miss work, caring for elders, and other family and work obligations, as well as other socioeconomic challenges. Moreover, less well-recognized issues exist, such as long-standing mistrust of governmental agencies, discrimination in clinical settings attributable to implicit and explicit bias leading to mistrust of health care and of health care–related research, and the cumulative burden of generations of unresolved traumas and racism.[5–8] This policy statement explores the roles historical trauma and health inequities have played in shaping the current socioeconomic and health status of AI/AN youth. Disproportionate needs in mental and cardiovascular health and disease processes that are overrepresented in AI/AN youth are discussed to provide a summary of salient issues for pediatric care providers. This statement also provides strategies for culturally sensitive family-centered care to mitigate morbidity and policy recommendations to facilitate institutional and system changes needed for improved health outcomes.

Of note, Native Hawaiians and Pacific Islanders are considered a unique population of Indigenous people who live within the territories discussed but are not considered AI. They have their own distinct cultural identity as well as distinct health outcomes and needs. In addition, they are not considered tribes by the US federal government, so they are not beneficiaries of the Indian Health Service (IHS) or eligible for funding from the Bureau of Indian Affairs. Given these differences and the need for them to be addressed fully, this policy statement does not address this population.

Many of the cited publications in this document compare AI/AN youth to non-Hispanic white youth; the authors would like to note that this phenomenon can lead to white centering. Where possible, we avoided comparing racial groups in this way but were somewhat limited by the available studies.

ACES

The call to pediatricians to employ strategies to mitigate toxic stress caused by ACEs is especially critical for AI/AN children.[9] In a landmark study of more than 13 000 adults, categories of childhood abuse, neglect, and other forms of household dysfunction were linked to adult mortality and morbidity. Risk was quantified by using an ACE score, or the number of categories experienced by an individual before age 18 years.[10] A higher ACE score's association with poor health outcomes is postulated to stem from altered neurodevelopment with subsequent social, emotional, and neurocognitive impairment, which in turn leads to detrimental health behavior and poor health outcomes. For example, compared with those without ACEs, adults with an ACE score of 3 or more are twice as likely to smoke or have cardiovascular disease and 1.5 times more likely to have severe obesity or diabetes.[11,12] AI adults and children experience a disparate number of ACEs compared with the general US population. A recent study of 516 AI adults from South Dakota revealed an ACE score of 3 or more in 45.4% of participants as compared with 17.4% of region-matched controls.[13] Among AI adults from 7 geographically diverse tribes, AI adults were 5 times more likely than non-AI adults to have had 4 or more ACEs.[14] According to the National Survey of Children's Health data collected in 2011 and 2012, 1453 AI children and adolescents aged 0 to 17 years were more likely to have had multiple ACEs compared with non-Hispanic white (NHW) children.[15] In that study, >25% of AI youth had 3 or more ACEs, compared with only 11.5% of NHW children. Regarding the types of ACEs endured, AI populations suffer from a disproportionate prevalence of emotional and physical neglect, substance use disorder, and incarceration among family members, as well as witnessed intimate partner violence, when compared with the general population.[13–16] The authors of another study of AI adolescents and young adults also found that historical loss–associated symptoms and perceived discrimination are relevant factors in considering ACEs for Indigenous children and youth, suggesting the importance of considering loss of culture and structural racism as contributors to childhood adversity in this population.[16]

OBESITY

Obesity prevalence in AI/AN youth is among the highest of all races and ethnicities.[17–19] Obesity onset occurs at a younger age compared with other racial and ethnic groups in the United States; AI children between 2 and 5 years of age have a higher combined prevalence of overweight and obesity (58.8%) than children of all other races or ethnicities (30%).[17,20,21]

Moreover, AI/AN children experienced an increase in obesity prevalence between 2003 and 2008, whereas the prevalence for other US racial groups declined. Recent data have revealed an alarmingly high prevalence of obesity compared with the general US population but suggest that obesity prevalence (29.7%) in AI/AN children 2 to 19 years of age may have stabilized.[22,23] Although recent research from 2010–2014 suggests a decline in severe obesity among children 2 to 4 years of age from low-income families, severe obesity remains high for young AI/AN children and is among the highest of all racial and/or ethnic groups receiving benefits through the Special Supplemental Nutrition Program for Women, Infants, and Children.[24] It follows that a significant portion of AI children with obesity have significantly abnormal blood lipid levels, higher blood glucose levels, and higher abdominal adiposity compared with children with normal-weight.[25]

Obesity may largely be determined in infancy, with excess prenatal maternal weight gain, macrosomia, and premature cessation of breastfeeding significantly predicting BMI at 1 year of age in a previous study.[26] In the same children, overweight or obesity status at age 1 year persisted to ages 5 to 8 years and was associated with unhealthy levels of low-density lipoprotein. In AI children, once obesity is established, it likely persists into adulthood and increases the risk of chronic disease.[27,28] The prevalence of disproportionate rates of obesity emerge in early childhood[17,20,29]; thus, tailored prevention and intervention strategies are needed for young AI/AN children.

Given the high rates of obesity, AI/AN youth also experience high rates of type 2 diabetes mellitus (T2DM). Testing, as recommended by the American Diabetes Association, for prediabetes and T2DM should be considered in AI/AN children and adolescents with overweight or obesity.[30,31] Further information is available in American Academy of Pediatrics technical and clinical reports on management of T2DM for children[32] and specifically for AI/AN youth.[33]

BREASTFEEDING

The benefits of human milk nutrition for infants are well documented and include wide-ranging effects, such as the reduction of respiratory tract infections, obesity and diabetes incidence, atopic disease, and infant mortality.[34] Although the breastfeeding initiation rate for the general US population is 75%, minority populations experience significant disparities in initiating and continuing breastfeeding at 6 and 12 months.[35] AI/AN women have the second-lowest prevalence of breastfeeding initiation, duration, and exclusivity compared with all other US racial and ethnic groups. In a previous study, only 59% of AI women initiated breastfeeding, and most of those (76%) stopped breastfeeding within 4 months.[26] Encouragingly, those who continued to breastfeed for 6 months tended to continue through infancy.[36] Health benefits of breastfeeding have been demonstrated in all populations, including AI/AN populations. For example, in a retrospective cohort study, a lower BMI was reported among AI/AN adolescents breastfed for >6 months.[37] Breastfeeding promotion is needed in AI/AN tribal communities and would ideally be coordinated by tribal entities and would involve community members, elders, and health care providers, including paraprofessionals.[38,39]

CHILDREN AND YOUTH WITH SPECIAL HEALTH CARE NEEDS

AI/AN children and youth with special health care needs (CYSHCN) are at particular risk of health disparities. Although there is no evidence of a higher prevalence of special health care needs among AI/AN children compared with NHW children, AI/AN children are more likely than NHW children to meet criteria for special health care needs on the basis of functional difficulties.[40] In addition, AI/AN CYSHCN are more likely than NHW CYSHCN to have 3 or more functional difficulties,[40] which can be interpreted as AI/AN CYSHCN likely having more disability. Although there are no studies on the prevalence of developmental delay, functional difference, or disability among AI/AN children, it is possible that there is a higher prevalence in AI/AN children, compared with the general population, because of a disproportionate burden of injury,[41] inadequate prenatal care,[42,43] preterm birth,[43] environmental stressors,[42,44] and other social determinants of health and function.

CYSHCN benefit from the accessible, comprehensive, and coordinated care provided by a medical home, but AI/AN CYSHCN are significantly less likely than children without special health care needs to receive care meeting the medical home definition (odds ratio 0.2; 95% confidence interval 0.1–0.4).[7] In addition to difficulties receiving medical home–based primary care, AI/AN CYSHCN may have challenges accessing subspecialty medical care or pediatric rehabilitation therapies; those who live in rural or remote communities may have to travel many hours to access specialized care. Even among urban AI/AN CYSHCN, there may still be barriers related to transportation,[45,46] funding, and wait times.[47] The care used by AI/AN CYSHCN may not be sensitive to the family's values[7] or address the child's functional needs related to their tribal culture.[48] Efforts should be made to identify CYSHCN in a timely manner, implement culturally sensitive medical home–based care for AI/AN

TABLE 1 Risk Behaviors and Emotional Distress Reported by Ninth- and 11th-Grade Students in a Minnesota Student Survey Sample

Reported	AI/AN LGBTQ (*n* = 149 Ninth- and 11th-Graders)	Full MSS Sample (*n* = 81 885 Ninth- and 11th-Graders)	All LGBTQ (*n* = 8758 Ninth- and 11th-Graders)
Substance use			
Smoked cigarettes (past 30 d)	32.9	6.1	14.1
Drank alcohol (past 30 d)	25.2	17.2	22.3
Binge drinking (past 30 d)	16.8	8.4	10.7
Smoked marijuana (past 30 d)	33.1	10.8	17.0
Sexual behaviors			
Ever had sex	33.8	22.1	28.8
≥2 partners (past year)[a]	18.3	8.7	14.7
Emotional distress			
Depressive symptoms	51.7	22.3	48.1
Self-harm (past year)	52.1	15.4	43.7
Suicidal ideation (ever)	60.5	21.0	53.6
Suicide attempt (ever)	37.7	7.7	24.4

Minnesota Student Survey (MSS) data were provided by public school students in Minnesota via local public school districts and are managed by the Minnesota Student Survey Interagency Team (M. Eisenberg, ScD, MPH, personal communication, 2018). LGBTQ, lesbian, gay, bisexual, transgender, and queer.

[a] Among sexually active ninth- and 11th-grade students only.

CYSHCN, and facilitate access to services that will help AI/AN CYSHCN achieve their full functional potential and be included in their communities.

SUICIDE AND MENTAL HEALTH

Suicide is the second-leading cause of death for AI/AN and non-AI/AN youth 10 to 24 years of age,[49,50] but the 2016 age-adjusted suicide mortality rate among AI/AN youth (15.59 per 100 000) is more than 1.5 times higher than that of the general population (9.60 per 100 000).[51] There is significant regional and intertribal variation in AI/AN youth suicide mortality, with some tribes having youth suicide rates 7 times higher than the national AI/AN rate and 12 times higher than the general population rate.[52,53]

In previous studies, differences in risk and protective factors that may attenuate that risk (such as having a connectedness to family and having the ability to discuss problems with family and friends[54]) explained the higher prevalence of suicidal behaviors among AI/AN students compared with other students.[55,56] ACEs were also associated with suicide attempts; after controlling for multiple factors, each additional ACE increased the risk of lifetime suicide attempt by 37% for AI youth.[16] AI/AN individuals of all ages who died by suicide were less likely than NHW individuals to have received mental health diagnoses or treatments and were more likely to have a family member or friend's death precipitate suicide.[57]

Suicide prevention initiatives that are strengths based, community driven, and culturally centered have been used in several AI/AN communities to reduce youth suicide behaviors.[57,58] For AI/AN youth who do not have access to a community-specific suicide prevention program, efforts should be made to identify youth with an increased burden of suicide risk factors and to strengthen protective factors, particularly cultural protective factors.[55] If available, school-based health centers may be used for adjunctive mental health care.[59]

INTERSECTIONS OF HEALTH AND IDENTITY

Lesbian, gay, pansexual, bisexual, transgender, gender queer, intersex, and Two-Spirit AI/AN youth experience exponential increases in risk for health disparities.[60–63] "Two-Spirit" is a unifying term that encompasses both gender identity and traditional Indigenous understandings of identity and is a widely used term in Indigenous communities across North America. In the 2015 US National Transgender Health Survey, AI/AN transgender respondents reported having experienced harassment (86%), physical assault (51%), and sexual assault (21%). Fifty-seven percent of AI/AN youth identifying as transgender have attempted or contemplated suicide, compared with 4.6% of the general US population and 33.7% of transgender youth as a whole.[64,65] In this same study, 23% of transgender respondents (all ages) identifying as AI/AN experienced unemployment in the last year.[66] In another study, youth at the intersection of gender and racial identity had higher rates of risk behaviors and emotional distress (Table 1). Careful attention to gender-affirming care and risk assessments may mitigate these effects.[67]

VIOLENCE

Violence affects AI/AN youth in unique but disproportionate ways. In a study using data from the National Trauma Data Bank, 11.8% of AI/AN children hospitalized for traumatic

injury experienced injury as a result of violent assaults, compared with only 4.2% of NHW children.[68] Many communities have started to focus on the crisis of missing and murdered Indigenous women and girls. Although limited data exist on rates of missing and murdered Indigenous women and girls and underreporting is extremely likely, a recent study completed by the Urban Indian Health Institute reveals staggering rates of violence toward Indigenous women and girls.[69] Pediatricians have an opportunity to advocate for better data collection and unbiased media coverage. The Urban Indian Health Institute has created a tool kit (https://www.uihi.org/resources/mmiwg-we-demand-more-partner-toolkit/) on how further work in this area can be tailored in a culturally appropriate manner.[69]

AI/AN youth and communities are also vulnerable to sex trafficking.[70] It is estimated that 30% of AI girls between 11 and 17 years old have a history of sexual abuse, and 11% have reported being raped.[71,72] Alaska Native women and girls make up 8% of the population in Alaska but represent 33% of sex-trafficking victims.[73] In turn, AI/AN girls are 5 times more likely to be incarcerated for prostitution than NHW girls.[73] It is important to recognize that men and nonbinary-gendered youth can also experience trafficking, and often times, finding data on these groups proves to be challenging. Identifying, preventing, and addressing trafficking and reducing violence is an integral part of caring for AI/AN communities.[74]

FOSTER CARE

The National Child Abuse and Neglect Data System, the Bureau of Indian Affairs, and the IHS report high rates of child protective services referrals for AI/AN youth.[75,76] In a previous study, AI/AN youth in foster care were more likely to have special health care needs compared with others in foster care.[77] Historically, AI/AN children were systematically removed from their homes in an effort to assimilate them into mainstream culture and to terminate the existence of tribal culture. Rates of ongoing referrals reflect both historical trauma and ongoing social and environmental determinants of inequities at work. The Indian Child Welfare Act was ratified in 1978 after decades of fierce advocacy by tribes for the right to keep their children within families that identify as AI/AN. Often used as a leverage point to threaten the sovereignty of tribal nations, the Indian Child Welfare Act remains an opportune protection for AI/AN children and adolescents.[78]

OTHER HEALTH DISPARITIES

The poor oral health status of AI/AN children is a major public health concern. AI/AN children have the highest rates of tooth decay among any racial and ethnic group in the United States.[79] The prevalence of tooth decay among AI/AN children between 2 and 4 years of age is 5 times greater than the average US rate.[79,80] AI/AN children also have limited access to dental services because of ongoing difficulties with recruitment and retention of qualified dentists in the IHS.[79] More severe early childhood caries frequently requires extensive treatment under general anesthesia, creating an additional health care access barrier for AI/AN children. More information is available in the joint American Academy of Pediatrics and Canadian Paediatric Society policy statement on early childhood caries and its impact on Indigenous communities.[81] In addition to oral health conditions, chronic otitis media and many other conditions disproportionally and inequitably affect AI/AN children and adolescents.[82,83] The authors have chosen some of the most prominent to focus on but do not consider this an exhaustive list.

GOVERNMENTAL AND POLITICAL INFLUENCES

The delivery of health care to AI/AN children is influenced by governmental policy at the federal, state, and tribal level. Treaties between the federal government and sovereign tribal nations established a trust relationship for health care. Although these treaties are unique agreements between tribal nations and the US government, failure of the government to honor them has also shaped mistrust among many AI/AN people and communities. Today, that treaty-based health care system is organized through the IHS, an agency within the US Department of Health and Human Services. Many health care settings serving AI/AN people receive funding through the IHS, including IHS federally operated clinics and hospitals, tribally operated clinics and hospitals, and urban AI clinics run by urban AI health organizations in metropolitan areas. Yet many AI/AN children receive health care services at clinics that are not associated with the IHS, including private clinics and federally qualified health centers.

Not all people who identify as AI/AN are members of tribes that have been federally recognized. Tribes that are not federally recognized are not eligible for federal funding from the IHS or the Bureau of Indian Affairs.

The IHS is chronically underfunded, with the budget determined by annual federal appropriations. By way of comparison, in 2017 the IHS was funded at $4078 per person, whereas the US government spent $10 692 per person in the Veterans Affairs system.[80] An underfunded IHS results in workforce instability and reduced ability to effectively deliver a full spectrum of necessary health

care. Chronic underfunding leads to infrastructure issues as well. Many facilities are overdue for updates, many locations have trouble providing housing for staff and providers, and much of the equipment is outdated. Furthermore, funding shortages lead to challenges in providing specialty care through contract health services.

Medicaid payment rates are directly tied to the likelihood of a practice accepting Medicaid patients, which is subsequently correlated with access to health care for children with Medicaid.[84,85] It follows, therefore, that increasing Medicaid payment rates and access to Medicaid coverage would potentially improve health care access for AI/AN youth. With more than 300 000 AI/AN children covered by Medicaid, there is an obvious need for continued and improved access to health services.[86,87] Continuing to expand access to Medicaid coverage for AI/AN children is essential for ensuring access to needed services.

Another complicating factor for many AI/AN communities is the inconsistent and overenforcement of punitive drug laws targeting pregnant women. Punitive drug screening practices for pregnant women lead to a decrease in prenatal visits, which, in turn, increases the risk of preterm birth.[88,89] Often, tribal laws differ from state and local laws, and in some instances, tribal jurisdictional boundaries may cross multiple states. Federally operated IHS facilities are bound by federal laws and policies. This overlap of governing bodies often results in confusing policies and a lack of standard and universal screening of pregnant AI/AN women, leading to late or inadequate detection of infants with a history of in utero substance exposure, including infants with neonatal opioid withdrawal syndrome.

RECOMMENDATIONS

Opportunities for Pediatric Care Providers in Practice

Pediatric care providers, because of their early interaction with AI/AN youth and their families, have a distinct opportunity to promote resilience and improve the health of these children, which will have far-reaching benefits as they age and raise their own children. Pediatricians and other pediatric care providers can implement systems in their practice that can help all patients and families, including AI/AN families, feel that they are welcome and will be treated respectfully and that high-quality family- and patient-centered care will be delivered regardless of social class, personal history, or cultural, spiritual, gender, racial, or ethnic identity. These strategies include providing trauma-informed care,[90–92] screening for substance use[93] and social determinants of health,[94–96] connecting to substance use prevention and treatment programs,[93] home visiting,[97] literacy programs,[98,99] and leveraging school-based health centers if available.[59] Addressing social determinants of health also includes addressing housing insecurity[100] and food insecurity.[101] The inclusion of the AI/AN perspective and disaggregated data in early childhood initiatives should be sought to improve outcomes within broader systems-based efforts. When implementing these strategies, pediatricians are encouraged to seek programs and interventions that incorporate AI/AN culture, tradition, and practices.[102] The following recommendations reflect the issues raised above and provide opportunities for pediatricians and others who provide care to AI/AN pediatric patients:

- Partner with local tribes and communities to set health priorities, understand historical experiences, and combine efforts already underway, such as cultural enrichment and preservation programs.
- Provide opportunities for adequate training of clinical and office staff in culturally sensitive care practices. Advocate for local and regional models that incorporate culturally and linguistically appropriate services tailored for local tribes.
- Provide evidence-based supports for parents and young children by promoting the use of home visiting models, high-quality child care, and early childhood programs, such as Early Head Start, Head Start, and Nurse-Family Partnership (https://www.nursefamilypartnership.org).[103]
- Start a Reach Out and Read program in AI/AN clinics and any clinic serving these families. Include books representing AI/AN and Indigenous children and families.
- Assess patients for ACEs and social determinants of health (eg, poverty, food insecurity, homelessness, lack of neighborhood safety, incarceration of parents or other family members, mental health conditions of parents or other household family members, housing inequity, access to schools, academic achievement, intimate partner violence, child abuse and neglect, and involvement with the juvenile legal system) to help families identify and implement practical solutions.
- Identify strengths and screen youth and families for protective factors to promote positive youth development.
- Create efforts to promote and strengthen protective factors for youth, focusing on cultural preservation–based efforts.
- Consider testing for prediabetes and T2DM in AI/AN children and adolescents with overweight or

obesity, as recommended by the American Diabetes Association.

- Promote breastfeeding in AI/AN tribal communities, ideally coordinated by tribal entities and involving community members, elders, and health care providers, including paraprofessionals.
- Include early childhood oral health as part of overall childhood health and well-being. Perform oral health screening during early childhood health assessments and provide referrals as needed to dental health providers. Be knowledgeable of fluoride levels in the drinking water for local tribal communities in your area.[81]
- Create a medical home that acknowledges and is sensitive to discrimination in clinical settings and generations of unresolved traumas and racism that AI/AN children and families experience. Work with local community hospitals and pediatric emergency departments, which may serve as a referral source, to become a medical home for AI/AN children whose families use emergency departments rather than seek primary care.
- Create a medical home model that facilitates access to services that will help AI/AN CYSHCN achieve their functional potential. Identify AI/AN CYSHCN, engaging staff, including care coordinators, in cultural competency training and partnering with the community.
- Assess patients for mental health conditions, including signs of posttraumatic stress, anxiety, grief, depressive symptoms, and suicidality, as well as their mothers for perinatal depression[104] using validated screening tools and a trauma-informed approach. Participate in strengths-based, community-driven, and culturally centered suicide prevention programs.[58]
- Screen AI/AN youth for substance use, and if identified, conduct a brief intervention and then refer for ongoing treatment.[105–107]
- Work with local schools to identify AI/AN students in need of mental health and educational services.
- Offer gender-affirming care in line with the previously published American Academy of Pediatrics policy statement.[67]
- Work to prevent, identify, and address sex trafficking in AI/AN youth.

Opportunities for Public Policy Advocacy

Pediatricians also have an opportunity to advocate for systems change that addresses health inequities and other systemic factors that contribute to ongoing health disparities experienced by AI/AN children and youth. The following recommendations are intended to support the policies and systems needed to promote and protect the health of AI/AN children and youth:

- Advocate for community initiatives and develop partnerships to address health disparities, such as altering practices of frequent consumption of sugar-sweetened beverages through education and improving the selection of foods locally available, to address healthy weight and oral health.
- Share information with the US Congress, state legislatures, foundations, and other appropriate advocacy groups about the inequities and tremendous health disparities that exist between AI/AN populations and the general US population.
- Invest in new research and clinical pathways to create culturally relevant screening and interventions for ACEs.
- Advocate for federal, state, and local policy to end AI/AN homelessness through consultation and engagement with tribal leaders, AI/AN communities, and AI/AN young people with lived experience of homelessness. Advocate for the investment in improved data collection on homelessness among both rural and urban AI/AN youth and culturally responsive interventions to address homelessness among diverse tribal nations.
- Work with local tribes and communities to address the need for research and advocacy around missing and murdered Indigenous women and girls.[69]
- Advocate for the protection and enforcement of the Indian Child Welfare Act.
- Advocate for increased Medicaid coverage for children and families as well as increased payment for services.
- Advocate for improved IHS budget and funding, which is chronically underfunded. IHS expenditures are among the lowest per capita compared with other federal health care expenditures, such as Medicare and the Veterans Health Administration. This disparity contributes significantly to the ongoing health inequities experienced by AI/AN people. Advocate for policies such as advanced appropriations or mandatory funding to provide the IHS with predictable and continuous funding.
- Work with local government and tribal communities to understand and mitigate the negative effects of punitive drug laws for pregnant women.

Child Life Services

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Child Life Services

Barbara Romito, MA, CCLS,[a] Jennifer Jewell, MD, FAAP,[b] Meredith Jackson, MD, FAAP,[b] AAP COMMITTEE ON HOSPITAL CARE; ASSOCIATION OF CHILD LIFE PROFESSIONALS

Child life programs are an important component of pediatric hospital-based care; they address the psychosocial concerns that accompany hospitalization and other health care experiences. Child life specialists focus on the optimal development and well-being of infants, children, adolescents, and young adults while promoting coping skills and minimizing the adverse effects of hospitalization, health care encounters, and/or other potentially stressful experiences. In collaboration with the entire health care team and family, child life specialists provide interventions that include therapeutic play, expressive modalities, and psychological preparation to facilitate coping and normalization at times and under circumstances that might otherwise prove overwhelming for the child. Play and developmentally appropriate communication are used to (1) promote optimal development, (2) educate children and families about health conditions, (3) prepare children and partner with families for medical events or procedures, (4) plan and rehearse useful coping and pain-management strategies with patients and families, (5) help children work through feelings about past or impending experiences, and (6) partner with families to establish therapeutic relationships between patients, siblings, and caregivers. Child life specialists collaborate with the entire interdisciplinary team to promote coping and enhance the overall health care experience for patients and families.

CHILD LIFE INTERVENTIONS: PSYCHOLOGICAL PREPARATION

Preparing children for hospitalization, clinic visits, surgeries, and diagnostic and/or therapeutic procedures is essential during a child's hospitalization and an important element of a child life program. It is estimated that 50% to 75% of children develop significant fear and anxiety before surgery; recognized risk factors include age, temperament, baseline anxiety, past medical encounters, and caregiver anxiety.[1] Children's anxiety in the perioperative environment is associated with impaired postoperative behavioral and clinical recovery, including increased analgesic requirements and delayed discharge from the recovery room.[2,3] Preparation can reduce anxiety and distress before surgery and/or during mask induction and may also decrease emergence

delirium after surgery.[4–7] More than 50 years of research and experience supports 3 key elements of the preparation process: (1) the provision of developmentally appropriate information, (2) the encouragement of questions and emotional expression, and (3) the formation of a trusting relationship with a health care professional.[3] A recent systematic review of preparation effectiveness evidence concluded that children who were psychologically prepared for surgery experienced fewer negative symptoms than did children who did not receive formal preparation.[3] Findings included a decrease in posttraumatic stress, lower levels of fear and anxiety, increased cooperative behaviors, and better long-term coping and adjustment to future medical challenges. Research also demonstrates that preparation and coping facilitation interventions decrease the need for sedation in procedures such as MRI and radiotherapy, resulting in lower risks for the child and cost savings in personnel, anesthesia, and throughput-related expenses.[8–12]

Preparation techniques, materials, and language must be adapted to the developmental level, personality, and unique experiences of each child and family. Learning is enhanced with hands-on methods versus exclusively verbal explanations. Photographs, diagrams, tours of surgical or treatment areas, actual and pretend medical equipment, and various models (dolls, puppets) are used to reinforce learning and actively engage the child.[1,13] Caregivers should be included in the preparation process because this can decrease parental anxiety and allow them to provide essential family-centered support.[14,15]

An experimental evaluation of one child life program model revealed that child life interventions resulted in less emotional distress, better overall coping during the hospital stay, a clearer understanding of procedures, and a more positive physical recovery as well as posthospital adjustment for children enrolled.[16] Patients spent less time on narcotics, the length of stay was slightly reduced, and caregivers were more satisfied. In other studies, researchers have found that child life interventions play a major role in calming children's fears and result in higher parent satisfaction ratings of the entire care experience.[8,17,18]

CHILD LIFE INTERVENTIONS: PAIN-MANAGEMENT AND COPING STRATEGIES

When combined with preparation and appropriate pharmacologic interventions, nonpharmacologic pain- and distress-management strategies have proven successful in terms of patient and family experience, staff experience, and cost-effectiveness.[17,19,20] Strategies such as swaddling, oral sucrose, vibratory stimulation, breathing techniques, relaxation, and guided imagery have been shown to decrease behavioral distress and pain experience in children during invasive medical procedures.[21–25]

Distraction strategies have been highly effective in reducing reported and observed pain and distress in children in inpatient, emergency department (ED), and clinic settings.[26–32] The emergence of virtual reality, Internet technology, and electronic and digital devices has been found to be an effective means of distraction in reducing pain.[7,33–38] Child life specialists may also develop comfort kits for use in treatment areas to include age-appropriate distraction items, such as bubbles, pop-up and sound books, light-up toys, and other visual or auditory tools.[39] Distraction techniques have also been shown to be successful in lowering a parent's fear and distress during an invasive procedure.[27]

Child life specialists can effectively provide developmentally appropriate nonpharmacologic pain management and provide coaching and support to patients and caregivers before, during, and after medical procedures.[40,41] They can also provide valuable education and training to nurses, physicians, students, and other personnel, supporting health care team member competencies in the provision of developmentally appropriate, psychosocially sound care.[42,43] Multifaceted institution-wide protocols, such as the Ouchless Place and other similar programs, incorporate the standard use of both pharmacologic and nonpharmacologic techniques, preparation of the patient and family, environmental considerations, and training of all health care team members.[44,45]

Research has demonstrated that children are less fearful and distressed when positioned for medical procedures in a sitting position rather than supine.[46] Child life specialists are often involved in facilitating the use of "comfort holds," techniques for positioning children in a parent or caregiver's lap or other comforting position. In addition to reducing the child's distress and gaining cooperation, these techniques generally require fewer staff to be present in the room, facilitate safe and effective accomplishment of the medical procedure, decrease parent anxiety, and increase parent satisfaction.[47,48] With a goal to severely limit the use of papoose boards and eliminate the practice of multiple staff members holding a child down, these techniques provide a viable and more humane alternative in most cases.

CHILD LIFE INTERVENTIONS: THE THERAPEUTIC VALUE OF PLAY

Therapeutic play during health care experiences is essential and a major component of a child life program and

of the child life professional's role. Play is crucial to a child's social, emotional, and cognitive development and is even more critical during adversity or stress points in a child's life.[49] In addition to its developmentally supportive benefits and as a normalizing activity for children and youth of all ages, play is particularly valuable for children who are anxious or struggling to cope with stressful circumstances of hospitalization, illness, or grief.[50] Erik Erikson[51] writes, "To play out is the most natural auto-therapeutic measure childhood affords. Whatever other roles play may have in the child's development…the child uses it to make up for defeats, sufferings, and frustrations." Play in the health care setting is adapted to address unique needs on the basis of developmental level, self-directed interests, medical condition and physical abilities, psychosocial vulnerabilities, and setting (eg, bedside, playroom, clinic). Play as a therapeutic modality, including health care play or "medical play," has been found to reduce children's emotional distress and help them cope with medical experiences.[52] Research has revealed that physiologic responses, such as palm sweating, excessive body movement, tachycardia, and hypertension, can be reduced with therapeutic play interventions.[53]

Play can be adapted to address the developmental and psychosocial needs of patients in every pediatric age group. For example, infants and toddlers benefit from exploratory and sensorimotor play, and preschoolers enjoy fantasy play and creative art activities.[54] Opportunities for parents to engage in play activities with their young children are beneficial to both the patient and family, alleviating some feelings of helplessness that can be common in caregivers and assisting in the child's adjustment to the hospital.[55]

School-aged children and adolescents seek play that contributes to feelings of mastery and achievement (one reason video games are so popular with this age group[56]). Patients in this age group also benefit from activities that allow them to maintain relationships with peers and establish new connections through, for example, online networking and the availability of teen-aged activity rooms in the hospital setting.[57]

Auxiliary programs, such as animal-assisted therapy, infant massage instruction, therapeutic clowning, performing arts, and artist-in-residence programs, often used in conjunction with child life services and incorporated into child life departments, provide additional outlets for patients of all ages and their families.[58–60] Live, interactive programming using closed-circuit television systems and studios can be a particularly effective way to engage patients restricted to their rooms for infection-control or medical reasons. Other interactive technology, such as video conferencing, can help patients engage with people outside the hospital, including their peers, the community, and their schools. The ability to connect with a child's school, community, and home helps normalize the experience by minimizing disruption of usual routines. Expressive therapies, such as those provided by distinctly certified play therapists, music therapists, and art therapists, can be offered to complement child life programs and to provide support for particularly vulnerable patients.[26,61,62]

CHILD LIFE INTERVENTIONS: PARTNERING WITH FAMILIES TO PROVIDE SUPPORT

The presence and participation of and partnership with family members is a fundamental component of patient- and family-centered care and has a significant positive effect on a child's adjustment to the health care experience.[63] When parents or other family members are highly anxious about the child's illness or diagnostic and treatment regimens, such anxiety is easily transmitted to the patient.[64] Child life specialists help facilitate the family's adjustment to the child's illness and health care experience by providing psychosocial support and coping strategies for caregivers. They can help family members understand their child's response to treatment and support caregiving roles by promoting parent-child play sessions and sharing strategies for comforting or coaching their children during medical procedures. In addition, child life specialists play a pivotal role in encouraging and facilitating family involvement in the patient's care as well as promoting communication between family members, providers, and the interdisciplinary team.

Siblings of pediatric patients present with their own unique anxieties and psychosocial needs, not often assessed or addressed. Siblings, much like children of adult patients, can be helped to comprehend a family member's illness via therapeutic play and educational interventions or by offering support during hospital visits, including diagnoses, critical care, and end-of-life situations.[65,66] Although sibling support is essential in all areas, a critical care hospitalization in the neonatal or pediatric ICU presents additional stressors for the entire family, and child life interventions are often focused on the siblings' psychosocial needs. Sibling support may include preparing the sibling(s) for an initial visit and providing ongoing emotional support throughout the patient's hospital stay. Child life specialists are often involved in providing bereavement support to patients as well as siblings and other family members. Grief support and legacy activities, such as hand molds or memory boxes for siblings and family members, are often provided at the end of life for both pediatric and adult patients throughout the hospital. In conjunction with the interdisciplinary team, child life specialists are critical in helping all family members

understand how to support children in age-appropriate ways during end-of-life events.

RECENT BENCHMARKING DATA

In 2016, the Association of Child Life Professionals (ACLP) constructed the Child Life Professional Data Center (CLPDC), an online database to house comprehensive child life program data and metrics, including staffing models, staffing ratios, budget allocation data, and hospital descriptors.[67] Using a systematic and evidence-based approach to measure the impact of psychosocial services provided to pediatric patients and families, this database has synthesized information from more than 160 child life programs. In addition, the ACLP established a productivity metric measuring the number of patient and family encounters a child life specialist provides in a specified setting within the hospital during a shift. Currently, more than 50 programs have participated in the productivity data collection. The productivity metric is a numerical indicator of the number of patient and family encounters that can be expected during the child life specialist's shift. This measure of productivity is collected for 6 distinct areas of service: (1) inpatient acute care units, (2) critical care, (3) radiology, (4) presurgery, (5) outpatient ambulatory care, and (6) the ED. These 6 distinct areas are being used to collect and segment data because the type and length of child life intervention can depend on which medical service is being provided. A patient encounter is defined as a child life specialist–provided interaction with a patient, sibling, or caregiver, and this serves as the numerator of the productivity metric. The denominator is the length of the child life specialist's shift (eg, 8 hours). The final metric given is the measure of patient and family encounters per hour. These metrics account for nondirect patient care activities and direct patient care interventions. By using the shift length as the denominator, additional nonpatient care responsibilities are accounted for in the productivity calculation, including such things as meetings, committee work, student and staff education, and donor events.[67]

Figure 1 identifies the total number of individual patient and family encounters an individual child life specialist provides in an 8-hour shift in each of the 6 service areas. In radiology, the median productivity is 0.74 patient encounters per hour, or approximately 6 encounters in an 8-hour day. Of all 6 areas of service, radiology encounters trend the longest because radiologic procedures often require significant preparation and support during the procedures, which may be lengthy. Child life specialists in presurgery and the ED have the highest median productivity, with an average of 1.2 patient encounters every hour, roughly 10 patients seen per 8-hour shift in each of these areas.

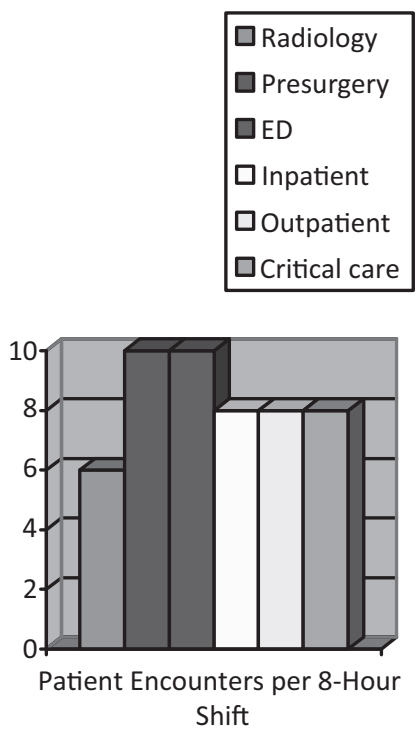

FIGURE 1
Average patient/family encounters per 8-hour shift for child life specialists in various hospital settings.

The remaining 3 areas, inpatient acute care, outpatient ambulatory clinics, and critical care units, all have similar productivity, with approximately 1 patient encounter per hour, or 8 in an 8-hour shift.

The productivity data allow participating hospitals to clearly identify how their program compares to the national average or similar hospitals on the basis of median scores. The data also serve as a tool to support appropriate staffing during hospital program growth by offering a benchmark to adjust staffing depending on changes in patient volumes.

Although these ratios establish national benchmarking and staffing trends, other factors should influence staffing allocations. Child life services should be available to meet identified patient and family needs 7 days per week. Staffing plans should be sufficient to meet fluctuations in anticipated and unanticipated staff absences, seasonal swings in the patient census, and nonclinical community activities (such as school programming, outreach events, and increased visits and in-kind donations during the holiday season). Child variables (such as age, temperament, coping style, and cognitive abilities), family variables (such as caregiver anxiety, presence, and involvement) and diagnosis and treatment variables (acute versus chronic, repeat admissions, number of invasive procedures) are known to affect psychosocial vulnerability and, thus, influence the child's particular child life needs.[68] A combination of psychosocial risk assessment, medical and/or treatment variables (eg, the proportion of patients on isolation precautions and the volume of patient and family teaching needs), and the time requirements associated with particular interventions directly affect operational staff-to-patient ratios in both inpatient and outpatient settings and could necessitate a lower ratio of patients to child life specialist.[69,70]

In addition to establishing a benchmarking standard for child life specialist and patient encounters, the CLPDC houses multifaceted information, such as types of organizations in which child life specialists work, staffing, program funding, reporting structure, services provided, and special services. The CLPDC should be used as a resource for programs and hospitals in evaluation and continuous performance improvement of child life programming.

CHILD LIFE STAFFING AND ROLES

Child life specialists are part of an interdisciplinary, patient- and family-centered model of care, collaborating with the family, physicians, advanced practice providers, nurses, social workers, and other members of the health care team to develop a comprehensive plan of care. Child life contributions to this plan are based on the patient's and family's psychosocial needs, cultural heritage, and responses to the health care experience. Child life specialists can participate in the care plan by, for example, teaching a child coping strategies for adjusting to a life-changing injury, promoting coping with examinations for alleged abuse, assisting families in talking to their children about death, facilitating nonpharmacologic pain-management techniques, preparing and educating children about their medical care in age-appropriate ways, and communicating the child's developmental and individual needs and perspective to others. These interventions are most effective when delivered in collaboration with the entire health care team.

The credentials of a certified child life specialist (CCLS) currently include the minimum of a bachelor's degree in child life, child development, or a closely related field; the successful completion of a 600-hour child life internship under the supervision of a CCLS; and passing a standardized certification examination.[71] Ongoing and future requirements for the CCLS credential are determined by the Child Life Certification Commission of the ACLP.

In some settings, child life services are augmented by child life assistants (or activity coordinators, child life technicians, etc). Child life assistants are typically required to have core college coursework, such as an associate degree in child development, and experience with children in group settings. They generally focus on the normalization of the health care experience, providing play activities, coordinating special events (community visitors, holiday celebrations, etc), and maintaining the playroom environment. Both child life specialists and assistants actively participate in the orientation, training, and supervision of volunteers, thereby contributing to volunteer effectiveness, satisfaction, and retention. This collaboration enables the child life specialist to conduct an assessment and delegate as appropriate, allowing patients with varying degrees of psychosocial vulnerability and activity levels to be supported by the team member whose skills and knowledge are most closely aligned with patient and family needs. Although volunteers are a valuable supplement, they can never be considered an adequate replacement for CCLSs.

EVOLUTION OF CHILD LIFE SERVICES

The provision of child life services is a quality benchmark of an integrated patient- and family-centered health care system, a recommended component of medical education, and an indicator of excellence in pediatric care.[72–74] There are more than 430 child life programs in operation in North America[75]; most are located in freestanding children's hospitals, children's hospitals within hospitals, community hospitals with pediatric units, and EDs.

The scope of child life programs has developed beyond pediatric inpatient acute care settings to include outpatient and other areas in which child life expertise can be effectively applied to support children and families in stressful situations. Child life specialists provide services to presurgery and surgical centers, radiology and imaging departments, dialysis centers, ambulatory clinics, NICUs, urgent care centers, psychiatric units, hospice programs, camps for children with chronic illness, rehabilitation settings, and some outpatient dental and physician offices.[76] Because the majority of children with medical complexities are being treated on an outpatient basis, child life services are increasingly common outside the hospital.[77] Increasingly, CCLSs are also part of interdisciplinary health care teams, including palliative care, behavioral health, trauma, and child protective services. In cases of hospitalized or ill adults, child life specialists may be consulted to work with children of adult patients, particularly in end-of-life, trauma, and critical care situations.

Child life programs continue to evolve and adapt to meet the changing health care needs of patients and families. Children with special health care needs now represent 18.8% of all children, up from 12.8% in 2001.[78] Specifically, the increase in patients with a diagnosis of autism spectrum disorder presents opportunities for child life specialization in supporting this population in medical settings.[36,79,80] In addition, the number of children with mental health and developmental disabilities conditions is increasing, either alone or comorbid with a physical health condition.[81,82] Hospitals are also admitting children with more complex medical conditions, with rates doubling between 1991 and 2005, and may need greater individualization of care from the CCLS.[83,84] The numbers of children with disabilities and

medical complexities are increasing, likely because of the increases in technology that ensures the survival of patients with previously lethal conditions.[85] Given the increasing survival rate of patients with cystic fibrosis, cardiac conditions, spina bifida, short gut, cancer, and other chronic illnesses, more teenagers and young adults face the challenging transition to adult health care.[86] Acknowledging team goals to normalize the transition process and address patient and family anxieties or questions, child life specialists can assist in this transition by providing education and helping patients to communicate their needs, fears, hopes, and expectations.87–89

In recent years, patient experience and/or patient satisfaction has become a key quality and performance indicator. Although the definition of patient experience continues to be explored and honed by health care leaders, there is common agreement that when evaluating health care quality, patient satisfaction is an important metric that translates to health care ratings and payment.[90] Family-centered care is a core principle for child life specialists; the recent emergence of the patient experience as a key quality indicator has resulted in child life specialists often taking the lead in family-centered care and patient experience initiatives. Research studies have demonstrated the positive impact of child life intervention on patient and parent perception and evaluation of the hospital experience, which is increasingly important for incentive-based reimbursement, accreditation, marketing, and public reporting of outcomes.[8,17,34,67,91] Health care professionals and organizations acknowledge the significant impact child life specialists have on the patient experience as well as the role child life plays in helping the concept of patient experience continue to evolve and grow.[80]

Although evidence supports the value of child life services, financial pressures in many health care settings have threatened the growth and sustainability of child life services. In addition to contributions to the patient experience, the literature has also demonstrated financial benefits of child life interventions, including reduced sedation-related costs, and increased compliance during procedures, resulting in procedure completion.[8–12] A child life program improves quality and decreases costs and, therefore, should be included in the value-added equation and discussion of health care cost, including with payers.

ADDITIONAL CONSIDERATIONS

Child life services contribute to an organization's efforts to meet the standards set forth by The Joint Commission and other accreditation agencies, including effective communication, patient- and family-centered care, age-specific competencies, and cultural competence.[92] Child life specialists' psychosocial and developmental expertise and their keen awareness of the benefits of patient- and family-centered care provide a useful perspective at a systems level. Child life input is often incorporated into hospital committees, such as ethics, family-centered care, patient experience, safety, environmental design, bereavement, and strategic planning. Child life expertise has applications beyond conventional hospital care. Interventions can help children transition back to their homes, schools, communities, and medical homes.[11,93] Child life specialists often collaborate with local school districts to arrange hospital or homebound education, and hospital-based teachers may be incorporated into child life program administration. These interventions help provide continued normalization and help make the transition to and from the hospital to the home setting less disruptive. Child life specialists also provide services outside hospital-based settings, including private practice, community agencies, and hospice care, and are becoming increasingly involved in providing support to children and families during catastrophic events.

For hospitals or other health care settings considering the initiation or expansion of child life services, the ACLP offers a consultation service to support existing program review and development, new program startup, interdisciplinary education, and written practice guidelines.[94] In community hospital settings with few pediatric beds and minimal pediatric outpatient or ED visits, the provision of full-time child life services may not be financially feasible. In such cases, part-time or consultative services of a CCLS may be obtained to assist in the ongoing education of staff, students, and volunteers as well as to advise on a psychosocially sound, developmentally appropriate patient- and family-centered approach to care. The advancement of telemedicine also presents an opportunity for child life specialists to intervene when they cannot be on-site. Advocating for child life services as an essential part of the interdisciplinary team is a responsibility of health care organizations to ensure it is a standard of pediatric care and should occur on local and national levels as well as in regulatory and accrediting organizations.

CONCLUSIONS

Child life services are associated with improved quality, outcomes, and patient and family experiences as well as decrease costs in pediatric care. There is evidence that child life services help to contain costs by reducing the length of stay, decreasing the need for sedation and analgesics, and increasing patient satisfaction ratings. Patient

experience data and interdisciplinary team member feedback further confirm the positive effects of child life programs on children, families, and staff. It remains essential for child life services to adapt and grow with the changing health care delivery system in support of the highest possible quality of care for children and their families.

RECOMMENDATIONS

1. Child life collaboration with the entire interdisciplinary team is essential to meeting the overall health care needs of children and families.
2. Child life services are part of an integrated patient- and family-centered model of care and can be used as a quality measure in the delivery of health care services for children and families.
3. Child life services, provided directly by CCLSs, are recommended in pediatric inpatient units, EDs, chronic care centers, and other diagnostic and treatment areas to the extent appropriate for the population served. In hospitals with a small number of inpatient or outpatient pediatric visits, ongoing consultation with a CCLS is needed to educate health care team members and support developmentally appropriate patient- and family-centered practice.
4. Child life services staffing must be individualized to address the needs of specific inpatient and outpatient areas. The ratio of child life specialist to patient should be adjusted to account for the patient's medical, psychosocial, and developmental complexity and vulnerability as well as family needs and preferences. Child life services need to continuously evolve to meet the changing needs in pediatric health care, including the significant increases in children with disabilities and medical complexity.
5. Child life services optimize pediatric health care and, therefore, should be included in the hospital operating budget; they cannot solely rely on contingency or philanthropic funding.
6. Legislative advocacy of child life services by pediatricians and other stakeholders is recommended at the state and federal levels.
7. Additional research is needed to further identify the impact of child life services on patient care outcomes, including patient experience, cost-effectiveness, and quality and safety measures.

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Collaborative Care in the Identification and Management of Psychosis in Adolescents and Young Adults

Liwei L. Hua, MD, PhD, COMMITTEE ON ADOLESCENCE

Pediatricians are often the first physicians to encounter adolescents and young adults presenting with psychotic symptoms. Although pediatricians would ideally be able to refer these patients immediately into psychiatric care, the shortage of child and adolescent psychiatry services may sometimes require pediatricians to make an initial assessment or continue care after recommendations are made by a specialist. Knowing how to identify and further evaluate these symptoms in pediatric patients and how to collaborate with and refer to specialty care is critical in helping to minimize the duration of untreated psychosis and to optimize outcomes. Because not all patients presenting with psychotic-like symptoms will convert to a psychotic disorder, pediatricians should avoid prematurely assigning a diagnosis when possible. Other contributing factors, such as co-occurring substance abuse or trauma, should also be considered. This clinical report describes psychotic and psychotic-like symptoms in the pediatric age group as well as etiology, risk factors, and recommendations for pediatricians, who may be among the first health care providers to identify youth at risk.

INTRODUCTION

Psychosis is defined as impairment in thought and behavior so severe that the ability to distinguish reality from nonreality is lost. Psychotic symptoms include delusions, fixed and false beliefs, and hallucinations or false sensory perceptions.[1] Although these symptoms do not necessarily portend a primary psychotic disorder, there is a strong association with the presence or future development of other psychiatric disorders.[2,3] Primary mood or anxiety disorders with concurrent psychotic symptoms often indicate a more severe form of mood or anxiety disorder, such as bipolar disorder, with psychotic features and imply more impaired functioning.[4–6]

Pediatricians in the medical home may be the first point of contact for adolescents who report psychotic-like symptoms, which may be attributable in part to the ease of access to pediatricians and/or to a shortage of child and adolescent psychiatrists.[7] Therefore, pediatricians should be familiar and comfortable with asking additional questions when patients present with vague or overt psychotic symptoms, to determine the appropriate level of care (eg, close monitoring with specialty mental health consultation with psychiatrist, psychologist, or psychotherapist, or urgent emergency department [ED] evaluation). Management decisions will depend on the severity of the psychotic-like symptoms, how deeply entrenched the beliefs are (level of insight), level of distress, functional impact, and safety of the individual and others.

This clinical report aims to provide pediatricians with a framework for identification, initial assessment, and mental health referral and consultation for youth presenting with psychotic-like symptoms. This report strongly encourages collaboration between pediatricians and mental health specialists to determine the best course of treatment of patients presenting with psychotic-like experiences or psychosis.

EPIDEMIOLOGY

Each year, approximately 100 000 adolescents and young adults in the United States experience a first-episode psychosis (FEP).[8,9] Estimates of the prevalence of early-onset schizophrenia (onset prior to 18 years of age) is approximately 0.5%, whereas the prevalence of schizophrenia in general is believed to be about 1%.[1] In the United States, childhood-onset schizophrenia (onset prior to 13 years of age), with a more severe course and worse prognosis, is rarer, with an estimated prevalence of approximately 0.04%.[1]

In general, the peak onset of psychotic disorders occurs between 15 and 25 years of age.[8] Researchers in a large study of FEP found approximately 18% of adults with schizophrenia experienced their first episode before 18 years of age (53.4% male).[10] In another study, researchers found 11% to 19% of a first-episode schizophrenia sample and 23% to 35% of a clinical high-risk syndrome sample reported onset of attenuated psychotic symptoms in childhood (manifesting at 13 years or younger).[11] Patients who are at clinical high risk (CHR) demonstrate nonspecific and attenuated psychotic symptoms, with subtle changes in cognition, behavior, and affect that are different from their previous baseline functioning. Patients at CHR may also have a history of social isolation or withdrawal as well as odd or suspicious behavior. Family and friends may be the first to notice these symptoms, but eventually individuals themselves may begin to experience distress as well. Patients at CHR have higher likelihood of transitioning to overt psychotic symptoms, such as auditory hallucinations and/or delusions.[12] Increased level of distress experienced with the psychotic symptom or psychotic-like experience appears to differentiate CHR status from non-CHR status, which leads to more help seeking.[13]

The prodrome is the phase before a full psychotic episode but can only be defined retrospectively after a psychotic disorder has developed. Studies indicate that the prodromal period may be an important time for early intervention.[14] The duration of untreated psychosis (DUP) is defined as the period between first presentation of psychotic symptoms and treatment. The median DUP was approximately 74 weeks from a sample of patients (15–40 years of age) in community mental health centers.[15] Individuals with shorter DUP appear to have better response to treatment and better overall prognosis, thus emphasizing the need for early identification and intervention.[15]

TABLE 1 Common Themes of Delusions

Delusions	Definitions
Persecutory	Belief that one is being or is going to be harmed
Referential	Belief that certain occurrences are directed at oneself
Grandiose	Belief that one has special abilities
Erotomanic	Belief that another is in love with oneself
Nihilistic	Belief that a catastrophe will occur or that the world will end
Somatic	Intense preoccupation with health and organ function

CLASSIFICATION AND DEFINITIONS

The key features defining psychotic disorders are delusions, hallucinations, disorganized thinking (speech), grossly disorganized or abnormal motor behavior (including catatonia), and negative symptoms. See the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5)[1] section on schizophrenia spectrum and other psychotic disorders diagnoses for specific diagnoses and criteria.

CORE SYMPTOMS

Delusions

Delusions are fixed, false beliefs.[1] Even if evidence is shown to the contrary of the belief, the belief remains unchanged. See Table 1 for common themes of delusions.

The DSM-5 generally classifies delusions as bizarre or nonbizarre.[1] Thought withdrawal, the belief that one's thoughts are being or have been removed; thought insertion, the belief that an outside force has placed

thoughts in one's head; and delusions of control, the belief that an outside force is controlling one's body, are all categorized as bizarre delusions. Nonbizarre delusions are those that could be plausible, such as the belief that one is being monitored by the police or FBI or that one's phone has been hacked by another person, despite a lack of evidence.

Hallucinations

The DSM-5 defines hallucinations as vivid perception-like experiences occurring in the absence of any external stimuli.[1] Auditory hallucinations are the most common, although visual, tactile, gustatory, and olfactory hallucinations also occur. Patients report most auditory hallucinations as voices that may be familiar or unfamiliar and are distinct from one's own thoughts. Hallucinations occurring when one is falling asleep (hypnagogic) or waking up (hypnopompic) are considered normal in the general population. Hallucinations occur more commonly in youth than delusions, and auditory hallucinations are more common than other sensory hallucinations.

Disorganized Thinking

Providers may assess for disorganized thinking by observing the patient's speech. Jumping from topic to topic may be indicative of derailment or loose associations; inability to answer a question in a goal-directed manner or answering a question that was not asked may reflect tangential thinking. A speech pattern so disorganized that it may not be understood by others is known as incoherence or "word salad" (random words or phrases that are strung together in sentence form but do not make sense).[1]

Disorganized Behavior

The DSM-5 defines grossly disorganized or abnormal motor behavior as difficulty in performing goal-directed behavior, affecting functioning. Catatonia is decreased reactivity to the environment, and it may consist of a range of behaviors from negativism (not following directions) to mutism and stupor (not responding verbally or with appropriate motor responses, respectively) to catatonic excitement (purposeless and excessive motor movement). Catatonia may also include repeated stereotyped movements, echolalia, posturing, or grimacing. Catatonia is more likely to be associated with schizophrenia but can also be found with other psychiatric disorders or medical conditions, including autism spectrum disorder (ASD).[1]

Negative Symptoms

Negative symptoms consist of diminished emotional expression, avolition (lack of motivation), alogia (poverty of speech), anhedonia (inability to experience pleasure), and asociality (reduced desire or motivation to form relationships).[1,16]

RISK FACTORS FOR CONVERSION TO PRIMARY PSYCHOTIC DISORDER

The North American Prodrome Longitudinal Study (NAPLS), a consortium of 8 research centers, aimed to study CHR populations and determine mechanisms of conversion to psychosis to predict conversion in a high-risk population with an age range of participants from 12 to 35 years. In a 2.5-year follow-up, risk of conversion from CHR to full psychotic disorder was 35%, whereas approximately one-third remitted and one-third continued to demonstrate attenuated positive symptoms with poorer overall functioning.[17,18] Once an individual receives a schizophrenia spectrum diagnosis, prognosis is generally poor unless they receive appropriate treatment. Researchers in 1 study using the Multi-Payer Claims Database demonstrated 12-month mortality after initial diagnosis was 1968 per 100 000 compared with the general population, in which it is 89 per 100 000 people.[19] The authors also found teenagers and young adults in whom psychotic disorder is diagnosed have about a 24-times greater 12-month mortality rate than their peers, suggesting that during the year after diagnosis, it is crucial to optimize outcomes by increasing monitoring with regular follow-up and early intervention.[19] An analysis of the database found it did not report cause of death, leaving the authors to speculate that the reason for death might have included suicide or substance use–related accidents.[19]

NAPLS described variables contributing uniquely to psychosis prediction to be genetic risk for schizophrenia with recent worsening of functioning, greater impairment in social functioning, history of substance use, increased levels of suspiciousness or paranoia, and increased levels of unusual thought content.[18] In NAPLS, 92% of the CHR sample had at least 1 positive symptom, the most common of which was unusual thought content and perceptual abnormalities, followed by suspiciousness. Eighty-two percent of subjects endorsed at least 1 negative symptom, of which avolition and poor occupational functioning were the most common, and 44% demonstrated 3 or more negative symptoms. Disorganized communication occurred infrequently and grandiosity less.[15] Greater levels of unusual thought content and suspiciousness, greater decline in social functioning, greater prodromal symptom severity, lower verbal learning and memory performance, more delayed processing speed, and younger age at symptom onset contributed to increased risk of conversion from CHR status to psychosis.[20] Social dysfunction in early adolescence is of particular significance in conversion to psychosis in CHR individuals.[21]

PSYCHOTIC-LIKE SYMPTOMS PRESENTING IN YOUTH

Many children and adolescents report psychotic-like experiences, but most do not go on to develop true psychotic illness.[22,23] Clinically significant psychosis usually involves mental status and behavioral changes and usually imparts a high level of distress. However, data suggest that psychotic-like experiences in childhood and adolescence can be associated with development of other psychiatric disorders in the future, and strong symptomatology in childhood may be associated with increased likelihood of psychotic disorder as adults.[24]

Youth who report psychotic symptoms also have a higher likelihood of experiencing current mental health difficulties than those who do not; however, psychotic-like symptoms that present during childhood and/or adolescence frequently resolve. Jardri et al[25] reported that hallucinations are common in children and may not signify psychiatric pathology; however, persistence of hallucinations into adolescence increases risk of developing psychosis five- to sixfold. In a study of adolescents with hallucinations, half reported no symptoms after 1 year.[26] Similarly, researchers in the Philadelphia Neurodevelopmental Cohort, a 2-year prospective follow-up study, reported 51% persistence or worsening of psychotic symptoms after 2 years.[27]

In youth presenting with delusions or hallucinations, mood disorders should be considered; although pediatric bipolar disorder is rare, early-onset schizophrenia is even rarer.[28] Ulloa et al[29] reported approximately 10% of youth (n = 2031) seen in a pediatric mood and anxiety disorders clinic had psychotic symptoms. Of the 10% reporting psychotic symptoms, 62% of patients had a diagnosis of a depressive disorder, 24% had a diagnosis of bipolar disorder, and 14% had a diagnosis of schizophrenia.

In a general population of youth, hallucinations were more prevalent than delusions.[30] Youth report auditory hallucinations, often with commands and comments, more commonly than conversing voices. Visual and tactile hallucinations may occur with auditory hallucinations. True hallucinations occur when one is fully awake; they are vivid and evoke a response.[30] Delusions may occur but are vague and are usually related to the hallucinations. Symptoms that are specific to a certain situation (such as occurring only at nighttime or only when the individual is angry), overly detailed, and not associated with disorganized thoughts or behaviors are less likely to be indicative of a true psychotic disorder as well.[22]

Adolescents report fewer hallucinations than children do. Kelleher et al[31] found that a median of 17% of 9- to 12-year-olds and a median of 7.5% of 13- to 18-year-olds report auditory hallucinations. An increase in lifetime history of psychiatric disorders also correlated with an increased reporting of hallucinations. Those reporting psychotic-like symptoms were more likely to have a mental health disorder, including anxiety and mood disorder, at the time of presentation and even more likely over the course of their lifetimes. In a mental health clinic sample, Kelleher et al[32,33] found that patients presenting with psychotic experiences were more likely to have multiple psychiatric disorders and socio-occupational difficulties as well as a higher risk for suicidal behavior. A meta-analysis of 10 prospective cohort studies published between 2013 and 2017 found patients who reported psychotic experiences had twofold increased odds of later suicidal ideation, threefold increased odds of later suicide attempt, and fourfold increased odds of subsequent death by suicide.[34]

In a 15-year longitudinal study that followed individuals from 11 to 26 years of age, more than 40% of patients in whom schizophreniform disorder was diagnosed in early adulthood had disclosed symptoms at younger age. Of those who reported the most severe psychotic-like symptoms in preadolescence, approximately 25% had a diagnosis of schizophreniform disorder in early adulthood, and 70% experienced at least 1 of the following: hallucinations, delusions, disorganized speech, catatonia, or anhedonia. Almost all experienced poor occupational or social functioning.[2] When followed out to 38 years of age, those who had reported psychotic symptoms at a young age were at increased likelihood of having a diagnosis of schizophrenia and posttraumatic stress disorder and were also more likely to have attempted suicide. Very few had no psychiatric diagnosis at all.[24]

Youth reporting psychotic symptoms appear to have worse global functioning.[35] Approximately 75% of youth reported that the psychotic-like experiences were distressing to them.[35] Other studies reported those with FEP have significantly slower processing speed; processing speed also predicts social functioning 1 year later.[36] Patients with adolescent-onset psychosis did not demonstrate improvements in processing speed as they aged, which negatively affects functional outcomes. These findings support the idea that adolescent-onset psychosis is associated with a disruption in adolescent brain development, such as myelination.[36] In a study examining a CHR population, comparing those who developed psychosis during the course of the study versus those who did not, authors found only people with psychosis had impaired cognition, with specific impairments

in processing speed, verbal memory, sustained attention, and executive functioning. This finding suggests cognitive deficits exist before manifestation of psychotic symptoms. Carrión et al[37] reported that these deficits persist but do not worsen over the course of the illness.

Although there is overlap, the risks and manifestations of psychotic-like symptoms in youth are heterogeneous. Other presentations that can be confused and/or associated with psychotic-like symptoms are described below. See Appendix 1 for sample case scenarios of psychotic and psychotic-like presentations that may occur in the pediatric ambulatory setting.

Benign Hallucinations

Some adolescents may mention hearing their name called with no other concerning symptoms. The Washington University in St Louis Kiddie Schedule for Affective Disorders and Schizophrenia, which assesses for hallucinations that are benign or pathologic, defines these as "benign hallucinations," because they do not impair functioning, are nonthreatening in content, and occur infrequently.[38] Pathologic hallucinations, such as a voice telling one to harm oneself or others, do impair functioning.[38] A recent review of "healthy voice-hearer" literature found there appeared to be a continuum of voice hearing from healthy controls (no auditory hallucinations) to "healthy voice-hearers" (low frequency, low distress) to "clinical voice-hearers" (high frequency, high distress).[39] Although healthy voice hearers seem to be at higher risk of transitioning to mental health disorders, only a minority end up transitioning.[39]

Illusions are distinct from hallucinations but warrant mention. Illusions are defined as a misperception and/or misinterpretation of an actual stimulus, such as seeing a rope on the ground and thinking it is a snake for an instant, whereas hallucinations consist of perceiving something that is not actually there.[1] Illusions are not necessarily pathologic and can be experienced by people with no psychiatric disorders. In a white noise speech illusion study (hearing speech when only white noise was being played) in adults, there was no association of white noise speech illusion with psychosis in a nonclinical population.[40]

Imaginary Friends

Imaginary friends, which could also be called "hallucination-like phenomenon," are reported in 28% to 65% of children 5 to 12 years of age, and up to 65% of children 7 years of age and younger have imaginary companions.[25,41] There is scarce literature on imaginary companions and association with psychotic symptoms. An imaginary companion could be invisible or embodied by a doll or stuffed animal.[42] Imaginary companions during childhood are normative and are thought to help with development of appropriate social interactions and emotional regulation.[42] Children can identify that imaginary companions are not real.[42] Youth are usually able to make imaginary friends go away, unlike hallucinations.[30] Because of concerns for prognosis and relevance to future mental health disorders, a longitudinal study of "high-risk" middle school students 11 to 14 years of age with imaginary companions, described by their teachers as having the most "problem behaviors" (as assessed by the Child Behavior Checklist 4–18) in school, was performed. The researchers found that although these children had the most behavioral issues and the least social acceptance, they were not at higher risk for any psychiatric disorders and seemed to have greater positive adjustment.[43]

Cultural and Religious Considerations and Bereavement

It is important for pediatricians to consider cultural issues or family background when asking about psychotic-like symptoms, because some symptoms that sound pathologic may be normal cultural or developmental responses. For example, if a youth describing a presence or shadow in their room at night comes from a family that believes strongly in spirits or ghosts, such an experience may not reflect an actual visual hallucination. During bereavement and mourning, youth may report auditory or visual hallucinations of the deceased person.[44–47] In these situations, the individual's degree of distress can be helpful in determining the pediatrician's next step. When symptoms are described as comforting or neutral, they are less likely to be an indication of a psychotic disorder. Distress would indicate something more problematic, and referral to a psychotherapist would be recommended.

Intellectual Disability

People with intellectual disability (ID) may report psychotic-like symptoms, and pediatricians and developmental and behavioral pediatricians can assist with providing a differential diagnosis for youth with ID and ASD and help coordinate a plan of care related to special educational needs and therapies. Providers may consider using a neurodevelopmental framework to assess psychotic-like symptoms. Symptoms suggestive of psychosis in this population could instead reflect self-talk, imaginary friends, or fantasies, depending on an individual's developmental level.[47] Stressful experiences, such as the loss of a loved one, may trigger or exacerbate psychotic-like symptoms.[47] When assessing adolescents or young adults with ID, it is important to determine if they understand the questions being asked

to ensure a valid assessment. Individuals with intellectual limitations and delayed emotional development may feel pressured to answer a question a certain way to please the interviewer or blame negative behaviors on voices in their head to avoid getting in trouble.[44]

Co-occurring mental disorder and ID in youth is common and often persists through the life span.[48] Relative to children and adolescents without ID, the rate of co-occurrence of mental disorders in youth with ID is 3 to 4 times greater.

ASD

Core features of ASD consist of social communication and social interaction deficits as well as restricted interests, stereotyped or repetitive behaviors, and sensory sensitivities. Some of these symptoms may overlap with those occurring in schizophrenia spectrum disorders (SSDs). In addition, a number of individuals with ASD may experience transient hallucinations and engage in vivid fantasies, which may be mistaken for true psychotic symptoms. Although there is a level of co-occurrence of ASD and SSDs, one must be careful to distinguish the overlapping symptoms before giving both diagnoses.[49] Common genetic regions and brain regions may contribute to the comorbidity of ASD and SSDs.[50]

Co-occurring ASD and SSD should be considered when perceptual abnormalities and beliefs or behaviors are noted to be different from those at baseline, especially with associated change in functioning.[50] Thorough developmental, medical, and psychiatric history, as well as any other useful collateral information, is important when assessing for co-occurring conditions. In addition, genetic testing should be considered if not already completed. Clinicians should also monitor for catatonia.

Trauma

In addition to serving as a risk factor for psychotic disorder, trauma can result in posttraumatic symptoms that can be mistaken for psychotic symptoms. For instance, flashbacks can be mistaken for visual and/or auditory hallucinations, and hypervigilance or hyperarousal can be mistaken for paranoid delusions. Withdrawal and avoidance could be mistaken for negative symptoms.[51] Assessment to determine if symptoms are psychotic-like or truly psychotic in nature may need to take place over time to determine the most appropriate course of treatment.

Dissociative episodes can also be associated with trauma and may serve as a protective mechanism to mentally or emotionally escape physical trauma. Dissociation is a detachment from reality, whereas psychosis is a loss of reality. Although the two are distinct, some researchers hypothesize that dissociation may mediate the relationship between traumatic life events and the development of attenuated positive psychotic symptoms.[52]

ETIOLOGY OF PSYCHOTIC SYMPTOMS AND DISORDERS

Neuroanatomical Abnormalities

Schizophrenia is a heterogeneous disorder, but disruptions in brain connectivity and synaptic functioning likely underlie the development of schizophrenia.[53] These disruptions appear to occur first in neural circuits involved in referencing occurrences by time, place, and saliency, potentially resulting in an inability to recognize that certain thoughts have been self-generated, which could eventually contribute to loss of reality testing. Axonal pathology, such as disruption in myelination, may also be involved.[53] Excessive synaptic pruning may also be a factor, possibly associated with the immune system, namely upregulation of complement genes and activation of microglia.[54]

Scientists have found abnormalities in brain structure, likely progressive, including bilateral enlargement of lateral ventricles and volume decreases in the frontal lobe, hippocampus, and thalamus.[55,56] Rapoport et al[57] demonstrated reduced frontal and temporal gray matter volume compared with healthy controls. People with childhood-onset schizophrenia seem to lose more gray matter in the cortex than do children who report brief psychotic episodes.[57] Those with early-onset schizophrenia also show significant gray matter volume decrease and decrease in cortical folding.[55,58]

Neurotransmitters

Schizophrenia is primarily associated with dopamine dysfunction, with increased dopamine synthesis and release leading to psychosis; however, multiple other neurotransmitters and pathways are believed to be involved.[59,60] Olney and Farber found that animals given *N*-methyl-D-aspartate receptor antagonists develop neurotoxic changes similar to those observed in brains of patients with schizophrenia.[61] Administration of agents that increase glutamate, such as phencyclidine or ketamine, increase the likelihood of psychotic symptoms.[62] Serotonin antagonism, as found in some second-generation antipsychotic medications, appears to provide some benefit for extrapyramidal symptoms and for mood symptoms associated with schizophrenia.[63] Serotonergic antagonists also show promise for treatment of negative and cognitive symptoms of schizophrenia.[60,63,64] The muscarinic cholinergic system may play a role in schizophrenia, because blockade of acetylcholine receptors can result in psychotic symptomatology.[60,65] In addition, alterations in the γ-aminobutyric acid neurotransmitter system may also have a role in schizophrenia.[60] Abnormalities in these neurotransmitter systems form the

basis for pharmacologic treatment of psychotic disorders and/or schizophrenia.

Genetic Factors

Family, twin, and adoption studies indicate genetic involvement in schizophrenia. The risk of developing schizophrenia is 5 to 20 times higher in first-degree relatives of patients with schizophrenia.[55,66] Concordance rates are 40% to 60% between monozygotic twins and 5% to 15% in dizygotic twins and other siblings.[55,66] A number of genomic disorders resulting from duplication or deletion of genetic material have been associated with ID, ASD, and schizophrenia. See Table 2 for a list of medical illnesses for which symptoms can include psychosis.[67–69]

Environmental Exposure

Environmental exposure can cause direct neurologic damage or may mediate risk of future development of psychosis with new mutations or epigenetic effects.[55] Environmental exposures include exposure in utero, like maternal starvation, obesity, or infection (such as *Toxoplasma gondii*); obstetric complications (such as hypoxia, pregnancy bleeding, preeclampsia); substance exposure (marijuana, tobacco, alcohol); and advanced paternal age.[55,70–73] The effect of in utero stressors on the development of a psychotic disorder and other psychiatric disorders may be mediated by inflammation, although substances are believed to have negative effects on brain development, neurotransmitters, and cognition.[73–75] Substances that have been most studied are tobacco, alcohol, and marijuana, all of which have been associated with later development of psychosis in offspring exposed in utero.[75–77]

Trauma

Childhood trauma experienced from 0 to 17 years of age, including emotional neglect, physical abuse, sexual abuse, emotional abuse, domestic violence, or bullying, increase the odds of psychotic experiences at 18 years or older.[78] Exposure to more than 1 type of trauma or experience of repeated trauma over multiple age periods further increase the odds of psychotic experiences.[78] Evidence suggests adverse childhood experiences can interact with genetic risk factors to contribute to the development of psychotic disorders or other psychiatric disorders. In a recent review of trauma and stressful life events in a population at high risk for psychosis, up to 80% of adolescents

TABLE 2 Medical Causes Associated With Psychotic Episodes

Causes	Testing to Consider
Infections or fever	CBC, lumbar puncture
Viruses (HSV, HPV, HIV, CMV, measles, mumps, rubella, etc)	And serum titer, HIV ELISA/PCR
Bacteria (*Treponema pallidum*, *Mycoplasma pneumoniae*, Lyme disease, etc)	And antitreponemal IgG, serum titer, lumbar puncture
Parasitic infections (*Toxoplasma gondii*, malaria, TB)	And MRI, skin test
Encephalitis (viral, bacterial)	
Neurologic	MRI
Migraine	And history
Seizures and epilepsy	And EEG
Neoplasms	
Metabolic	CMP
Thyroid disorders	And thyroid function tests
Parathyroid disorders	And thyroid function tests, PTH
Adrenal disorders	And ACTH stimulation test, morning cortisol, CRH stim test
Beriberi	And blood and urine tests for thiamine
Electrolyte disturbances	And testing for specific electrolytes
Genetic	Genetic testing
Fragile X syndrome	And blood and urine tests
Klinefelter syndrome (47, XXY)	And urine porphyrins
Metachromatic leukodystrophy	And ceruloplasmin
Porphyria	
Prader–Willi syndrome	
Velocardiofacial syndrome (22q11.2 deletion)	
Wilson disease	And eye exam (slit lamp for Kayser-Fleischer rings)
Nutritional deficiencies	CBC, magnesium, vitamins A, D, B_1, B_3, B_{12}
Sleep disorders	Polysomnography
Narcolepsy	
Hypnopompic and hypnogogic hallucinations	
Medications	Urine toxicology
Steroids	
Stimulants	
Anticholinergics	
Drug intoxication and abuse	Urine toxicology
Hallucinogens	
Cannabis	
Ecstasy (3,4-methylenedioxymethamphetamine)	
Cocaine	
Amphetamines	
Barbiturates	
Opiates	
Toxicological causes	
Carbon monoxide poisoning	Carboxyhemoglobin
Heavy metal poisoning (eg, lead, mercury)	Physical examination, blood or urine mercury levels, lead levels

ACTH, adrenocorticotropic hormone; BMP, basic metabolic panel; CBC, complete blood cell count; CMV, cytomegalovirus; CRH, corticotropin-releasing hormone; ELISA, enzyme-linked immunosorbent assay; HPV, human papillomavirus; HSV, herpes simplex virus; IgG, immunoglobulin G; PCR; polymerase chain reaction; PTH, parathyroid hormone; TB, tuberculosis.

and young adults reported a history of childhood trauma, including bullying.[79] In adolescents and young adults with history of trauma, the overall odds of experiencing psychotic symptoms or developing a psychotic disorder range between 2.8 and 11.5.[80] A large-scale twin study in England and Wales with mental health assessments performed at 11 and 16 years of age found that bullying resulted in anxiety, mood, and conduct problems, and paranoid thoughts and cognitive disorganization persisted for 5 years.[81] Sexual trauma has the highest risk of conversion to psychosis, followed by physical trauma (eg, abuse, bullying, neglect).[79] Researchers in studies of people with CHR and FEP found both groups showed higher rates of suicide attempts and hospitalizations and generally demonstrated poorer functioning.[79] In the CHR population, there is a higher likelihood of comorbid posttraumatic stress disorder as compared with the healthy control population.

Some longitudinal studies found traumatic life experiences may predict the development of psychotic symptoms.[80–82] People presenting with psychosis who have a history of trauma have increased severity of psychotic symptoms, more frequent hospitalizations, increased number of comorbid disorders, more cognitive deficits, and increased treatment resistance.[80] In a longitudinal cohort study of a CHR population, researchers found a positive association between sexual abuse in childhood and conversion to a psychotic disorder.[83] Therefore, for patients who report a history of trauma, including physical or sexual abuse or bullying, providers may consider inquiring about any experience of psychotic symptoms.

History of trauma is associated with increased risk for future development of borderline personality disorder.[84] Borderline personality disorder can also present with psychotic-like experiences and/or psychotic symptoms and dissociative episodes. In a European study of adolescents 15 to 18 years of age, those with full threshold borderline personality disorder were more likely to experience psychotic symptoms; these symptoms predicted severity of borderline personality disorder.[85] Auditory and visual hallucinations, paranoia, and thought problems, like strange thoughts and confusion, were common and presented early in the course of the disorder. Another study suggested that borderline traits mediate the relationship between history of trauma and psychotic-like experiences in the context of high stress.[86]

Substance Use

The ingestion or use of multiple illicit substances, such as hallucinogens and stimulants, can result in psychotic experiences, although no causal link has been established. In a study of help-seeking youth, those at risk for developing a psychotic disorder had higher rates of tobacco, alcohol, and cannabis use than those individuals who were not.[87] In a study of 404 participants from the Recovery After an Initial Schizophrenia Episode–Early Treatment Program (RAISE-ETP), up to half of adolescents and young adults with FEP reported use of alcohol or cannabis within the month before starting treatment.[88] In addition, about half of this population also reported use of tobacco at the time of enrollment in RAISE-ETP. Authors found that cigarette smoking was associated with reports of more psychiatric symptoms and poorer functioning, more missed pills, and decreased quality of life. Use of alcohol was associated with decreased adherence to medication regimen, and cannabis use was related to increased severity of illness and positive symptoms of schizophrenia.[88] Other meta-analyses of observational and longitudinal studies have demonstrated that daily tobacco use is associated with increased psychosis risk as well as earlier age when psychotic symptoms begin; researchers in these studies concluded that a causal link between tobacco smoking and development of psychosis should be considered and that further studies should be performed.[89–91]

Most studies suggest a consistent association between marijuana use in adolescence and development of psychosis, and persistent use after an initial psychotic episode is associated with poorer prognoses.[92–94] There is also evidence suggesting earlier age at first marijuana use correlates with earlier age at onset of psychotic symptoms, regardless of whether or when marijuana users discontinued use; therefore, cannabis use is a preventable risk factor in psychosis.[93,95,96] There remains controversy over the level of risk for development of psychosis attributed to the use of cannabis and the level to which cannabis use can precipitate people without genetic predisposition to psychosis into illness.[92] One recent multisite study in Europe and Brazil demonstrated daily cannabis use and use of high-potency cannabis were the strongest independent predictors of having a psychotic disorder.[97] The odds of having a psychotic disorder for individuals using cannabis daily was 3.2 times higher than for those who never used cannabis ("never-users"). The odds of having a psychotic disorder in those who used high-potency cannabis versus never-users was 1.6 times higher. Because of the multiple sites and knowledge of incidence rates of psychotic disorders at those sites, researchers of this study were able to demonstrate that the association between use of cannabis and risk of psychosis varies by location depending on how and what kind of cannabis is used in that region. The authors report that in regions where cannabis is used daily and where high-potency cannabis tends to be

used more frequently, there are more cases of psychotic disorders.[97] Synthetic cannabinoids (K2, spice) can also induce psychotic symptoms.[98] Routine urine toxicology screens do not screen for synthetic cannabinoids.[99]

In a study in Denmark following patients with substance-induced psychosis, researchers found that more than 30% converted to bipolar disorder or primary psychotic disorder. In the case of cannabis-induced psychosis, almost half converted. Approximately half of those patients who transitioned to schizophrenia did so within 2 years of diagnosis. A Scottish longitudinal study reported a 15.5-year cumulative hazard rate of 17.3% for diagnosis of schizophrenia after an initial hospital admission with substance-induced psychotic disorder (including cannabis, stimulants, and alcohol). Approximately half of these patients transitioned to schizophrenia within 2 years (80% by 5 years). These studies suggest that follow-up of patients in whom substance-induced psychosis is initially diagnosed could benefit from follow-up of 2 to 5 years to optimize early intervention and mitigate negative outcomes.[100,101]

Perhaps of particular relevance to pediatricians, because they may be more likely to prescribe stimulants for children with attention-deficit/hyperactivity disorder (ADHD), researchers of a recent study using data from 2 commercial insurance claims databases compared the diagnosis of new-onset psychosis in adolescents and young adults with a diagnosis of ADHD treated with either a methylphenidate or amphetamine formulation. Although both classes of stimulants increase overall dopamine, amphetamines potently increase dopamine release from neurons (similar to neurotransmission in a primary psychotic disorder), whereas methylphenidates inhibit dopamine transport, thereby decreasing reuptake of dopamine into the presynaptic terminal.[102] In this large-scale study of adolescents and young adults with stimulant prescriptions, researchers determined that 0.1% in the methylphenidate group and 0.2% in the amphetamine group required treatment of stimulant-induced psychosis. On the basis of this study, authors determined that approximately 1 in 660 patients with ADHD who are treated with a stimulant will develop a new-onset psychosis.[102] Analyses of data from the US Food and Drug Administration (FDA) and case reports demonstrated that stimulant-induced psychotic symptoms generally did not last long and often resolved with cessation of stimulant alone.[103] Cathinones (bath salts) fall under the category of stimulants and can also induce psychosis. Cathinones do not show up on routine urine drug screens.[99]

These data indicate that substance use increases vulnerability for those who are at risk for developing psychotic symptoms.

EVALUATION OF PATIENTS WITH PSYCHOTIC-LIKE SYMPTOMS

The presentation of adolescents and young adults with psychotic-like symptoms can be varied, and a wide differential diagnosis should be considered, including psychiatric disorders, physical illness, and intoxication (see Tables 2 and 3). Pediatricians may initially encounter a patient presenting with vague feelings that something is wrong or "off," with a correlating drop in grades and/or work performance or increased isolation, which may be attributable to suspicions and mistrust of others. Patients may also present with decrease in hygiene and/or self-care, difficulty communicating or confused speech, and new-onset difficulty in concentrating. Additionally, adolescents may present with difficulty separating fantasy from reality. Early-onset schizophrenia can also present with cognitive delays. One of these symptoms merits consideration of referral to a mental health specialist for further evaluation and monitoring and therapy (eg, cognitive behavioral therapy [CBT]), and multiple symptoms warrant referral to a child and adolescent psychiatrist and a therapist. Collaboration with developmental and behavioral pediatricians should also be considered, especially in the context of ID and ASD. If symptoms are more overtly psychotic and could potentially lead to unsafe behavior with possible suicidal or homicidal ideation, pediatricians should arrange for immediate safety evaluation in a mental health facility or ED with resources to stabilize and evaluate children and adolescents with mental health problems.

Screening for psychosis with validated screens, such as the Prodromal Questionnaire–Brief, the PRIME early psychosis screen, and the Youth Psychosis At-Risk Questionnaire, can be helpful to screen for psychotic symptoms

TABLE 3 Nonschizophrenia Spectrum Psychiatric Conditions Associated With Psychotic Episodes in Children and Adolescents

Adjustment disorders
ASDs
Anxiety disorders, severe stress
Bipolar disorder
Catatonia
Delirium
Delusional disorders
Disruptive behavioral disorders
Factitious disorders
Grief or bereavement
Intellectual and/or developmental delay

Obsessive-compulsive disorder
Parasomnias
Personality disorders
Posttraumatic stress disorder, trauma-related disorders, adjustment disorders
Substance-induced psychotic disorders
Tourette's syndrome

Sources: refs 44 and 67.

regularly because they are relatively short and have high specificity. Other longer screens are mostly used in research settings, such as the Structured Interview for Prodromal Symptoms (SIPS), the gold standard for psychosis risk, and the Comprehensive Assessment of At-Risk Mental States (CAARMS), both of which are labor-intensive and require special training by the administrator of the screen.[104,105]

In the case of an adolescent presenting with an acute psychotic break, additional concerns may be relevant, and there should be consultation with a child and adolescent psychiatrist if available. Although the below recommendations and suggestions for interviewing and examination of the patient remain important, pediatricians will also likely have more concern for trauma or signs of intoxication or withdrawal. There may also be more concern for agitation. Early signs of agitation include restlessness, irritability, and inappropriate or aggressive behaviors, which could require pharmacologic interventions, such as an antipsychotic (haloperidol is often used) and/or a benzodiazepine, such as lorazepam. It is best to offer these medications orally to allow the patient to feel that he or she has some control in the situation.[106] Because of safety concerns, these patients may ultimately be admitted to psychiatric inpatient units. If other physical or medical issues are discovered and the adolescent must be hospitalized in a pediatric unit, consultation with a psychiatrist may be helpful to manage agitation.

Interviewing Patients With Psychotic Symptoms

Pediatricians should interview patients in a quiet and private setting, with as few distractions as possible. Parents and guardians may be able to provide more information and a better time line than the patient, depending on the patient's mental status. Attempting to construct a time line of symptom progression is also useful and includes asking about recent stressors or possible precipitating or exacerbating events, such as trauma in the form of physical or sexual abuse, bullying, or the loss of a loved one (or anniversary of such a loss).[55]

Although it is essential to gather history from parents or guardians, it is also important to talk alone with the adolescent. Careful attention to and documentation of the mental status of the adolescent is necessary (such as his or her presentation and hygiene, engagement, response to internal stimuli). When asking about possible psychotic symptoms, it is important for providers to normalize the symptoms if possible. Asking when these symptoms occur (when one is stressed or depressed, at night when one is alone) and how often they occur (randomly, only in stressful situations, constantly) is also helpful. In addition to asking about specific symptoms, it is helpful and important to ask reality-testing questions (testing how valid the patient's beliefs are and trying to differentiate the patient's internal experience from that of real life), which indicate how entrenched the belief is. If patients report hearing voices of others talking about them but feel that the voices could actually be their own thoughts or that there could be other explanations for the feeling that they are being watched, this would be less acutely concerning. Other important information including medical history (birth history, including age of parents, and developmental history); family psychiatric history; history of abuse or other trauma, including bullying; and history of substance use can shed light on possible risk factors and etiology. Although understanding of current symptoms is critical, it is also important to assess premorbid functioning to understand the patient's degree of change from baseline.

Pediatricians also may consider gathering collateral information from teachers, counselors, or coaches, with consent, after the initial interview to gain different perspectives on the adolescent's behavior and functioning. For example, if parents notice increased isolation and withdrawal as well as refusal to engage in regular hygiene, but the teacher states that grades continue to be good and the adolescent continues to engage in appropriate social interactions with peers (who also do not shower regularly), this might be less concerning for a prodromal presentation. See Appendix 2 for example questions.

Patients presenting with psychotic symptoms are at greater risk for suicide; therefore, it is critical to inquire about thoughts of self-harm or suicidal ideation, passive or active, with or without plan or intent. The Ask Suicide Screening Questions screening tool is helpful in determining the presence of suicidal thinking, and the Columbia-Suicide Severity Rating Scale can be used to determine the level of risk.[107,108] Patients may report command hallucinations telling them to hurt or kill themselves or others; derogatory hallucinations, such as voices that say negative things about them or put them down; or persecutory or religious delusions in which they could report feeling threatened by others or "the devil." If there are concerns for safety to self or others, it is important for providers to refer immediately to the ED for evaluation and to ensure safe transportation. Other concerning symptoms that warrant referral to the ED include severe impairment in functioning, such as lack of self-care (eg, severe weight loss because of worry that the food is being poisoned) or complete isolation (eg, refusal to leave the room or home because of a belief that others will place thoughts in their

heads). If there are no acute safety concerns but symptoms seem to be fully psychotic rather than attenuated, the patient is unable to come up with alternative explanations to delusions, the patient appears to be in distress, and/or functioning is affected, the pediatrician should refer the patient to a child and adolescent psychiatrist.

Physical Examination

When a patient presents with psychotic-like symptoms, providers should perform a thorough physical examination with a detailed neurologic examination to exclude medical etiologies. Focal neurologic findings may warrant urgent consultation with neurology and may require additional evaluation such as EEG and brain imaging. Hallucinations that are primarily gustatory or olfactory can be suggestive of organic causes, such as seizure disorder or tumor,[109] although a more recent study suggests tactile, olfactory, and gustatory hallucinations are actually common in primary psychotic disorders and not necessarily indicative of organic brain disease.[110] Authors also found an association of tactile, olfactory, and gustatory hallucinations with earlier age of onset with psychosis.[110] Hallucinations associated with headaches warrant referral to a neurologist as well.[44]

Laboratory and Imaging Studies

Pediatricians may consider the following laboratory tests: complete blood cell count, comprehensive metabolic panel (including glucose, serum urea nitrogen/creatinine, liver function tests), thyroid-stimulating hormone, calcium and phosphorus, ceruloplasmin (to evaluate for Wilson disease), antinuclear antibodies, erythrocyte sedimentation rate, syphilis screening, HIV screening, vitamin B_{12} and folate concentrations, and urinalysis and urine toxicology.[111] Testing levels of heavy metals may also be considered if clinically indicated. Testing for copy number variants in patients with psychosis may be considered when there is suspicion for a genetic syndrome.[112] See Table 2 for a list of medical illnesses, the symptoms of which can include psychosis, and recommended testing.[67–69]

There is limited evidence supporting imaging studies for patients who do not present with associated focal neurologic signs, although it may be helpful in those with a history of head trauma.[30] Patients with positive antinuclear antibody titers should be referred to pediatric rheumatology, and neuroimaging studies should be performed for evaluation of possible lupus cerebritis.[113] The American College of Radiology appropriateness criteria of evidence-based imaging guidelines for specific clinical presentations suggest that MRI or a computed tomographic scan may be appropriate initially in new-onset psychosis but that the yield of brain imaging for psychosis onset was low unless there was an evident neurologic deficit.[114]

There is also insufficient evidence to routinely perform EEG. However, in a patient presenting with FEP who has a history of a seizure disorder, EEG may rule out the possibility of ictal or interictal psychosis.[111,115] Some studies support prognostic, rather than diagnostic, implications of EEG, with abnormal EEG findings reflecting poorer prognosis.[116]

WHEN TO REFER TO SPECIALTY CARE OR ED

As noted previously, if attenuated symptoms worsen or become fully psychotic, pediatricians should refer patients for psychiatric care. If there are any concerns for safety, such as suicidal thoughts, self-harming thoughts or behaviors, or homicidal ideations because of suspicion of others, the pediatrician should immediately refer the patient to the ED or other mental health facility with means to evaluate and stabilize the patient or summon an ambulance for emergency transport to the ED depending on acuity of safety concerns. Although providers should maintain confidentiality for many mental health care concerns, in the event of concerns for danger, such as suicidal or homicidal ideation, abuse, or disorganization that is so severe that basic functioning is lost (such as not eating, drinking, or sleeping), providers must breach confidentiality to protect the minor patient and others from harm and document that they are doing so. If a patient reports symptoms that are not potentially dangerous and do not seem to affect functioning, these can be kept confidential between the patient and the treating physician and documented in a confidential section of the electronic medical record if available. The physician is advised to use his or her clinical judgment with regard to confidentiality and may encourage the patient to discuss these issues with the parent or guardian (even offering to be present during the discussion to lend support). In the case of a young adult, over 18 years, who has capacity and who presents with a parent or guardian, the clinician is able and encouraged to gather collateral information; however, the clinician cannot share confidential information with the family unless the patient asks him or her to do so. If a patient is considered a danger to self or others or is not able to conduct basic activities of daily living because of the severity of symptoms and needs to be psychiatrically hospitalized, the parent or guardian cannot be told unless the patient asks specifically that this be done or the parent has guardianship.

If a patient is at imminent risk to the safety of himself or herself or others or deemed unsafe or unwilling to engage in care, emergency medical services or police transport is

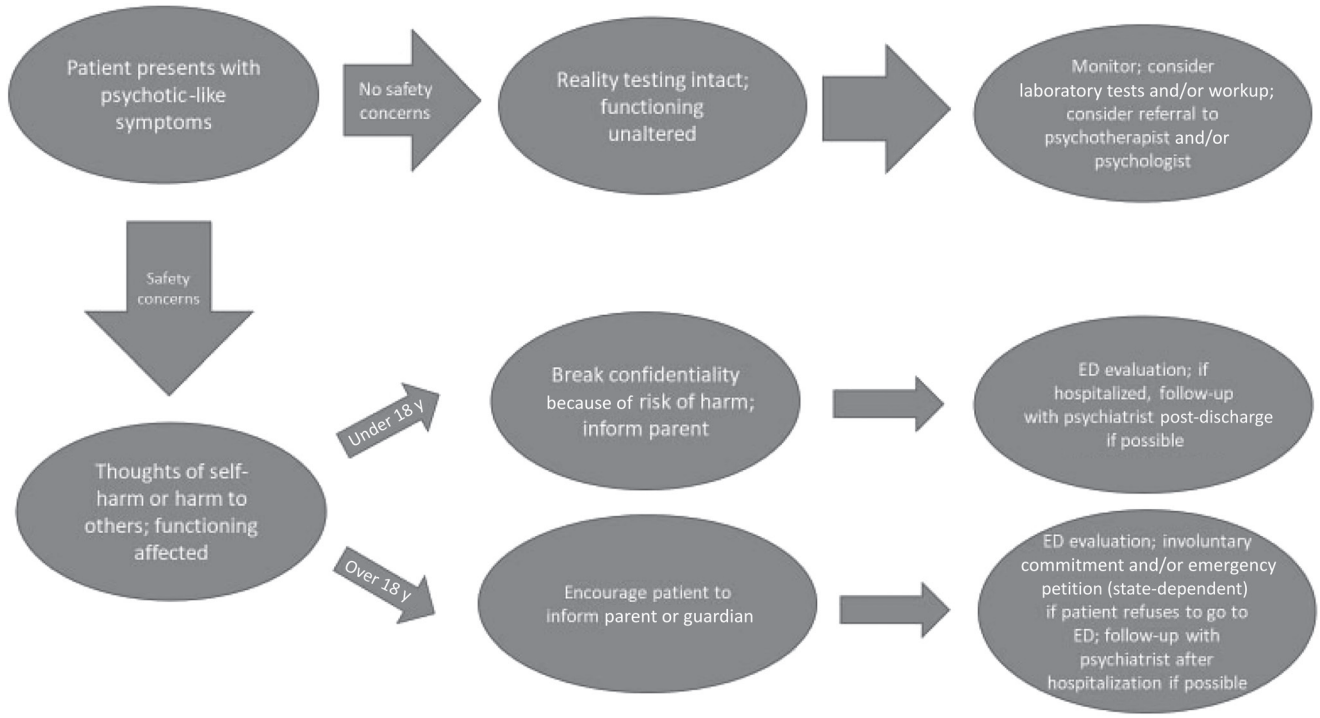

FIGURE 1
Basic algorithm to determine next steps when a patient presents with psychotic-like symptoms.

advised, and referral communication to the ED is recommended. Some states have special procedures to mandate transfer, as well as documents that may accompany patients to indicate the pediatrician's assessment that the patient needs emergency evaluation. Providing this documentation to the guardian who takes the patient to the ED may improve the likelihood of psychiatric hospitalization. States have varying legal requirements for involuntary evaluation and/or treatment of patients, and pediatricians are advised to consult their state department of health Web sites to determine the relevant mental health laws of their state. Although collaboration with a psychiatrist on appropriateness of transfer would be ideal, this is not always possible given the shortage of child psychiatrists. Therefore, in acute situations in which safety is a concern, a pediatrician should feel justified in sending a patient directly to the ED with the guardian if guardian is cognizant of the urgency of the situation and will take the patient to the ED or call 911 to transport the patient. See Fig 1 for consideration of monitoring, breaking confidentiality, and transport to ED for emergency evaluation.

TREATMENT

Pediatricians may be the first providers to assess and identify psychotic-like symptoms. Because visits to the pediatrician may decrease in adolescence, pediatricians should be vigilant in assessing for mental health concerns and changes in functioning or unusual beliefs.[117] Because adolescence can be a difficult time for youth and parents alike, addressing stressors at home and in the environment can be beneficial for all adolescents, including those manifesting psychotic-like symptoms. Recommendations to spend more time in familiar settings among family members and/or close friends can be helpful. Helping the patient to obtain educational or career supports and appropriate psychiatric care earlier may decrease DUP and improve outcomes. In a study of patients presenting with psychotic symptoms associated with a nonpsychotic primary disorder, enhancement of coping skills was associated with improved outcomes.[5]

NAPLS provides a relatively new concept of "clinical staging" for psychotic disorders that may help determine treatment at different levels of presentation and symptom manifestation. Patients presenting with less severe symptoms and/or risk factors receive psychosocial treatments initially, and individuals with increased severity of symptoms and/or more risk factors receive pharmacotherapy in addition to psychosocial treatments.[118] Once a pediatrician identifies psychotic symptoms in an adolescent, it is likely that a referral to a mental health provider will result. Below are the

current treatment modalities for psychotic disorders.

CBT

CBT is an evidence-based treatment of patients presenting with psychotic-like symptoms. CBT aims to lower distress and disability through working with delusions, hallucinations, and negative symptoms, using the "ABC method" (activating event leading to an automatic thought, which in turn affects affect and behavior). CBT aims to derive alternative explanations for the patient's psychotic symptoms that are acceptable to the patient and the therapist and to decrease the patient's distress from the symptom(s).[119,120] In a systematic review and meta-analysis, researchers found CBT lowered the risk of progression to psychosis at 6, 12, and 18 to 24 months and decreased symptoms at 12 months.[121] Authors of a more recent meta-analysis found that CBT resulted in a trend toward significant reduction of attenuated psychotic symptoms at 12 months.[122] In the Dutch Early Detection Intervention Evaluation Trial, authors studied people at "ultrahigh risk" of psychosis who received CBT in addition to routine care compared with a control group with routine care only. CBT plus routine care demonstrated averted transition to psychosis and reduced costs.[123] In addition, the National Institute for Health and Care Excellence recommends CBT with or without family therapy for patients presenting with attenuated psychotic symptoms.[124]

CBT in early psychosis has also revealed some benefit as a stand-alone treatment of psychosis, although most studies have been conducted with CBT in combination with antipsychotic medication treatment. CBT may be more acceptable to patients because of its lower side effect profile and decreased stigma; in addition, discontinuation of CBT is less common than discontinuation of treatment with antipsychotic medications.[125–127]

Other Psychosocial Interventions

Aside from CBT, family-focused interventions, social skills training, supported education and employment, and healthy lifestyle training are early interventions that can be helpful for CHR patients.[128] Family interventions include family psychoeducation and improving communication between family members. In a meta-analysis, family therapy was found to show a nonsignificant trend toward decreasing attenuated psychotic symptoms at 6 months.[122] Because impairment in social skills can be associated with difficulty making friends, bullying, and poor occupational functioning, social skills training can involve role playing as well as practicing specific social skills to improve interpersonal skills.[128] CHR youth may be at higher risk for academic difficulties, so they may benefit from special education services, such as a 504 or individualized education program. Increased resources and appropriate accommodations can help these youth feel successful. In addition, supported employment can be helpful for patients at CHR, who may have trouble finding and maintaining jobs. Healthy lifestyle interventions include emphasis on proper nutrition, physical activity, getting enough sleep, managing stress, and not engaging in behaviors like smoking, substance use, and risky sexual practices.[128]

The Schizophrenia Patient Outcomes Research Team psychosocial treatment recommendations, which report evidence-based psychosocial treatments for people with schizophrenia, include assertive community treatment, supported employment, skills training, CBT, token economy interventions (positive reinforcement for target behaviors), family-based services, psychosocial interventions for alcohol and substance use disorders, and psychosocial intervention for weight management.[129] Correll et al[130] reported that early intervention services were superior to treatment as usual in FEP.

Medications

Initiating medication for the treatment of psychotic symptoms is generally out of the scope of pediatricians. However, limited access to mental health specialists may necessitate prescribing in some circumstances, ideally with consultation from a child and adolescent psychiatrist or developmental-behavioral pediatrician.

Several antipsychotic medications may alleviate psychotic symptoms if the symptoms are caused by a primary psychotic disorder (see Tables 4 and 5), although it is important to mention that ziprasidone and asenapine failed to separate from placebo in treatment of adolescents with schizophrenia.[131,132] When selecting an antipsychotic medication, those with FDA approval should be considered first. Other factors that may help guide the choice of treatment include side effect profile, patient and family preference, cost, insurance coverage, and availability of the medication.[133]

If psychotic symptoms are caused by another psychiatric disorder, the primary disorder (such as depression, bipolar disorder, or anxiety) should be treated first, unless the psychotic symptoms are so severe that brief treatment with an antipsychotic medication concurrently with a medication to treat the primary disorder should be considered. Given the adverse effects associated with antipsychotic medications, great care and consideration are advised before prescribing these medications.

TABLE 4 Commonly Used Antipsychotic Medications and Adverse Effects

	Akathisia	TD	Sedation	Anticholinergic Side Effects	Orthostatic Hypotension	Wt Gain	Dyslipidemia	Hyperglycemia	Prolactin Elevation	QTc Prolongation
First generation										
Chlorpromazine	Mild	Moderate	Moderate	Moderate	Moderate	Severe	Severe	Severe	Mild	Minimal
Haloperidol	Severe	Moderate	Mild	None	None	Mild	Minimal	Minimal	Moderate	Minimal
Second generation (atypical)										
Aripiprazole	Moderate	Minimal	Minimal	None	Minimal	Minimal	Minimal	Minimal	None	Minimal
Clozapine	Mild	None	Severe	Severe	Moderate	Severe	Severe	Severe	Mild	Moderate
Lurasidone	Mild to moderate	Minimal	Mild to moderate	None	Minimal	Minimal	Minimal	Minimal	Mild	Minimal
Olanzapine	Mild	Minimal	Mild to moderate	Moderate	Mild	Severe	Severe	Severe	Mild to Moderate	Minimal
Paliperidone	Mild	Minimal	Minimal	None	Mild	Moderate	Mild	Mild	Severe	Mild
Quetiapine	Mild to moderate	Minimal	Moderate	Mild to moderate	Moderate	Moderate	Moderate	Moderate	None	Mild
Risperidone	Mild	Minimal	Mild	None	Mild	Moderate	Mild	Mild	Severe	Mild
Ziprasidone	Mild to moderate	Minimal	Mild	None	None	Minimal	Minimal	Minimal	Mild	Moderate

Sources: 151 and 152. TD, tardive dyskinesia.

With regard to dosing, the mantra is to "start low, and go slow," always monitoring for adverse effects. Generally, lower doses should be effective in patients with FEP.[111] A meta-analysis and pooled data from 7 randomized controlled trials indicate an observable response usually within 2 weeks and that the initial improvement (in 2 weeks) is greater than in the subsequent 2 weeks.[134,135] See Table 4 for a list of antipsychotic medications and side effects and Table 5 for dose ranges and FDA approval for children and adolescents.

There have been trials comparing efficacy of first-generation and second-generation antipsychotic medications, including the Clinical Antipsychotic Trials of Intervention Effectiveness and European First Episode Schizophrenia Trial. Researchers in these studies did not find significant differences among efficacy of these antipsychotics but did find different side effect profiles, which influenced time to discontinuation.[136,137]

There are 2 main treatment studies of adolescents and young adults with schizophrenia. Researchers in the Treatment of Early-Onset Schizophrenia Symptoms (TEOSS) study compared the efficacy of first-generation or atypical (second generation) antipsychotic medications on early-onset schizophrenia and schizoaffective disorder because providers were prescribing more atypical antipsychotics because of better efficacy and tolerability, although there was no clear evidence of this.[138,139] The study included patients between 8 and 19 years of age receiving risperidone, olanzapine (both atypical antipsychotics), or molindone (first-generation antipsychotic). The 3 medications had similar efficacy (50% treatment response), but adverse effect profiles differed.[138] Molindone was associated with

TABLE 5 Second-Generation Antipsychotic Medications: FDA Approval and Dose Ranges for Adolescents With Schizophrenia

	FDA Approval	Recommended Dose	Starting Dose	Maximum Dose, mg
Aripiprazole	Schizophrenia: ≥13 y	10 mg	2 mg	30
Lurasidone	Schizophrenia: ≥13 y	40–80 mg	20 mg	80
Olanzapine	Schizophrenia: ≥13 y	10 mg	2.5 mg	20
Paliperidone	Schizophrenia: ≥12 y	Wt <51 kg: 3–6 mg	3 mg	6
	Schizophrenia: ≥12 y	Wt >51 kg: 3–12 mg	3 mg	12
Quetiapine	Schizophrenia: ≥13 y	400–800 mg/d	25 mg to 25 mg BID	800
Risperidone	Schizophrenia: ≥13 y	0.5–6 mg/d	0.25–0.5 mg	6

akathisia, an inner feeling of restlessness that compels people to be in motion; olanzapine and risperidone were associated with weight gain and metabolic changes. Risperidone also caused increase of prolactin levels.[138]

The National Institute of Mental Health Recovery After Initial Schizophrenia Episode (RA1SE) study of participants 15 to 25 or 30 years of age aimed to develop and implement integrated treatment protocols in FEP. The treatment program is NAVIGATE, named as such to support and guide patients and their families through the experience of FEP toward recovery.[140] NAVIGATE is a team-based comprehensive, multidisciplinary treatment program designed for implementation in community mental health facilities. Treatment interventions include individualized medication treatment (shared decision-making), family education program, individual resiliency training, and supported education and employment.[141,142] Coordinated specialty care with these components is now considered evidence-based care in treatment of early-onset psychosis and is tightly coordinated with primary medical care to optimize both mental and physical health. In a comparison of NAVIGATE and usual community care, NAVIGATE participants continued treatment of longer periods of time, had more improvement in symptoms and quality of life, and were more involved in school and work over a period of 2 years.[141] Patients also had fewer adverse effects and were less depressed.[143] Patients with shorter DUP seemed to benefit more from NAVIGATE than those with longer DUP.[141]

Adverse Effects of Antipsychotic Medications and Recommended Monitoring

The pediatrician may be asked to evaluate a patient with medical symptoms that could be related to antipsychotic medication. Moreover, because of geographic limitations and cost concerns, families may rely on the pediatrician in the medical home to work collaboratively with the psychiatrist to monitor for certain side effects of antipsychotic medications. Adverse effects of antipsychotic medications include extrapyramidal symptoms, weight gain, impaired glucose metabolism, increased lipid concentrations, increased prolactin concentrations (leading to menstruation irregularities and galactorrhea), increased QTc interval, and sedation. Extrapyramidal symptoms include bradykinesia (decreased movement), akathisia, tremor, muscle rigidity, dystonia (intermittent or sustained muscle contractions), and tardive dyskinesia (involuntary and repetitive athetoid or choreiform movements of the body, lasting at least a few weeks).[144,145] Tardive dyskinesia can develop in association with the use of a neuroleptic medication for at least a few months and can persist beyond 4 to 8 weeks[1] (see Table 4).

The American Academy of Child and Adolescent Psychiatry practice parameter provides guidelines on metabolic monitoring for pediatric patients receiving antipsychotics, as second-generation antipsychotics are more likely to increase risk of metabolic syndrome, with increased waist circumference and blood pressure as well as hypertriglyceridemia, hyperglycemia, and low high-density lipoprotein ("good cholesterol") concentration.[144,146,147] The guideline recommends baseline measurement of BMI, waist circumference, fasting blood glucose concentration, hemoglobin A1c, and fasting lipid concentrations. Additionally, monitoring includes BMI and waist circumference monthly for the first 3 months, at 6 months, and then yearly, unless there is a change in medication dose (in which case more frequent measurements should be made until dose stabilization). The guidance recommends measuring fasting glucose concentration, lipid concentrations, and hemoglobin A1c at 3 months and then yearly.[146,147] Providers may consider more frequent monitoring of children and adolescents.

Neuroleptic malignant syndrome (NMS) is a rare but life-threatening adverse effect of treatment with antipsychotic medications caused by excessive dopamine blockade. Symptoms include "lead-pipe" muscle rigidity, fever, autonomic dysfunction, and altered mental status. NMS is mostly likely to occur within hours to days of taking the medication, with the most common laboratory finding of elevated creatine concentrations of 1000 μg/L.[148] Initial management of NMS includes cessation of the causative drug and supportive medical care. Severe NMS may require treatment with bromocriptine

mesylate, which is a dopamine agonist, and dantrolene sodium, a muscle relaxant.[148] If pediatricians detect potential NMS symptoms, it is important that the patient receive immediate assessment and treatment, because it is a potentially fatal emergency.[149]

AVOIDING MISDIAGNOSIS AND UNNECESSARY TREATMENT

Encountering a patient with psychotic-like or frank psychotic symptoms may be unsettling to pediatricians, who may have limited experience with mental health disorders. Psychotic-like symptoms can be frightening and debilitating, often fueling the pressure to treat with medication. Although data have shown an improved prognosis for shorter DUP, these data do not suggest that all psychotic symptoms should be treated with antipsychotic medication.

Pediatricians should proceed cautiously and thoughtfully with their evaluation, keeping a broad differential diagnosis in mind and attending to possible safety concerns. Because presentation of psychotic-like or frank psychotic symptoms can be complex, consultation with a child psychiatrist is generally warranted to avoid misdiagnosis and unnecessary treatment with antipsychotic medications. Additionally, we advise caution before making a diagnosis of unspecified psychotic disorder or any other psychotic disorder because these diagnoses often persist and may unnecessarily stigmatize patients.

RESOURCES FOR PEDIATRICIANS

Because of the shortage of child psychiatrists, there are resources within states that allow "live, real-time" consultations with child and adolescent psychiatrists in the area. Programs across the nation consisting of telephone or video consultations with a range of mental health providers are excellent resources that can guide diagnosis and treatment. These programs are free to primary care physicians, sometimes only within a certain geographic area, and are often funded by the state department of health.[150] Pediatricians can generally call the number for the program and undergo an orientation before beginning use of the telephone consult and, in some cases, telepsychiatry or physical consultation services. Some programs are open only to patients with medical assistance (Medicaid). Other programs not only offer consultation services but also offer training programs or continuing medical education opportunities to primary care physicians on the assessment and management of mental health issues. In some programs, if phone consultations are insufficient, pediatricians can schedule in-person evaluations within a few days of the phone consultation, which may be especially helpful to those practicing in remote or more rural areas where there are few to no child psychiatric providers. Other helpful resources for pediatricians are listed in Appendix 3. The resources include a link for coding recommendations, including new collaborative care codes used in the Psychiatric Collaborative Care Model, with a primary treating practitioner collaborating with a behavioral health care manager and a psychiatric consultant.

CONCLUSIONS

Psychotic symptoms can be frightening and confusing for patients, caregivers, and providers. Pediatric providers are unique in that they may be the first providers to observe attenuated psychotic symptoms or the first providers parents and guardians turn to if they observe such symptoms in their children. Understanding risk factors and symptoms to evaluate in patients who present with attenuated or psychotic symptoms is helpful in the evaluation of these youth and direct intervention, treatment, and referral, as early intervention can improve prognosis and level of functioning.

ADVICE FOR PEDIATRICIANS

1. In patients who present with psychotic-like or full psychotic symptoms, follow-up questions to better characterize the patient's presentation and disposition are helpful.
2. In patients presenting with psychotic-like experiences, pediatricians should evaluate for history of trauma, including sexual, physical, or emotional abuse, neglect, and bullying; substance use; and developmental delays.
3. Clinical interview, comprehensive physical examination including neurologic examination, laboratory studies, and imaging (when clinically indicated) may be helpful in determining an underlying cause of psychotic symptoms.
4. Pediatricians should facilitate referrals to specialists (therapist, psychologist, or child and adolescent psychiatrist or general psychiatrist) according to severity of symptoms. Consultation with psychiatry, if available, can be helpful in ensuring that the appropriate referrals are made. For those with ID or ASD, referral to a developmental-behavioral pediatrician should be considered as well. The medical home model can be helpful in coordinating care and supporting the patient and family as they navigate the mental health system.
5. Screening for suicidal thoughts is an essential component of the evaluation process because psychosis is associated with increased suicidal ideation; if there are suicidal thoughts or thoughts to hurt others, the patient should be transported immediately to the ED for evaluation. Severe decrease in functioning, such as inability to

care for or feed oneself, may also warrant ED evaluation.

6. The time between presentation of attenuated psychotic symptoms and full-blown psychosis is a critical time for monitoring and early intervention. Collaboration with psychiatry can assist in the determination of whether monitoring or referral to another provider would be appropriate. Although care to avoid premature diagnosis of a psychotic disorder is important, evidence shows that minimizing the DUP mitigates symptoms and improves prognosis.
7. Researchers have found that multidisciplinary coordinated specialty care consisting of medication treatment (where indicated), family education, individual resiliency training, and supported education and employment is beneficial in FEP. Patients should be referred to such resources where available, and continued funding and expansion of such programs should be supported.
8. When starting antipsychotic medication, "start low and go slow" and provide regular monitoring for adverse effects. Pediatricians would generally not be expected to initiate antipsychotic medications. However, in some circumstances (eg, severe symptoms that do not meet inpatient criteria in the setting of limited access to mental health care), it may be appropriate for the pediatrician to start or manage a medication while awaiting subspecialty care, ideally with ongoing consultation with a child psychiatrist.
9. In some states, free, state-funded services with telephone, and sometimes in-person, consultations with child and adolescent psychiatrists are available. These programs can be helpful in supporting pediatricians to extend their mental health expertise and should be used where available. Expansion of these programs and continued funding support for them are encouraged.

APPENDIX 1: CASE VIGNETTES

Primary Psychotic Disorder

A 14-year-old patient presented with derogatory auditory hallucinations as well as visual hallucinations of eyes watching him. He had a history of declining grades, social relationships, and self-care. He described a recent visit to the ED after smoking cannabis that he believed may have been laced with something. He believed that he died or fell into a coma after that experience and that nothing is real now. When asked if there could be any other possible explanation, the patient replied that it could be aliens. The patient admitted that he was terrified by these thoughts and contemplated suicide, although part of him believed that he would not actually die if he tried to kill himself, because nothing was real. Because of the patient's level of distress, delusions, and loss of reality testing, he was believed to be in real danger of harm to himself and/or others. He was transported to the ED for further evaluation and safety assessment.

Mood Disorder With Psychotic Features

A 15-year-old, high-achieving patient presented with delusions and auditory hallucinations that peers were talking about her. She believed that her parents were poisoning her food and telling peers about her weaknesses and vulnerabilities to use them against her. Her parents reported that she had been staying up late doing homework and sleeping only 1 to 2 hours a night, with associated racing thoughts, pressured speech, poor concentration, and inability to complete the many tasks she started. Because of the paranoid delusions and effect on her functioning, the patient was transferred to the ED. As part of the evaluation, no suicidal or homicidal ideations were noted, and the parents believed that they could ensure her safety. The patient was discharged from the hospital and referred to a child and adolescent psychiatrist, who ultimately diagnosed the patient with bipolar disorder, type I, severe with psychotic features, most recent episode manic. She was started on an atypical antipsychotic medication initially because of the severity of psychotic symptoms, as a mood stabilizer was slowly titrated to therapeutic level. She also began therapy. When the psychotic symptoms resolved, she returned to school and did well. At that time, her provider slowly discontinued the antipsychotic medication, and she remained on a mood stabilizer. She graduated from high school and went on to college.

Anxiety

A 16-year-old presented with hallucinations of people talking about her and making derogatory comments. She had previously done well but was now unwilling to leave her home because of severe anxiety attacks. The patient was referred to a child and adolescent psychiatrist as well as a psychotherapist. She eventually received a diagnosis of social anxiety disorder and was treated with a selective serotonin reuptake inhibitor (SSRI). She was able to return to school, and social relationships gradually resumed. After a period of stability, the patient returned to her pediatrician to manage her medication but continued to see a therapist.

Obsessive-Compulsive Disorder

A 17-year-old patient presented with intrusive sexual thoughts about her father and friends and worried that people and objects were dirty if they accidentally rubbed against her genitalia. She also expressed fears

APPENDIX 2 Examples of Questions to Ask When Interviewing Adolescents About Psychotic-Like Experiences

Sometimes when people get very, very sad or very, very worried, they may feel like they are hearing voices that other people do not hear. Has this ever happened to you?
Sometimes when people get very, very sad or very, very worried, they may feel like they are seeing things that other people do not see. Has this ever happened to you?
Have you ever felt like people are watching you?
Have you ever felt like people are trying to hurt you or are out to get you?
Have you ever felt like something was putting thoughts into your mind or controlling your thoughts?
Do you sometimes feel that you are getting special messages from the television or a video game?
Do you hear voices/see things when you are sad? Angry? Frightened?
Does anything make the voices/visions/thoughts better or worse?
Do they only occur at certain times of the day or all the time?
Does this (do these) symptom(s) bother you?
If patients report experiencing these symptoms, it is also important to ask reality-testing questions, such as:
Is it possible that your eyes are playing tricks on you?
Is it possible that people are not really talking about you?
Is there another possible explanation?

that she was homosexual when she thought another girl was attractive and would perseverate on this belief for hours to anyone who would listen at home. The patient was devoutly Catholic and feared that having these thoughts meant she was evil and deserved to die, although the thought of doing harm to herself was frightening to her. She began to pray multiple times a day to rid herself of these thoughts. Her pediatrician referred her to a psychologist, who referred her to a psychiatrist while continuing to work with her in therapy. With a combination of intensive CBT and an SSRI, the patient was able to overcome the obsessive thoughts and compulsions. Although she would sometimes still have them, she was able to tell herself that her mind was playing "tricks" on her and challenge these thoughts. She ultimately returned to her pediatrician for management of the SSRI and continued to have "booster" CBT sessions with the psychologist as needed.

ASD

A 14-year-old patient presented with auditory hallucinations consisting of multiple characters in a fantasy world he had created from a young age. He would often isolate himself to immerse himself in this fantasy world, which he preferred to "real life." He had endured years of bullying and had no friends but was able to maintain good grades at school. The parents reported poor peer relationships and better social interactions with adults and younger children. He was obese, which correlated with multiple trials of antipsychotic medications, all of which had been stopped because of reported lack of efficacy. Because of concerns about impaired social interactions and restricted interests, the pediatrician referred the patient to a developmental-behavioral pediatrician for evaluation. After a thorough evaluation, the patient received a diagnosis of ASD. Genetic testing was completed and the result was negative. The developmental pediatrician recommended slow discontinuation of the antipsychotic medication because it became clear that the fantasy characters were a manifestation of ASD and caused no distress; in fact, they served as a coping mechanism against the challenges of real life. He began to participate in psychotherapy and a social skills group. Insight into his diagnosis and improved social interactions developed over time.

ID

A 13-year-old patient reported in a childlike sing-song voice that her mood was happy but that she would often see a shadow figure at night and sometimes visions of a little girl who wanted to give her flowers. She stated that her parents had been telling her she should pray whenever these figures would come, which she would always do. She had an individualized education plan, and past neuropsychological testing indicated low IQ. The pediatrician recommended follow-up in 2 weeks to determine if the visual

hallucinations or perceptions were distressing to the patient and whether the symptoms warranted a referral to a mental health specialist. At the 2-week follow-up, the patient began stating that these figures were becoming increasingly frightening, causing trouble sleeping, school refusal, and mood changes. The pediatrician referred her to a child psychiatrist for further assessment. Although the psychiatrist felt strongly that ID and possibly ASD were playing a large role in the patient's presentation, the child's report of distress and subsequent reports of hearing "terrifying" screaming while in school indicated need for medication initiation.

Cultural and Family Beliefs

A 15-year-old patient in treatment for ADHD for several years suddenly confessed to seeing ghosts in his room and feeling them touch him at times. He reported that these ghosts terrified him, so he had taken to wearing crosses, which he believed protected him. When the pediatrician asked if he had told anyone about these ghosts, he reported he had told his mother and father, both of whom also see ghosts. He stated that the ghosts were worse in his parents' home, although he also felt the presence of different ghosts at his aunt's home. Grades continued to be average, and he continued to have appropriate social interactions with peers at school. The provider routinely asked about these ghosts, as well as the patient's functioning, at every follow-up visit but ultimately determined the patient's reports to be associated with family beliefs or superstitions and provided no additional medications or referrals.

Trauma

A 16-year-old female adolescent confidentially told her adolescent medicine provider that she had been sexually assaulted at a party about a month ago and that since then, she was "paranoid" whenever she went out that someone was going to hurt her. If it was dark when she returned home from a school activity or work, she would constantly think that she was hearing footsteps behind her and seeing shadowy figures following her. The pediatrician asked about how she was doing at school, and the patient replied that although her concentration was decreased because of anxiety and flashbacks, she was maintaining good grades and was still managing to function at work. The pediatrician suggested seeing a therapist about the trauma that had occurred but held off on referral to a psychiatrist; he also increased frequency of follow-up visits for a few months, during which he monitored the status of the flashbacks and hyperarousal. With the help of the therapist, who used a combination of trauma-focused CBT and dialectical behavioral therapy techniques to treat the patient, these symptoms steadily decreased without need for medication.

Adverse Effect to Medication

A 7-year-old child with a history of ADHD, combined type, returned to his pediatrician's office 2 weeks after starting a stimulant medication to help with school functioning. The parents expressed concern that the child reported seeing faces and feeling like insects were crawling on his skin. Knowing that psychotic symptoms were a rare adverse effect of stimulant treatment, the pediatrician stopped the medication. Symptoms quickly resolved.

Temporal Lobe Epilepsy

A 19-year-old young adult with no psychiatric history presented with delusions of being dirty and thinking she could not clean herself or rid herself of a foul stench. She also reported the taste of peppermint. Because of the olfactory and gustatory hallucinations, a computed tomographic scan of the head and an EEG were performed. The EEG revealed abnormal brain wave activity, and the pediatrician referred the patient to a neurologist.

LEAD AUTHOR

Liwei L. Hua, MD, PhD

COMMITTEE ON ADOLESCENCE, 2019–2020

Elizabeth M. Alderman, MD, FSAHM, FAAP, Chairperson
Richard J. Chung, MD, FAAP
Laura K. Grubb, MD, MPH, FAAP
Janet Lee, MD, FAAP
Makia E. Powers, MD, MPH, FAAP
Krishna K. Upadhya, MD, FAAP
Stephenie B. Wallace, MD, MSPH, FAAP

PAST COMMITTEE MEMBER

Cora C. Breuner, MD, MPH, FAAP, Former Chairperson

LIAISONS

Liwei L. Hua, MD, PhD – *American Academy of Child and Adolescent Psychiatry*
Ellie Vyver, MD – *Canadian Pediatric Society*
Anne-Maria Amies, MD – *American College of Obstetricians and Gynecologists*
Seema Menon, MD – *North American Society of Pediatric and Adolescent Gynecology*
Lauren B. Zapata, PhD, MSPH – *Centers for Disease Control and Prevention*

STAFF

Karen Smith
James Baumberger, MPP

ABBREVIATIONS

ADHD: attention-deficit/hyperactivity disorder
ASD: autism spectrum disorder
CBT: cognitive behavioral therapy
CHR: clinical high risk
DSM-5: *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition*
DUP: duration of untreated psychosis
ED: emergency department
FDA: US Food and Drug Administration
FEP: first-episode psychosis
ID: intellectual disability
NAPLS: North American Prodrome Longitudinal Study
NMS: neuroleptic malignant syndrome
SSRI: selective serotonin reuptake inhibitor

FUNDING: No external funding.

POTENTIAL CONFLICT OF INTEREST: The authors have indicated they have no potential conflicts of interest to disclose.

COVID-19 Vaccines in Children and Adolescents

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

COVID-19 Vaccines in Children and Adolescents

Committee on Infectious Diseases

Vaccines are safe and effective in protecting individuals and populations against infectious diseases. New vaccines are evaluated by a long-standing, rigorous, and transparent process through the US Food and Drug Administration and the Centers for Disease Control and Prevention (CDC), by which safety and efficacy data are reviewed before authorization and recommendation.

RECOMMENDATIONS

The American Academy of Pediatrics (AAP) recommends the following related to coronavirus disease 2019 (COVID-19) vaccine in children and adolescents:

- The AAP recommends COVID-19 vaccination for all children and adolescents 12 years of age and older who do not have contraindications using a COVID-19 vaccine authorized for use for their age.
- Any COVID-19 vaccine authorized through Emergency Use Authorization by the US Food and Drug Administration, recommended by the CDC, and appropriate by age and health status can be used for COVID-19 vaccination in children and adolescents.
- Given the importance of routine vaccination and the need for rapid uptake of COVID-19 vaccines, the AAP supports coadministration of routine childhood and adolescent immunizations with COVID-19 vaccines (or vaccination in the days before or after) for children and adolescents who are behind on or due for immunizations (based on the CDC and AAP Recommended Child and Adolescent Immunization Schedule) and/or at increased risk from vaccine-preventable diseases.

Early Childhood Caries in Indigenous Communities

Steve Holve, MD,[a] Patricia Braun, MD, MPH,[b,c] James D. Irvine, MD,[d] Kristen Nadeau, MD, MS,[e] Robert J. Schroth, DMD, MSc, PhD,[f,g,h] AMERICAN ACADEMY OF PEDIATRICS COMMITTEE ON NATIVE AMERICAN CHILD HEALTH AND SECTION ON ORAL HEALTH, CANADIAN PAEDIATRIC SOCIETY FIRST NATIONS, INUIT, AND MÉTIS HEALTH COMMITTEE

abstract

The oral health of Indigenous children of Canada (First Nations, Inuit, and Métis) and the United States (American Indian and Alaska native) is a major child health disparity when compared with the general population of both countries. Early childhood caries (ECC) occurs in Indigenous children at an earlier age, with a higher prevalence, and at much greater severity than in the general population. ECC results in adverse oral health, affecting childhood health and well-being, and may result in high rates of costly surgical treatment under general anesthesia. ECC is an infectious disease that is influenced by multiple factors, but the social determinants of health are particularly important. This policy statement includes recommendations for preventive and clinical oral health care for infants, toddlers, preschool-aged children, and pregnant women by primary health care providers. It also addresses community-based health-promotion initiatives and access to dental care for Indigenous children. This policy statement encourages oral health interventions at early ages in Indigenous children, including referral to dental care for the use of sealants, interim therapeutic restorations, and silver diamine fluoride. Further community-based research on the microbiology, epidemiology, prevention, and management of ECC in Indigenous communities is also needed to reduce the dismally high rate of caries in this population.

Early Childhood Caries in Indigenous Communities. *Pediatrics*. 2021;147(6):e2021051481

INTRODUCTION

Indigenous children of Canada (First Nations [FN], Inuit, and Métis) and the United States (American Indian and Alaska native [AI/AN]) face significant health disparities compared with non-Indigenous populations. The oral health disparities Indigenous children experience exemplify the inequities and major need for oral health promotion, caries prevention, and early, locally available dental care services for them. Although general guidelines on oral health promotion, caries prevention, and risk assessment exist, the severity of dental disease and the barriers to care in Indigenous communities require special consideration.

Early childhood caries (ECC) is defined as tooth decay in any primary tooth in a child younger than age 6 years.[1] Also referred to as early childhood tooth decay or baby-bottle tooth decay, the term ECC better characterizes the disease as complex and involving transmission of infectious bacteria, dietary habits, and oral hygiene. ECC is an infectious disease, with *Streptococcus mutans* being the most commonly recognized causative organism. The causative triad for caries includes cariogenic bacteria, fermentable carbohydrates, and host susceptibility (integrity of tooth enamel). Caries has been described as the most prevalent pediatric infectious disease and the most common chronic disease of children.[2]

Tooth loss as a result of ECC may result in malocclusion and low oral health–related quality of life.[3] Children with ECC are at increased risk of further caries throughout childhood and adolescence.[4,5] The effects of ECC go beyond the oral cavity and influence overall childhood health and well-being, which are already compromised for many Indigenous children.[3,6–8]

Severe early childhood caries (S-ECC) is an aggressive form of ECC and is classified by location of the caries, number of teeth affected, and age.[1] S-ECC commonly requires surgical treatment under general anesthesia (GA).[9] Children with S-ECC experience more nutritional problems, including iron-deficiency anemia, low vitamin D, and overweight or obesity. S-ECC that penetrates the tooth pulp can lead to painful dental infections or abscesses and, rarely, death.[6–8,10]

ORAL HEALTH STATUS IN INDIGENOUS CHILDREN

In 2011, the prevalence of ECC in 3- to 5-year-old FN and Inuit children was 85%, and the prevalence of S-ECC was as high as 25%.[11–13] Oral health surveys performed by the Indian Health Service (IHS) in 2014 revealed that 75% of AI/AN children between the ages of 3 and 5 years had ECC, and in many communities, the caries rate was >90% (5 times greater than that of the general US child population).[14,15] The true burden of ECC in Indigenous children is not only the disparate ECC prevalence but also the disease severity. The average number of decayed or filled teeth in AI/AN children 2 to 5 years old was 5.8, almost 5 times that of the general US preschool population.[15,16]

An important consequence of ECC severity is the need for dental surgery under GA.[9,13,17] Rehabilitative surgery is expensive and carries the potential risks of GA. Overall, the rate of dental surgery to treat ECC under GA in Canada was 7 times higher for children from communities with a high proportion of Indigenous peoples than communities with lower Indigenous populations.[9,17] In the more remote Indigenous regions of Canada, the rates of dental surgery under GA exceed 200 per 1000 children younger than 5 years each year, a rate 15 times higher than the overall annual Canadian rate.[9,17] Exact data on the overall number of AI/AN children undergoing dental surgery for caries are limited, but one study in the Yukon–Kuskokwim Delta of Alaska reported that by 6 years of age, 73% of Alaska native children had undergone dental surgery under GA, a rate at least 50 times that in the general US population.[18]

EPIDEMIOLOGY OF ECC

Indigenous children often develop ECC at earlier ages than other children. The 2014 IHS Oral Health Survey reported that 21% of AI/AN 1-year-olds and 40% of AI/AN 2-year-olds had caries, whereas most dental surveys suggest ECC is rare among US children before 12 months of age, and only 10% of US children younger than 2 years have ECC.[19] The etiology of ECC in Indigenous children is multifactorial. The typical "window of infectivity" for the acquisition of cariogenic microorganisms, including *S mutans*, is between 19 and 31 months. However, 2 recent studies reported that AI/AN children acquire *S mutans* at earlier ages: 37% of 12-month-olds and 60% of 16-month-olds had *S mutans* colonization.[20,21] Additionally, primary teeth erupt at an earlier age in AI/AN infants, which may result in earlier *S mutans* colonization and earlier progression to caries.[22] Authors of a recent review of caries reiterate that newly erupted teeth are much more prone to caries.[23] Additionally, a recent study of Canadian FN children revealed that children with S-ECC had a significantly different plaque microbiome than their caries-free counterparts, with the S-ECC group harboring higher levels of known cariogenic organisms, particularly *S mutans*.[24] The early acquisition of *S mutans* in Indigenous children is likely mediated by factors associated with poverty, including household crowding, family size, nutrition, and other health behaviors.[25] Unfortunately, Indigenous children in the United States and Canada experience poverty at rates 2 to 3 times greater than the general population. For children younger than 5 years, 52% of FN children live in poverty, as do 25% Inuit and 23% of Métis children, compared with 13% of nonracialized Canadian children.[26] More than 37% of AI/AN children in the United States live in poverty, compared with 10% of their white American counterparts.[27]

Other known ECC risk factors are commonly found in Indigenous children. Caries in parents is associated with increased risk in their infants.[28] ECC is also associated with prolonged bottle-feeding, consumption of sugar-containing drinks, high frequency of sugary snacks,[29–33] and exposure to tobacco

smoke.[13,34] Breastfeeding for up to 12 months of age can reduce ECC risk by half, most likely via immune-modulating effects and promotion of a healthy microbiome. Furthermore, a recent study demonstrated that breastfeeding did not provoke a decrease in biofilm pH and, therefore, did not facilitate ECC.[35] If the infant breastfeeds to sleep, the gums and erupting teeth should be wiped to minimize the risk of caries.[36] However, breastfeeding beyond 12 months of age, especially with at-will nighttime feeding, is associated with increased risk of ECC.[37–39] Obesity has also been shown to be associated with ECC, although it is unclear whether this risk occurs independently from dietary factors.[3,10,40–42] In addition, gestational diabetes, which is prevalent in Indigenous populations, may have an effect on early childhood dental development and caries risk.[43–45]

PREVENTION STRATEGIES

Prenatal Oral Health Care

ECC prevention is optimal if initiated prenatally.[46] Given the evidence for transmission of cariogenic bacteria from mother to child, routine dental assessments and preventive dental care, oral hygiene education, optimal prenatal nutrition, and the use of fluoride toothpaste for pregnant women are strategies that may prevent or delay ECC in their children.[46] Recent guidelines conclude that dental care in pregnancy is safe.[47–49]

Fluoride

All major Canadian and American dental and pediatric societies endorse the use of fluorides as safe and effective for caries prevention.[50–54] All of the aforementioned organizations support the use of fluoridated toothpaste twice daily for all children. They recommend that children younger than 3 years have their teeth brushed by an adult with a grain of rice–sized portion of fluoridated toothpaste and that children 3 to 6 years of age be assisted with brushing with a green pea–sized portion of fluoridated toothpaste.[51,52]

Community water fluoridation is safe, effective, and inexpensive and does not require daily adherence.[55,56] Community water fluoridation in AN communities has been associated with a 40% reduction in caries.[57] In North America, there is wide disparity in the access to community water fluoridation. In 2017, 38.7% of Canadians using community water supplies had access to fluoridated water, compared with only 2.3% of FN people.[58] Although 74.4% of US residents had access to fluoridated community water, only 50% of Alaskans received fluoridated community water, with only 5.3% receiving optimal fluoride levels.[18,59]

Topical fluorides have been shown to be effective in preventing caries.[18,59] Studies in Indigenous children in Canada and the United States have shown reduction in caries with fluoride varnish, although the results were not statistically significant.[60,61]

These modestly favorable results for fluoride varnish in AI/AN children are tempered by 2 larger studies with longer follow-up. First, a 5-year IHS program targeting AI/AN children initially resulted in a small decrease in ECC in children younger than 2 years, but these benefits were lost for children 2 to 5 years of age.[62] A second cluster-randomized controlled trial (RCT) testing 4 fluoride varnish applications (and oral health–promotion activities) by trained tribal health workers in Head Start classrooms did not yield a reduction in ECC.[63] These studies suggest that fluoride varnish should be initiated with the first tooth eruption in Indigenous children to achieve maximal benefit. Although the data on fluoride varnish are mixed for Indigenous populations, fluoride varnish is still recommended because the potential benefits far outweigh any risks. Fluoride varnish applications help to enhance both the mineralization of healthy enamel (making it more resistant to caries) and the remineralization of early incipient caries lesions (ie, white spot lesions) in primary and permanent teeth that have not yet progressed to the cavitation (ie, cavity) stage. The American Dental Association still recommends fluoride varnish for all children. However, the challenge is that fluoride varnish is not effective in arresting and remineralizing more advanced lesions that have cavitated through the enamel (ie, cavities), which are known to be more prevalent in young Indigenous children. Therefore, early applications of fluoride varnish to newly erupted teeth, beginning at the eruption of the first primary tooth at the 6-month developmental age milestone, is paramount.

Oral Health Education

Evidence surrounding the effectiveness of conducting dental examinations and provision of parental counseling to prevent ECC in preschool-aged children is mixed.[60,61,64,65] Studies of oral health education in Indigenous families resulted in increased parental knowledge but rarely demonstrate reduction in caries.[63,66] One large RCT of motivational interviewing in parents of AI preschool-aged children reported increased parent and caregiver knowledge but no reduction in ECC.[63] A previous Canadian RCT reported that motivational interviewing was associated with a reduction in the degree of severe caries among Cree children in northern Quebec.[64] Other studies suggest that oral health education for pregnant women and mothers of infants can reduce S-ECC from 32% to 20%.[67–69] Like the early receipt of fluoride varnish, evidence suggests that receiving oral health education at

the time of first tooth eruption is more beneficial.

Community-Based Strategies

Evidence is clear that caries were rare in Indigenous communities until the introduction to European settler diets, including refined sugar and other processed foods.[70–73] In Canada, there are several community-based efforts to reduce ECC, some of which promote traditional Indigenous diets.[74–77] One program in a Cree community encourages breastfeeding and promotes the introduction of traditional first foods instead of processed infant foods.[78] These efforts are promising, but there are no data regarding their effects on ECC.

ASSESSMENT AND TREATMENT STRATEGIES

Caries Risk Assessment

Timely caries risk assessment (CRA) is an important first step to reduce the risk for ECC. Several pediatric and dental organizations have developed easy-to-use CRA tools that can identify a child's risk of developing caries.[79] CRAs also assist nondental primary health care providers in assessing the need for anticipatory guidance, fluoride varnish, and referral for dental evaluation.

Sealants

Pit and fissure dental sealants have traditionally been used on occlusal tooth surfaces of permanent molars to reduce dental caries. Recent reviews concur that in populations at high risk of caries, such as Indigenous children, sealants can be placed on primary molars after eruption.[80,81] Studies suggest that 74% of sealed primary molars remain caries-free and that sealing primary molars is cost-effective in reducing caries progression and the need for operative repair.[82] The American Dental Association recommends sealants on primary molars and fluoride varnish every 3 to 6 months to arrest or reverse noncavitated carious lesions on the occlusal surfaces of primary teeth.[83] However, dental sealants may be challenging to apply on the teeth of infants and toddlers.

Interim Therapeutic Restorations

Minimally invasive dental restorative techniques, such as glass ionomer products, provide a practical option for managing cavitated lesions in young children. Interim therapeutic restorations can be used to restore and prevent caries progression in young and uncooperative children, in children with special health care requirements, and in circumstances in which the placement of traditional restorations is not possible.[84] Interim therapeutic restorations can be provided by midlevel dental professionals, including dental therapists (DTs) and hygienists, in many locales.

Silver Diamine Fluoride

Silver diamine fluoride (SDF) has been used extensively outside North America for caries arrest, with good results.[85,86] SDF is indicated for the arrest of cavitated caries lesions in primary teeth as part of a comprehensive caries management program.[83] SDF will turn the carious lesion hard and black, but this side effect is generally well accepted by parents.[87] At present, the use of SDF in the United States and Canada is limited to the dental profession, because there are no formal guidelines for its use outside of dentistry.

Frank Mendoza, DDS, an IHS dentist, pioneered the use of silver ion products at a tribal health clinic for caries arrest and demonstrated that only 2% of treated patients needed eventual operative repair.[19] Several other IHS and tribal programs now use SDF, with positive results.[88] There is an emerging consensus that SDF may be an important treatment option for children at high risk for progression to severe ECC.[89] If the use of SDF becomes more widespread, primary care health providers will play a critical role in identifying patients for referral and in promoting adherence to treatment. Evidence-based clinical guidelines from the American Dental Association and the American Academy of Pediatric Dentistry for nonrestorative treatment of caries recommend biannual applications of 38% SDF to arrest advanced cavitated lesions on primary teeth, with the recognition that additional applications may occasionally be necessary.[90]

Repair Under GA

Given the prevalence and severity of ECC in Indigenous children, operative repair is often required. However, because ECC is largely preventable, each child requiring operative repair is a costly failure of our preventive and treatment systems. Operative repair is expensive, and prevention is more cost-effective, less painful, and less time-consuming for the patient.[9,91] Furthermore, the acute risks associated with anesthesia and the evidence that GA in young children may have potential cognitive effects are additional reasons to avoid this consequence of ECC.[92,93]

Authors of a cost-effectiveness review of preventive interventions such as water fluoridation, fluoride varnish, tooth brushing with fluoride toothpaste, and use of sealants concluded that these interventions are collectively relatively inexpensive and cost-saving and, if fully used, could reduce S-ECC requiring operative repair.[18] The major benefit of increased use of SDF is the arrest of the progression of already established caries and a subsequent reduction in the need for operative repair with GA.

ACCESS TO EARLY ORAL HEALTH CARE

Severe dental workforce shortages in Indigenous communities contribute to the high rates of untreated caries in

Indigenous children. The 2014 Oral Health Survey reported the ratio of dentists per person was 1:2800 for AI/AN communities compared with the US average of 1:1500[16] and that 45% of 5-year-old AI/AN children had untreated caries compared with 19% of US children.[15]

All major Canadian and American dental and pediatric societies have called for comprehensive dental health care from dentists for children by 12 months of age: the "age-one dental visit."[94,95] The chronic shortage of dentists in Indigenous communities suggests we look to expanded roles of other dental providers (eg, DTs and hygienists) and other nondental providers to increase access to oral health care, with an emphasis on preventive services.

In the 1970s, Health Canada supported the use of DTs for FN communities, and many began practice in the northern communities of Canada.[96] DTs are midlevel dental providers who work under the supervision of a dentist. Reviews of DTs in more than 50 countries reported that DTs expand access to dental care in a safe and effective manner.[97] Unfortunately, over time, an increasing number of Canadian DTs chose to work in urban settings rather than rural communities. The urban migration of DTs and the ongoing opposition by professional dental societies led the Canadian federal government to discontinue funding DT training programs in 2011.[98]

As Canada was reducing its support for the training of DTs, the Alaska Native Tribal Health Consortium began a dental health aide therapist (DHAT) program. The Alaska DHAT program has been linked to better oral health access and outcomes in remote villages and has been well received by health care providers and community members.[99–101] DHAT programs also have been implemented in tribal clinics in the states of Washington and Minnesota. The National Indian Health Board champions the use of DHATs as a strategy to increase access to oral health and a legitimate exercise of tribal sovereignty.[102] The Department of Indigenous Services Canada and the Canadian Dental Hygienists Association have recently proposed the reestablishment of a training program for dental therapy that would see dental hygienists complete an extra year of education to be able to provide expanded oral health services.[103]

Primary care providers (pediatricians, family physicians, nurse practitioners, community health nurses, physician assistants, and dietitians) in Indigenous communities in North America are in unique positions to complement the work of dental health professionals. These nondental providers provide early and frequent care to children before they see a dental provider. In many Indigenous communities, well-infant, infant health, and immunization clinics are provided on a regular basis through community health nurses and physicians. These nondental providers have an opportunity to assess children's risk for caries and promote oral health as part of their overall health-promotion activities. In addition, they can provide oral health screening for infants and young children, provide fluoride varnish, and coordinate referrals to dental health professionals. Moreover, because of the high rates of obesity and type 2 diabetes mellitus in Indigenous populations, Indigenous youth may undergo dietary assessments and may be seen by dietitians. These visits provide opportunities for collaboration between primary care and dentistry to encourage limited consumption of sugars, a shared risk factor for both obesity and caries.

ORAL HEALTH RECOMMENDATIONS FOR INDIGENOUS COMMUNITIES

Caries prevention interventions that have worked well in the general population have been less effective in Indigenous children; therefore, the prevention and treatment recommendations described here should be informed by what is known of ECC epidemiology in Indigenous children. Indigenous children acquire *S mutans* colonization at an earlier age, develop caries at an earlier age, and commonly experience severe ECC. The health care community needs to recognize that "two is too late" for preventive interventions in Indigenous children to be successful and that new strategies with earlier intervention are needed to reduce this health disparity.

Community-Based Promotion Initiatives

- Promote changes in Indigenous communities to reduce frequent consumption of sugar-containing drinks and sugary snacks through education and improved access to healthy foods in communities.
- Emphasize the importance of oral health for the pregnant woman and her infant(s) through community-based activities.
- Promote exclusive breastfeeding for the first 6 months and breastfeeding until 12 months of age.
- Ensure that Indigenous communities benefit from community water fluoridation and know the fluoridation level of their water supply.
- Promote collaboration between oral health and obesity and type 2 diabetes mellitus prevention efforts for Indigenous communities.

Clinical Care Recommendations

- Consider early childhood oral health as an integral part of overall childhood health and well-being.

- Ensure that Indigenous women receive preconception and prenatal screening for oral health, anticipatory guidance for oral health and hygiene, and referral for dental care.
- Discuss oral health during well-child care visits with a CRA and anticipatory guidance on oral hygiene and diet, starting with the first tooth eruption.
- Recommend the establishment of a dental home by 12 months of age.
- Promote supervised twice-daily use of fluoridated toothpaste for all Indigenous children beginning with the eruption of the first tooth (rice grain–sized portion of toothpaste for children <36 months of age and a green pea–sized portion for children ≥36 months of age).
- Provide fluoride varnish by either dental or nondental health care providers in primary care settings and by trained lay workers in other settings starting with the first tooth eruption (and then every 3–6 months thereafter).
- Promote the incorporation of SDF into caries management protocols for Indigenous children with ECC to decrease or arrest caries progression and reduce or avoid the reliance on GA to facilitate operative repair.
- Consider promoting the incorporation of interim therapeutic restoration into caries management protocols.
- Consider promoting the use of sealants on primary molars to prevent caries and the need for operative repair.

Workforce and Access

- Provide early access to dental health professionals by 12 months of age to establish a dental home with the full range of oral health–promotion and interceptive disease-prevention services.
- Consider roles that DTs, dental hygienists, and primary health care providers can assume in areas where it is difficult to recruit and retain a sufficient number of dentists to provide early oral health services.
- Ensure that dentists, dental hygienists, DTs, and assistants working in Indigenous communities receive education to practice in a culturally appropriate manner.

Advocacy

- Advocate for an adequate dental workforce that can include the training and use of midlevel professionals such as DTs.
- Advocate for increased representation of Indigenous people in oral health professions.
- Advocate for regular and sustained ambulatory dental care in or near Indigenous communities.

Research

- Support further community-based participatory research on the epidemiology, prevention, management, and microbiology of ECC and ECC-prevention projects in Indigenous communities.

Ethical Considerations in Pediatricians' Use of Social Media

- *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Ethical Considerations in Pediatricians' Use of Social Media

Robert Macauley, MD, FAAP,[a] Nanette Elster, JD, MPH,[b] Jonathan M. Fanaroff, MD, JD, FAAP,[c] COMMITTEE ON BIOETHICS, COMMITTEE ON MEDICAL LIABILITY AND RISK MANAGEMENT

Increasing use of social media by patients and clinicians creates opportunities as well as dilemmas for pediatricians, who must recognize the inherent ethical and legal complexity of these communication platforms and maintain professionalism in all contexts. Social media can be a useful tool in the practice of medicine by educating both physicians and patients, expanding access to health care, identifying high-risk behaviors, contributing to research, promoting networking and online support, enhancing advocacy, and nurturing professional compassion. At the same time, there are confidentiality, privacy, professionalism, and boundary issues that need to be considered whenever potential interactions occur between physicians and patients via social media. This clinical report is designed to assist pediatricians in identifying and navigating ethical issues to harness the opportunities and avoid the pitfalls of social media.

INTRODUCTION

Increasing use of social media by patients and clinicians creates opportunities as well as dilemmas for pediatricians, who must recognize the inherent ethical and legal complexity of these communication platforms and maintain professionalism in all contexts. This clinical report is designed to assist pediatricians in identifying and navigating ethical issues to harness the opportunities and avoid the pitfalls of social media. As Parikh et al[1] rightly observe, "Connectivity need not come at the price of professionalism." In fact, striking a proper balance may be considered an ethical imperative, with the goal that social media (to the extent that it is used) augment in-person care rather than take the place of it.

More than 300 million people in the United States now use the Internet,[2] with more than 90% of them also using e-mail to communicate.[3] With the creation of social media outlets (also known as Web 2.0) at the dawn of the 21st century, the capacity for sharing information among huge numbers of people with little or no time lag reached new heights. "Social media" refer to Web-based services that allow users to create personal

profiles and post content[4] as well as "articulate a list of other users with whom they share a connection."[5] E-mail and other forms of electronic communication specifically designed to be used between a single user and another, such as electronic patient portals, are not considered social media[6] and are not the focus of this report. Seventy-two percent of Americans, including 90% of teenagers, engage in social media,[7–9] with Facebook among the best known and most frequently used by adults. Others include Instagram, Twitter, LinkedIn, Tumblr, Snapchat, and Pinterest. Newer social media options are being created regularly as public needs and demands shift.[10] Social channels are evolving and changing with time, allowing for instant and disappearing messages, back-channel connections, live video streaming, and one-to-many communications. Some social channels have been specifically designed for physician communication, either with peers, patients, or the public.

Because of social media's ubiquity and ease of use, a high percentage of patients want or expect to use it to communicate with their physician. In a recent Harris Poll survey conducted on behalf of the American Osteopathic Association, it was found that "more than half of millennials (54%) and more than four out of 10 (42%) adults are or would like to be friends with or follow their health care providers on social media."[11] Research reveals that patients who do not currently use social media would consider doing so to improve physician-patient communication.[12] This is particularly true of pediatric patients, who as "digital natives" (ie, people born or raised in the age of digital technology[13]) are more familiar with communicating with and expressing themselves through social media than are many adults.[14]

Pediatricians, however, are, depending on their generation and experience, a blend of digital natives and "digital immigrants" (defined as people born before 1980) and, thus, have varying understanding and facility with social media.[13] This relative unfamiliarity, coupled with reports of violations of online professionalism (which more than 90% of state medical boards have received, leading to sanctions ranging from suspension to revocation of the physician's license[15]), may cause some pediatricians to be reluctant to engage with social media.

Avoiding social media, however, sacrifices opportunities for communication, education, and advocacy with patients and families. As Parsi and Elster[16] note, "If we fail to engage this technology constructively, we will lose an important opportunity to expand the application of medical professionalism within contemporary society." Both the potential benefits and risks of social media need to be considered to appropriately incorporate it into one's clinical practice.

POTENTIAL BENEFITS OF SOCIAL MEDIA

Professional Education and Collaboration

Faced with multiple competing obligations and rigorous productivity expectations, physicians may need to consult with colleagues about challenging cases or research current evidence quickly. Social networking sites can help close this gap, as long as they are compliant with privacy requirements of the Health Insurance Portability and Accountability Act (HIPAA) (which would include identity verification and sufficient encryption). Physician-to-physician communication can also occur on public channels such as Twitter, through which groups of physicians congregate and "follow" each other for information sharing, thought leadership, and advocacy in pediatric public health. The American Academy of Pediatrics (AAP), for example, maintains a list of more than 700 tweeting AAP members, known as "Tweetiatricians."[17]

Overall, 90% of physicians today use social media for professional purposes, including finding and reading relevant medical information.[18] Social media are especially popular with early-career pediatricians who may be more familiar with digital technology, have received mentoring in its use during training, or attend conferences in which tweeting is encouraged to ask questions or provide feedback. Social media allow learners to express their opinions and ask questions without fear of embarrassment and has been observed to "flatten the hierarchy" of medicine by giving each person an equal voice.[19]

Patient Education and Advocacy

Studies have revealed that 8 in 10 Internet users go online for health information,[20] and more than half of these people get medical information specifically from social media.[21] Social media tools can be used to share relevant and important public health topics and to guide the public, patients, and families who follow a physician's channels to creditable resources that have been reviewed by physicians (such as online media articles, blogs, journal articles, or important recall or safety information). Communication may range from general advice, such as encouragement to get the seasonal influenza immunization, to broad-ranging notifications about public health emergencies.

Beyond mere ease and scope, education via social media may be preferable for patients who have moved beyond the model of acquiring knowledge from a medical professional in the clinical workspace. Some patients prefer "disintermediation," or gathering information directly from online sources. Recognizing that not every such source is trustworthy, physicians

can encourage a middle ground. The so-called "apomediary model" allows physicians to guide patients to reliable information that they can access independently before turning to their physician for consultation and clarification.[22]

Social media can also be used to implement advocacy initiatives to enhance public health. Examples include appeals to contact elected officials to advocate for policies and legislation that improve the health of children and their families and the promotion of public and community health via immunization campaigns. Recent polls suggest that fully two-thirds of Americans believe that social media are important for getting elected officials to pay attention to issues and that social media platforms are "at least somewhat important for creating sustained movements for social change."[23]

These social media opportunities are widely accessible to, and can be used to influence, public opinion, as recent interference in US elections attests.[24] Opponents of certain medical recommendations or public policies can provide conflicting or inaccurate information that may trigger discussions and debate.[25] Although currently only 9% of physicians use social media to comment on posts or participate in group discussions or online chats,[18] physicians participating in social media may help prevent misconceptions from dominating online discussions.

Social media can help patients and families understand the range of expertise of a given practice and learn of additional resources in their community. In some cases, with patient authorization, social media can permit the transmission of personalized information (such as appointment or medication refill reminders), which can help improve adherence to treatment regimens.[26]

Social media can also benefit patients by increasing awareness of community health needs. For instance, appeals for voluntary blood donation on social media can help to mitigate acute shortages. Organ donation recruitment has also increased in response to Facebook appeals.[27]

Patient Empowerment

Social media have made the world smaller and have provided a global community to support patients with special needs and chronic health conditions as well as individuals who may be experiencing social isolation or discrimination. Peer-to-peer health care affords patients the opportunities to develop a support network, share experiences, and learn about new opportunities for research or treatment.[28] Many private companies,[29,30] including some focused on pediatrics,[31] have such online communities for patients to connect with each other and work to systematically improve their health outcomes. Facebook[32] and Twitter[33] have both allowed the creation of "supportive disease subcultures." As one patient noted, "The internet has made our small disease larger and we are able to educate many more people now."[34]

In addition to fostering community and providing education, social media also hold the promise of improved diagnostics. Patients (and their advocates) can now share reports online of unusual symptom complexes that have stumped local physicians. These disclosures may be similar to diagnostic dilemmas among other patients and provide physicians with diagnostic clues.[26] Identifying groups of patients with a common condition can also spur further research on that disease's pathophysiology and treatment.[35,36] This process has been likened to crowdsourcing, or bringing together the collective wisdom of diverse groups of patients and physicians.[22]

Increased Patient Access

In regions with inadequate infrastructure to support optimal telemedicine, social media sites, such as Facebook, have been used instead.[37] Ideally, social media should not replace face-to-face encounters with physicians, but social media may supplement those encounters by creating virtual clinics, thus allowing a more rapid response to an urgent health care situation.

Clinical Research and Recruitment

Social media can expand research opportunities and connect researchers to peers, novel ideas, and potential human subjects or study participants. Social media tools are not only used to broadcast ideas; they can also be used to search for information, opinions, and ideas or simply to listen. Such tools allow researchers to contact patients with rare conditions and locate research subjects lost to follow-up as well as reach out to younger patients who might otherwise not learn about or become interested in participating in research.[38] Social media can inform researchers about patient responses to treatment and adverse drug effects and trigger modifications in treatment plans.[39]

Use of social media in research is ethically complex, however. Whereas most research studies are developed by experienced researchers and approved by their organization's institutional review board or human subjects committee, studies involving social media may bypass this review process because social media use is seen as public, thus calling into question whether it is necessary to obtain the participants' informed consent.[40] Protection of human subjects is critical, however, and researchers who use social media in their studies should continue to follow the policies of their institution's ethics committee or institutional review board. Investigators should disclose that

a research study is being considered, be clear about the risks and benefits of the research, and, if possible, obtain consent from potential study subjects before proceeding with the study rather than merely lurking to obtain data.[38] Without such transparency, potential subjects might post personal items on social media that they would have kept private if they had been aware of the research taking place (from a practical viewpoint, there should be no expectation of privacy for information voluntarily posted online[41]).

Identification of and Counseling for High-risk Behaviors

As digital natives, most pediatric patients expect to communicate through social media. Adolescents, in particular, spend a great deal of time online[42] and may feel more at ease sharing personal information in that context rather than in face-to-face conversation. Teenagers may also be more open to health-related messages and advice communicated through social media.[43] Social media can, therefore, be used to identify self-disclosed high-risk behaviors and explore ways of mitigating risk and accessing appropriate resources.[44,45] Such conversations are more straightforward when the pediatric patient has specifically granted the physician access to material posted on social media, although such communication itself raises issues related to blurring of appropriate boundaries (as discussed below). Greater discretion is required regarding social media information that is in the public domain.

Acquisition of Important Information

In rare cases, social media have been used to obtain specific and important information relevant to patient care. For instance, the authors of one case study describe how a Facebook search allowed a medical team to locate the family of a patient with amnesia.[46] Taken too far, however, indiscriminate queries (sometimes referred to as "patient-targeted googling") present significant ethical complexity and concerns, which will be addressed below.

Nurturing Compassion Through Narrative

Medical practice today can be challenging and exhausting. Sharing inspirational anonymized patient stories can nurture compassion among health professionals, reminding them about why they chose the profession in the first place.[47] Humor has also been shown to prevent burnout,[48] and so-called "collective venting" can be cathartic.[49]

By the same token, because social media are publicly accessible, insufficiently anonymized patient narratives (and even sufficiently anonymized ones that are written in a negative venting tone) may reflect negatively on the authoring physician. Even deidentified patient information holds the potential to be hurtful, both to that specific patient and to other patients who might fear that their private information could be shared in a similar manner. Denigrating language is inherently personal and reflects poorly on the physician and the profession of medicine itself.[50] There is evidence that sharing dehumanizing narratives and language begins early in medical training, with medical students shown to frequently express themselves in this way online.[51] A majority of medical schools now report unprofessional online conduct.[48] For precisely this reason, schools are starting to put forth policies regarding social media expression.[52]

Even when details are deidentified and a patient narrative is expressed in respectful terms, a majority of medical educators still believe that discussing it on social media requires explicit patient consent.[53,54] Given the abundance of readily accessible information, nondisclosure of names, addresses, or other traditionally verifiable information is not a guarantee that one's identity will remain anonymous.

POTENTIAL RISKS OF SOCIAL MEDIA

Inappropriate Self-Disclosure

Despite the potential benefits of social media, significant risks remain. One important risk is inappropriate personal self-disclosure by physicians online, which can negatively impact a physician-patient relationship or one's employment. Even if an inappropriate posting on social media is entirely unrelated to one's medical practice, it nevertheless reflects on one's professionalism.[55] As the American Medical Association Code of Ethics states, "The ethical obligations of physicians are not suspended when a physician assumes a position that does not directly involve patient care."[56] This includes online disclosures, and all professionals, not just physicians, are judged by how they comport themselves online.[57]

By its very nature, social media invite inappropriate posting because "anonymity can breed disinhibition."[58] Some posts are clearly inappropriate, such as selfies of grinning clinicians posing with weapons during a humanitarian mission[59] or uncivil microblog posts (eg, tweets).[60] Some posts may be more ambiguous but in the absence of nonverbal cues can easily be misinterpreted. Comments addressing patients, as well as those regarding one's employer or clinical setting, reflect negatively on both the subject, the poster, and the professional, potentially leading to disciplinary action or even termination. Tweeting or posting from work, especially if excessive, may be perceived as not paying attention to clinical duties and may violate institutional policy.[61]

There are permanent implications to such disclosure, too, because despite

subsequent attempts to purge one's online profile, what goes online stays online. Unflattering social media content may affect a clinician's future employment opportunities.[62] Despite this risk, one study revealed that only one-third of medical students set their Facebook pages to private.[63] This may be significant given that some institutions may consider social media and the content of postings in promotion and tenure.[64]

From a specifically pediatric perspective, poor digital citizenship undermines a pediatrician's important duty to serve as a role model for patients and families using social media. The AAP has previously encouraged pediatricians "to increase their knowledge of digital technology so that they can have a more educated frame of reference for the tools their patients and families are using, which will aid in providing timely anticipatory media guidance as well as diagnosing media-related issues should they arise."[42]

To prevent inappropriate disclosure, it is best to pause before posting by taking a moment to reflect on the potential impact of a post should it be seen by one's colleagues, patients, or families. It is in a physician's best interest to consider separating their personal and professional social media presence and efforts. The professional platforms can have public settings and content for education and advocacy, and the personal platforms can be set to private. Restricting access to one's private social media accounts may be beneficial in light of reports of a few patients using social media to stalk their physicians.[65] It is also wise to remember that online postings are discoverable in legal proceedings. Facebook's privacy policy clearly states that they may "access, preserve and share your information…in response to a legal request (like a search warrant, court order, or subpoena) if [they] have a good faith belief that the law requires [them] to do so."[66]

Simply having a presence on Facebook could permit a process called tagging. Tagging involves a facial recognition algorithm that identifies an individual from photographs posted online. An unprofessional pose from a friend's party could end up appearing on one's own Facebook feed. To prevent being tagged, Facebook settings can be modified.

Unfortunately, tagging may also occur from many social media platforms through comments and tweets. Even if a pediatrician were to elect not to have a social media presence at all, others are able to post information and photographs about the physician, including videos recorded and photographs taken without the physician's knowledge or consent. For this reason, routinely monitoring and curating one's online presence is recommended. Pediatricians can get a sense of their online "footprint," as well as their online "fingerprint" generated by their online work and advocacy, by regularly searching their online presence.

Blurring Relationship Boundaries

As stated above, a recent poll found that most millennials and nearly half of adults want to follow or connect with a health care provider on social media.[11] In one study, nearly 20% of adult patients attempted to communicate with their physician through Facebook.[67] Accepting this type of relationship can be problematic, however. "Friending" blurs the boundaries of the professional relationship, not only heightening the possibility of inappropriate physician self-disclosure[68] but also introducing a level of mutuality that can undermine a patient's privacy and patient-physician interactions. For example, if a physician discovers something on a patient's Facebook page that is not consistent with the patient's self-report, should the physician raise this issue with the patient directly? How might that discussion impact the patient's perception of privacy? Accepting a friend request may also raise expectations of off-duty availability or that clinical questions will be answered via less secure social media.

Recognizing this ethical challenge, 75% of physicians decline friend requests from patients[18] and only 5% have ever initiated one.[7] More than 80% of medical educators believe that it is never or rarely acceptable to become social networking friends with patients.[53,54] The American College of Physicians,[69] American Medical Association,[26] British Medical Association,[70] and Federation of State Medical Boards[15] all discourage accepting (and certainly initiating) friend requests with current or former patients, although the recent American College of Obstetrics and Gynecology statement permits some measure of discretion in this area.[71] Additionally, some employers prohibit friending patients.

This question becomes more complex in a pediatric context given the reliance of pediatric patients on social media as a forum for expression and communication. It is generally inadvisable for pediatricians to accept friend requests from current patients (and certainly to initiate them). However, declining a friend request might seem like it could compromise communication or even give offense to the requestor. If so, the physician should meet face to face and talk with the requestor and discuss with them why a dual relationship is not wise or in the patient's best interest. An alternative way to maintain communication would be to redirect the requestor to the pediatrician's professional site or a separate platform on which no other personal or professional posts are made.

Unlike in other specialties, pediatric patients "age out" of the therapeutic relationship with their physicians. Social media present a way for pediatricians to stay in contact with former patients. When not doing so is felt to represent a significant mutual loss, it is up to the pediatrician's discretion whether to remain in touch with former patients via social media.

Becoming social media friends with the parent of one's patient is also not without ethical complexity given that that the parent is usually tasked with making decisions for the patient and may be unduly influenced in the decision-making by the friend relationship. Such friending may also create an avenue of communication that could lead to an unintended disclosure of identifiable health information to the patient and family. Ethical issues in this friendship may become even more complicated if the social media relationship continues once the pediatric patient reaches the age of majority and the parent is no longer responsible for making decisions for the patient. It is, therefore, problematic to engage in social media contact with parents of patients if social media are the only basis of the relationship.

In some instances, however (such as small communities or areas in which the physician and the parent have other mutual interests), such contact can be a normal expression of friendship. Once again, it is imperative to maintain proper boundaries by reserving clinical discussions for separate forums.

Up to this point the discussion has been focused on established patients attempting to become friends on Facebook, but the reverse process (ie, friends on Facebook becoming patients) has also occurred. Generally speaking, a physician-patient relationship consists of a patient seeking assistance in a health-related matter and the physician agreeing to undertake diagnosis and treatment.[72] This does not require an in-person meeting and could conceivably occur online. Although specific requirements vary from state to state, it is likely that, regarding social media, the broadest notion of what constitutes a physician-patient relationship could be adopted.[71] Clinical questions posed through social media could, therefore, potentially create a professional obligation with documentation and follow-up requirements similar to those of an office visit as well as a potential liability risk, which may not be covered by malpractice insurance. What began as a kind-spirited attempt to offer general assistance could ultimately result in medicolegal obligations (and liability), underscoring the need for physicians to be extremely cautious about health care communications with personal friends and about posting anything that could be construed as representing a diagnosis or treatment.

Conflict of Interest

As noted above, social media provides valuable opportunities for health advocacy and patient education but can also raise the possibility of conflict of interest. For example, 11% of physician-written health care blogs include named products.[73] Tweets may involve "suspect promotions."[74] Because using social media is relatively easy, many more clinicians may be tempted to consider a paid promotion without understanding the ethical and legal implications of such conflicts of interest if promulgated without appropriate disclosure. Such arrangements have also occurred in traditional media and violate journalistic and educational ethics (not to mention Federal Trade Commission regulations[75]) if not publicly disclosed. Even an individual message on Twitter (a tweet) allows pediatricians to include a conflict of interest statement despite the 280-character limit. Employment relationships should be revealed in online profiles and biographies whenever possible.

Confidentiality

The Hippocratic Oath states, "I will respect the privacy of my patients, for their problems are not disclosed to me that the world may know." The HIPAA Privacy Rule, which covers "individually identifiable health information" based on 18 possible identifiers, including "full-face photographic images (and any comparable images),"[76] also applies to social media, as do state privacy laws.[50] Physicians have an ethical and legal obligation to keep protected health information confidential. Despite this duty, there have been reports of physicians sharing details about patients or inadequately deidentifying facts and photographs[77,78] because even blocked-out faces in photographs may still be identifiable. Social media postings that reference a medical encounter with a specific time and date could be seen by patients and damage trust in the physician-patient relationship and likely violate HIPAA.

To facilitate appropriate use of such digital communication, several legal issues need to be addressed. These include licensure across state lines or international borders,[79] adequate malpractice insurance coverage, reimbursement for telecare (if available), and maintaining confidentiality (because HIPAA also applies to social media communications). When a physician is communicating about health care or rendering advice directly to patients or families, HIPAA compliance requires the use of a secure site with encryption. Removing any identifiable patient details preserves the patient's anonymity and underscores the practice's compliance with state and federal law. The option of 24/7 patient communication also demands appropriate attention to the physician's own work-life balance.

Impact on Professional Reputation

A significant number of patients use online rating sites to choose their physician. Given the impact of one's online presence on professional reputation, it is advisable for physicians to monitor the status of their online identity.[80] Although most physician ratings are positive,[71,81,82] there have been reports of ratings sabotage (ie, fabricated negative reviews) by competing professionals or disgruntled patients.[81] Given the anonymity of many reviews, such a situation may be difficult to remedy.[83]

Responding thoughtfully and positively to critical reviews can be helpful. Physicians must remember that patients can post whatever they want about a situation, but the physician remains bound by confidentiality obligations. Responses must always be generalized, not specific to an individual. It is important to recall that HIPAA regulations prevent physicians from disclosing any protected health information about the patient, including acknowledging that the person is or was a physician's patient.

Unfair or potentially fabricated reviews can be reported to the rating Web site or, depending on one's work context, to the public relations division of one's employer. Another solution can be to optimize search engine results so that one's own practice site comes up first, before any potentially negative reviews. Encouraging more patients to review the practice online will likely provide a balanced and generally positive view.

The American Medical Association Code of Ethics not only mandates ethical behavior on the part of physicians but also requires physicians to report unprofessional behavior on the part of their peers.[56] This mandate extends to the unprofessional use of social media by other physicians. Difficulties inherent in such reporting, which include having to determine what content crosses the line and not wanting a colleague to get in trouble, may explain why few other codes include this requirement, although it is frequently included in social media guidelines written by hospitals, academic centers, and other health care employers.

Given these concerns, pediatric practices and other health care organizations may wish to formulate social media policies for their employees, which can clarify expectations, provide valuable tools and information, and ultimately protect patient confidentiality and privacy. These policies may also include expectations and standards for communicating with patients through social media, such as response time and documentation.[84]

Inappropriate Acquisition of Information via Social Media

As noted above, there may be instances in which social media can be used to obtain specific and relevant information about patients (such as the example of locating the family of a patient with amnesia through Facebook). This practice has become increasingly common. In one study, 1 of 6 pediatric trainees had conducted Internet or social media searches for more information about a patient, and a similar percentage of faculty believed they would do so if that might help in patient care.[85]

This practice could, however, expand to indiscriminate searches for information about patients.[86] So-called patient-targeted googling can be motivated by a genuine desire to understand more about one's patients and perhaps gauge their adherence to treatment plans. But it can also stem from "curiosity, voyeurism, and habit."[15]

Patient-targeted googling can generate 2 types of information, the first coming from the patient directly. Physicians may understandably be unsure how to use information gathered from social media sources.[54] For example, if an adolescent patient denies drinking alcohol but has posted on social media about drinking to excess, should the pediatrician confront the patient with this newfound information? To do so might compromise trust, but not doing so might preclude thoughtful intervention.

The other type of information patient-targeted googling may generate comes from third-party sources, ranging from news articles to posts from someone other than the patient. Such non–user-generated Internet content presents a different set of challenges. First, there is no guarantee that the information is accurate. Even if it is, acquiring knowledge about a patient that the patient did not directly provide (and may not be aware that the physician is in possession of) threatens to compromise trust. Uncertainty remains as to whether to reveal one's knowledge of this information to the patient, either to confirm its veracity or engage in discussion about its content.

Before pediatricians engage in patient-targeted googling, it is important to identify the information they are seeking to acquire and determine if it is of sufficient importance to justify such a search. Clinton et al[87] suggest 6 questions to consider before engaging in patient-targeted googling:

- "Why do I want to conduct this search?"
- "Would my search advance or compromise the treatment?"
- "Should I obtain informed consent from the patient prior to searching?"
- "Should I share the results of the search with the patient?"
- "Should I document the findings of the search in the medical record?"
- "How do I monitor my motivations and the ongoing risk-benefit profile for searching?"[87]

It is generally advisable to disclose any relevant patient information discovered through the Internet or social media to the patient so that everyone is working with the same set of facts. This disclosure is especially important before entering any information gleaned through that route into the patient record.[88]

CONCLUSIONS

Social media can be a useful tool in the practice of medicine by educating both physicians and patients, expanding access to health care, identifying high-risk behaviors, contributing to research, promoting networking and online support, enhancing advocacy, and nurturing professional compassion. At the same time, there are confidentiality, privacy, professionalism, and boundary issues that need to be considered whenever potential interactions occur between physicians and patients via social media. The following recommendations can help pediatricians use social media appropriately and effectively.

RECOMMENDATIONS

1. Pediatricians who choose to use social media should have separate personal and professional social media pages, with patients and their parents directed to the professional page.
2. A pediatrician's personal page should have adequate privacy settings to prevent unauthorized access. Professional pages should be set to prevent tagging.
3. It is wise to pause before posting, given that information posted online can exist in perpetuity and can be captured and redisseminated by viewers before it can be deleted.
4. Pediatricians should follow state and federal privacy and confidentiality laws as well as the social media policies of their health care organization and any professional society to which they belong.
5. Independent practitioners should develop social media policies for their practices to protect patients and clarify expectations. These policies should be in writing and widely distributed to all staff and clinicians. If restrictions on communicating with patients are in place in such policies, this should be shared with patients. Given advances in technology, these policies should be reviewed regularly and updated as needed.
6. Conflicts of interest, including in tweets, blog postings, and media appearances by pediatricians, should be disclosed.
7. Pediatricians should use a HIPAA-compliant secure site with encryption when communicating about health care or rendering advice directly to patients or families. Individually identifiable protected health information should not be shared through social media without documented authorization from the patient or guardian.
8. Before posting on social media, protected health information should be deidentified (and clearly noted to be so) and presented respectfully.
9. Professional boundaries should be maintained in the use of social media. Accepting (and certainly initiating) friend requests from current patients is discouraged. It is up to the pediatrician's discretion whether to accept such requests from former patients. It may be appropriate to accept a friend request from a patient's parent if the physician's relationship to that person extends beyond the clinical environment.
10. Searching for patient information through the Internet or social media should have a specific purpose with clear clinical relevance. Any information obtained through this route should be shared directly with the patient to maximize transparency and before recording any such information in the patient's chart.
11. Pediatricians should monitor their online profile to protect against inaccurate postings. Negative online reviews warrant a thoughtful response that honors confidentiality requirements, including the fact that the reviewer is or was the physician's patient.
12. Pediatricians should recognize that providing specific medical advice to an individual through social media may create a physician-patient relationship that may have documentation, follow-up, state licensing, and liability implications.

Half Century Since SIDS: A Reappraisal of Terminology

- *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Half Century Since SIDS: A Reappraisal of Terminology

Carrie K. Shapiro-Mendoza, PhD, MPH,[a] Vincent J. Palusci, MD, MS, FAAP,[b] Benjamin Hoffman, MD, FAAP,[c] Erich Batra, MD, FAAP,[d] Marc Yester, MD, FAAP,[e] Tracey S. Corey, MD,[f] Mary Ann Sens, MD, PhD[g]
AAP TASK FORCE ON SUDDEN INFANT DEATH SYNDROME, COUNCIL ON CHILD ABUSE AND NEGLECT, COUNCIL ON INJURY, VIOLENCE, AND POISON PREVENTION, SECTION ON CHILD DEATH REVIEW AND PREVENTION, NATIONAL ASSOCIATION OF MEDICAL EXAMINERS

After a sudden infant death, parents and caregivers need accurate and open communication about why their infant died. Communicating tragic news about a child's death to families and caregivers is difficult. Shared and consistent terminology is essential for pediatricians, other physicians, and nonphysician clinicians to improve communication with families and among themselves. When families do not have complete information about why their child died, pediatricians will not be able to support them through the process and make appropriate referrals for pediatric specialty and mental health care. Families can only speculate about the cause and may blame themselves or others for the infant's death. The terminology used to describe infant deaths that occur suddenly and unexpectedly includes an assortment of terms that vary across and among pediatrician, other physician, or nonphysician clinician disciplines. Having consistent terminology is critical to improve the understanding of the etiology, pathophysiology, and epidemiology of these deaths and communicate with families. A lack of consistent terminology also makes it difficult to reliably monitor trends in mortality and hampers the ability to develop effective interventions. This report describes the history of sudden infant death terminology and summarizes the debate over the terminology and the resulting diagnostic shift of these deaths. This information is to assist pediatricians, other physicians, and nonphysician clinicians in caring for families during this difficult time. The importance of consistent terminology is outlined, followed by a summary of progress toward consensus. Recommendations for pediatricians, other physicians, and nonphysician clinicians are proposed.

BACKGROUND

Tremendous progress has been made since sudden infant death syndrome (SIDS) was first defined in 1969.[1] Substantial reductions in

sudden infant deaths have been largely attributable to the promotion of safe sleeping environments, especially supine sleep position.[2] Yet, every year in the United States, approximately 3500 infants still die suddenly and unexpectedly, and further declines in these deaths have slowed considerably since 1999.[3] Although death-scene evidence and witness accounts may help provide some clues about why and how deaths occur, these deaths are often unobserved or unwitnessed events, and the lack of standardized death-scene investigation and autopsy practices means that many remain a mystery.

To determine the cause and manner of a sudden unexpected infant death (SUID), a formal case investigation should be undertaken, examining medical, social, and other factors that might have played a role. Because there is no biological marker to conclusively diagnose suffocation, whether intentional or unintentional, information from the scene investigation, together with witnessed accounts of the events leading to the death, are critical for establishing cause. Without a thorough case investigation, child abuse, unsafe products and environments, and other threats to public health cannot be identified, and effective intervention strategies cannot be implemented.

Ideally, the investigation includes a scene investigation with caregiver and witness interviews, a doll reenactment, documentation and photographs describing the sleep environment and other environmental characteristics, a review of the child's clinical history, and a full postmortem examination and testing.[4–7] Information about the circumstances and events surrounding the death is dependent on the quality and depth of the death-scene investigation and documentation from first responders, law enforcement, medicolegal death investigators, and other health and social service providers. Standardized scene investigation[8] and autopsy protocol[9,10] guidance exists but is not followed universally.[11] In addition, many medical examiner and coroner offices lack sufficient training and resources to conduct thorough, consistent case investigations.[12] Even when sophisticated tools, such as genetic testing, are available, the extent that a neurologic condition or cardiac defect may have contributed to a SUID may not be known.[13–15] It is not often possible to determine if a specific condition or defect caused the death or whether the condition or defect was an unrelated finding.

Consider a common sudden death scenario: a healthy infant is placed to sleep in an adult bed with pillows and blankets, and an exhausted caregiver falls asleep next to the infant. The caregiver awakens hours later and finds the infant unresponsive and unable to be resuscitated. Although the infant was asleep in an unsafe sleep environment, the events leading to the death were unobserved. Evidence to substantiate that the infant was overlaid or the infant's airway had been obstructed by soft bedding is not available. There are no biological markers to differentiate suffocation from a possible natural cause.[4] If the cause of death cannot be determined after a thorough scene investigation, it will be considered a result of indeterminable cause.

What should these deaths be called? How should they be classified? The terminology used to classify these infant deaths varies among US death certifiers (medical examiners and coroners) and includes a variety of terms and acronyms, including undetermined, unexplained, and unknown cause as well as SIDS, SUID, and accidental suffocation or asphyxia in an unsafe sleeping environment.[16,17] This report describes the history of SIDS terminology and summarizes the debate over the terminology and its resulting diagnostic shift. The importance of consistent terminology is outlined, followed by a summary of progress toward consensus. Recommendations for pediatricians, other physicians, and nonphysician clinicians to facilitate consensus are proposed. Because terminology and clinical guidance for brief resolved unexplained events (formerly, apparent life-threatening events) was published by the American Academy of Pediatrics (AAP) in 2016, this subject is not addressed in this report.[18]

HISTORY OF SIDS TERMINOLOGY

SIDS was first coined and defined by Dr Bruce Beckwith in 1969.[1,19] Beckwith defined SIDS as "the sudden death of any infant or young child, which is unexpected by history, and in which a thorough post-mortem examination fails to demonstrate an adequate cause for death"[1] (Table 1). Sudden refers to the fact that death comes without warning, and unexpected means that there was no preexisting condition known that could have reasonably predicted it. When the definition was first introduced, it established a common term, focusing attention on this group of infant deaths, and helped to address the stigma associated with these deaths. The term SIDS and its definition were subsequently adopted internationally,[20,21] allowing researchers and policymakers to establish a scientific research agenda to explore its epidemiology and etiology. However, even with wide acceptance, SIDS remains a diagnosis of exclusion without clearly defined objective criteria. The use of the term SIDS and how it

TABLE 1 Selected Terminology and Definition or Criteria to Classify Unexplained Sudden Deaths in Infants and Accidental Asphyxiation

Terminology	Case Definition
Beckwith, 1969[1]	
Sudden Infant Death Syndrome (SIDS)	"The sudden death of any infant or young child, which is unexpected by history, and in which a thorough post-mortem examination fails to demonstrate an adequate cause for death."
Willinger et al, 1989[6]	
Sudden Infant Death Syndrome (SIDS)	"The sudden death of an infant under one year of age, which remains unexplained after a thorough case investigation, including performance of a complete autopsy, examination of the death scene, and review of the clinical history."
Undetermined or unexplained cause	"Cases that are autopsied and carefully investigated, but which remain unresolved may be designated as 'undetermined,' 'unexplained,' or the like. 'Unresolved' cases are those for which the history, investigation, or autopsy reveals information that places death outside the SIDS category but does not explain the cause of death. Examples of the latter, are suspected cases of abuse, neglect, or accidental suffocation; cases with episodes of vomiting or diarrhea in 24 hours prior to death without pathologic evidence of infection; or cases in which the information regarding death is not reliable."
Krous et al, 2004[5]	
General definition: Sudden Infant Death Syndrome (SIDS)	"Sudden unexpected death of an infant less than 1 year of age, with onset of the fatal episode apparently occurring during sleep, that remains unexplained after a thorough investigation, including performance of a complete autopsy and review of the circumstances of death and the clinical history."
Category IA SIDS: classic features of SIDS present and completely documented	"Infant deaths that meet the requirements of the general definition and also all of the following requirements. Clinical • More than 21 days and <9 months of age. • Normal clinical history, including term pregnancy (gestational age of ≥37 weeks). • Normal growth and development. • No similar deaths among siblings, close genetic relatives (uncles, aunts, or first-degree cousins), or other infants in the custody of the same caregiver. Circumstances of Death • Investigation of the various scenes where incidents leading to death might have occurred and determination that they do not provide an explanation for the death. • Found in a safe sleeping environment, with no evidence of accidental death. Autopsy • Absence of potentially fatal pathologic findings. Minor respiratory system inflammatory infiltrates are acceptable; intrathoracic petechial hemorrhage is a supportive but not obligatory or diagnostic finding. • No evidence of unexplained trauma, abuse, neglect, or unintentional injury. • No evidence of substantial thymic stress effect (thymic weight of <15 g and/or moderate/severe cortical lymphocyte depletion). Occasional 'starry sky' macrophages or minor cortical depletion is acceptable. • Negative results of toxicological, microbiologic, radiologic, vitreous chemistry, and metabolic screening studies."
Category IB SIDS: classic features of SIDS present but incompletely documented	"Infant deaths that meet the requirements of the general definition and also meet all of the criteria for category IA except that investigation of the various scenes where incidents leading to death might have occurred was not performed and/or 1 of the following analyses was not performed: toxicological, microbiologic, radiologic, vitreous chemistry, or metabolic screening studies."
Category II SIDS	"Infant deaths that meet category I criteria except for ≥1 of the following: Clinical • Age range outside that of category IA or IB (ie, 0–21 days or 270 days [9 months] through first birthday). • Similar deaths among siblings, close relatives, or other infants in the custody of the same caregiver that are not considered suspect for infanticide or recognized genetic disorders. • Neonatal or perinatal conditions (for example, those resulting from preterm birth) that have resolved by the time of death. Circumstances of Death • Mechanical asphyxia or suffocation caused by overlaying not determined with certainty. Autopsy

TABLE 1 Continued

Terminology	Case Definition
	• Abnormal growth and development not thought to have contributed to death. • Marked inflammatory changes or abnormalities not sufficient to be unequivocal causes of death."
Unclassified sudden infant death	"Infant deaths that do not meet the criteria for category I or II SIDS but for which alternative diagnoses of natural or unnatural conditions are equivocal, including cases for which autopsies were not performed."
Goldstein et al, 2019[15]	
Unexplained sudden death in infancy or Sudden Infant Death Syndrome	"The sudden unexpected death of an apparently healthy infant under one year of age that remains unexplained after a thorough case investigation, including performance of a complete autopsy with ancillary testing, examination of the death scene, and review of the clinical history." Special note: "Infant deaths with adequate death scene investigation and autopsy, with a history of bed/sleep surface sharing, soft bedding, or non-supine sleep, and without physical evidence of asphyxia, may be more appropriately certified as unexplained sudden death in infancy or sudden infant death syndrome."
Other ill-defined or unspecified causes of death (undetermined)	"The investigation, death scene examination, or autopsy was substantially limited, incomplete or insufficient (eg, legal/religious restrictions, delayed report of death that limits scene investigation, or decomposition)." Or "The investigation, death scene examination, or autopsy had inconsistent accounts or other findings raise competing conclusions about the cause of death."
Unintentional threat to breathing (accidental asphyxia): certification of asphyxia	"Adequate evidence must be documented to substantiate asphyxiation, given the decedent's age and stage of development. There cannot be a reasonable competing cause of death after a complete autopsy with ancillary testing, examination of the death scene (with a doll re-enactment when appropriate), and review of the clinical history. Bed/sleep surface sharing, soft bedding, or prone sleep, without adequate evidence for airway obstruction or chest wall compression, are insufficient to certify a death as due to asphyxia. These deaths may be more appropriately certified as unexplained sudden death or SIDS. The use of 'possible' or 'probable' asphyxia will result in the death being classified as asphyxia."
National Association of Medical Examiners Panel on Sudden Unexpected Death in Pediatrics, 2020[10,14]	
Unexplained sudden death (no identified intrinsic or extrinsic factors)	"Infant less than one year of age in apparent good health that dies suddenly and unexpectedly. • For Sleep-related Deaths: o Placed alone, supine, in infant-specific sleep environment (eg, crib, bassinet, portable crib, play pen) with flat, firm sleep surface, uncluttered by objects, and without potential areas of entrapment. o Found unresponsive or dead, in the same sleep environment, with no obstruction of the nose and/or mouth or compression of neck/chest to cause asphyxia given the developmental abilities of the infant, as described by finder and demonstrated by doll reenactment. • The infant was not overly dressed or bundled for the environmental temperature. • Competent caregiver not impaired by drugs or alcohol. • Physical findings on body and at scene consistent with history provided by caregiver. • Completion of scene investigation and doll reenactment unless caregiver declines. • Review of child medical records and family health history. • Complete autopsy with histology, comprehensive toxicology testing (including vitreous chemistries if possible), and skeletal survey. • No anatomic, metabolic, toxicological, chemical, historical, or external cause of death identified. Genetic testing is recommended but not required for this certification. • No extrinsic or intrinsic risk factors are identified."
Unexplained sudden death (intrinsic factors identified)[a]	• "A cause of death cannot be determined and criteria for Unexplained Sudden Death (No Identified Intrinsic or Extrinsic Factors) are not met due to o intrinsic/natural abnormalities that are either known risk factors for sudden death (including, but not limited to, low birth weight, preterm birth, small for gestational age, concurrent non-lethal illness, febrile seizures) o or are of unknown significance (including, but not limited, to mutations of unknown significance). • Trauma and other unnatural etiologies are sufficiently excluded."

TABLE 1 Continued

Terminology	Case Definition
Unexplained sudden death (extrinsic factors identified)[b]	"A cause of death cannot be determined and criteria for Unexplained Sudden Death (No Identified Intrinsic or Extrinsic Factors) are not met due to the presence of unintentional extrinsic factors that increase risk for unnatural death. This may include, but is not limited to, non-lethal injuries or injuries of unknown significance, nonlethal toxicological findings of unknown significance, or circumstances otherwise concerning for unnatural death."
Unexplained sudden death (intrinsic and extrinsic factors identified)[a,b]	"A cause of death cannot be determined and criteria for Unexplained Sudden Death (No Identified Intrinsic or Extrinsic Factors) are not met due to a combination of intrinsic and extrinsic factors as described above."
Undetermined (not further specified)	"A cause of death cannot be determined due to circumstances or findings that make the above classifications inapplicable. Examples may include: Inconsistent histories and/or other evidence that raise uncertainty about manner of death, and competing causes of death. Cases which remain undetermined but were not sudden."
Undetermined (insufficient data)	"A cause of death cannot be determined because investigation, death scene examination, or autopsy were substantially limited, incomplete, or insufficient. Examples may include legal/religious restrictions, delayed report of death that limits scene investigation, and/or decomposition."
Asphyxia	"The case must have a complete/full autopsy. Toxicology, histology, vitreous electrolytes, cultures, and review of medical history are to be performed, as necessary as determined by investigation and autopsy. The infant must have obstruction of both nose and mouth or compression of the neck or chest, that is reliably witnessed or demonstrated by doll reenactment, or other reliable evidence of overlay or entrapment. Asphyxiation must be probable given infant's age and stage of development. There cannot be a reasonable competing cause of death."

[a] "Intrinsic factors are: natural conditions or risk factors associated with abnormal physiology or anatomy that are concerning as contributors to death but are insufficient as a cause (eg, low birth weight, preterm birth, small for gestational age, concurrent non-lethal illness, history of febrile seizures), or natural conditions of unknown significance (eg, cardiac channelopathy or seizure gene variants of unknown significance)."

[b] "Extrinsic factors are: conditions in the child's immediate environment that are a potential threat to life but cannot be deemed the cause of death with reasonable certainty (eg, side or prone sleep if unable to roll to supine, over-bundling without documented hyperthermia, objects in immediate sleep environment, sleep environment not specifically designed for infant sleep, soft or excessive bedding, and sleep surface sharing), injuries or toxicologic findings that are either non-lethal or of unknown lethality, or circumstances/findings otherwise concerning for unnatural death."

should be labeled and defined are controversial and complex topics that remain debated.[16,17,19] Many classifications and definitions exist, but none have been accepted universally.[1,5,6,10,15,22–26]

In 1989, 20 years after SIDS was first defined, the National Institutes of Health (NIH) convened a multidisciplinary panel of 12 experts to update the original SIDS definition (Table 1).[6] The panel described SIDS as "the sudden death of an infant under one year of age, which remains unexplained after a thorough case investigation, including performance of a complete autopsy, examination of the death scene, and review of the clinical history" (Table 1). Although similar to the 1969 definition, the revised definition limited SIDS to infants younger than 1 year and required a review of the history and examination of the death scene. The explicit requirement of a scene investigation was in part because of the recognition of the investigation's value in identifying specific causes of death.[6,27] Ultimately, this requirement led to the 1996 creation and adoption of recommended standards on how to conduct a scene investigation for these infants, which included the Centers for Disease Control and Prevention's Sudden Unexplained Infant Death Investigation Reporting Form, investigation guidelines, and national training.[8,28]

In 2004, an international group of SIDS experts met in San Diego, California, to again refine the SIDS definition.[5] The expert group of 10 pediatric pathologists, forensic pathologists, and pediatricians included Dr Beckwith and was led by Dr Henry Krous. The group agreed on a revised general definition and series of subcategory definitions for sudden infant deaths (Table 1).[5] The revised definition, often referred to as the "San Diego definition," characterized SIDS as the "sudden unexpected death of an infant less than 1 year of age, with onset of the fatal episode apparently occurring during sleep, that remains unexplained after a thorough investigation, including performance of a complete autopsy and review of the circumstances of death and the clinical history." This revised definition, like previous iterations, emphasized that SIDS was a diagnosis of exclusion. New to the definition was identifying that these

deaths occurred during sleep. Furthermore, subcategories of sudden infant death were introduced: category IA SIDS (classic features of SIDS present and completely documented); category IB SIDS (classic features of SIDS present but incompletely documented); category II SIDS; and unclassified sudden infant death (Table 1). The unclassified sudden infant death category was intended to capture cases in which "alternative diagnoses of natural or unnatural conditions are equivocal, including cases for which autopsies were not performed." Of note, the 1989 NIH panel had similarly recommended that cases lacking a postmortem examination and that remained "unresolved" after a thorough case investigation be classified as undetermined or unexplained cause and not as SIDS.[6] Examples of unresolved cases were "suspected cases of abuse, neglect, or accidental suffocation; cases with episodes of vomiting or diarrhea in 24 hours before death without pathologic evidence of infection; or cases in which the information regarding death is not reliable."

TERMINOLOGY DEBATE

Even with periodic revisions and updates to the 1969 SIDS definition, vigorous debate continues regarding the labeling and classification of sudden unexplained infant deaths. SIDS is the favored term for many academic and clinical researchers because it was the term used most often in published etiologic and observational risk factor studies during the 1970s–1990s. However, in the US forensic medicine community, many medical examiners and coroners have discontinued using the term SIDS and often use other designations, such as undetermined cause, sudden unexplained infant death, and other terms that reflect a possible accidental suffocation in an unsafe sleep environment.[16] There is also disagreement among US medical examiners and coroners as to whether infant deaths meeting the SIDS definitions could constitute a "syndrome"[4,17]: a term that refers to a disease or condition with a common group of signs and symptoms.[5] These sudden deaths occur in apparently healthy infants with no identified medical conditions or disease; therefore, many argue against the use of the word syndrome.[5,17] Others argue that the term SIDS conveys a certainty of diagnosis, although the underlying cause of SIDS remains unknown.[5,17] Others believe that SIDS is a diagnosis of exclusion, and, although a natural or unnatural cause may or may not exist, the degree of uncertainty precludes a more definitive cause determination.[10,17]

Because there is no universally accepted standard procedure regarding classification of sudden infant deaths, variable terms and acronyms have been used in scientific, practice, and policy documents. Frequently used acronyms and terms include SIDS, SUID, "SUDI," unexplained, unexpected, and undetermined causes. SUID has become an umbrella term to describe sudden infant deaths, including those deaths previously called SIDS.[15,29,30] The "U" in SUID can refer either to unexpected or unexplained. SUID terms are frequently used interchangeably, often without careful reflection as to what the "U" signifies. In the United Kingdom, Europe, Australia, and New Zealand, "SUDI" is often used in place of SUID, referring to sudden unexpected death in infancy or sudden unexplained death in infancy. Most would agree, however, that before investigation, when an immediate cause is not obvious, deaths are both unexpected and unexplained. After investigation, the death is either explained or remains unexplained. Because these deaths commonly occur in an unsafe sleeping environment, they are increasingly referred to as sleep-related infant deaths. The AAP has acknowledged terms other than SIDS, including SUID and sleep-related infant deaths, in their clinical reports "SIDS and Other Sleep-Related Infant Deaths: Evidence Base for Updated 2016 Recommendations for a Safe Infant Sleeping Environment"[2] and "Identifying Child Abuse Fatalities During Infancy."[7]

For the forensic medicine community, evidence at the death scene may point to a possible asphyxiation caused by caregiver overlay or soft bedding, but the unobserved and unwitnessed nature of most of these deaths and lack of conclusive findings indicating a medical condition at autopsy can prevent the death certifier from attributing a specific cause. For example, some cases interpreted as SIDS may be an intentional smothering, but smothering, like drowning and many other asphyxia related conditions, may have no demonstrable findings at autopsy. Given this conundrum, some medical examiners and coroners may prefer to classify infant deaths occurring in an unsafe sleep environment as undetermined cause or possible or probable accidental asphyxiation in an unsafe sleep environment. Some medical examiners and coroners will be comfortable certifying these deaths as accidental suffocation or asphyxiation. Factors contributing to explained suffocation deaths, such as shared sleep surface and soft bedding in the sleep environments, are also risk factors for, but not necessarily causes of, SIDS.[4,31] Classification decisions may be influenced by office policies,[32] personal beliefs and biases,[33]

previous training,[4] and diagnostic preferences.[16]

DIAGNOSTIC SHIFT

Inconsistent reporting practices, lack of consensus on terminology, and changes in understanding why these deaths occurred have resulted in a diagnostic shift among medical examiners and coroners.[3,34,30] As previously noted, US death certifiers have moved away from reporting SIDS and toward reporting other designations, such as undetermined cause and accidental suffocation and strangulation in bed.[3,16] This diagnostic shift, which has also been observed in other countries such as New Zealand and Australia,[35,36] affects both surveillance and epidemiological and etiologic research. Importantly, for surveillance and research that rely on death certificate data, the diagnostic shift has resulted in variability in attribution of cause, making it difficult to accurately differentiate explained causes (ie, accidental suffocation and strangulation in bed) from unexplained causes (ie, SIDS and other undetermined causes). These explained and unexplained causes share risk factors, but the level of evidence used to determine the cause is inconsistent among death certifiers.[16]

The diagnostic shift and difficulty in differentiating causes of death is compounded by mortality coding rules in the *International Statistical Classification of Diseases and Related Health Problems* (ICD).[20,21] ICD codes are applied to cause-of-death determinations used to certify sudden infant deaths, but the codes applied do not always reflect the certifier's intent.[15,16] By law, the official cause of death for these cases must be determined and reported by the medicolegal death investigation system (ie, medical examiner) and not by the pediatrician. Codes in the *International Statistical Classification of Diseases and Related Health Problems*, *10th Revision*, (ICD-10)[21] differ from those in the *International Statistical Classification of Diseases and Related Health Problems*, *10th Revision*, *Clinical Modification*, (ICD-10-CM).[37] The *ICD-10-CM* was adapted from the *ICD-10* for classifying and reporting diseases and other morbidities in US health care settings. The *ICD-10*, not the *ICD-10-CM*, is used for official reporting of mortality statistics in the United States and other nations.

For mortality surveillance that relies on ICD coding from death certificates, it has become customary in the United States to group sudden infant death causes into 1 of 3 categories: SIDS (ICD-10 code R95), unknown or unspecified causes (ICD-10 code R99), and accidental suffocation and strangulation in bed (ICD-10 code W75). These 3 causes are included in the larger category called SUID.[3,29,30] This larger category allows for consistent monitoring of mortality trends and comparisons across jurisdictions and includes deaths from both explained (ie, accidental suffocation and strangulation in bed) and unexplained causes (ie, SIDS, unknown and unspecified causes). For research purposes, this categorization may be reasonable if the goal is to capture all SUIDs initially and then, after a careful examination and assessment, further categorize deaths to meet a study's case definition of an unexplained or explained cause.

IMPORTANCE OF CONSISTENT TERMINOLOGY

When an infant dies, shared and consistent terminology is essential to help pediatricians, other physicians, and nonphysician clinicians (eg, family physicians, obstetricians, nurses, social workers, and home visitors) improve communication with families and among themselves. A lack of consistent practices and consensus on terminology, including the use of acronyms, creates confusion for and possibly alienation of stakeholders and partners: including parents, caregivers, pediatricians, program prevention planners, and other medical and scientific professionals. The current use of inconsistent terminology can lead to communication errors and unnecessary misunderstandings. It can affect the development of public policies designed to reduce sleep-related infant deaths, including child product safety legislation and regulation focused on promoting safe sleep environments. Inconsistent terminology may also have unintended consequences for prevention messages and interventions for parents and caregivers. In addition, it can negatively affect the bereavement response and support being provided after a sudden infant death.

HOW TO SENSITIVELY COMMUNICATE WITH PARENTS

After an infant death, pediatricians, other physicians, and nonphysician clinicians (especially hospital-based physicians) are often the ones who first speak to grieving parents about possible causes of death. Shared consistent terminology during these interactions with families is necessary for effective communication. Pediatricians, other physicians, and nonphysician clinicians serving the infant's family members continue their support of families through counseling and assessment of surviving siblings for potential shared congenital or genetic conditions. Increasingly, they participate in multidisciplinary child death reviews, consult with forensic medical specialists, and help support families through the investigation process, providing resources and referrals after the death. These physicians and nonphysician clinicians, especially pediatricians,

are crucial and trusted sources of information for families and communities, facilitating the adoption of safe sleep practices and other strategies to reduce the risk of infant sleep-related deaths.[7]

It is important, when communicating with families after an infant death, to not assign blame to the family or incite feelings of guilt, while at the same time acknowledging potentially unsafe behaviors or hazards in the environment to effectively message how risks in the prenatal period or unsafe sleep practices may continue to pose a risk to surviving or subsequent children. The appropriate ethical medical professional response to every child death must be compassionate, empathic, supportive, and nonaccusatory, even if child abuse is suspected.

Concerns about unsafe sleep and bed-sharing as possible contributors to a child's death should be shared with parents as appropriate at some time during the investigation. Several resources have been developed to facilitate this sensitive communication. The AAP and others have identified key principles and resources to assist pediatricians, other physicians, and nonphysician clinicians and families during investigation. Recommendations for these discussions for families include saying things like "I am so sorry for your loss," "I am here to help," and "I have some resources that might be of help. They have been helpful to others." It is important for pediatricians, other physicians, and nonphysician clinicians to be truthful and sensitive, while sharing their willingness to help the family understand the death, the status of the investigation, and what steps, if any, should be taken to help surviving family members, including but not limited to evaluations for potential underlying conditions or referrals to pediatric specialists and mental health professionals.[38–45]

PROGRESS ON REACHING CONSENSUS

There are implications in reaching consensus on terminology to consider, including historical convention, uncertainty regarding circumstances at the time of death, geographical variations in practice, training of death-scene investigators and death certifiers, and caregiver guilt and shame. In addition, several perspectives must be addressed. First, it is essential for the forensic community and health care professionals to incorporate terminology that avoids placing blame or increasing feelings of guilt on the part of a caregiver suffering a tragic loss and objectively and accurately describes the circumstances around an infant's death. Second, the medical examiner or coroner needs to effectively communicate investigation and autopsy findings and explain why the conclusions about cause of death may be inconclusive. Third, the forensic, pediatric, and public health communities need consistent communication tools to allow them to acknowledge unsafe behaviors (eg, bed-sharing) or the presence of hazards in the environment (eg, crib bumpers or soft bedding) without assigning blame or inciting feelings of guilt. Finally, pediatricians, other physicians, and nonphysician clinicians must effectively message how risks identified in the prenatal period (eg, smoking and drinking during pregnancy) or unsafe sleep practices may continue to pose a risk to surviving children. The goal of this careful communication is to prevent from assigning blame or increasing feelings of guilt of any party. It is important that the facts and potential contributing factors to a death be fully shared. In sharing this information, it is important to provide accurate information regarding the deceased but also to identify and address any preventable risk factors for future children or circumstances.

Although there is agreement that all infant deaths are tragic events with precious lives lost, there is a need to consistently classify these sudden infant deaths for which the cause remains undetermined or unexplained. Consensus is also needed on how to classify accidental suffocation deaths that occur in an unsafe sleep environment: that is, what evidence is needed to classify a death as an explained suffocation in the absence of a biological marker to determine the cause. Current terminology and acronyms may exacerbate confusion. Consistency in describing these deaths should be a key goal. In 2017, a group of US experts came together to find common ground for classifying sudden infant deaths.[10] The group, the National Association of Medical Examiners (NAME) Panel on Sudden Unexpected Death in Pediatrics, included forensic pathologists representing NAME, pediatricians representing the AAP, and federal liaisons from the Centers for Disease Control and Prevention and NIH. In addition, in November 2018, an international expert panel (forensic pathologists, pediatricians, emergency physicians, family physicians, researchers, epidemiologists, and parents) met to discuss the terminology and nomenclature for sudden infant and child deaths at Radcliffe College, making ICD coding recommendations to the World Health Organization (WHO) for *International Statistical Classification of Diseases and Related Health Problems, 11th Revision* (*ICD-11*).[15] Many participants from the Radcliffe Congress meeting also participated in the NAME Panel. Both groups acknowledged that the forensic pathology experts had moved away

from calling these deaths "SIDS" and had rejected the idea that the etiology of these deaths satisfied the definition of a syndrome. Regardless, researchers at the Radcliffe meeting, many with 30 to 40 years of SIDS experience, still preferred the term "SIDS." Forensic pathologists at the Radcliffe Congress agreed with other participants that the title of the code in ICD-11 should include both unexplained sudden death in infancy and SIDS, to reflect that both certifications could be classified under the same code (Table 1). This recommendation was echoed by the NAME Panel in its 2019 publication.[10] In addition, the NAME Panel recommended that certifiers use "unexplained sudden death" (and not SIDS) and specify whether intrinsic and extrinsic risk factors (Table 1) were identified in the cause-of-death statement for unexplained sudden pediatric (infants <1 year and children 1 year old and older) deaths, including those that meet the current definition of SIDS (Table 1). Both groups also identified a set of criteria for determining accidental suffocation as a cause in sleep-related deaths.

PRACTICAL CONSIDERATIONS

The lack of consistency in how sudden infant deaths are categorized or described across the United States has created confusion and has had unintended consequences for bereaved families, pediatricians, other physicians, nonphysician clinicians, and policymakers. In addition, inaccurate and inconsistent classification of sudden infant deaths has affected our ability to: (1) reliably and accurately monitor mortality trends; (2) understand the pathophysiology and epidemiology of sudden infant deaths; and (3) develop effective data-driven public health and preventive messages.[3,10,15] It remains to be seen whether the WHO will accept the changes proposed by the Radcliffe Congress for ICD classification and coding of unexplained sudden deaths; as of August 2021, this proposal is under review. The *ICD-11* will officially go into effect among WHO member states in January 2022. It is also too early to determine to what extent the forensic community will adopt the NAME Panel's recommendations and use of the phrase "unexplained sudden death."

Because pediatricians, other physicians, and nonphysician clinicians are often the conduit of information between bereaved families and medical examiners, coroners, and death-scene investigators, it is important for these health care professionals to be cognizant of the terminology used and its implications to enable them to help families, review deaths, and prevent further fatalities. In response, the AAP recommends the following:

- Advocating for the rapid adoption of the NAME Panel's terminology because the terminology is definitive and positioned to aid surveillance monitoring activities and epidemiological analysis.[10,14] Increased understanding of mortality trends, etiology, and risk factors can inform effective interventions and guide future research, ultimately reducing future fatalities.
- If the proposal of the Radcliffe Congress for changing the ICD classification and coding of unexplained sudden deaths is approved by the WHO, encouraging adaption of ICD-11 coding by the United States and other WHO member states by January 2022.
- Advocating that state child protective service agencies use the NAME Panel's terminology in their assessments.
- NAME, in collaboration with the AAP, should develop an algorithm to lead a medical examiner, through consideration of the history, the findings at the scene, and possible intrinsic and extrinsic contributing factors, to the final adjudication of cause of death.
- Encouraging the medical examiner to have a formal reporting mechanism back to the primary care pediatrician, other physician, or nonphysician clinician. The pediatrician, other physician, or nonphysician clinician should, in turn, offer the family a chance to meet and review the findings of any investigation, including discussing possible contributing or confounding factors that may have played a role in the infant's death and possibly be used to prevent future deaths and providing any needed referrals for pediatric specialist or mental health care.
- Training for physicians, nonphysician clinicians, and the forensic community about effective communication practices that prioritize empathy and sensitivity in sudden infant death and all fatality investigations.
- Affirmation that when child abuse is eliminated, other risk factors such as sleeping environment, drug or alcohol use of caregivers, prenatal exposures, and poverty are matters of public health and family health. The mere presence of risk factors should not support legal charges.

Health Disparities in Tobacco Use and Exposure: A Structural Competency Approach

Jyothi Marbin, MD, FAAP,[a] Sophie J. Balk, MD, FAAP,[b] Valerie Gribben, MD, FAAP,[a] Judith Groner, MD, FAAP,[c] SECTION ON TOBACCO CONTROL

abstract

Fourteen percent of US adults use tobacco products. Because many of those who use tobacco are parents and/or caregivers, children are disproportionately exposed to tobacco smoke. People who use tobacco products often become addicted to nicotine, resulting in tobacco dependence, a chronic, relapsing disease. Tobacco use and exposure are more likely to occur in vulnerable and marginalized groups, including those living in poverty. Although some view tobacco use as a personal choice, evidence suggests that structural forces play an important role in tobacco uptake, subsequent nicotine addiction, and perpetuation of use. Viewing tobacco use and tobacco dependence through a structural competency lens promotes recognition of the larger systemic forces perpetuating tobacco use, including deliberate targeting of groups by the tobacco industry, lack of enforcement of age-for-sale laws, inferior access to health insurance and health care, poor access to cessation resources, and economic stress. Each of these forces perpetuates tobacco initiation and use; in turn, tobacco use perpetuates the user's adverse health and economic conditions. Pediatricians are urged to view family tobacco use as a social determinant of health. In addition to screening adolescents for tobacco use and providing resources and treatment of tobacco dependence, pediatricians are encouraged to systematically screen children for secondhand smoke exposure and support family members who smoke with tobacco cessation. Additionally, pediatricians can address the structural issues perpetuating tobacco use by becoming involved in policy and advocacy initiatives.

BACKGROUND

Tobacco use results in exposure to nicotine, a powerfully addictive substance, often leading to tobacco dependence. Tobacco dependence is considered a pediatric disease because most tobacco use and subsequent

addiction begin in adolescence.[1,2] Tobacco dependence is a chronic disease,[3] and users are prone to relapse and remission.[4] People who use tobacco suffer consequences, including disease and premature death. Their children suffer from the direct impact of parental tobacco use, including prenatal, secondhand smoke (SHS), and thirdhand smoke (THS) exposure, as well as the economic and social consequences of family tobacco use. Most tobacco users want to quit, and many make multiple quit attempts. People who smoke are more likely to quit when they receive treatment from clinicians.[4]

Although the overall use of combustible tobacco products is declining,[5] tobacco use and exposure continue to affect marginalized* populations disproportionately. These groups include people living in poverty, people suffering from mental illness, and people with lower educational attainment. Other groups are highlighted in Table 1. The consequences of tobacco use and exposure are more concentrated in people already more likely to face greater health and economic challenges.[6]

The same children who are exposed to SHS are exposed to THS, or the "residues left behind by smoking," which can include chemicals that "remain, react, re-emit, and/or are resuspended long after active smoking ends."[11] Children are uniquely exposed to THS because of home exposure, dermal uptake from crawling, and increased respiratory rates compared with adults. However, distinguishing health effects of THS from SHS is challenging. For the purpose of this clinical report, the term SHS exposure is used, understanding that this designation may refer to both SHS and THS.

Although combustible tobacco use has declined in the United States, electronic cigarette (e-cigarette), vaping, or Juuling usage has accelerated, reaching epidemic proportions among youth[12]; more than 20% of high school students now vape.[13] The American Academy of Pediatrics (AAP) policy statement "E-Cigarettes and Similar Devices" details the clear links between e-cigarette companies' coordinated, targeted advertising to youth and subsequent rapid increase in e-cigarette initiation among youth. That report also highlights research showing that adolescents and young adults who vape are 3.6 times more likely to progress to traditional cigarettes than those who never vaped, paving the way for new cycles of addiction.[14] Although it is clear that e-cigarette use is rapidly changing the landscape of tobacco use and nicotine addiction, a comprehensive review of disparities related to e-cigarette use is beyond the scope of this clinical report. This report will focus on disparities related to combustible tobacco, recognizing the need for a separate report on disparities related to e-cigarette uptake and use.

This report proposes interventions to reduce disparities in combustible tobacco use and exposure using a structural competency framework. Pediatricians treating children whose parents or other caregivers use tobacco (and adolescents using tobacco) are urged to offer consistent cessation advice and tobacco-dependence treatment. Parents who have a primary care provider should also be advised to seek additional counseling and support from that clinician. If caregivers are unable to stop smoking, pediatricians should advise maintaining smoke-free clothing, homes, and cars.[1] Pediatricians may feel frustrated when counseling patients and caregivers who continue to smoke despite discussions about cessation[15,16]; however, pediatricians who gain a deeper understanding of structural factors perpetuating tobacco dependence may be better able to help families break the cycle of tobacco use. Viewing family tobacco use as a social determinant of health (SDH), systematically screening for tobacco exposure, and offering tobacco-dependence treatment to caregivers who smoke are ways to overcome structural barriers to smoking cessation. Advocacy steps and policy changes are also recommended to address structural inequalities reinforcing tobacco use.

STRUCTURAL ISSUES PERPETUATING DISPARITIES IN TOBACCO USE

Why Use a Structural Competency Framework?

Although some see tobacco use as a personal choice among adult informed decision-makers, looking at tobacco use through a structural competency framework calls attention to the larger societal forces that lead people to use tobacco. The structural competency approach frames health inequities "in relation to the institutions and social conditions that determine health related resources" and is focused on structural changes to address upstream causes of health disparities.[17] The structural competency framework adds to the SDHs approach by acknowledging that social injustice and power dynamics underlie health inequity.[18] Although the structural competency approach is used in social work and public health, it may be a new paradigm for clinicians focused on the care of individual patients.

Many structural issues perpetuate tobacco initiation and use on both a global and domestic scale. The

* The authors use the term "marginalized" to include social groups that are intentionally excluded from mainstream society through social and political oppression. The authors recognize that it is the social processes (and not any characteristic intrinsic to the people themselves) that lead to health disparities.[104]

TABLE 1 Effects of Tobacco Use and Exposure on Marginalized Populations

High-risk Group[a]	Smoking Rate	Coexisting Challenges (Examples)	Comments
Black or African American people[7]	Black or African American people usually smoke fewer cigarettes and start smoking at older ages compared with white people.	Black or African American people are more likely to die of smoking-related diseases than are white people.	Black or African American children and adults are more likely to be exposed to SHS than other racial or ethnic groups.
Hispanic people[b]	Cigarette smoking prevalence generally is lower than for most other US racial or ethnic groups, but rates are significantly higher for men compared with women.	Acculturation plays a role: smoking prevalence is higher among Hispanic people born in the United States.	Current prevalence is higher among Puerto Rican adults compared with Cuban, Mexican, and Central or South American adults.
Immigrants and refugees[c]	Smoking rates among immigrants to the United States (especially female immigrants) generally are lower than rates in US populations.	Smokers from these groups have vulnerability compounded by economic disadvantage, preimmigration experiences, attitudes toward smoking, and sociocultural and/or language barriers influencing access to care, including smoking cessation.	Research is limited because studies have been focused mainly on Mexican, other Hispanic, and Asian populations. More research is needed to investigate tobacco exposure in these and other immigrant populations.
Incarcerated people[d]	Smoking prevalence is approximately 4 times higher in criminal justice populations than in the general population.	Characteristics often found in individuals who are incarcerated, (eg, history of substance abuse, mental illness, poverty, low educational attainment) also increase likelihood of tobacco use.	The United States has the highest rate in the world of incarcerating adults. People of racial and ethnic minority groups are disproportionately affected; Black men are incarcerated at higher rates than non-Hispanic white men and Hispanic men.
LGBTQ people[e]	Of lesbian, gay, and bisexual adults, 20.5% smoke cigarettes, versus 15.3% of straight adults; 30.7% of transgender individuals smoke.	Gay men have high rates of HPV infection; coupled with tobacco use, this increases risk for anal and/or other cancers; LGBTQ individuals are less likely to have health insurance, which may affect cessation treatment options.	The tobacco industry targets LGBTQ individuals.
American Indian people[f]	The American Indian population has the highest cigarette smoking rates compared with other US racial or ethnic groups.	More American Indian women smoke during the last 3 mo of pregnancy compared with all other groups.	Some American Indian populations use tobacco for religious, ceremonial, or medicinal reasons. It is important to distinguish traditional versus commercial use. In addition, casino smoke exposure is difficult to regulate because of jurisdictional issues on reservations.
People of low socioeconomic status[g]	Adults below the poverty level are approximately 2 times more likely to use cigarettes, cigars, and smokeless tobacco as adults who live at greater than twice the poverty level.	There are higher lung cancer rates in those living in poverty compared with affluent groups; there is also less access to health care; therefore, tobacco-related conditions are diagnosed at later stages.	Low-income neighborhoods have a higher concentration of tobacco retailers.
People with mental illness and substance use disorders[8]	Approximately 25% of US adults have some form of mental illness or substance use disorder; these adults consume approximately 40% of all cigarettes smoked by adults.	People with mental illness more likely to have stressful living conditions, have low annual household income, and have inferior access to health insurance, health care, and help with quitting.	The tobacco industry perpetuates idea that it is impossible for these individuals to stop smoking.
People living in Tobacco Nation[9]	Twenty-two percent of Tobacco Nation's adults smoke, compared with 15% of adults in the rest of the United States. Those in Tobacco Nation smoke many more cigarettes per capita annually (66.6 packs) than those in the rest of the United States (40.6 packs).	Residents of Tobacco Nation earn 20% less than those in the rest of the United States. There are 12% fewer doctors in Tobacco Nation, meaning that accessing primary care can be more challenging.	Compared with the rest of the country, Tobacco Nation has fewer smoke-free laws and tobacco-control policies, measures which have been proven to protect the public, deter youth smoking, and encourage cessation.
People living in rural communities[10]	The prevalence of cigarette smoking among US adults is highest among those living in rural areas (28.5%).	The health of people living in rural areas is affected by tobacco more than the health of those living in urban and metropolitan areas, in part because of socioeconomic factors and lack of health care options.	Adolescents in rural regions begin smoking cigarettes earlier in life. Thirty-five percent of children in rural areas live in a household where someone smokes.

HPV, human papillomavirus.

tobacco industry aggressively targets vulnerable and marginalized groups, including children. People who smoke often have poor access to health insurance and health care, lack access to cessation resources, and live in poverty, all of which, in addition to other factors, perpetuate tobacco use and dependence. The lack of effective enforcement of age-for-sale laws means that too often youth have unregulated access to tobacco products.[19,20] Tobacco dependence and exposure reinforces existing health disparities, and these health disparities perpetuate tobacco dependence, creating a cycle of intergenerational tobacco dependence, poverty, and poor health (Fig 1). Pediatricians can continue to engage and support individuals in cessation attempts while also recognizing and addressing economic, social, and political structures that reinforce tobacco dependence and exposure. Adding a structural competency approach to individual clinical interventions will help pediatricians recognize and address some of the structural factors promoting tobacco dependence and will allow pediatricians to push back against a cycle of addiction and disadvantage that reinforces its use.

Structural Barriers: The Tobacco Industry

Targeting vulnerable populations is a well-established tactic used by the tobacco industry to recruit new smokers and maintain current smokers. Children, the most vulnerable group, have long been targeted and tasked to serve as "replacement smokers" by the tobacco industry.[21] The rapidly developing adolescent brain is uniquely susceptible to nicotine addiction,[22] and 90% of adults who smoke started smoking before 19 years of age,[23] thus giving tobacco companies great incentive to recruit youth smokers. Documents reveal that the tobacco industry has clearly recognized this opportunity. Philip Morris executives noted, "Today's teenager is tomorrow's potential customer..."[24] The 2014 US Surgeon General's report acknowledged that "the root cause of the smoking epidemic is evident: the tobacco industry aggressively markets and promotes lethal and addictive products, and continues to recruit youth and young adults as new consumers of these products."[2] Although tobacco companies deny intentional marketing to children, they continue to advertise tobacco in outlets designed to reach children.[25]

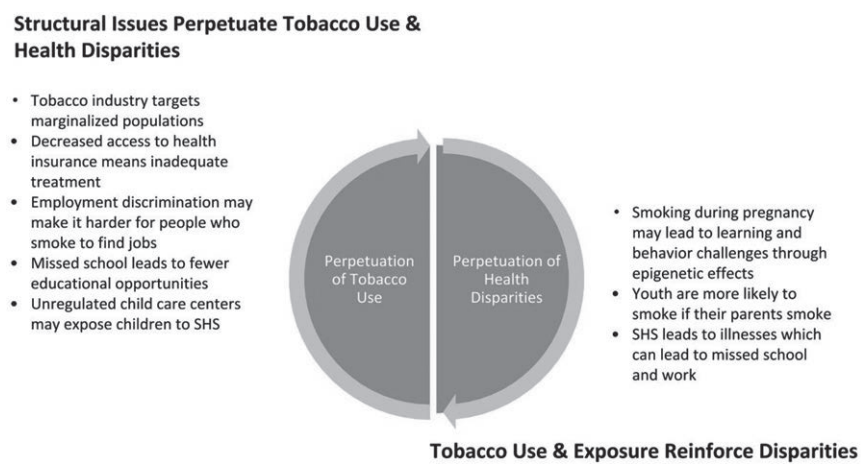

FIGURE 1
Tobacco use and exposure reinforce existing health disparities, and these health disparities perpetuate tobacco use.

Lesbian, gay, bisexual, transgender, and queer (LGBTQ) individuals are a focus of targeted campaigns, likely contributing to higher smoking rates compared with non-LGBTQ individuals. In 1992, a tobacco industry memo stated, "We see the gay community as an area of opportunity.… Philip Morris would be one of the first (if not the first) tobacco advertiser in this category and would thus 'own the market.'"[26] The tobacco industry subsequently began advertising in publications aimed at the LGBTQ community and financially supporting LGBTQ organizations.[27]

Black and African American youth and adults have been systematically targeted through advertisements, retailers, and promotion of menthol products. More tobacco advertisements are found in communities with a higher density of Black and African American residents. In these communities, Black and African American youth have been recruited to smoke through advertising and the distribution of free cigarette samples.[28] The proportion of Black and African American smokers who use menthol cigarettes increased from 5% in 1952 to 89% in 2011, likely because of aggressive racial targeting by the menthol cigarette industry. Between 1998 and 2002, *Ebony* magazine, a monthly publication with a large Black and African American readership, was nearly 10 times as likely to contain ads for menthol cigarettes as *People* magazine, which has a larger readership among white Americans.[29] This targeted advertising has contributed to nearly 90% of Black and African American smokers using menthol cigarettes, which are more addictive and more harmful than nonmenthol cigarettes.[7]

American Indian and Alaskan native people are also subject to predatory targeting by the tobacco industry. Tobacco companies exploit the federal exemptions that accompany

the unique sovereign status of tribal lands to increase their own economic profit, using tactics such as promotional coupons, price reductions, giveaways, and sponsorships.[30] Tobacco companies employ manipulative strategies to exploit sacred use of tobacco. For example, the Santa Fe Natural Tobacco Company, now owned by R.J. Reynolds, produced "an exclusive line of authentic reproductions of Native American pipes, snuff containers, tobacco pouches, and other natural tobacco implements."[31] These and other tactics are believed to contribute to the disproportionate burden of tobacco-related disease in Indigenous populations.[30]

Since the 1920s, women have been targeted through appealing tobacco advertising that gave them perceived psychosocial needs around weight loss, independence, stress relief, and the need to escape.[32] As smoking rates for increasingly educated women started to decrease, targeting of low-income women increased, with significant resources devoted to understanding the psychological profiles of potential customers.[32] R.J. Reynolds Tobacco Company attempted to distribute coupons for packs of cigarettes in envelopes with foods stamps. Coupons were for individual packs, not cartons, because "the lower-income groups tend to buy single packs."[32]

People living in rural areas are also at higher risk of smoking and tobacco-related disease. Rural adolescents start smoking earlier and are more likely to be daily smokers than adolescents living in nonrural areas. Young rural men have historically been targeted through tobacco advertisements featuring cowboys, hunters, and other "rugged images." Antitobacco media are less likely to reach youth living in rural areas.[10] This targeting contributes to higher rates of tobacco use and lower life expectancies in the 12 contiguous states collectively known as "Tobacco Nation"[9]: Alabama, Arkansas, Indiana, Kentucky, Louisiana, Michigan, Mississippi, Missouri, Ohio, Oklahoma, Tennessee, and West Virginia.

The industry also cultivated relationships with organizations working with people with mental illness and funded research to encourage the erroneous ideas that cessation is too stressful for people with mental illness and that people with mental illness need to self-medicate with nicotine to relieve negative moods.[8]

Tobacco companies use targeted marketing strategies because they are incredibly effective in recruiting smokers. As "big tobacco" and "big vaping" become increasingly entwined,[33] a resurgence of these advertising tactics aimed at attracting youth to e-cigarettes has been observed. Pediatricians need to be aware of this targeted advertising and its impact on vulnerable populations.[34]

Structural Barriers: Decreased Access to Insurance

Structural barriers maintain intergenerational smoking by reinforcing economic disparities and limiting access to tobacco-dependence treatment.

Access to health insurance is one example. In more than 40 states, people who smoke can be charged higher insurance rates than those who do not smoke[35]; in some states, these rates can be up to 25% higher than rates for nonsmokers.[36] People from marginalized groups are already much less likely to have health insurance; raising premiums for people who smoke makes health insurance even harder and more expensive to obtain. In a 2016 study, authors examined the impact of tobacco surcharges on insurance coverage and cessation among people who smoked and found that smokers were 7.3% less likely to have health insurance coverage than nonsmokers.[37] The authors also noted that "tobacco surcharges increased neither smoking cessation nor financial protection from high health care costs."[37] Without health insurance, tobacco users may have limited access to care for smoking-related illnesses as well as less access to tobacco-dependence treatment. The treatment they can access may be inadequate, for example, providing limited medication only for a limited period of time. Such regressive policies do little to treat nicotine addiction as a chronic illness; instead, they limit access to treatment for people who are addicted to nicotine.[36]

Life insurance is also more expensive for people who smoke,[38] which affects the ability of those who smoke, who have a higher mortality rate from numerous health problems, to provide financial security for their survivors, including minor children or grandchildren, in the event of their demise.

Structural Barriers: Employment Challenges

Discrimination in employment is another example of a structural barrier. Cross-sectional studies have consistently demonstrated an association between smoking and unemployment.[39] A 2006–2007 study of more than 52 000 construction workers found that those who smoked were more likely to be unemployed than those who did not smoke.[40] In one study of unemployed job seekers, people who smoke were found to be less likely to be reemployed after 1 year than those who did not smoke and were paid less when they were rehired.[39] The cost of hiring someone who smokes is estimated at nearly $6000 more than the cost of hiring a nonsmoker,[41] meaning that some employers simply refuse to hire people who smoke.[42] Those who are living in poverty, are unemployed, and have less formal education are more likely to use tobacco. Refusing to employ smokers

effectively restricts access to jobs and ensures that people who smoke remain at an economic disadvantage.[43]

Structural Barriers: Missing Work and School

Adding to the economic burden is hardship caused by missed work because of caregiver or child illness. Children are more likely to be absent from school if their caregiver smokes,[44] meaning caregivers may have to miss work to care for their sick child. The cost of missing work to care for a sick child can be high; caregivers lose an estimated $227 million per year caring for ill children,[44] which reinforces economic disparities. Repeated school absences can hinder a child's school performance[45] and, in the long-term, may influence career trajectory and earning potential.[44]

The cycle of health and economic disparities among people who use tobacco is self-perpetuating; adults who smoke who are unable to escape the cycle of addiction are more likely to have children who smoke,[46,47] giving rise to new generations addicted to nicotine and susceptible to these same economic hardships.

Structural Barriers: Exposure in Child Care Settings

For young children, out-of-home child care may represent a significant portion of their day and a source of exposure, particularly for parents who have low incomes, do not speak English, have lower educational levels, or are single parents. These families are more likely to use non–center-based care[48] and instead may rely on child care with less oversight, where children may be more likely to be exposed to SHS.

INTERGENERATIONAL FACTORS PERPETUATING DISPARITIES

Smoking Rates During Pregnancy Are Higher in Marginalized Groups

Smoking during pregnancy is a risk factor for perpetuating intergenerational health disparities. Data from the Pregnancy Risk Assessment Monitoring System reveal that although prevalence of maternal smoking during pregnancy declined significantly between 2000 and 2010,[49] differences in prevalence by race and/or ethnicity persist. In 2010, smoking during pregnancy was highest among American Indian women (26.0%), followed by non-Hispanic white women (14.3%), non-Hispanic Black women (8.9%), Hispanic women (3.4%), and Asian American and/or Pacific Islander women (2.1%).[49] Birth certificate data for 2014 reveal that, overall, approximately 8.4% of women smoked at any time during pregnancy. Higher smoking rates during pregnancy were observed in women with fewer than 12 years of education (14.1%), women with Medicaid coverage (14.0%), women between 20 and 24 years of age (13.0%), unmarried women (14.7%), and non-Hispanic American Indian women (18.0%).[50] Smoking during pregnancy is associated with maternal vulnerability: women who experienced intimate partner violence were more likely to smoke during pregnancy and less likely to stop smoking.[51]

Smoking During Pregnancy Perpetuates Disparities

A large body of literature describes links between smoking during pregnancy and short- and long-term health issues in offspring, including increased infant mortality, sudden unexpected infant death,[52] low birth weight, and respiratory problems. In addition to these detrimental outcomes of exposure to smoking in utero, epidemiological observational evidence links prenatal smoking to increased risks of obesity, behavioral problems, conduct disorder, attention-deficit/hyperactivity disorder (ADHD), and cognitive issues in children.[53–59] Recent research has revealed a dose-response relationship between maternal cotinine concentrations (indicating nicotine exposure) during pregnancy and presence of ADHD in children.[60] These associations remain even after controlling for confounding factors, such as maternal income and education and maternal and paternal ADHD diagnoses, and are linked to poor health and lower educational attainment. The research cited here has been conducted internationally (United States, Canada, and Europe), so it does not reflect a particular geographic confounding factor to explain the association between smoking during pregnancy and poor outcomes in children. Such pregnancy exposure can be said to perpetuate disparities because children with behavioral, conduct, and learning issues are likely to have a more difficult time throughout the life span. The potential mechanisms for adverse outcomes from prenatal smoking include direct effects of nicotine, carbon monoxide, and other tobacco toxicants on the developing fetal brain along with the potential for fetal adaptation to an adverse prenatal environment, potentially through epigenetic changes. Although epigenetic research is in the early stages,[61] smoking-related epigenetic modifications of gene transcription in specific cells may be mechanisms by which the effects of maternal smoking during pregnancy are transmitted to the next generation.[61,62] Further research will elucidate the epigenetic effects of prenatal smoking on alterations in neural circuitry during fetal development[62] and may help establish mechanisms of the relationships between prenatal smoking and poor behavioral and cognitive outcomes in children.

Women who stop smoking during pregnancy are at risk for relapse after birth, leading to SHS exposure in infants and children.[63] Relapse may also perpetuate the cycle of beginning the next pregnancy with fetal exposure to maternal smoking.

SHS Exposure and Childhood Disparities

Children's SHS exposure is a socioeconomic and educational disparity[4] that leads to differences in health outcomes. It can be difficult to separate effects of prenatal smoking and postnatal SHS exposure; several of these outcomes, including sleep problems (sleep-disordered breathing, sleep apnea, nighttime awakenings)[64–67] and sudden infant death syndrome,[68–70] are linked to both prenatal smoking and postnatal smoke exposure. Impaired sleep itself during childhood is linked to cognitive and behavior issues and poor quality of life.[71–75]

Children exposed to SHS are more likely to develop asthma, and their asthma is more severe than that in nonexposed children.[76–80] The prevalence and severity of bronchiolitis, acute otitis media, chronic otitis media, influenza, and preclinical cardiovascular changes[81–88] is linked to childhood SHS exposure. Smoke exposure in utero and during childhood sets children up for poorer physical and mental health throughout their lives, which leads to poor school performance and may affect future job success and earning potential.

Finally, parents who are addicted to tobacco may prioritize tobacco over food and other basic needs,[89–93] exacerbating negative health outcomes for children.

OFFICE-LEVEL INTERVENTIONS FOR PEDIATRICIANS

Pediatricians are well-positioned to help break the cycle of tobacco dependence at both the individual and structural levels. In this section, office-level interventions are described.

Screening for Tobacco Use and Exposure as SDHs

Tobacco use and exposure are SDHs that contribute to a more difficult future for already marginalized children, adolescents, and adults. Pediatricians have embraced screening and referral systems for other SDHs (eg, food insecurity, insurance access, mental health concerns, housing insecurity, unstable employment) that connect families to necessary resources.[94,95] SDHs are complex and often intertwined, increasing the challenge of addressing them, but tobacco use in parents and other caregivers is an SDH for which there currently are effective and actionable interventions.

Effective Interventions for Tobacco Cessation

Adults who smoke are able to achieve quit rates of more than 30% with a combination of medication and counseling from a primary care provider.[96] The pediatric visit provides a unique opportunity for pediatricians to offer tobacco-dependence treatment to parents and caregivers because most young parents see their children's pediatrician more frequently than they see their own health care providers. Pediatricians can identify children who are exposed to tobacco smoke and assist parents, caregivers, and other household members who want to stop smoking.

The AAP policy statement "Clinical Practice Policy to Protect Children from Tobacco, Nicotine, and Tobacco Smoke"[1] clearly delineates mechanisms for screening for tobacco use and exposure at each visit and providing support to people who smoke. This assistance may include connecting them to state quitlines (such as 1-800-QUIT-NOW) or cessation services and recommending

TABLE 2 AAP Policy Statements and Other Resources for Tobacco and E-cigarettes

or prescribing nicotine replacement therapy (NRT). This policy addresses parameters for prescribing NRT to parents, including potential liability, disease assessment, risks versus benefits, and documentation.[1]

There are many ways to help caregivers cut down on or stop smoking[96]; accessible resources are available from the AAP (Table 2). One option for office practices is Clinical Effort Against Secondhand Smoke Exposure (CEASE), a program for clinicians designed to increase smoking cessation through brief motivational interviewing, a recommendation or prescription for NRTs, and referral to cessation helplines.[97,98] CEASE has been shown to increase tobacco-dependence treatment offered by pediatric clinics; recent research has revealed promising results that parents who received CEASE interventions at their child's clinic were more likely to quit smoking.[96,99]

Social networks also affect smoking cessation. Smoking cessation by a spouse, sibling, friend, or co-worker increases the chance that an individual will also stop smoking.[100] Therefore, it may be beneficial to ask about other people who use tobacco within a tobacco user's social network and to suggest cessation resources for those people as well. In addition,

TABLE 3 Suggested Structural Interventions to Reduce Tobacco-Related Disparities

Structural Intervention	Rationale	Comment
End predatory targeting by the tobacco industry	Tobacco companies target vulnerable and marginalized groups.	Regulating predatory marketing tactics used by tobacco companies will protect children and other vulnerable groups and reduce tobacco initiation.
Ensure basic health coverage for all	Adequate health care would include the following: (1) access to evidence-based therapies for smoking cessation, (2) early recognition and treatment of tobacco use–related diseases, and (3) coverage for mental health services.	Coverage also increases the likelihood that people with mental health problems who also smoke receive needed health services.
Make funds for tobacco-dependence treatment available for people without insurance	Adequate tobacco-dependence treatment should be accessible to all.	Tobacco taxes are a potential source of funding.
Advocate for employers to provide effective tobacco-dependence treatment to employees who smoke	Tobacco-dependence treatment in the workplace may help workers stop smoking, stay in the workforce, and gain a better economic footing.	Efforts may thus reduce the burden of unemployment on those already experiencing poverty.
Incorporate smoking cessation for caregivers into pediatric visits	Caregivers often visit pediatric clinicians more frequently than their own clinicians, creating important opportunities to discuss tobacco use and need for cessation.	Clinicians aware of structural issues may be more likely to understand counseling efforts as interventions to address these issues. They may be more likely to use a chronic disease model and motivational interviewing techniques.
Support reimbursement for clinicians treating caregivers who smoke; ensure consistent coverage for tobacco-dependence treatment	Pediatricians should be compensated for time spent treating caregivers' tobacco dependence.[102] Consistent payment by health insurers for health risk assessments and preventive care counseling, already defined by CPT coding, and consistent health coverage of FDA-approved medications for tobacco-dependence treatment of household contacts,[102] even when available over the counter, may improve cessation rates.	ICD-10 codes allow pediatricians to code for SHS exposure[a] but not for time to assist caregivers with smoking cessation.
Improve access to counseling and medications by investing in streamlined referrals from EHRs to smoking quitlines	Greater access may improve referral rates to counseling services; many quitlines provide free NRT to their users.	EHR systems also can be modified to allow opening a linked medical record for the child's caregiver. This can facilitate documentation of pediatrician support given to the caregiver.
Partner with schools to monitor absences; provide educational opportunities for children chronically absent because of illness	Children exposed to SHS are more likely to miss school, impeding academic achievement.	Strategies to help children stay on track educationally may help improve educational outcomes.
Urge all child care centers to follow guidance about tobacco exposure	For young children, out-of-home care may represent a significant portion of their day and a source of exposure—particularly for low-income parents who may rely on family day care with less oversight when it comes to these issues. Currently, even teachers in centers are often subject to the structural SDHs as they tend to be low wage workers as well.	This guidance is provided by the National Resource Center for Health and Safety in Child Care and Early Education in *Caring for Our Children*.[103]

CPT, *Current Procedural Terminology*; EHR, electronic health record; FDA, US Food and Drug Administration; ICD-10, *International Classification of Diseases, 10th Revision*.

tobacco users may be able to help identify ways in which their social networks can support cessation.

EDUCATION AND TRAINING

Evidence-based smoking cessation counseling techniques can be integrated into curricula for medical students and residents so that trainees become familiar with behavioral and pharmacologic strategies to help people stop smoking.[1] Trainees should learn that tobacco dependence is a chronic disease similar to other chronic diseases that need consistent treatment by clinicians. Important components of treatment include cessation medications approved by the US Food and Drug Administration, including the nicotine patch, gum, and lozenge. E-cigarettes and similar devices should not be prescribed for tobacco-dependence treatment.[13] Counseling and recommending or prescribing NRT can be incorporated into their practice. Trainees who plan to prescribe NRT for parents should review the guidelines described above.[1] In addition, as part of their curriculum, trainees can be educated on big tobacco's history of deceptive, targeted marketing techniques and encouraged to discuss potential parallels with the current vaping epidemic. Framing this information as a structural issue will make it clearer to trainees that tobacco use and its consequences are not uniformly distributed in the population.

Including smoking cessation counseling as part of pediatric graduate medical education will help trainees recognize that the most effective way to treat children exposed to SHS (and to prevent the children from using tobacco themselves) is to treat their caregivers. Regular trainings in this area will increase workforce capacity to treat tobacco dependence in families, which will decrease structural barriers to smoking cessation and eventually help improve child outcomes. Trainees can be taught smoking cessation approaches by using a structural competency framework as part of the advocacy curriculum required in pediatric residency training.[101]

TOBACCO-RELATED ADVOCACY AND POLICY INTERVENTIONS

Pediatricians are trusted members of their communities and can play important roles in advocating for policies to protect children from tobacco use. Although a comprehensive review of advocacy strategies is beyond the scope of this document, we encourage readers to consult the resources available through the AAP (Table 2) for advocacy and policy actions related to tobacco use.

STRUCTURAL INTERVENTIONS TO REDUCE DISPARITIES

Larger systems that keep people in poverty need to change to address the disparities that perpetuate tobacco use. Changing these systems may be difficult because they have significant up-front costs and may threaten existing power structures. These structural changes are discussed above; Table 3 includes several key recommendations. Actions taken by pediatricians at local, state, and federal levels can support these and other initiatives aimed at addressing structural barriers that perpetuate intergenerational cycles of tobacco dependence and health disparities.

CONCLUSIONS

Tobacco dependence is a chronic, relapsing, addictive disease, and tobacco use causes 480 000 deaths in the United States every year. Structural barriers ensure that some marginalized groups initiate and use tobacco at disproportionately high rates. Members of these groups continue to experience health and economic disparities because of tobacco dependence, which, in turn, perpetuate tobacco dependence through generations. Pediatricians have opportunities to reframe their understanding of tobacco-dependence treatment to include both individual and structural interventions. Viewing tobacco exposure as an SDH can help pediatricians systematically identify and provide support to family members using tobacco. Framing tobacco dependence through a structural competency lens and supporting appropriate advocacy and policy actions can disrupt tobacco use patterns and increase opportunities for children and their caregivers to live healthy, tobacco-free lives.

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Identification and Management of Eating Disorders in Children and Adolescents

Laurie L. Hornberger, MD, MPH, FAAP,[a] Margo A. Lane, MD, FRCPC, FAAP,[b] THE COMMITTEE ON ADOLESCENCE

Eating disorders are serious, potentially life-threatening illnesses afflicting individuals through the life span, with a particular impact on both the physical and psychological development of children and adolescents. Because care for children and adolescents with eating disorders can be complex and resources for the treatment of eating disorders are often limited, pediatricians may be called on to not only provide medical supervision for their patients with diagnosed eating disorders but also coordinate care and advocate for appropriate services. This clinical report includes a review of common eating disorders diagnosed in children and adolescents, outlines the medical evaluation of patients suspected of having an eating disorder, presents an overview of treatment strategies, and highlights opportunities for advocacy.

INTRODUCTION

Definitions

Although the earliest medical account of an adolescent patient with an eating disorder was more than 300 years ago,[1] a thorough understanding of the pathophysiology and psychobiology of eating disorders remains elusive today. The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*) includes the latest effort to describe and categorize eating disorders,[2] placing greater emphasis on behavioral rather than physical and cognitive criteria, thereby clarifying these conditions in those children who do not express body or weight distortion. *DSM-5* diagnostic criteria for several of the eating disorders commonly seen in children and adolescents are presented in Table 1.

Notable changes in *DSM-5* since the previous edition include the elimination of amenorrhea and specific weight percentiles in the diagnosis of anorexia nervosa (AN) and a reduction in the frequency of binge eating and compensatory behaviors required for the diagnosis of bulimia nervosa (BN). The diagnosis "eating disorder not otherwise specified" has been

TABLE 1 Diagnostic Features of Eating Disorders Commonly Seen in Children and Adolescents

DSM-5 Eating Disorder Diagnosis	Diagnostic Features
Anorexia nervosa (AN)	
	A. Restricted caloric intake relative to energy requirements, leading to significantly low body weight for age, sex, projected growth, and physical health
	B. Intense fear of gaining weight or behaviors that consistently interfere with weight gain, despite being at a significantly low weight
	C. Altered perception of one's body weight or shape, excessive influence of body weight or shape on self-value, or persistent lack of acknowledgment of the seriousness of one's low body weight
	Subtypes: restricting type (weight loss is achieved primarily through dieting, fasting, and/or excessive exercise. In the previous 3 mo, there have been no repeated episodes of binge eating or purging); binge-eating/purging type (in the previous 3 mo, there have been repeated episodes of binge eating or purging; ie, self-induced vomiting or misuse of laxatives, diuretics, or enemas)
Bulimia nervosa (BN)	
	Repeated episodes of binge eating. Binge eating is characterized by both of the following: within a distinct period of time (eg, 2 h), eating an amount of food that is clearly larger than what most individuals would eat during a similar period of time under similar circumstances and a sense that one cannot limit or control their overeating during the episode
	Repeated use of inappropriate compensatory behaviors for the prevention of weight gain, such as self-induced vomiting; misuse of laxatives, diuretics, or other medications; fasting; or excessive exercise
	On average, the binge eating and compensatory behaviors both occur at least once a week for 3 mo
	Self-value is overly influenced by body shape and weight
	The binge eating and compensatory behaviors do not occur exclusively during episodes of AN
Binge-eating disorder (BED)	
	Recurrent episodes of binge eating. An episode of binge eating is characterized by both of the following: within a distinct period of time (eg, 2 h), eating an amount of food that is clearly larger than what most individuals would eat during a similar period of time under similar circumstances and sense that one cannot limit or control their overeating during the episode
	The binge-eating episodes include 3 or more of the following: eating much more quickly than normal, eating until uncomfortably full, eating large amounts of food when not feeling hungry, eating alone because of embarrassment at how much one is eating, and feeling guilty, disgusted, or depressed afterward
	Marked anguish is experienced regarding binge eating
	On average, the binge eating occurs at least once a week for 3 mo
	The binge eating is not associated with the use of inappropriate compensatory behavior as in BN and does not occur only in the context of BN or AN
Avoidant/restrictive food intake disorder (ARFID)	
	A disrupted eating pattern (eg, seeming lack of interest in eating or food; avoidance based on the sensory qualities of food; concern about unpleasant consequences of eating) as evidenced by persistent failure to meet appropriate nutritional and/or energy needs associated with 1 (or more) of the following: significant weight loss or, in children, failure to achieve expected growth and/or weight gain, marked nutritional deficiency, reliance on enteral feeding or oral nutritional supplements, significant interference with psychosocial functioning
	The disturbance cannot be better explained by lack of available food or by an associated culturally sanctioned practice
	The eating disturbance cannot be attributed to a coexisting medical condition nor better explained by another mental disorder. If the eating disturbance occurs in the context of another condition or disorder, the severity of the eating disturbance exceeds that routinely associated with the condition or disorder
Other specified feeding or eating disorders, examples	
	Atypical AN: all of the criteria for AN are met yet the individual's weight is within or above the normal range despite significant weight loss
	BN (of low frequency and/or limited duration): All of the criteria for BN are met, but, on average, the binge eating and compensatory behaviors occur less than once a week and/or for <3 mo
	BED (of low frequency and/or limited duration): All of the criteria for BED are met, but, on average, the binge eating occurs less than once a week and/or for <3 mo
	Purging disorder: recurrent purging behavior (eg, self-induced vomiting; misuse of laxatives, diuretics, or other medications) in the absence of binge eating with the intent to influence weight or body shape

Adapted from the *DSM-5*, American Psychiatric Association, 2013.[2]

eliminated, and several diagnoses have been added, including binge-eating disorder (BED) and avoidant/restrictive food intake disorder (ARFID).[3–5] The diagnosis of ARFID encompasses feeding behaviors previously categorized in the fourth edition (*DSM-IV*) as "feeding disorder of infancy and early childhood" and

expands these into adolescence and adulthood. Individuals with ARFID intentionally limit intake for reasons other than for concern for body weight, such as the sensory properties of food, a lack of interest in eating, or a fear of adverse consequences with eating (eg, choking or vomiting). As a result, they may experience weight loss or failure to achieve expected weight gain, malnutrition, dependence on nutritional supplementation, and/or interference with psychosocial functioning.[6–9] The category "other specified feeding and/or eating disorder" is now applied to patients whose symptoms do not meet the full criteria for an eating disorder despite causing significant distress or impairment. Among these disorders is atypical AN in which diminished self-worth, nutritional restriction, and weight loss mirrors that seen with AN, although body weight at presentation is in the normal or above-normal range. Efforts are ongoing to further categorize abnormal eating behaviors and refine diagnoses.[10]

Epidemiology

Prevalence data for eating disorders vary according to study populations and the criteria used to define an eating disorder.[11] A systematic review of prevalence studies published between 1994 and 2013 found widely varied estimates in the lifetime prevalence of eating disorders, with a range from 1.0% to 22.7% for female individuals and 0.3% to 0.6% for male indnividuals.[12] A 2011 cross-sectional survey of more than 10 000 nationally representative US adolescents 13 to 18 years of age estimated prevalence rates of AN, BN, and BED at 0.3%, 0.9%, and 1.6%, respectively. Behaviors suggestive of AN and BED but not meeting diagnostic thresholds were identified in another 0.8% and 2.5%, respectively. The mean age of onset for each of these disorders was 12.5 years.[13] Several studies have suggested higher BED prevalence rates of 2% to 4%, with a more equal distribution between girls and boys, making it perhaps the most common eating disorder among adolescents.[14] In contrast, the diagnoses seen in treatment may belie the relative prevalence of these disorders. In a review of 6 US adolescent eating disorder treatment programs, the distribution of diagnoses was 32% AN, 30% atypical AN, 9% BN, 19% ARFID, 6% purging disorder, and 4% others. [15] This may reflect the underrecognition and/or undertreatment of disorders such as BED.

Although previously mischaracterized as diseases of non-Hispanic white, affluent adolescent girls, eating disorder behaviors are increasingly recognized across all racial and ethnic groups[16–20] and in lower socioeconomic classes,[21] preadolescent children,[22] males, and children and adolescents perceived as having an average or increased body size.

Preteens with eating disorders are more likely than older adolescents to have premorbid psychopathology (depression, obsessive-compulsive disorder, or other anxiety disorders) and less likely to have binge and purge behaviors. There is a more equal distribution of illness by sex among younger patients and, frequently, more rapid weight loss, leading to earlier presentation to health care providers.[23]

Although diagnosis in males may increase with the more inclusive *DSM-5* criteria,[24,25] it is often delayed because of the misperception of health care providers that eating disorders are female disorders.[26] In addition, disordered eating attitudes may differ in male individuals,[27] focusing on leanness, weight control, and muscularity. Purging, use of muscle-building supplements, substance abuse, and comorbid depression are common in males.[28–30]

Eating disorders can occur in individuals with various body habitus, and their presence in those of larger body habitus is increasingly apparent.[31–34] Weight stigma (the undervaluation or negative stereotyping of individuals because they have overweight or obesity) seems to play a role. Adolescents with larger body habitus are exposed to weight stigma through the media, their families, peers, and teachers, and health care professionals, resulting in depression, anxiety, poor body image, social isolation, unhealthy eating behaviors, and worsening obesity.[35] When presenting with significant weight loss but a BMI still classified in the "healthy," overweight, or obese ranges, patients with eating disorders such as atypical AN may be overlooked by health care providers[36,37] but may experience the same severe medical complications as those who are severely underweight.[38–40]

Increased rates of disordered eating may be found in sexual minority youth.[41–43] Analysis of Youth Risk Behavior Survey data reveals lesbian, gay, and bisexual high school students have significantly higher rates of unhealthy and disordered weight-control behaviors than their heterosexual peers.[44,45] Transgender youth may be at particular risk.[46,47] In a survey of nearly 300 000 college students, transgender students had the highest rates of self-reported eating disorder diagnoses and compensatory behaviors (ie, use of diet pills or laxatives or vomiting) compared with all cisgender groups. Nearly 16% of transgender respondents reported having been diagnosed with an eating disorder, as compared with 1.85% of cisgender heterosexual women.[48]

Adolescents with chronic health conditions requiring dietary control

TABLE 2 Example Questions to Ask Adolescents With a Possible Eating Disorder

History/Information	Example Questions
Weight history	
	What was your highest weight? How tall were you? How old were you?
	What was your lowest weight? How tall were you? How old were you?
Body image	
	What do you think your weight should be? What feels too high? What feels too low?
	Are there body areas that cause you stress? Which areas?
	Do you do any body checking (ie, weighing, body pinching or checking, mirror checking)?
	How much of your day is spent thinking about food or your body?
Diet history	
	24-h diet history
	Do you count calories, fat, carbohydrates? How much do you allow? What foods do you avoid?
	Do you ever feel guilty about eating? How do you deal with that guilt (ie, exercising, purging, eating less)?
	Do you feel out of control when eating?
Exercise history	
	Do you exercise? What activities? How often? How intense is your workout?
	How stressed do you feel when you are unable to exercise?
Binge eating and purging	
	Do you ever binge? On what foods? How much? How often? Any triggers?
	Do you vomit? How often? How soon after eating?
	Do you use laxatives, diuretics, diet pills, caffeine? What types? How many? How often?
Family history	
	Does anyone in your family have a history of dieting or an eating disorder? Anyone on special diets (eg, vegetarian, gluten-free)? Anyone with obesity?
	Does anyone in your family have a history of depression, anxiety, bipolar disorder, obsessive-compulsive disorder, substance abuse, or other psychiatric illness?
	Does anyone in your family take psychiatric medication?
Review of systems	
	Dizziness, syncope, weakness or fatigue?
	Pallor, easy bruising or bleeding, cold intolerance?
	Hair loss, lanugo, dry skin?
	Constipation, diarrhea, early fullness, bloating, abdominal pain, heartburn?
	Palpitations, chest pain?
	Muscle cramps, joint pains?
	Excessive thirst and voiding?
	For girls: Age at menarche? Frequency of menses? LMP? Weight at time of LMP?
Psychosocial history (HEADSS)	
Home	
	Who lives in the home?
	How well do the family members get along with each other?
	Is the family experiencing any stressors?
Education	
	Where do you attend school? What grade? Regular classroom?
	Is school challenging for you? What grades do you receive? Has there been a change in your grades?
Activities	
	What activities are you involved in outside of the classroom?
	Do you have friends you can trust? Have you experienced any bullying?
	What Web sites do you most often visit when you go online? How much time is spent each day online?
Drug use	
	Have you ever used tobacco, e-cigarettes, alcohol, or drugs? Which ones? How much? How often?
	Have you ever used anabolic steroids or stimulants? Caffeine consumption? Other substances?
Depression/suicide	
	How is your mood? Increased irritability? Feelings of depression or hopelessness? Any anxiety or obsessive-compulsive thoughts or behaviors?
	Any history of cutting or self-injury?
	Have you ever wished you were dead? How often do you have these thoughts? When was the last time? Any thoughts of suicide? What methods have you imagined? Any attempts?
	History of physical, sexual or emotional abuse?
	Any previous mental health care?

TABLE 2 Continued

History/Information	Example Questions
Sexual history	
	Do you feel that the gender you feel inside matches your body on the outside?
	Are you romantically or sexually attracted to guys, girls, or both? Not sure?
	Have you had any sexual contact with another person? If yes, was it with guys, girls or both? Use of condoms? Use of contraceptives? History of pregnancy or sexually transmitted infection?
	Has anyone touched you sexually when you didn't want to be touched?

Adapted from Rome and Strandjord.[89] LMP, last menstrual period.

(eg, diabetes, cystic fibrosis, inflammatory bowel disease, and celiac disease) may also be at increased risk of disordered eating.[49–51] Among teenagers with type 1 diabetes mellitus, at least one-third may engage in binge eating, self-induced vomiting, insulin omission for weight loss, and excessive exercise,[52,53] resulting in poorer glycemic control.[54]

Many adolescents engage in dietary practices that may overlap with or disguise eating disorders. The lay term "orthorexia" describes the behavior of individuals who become increasingly restrictive in their food consumption, not based on concerns for quantity of food but the quality of food (eg, specific nutritional content or organically produced). The desire to improve one's health through optimal nutrition and food quality is the initial focus of the patient, and weight loss and/or malnutrition may ensue as various foods are eliminated from the diet. Individuals with orthorexia may spend excessive amounts of time in meal planning and experience extreme guilt or frustration when their food-related practices are interrupted.[55,56] Psychologically, this behavior appears to be related to AN and obsessive-compulsive disorder[57] and is considered by some to be a subset within the restrictive eating disorders. Vegetarianism is a lifestyle choice adopted by many adolescents and young adults that may sometimes signal underlying eating pathology.[58,59] In a comparison of adolescent and young adult females with and without a history of eating disorders, those with eating disorders were more likely to report ever having been vegetarian. Many of these young women acknowledged that their decision to become vegetarian was primarily motivated by their desire for weight loss, and most reported that they had done so at least a year after first developing eating disorder symptoms.[60]

In an attempt to improve performance or achieve a desired physique, adolescent athletes may engage in unhealthy weight-control behaviors.[61] The term "female athlete triad" has historically referred to (1) low energy availability that may or may not be related to disordered eating; (2) menstrual dysfunction; and (3) low bone mineral density (BMD) in physically active females.[62–65] Inadequate caloric intake in comparison to energy expenditure is the catalyst for endocrine changes and leads to decreased bone density and menstrual irregularities. Body weight may be stable. This energy imbalance may result from a lack of knowledge regarding nutritional needs in the athlete or from intentional intake restriction associated with disordered eating.

Hormonal disruption and low BMD can occur in undernourished male athletes as well.[66] Increased recognition of the role of energy deficiency in disrupting overall physiologic function in both male and female individuals led a 2014 International Olympic Committee consensus group to recommend replacing the term female athlete triad to the more inclusive term, "relative energy deficiency in sport."[67,68] Athletes participating in sports involving endurance, weight requirements, or idealized body shapes may be at particular risk of relative energy deficiency in sport. Signs and symptoms of relative energy deficiency, such as amenorrhea, bradycardia, or stress fractures, may alert pediatricians to this condition.

SCREENING FOR EATING DISORDERS

Pediatricians are in a unique position to detect eating disorders early and interrupt their progression. Annual health supervision visits and preparticipation sports examinations offer opportunities to screen for eating disorders. *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*, fourth edition, offers sample screening questions about eating patterns and body image.[69] Reported dieting, body image dissatisfaction, experiences of weight-based stigma, or changes in eating or exercise patterns invite further exploration. Positive responses on a standard review of symptoms may need further probing. For example, oligomenorrhea or amenorrhea (either primary or secondary) may indicate energy deficiency.[70] Serial weight and height measurements plotted on growth charts are invaluable. Weight loss or the failure to make expected weight gain may be more obvious when documented on a graph. Similarly, weight fluctuations or rapid weight gain may cue a health care provider to question binge eating or BN symptoms. Recognizing that

TABLE 3 Notable Physical Examination Features in Children and Adolescents With Eating Disorders

Features related to inadequate energy intake or malnutrition:
Deviation from previous growth trajectory when plotted on height, weight, and BMI graphs
Abnormal vital signs:
Low resting HR or BP
Orthostatic increase in HR (>20 beats per min) or decrease in BP (>10 mm Hg)
Hypothermia
Flat or anxious affect
Pallor, dry sallow skin; carotenemia (particularly palms and soles)
Cachexia: facial wasting, decreased subcutaneous fat, decreased muscle mass
Dull, thin scalp hair or lanugo
Cardiac murmur (one-third with mitral valve prolapse), cool extremities; acrocyanosis; poor perfusion
Stool mass left lower quadrant
Delayed or interrupted pubertal development
Small breasts; vaginal dryness
Small testes
Features related to purging:
Abnormal vital signs:
Orthostatic increase in HR (>20 beats per min) or decrease in BP (>10 mm Hg)
Angular stomatitis; palatal scratches; dental enamel erosions
Russell's sign (abrasion or callous on knuckles from self-induced emesis)
Salivary gland enlargement (parotid and submandibular)
Epigastric tenderness
Bruising or abrasions over the spine (related to excessive exercise or sit ups)
Features related to excess energy intake:
Deviation from previous growth trajectory when plotted on height, weight, and BMI curves
Obesity
Elevated BP or hypertension
Acanthosis nigricans, acne, hirsutism
Hepatomegaly
Premature puberty
Musculoskeletal pain

Adapted from Rosen; American Academy of Pediatrics.[208]

many patients who present to eating disorder treatment programs have or previously had elevated weight according to criteria from the Centers for Disease Control and Prevention,[71] it is worthwhile to carefully inquire about eating and exercise patterns when weight loss is noted in any child or adolescent. Screening for unhealthy and extreme weight-control measures before praising desirable weight loss can avoid inadvertently reinforcing these practices.

ASSESSMENT OF CHILDREN AND ADOLESCENTS WITH SUSPECTED EATING DISORDERS

A comprehensive assessment of a child or adolescent suspected of having an eating disorder includes a thorough medical, nutritional, and psychiatric history, followed by a detailed physical examination. A useful web resource for assessment is published in multiple languages by the Academy for Eating Disorders.[72] Relevant interview questions are listed in Table 2. A collateral history from a parent may reveal abnormal eating-related behaviors that were denied or minimized by the child or adolescent.

A full psychosocial assessment, including a home, education, activities, drugs/diet, sexuality, suicidality/depression (HEADSS) assessment is vital. This evaluation includes screening for physical or sexual abuse by using the principles of trauma-informed care and responding according to American Academy of Pediatrics guidance on suspected physical or sexual abuse or sexual assault[73–75] as well as state laws. Vital to the HEADSS assessment is an evaluation for symptoms of other potential psychiatric diagnoses, including suicidal thinking, which may have been unrecognized previously.

A comprehensive physical examination, including close attention to growth parameters and vital signs, allows the pediatrician to assess for signs of medical compromise and for signs and symptoms of eating disorder behaviors; findings may be subtle and, thus, overlooked without careful notice. For accuracy, weights are best obtained after the patient has voided and in an examination gown without shoes. Weight, height, and BMI can be evaluated by using appropriate growth charts. Low body temperature, resting blood pressure (BP), or resting heart rate (HR) for age may suggest energy restriction. Because a HR of 50 beats per minute or less is unusual even in college-aged athletes,[76] the finding of a low HR may be a sign of restrictive eating. Orthostatic vital signs (HR and BP, obtained after 5 minutes of supine rest and repeated after 3 minutes of standing)[77,78] revealing a systolic BP drop greater than 20 mm Hg, a diastolic BP drop greater than 10 mm Hg, or tachycardia may suggest volume depletion from restricted fluid intake or purging or a compromised cardiovascular system.

Pertinent physical findings in children and adolescents with eating disorders are summarized in Table 3. A differential diagnosis for the signs and symptoms of an eating disorder is found in Table 4, and selected medical complications of eating disorders are provided in Table 5.

LABORATORY EVALUATION

Initial laboratory evaluation is performed to screen for medical complications of eating disorders or to rule out alternate diagnoses (Tables 4 and 5). Typical initial laboratory testing includes

TABLE 4 Selected Differential Diagnosis for Eating Disorders According to Presentation

Clinical Presentations	Differential Diagnosis
Weight loss	
Gastrointestinal	Inflammatory bowel disease; celiac disease
Endocrine	Hyperthyroidism; diabetes mellitus; adrenal insufficiency
Infectious	Chronic infections, such as tuberculosis or HIV; intestinal parasite
Psychiatric	Depression; psychosis; anxiety or obsessive-compulsive disorder; substance use
Other	Neoplasm; superior mesenteric artery syndrome
Vomiting	Gastroesophageal reflux disease
Gastrointestinal disease	Gastroesophageal reflux disease
	Eosinophilic esophagitis
	Pancreatitis
	Cyclic vomiting
Neurologic	Increased intercranial pressure
	Migraine
Other	Food allergy
Binge eating or unexplained weight gain	
Endocrine	Hypothyroidism; hypercortisolism
Psychiatric	Depression
Iatrogenic	Medication side effect
Genetic	Prader Willi syndrome; Kleine-Levin syndrome

Adapted from Rome and Strandjord[89] and Rosen; American Academy of Pediatrics.[208]

a complete blood cell count; serum electrolytes, calcium, magnesium, phosphorus, and glucose; liver transaminases; urinalysis; and thyroid-stimulating hormone concentration.[72] Screening for specific vitamin and mineral deficiencies (eg, vitamin B_{12}, vitamin D, iron, and zinc) may be indicated on the basis of the nutritional history of the patient. Laboratory investigations are often normal in patients with eating disorders; normal results do not exclude the presence of serious illness with an eating disorder or the need for hospitalization for medical stabilization. An electrocardiogram is important for those with significant weight loss, abnormal cardiovascular signs (such as orthostasis or bradycardia), or an electrolyte abnormality. A urine pregnancy test and serum gonadotropin and prolactin levels may be indicated for girls with amenorrhea; a serum estradiol concentration may serve as a baseline for reassessment during

TABLE 5 Selected Medical Complications Resulting From Eating Disorders

Eating Disorder Behaviors	Medical Complications
Related to dietary restriction or weight loss	
Fluids and electrolytes	Dehydration; electrolyte abnormalities: hypokalemia, hyponatremia
Psychiatric	Depressed mood or mood dysregulation; obsessive-compulsive symptoms; anxiety
Neurologic	Cerebral cortical atrophy; cognitive deficits; seizures
Cardiac	Decreased cardiac muscle mass, right axis deviation, low cardiac voltage; cardiac dysrhythmias, cardiac conduction delays; mitral valve prolapse; pericardial effusion; congestive heart failure; edema
Gastrointestinal	Delayed gastric emptying, slowed gastrointestinal motility, constipation; superior mesenteric artery syndrome; pancreatitis; elevated transaminases; hypercholesterolemia
Endocrinologic	Growth retardation; hypogonadotropic hypogonadism: amenorrhea, testicular atrophy, decreased libido; sick euthyroid syndrome; hypoglycemia/hyperglycemia, impaired glucose tolerance; hypercholesterolemia; decreased BMD
Hematologic	Leukopenia, anemia, thrombocytopenia, elevated ferritin; depressed erythrocyte sedimentation rate
Related to vomiting	
Fluid and electrolytes	Electrolyte disturbance: hypokalemia, hypochloremia, metabolic alkalosis
Dental	Dental erosions
Gastrointestinal	Gastroesophageal reflux, esophagitis; Mallory-Weiss tears; esophageal or gastric rupture
Related to laxative use	
Fluids and electrolytes	Hyperchloremic metabolic acidosis; hypocalcemia
Gastrointestinal	Laxative dependence
Related to binge eating	Obesity with accompanying complications
Related to refeeding	Night sweats; polyuria, nocturia; refeeding syndrome: electrolyte abnormalities, edema, seizures, congestive heart failure (rare)
Seen among all eating disorder behaviors	Suicide

recovery.[79] Similarly, serum gonadotropin and testosterone levels can be useful to assess and monitor for central hypogonadism in boys with restrictive eating. Bone densitometry, by using dual radiograph absorptiometry analyzed with age-appropriate software, may be considered for those with amenorrhea for more than 6 to 12 months.[80,81] If there is uncertainty about the diagnosis, other studies including inflammatory markers, serological testing for celiac disease, serum cortisol concentrations, testing stool for parasites, or radiographic imaging of the brain or gastrointestinal tract may be considered. In the occasional patient, both an eating disorder and an organic illness, such as celiac disease, may be discovered.[82]

MEDICAL COMPLICATIONS IN PATIENTS WITH EATING DISORDERS

Eating disorders can affect every organ system[83,84] with potentially serious medical complications that develop as a consequence of malnutrition, weight changes, or purging. Details of complications are described in reviews[85–89] and are summarized in Table 5. Most medical complications resolve with weight normalization and/or resolution of purging. Complications of BED can include those of obesity; these are summarized in other reports and not reiterated here.[84,90]

Psychological and Neurologic Effects

Psychological symptoms can be primary to the eating disorder, a feature of a comorbid psychiatric disorder, or secondary to starvation. Initial symptoms of depression and anxiety may abate with refeeding.[91] Rumination about body weight and size is a core feature of AN, whereas rumination about food decreases as starvation reverses.[92] Difficulty in emotion regulation occurs across the spectrum of eating disorders but is more severe in those who binge eat or purge.[93] Cognitive function studies in a large population-based sample of adolescents revealed eating disorder participants had deficits in executive functioning, including global processing and cognitive flexibility but performed better than control participants on measures of visual attention and vigilance.[94]

Structural brain imaging studies to date have yielded inconsistent results, likely explained, at least in part, by methodologic differences and the need to control for many variables, including nutritional state, hydration, medication use, and comorbid illness.[95] A longitudinal study revealed that global cortical thinning in acutely ill adolescents and young adults with AN normalized with weight restoration over a period of approximately 3 months.[96]

Dermatologic Effects

Common skin changes in underweight patients include lanugo, hair thinning, dry scaly skin, and yellow discoloration related to carotenemia. Brittle nails and angular cheilitis may also be observed. Acrocyanosis can be observed in underweight patients and may be a protective mechanism against heat loss. Abrasions and calluses over the knuckles can occur from cutting the skin on incisors while self-inducing emesis.[97]

Dental and/or Oral Effects

Patients with eating disorders experience higher rates of dental erosion and caries. This occurs more frequently in those who self-induce emesis but can also be observed in those who do not.[98] Normal dental findings do not preclude the possibility that purging is occurring.[99] Hypertrophy of the parotid and other salivary glands, accompanied by elevations in serum amylase concentrations with normal lipase concentrations, may be a clue to vomiting.[99] Xerostomia, from either salivary gland dysfunction or psychiatric medication side effect, can reduce the oral pH, which can lead to increased growth of cariogenic oral bacteria.[98,100]

Cardiovascular Effects

Reports of cardiac complications in eating disorders are focused predominantly on restrictive eating disorders. Common cardiovascular signs include low HR, orthostasis, and poor peripheral perfusion. Orthostatic intolerance symptoms (eg, lightheadedness) and vital sign findings may resemble those of postural orthostatic tachycardia syndrome[101,102] and may contribute to a delay in referral to appropriate care if eating disorder behaviors are not disclosed or appreciated.

Cardiac structural changes include decreased left ventricular (LV) mass, LV end diastolic and LV end systolic volumes, functional mitral valve prolapse, pericardial effusion, and myocardial fibrosis (noted in adults).[103–105] Electrocardiographic abnormalities, including sinus bradycardia, and lower amplitude LV forces are more common in AN than in nonrestrictive eating disorders.[106] One study reported a nearly 10% prevalence of prolonged (>440 milliseconds) QTc interval in hospitalized adolescents and young adults with a restrictive eating disorder.[107] Repolarization abnormalities, a potential precipitant to lethal arrhythmia,[108] may prompt clinicians to also consider other factors, such as medication use or electrolyte abnormalities, that may affect cardiac conduction.[107,109]

Gastrointestinal Tract Effects

Gastrointestinal complaints are common and sometimes precede the diagnosis of the eating disorder. Delayed gastric emptying and slow intestinal transit time often contribute to reported sensations of nausea, bloating, and postprandial fullness[110] and may be a presenting feature of restrictive eating.

Constipation is a frequent experience for patients and multifactorial in etiology.[111] Esophageal mucosal damage from self-induced vomiting, including scratches, and bleeding secondary to Mallory-Weiss tears can occur.[99] Superior mesenteric artery syndrome may develop in the setting of severe weight loss.[111] Hepatic transaminase concentrations and coagulation times can be elevated as a consequence of malnutrition and, typically, normalize with appropriate nutrition.[110]

Renal and Electrolyte Effects

Fluid and electrolyte abnormalities may occur as a result of purging or cachexia.[99,112] Dehydration can be present in any patient with an eating disorder. Disordered osmotic regulation can present in many patterns (central and renal diabetes insipidus, syndrome of inappropriate antidiuretic hormone).[112] Patients who vomit may have a hypokalemic, hypochloremic metabolic alkalosis resulting from loss of gastric hydrochloric acid, chronic dehydration, and the subsequent increase in aldosterone that promotes sodium reabsorption in exchange for potassium and acid at the distal tubule level.[113] Patients who abuse laxatives may experience a variety of electrolyte and acid-base derangements.[113] Dilutional hyponatremia can be observed in patients who intentionally water load to induce satiety or to misrepresent their weight at clinic visits. Abrupt cessation of laxative use may be associated with peripheral edema and, therefore, motivate further laxative[114] or diuretic misuse.

Endocrine Effects

Restrictive eating disorders commonly cause endocrine dysfunction.[80,115] Euthyroid sick syndrome (low triiodothyronine, elevated reverse triiodothyronine, or normal or low thyroxine and thyroid-stimulating hormone) is the most common thyroid abnormality.[116] Functioning as an adaptive mechanism to starvation, supplemental thyroid hormone is not indicated when this pattern is noted.[116] Hypercortisolemia may be seen in AN.[81,116] Hypothalamic-pituitary-gonadal axis suppression may be attributable to weight loss, physical overactivity, or stress. Female individuals with AN may have amenorrhea, and male individuals can have small testicular volumes[117] and low testosterone concentrations.[118]

Growth retardation, short stature, and pubertal delay may all be observed in prepubertal and peripubertal children and adolescents with eating disorders.[115] AN is associated with low levels of insulin-like growth factor-1 and growth hormone resistance.[119] Catch-up growth has been inconsistently reported in the literature; younger patients may have greater and more permanent effects on growth.[120,121] Adolescent boys may be at an even greater risk for height deficits than girls; because boys typically enter puberty later than girls and experience their peak growth at a later sexual maturity stage, they are less likely to have completed their growth if an eating disorder develops in the middle teenage years.[119]

Low BMD is a frequent complication of eating disorders in both male and female patients[117] and is a risk in both AN and BN.[122] Low BMD is worrisome not only because of the increased risk of fractures in the short-term[123] but, also, because of the potential to irreversibly compromise skeletal health in adulthood.[124]

TREATMENT PRINCIPLES ACROSS THE EATING DISORDER SPECTRUM

The ultimate goals of care in eating disorders are that children and adolescents are nourished back to their full healthy weight and growth trajectory, that their eating patterns and behaviors are normalized, and that they establish a healthy relationship with food and their body weight, shape, and size as well as a healthy sense of self. Independent of a specific *DSM* diagnosis, treatment is focused on nutritional repletion and psychological therapy. Psychotropic medication can be a useful adjunct in select circumstances.

The Pediatrician's Role in Care

After diagnosing an eating disorder, the pediatrician arranges appropriate care. Patients who are medically unstable may require urgent referral to a hospital (Table 6). Patients with mild nutritional, medical, and psychological dysfunction may be managed in the pediatrician's office in collaboration with outpatient nutrition and mental health professionals with specific expertise in eating disorders. Because an early response to treatment may be associated with better outcomes,[125,126] timely referral to a specialized multidisciplinary team is preferred, when available. If resources do not exist locally, pediatricians may need to partner with health experts who are farther away for care. For patients who do not improve promptly with outpatient care, more intensive programming (eg, day-treatment programs or residential settings) may be indicated.

Often, an early task of the pediatrician is to identify a treatment goal weight. This goal weight may be determined in collaboration with a registered dietitian. Pediatricians who are planning to refer the patient to a specialized treatment team may opt to defer the task to the team. Acknowledging that body weights naturally fluctuate, the treatment goal weight is often expressed as a goal range. Individualized treatment goal weights are formulated on the basis of age, height, premorbid growth trajectory, pubertal stage, and menstrual history.[87,127] In a study of adolescent girls with AN, of those who resumed menses during

TABLE 6 Indications Supporting Hospitalization in an Adolescent With an Eating Disorder

One or More of the Following Justify Hospitalization
1. ≤75% median BMI for age and sex (percent median BMI calculated as patient BMI/50th percentile BMI for age and sex in reference population × 100)
2. Dehydration
3. Electrolyte disturbance (hypokalemia, hyponatremia, hypophosphatemia)
4. ECG abnormalities (eg, prolonged QTc or severe bradycardia)
5. Physiologic instability:
a. Severe bradycardia (HR <50 beats per min daytime; <45 beats per min at night);
b. Hypotension (90/45 mm Hg);
c. Hypothermia (body temperature <96°F, 35.6°C);
d. Orthostatic increase in pulse (>20 beats per min) or decrease in BP (>20 mm Hg systolic or >10 mm Hg diastolic)
6. Arrested growth and development
7. Failure of outpatient treatment
8. Acute food refusal
9. Uncontrollable binge eating and purging
10. Acute medical complications of malnutrition (eg, syncope, seizures, cardiac failure, pancreatitis and so forth)
11. Comorbid psychiatric or medical condition that prohibits or limits appropriate outpatient treatment (eg, severe depression, suicidal ideation, obsessive-compulsive disorder, type 1 diabetes mellitus)

Reprinted with permission from the Society for Adolescent Health and Medicine.[85] ECG, electrocardiogram.

treatment, this occurred, on average, at 95% of the treatment goal weight.[128] Health care providers may be pressured by patients, their patients' parents, or other health care providers to target a treatment goal weight that is lower than the previous growth trajectory or other clinical indicators would suggest is appropriate. If a treatment goal weight is inappropriately low, there is an inherent risk of offering only partial weight restoration and insufficient treatment.[129] The treatment goal weight is reassessed at regular intervals (eg, every 3–6 months) to account for changes in physical growth and development (in particular, age, height, and sexual maturity).[87,127]

An important role for the pediatrician is to offer guidance regarding eating and to manage the physical aspects of the illnesses. For all classifications of eating disorders, reestablishing regular eating patterns is a fundamental early step. Meals and snacks are reintroduced or improved in a stepwise manner, with 3 meals and frequent snacks per day. Giving the message that "food is the medicine that is required for recovery" and promoting adherence to taking that medicine at scheduled intervals often helps patients and families get on track.[130] A multivitamin with minerals can help ensure that deficits in micronutrients are addressed. To optimize bone health, calcium and vitamin D supplements can be dosed to target recommended daily amounts (elemental calcium: 1000 mg for patients 4–8 years of age, or 1300 mg for patients 9–18 years of age; vitamin D: 600 IU for patients 4–18 years of age).[87,131] Patients can be reassured that the bloating discomfort caused by slow gastric emptying improves with regular eating. When constipation is troubling, nutritional strategies, including weight restoration, are the treatments of choice.[111] When these interventions are inadequate to alleviate constipation, osmotic (eg, polyethylene glycol 3350) or bulk-forming laxatives are preferred over stimulant laxatives. The use of nonstimulant laxatives decreases the risks of electrolyte derangement and avoids the potential hazard of "cathartic colon syndrome" that may be associated with abuse of stimulant cathartics (senna, cascara, bisacodyl, phenolphthalein, anthraquinones).[99,114]

To optimize dental outcomes, patients can be encouraged to disclose their illness to their dentist. Current dental hygiene recommendations for patients who vomit include the use of topical fluoride, applied in the dental office or home, or use of a prescription fluoride (5000 ppm) toothpaste. Because brushing teeth immediately after vomiting may accelerate enamel erosion, patients can be advised to instead rinse with water, followed by using a sodium fluoride rinse whenever possible.[132]

AN

Collaborative Outpatient Care

Most patients with AN are treated in outpatient settings.[85,133] Pediatricians play an important role in the medical management and coordination of the treatment of these patients. The pediatrician plays a primary role in assessing for and managing acute and long-term medical complications, monitoring treatment progress, and coordinating care with nutritional and mental health colleagues.[85,130,134] Although some primary care pediatricians feel comfortable coordinating care, others choose to refer patients to providers with expertise in pediatric eating disorders. Ideally, all members of the treatment team are sensitive to the unique

developmental needs of children and adolescents.[133]

Educating young people and their parents about the physiologic and psychological effects of food restriction is an early component of care. Parents are empowered to feed their children regularly (typically 3 meals and 2–3 snacks per day) and adjust portion size and energy richness based on weight progress. Many parents are amazed to discover the amount of energy (3500 kcal or more) that may be required to restore weight for their children. Detailed tracking of caloric intake is not necessary. Serving foods with high caloric density and ensuring that beverages are energy rich (eg, choosing fruit juice or milk instead of water) are effective strategies to maximize energy intake without requiring large increases in volume. Parents can relieve adolescents of having to decide on appropriate serving sizes by plating meals for them. Accommodating special diets, such as vegetarian or vegan, can make meeting nutritional goals especially challenging. Reintroducing foods that have been avoided or that induce fear of weight gain are essential steps on the path to recovery.

Family-Based Treatment and Parent-Focused Therapy

Over the past 2 decades, a specialized eating disorder–focused, family-based intervention, commonly referred to as family-based treatment (FBT), has emerged as the leading first-line treatment approach for pediatric eating disorders.[135] Effectiveness is well established for AN.[133,136] Rather than dwelling on possible causes of the eating disorder, FBT is focused on recovery from the disease. FBT consists of 3 phases and contends that parents are not to blame for their child's illness, eating disorders are not caused by dysfunctional families, and parents play an essential role in recovery.[136] During appointments, the entire family unit meets with the therapist. In phase 1, weight restoration is the primary goal. Parents, supported by the therapist, take responsibility to ensure that their child eats sufficiently and limit pathologic weight-control behaviors. Parents are encouraged to take responsibility for meal planning and preparation. Pediatricians can be helpful by reminding parents of the importance of fighting the disease effectively in the early stages, with the goals of reaching a truly healthy weight, resuming pubertal development, reversing medical complications, and restoring normal cognitions. Early weight gain (4–5 pounds by session 4, typically correlating with 4 weeks of treatment) is predictive of better outcomes in adolescents.[126,137,138] By phase 2, substantial weight recovery has occurred, and the adolescent gradually resumes responsibility for his or her own eating. By phase 3, weight has been restored, and the therapy shifts to address general issues of adolescent psychosocial development.[136] This therapy is detailed in manuals for providers[137] and families.[139] FBT with experienced providers is not available in all communities. Nevertheless, community providers may integrate the essential principles of FBT in their work with patients and families.[130]

Parent-focused therapy is an adaptation of FBT wherein the therapist supports the parents to renourish the patient and limit weight-control behaviors but, after the initial appointment, meets only with the parents.[140] The patient has brief visits with a nurse or physician for the assessment of weight and acute mental health issues but is not directly involved with a therapist.

The role pediatricians serve in the care of an adolescent in FBT differs from the customary role of a physician with patients.[134] In the FBT setting, the pediatrician does not weigh the patient because that task is performed by the therapist. The pediatrician directs the care only when there are immediate medical safety concerns. If the pediatrician identifies an urgent medical issue that requires intervention or hospitalization, he or she is obligated to provide recommendations to the patient, the parents, and the primary therapist. For the medically stable patient, the pediatrician acts as a consultant to the parents and primary therapist. When a parent asks a question related to treatment, instead of directly advising the parents what to do, the pediatrician, ideally, redirects that treatment decision back to the parent: "You know your child the best. What do you think will best help in your child's recovery?" In this way, the physician empowers parents to make their own decisions, enhancing their confidence to care for their ill child.

Day-Treatment Programs

Day-treatment programs (day hospitalization and partial hospitalization) provide an intermediate level of care for patients with eating disorders who are medically stable and do not require 24-hour supervision but need more than outpatient care.[133,141] These programs may prevent the need for higher levels of care or may be a "step-down" from inpatient or residential to outpatient care. Day treatment typically involves 8 to 10 hours per day of care (including meals, therapy, groups, and other activities) by a multidisciplinary staff 5 days per week. Reported evaluations of child and adolescent day-treatment programs are few and observational in design.[142–145] Despite the absence of systematic data supporting their usefulness, these programs are generally believed to have an important role in the continuum of care.

Residential Treatment

Residential treatment may be necessary for a minority of medically stable patients with eating disorders. Indications for residential treatment include a poor motivation for recovery, need for structure and supervision to prevent unhealthy behaviors (eg, food restriction, compulsive exercise), lack of a supportive family environment, absence of outpatient treatment in the patient's locale,[146] or outpatient interventions having been unsuccessful.[133] Residential treatment typically includes 24 hour per day supervision, medical oversight, group-based psychoeducational therapy, nutritional counseling, individual therapy, and family therapy. The length of stay can be weeks to months, depending on the severity of illness and financial resources. Outcome studies reported by residential programs, generally, reveal improved symptomatology at discharge,[147] but the results at long-term follow-up are mixed.[148,149] However, few outcome studies are focused on adolescents, compare the efficacy of residential to outpatient treatment, or make comparisons across programs or treatment modalities.

Although some adolescents require this higher level of care, health care providers and families are encouraged to exercise caution when selecting a residential treatment program. The number of residential programs has more than tripled in the last decade, with many operated by for-profit companies. Marketing practices by some are questionable.[150] Outcome studies demonstrating program efficacy may be misleading because of a lack of rigorous design or peer review.[151] Until recently, there was no certification process to ensure program quality and safety. In 2016, The Joint Commission implemented new accreditation standards for behavioral health care organizations that provide outpatient or residential eating disorder treatment.[152] It remains to be seen how many programs will pursue this accreditation.

The National Eating Disorders Association Web site offers useful suggestions for evaluating treatment programs (www.nationaleatingdisorders.org).

Hospital-Based Stabilization

Suggested indications for the hospitalization of children and adolescents with eating disorders published by the Society for Adolescent Health and Medicine are listed in Table 6.

The most common goal for hospital-based stabilization is nutritional restoration. Variation occurs with regard to how quickly hospitalized patients with AN are refed.[153,154] It is important to balance 2 competing goals: achieve weight gain swiftly and avoid refeeding syndrome.[155] Refeeding syndrome refers to the metabolic and clinical changes that occasionally occur when a malnourished patient is aggressively nutritionally rehabilitated; the hallmarks are hypophosphatemia and multiorgan dysfunction.[155–157] A systematic review of hospitalized adolescents with AN reported an average incidence of refeeding hypophosphatemia (without necessarily organ dysfunction) of 14%.[158] Over the past decade, a long followed maxim, "start low and go slow," has been challenged.[87,155] Several centers have described starting calories at 1400 kcal or more per day,[154] including recent reports demonstrating safe treatment of mildly and moderately malnourished adolescents by using initial caloric prescriptions of 2200 to 2600 kcal per day, while achieving a weight gain of approximately 3 to 4.5 pounds per week.[159,160] Because the risk of refeeding hypophosphatemia may correlate with the degree of starvation, pediatricians may opt to take a more cautious approach in severely malnourished (<70% median BMI) children until further studies are reported.[87,154]

Nasogastric tube (NGT) feeding may be necessary for some hospitalized adolescents, but opinions vary regarding when they should be initiated.[161] Most North American programs reserve NGT feeds for when patients are not able to complete meals; however, internationally, some centers report the routine use of NGT feeding, either exclusively at first or in combination with meals.[162,163] Potential benefits of NGT feeding include faster weight gain and medical stabilization, with a possibility for a reduced hospital length of stay.[162,163] Although viewed by some health care providers as invasive or punitive, others view NGT feeding as empathic, by reducing both physical and psychological pain in the early treatment stages.[161] There is insufficient evidence to recommend one approach over another.[154] Independent of whether NGT feeds are used routinely, physicians involved in the treatment of hospitalized medically unstable patients may be called on to provide nutrition via an NGT when nutritional needs are not being met. The use of total parenteral nutrition carries higher risks of medical complications, is costly, and is not recommended unless other forms of refeeding are not possible.[154]

High-quality studies in which researchers examine the impact of inpatient care are limited, and the best end point for hospital treatment of children and adolescents is unclear. A US multicenter research collaborative showed that, in a national cohort of low-weight 9- to 21-year-olds with restrictive eating disorders, those who were hospitalized had a greater odds of being at 90% of the median BMI at 1-year follow-up.[164] However,

a randomized controlled trial (RCT) of treatment of adolescent AN in the United Kingdom revealed no benefits of inpatient over outpatient care[165]; this study was limited by poor adherence to the allocated treatment. An RCT in Germany in 2014 revealed that inpatient adolescents discharged earlier to outpatient treatment fared as well as those discharged later.[141] Similarly, an RCT conducted in Australia in 2015 revealed that adolescents who were discharged to FBT as soon as they were medically stable fared at least as well as adolescents who remained inpatients until achieving 90% of their treatment goal weight.[166] The recently reported average length of stay in the United States for patients admitted for medical stabilization by using higher caloric prescriptions was 3 to 12 days.[159,167,168]

Pharmacotherapy for AN

A variety of medications have been studied for the treatment of AN, primarily in adults, but none have been approved for this indication by the US Food and Drug Administration (FDA).[169] Despite their demonstrated ineffectiveness,[170] more than one-half of adolescents with restrictive eating disorders are prescribed psychotropic medications, most likely in attempts to treat comorbid conditions, such as depression and anxiety.[171] Selective serotonin-reuptake inhibitors (SSRIs) have been tried but are not effective in acutely ill, malnourished patients and have not been shown to prevent disease relapse in those who are weight restored.[172–174] A number of atypical antipsychotic medications have also been studied, including quetiapine, risperidone, and olanzapine. Results have generally revealed little benefit in weight gain or improvement in eating-disorder thinking.[169,175–178] Initial studies of augmentation of SSRIs with atypical antipsychotics in adult patients have been promising.[179]

The current recommendations to optimize bone health are full weight restoration with physiologic resumption of menses and supplementation with calcium and vitamin D.[79,81,87,115] Bisphosphonate treatment is not recommended.[79,87,115] Estrogen supplementation in the form of combined estrogen-progesterone oral contraceptive pills is not effective in enhancing BMD in adolescents with AN.[81] Small trials with transdermal estrogen[180] or with low-dose combined oral contraceptive pills plus dehydroepiandrosterone[181] have shown a positive effect on BMD compared with controls, but further studies are needed before these are considered standard care. Although cyclic vaginal bleeding may be induced with the use of exogenous hormones, this may reinforce a patient's denial of the medical consequences of her disease and masks the spontaneous return of menses.

BN and BED

Collaborative Outpatient Care

Most patients with BN and BED are managed in outpatient settings with the collaboration of a medical and mental health care providers as well as a dietitian, as needed.

Psychological treatment studies are more limited in BN compared with AN and are especially lacking in BED.[133] Cognitive behavioral therapy (CBT) has a modest evidence-base for BN and BED.[133,182] CBT explicitly recognizes the interrelationships among an individual's thoughts, feelings, and actions, and its principles can be used by all disciplines. Reestablishing regular eating patterns is a central goal, and educating patients about the perpetuating nature of the restriction-binge-purge cycle is an early focus. Patients with BN and BED can minimize the urge to binge that is typically experienced late in the day, if they eat regularly throughout the day. Decreasing the binge amount and frequency may decrease guilt and shame and the ensuing negative self-assessment. During CBT, patients are taught to question their distorted thoughts and remodel their eating behaviors.[182]

FBT

Although there is a manual to guide FBT for patients with BN,[183] it is based on more limited evidence than FBT for AN.[182] An RCT comparing FBT with CBT revealed patients in the FBT group were more likely to abstain from binge eating and purging at the end of the 18-week treatment (39% vs 20%) with no statistical difference (49% vs 32%) at 1-year follow-up.[184] There are no published studies in which researchers examine FBT for BED.

Pharmacotherapy for BN

As with other pharmacotherapy research, studies of treatment of BN have primarily been in adult subjects. Several pharmacologic agents, including SSRIs, have been demonstrated to be effective for the treatment of adult BN, although only fluoxetine has FDA approval. Although not approved for pediatric BN, fluoxetine is FDA approved for child and adolescent depression and obsessive-compulsive disorder, so it is a reasonable option if pharmacologic treatment of BN is considered.[169] The antiepileptic topiramate has been shown to significantly decrease binge eating in adults who do not respond to or are not able to tolerate SSRIs. However, cases of topiramate triggering eating disorder symptoms in adolescents have been reported.[185] Other drugs, including naltrexone and ondansetron, are being used with some success in adult BN, although data are lacking to recommend their use more broadly.[169]

Pharmacotherapy for BED

Research on the treatment of binge eating lags behind that for other eating disorders and has been focused on adult subjects. SSRIs have rarely differed from placebo in their effect on BED and show no better outcome than behavioral therapy alone. Although the use of topiramate has been shown to reduce binge eating and help with weight loss, the rates of adverse effects are relatively high.[186] Lisdexamfetamine, a central nervous system stimulant approved for treatment of attention-deficit/hyperactivity disorder, was approved by the FDA in 2015 for the treatment of moderate to severe BED in adults. Although it has been demonstrated to reduce the frequency of binge-eating episodes, lisdexamfetamine is not indicated for weight loss. As with the use of other central nervous system stimulants, there is a potential for abuse and dependence as well as serious cardiovascular reactions.[187]

ARFID

ARFID is a relatively new diagnosis, and, consequently, there is limited literature describing treatment.[188,189] Because patients with ARFID vary in terms of underlying psychological motivations for restrictive eating, individualized behavioral treatment strategies are needed.[182,190] Despite varying characteristics of the disorder, the dual goals of refeeding and normalization of eating align with the goals of treating other eating disorders. A study of pediatric and young adult patients admitted with ARFID at a single academic medical center reported that ARFID patients were more likely to require enteral nutrition and stayed in the hospital longer than patients with AN.[9]

No medication is specifically indicated for use in ARFID; pharmacotherapy is directed at treating underlying comorbid illness (eg, anxiety) as necessary.

FINANCIAL CONSIDERATIONS

The treatment of eating disorders is multidisciplinary, often long-term, and may require expensive, high-level care, such as inpatient stabilization or residential or partial hospitalization programs. The costs associated with treatment can create substantial financial burdens for families.[191] Having medical insurance, public or private, is no guarantee that these costs will be covered.[192] Insurance carriers are able to define their own criteria for eating disorder treatment, leading to wide variations in coverage from state to state. Some states do not identify eating disorders as life-threatening conditions, thereby limiting treatment coverage. State-sponsored public insurance plans may not cover out-of-state treatment programs, even when no comparable treatment programs exist within that state. Outpatient mental health providers who are willing to accept the lower payments from public insurance may have no expertise in treating eating disorders. Those who do and will see publicly insured patients or those in managed care plans typically limit the number of these patients in their panels. Private insurance may increase access to treatment but dictate lower levels and shorter periods of care than is indicated by a patient's clinical status and health care provider recommendation. Families of patients with eating disorders typically will need assistance navigating the financial aspects of treatment. The National Eating Disorders Association offers general information online for families regarding financial coverage for treatment (www.nationaleatingdisorders.org).

PROGNOSIS

The prognoses reported for adolescents with eating disorders vary widely, depending on research methodology, definitions of recovery, and duration of follow-up. Generally, adolescents have greater success in recovery from eating disorders than their adult counterparts,[193] with overall recovery rates of approximately 70%.[194]

In a review of 11 adolescent eating disorder treatment programs, 54% of patients treated for restrictive disorders had restored to at least 90% of their median body weight (MBW) for age and height at 1-year follow-up. This is essential for catch-up growth and resumption of menses in girls. Two significant predictors of weight recovery were a higher percentage of MBW at initial presentation and shorter duration of symptoms, highlighting the importance of early identification of these disorders. Outcomes did not vary meaningfully across programs, suggesting that all treatment models were helpful.[195]

In a more-recent study, researchers examined the weight restoration of patients from 14 adolescent treatment programs with a diagnosis of a restrictive eating disorder by *DSM-5* criteria. At 1-year follow-up, those with ARFID were the least likely (43%) to have regained ≥90% MBW and were also more likely to be younger, have had a longer duration of symptoms, and have left treatment prematurely. Eighty-two percent of those with atypical AN and 64% of those with AN had regained ≥90% MBW. Having received a higher level of care (eg, partial hospitalization and/or residential care) did not increase the likelihood of weight recovery. Again, there were no significant differences in outcomes between programs, despite various treatment modalities.[196]

Information on the long-term prognosis of adolescents with AN

is limited. In a study of adolescents who completed a 12-month outpatient AN treatment study (either FBT or adolescent-focused therapy), approximately one-third of patients were in full remission 1 year after completion, with better rates in the FBT group (49%) than in the adolescent-focused therapy group (23%).[197] Follow-up in a convenience sample of the original study 2 to 4 years after treatment revealed less than 10% of patients relapsed, with no difference between the 2 groups.[198] An RCT comparing parent-focused therapy with FBT demonstrated equivalent outcomes between the groups at 12-month follow-up (37% vs 29%).[140]

Information about recovery from BN, BED, and purging disorder in adolescents is less available but suggests higher rates of relapse and the development of comorbidities. Outcome studies on BN in adults reveal variable recovery rates, ranging from approximately 50% to 70% at 4- to 6-year follow-up, with relapse rates of 30% and about 25% having chronic disease.[194] A longitudinal study of adolescent girls with BED and purging disorders into early adulthood revealed that one-quarter of these girls started to use drugs other than marijuana, more than one-third began to binge drink frequently, and 27% demonstrated high levels of depressive symptoms.[199] Not surprisingly, misuse of drugs and alcohol among patients with eating disorders is associated with a poorer outcome or death.[193]

Mortality rates among individuals with eating disorders are substantially elevated in comparison with those of the general population, with death typically occurring in adulthood. Premature death is 4 to 5 times higher for patients with AN and 2 to 3 times as high for those with BN.[200–203] Suicide rates are increased among patients with eating disorders[204] and, in one study, accounted for 30% deaths.[203] In a national survey of adolescents, 35% of those meeting criteria for BN, 15% of those meeting criteria for BED, and 8% of those meeting criteria for AN reported having made a suicide attempt.[205] The risk of suicide among patients with eating disorders appears to be declining and has been attributed to an increased recognition of eating disorders and effective treatment.[206]

PEDIATRICIAN'S ROLE IN PREVENTION AND ADVOCACY

Efforts to prevent eating disorders may occur in clinical practice and community settings. By using sensitive, nonstigmatizing language and demonstrating supportive attitudes toward children and adolescents of all body shapes and sizes, pediatricians create a welcoming clinical setting for discussions about weight and weight-related behaviors. The American Academy of Pediatrics clinical report "Preventing Obesity and Eating Disorders in Adolescents" highlights steps that pediatricians can take to prevent both conditions.[207] These steps include focusing on healthy habits with patients and families rather than weight and dieting, encouraging more frequent family meals, discouraging "weight talk" and "weight teasing" in the home, closely monitoring weight loss in patients advised to lose weight, and promoting a healthy body image in all children and adolescents.[207] Pediatricians may also advise teachers, coaches, and athletic trainers about healthy approaches to nutrition and exercise, raise awareness of the detrimental effects of weight stigmatization, and alert them to the warning signs of eating disorders.

Pediatricians can join others in advocating for improved access to quality eating disorder treatment services. The limited availability of developmentally appropriate mental health services, lack of mental health parity, and service "carve-outs" all have been barriers to patients and families who seek necessary treatment and seem to be disproportionately problematic for patients with eating disorders. Despite evidence of its effectiveness, FBT is not available in many communities. Through advocacy, pediatricians can help support health care reform efforts that will enable children and adolescents with eating disorders to access necessary care.

GUIDANCE FOR PEDIATRICIANS

1. Pediatricians should be knowledgeable about the variety of risk factors and early signs and symptoms of eating disorders in both male and female children and adolescents. Pediatricians should screen patients for disordered eating and unhealthy weight-control behaviors at annual health supervision visits. Pediatricians should evaluate weight, height, and BMI by using age- and sex-appropriate charts, assess menstrual status in girls, and recognize the changes in vital signs that may signal the presence of an eating disorder.
2. When an eating disorder is suspected, pediatricians, in conjunction with appropriate consultants, should initiate a comprehensive evaluation of the patient that includes both medical and psychological assessments as well as suicide risk appraisal. Once diagnosed, patients should be monitored for medical and nutritional

complications by their pediatrician or referred to other qualified practitioners for medical oversight.

3. To facilitate multidisciplinary care, pediatricians should refer their patients with eating disorders to treatment resources in their region when available. Ideally, these treatment program providers should have expertise in the unique developmental needs of this age group.
4. Pediatricians are encouraged to advocate for legislation and policy changes that ensure appropriate services for patients with eating disorders, including medical care, nutritional intervention, mental health treatment, and care coordination, in settings that are appropriate for the developmental level of the patient and severity of the illness.

Immunizing Against Hate: Overcoming Asian American and Pacific Islander Racism

Immunizing Against Hate: Overcoming Asian American and Pacific Islander Racism

Lee Savio Beers, MD, FAAP,[a] Moira Szilagyi, MD, PhD, FAAP,[b] Warren M. Seigel, MD, MBA, FAAP,[c] Wendy S. Davis, MD, FAAP,[d] Yasuko Fukuda, MD, FAAP,[e] Madeline Joseph, MD, FAAP,[f] Joseph L. Wright, MD, MPH, FAAP,[g] Sara H. Goza, MD, FAAP,[h] AMERICAN ACADEMY OF PEDIATRICS BOARD OF DIRECTORS EXECUTIVE COMMITTEE, BOARD COMMITTEE ON EQUITY

It has been more than a year since Immediate Past President of the American Academy of Pediatrics (AAP), Sally Goza, MD, FAAP, warned against the threat severe acute respiratory syndrome-coronavirus 2 (SARS-CoV-2) posed to children and families, including the harm coronavirus disease 2019 (COVID-19)–fueled racism and xenophobia could cause the Asian American community. Sadly, as the COVID-19 pandemic spread, racism and violent attacks on Asian Americans spread along with it.

COVID-19–FUELED RACISM AND ATTACKS ON ASIAN AMERICANS

Since March 2020, increases in racist rhetoric have coincided with increases in racist abuse, bullying, and attacks. According to Human Rights Watch,[1] an organization that investigates abuses happening throughout the world, reports of discrimination and violence against Asians and people of Asian descent have surged both in the United States and worldwide. A new study of police department statistics[2] from 16 of America's largest cities reveals that hate crimes against Asian Americans rose nearly 150% in 2020, despite overall hate crimes dropping by 7%.

Stop AAPI Hate,[3] a national coalition that tracks incidents of violence and harassment against Asian Americans and Pacific Islanders in the United States, reported nearly 3800 instances of discrimination against Asians between March 19, 2020, and February 28, 2021. Although these reports may represent only a fraction of the hate incidents that occur, it is an indication of how vulnerable Asian Americans have become to racial attacks and discrimination.

Widespread media coverage of violence committed against elderly Asian Americans in cities across the country is stirring up fear and a sense of increased vulnerability. These horrific, unprovoked attacks are not only heartbreaking to witness, they erode the sense of personal safety and well-being of the entire Asian American community. In addition, these hate crimes against the elderly are particularly devastating in light of the Asian American cultures influenced by values that promote positive views of aging and teach younger people to respect, obey, and care for their elders. Our Asian American patients tell us that they are afraid to walk or ride the bus to school, go to

church, or play outside, because they, too, have been targets of taunts and harassment. But even staying inside the home does not protect them. Many children say they have experienced cyberbullying or feel shunned and anxious because of hateful, racist language online. Their parents tell us that although they themselves have previously experienced anti-Asian racism in the United States, never before have they felt so unsafe. It is no longer a sense of "not belonging," it is a sense of being on high alert. The alarming statistics and the trauma behind them illustrate that America is again waging a battle against two pandemics: COVID-19 and racism.

HISTORY OF ANTI-ASIAN RACISM AND DISCRIMINATION IN THE UNITED STATES

Unfortunately, the racialization of a disease and the tendency to offer up scapegoats in times of crisis are not new phenomena. People of Chinese descent were implicated in the 2003 severe acute respiratory syndrome (SARS) pandemic. Such stigmatization invoked widespread fear and distrust and had damaging social and economic consequences for many Asian Americans.

In a 2020 commentary in *Pediatrics,* Cheng and Conca-Cheng[4] wrote about the long legacy of anti-Asian racism in the United States. They pointed to the Chinese Exclusion Act of 1882, which prevented Chinese laborers from immigrating to the United States, the Immigration Act of 1924, which extended these restrictions to other Asian immigrant groups, and President Franklin Roosevelt ordering forced relocation and internment of 120 000 individuals of Japanese ancestry during World War II. In times of crisis and fear, the instinct throughout history has been to find someone to blame. Often, this is targeted at communities that have been historically marginalized and people who are least able to defend themselves.

RACISM AS A SOCIAL DETERMINANT OF HEALTH

The 2019 AAP policy statement[5] titled "The Impact of Racism on Child and Adolescent Health" declared racism "a social determinant of health that has a profound impact on the health status of children, adolescents, emerging adults, and their families." The policy states, "The social environment in which children are raised shapes child and adolescent development, and pediatricians are poised to prevent and respond to environmental circumstances that undermine child health." This is one of those times when we must step up to the plate.

In a 2020 article in the *American Journal of Public Health*, "Potential Impact of COVID-19-Related Racial Discrimination on the Health of Asian Americans,"[6] Chen et al warned that COVID-19–related racial discrimination will exert harmful effects on Asian American health. They pointed to historical precedent of the association between racial discrimination and worsened psychological and physical health outcomes. Examples included the findings that Japanese Americans confined to internment camps during World War II experienced roughly double the rates of suicide and cardiovascular disease compared with their noninterned counterparts later in life and that Arab and Muslim Americans had greater psychological distress and short- and long-term health problems after the increase in Islamophobia, anti-Muslim rhetoric, and hate crimes that stemmed from the 9/11 terrorist attacks. In addition, the basic science and epigenetic elucidation of intergenerational transmission of historically experienced racism is evolving and supports these clinical observations.[7,8]

PROTECTING AND PROMOTING MENTAL HEALTH

In a 2020 article in *Pediatrics*, Cheah et al[9] examined the rates of COVID-19–related racism and racial discrimination experienced by Chinese American parents and youth and the associations with their mental health. The authors found that nearly half of parents and youth reported being directly targeted by COVID-19 racial discrimination online and that higher levels of perceived racism and racial discrimination were associated with poorer mental health.

For the past decade, rates of suicide, depression, and anxiety have been increasing for all children and adolescents. Many factors unique to the pandemic are adding to the toll on children's emotional and behavioral health: isolation from friends, family, and other community supports; emotional challenges, such as grief, fear, and disappointment; parental stress; and economic hardship. Asian American youth are further affected by having to wrestle with Sinophobic discrimination, slurs, and attacks, as well as the frightening reality that people from Black, Asian, and minority ethnic backgrounds are at greater risk of becoming severely ill and more likely to die of COVID-19 if infected.[10] Although we do not yet have complete data on the pandemic's impact on children's mental health, evidence is emerging that suggests both the prevalence and severity of mental health issues have worsened over the past year.

RENEWING THE CALL TO ACTION AGAINST RACISM

We urge all pediatricians to refamiliarize themselves with the AAP policy statement "The Impact of Racism on Child and Adolescent Health,"[5] to examine our own biases, be prepared to discuss and counsel Asian American families on the effects of exposure to racism, and make appropriate mental health referrals as needed.

And we echo and reemphasize the urgency of Dr Goza's call not only to vaccinate children against COVID-19 but also to strengthen our children's immunity to the virus of hate. The AAP's commitment[11] to dismantling racism has been, and will continue to be, at the forefront of our highest priorities.

Integrating Web Services/Applications to Improve Pediatric Functionalities in Electronic Health Records

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Integrating Web Services/Applications to Improve Pediatric Functionalities in Electronic Health Records

Stuart T. Weinberg, MD, FAAP, FAMIA,[a] Craig Monsen, MD, MS,[b] Christoph U. Lehmann, MD, FAAP, FACMI, FIAHSI,[c] Michael G. Leu, MD, MS, MHS, FAAP, FAMIA,[d] COUNCIL ON CLINICAL INFORMATION TECHNOLOGY

The past decade has seen a substantial increase in the use of electronic health records (EHRs) by health care providers caring for children. However, gaps in pediatric-specific functionalities continue to exist in some EHR systems, including population-specific growth curves, immunization clinical decision support, weight-based medication dosing with rounding, calculation of pediatric hypertension percentiles, age-specific developmental assessment, newborn bilirubin nomograms, anticipatory guidance reminders, and other functionalities described elsewhere. Implementing pediatric functionalities into EHRs is critical to the provision of safe pediatric care. As an alternative to direct implementation in EHRs, EHR vendor agnostic Web applications, Web services, and application programming interfaces offer an opportunity to provide pediatric functionalities and eliminate the need for each vendor to develop these functionalities. Successful implementation of Web services and related technologies requires responsible attention from both EHR vendors and developers of Web services, Web applications, and application programming interfaces to the use of data terminology standards, adherence to privacy and security requirements, rigorous testing, change management processes, and robust system support and maintenance. Education of health care providers about opportunities to improve pediatric functionalities in EHRs by using these services can facilitate discussions in EHR user groups in which vendors can be lobbied to implement them. This policy statement emphasizes the need to address pediatric-specific functionalities in EHRs by providing insight and recommendations into the development, maintenance, integration, and support of these novel solutions.

To cite: Weinberg S T, Monsen C, Lehmann C U, et al. Integrating Web Services/Applications to Improve Pediatric Functionalities in Electronic Health Records. *Pediatrics*. 2021;148(1):e2021052047

BACKGROUND

Between 2008 and 2015, adoption of a basic electronic health record (EHR) by children's hospitals increased from 10% to 55%. The percentage of acute care hospitals using a certified EHR by 2015 was 96%.[1] The percentage of office-based physicians in the United States using a certified EHR system was estimated to be 77.9% in 2015[2] and 94% in 2016.[3]

Many EHR systems lack pediatric functionalities, including plotting growth charts, computing anthropometric percentiles, tracking adherence to well-child visits and immunization schedules, and supporting weight-based dosing.[4,5] These core pediatric functionalities have been described for both the outpatient[6] and inpatient[7] settings. More recently, as part of the 21st Century Cures Act, additional core pediatric functionalities were recommended by the Health IT for the Care Continuum Task Force in conjunction with the Office of the National Coordinator for Health Information Technology as pediatric EHR certification criteria.[8] As an alternative to implementing these core features directly as core functionalities in EHR systems, Web services and Web applications offer opportunities to integrate and thereby increase the use of pediatric functionalities across multiple EHR systems by using standard technologies and terminologies for those EHR systems that provide access to Web services and applications.

STATEMENT OF THE PROBLEM

Emerging evidence supports continuous development and modification of guidelines and clinical policies. Examples include:

1. In October 2016, the Centers for Disease Control and Prevention released a new recommendation to the human papillomavirus vaccine schedule. The novel recommendation required only 2 doses spaced at least 6 months apart if the first dose was administered before age 15 years.[9]
2. In August of 2017, the American Academy of Pediatrics (AAP) published a clinical practice guideline that included "significant changes" in the screening and management of high blood pressure in children and adolescents, new normative pediatric blood pressure tables, and an action statement to include flags for abnormal blood pressure values both when the values are being entered and when they are being viewed.[10]
3. In February of 2017, the AAP published the fourth edition of *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents,* containing a periodicity schedule of screenings and recommendations for 31 age-specific visits, from the newborn visit through visits for 21-year-olds.

These are but a few examples of pediatric-specific clinical guideline changes that provide significant challenges to EHR vendors who want to keep their clinical content up to date. In the current product development model, every vendor has to invest development resources to implement these new functionalities, guidelines, and clinical decision support. Often, vendors instead deploy content development tools with which each customer maintains embedded clinical content at a significant cost. Web services and Web applications offer solutions that can be shared among multiple EHRs and health care settings.

Examples of Current Web Services and Web Applications

A Web service is software that resides on a server that can be accessed by multiple applications and computers and provides functionality that does not involve user interaction, such as credit card authorization or medical calculations. A Web application can be accessed through a browser and has a user interface. There are pediatric examples that could serve as models for the integration of Web services and Web applications into existing EHRs.[11–18] It is important to apply the key considerations listed below when using these Web services and applications, especially those related to accuracy, testing, and transparency. Because Web services are smaller, more specialized software modules compared with EHRs, they have the advantage that they are easier to develop, test, and augment in a more rapid development cycle and do not have to rely on vendors to prioritize functions for development.

Key Considerations in the Development, Integration, and Use of Web Services

As these resources continue to be developed and implemented, several key issues need to be considered by developers, vendors integrating these tools, organizations, and end-users:

1. Dependability, access time, and speed: The use of a Web service or Web application introduces an external dependency, which needs to be reliable. Vendors must ensure that EHRs fail gracefully when the Web service or Web application is unavailable and allow users to complete their tasks.
2. Privacy, security, and confidentiality: Developers of these tools and the EHR vendors that integrate them need to be compliant with all relevant Health Insurance Portability and Accountability Act regulations. Business associate agreements between developers and vendors may need to be

developed. Because health care providers assume responsibility, as per Health Insurance Portability and Accountability Act security rules, to "ensure the confidentiality, integrity, and availability of all e-PHI they create, receive, maintain, or transmit,"[19] it is important that vendors provide security information documenting this compliance. Audit logs of data sent to and received from the Web service should be maintained in the EHR.

3. Accuracy, testing, versioning, and change management: Developers need to rigorously test the performance and accuracy of their tools. The developer, in collaboration with the EHR vendor, should test the system in a production environment using exhaustive testing scenarios to ensure that (a) the Web service is available and functions properly and its performance is acceptable to users; (b) the Web service fails gracefully, informing the user and allowing tasks to be completed later (eg, if the Web service is not available, the health care provider can still use the EHR); and (c) the version of the Web service and data used to generate calculations and/or recommendations are recorded with each use. The latter will allow retrospective validation of past calculations and/or recommendations once an upgrade of the Web service becomes available. As new versions are developed, a versioning history should be in place so that end-users are aware of changes, and EHR vendors should have a clear process to communicate those changes. Before going live, health care provider end-users must have an opportunity to test the system using realistic patient data.
4. Standards in technology and terminology: There are well-established technical and terminology standards related to data structure, data transport, and medical vocabularies (such as SNOMED CT, LOINC, and RxNorm) that should be adopted by Web services and Web applications.
5. Usability and transparency: Particularly with tools that deliver clinical decision support, Web application and/or service developers should provide, and EHR vendors should display, "show your work" functionality that allows end-users to understand underlying algorithms and how and why alerts and recommendations are generated.
6. Business models: Several business models exist for the use of Web services and Web applications by EHR vendors, including a subscription model, a per-use model, or a hybrid of the two. Vendors should be transparent if these costs are being transferred to end-users.

RECOMMENDATIONS

The AAP recommends the following basic principles for the ideal integration of Web services, Web applications, and application programming interfaces into EHR systems:

1. Health care providers and other users of EHRs should know how to access their EHR vendor user groups, through which requests for additional pediatric functionalities can be addressed. Within these user groups, they should research whether Web services or Web applications exist that can be used without the vendor redeveloping the same functionality (eg, in application marketplaces).
2. EHR vendors should support the ability to integrate Web services and Web applications within their systems, consistent with current standards for data terminologies, transport protocols, and privacy and/or security compliance. Vendors should be encouraged to make their interfaces uniform so that services can be available to different EHRs simultaneously.
3. Qualified health system or EHR vendor staff should consider integrating a Web service or Web application if:
   a. pediatric functionality provided by an available Web service or Web application is not present in the EHR or
   b. the functionality provided by the Web service or Web application enhances existing EHR functionality; and
   c. uptime, privacy, and security are within acceptable parameters.
4. EHR vendors that integrate Web services and Web applications should actively communicate and be transparent with users about any changes in the content or delivery of these tools. For example, vendors should inform users when an integrated Web service or application has been updated and allow end-users the opportunity to steward Web services by providing feedback to mitigate any issues with accuracy.
5. Web service developers should demonstrate sustainability and support continued development and maintenance as clinical guidelines and technical standards change.
6. Web service developers should employ current standards for data terminologies, transport protocols, and privacy and/or security compliance in a uniform manner so that Web services do not need to be customized for various platforms.
7. Web service developers should engage pediatric subject matter experts in the creation and testing of Web services with pediatric clinical content. In addition, physician groups should make it easier to identify informaticians

who are willing to work with these developers and EHR vendors.

CONCLUSIONS

Web services, Web applications, and application programming interfaces offer opportunities to extend and improve pediatric functionalities of existing EHRs. An increasing number of EHR vendors are making access to these tools possible. Pediatricians' awareness of these tools can facilitate discussions with EHR vendor user groups to implement these solutions where useful and feasible.

Leukodystrophies in Children: Diagnosis, Care, and Treatment

- *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Leukodystrophies in Children: Diagnosis, Care, and Treatment

Joshua L. Bonkowsky, MD, PhD, FAAP,[a] Stephanie Keller, MD, FAAP,[b] AAP Section on Neurology, Council on Genetics

Leukodystrophies are a group of genetically determined disorders that affect development or maintenance of central nervous system myelin. Leukodystrophies have an incidence of at least 1 in 4700 live births and significant morbidity and elevated risk of early death. This report includes a discussion of the types of leukodystrophies; their prevalence, clinical presentation, symptoms, and diagnosis; and current and future treatments. Leukodystrophies can present at any age from infancy to adulthood, with variability in disease progression and clinical presentation, ranging from developmental delay to seizures to spasticity. Diagnosis is based on a combination of history, examination, and radiologic and laboratory findings, including genetic testing. Although there are few cures, there are significant opportunities for care and improvements in patient well-being. Rapid advances in imaging and diagnosis, the emergence of and requirement for timely treatments, and the addition of leukodystrophy screening to newborn screening, make an understanding of the leukodystrophies necessary for pediatricians and other care providers for children.

INTRODUCTION

Inherited leukodystrophies are a group of genetically diverse diseases with more than 30% mortality by 8 years of age. Leukodystrophies, which are attributable to abnormalities of the brain myelin (white matter), are individually rare but collectively common, with a published incidence of 1 in 4700 live births.[1–4] Leukodystrophies can present at any age from preterm infants and neonates to late adulthood[5,6] and have been reported across all ethnicities and regions of the world.[7–13] Clinical recognition of leukodystrophies accelerated with the widespread clinical adoption of MRI in the 1980s and 1990s,[14,15] and recent improvements in genetic diagnosis techniques have led to specific diagnosis in more than half of all patients with leukodystrophy.[2,16,17]

Today, definitive cures exist only for a few leukodystrophies. However, there is tremendous excitement for patients, providers, and families because of a multitude of clinical trials and genetic therapies that are being pursued and rapidly becoming available.[18] In addition, a crucial point is that all leukodystrophies are treatable. Improved general care and quality of life for patients and their families is recognized as a central goal of treatment. An analogous dramatic example is that of cystic fibrosis, for which average life expectancy has increased from 30 days to 30 years even in the absence of a genetic cure.[18,19] These gains in longevity were largely derived from incremental improvements in the approach to routine care (eg, aggressive physiotherapy, antibiotics), and applying standard preventive health maintenance has the potential to improve overall health.[20]

Because of the potential for treatment when recognized early, the US Health and Human Services Advisory Committee on Heritable Disorders in Newborns and Children (ACHDNC) Recommended Uniform Screening Panel (RUSP) now recommends universal newborn screening (NBS) for X-linked adrenoleukodystrophy (X-ALD).[21] New York, Connecticut, Pennsylvania, Minnesota, and California now include some leukodystrophies in their NBS panels, and more than 15 states added testing for X-ALD in their panels in 2019 and 2020.[22] Additional states are in the evaluation process for consideration to add X-ALD and/or Krabbe disease to their NBS panels.

The general pediatrician plays an important role for children with leukodystrophies. The pediatrician may need to assist with prompt and appropriate referral for NBS results, provide a medical home for patients and families as they navigate between different subspecialists for treatments, provide long-term follow-up after therapies such as hematopoietic stem cell transplant (HSCT), and counsel families who have an affected child or an affected relative. These roles for the pediatrician are new and transforming rapidly and often have not been addressed in residency training.

This clinical report from the AAP on leukodystrophies will help guide policy management for NBS, approaches to diagnosis, timing and choice of treatment, and supportive therapies. Leukodystrophies, formerly considered a rare neurologic disorder that would not be seen by a general pediatrician, are relatively common as a group of disorders. Therefore, familiarity with the general principles for diagnosis and supportive management in leukodystrophies is important for all pediatricians. The primary take-home message is that recognizing and diagnosing a leukodystrophy is important, because some leukodystrophies require urgent treatment.

CATEGORIES AND DISEASES

What is a leukodystrophy? Broadly speaking, it is any genetic disease affecting the myelin of the central nervous system (CNS). Table 1 presents a list of commonly used terms, definitions, and abbreviations used in leukodystrophies. Leukodystrophies fall into broad categories: (1) hypomyelination, in which there is absent or diminished myelin production; (2) dysmyelination, in which there is abnormal myelin development; or (3) demyelination, in which there is loss and/or destruction of previously established myelin. Demyelinating leukodystrophies tend to be the more well-known leukodystrophies, including Krabbe disease, X-ALD, and metachromatic leukodystrophy (MLD). Better-known hypomyelinating leukodystrophies include Pelizaeus-Merzbacher disease (PMD), RNA polymerase III–related leukodystrophies/4-H syndrome (hypomyelination, hypogonadotropic hypogonadism, and hypodontia), and hypomyelination with atrophy of the basal ganglia and cerebellum. A single disease can fall into more than one category, even in the same individual. Also, this categorization theme is based mostly on the appearance of the leukodystrophy by using MRI, which can be subjective.

There is disagreement over the exact definition of a leukodystrophy and whether certain conditions meet required criteria.[2,3] Further complicating this lack of consensus are differences in the severity of the disease. For example, the exact same genetic mutation of *ABCD1* (the gene responsible for X-ALD) in twin brothers can lead to rapid cerebral demyelination in childhood or to a slow and chronic effect mostly of the peripheral nerves. Finally, next-generation sequencing techniques are revealing complex genotype-phenotype disease relationships of leukodystrophy genes, which were unsuspected and unknown 5 years ago.

One standard for definition of leukodystrophies was published in 2015 based on the consensus opinion of a panel of inherited white matter disease experts.[23] The group classified 30 diseases as leukodystrophies, defined as heritable disorders affecting the white matter of the CNS with or without peripheral nervous system involvement.[23] This does not include acquired CNS myelin disorders, such as multiple sclerosis, and related acquired CNS demyelinating processes. Inborn errors of metabolism, in which the clinical

TABLE 1 Definitions and Terms Used in the Text

Brainstem auditory evoked potential: A test for intactness of the auditory nerve and CNS auditory centers.
BMT: often used interchangeably with HSCT or UCB transplant. Used as a treatment of certain leukodystrophies.
CNS: including the brain, spinal cord, retina, and optic and olfactory nerves.
Demyelination: loss and/or destruction of previously established myelin.
Dysmyelination: abnormal myelin development.
EMG: typically performed with NCS, to evaluate muscle and nerve function.
HSCT: transplant of cells derived from a healthy donor source of hematopoietic lineages is curative for a few leukodystrophies (see Table 2). Types, technical aspects, benefits, and risks of transplant vary. The transplant source can be peripheral blood, BMT, or UCB transplant.
Hypomyelination: absent or diminished myelin production.
Leukodystrophy: a heritable disorder affecting the white matter of the CNS with or without peripheral nervous system involvement.[22] This does not include acquired CNS myelin disorders, such as multiple sclerosis and related acquired CNS demyelinating processes.
Leukoencephalopathy (genetic): a disease that may reveal significant white matter changes in the brain but the predominant symptoms of the disease are considered to arise from the gray matter or other organ systems.
MRI: important imaging tool for diagnosis and evaluation of leukodystrophy. Aspects of MRI analysis that may be helpful for diagnosis include T1, T2, and diffusion weighted imaging. For a few leukodystrophies, the specific findings on MRI can help make a diagnosis.
Myelin: the lipid layer providing insulation and support for axons and neurons in the CNS (the white matter of the CNS).
NBS: newborn screen.
NCS: to evaluate peripheral nerve function; often performed with EMG.
NGS: new, advanced, rapid sequence techniques including gene panel tests, WES, and WGS.
Visual evoked potential: a test for intactness of nerve pathways for vision.
WES: a type of NGS that analyzes all of the exons (coding sequences).
WGS: a type of NGS that analyzes all of the DNA.

Specific leukodystrophy diseases and their abbreviations are listed in Table 2. UCB, umbilical cord blood; BMT, bone marrow transplant; NGS, next-generation sequencing.

manifestations of systemic illness predominate, even with significant white matter abnormalities in the brain, were also excluded from characterization as leukodystrophies. These, as well as other genetic diseases, such as neuronal ceroid lipofuscinosis and mitochondrial diseases, were termed "genetic leukoencephalopathies." Although leukoencephalopathies may reveal significant white matter changes in the brain, the predominant symptoms of the disease are considered to arise from the gray matter or other organ systems.

CLINICAL PRESENTATION

The age of onset of symptoms in leukodystrophies may vary from prenatal to adult. In neonates and infants, presenting symptoms can include encephalopathy or developmental delay. In children, adolescents, and adults, symptoms can be more insidious, ranging from behavioral or psychiatric changes; loss of formerly achieved milestones; or deterioration in skills, vision changes, or ataxia or gait changes (often from spasticity). Attention-deficit/hyperactivity disorder and other subtle cognitive changes may be the presenting symptoms and often precede motor dysfunction in leukodystrophies with late childhood or juvenile onset.[24] In general, hypomyelinating leukodystrophies present more often with motor delay versus motor regression typically seen in demyelinating leukodystrophies.

Seizures are much more common than previously realized in children with leukodystrophies and affect up to 49% of children with the disease.[2] In rare cases, seizures may be the presenting symptom, such as in Alexander disease. Epilepsy is a common feature of Krabbe disease, megalencephalic leukoencephalopathy with subcortical cysts, sialic acid storage disorders, peroxisomal disorders, and L-2-hydroxyglutaric aciduria.[16]

A few leukodystrophies are more likely to have classic presentations. In a child with acute deterioration of neurologic status, particularly after a febrile illness or head injury, mitochondrial disease or vanishing white matter (VWM) disease are considerations. Infants with PMD often present at birth or within the first 2 months of life with hypotonia, rotary nystagmus, head titubation, and sometimes stridor attributable to vocal cord paralysis.[25] Macrocephaly is a common feature in megalencephalic leukoencephalopathy with subcortical cysts (MLC), Canavan disease, and Alexander disease, and microcephaly is a feature of Aicardi-Goutières syndrome and RNAse T2-deficient leukoencephalopathy.[16] In the neonatal period, Aicardi-Goutières syndrome may often be confused with a congenital cytomegalovirus infection shared symptoms of intracranial calcifications and microcephaly and, in some, hepatosplenomegaly and thrombocytopenia.[26] X-ALD can be considered in a school-aged boy with skin color changes and/or adrenal insufficiency (eg, Addison disease). Children with 4-H syndrome or RNA polymerase III–related leukodystrophies may be identified by their other systemic symptoms including dental abnormalities, progressive myopia (nearsightedness), and hypogonadotropic hypogonadism.[16]

The age of onset of symptoms and/or developmental regression may also help narrow the differential diagnosis. Although most leukodystrophies have both infantile and juvenile or adult forms, one of these groups is typically predominant. The most common forms of Aicardi-Goutières syndrome and PMD display symptoms from birth or within the first few months of life.[25,26] Ninety percent of patients with Krabbe disease are of infantile onset with symptoms presenting between 6 and 12 months of life.[27] The most common form of MLD is the late-infantile form with onset of symptoms between 1 and 2 years of age. Neurologic symptoms in boys with X-ALD occur most often in the elementary school years, between 4 and 10 years of age.

Developmental regression and loss of previously attained milestones can be a presentation of some leukodystrophies and is often the symptom that brings the child to medical attention. In this situation, an urgent evaluation with a pediatric neurologist should be considered.

MRI AND NEUROIMAGING

An MRI of the brain is the gold standard investigation in a patient with a suspected leukodystrophy or leukoencephalopathy.[16] Although computed tomography (CT) can indicate abnormal signal quality in the CNS myelin, the more detailed signal characteristics of an MRI can provide potentially diagnostic information. Furthermore, MRI is preferable to CT for visualizing abnormal signal and because it involves less radiation exposure. Many publications have identified MRI patterns in leukodystrophies that can be used for diagnosis.[28–33] Key features on MRI include the presence of contrast enhancement, the presence of cysts, calcifications, or more subtle structural abnormalities.[34] The predominant location, confluent versus multifocal nature of the white matter abnormalities, and signal changes, including hypomyelination versus high T2 signal abnormality and the relative T1 signal hyper- or hypointensity, are the primary discriminating MRI characteristics.[16,28] Although MRI algorithms are helpful for diagnosis,[28] there are limitations on their sensitivity and specificity, and they require skilled radiologic interpretation and experience.[29]

The changing appearance and characteristics of myelin with normal development can also cause complexity in interpreting MRIs.[35] There is a range of normal development of myelin appearance on MRI, and at age 2 years some children will not be fully myelinated. Hypomyelination can also be a result or accompanying feature of other genetic diseases, systemic disorders, or illnesses.[36,37] MRI interpretation is also complicated by normal developmental features: the T1 and T2 signal characteristics of myelin change between birth and 1 year; myelination proceeds from central brain structures to more peripheral white matter and posteriorly to anteriorly. In particular, until the age of 2 years, the CNS of children is normally relatively hypomyelinated compared with adults. Therefore, in a child younger than 1 year with possible hypomyelination, a follow-up MRI of the brain after 24 months, or serial MRIs every 6 to 12 months, is recommended to establish the diagnosis of hypomyelination.[16]

Despite these caveats, some leukodystrophies have key features on MRI, which can suggest a diagnosis for classic presentations (Fig 1, Table 2).[16,38,39] Although not completely sensitive and specific, multiple sclerosis (Fig 1) and other mimicking conditions (such as periventricular leukomalacia from prematurity) typically have different MRI features. Overall, the MRI findings should be interpreted in concert with the findings of the clinical history and physical examination.

DIAGNOSIS

A genetic diagnosis offers affected families a variety of important options, including disease-specific therapies in some cases and family planning advice in all cases. For a few leukodystrophies, early diagnosis can lead to a halt in disease progression and, in some instances, a cure.

After a diagnosis is suspected on the basis of clinical presentation and MRI findings, biochemical and/or genetic studies are required for a final determination. Depending on available expertise, early referral and involvement of a pediatric neurologist, geneticist, and genetic counselor are important for guiding diagnostic testing, care, and potential further referral (for example, if HSCT is indicated). However, in situations in which timely diagnosis is important, with appropriate guidance, a primary physician can initiate diagnostic tests. Further referral to a clinician or clinical center with expertise in leukodystrophy care can be helpful. For example, online leukodystrophy support groups such as the United Leukodystrophy Foundation or the Leukodystrophy Care Network can direct patients toward centers with leukodystrophy expertise.

Testing of other organ systems may provide additional information to help confirm a diagnosis or differentiate it from others.[40] Possible testing includes an ophthalmologic examination for indications of ocular involvement; electromyography (EMG) to evaluate

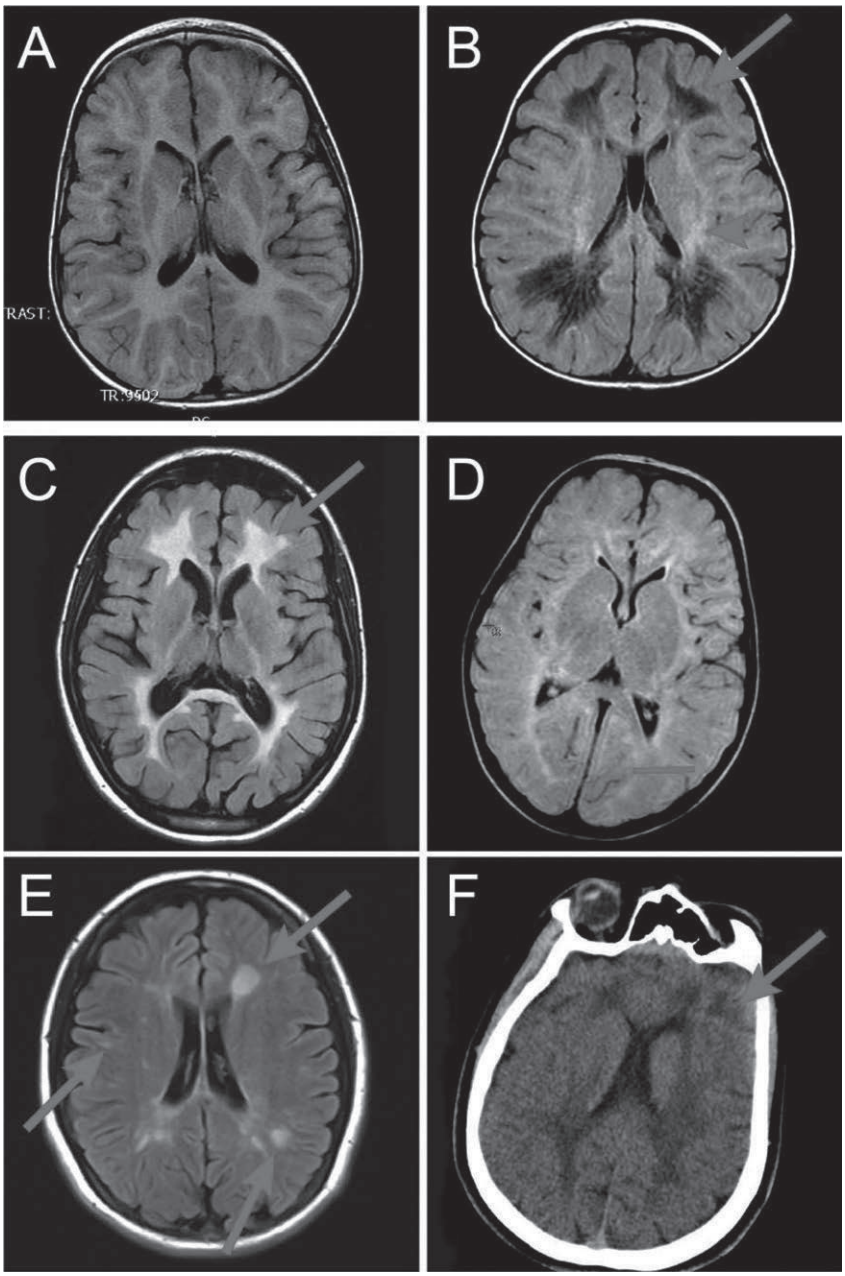

FIGURE 1 Illustrative examples of MRIs of different leukodystrophies and of leukodystrophy mimics. Images are axial slices. A, T2 image of normal brain. B, T2 MRI image of VWM disease; arrow points to hypodense (dark color) white matter; arrowhead points to abnormal hyperintense (bright) white matter. C, T2 image of MLD, with hyperintense (bright) signal in the white matter (arrow). D, T2 image of a hypomyelinating leukodystrophy, PMD, in which the relative paucity of myelin is seen (red line, compare with normal MRI of A). E, T2 image of multiple sclerosis, with scattered areas of hyperintense signal (arrows). F, CT image of VWM disease; abnormal signal in white matter is present (arrow) but is much easier to see on MRI (B).

for myopathies; a nerve conduction study (NCS), which may reveal a peripheral neuropathy; brainstem auditory evoked potential to evaluate for hearing loss; and visual evoked potentials to examine vision.[40] Lumbar punctures with cerebrospinal fluid (CSF) analysis may show protein elevation in active demyelination or a lactic acid elevation in mitochondrial disease. CSF leukocytosis and elevated interferon-α and neopterin suggest Aicardi-Goutières syndrome. Lastly, CSF N-acetyl aspartate (NAA) is elevated in Canavan disease.[16]

The Global Leukodystrophy Initiative published a clinical approach to diagnosis of patients with leukodystrophies in 2015. Its approach combines 3 elements: (1) testing for treatable diseases; (2) testing based on MRI features; and (3) next-generation sequencing technologies, particularly gene panel-based approaches and whole-exome sequencing (WES).[16] There is utility in making an expedient diagnosis by excluding treatable forms of leukodystrophies, curtailing other expensive and lengthy testing, and providing valuable reassurance and prognostic information to the patient and family.[16]

Steady advances in next-generation sequencing technologies are making WES a first-tier option for diagnosis of complex genetic disorders with reported yields of 25%.[41] Unbiased genome-wide approaches exemplified by WES or whole-genome sequencing (WGS) provide the potential for diagnosis of known diseases without stepwise ordering of multiple individual tests. Furthermore, genome-wide sequencing can contribute to ongoing discovery of novel disease genes. This testing and assistance with interpretation of results can be facilitated with the help of a geneticist and/or genetic counselor.

Next-generation sequencing technologies provide the potential for unbiased diagnosis of known diseases without individual ordering of multiple individual tests and will contribute to discovery of novel disease genes. However, continued limitations and problems associated with this technology

TABLE 2 Representative Leukodystrophies: Disease; Gene; Classic Features, Including Age at Onset, Symptoms, and MRI Findings; NBS; and Treatment (ERT, HSCT)

Disease	Gene	Typical Age at Onset	Classic Symptoms	Classic MRI Finding?	NBS?	Treatment?
Aicardi-Goutières	Multiple	Birth to 6 y	Microcephaly, seizures	Calcifications	—	—
Alexander disease	GFAP	Birth to 2 y	Delay, regression	—	—	—
Canavan disease	ASPA	3 mo to 1 y	Delay, macrocephaly	—	—	—
Gaucher disease	GBA	Birth to 6 mo	Seizures, spasticity	—	—	ERT
Krabbe (Globoid cell)	GALC1	2–6 mo	Regression, irritability	—	Yes	HSCT
MLD	ARSA	Birth to adult	Varies	—	—	HSCT
PMD	PLP1	Birth to 6 mo	Hypotonia, nystagmus, titubation	Hypomyelination	—	—
VWM	EIF2B	4 mo to 10 y	Symptoms after minor illness	"Stranding"	—	—
X-ALD	ABCD1	4–10 y	ADHD, school problems, Addison	Contrast enhancement	Yes	HSCT, hormones

ADHD, attention-deficit/hyperactivity disorder; GFAP, glial fibrillary acidic protein; —, not applicable.

include (1) substantial cost (up to $15 000 to $20 000), although these numbers are rapidly decreasing; (2) potential for identifying unanticipated disease variants unrelated to the test indication; (3) potential false-negative results because of imperfect exome coverage; and (4) methodologic limitations in the interpretation phase if a clear disease-associated variant is not identified. This fourth problem is significant because of the large number of deleterious gene variants in all humans that could plausibly be related to a phenotype (especially in the CNS), which could yield false-positive associations.

WES continues to become more accessible and may become the method of choice for the diagnosis of leukodystrophies, because it can avoid the diagnostic odyssey faced by many patients.[42,43] Researchers in a recent study used WES on a cohort of 71 patients with persistently unresolved white matter abnormalities with a suspected diagnosis of leukodystrophy or genetic leukoencephalopathy. Diagnostic pathogenic variants were identified in 35% (25 of 71) of patients and potentially pathogenic variants were found in clinically relevant genes in an additional 7% (5 of 71) of cases, giving a total yield of clinical diagnoses in 42% of individuals.[17] Sequencing is as cost-effective as a brain MRI and, with improved data analysis, will become as rapid. However, even after in-depth biochemical and genetic testing, a portion (around 25% to 40%) of leukodystrophy cases can remain undiagnosed.

There are important current limitations to use of next-generation sequencing approaches. There are unanswered questions about the disconnect between the underlying gene or biochemical defect, as in X-ALD or Krabbe disease, and actually developing the disease.[44,45] Additionally, WES does have caveats for diagnosis, including copy number variation mutations, mitochondrial genome mutations, and insufficient coverage of some exons to reliably call heterozygous variants. WGS is also becoming clinically available. It provides nearly complete information of DNA sequences but until recently has only been available in research studies. Some recent work suggests that WGS may be useful as a first-line diagnosis tool.[46] However, unresolved ethical questions surround the implementation of WGS as a screening or general diagnostic tool.[47,48] These ethical concerns include that WGS can reveal information unrelated to the patients' current symptoms but that may affect the health of the patient and his or her family, could reveal future health issues before the patient having decision-making capacity, could affect health insurance coverage, or could reveal unexpected issues such as consanguinity or unexpected parentage.[40]

NBS

NBS for selected leukodystrophies is being developed in several states.[44,49] X-ALD NBS has been added to the US Health and Human Services RUSP. X-ALD is the only leukodystrophy included (at the time of this publication) on the RUSP. X-ALD is gradually being added to state NBS panels, including (at the time of this publication) 18 states, Puerto Rico, and the District of Columbia.[22,50,51] There are a variety of resources for management of results, and a flow diagram of management for X-ALD (from the California Department of Public Health) is provided in Fig 2.

Krabbe disease has been included in NBS on the basis of legislative mandate in 7 states; Krabbe screening was not recommended by the ACHDNC.[44,49] Addition of conditions outside the ACHDNC process, such as occurred for Krabbe disease, has been controversial. Krabbe disease was proposed for inclusion on the RUSP, but it was not confirmed because of a lack of evidence of an effective treatment. In Krabbe disease, mutational analysis and residual

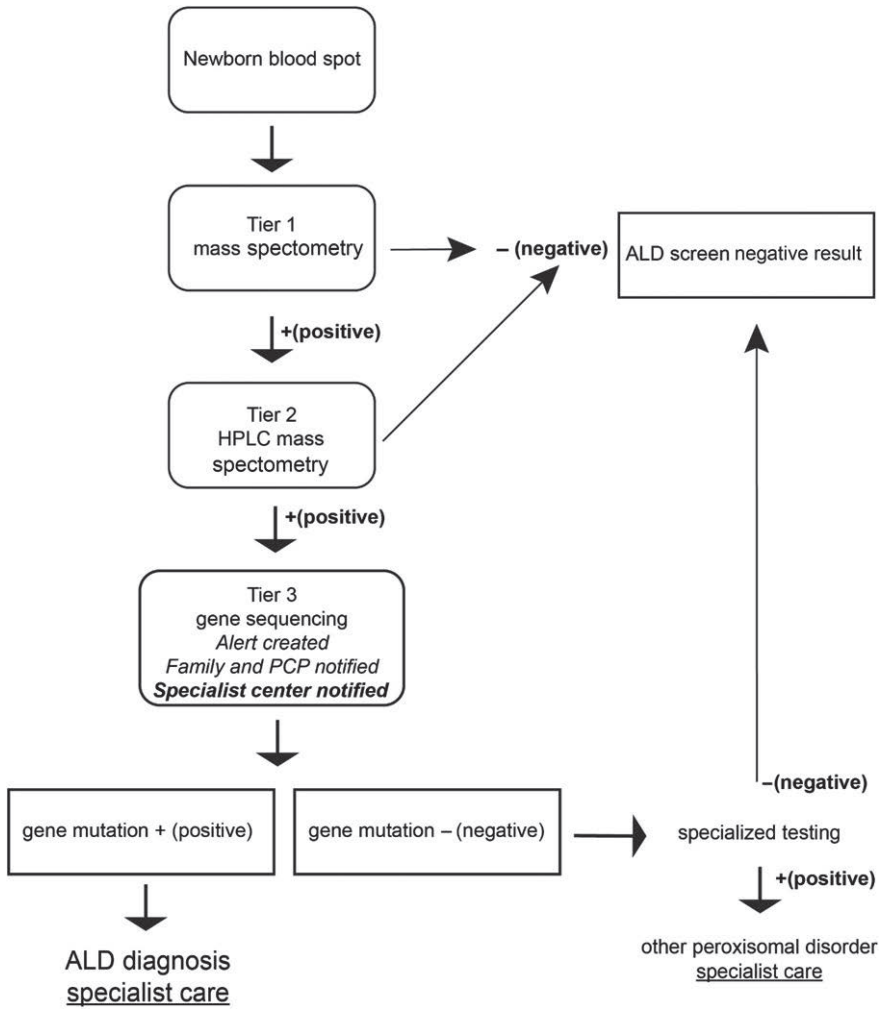

FIGURE 2 Simplified protocol for X-ALD NBS protocol (schematized from the California Department of Public Health). HPLC, high-performance liquid chromatography; PCP, primary care provider.

galactosylceramidase enzyme activity have only limited ability to predict age of disease onset and whether disease will occur.[45] In the first 8 years Krabbe disease was included in NBS in New York state, most of the infants judged to be high risk on the basis of screening protocols did not develop the infantile form of the disease and have remained asymptomatic.[52] Therefore, referring all high-risk infants for transplant would expose many of them to unnecessary risk, because HSCT is associated with significant morbidity and mortality. However, efforts are continuing to help identify which patients with Krabbe disease are most at risk, for example, incorporating measurement of psychosine by using liquid chromatography tandem mass spectrometry as a second-tier test. Psychosine is one of several substrates of the galactosylceramidase enzyme, and its accumulation may cause or contribute to the demyelination and neurodegeneration in patients with Krabbe disease.[53]

Despite the controversies highlighted by NBS for Krabbe disease, as technology advances and new therapies emerge, it is highly likely that other leukodystrophies will be considered for NBS. Factors affecting recommendation for NBS include variability in disease course, variability in penetrance and disease progression, and limited treatment options.[54–56] Generally, criteria for inclusion in NBS include availability of an appropriate test, a clinical history that includes a potential for impact with early intervention, and an effective therapy. As new therapies become available, additional conditions may become potential targets for NBS implementation. Once NBS is implemented, there is variability in each state as to the testing methodology used, the value or cutoff reported as positive, and means of

confirmatory and secondary testing. Finally, because treatments such as HSCT for Krabbe disease can be expensive or carry risk or have limited efficacy, a decision to implement NBS requires careful consideration of pros, cons, risks, benefits, and costs.[55]

Even for diseases with an available treatment, such as cerebrotendinous xanthomatosis, identifying a testing algorithm with a low false-positive rate and the ability to use existing equipment has been an ongoing area of development.[57,58] Additionally, the cost of test implementation and the development and organization of resources for the evaluation and treatment of identified affected children have been road blocks in NBS for leukodystrophies. Further debate revolves around the potential harm to families of children who have false-positive test results.

Screening for X-ALD is aimed at identifying infants before the onset of neurologic symptoms associated with the cerebral form of the disease, because early treatment with HSCT can prevent severe disability and death. Even for patients who do not develop cerebral disease, early identification can be life-saving by preventing adrenal crisis, because adrenal dysfunction occurs in approximately 90% of patients with X-ALD. For asymptomatic boys in childhood, endocrine monitoring is suggested with an annual clinical evaluation and with serum adrenocorticotropic hormone and cortisol tests every 6 months.

An annual neurologic evaluation is also recommended for X-ALD.[59] Approximately 30% to 40% of patients with X-ALD will go on to develop the cerebral form of the disease.[60,61] Because of the risk of morbidity and mortality with HSCT, boys do not receive transplants unless there is evidence of cerebral involvement.[59] Protocols have been developed to monitor for cerebral involvement with serial MRIs recommended every 6 months from 1 to 12 years of age. After 12 years of age, MRIs are performed yearly. If an abnormality is detected on MRI, the MRI is scored by using a specialized scoring system (Loes score) to determine if HSCT is appropriate.[58] HSCT is typically considered appropriate if the Loes score is less than 9, with a performance IQ of greater than 80.[59,62] HSCT in children in whom the Loes score is greater than 9 and who have significant neurologic involvement including IQ less than 80 is not recommended because of poor outcomes.

NBS for X-ALD can also identify other peroxisomal disorders such as Zellweger spectrum disorder, acyl-CoA oxidase deficiency, and D-bifunctional protein deficiency. Unfortunately, at this time, only supportive care is available for treatment of these other peroxisomal disorders.[61] As data from the experience of NBS for X-ALD and Krabbe disease from New York state become available, new complications may be identified, but also ways to improve screening, follow-up, and pathways to treatments can be developed.

TREATMENTS

Curative options for leukodystrophies are disappointingly sparse at the current time. The only option is HSCT. HSCT is only effective for a subset of leukodystrophies, chiefly X-ALD, MLD, and Krabbe disease,[63–65] and is only helpful if transplant is performed before substantial disease progression. However, it is important to note that even in the absence of a curative therapy, treatments, such as for spasticity or feeding problems, can improve the lives of children with leukodystrophies.

Although not a cure, HSCT can prolong life and preserve cognitive skills when performed in presymptomatic infants with Krabbe disease.[66,67] However, most treated children still experience spasticity, lower-than-average growth, and difficulties in expressive language, adaptive behavior, and motor function.[66,67] Infants receiving a transplant before 30 days of age, most of whom had Krabbe disease diagnosed in utero because of family history, had better survival and functional outcome than those who received transplants later.[68] Presymptomatic transplant is reported to result in normal receptive language,[40] attenuation of symptom severity,[40] and longer survival compared with untreated infantile Krabbe disease. However, most children have progressive gross motor delays ranging from mild spasticity to inability to walk independently, and a few have acquired microcephaly.[40]

A study performed on the outcomes of HSCT in patients with MLD showed that 7 out of 27 patients died of infection, regimen-related toxicity, or disease progression.[69] The researchers found that patients with motor function symptoms at the time of transplant did not improve after transplant. Transplant fails to correct disease in the peripheral nervous system, because enzyme is not delivered to the peripheral nerves, which greatly affected motor development as peripheral neuropathy can be severe as early as 3 month of age.[69] After HSCT, auditory evoked responses, visual evoked potentials, EEG, and/or peripheral nerve conduction velocities stabilized or improved in juvenile patients with MLD but continued to worsen in most patients with the late-infantile

presentation.[69] Lentiviral gene therapy correction of a patient's own bone marrow stem cells (hematopoietic stem cell gene therapy [HSC-GT], in which a normal copy of the gene is delivered by a lentivirus to replace the patient's mutant copy) appears to be well tolerated, including for infantile MLD.[70] Although lentiviral HSC-GT may offer reduced complications and the potential for improved treatment, outcomes data are not yet available.

HSCT is the only effective therapy for cerebral X-ALD that has been proven to date, and it is more likely to be effective if it is performed at an early stage of neurologic involvement with a light burden of disease on MRI. Favorable baseline disease characteristics for HSCT include one or fewer neurologic deficits and a Loes MRI score <9.[62] HLA antigen–matched siblings are also preferred. To determine if HSCT is indicated, presymptomatic boys are monitored with a yearly neurologic examination and with a brain MRI every 6 months from age 2 years to 12 years and then yearly to evaluate for the development of white matter signal abnormalities and contrast enhancement on MRI. HSCT does not prevent the adrenal involvement or the later development of the spinal cord and peripheral neuropathy (adrenomyeloneuropathy).[62]

Autologous, genetically modified HSCT (using lentiviral delivery of a wild-type copy of the gene into the patient's own cells; HSC-GT) has been studied in patients with X-ALD. Clinically, patients developed mild cognitive or functional deficits after treatment, although these stabilized with longitudinal assessments. On MRI, there was resolution of the contrast enhancement. The investigators concluded that this initial trial had outcomes similar to those observed in standard HSCT with reduced risk of graft-versus-host disease and the potential for improved long-term outcomes.[18]

Patients who undergo HSCT are at high risk for disease progression: first, because there is a time-lag between transplant and effective rescue, and second, because the HSCT process itself appears to accelerate disease progression in some patients. HSCT is not always successful and carries a substantial mortality risk approaching 20%. Donor sources for HSCT include cord blood, bone marrow, or peripheral blood stem cells.[66,71]

Enzyme replacement therapy (ERT) is an option for some of the lysosomal disorders (Gaucher disease, Fabry disease, mucopolysaccharidosis types I, II, and VI, and Pompe disease) which can have leukodystrophy as a component.[71,72] ERT has shown some efficacy in animal models in other leukodystrophies,[73] and clinical trials are being pursued but convincing effectiveness has not yet been shown.

"Lorenzo's oil" is a treatment that has been proposed to reduce progression of X-ALD in its cerebral form.[74] A 4:1 mixture of glyceryl trioleate and glyceryl trierucate, Lorenzo's oil can normalize levels of very-long chain fatty acids in plasma although as previously noted these do not show a correlation with disease progression, and current published data to do not demonstrate efficacy for inhibiting disease progression or altering outcomes.[75–77] In the United States, Lorenzo's oil can be obtained by foreign import via an expanded access program.

Gene therapy is rapidly progressing toward becoming clinically available. Thus far, it has shown promise in MLD and X-ALD.[78,79] A clinical trial of HSC-GT for the treatment of MLD was initiated in Milan, Italy, in 2010. Results showed reconstitution of arylsulfatase A (ARSA) activity in all hematopoietic lineages and in the CSF. The Gross Motor Function Measurement scores also showed that gross motor performance was similar to that of normally developing children for most of the patients who underwent HSC-GT up to the last follow-up. Initial reports indicate gene therapy may have less morbidity and mortality than HSCT while still being effective in halting disease.[80]

Promising clinical trials are ongoing in the treatment of Aicardi-Goutières syndrome with reverse transcriptase inhibitors.[81] In Alexander disease research, antisense oligonucleotides were used to successfully suppress glial fibrillary acidic protein in mouse models, resulting in improved body condition and rescue of hippocampal neurogenesis.[82] There is significant interest in using stem cells or modified induced pluripotent stem cells for the treatment of leukodystrophies.[83] Although of great potential, practical use still does not seem imminent. Novel drug discovery, or repurposing of known drugs, is another promising avenue of current therapies for several leukodystrophies.[77,84,85] Other possible disease-modifying treatments, such as vitamin D treatment of X-ALD, are also being studied.

Common challenges with rare disease research include the recruitment of adequate numbers of patients, obtaining natural history data, and identifying biomarkers for use in later clinical trials. The clinician plays an important role in helping patients and families with rare diseases connect to research and clinical trials. Although the

Internet and social media have increased awareness of clinical trials and research, clinicians can discuss with families the utility of natural history studies and other research, which may not directly benefit their child but will help children in the future.

THE ROLE OF PEDIATRICIANS IN CARE OF PATIENTS WITH LEUKODYSTROPHIES

Although there are significant limitations in the treatment of leukodystrophies, there are tremendous opportunities for improving the care of patients.[86] It is important to stress that not all leukodystrophies are progressive or worsen with time, an incorrect and formerly commonly held view. A patient-centric approach can prompt and facilitate discussions between the clinician and patient and family about what care and treatment is most important and most helpful. As has been demonstrated for other currently incurable genetic conditions (eg, cystic fibrosis), the strategies of routine symptomatic care can have a profound effect on both the quality and the duration of a patient's life.[87] Nationally and internationally, there is a wide variability in the care and costs of care or treatment of leukodystrophy patients: a greater than sevenfold difference in costs across children's hospitals in the United States.[88]

Complications of disease, even if the disease itself is not progressive, can lead to progressive disability requiring assistance for mobility and activities of daily living as well as surgery.[89,90] Patients with leukodystrophy can have significant health care requirements and costs, driven largely by inpatient admissions.[2,91] As expected, patients who undergo HSCT have much higher costs. However, even taking into account HSCT, patients with infections and patients needing mechanical ventilation have higher costs and health care needs.[91] Building from this analysis of health care use, a recent study showed that infection rates in patients with leukodystrophy correlate with potentially modifiable risk factors.[20] For example, failure to vaccinate annually against seasonal influenza significantly increases the risk for hospitalization with influenza, and urinary tract infections are associated with the presence of indwelling urinary catheters. Although these issues are common sense, they also outline a path for potential clinical care guidelines that could be implemented at this time to reduce hospitalizations and improve care.

Several organizations have been developed in concert between families, researchers, and clinicians to advance the recognition, diagnosis, treatment, and care of children with leukodystrophies. Preventive and symptomatic care guidelines for patients with leukodystrophies were first published in 2015 by Van Haren et al as part of an effort from the Global Leukodystrophy Initiative.[86] An updated consensus statement was published in 2017.[92] Additionally, guidelines in several areas of care for children with leukodystrophies are under development from the Leukodystrophy Care Network.

Pediatricians play a key role in the care of patients with leukodystrophy by providing an overall view of the patient from a multisystem approach. As possible, referral to a multidisciplinary clinic, as well as use of a team-based approach, offers potential improvement in patient care and facilitates the health care journey experienced by families.[93] Travel to see specialists can be difficult for patients with disabilities, so the local pediatrician becomes increasingly important for recognizing and preventing complications. Children with leukodystrophies benefit from referrals for occupational, physical, and speech therapy, as well as caregiver instructions for stretching and repositioning. Immunizations should be administered on a standard schedule unless otherwise contraindicated (for example, a patient who is immunosuppressed for a bone marrow transplant). In conjunction with referrals for orthotics and mobility equipment, these measures can have significant effects on the patient's quality of life and prevention of contractures and pressure ulcers.[94] Use of speech augmentative devices and teaching Braille or sign language in children with hearing and vision impairment can also improve quality of life and simplify caregiving.

Monitoring for feeding difficulties can help with the overall health and nutrition of the patient but also prevent complications such as aspiration pneumonia.[94] Constipation is a common complication for children with limited mobility. Medications used to treat spasticity and dystonia may also further compound the problem. Gastrointestinal tract motility may also be impaired and may be related to the brain injury from the disease.[67] Symptoms of constipation in a nonverbal disabled child can include irritability, vomiting, and/or urinary tract infections.

Other potential complications that require monitoring and treatment as the disease progresses include urinary retention, eye dryness and corneal abrasions from decreased blinking, and temperature instability. Irritability can be a presenting symptom of patients with Krabbe disease. Evaluating for the source of pain or discomfort is recommended, including urinary

tract infections, constipation, pressure sores, muscle spasms, and corneal abrasions. Medications such as gabapentin can be used, but nonpharmacologic techniques such as music and repositioning are also encouraged. Peripheral neuropathy can also cause pain in patients with mitochondrial diseases, MLD, and Krabbe disease.[16] Patients with some leukodystrophies including Krabbe disease and Aicardi-Goutières syndrome may develop autonomic instability including periodic fevers not associated with infection or have difficulty maintaining an adequate temperature.[16]

Early referral to specialists, such as pulmonologists, is recommended to help treat sialorrhea, increased lung secretions, and pulmonary insufficiency/weak cough, which can lead to pneumonia.[94] Chest physiotherapy, postural drainage techniques, and home suction machines can help extend life and improve the quality of life. To avoid respiratory infections, an annual influenza vaccination is also recommended.[94] Physiatry and/or orthopedics referral can be considered for spasticity management or monitoring and prevention of complications for hypotonia including scoliosis and hip dysplasia. Endocrinology consultation is necessary for some leukodystrophies such as X-ALD, Aicardi-Goutières syndrome, and 4-H syndrome.[16] Neurology may be involved with the initial evaluation and diagnosis but can also help with ongoing management of neurologic symptoms including seizures, spasticity, and pain and irritability. Palliative care can also be a valuable resource for patients and their families to provide additional support throughout the disease continuum.[95] Where available, pediatric palliative care teams can assist with pain and symptom management and advance care planning and can help maintain a focus on the child's quality of life. When clinically indicated, palliative care may also include hospice to provide end-of-life care and to ensure the comfort and dignity of children with these terminal illnesses.

An area of treatment that is often forgotten is the mental health of the family and caregivers. The leukodystrophy and its complications puts significant financial, physical, and mental stress on the family. Social workers or case managers can be extremely helpful to families by providing contact information on counselors and psychiatrists, financial services, respite care, and grief counseling. Family disease-specific organizations, local or via the Internet, can also provide resources and support. Importantly, stressors and mental health issues specific to leukodystrophies, as well as common to having a chronic disease, can affect children, adolescents, and adults with leukodystrophies. Mental health supports and services may be necessary for some patients.

CONCLUSIONS

The field of leukodystrophies has experienced a great expansion in interest and knowledge in the last decade. Collaboration between researchers, clinicians, and patient organizations has helped to organize and focus efforts in patient care and research. Excitement and opportunities have been created by the expanding genetic testing, accelerating gene and disease discovery, improved diagnosis and understanding of the mechanism of disease, and availability of novel treatment options. Leukodystrophies can affect children from all racial, ethnic, and socioeconomic backgrounds, and recognizing disparities is important to help all children with leukodystrophy receive a diagnosis and appropriate care.[96,97] It remains important to combine this excitement and hope with attention to currently available high-quality clinical care that will greatly improve the lives of patients with leukodystrophy and their families.

RECOMMENDATIONS FOR PEDIATRICIANS

1. Be aware of leukodystrophies as a disease entity and that treatments are available for some leukodystrophies.
2. Know that treatment of some leukodystrophies is urgent, because the stage of disease may determine the efficacy of treatment.
3. Recognize common presentations for leukodystrophies, including developmental delay or regression in early-onset cases and cognitive changes in older presentations.
4. Recognize disease-specific symptoms that suggest further evaluation, including neurologic deterioration in the setting of a febrile illness or head injury, as in the case of VWM disease and mitochondrial diseases, and skin color changes or Addison disease in a school-aged boy in the case of X-ALD.
5. Be aware that an MRI of the brain is a first step in evaluation for leukodystrophy. There can be characteristic MRI patterns that may help to determine the specific type of leukodystrophy.
6. Recognize the need for partnering with a specialist who is familiar with the diagnosis and care of patients with leukodystrophies, typically a pediatric neurologist and/or geneticist.

7. Ensure that a patient with a newly diagnosed or newly suspected leukodystrophy is referred urgently for diagnosis or has an urgent diagnostic evaluation overseen by a specialist.
8. Know that some leukodystrophies, including X-ALD and Krabbe disease, can be detected by using NBS.
9. Know that it is critical for patients with leukodystrophies to receive standard pediatric care, including immunizations.
10. Recognize that treatment and prevention of disease complications improves the quality of life and longevity of patients with leukodystrophy.

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Long-term Follow-up Care for Childhood, Adolescent, and Young Adult Cancer Survivors

Melissa M. Hudson, MD,[a] Smita Bhatia, MD, MPH,[b] Jacqueline Casillas, MD, MSHS,[c] and Wendy Landier, PhD, RN, CPNP,[b]
SECTION ON HEMATOLOGY/ONCOLOGY, CHILDREN'S ONCOLOGY GROUP, AMERICAN SOCIETY OF PEDIATRIC HEMATOLOGY/ONCOLOGY

Progress in therapy has made survival into adulthood a reality for most children, adolescents, and young adults with a cancer diagnosis today. Notably, this growing population remains vulnerable to a variety of long-term therapy-related sequelae. Systematic ongoing follow-up of these patients is, therefore, important to provide for early detection of and intervention for potentially serious late-onset complications. In addition, health counseling and promotion of healthy lifestyles are important aspects of long-term follow-up care to promote risk reduction for physical and emotional health problems that commonly present during adulthood. Both general and subspecialty health care providers are playing an increasingly important role in the ongoing care of childhood cancer survivors, beyond the routine preventive care, health supervision, and anticipatory guidance provided to all patients. This report is based on the guidelines that have been developed by the Children's Oncology Group to facilitate comprehensive long-term follow-up of childhood, adolescent, and young adult cancer survivors (www.survivorshipguidelines.org).

BACKGROUND INFORMATION

Cancer is diagnosed in approximately 20 000 children and 80 000 adolescents and young adults annually in the United States.[1] Before 1970, almost all children, adolescents, and young adults with cancer died of their primary disease. However, rapid improvements in multimodal treatment regimens (chemotherapy, radiotherapy, surgery, and immunotherapy), coupled with aggressive supportive-care regimens, have resulted in survival rates that continue to increase. The current estimated 5-year overall survival rate for childhood, adolescent, and young adult malignancies exceeds 80%,[2] which translates into increasing numbers of long-term survivors, now estimated to approach 500 000 in the United States, who may seek ongoing care from

community primary and subspecialty providers.[3] The Childhood Cancer Survivor Study, the largest and most extensively characterized cohort of 5-year survivors of childhood cancer in North America, reported that survivors receive most of their care from primary care providers.[4] Furthermore, the proportion of survivors reporting survivor-focused care that includes regular risk-based surveillance and prevention strategies related to their previous cancer and its treatment decreases with increasing time from cancer diagnosis. Thus, primary care providers (pediatricians, family practitioners, internists, practitioners trained in internal medicine and pediatrics, and advanced practice providers) are likely to have an increasingly vital role in caring for this rapidly growing population.

STATEMENT OF PROBLEM

Cancer and its treatment may result in a variety of physical and psychosocial effects that predispose long-term survivors to excess morbidity and early mortality when compared with the general population.[5–10] Virtually every organ system can be affected by the chemotherapy, radiation, surgery, and/or immunotherapy required to achieve a cure. Late complications of treatment may include problems with organ function, growth and development, neurocognitive function and academic achievement, and the potential for additional cancers. Cancer and its treatment also have psychosocial consequences that may adversely affect family and/or peer relationships, educational attainment (both formal and practical knowledge gained from real-world experience), vocational and employment opportunities, and insurance and health care access. In addition, survivors may experience troubling body image changes or suffer from chronic symptoms (eg, fatigue, dyssomnia, pain) that adversely affect emotional health and quality of life. A young person's and a family's lives are forever changed when touched by the cancer experience, and it is critical to provide rehabilitation services to survivors who highly value good health and unrestricted performance status. Equally important is reaching out to young adult survivors who may be separated from their families and face more challenges in adhering to healthy lifestyles and accessing health care services.

Late effects after childhood, adolescent, and young adult cancer are common. Two of every 3 childhood cancer survivors will develop at least 1 late-onset therapy-related complication; in 1 of every 4 cases, the complication will be severe or life-threatening.[6,11] Among clinically ascertained cohorts, the prevalence of late effects is higher because of the subclinical and undiagnosed conditions detected by screening and surveillance measures.[8] Childhood, adolescent, and young adult cancer survivors, therefore, require ongoing comprehensive long-term follow-up care to optimize long-term outcomes by successfully monitoring for and treating the late effects that may occur as a result of previous cancer therapies, as well as anticipatory guidance and health promotion efforts addressing primary and secondary prevention of chronic disease. Access to care and services that address health risks predisposed by cancer and its treatment can optimize achievement of independent living, employment, and insurance access, which is particularly important for a population at risk for multimorbidity.

Because health risks associated with cancer are unique to the age at treatment and specific therapeutic modality, it is important that follow-up evaluations and health screening be individualized on the basis of treatment history. To facilitate comprehensive and systematic follow-up of childhood, adolescent, and young adult cancer survivors, the Children's Oncology Group (COG) organized exposure-based health screening guidelines. This clinical report presents pediatricians and other health care professionals with guidance for providing high-quality long-term follow-up care and health supervision for survivors of pediatric, adolescent, and young adult malignancies by incorporating long-term follow-up guidelines developed by the COG into their practice[12] and by maintaining ongoing interaction with oncology subspecialists to facilitate communication regarding any changes in follow-up recommendations specific to the cancer survivors under their care.

METHODS: DEVELOPMENT OF LONG-TERM FOLLOW-UP GUIDELINES

The COG is a cooperative clinical trials group supported by the National Cancer Institute with more than 200 member institutions. In January 2002, at the request of the Institute of Medicine (now the National Academy of Medicine), a multidisciplinary panel within the COG initiated the process of developing comprehensive risk-based, exposure-related recommendations for screening and management of late treatment-related complications potentially resulting from therapy for childhood, adolescent, and young adult cancers. The resulting comprehensive resource, the *Children's Oncology Group Long-Term Follow-Up Guidelines for Survivors of Childhood, Adolescent, and Young Adult Cancers (COG LTFU Guidelines)*,[12] is designed to raise awareness of the risk of late

treatment-related sequelae to facilitate early identification and intervention for these complications, standardize follow-up care, improve quality of life, and provide guidance to health care professionals, including pediatricians, who supervise the ongoing care of young cancer survivors.

The *COG LTFU Guidelines* are designed for use in asymptomatic childhood, adolescent, and young adult survivors presenting for routine health maintenance at least 2 years after completion of cancer-directed therapy (eg, surgery, chemotherapy, radiation, immunotherapy), whether the survivor is receiving care in a pediatric cancer center, a specialized adolescent-young adult program, an adult-focused oncology program, a long-term follow-up program, or community primary care practice. The guidelines are not designed for primary cancer-related surveillance, which is an important component of survivorship care that generally continues under the guidance of the treating oncologist throughout the period when the patient remains at highest risk of relapse but may ultimately be transferred to community primary care providers (pediatricians, family physicians, internists, practitioners trained in internal medicine and pediatrics, and advanced practice providers). This period of risk varies depending on diagnosis and is generally highest in the first few years, with the risk decreasing significantly as time from diagnosis lengthens.

COG LTFU Guidelines Methodology

The methodology used in developing these guidelines has been described elsewhere.[12] Briefly, evidence for development of the *COG LTFU Guidelines* was collected by conducting a complete search of the medical literature for the previous 20 years via Medline. A panel of experts in the late effects of childhood and adolescent cancer treatment then reviewed and scored the guidelines using a modified version of the National Comprehensive Cancer Network Categories of Consensus system. Task forces within the COG monitor the literature on an ongoing basis and provide recommendations for guideline revision as new information becomes available. These task forces include general pediatricians and other primary care providers to incorporate a primary care perspective and facilitate effective dissemination of these guidelines into the real-world setting.

The *COG LTFU Guidelines* are updated on an every-5-year cycle to ensure that recommendations reflect currently available evidence published in peer-reviewed journals. Multidisciplinary system-based task forces (>160 COG members) are responsible for monitoring the late effects literature, performing systematic searches, summarizing and evaluating the evidence, and presenting recommendations for guideline revisions to a multidisciplinary panel of late effects experts. Task force activities involve senior leaders who mentor early career physicians and other health care professionals in acquiring the leadership and methodologic skills to sustain guideline activities as a task force chair or member. A formal training program has been developed that includes a series of webinars (available live and recorded and archived on COG Web site) and one-on-one mentorship activities with *COG LTFU Guideline* task force chairs and leadership.

COG LTFU Guidelines Version 5.0

The *COG LTFU Guidelines* is an online resource (available at www.survivorshipguidelines.org). The *COG LTFU Guidelines* Version 5.0 features 165 sections of risk-based exposure-related clinical practice guidelines for screening and management of late effects resulting from treatment of pediatric malignancies related to any cancer experience, blood product transfusion, specific chemotherapeutic agents, radiation exposures to targeted tissues and/or organs, hematopoietic cell transplant (as well as transplant with chronic graft-versus-host disease), specific surgical procedures, and adult-onset cancer screening for standard and high-risk groups. Version 5.0 features key changes, including guideline recommendations and content based on new research related to thresholds and risk factors for cardiovascular toxicity after treatment with anthracycline chemotherapy and chest radiation, prevalence data regarding pregnancy-associated cardiomyopathy, prevalence data related to occurrence of multiple hormonal deficiencies among survivors treated with cranial irradiation, and improved risk estimates about the contribution of radiation dose and treatment volume to risk of developing subsequent breast and colorectal carcinomas. In addition, previous radiation threshold doses linked to specific screening recommendations have been removed for all but 5 sections because organ dosimetry is often not available to guide implementation of screening. This approach provides uniform screening recommendations for survivors with target organs receiving radiation exposure at any dose, which the expert panel agreed was reasonable considering that the screening recommendations focus primarily on history and physical examination, with only limited recommendation for laboratory or other diagnostic evaluations. Finally, the guideline format has been substantially simplified to provide clinical users with concise presentation of specific therapeutic exposures,

potential late effects, screening recommendations, and relevant counseling and educational resources for the provider and survivors. Each guideline section features a brief summary of patient characteristics (eg, age, sex, preexisting or comorbid conditions, behavioral, etc) that have been reported to modify the risk of specific late effects and cancer- and treatment-related factors important for consideration in the delivery of personalized survivor-focused care,[13] clarifying information about the potential late effect or surveillance recommendations and representative references. The simplified guideline content is also featured in the Passport for Care, a Web--based resource that facilitates the generation of a personalized surveillance plan based on the *COG LTFU Guidelines* available at https://cancersurvivor.passportforcare.org/.[14]

This revised clinical report, "Long-term Follow-up Care for Childhood, Adolescent, and Young Adult Cancer Survivors," has been updated to enhance awareness among health care providers about the content and scope of this comprehensive resource and to offer time-efficient methods of using the large amount of valuable information in the *COG LTFU Guidelines* to streamline the provision of care for these survivors. Table 1 provides a summary of selected treatment exposures and associated late effects by organ system as outlined in the *COG LTFU Guidelines*. Figure 1 provides an example of an exposure-based recommendation from the *COG LTFU Guidelines*. Full details about 155 cancer treatment–related potential biomedical and psychosocial late effects, surveillance recommendations, patient educational materials, and other resources and Web sites pertinent to the specific health risks are available at www.survivorshipguidelines.org.

CLINICAL APPLICATION OF *COG LTFU GUIDELINES*

Malignancies presenting in childhood, adolescence, and young adulthood encompass a spectrum of diverse histologic subtypes that have been managed with heterogeneous and evolving treatment approaches. Over the last 20 years, treatment protocols for localized and biologically favorable presentations of cancers have been modified substantially to reduce the risk of therapy-related complications. Conversely, therapy has been intensified for many advanced and biologically unfavorable cancers to optimize disease control and long-term survival. Thus, not all childhood, adolescent, and young adult cancer survivors have similar risks of late treatment effects, including those with the same diagnosis. Importantly, cancer treatment strategies continue to evolve as a result of discoveries in cancer biology and therapeutics as well as improved understanding about late effects.

Evaluating a Survivor's Risk of Late Effects

In general, the risk of late effects is directly proportional to the intensity of therapy required to achieve and maintain disease control. Longer treatment with higher cumulative doses of chemotherapy and radiation, multimodal therapy, and relapse therapy increases the risk of late treatment effects. Specifically, the risk of late effects is related to the type and intensity of cancer therapy (eg, surgery, radiotherapy, chemotherapy, immunotherapy, and hematopoietic stem cell transplant) and the patient's age at the time of treatment. Chemotherapy most often results in acute effects, some of which may persist and cause problems as the survivor ages. Many radiation-related effects on growth and development, organ function, and carcinogenesis may not manifest until many years after cancer treatment. The young child is especially at risk for delayed treatment toxicity, affecting linear growth, skeletal maturation, intellectual function, sexual development, and organ function. It is important that health care professionals who provide care across a continuum of developmental periods also recognize that childhood cancer survivors face unique vulnerabilities related to their age at diagnosis and treatment. Table 2 provides examples of clinical and treatment factors that influence the risk of specific late effects after treatment of a common childhood (acute lymphoblastic leukemia) and adolescent-young adult (osteosarcoma) cancer. The diversity and potential interplay of factors contributing to cancer-related morbidity are further illustrated in the case presentations summarized in Table 3.

Using the *COG LTFU Guidelines* to Plan Survivorship Care

Risk-based care involving a systematic plan for lifelong screening, surveillance, and prevention that incorporates risks on the basis of previous cancer, cancer therapy, genetic predispositions, lifestyle behaviors, and comorbid health conditions is recommended for all survivors.[13] Information critical to the coordination of risk-based care includes the date of cancer diagnosis, cancer histology, organs and/or tissues affected by cancer, and specific treatment modalities (such as surgical procedures, chemotherapeutic agents, and radiation treatment fields and doses) and history of bone marrow or stem cell transplant and blood

TABLE 1 Potential Late Effects of Selected Therapeutic Interventions for Childhood, Adolescent, and Young Adult Cancer by Organ

	Therapeutic Exposures			
Organ	Chemotherapy	Radiotherapy Field(s)	Surgery	Potential Late Effect
Any organ or tissue		All fields		Subsequent neoplasms (skin, breast, thyroid, brain, colon, bone, soft tissues, etc)
Bones	Corticosteroids, methotrexate	—	—	Osteopenia or osteoporosis, osteonecrosis
Bones and/or soft tissues	—	All fields	—	Reduced or uneven growth; reduced function or mobility; hypoplasia, fibrosis; radiation-induced fracture; scoliosis or kyphosis (trunk fields only)
Bones and/or soft tissues	—	—	Amputation, limb sparing	Reduced or uneven growth, reduced function or mobility, chronic pain
Bowel	—	Abdomen, pelvis, spine (lumbar, sacral, whole)	Laparotomy, pelvic or spinal surgery	Chronic enterocolitis, GI tract strictures, adhesions or obstruction, fecal incontinence
Bladder	Cyclophosphamide, ifosfamide	Pelvic, spine (sacral, whole)	Spinal surgery, cystectomy	Hemorrhagic cystitis, bladder fibrosis, dysfunctional voiding, neurogenic bladder
Brain (cognitive function)	Methotrexate (intrathecal administration or IV doses $\geq$1000 mg/m^2), cytarabine (IV doses $\geq$1000 mg/m^2)	Head and/or brain, total body	Neurosurgery	Neurocognitive deficits (executive function, attention, memory, processing speed, visual motor integration), learning deficits, diminished IQ
Brain (motor and sensory function)	Methotrexate, cytarabine (intrathecal administration or IV doses $\geq$1000 mg/m^2)	Head and/or brain	Neurosurgery	Cranial nerve dysfunction; motor and sensory deficits, including paralysis; cerebellar dysfunction; seizures
Brain (hypothalamic-pituitary axis)	—	Head and/or brain, total body	Neurosurgery	Growth hormone deficiency, precocious puberty (altered gonadotropin secretion),

TABLE 1 Continued

Organ	Therapeutic Exposures			Potential Late Effect
	Chemotherapy	Radiotherapy Field(s)	Surgery	
				gonadotropin insufficiency, central adrenal insufficiency (XRT ≥30 Gy)
Brain (vascular)	—	Head and/or brain	Neurosurgery	Cerebrovascular complications (stroke, Moyamoya, occlusive cerebral vasculopathy)
Breast	—	Chest, axilla, total body	—	Breast tissue hypoplasia, breast cancer
Ear	Cisplatin, carboplatin (in myeloablative doses only)	Head and/or brain	—	Sensorineural hearing loss (XRT doses ≥30 Gy), conductive hearing loss (XRT only), eustachian tube dysfunction (XRT only)
Esophagus	—	Neck, chest, abdomen, spine (cervical, thoracic, whole)	—	Esophageal stricture
Eye	Busulfan, corticosteroids	Head and/or brain, total body	Neurosurgery	Cataracts, retinopathy (XRT only), ocular nerve palsy (neurosurgery only)
Heart	Anthracycline agents (eg, doxorubicin, daunorubicin)	Chest, abdomen, spine (thoracic, whole), total body	—	Cardiomyopathy, congestive heart failure, arrhythmia, subclinical left ventricular dysfunction, XRT only: valvular disease, atherosclerotic heart disease, myocardial infarction, pericarditis, pericardial fibrosis
Kidney	Cisplatin, carboplatin, ifosfamide, methotrexate	Abdomen, total body	Nephrectomy	Glomerular toxicity, tubular dysfunction, renal insufficiency, hypertension
Liver and biliary tract	Antimetabolites (mercaptopurine, thioguanine, methotrexate)	Abdomen	—	Hepatic dysfunction; veno-occlusive disease; hepatic fibrosis, cirrhosis; cholelithiasis
Lungs	Bleomycin, busulfan, carmustine, lomustine	Chest, axilla, total body	Pulmonary resection, lobectomy	Pulmonary fibrosis, interstitial pneumonitis, restrictive or obstructive lung disease, pulmonary dysfunction

TABLE 1 Continued

Organ	Therapeutic Exposures			Potential Late Effect
	Chemotherapy	Radiotherapy Field(s)	Surgery	
Nerves (peripheral)	Plant alkaloids (vincristine, vinblastine), cisplatin, carboplatin	—	Spinal surgery	Peripheral sensory or motor neuropathy
Ovary	Alkylating agents (eg, busulfan, carmustine, lomustine, cyclophosphamide, mechlorethamine, melphalan, procarbazine)	Pelvis, spine (sacral, whole), total body	Oophorectomy	Ovarian hormone insufficiency, delayed or arrested puberty, premature menopause, diminished ovarian reserve, infertility, uterine vascular insufficiency (XRT only), vaginal fibrosis or stenosis (XRT only)
Skin	—	All fields	—	Permanent alopecia, altered skin pigmentation, telangiectasias, fibrosis, dysplastic nevi
Spleen	—	Abdomen (doses ≥40 Gy)	Splenectomy	Life-threatening infection related to functional or anatomic asplenia[a]
Teeth	Any chemotherapy before development of secondary dentition	Head and/or brain, neck, spine (cervical, whole), total body	—	Dental maldevelopment (tooth and/or root agenesis, microdontia, enamel dysplasia), periodontal disease, dental caries, osteoradionecrosis (XRT doses ≥40 Gy)
Testes	Alkylating agents (eg, busulfan, carmustine, lomustine, cyclophosphamide, mechlorethamine, melphalan, procarbazine)	Testes, total body	Pelvic or spinal surgery, orchiectomy	Testosterone insufficiency, delayed or arrested puberty, impaired spermatogenesis, infertility, erectile or ejaculatory dysfunction
Thyroid	—	Head and/or brain, neck, spine (cervical, whole), total body	Thyroidectomy	Hypothyroidism, hyperthyroidism, thyroid nodules (XRT only)

This table briefly summarizes potential late effects for selected therapeutic exposures only; the complete set of long-term follow-up guidelines from the COG, including screening recommendations, is available at www.survivorshipguidelines.org. In addition to organ- or tissue-specific late effects, any cancer experience may increase the risk of adverse psychosocial and quality-of-life outcomes summarized at www.survivorshipguidelines.org (sections 1–6). Children's Oncology Group. Long-Term Follow-Up Guidelines for Survivors of Childhood, Adolescent and Young Adult Cancers, Version 5.0. Monrovia, CA: Children's Oncology Group; October 2018. Available at: www.survivorshipguidelines.org. Accessed April 21, 2021. GI, gastrointestinal; IV, intravenous; XRT, radiotherapy; —, not applicable.

[a] Functional asplenia can also occur as a consequence of active chronic graft-versus-host disease after hematopoietic stem cell transplant.

Additional Information

Consider patient and cancer/treatment factors, pre-morbid/co-morbid health conditions, and health behaviors, as appropriate, that may increase risk.
- Patient factors: Younger age at irradiation
- Cancer/Treatment factors: Radiation dose >10 Gy, especially radiation dose ≥15 Gy, TBI ≥6 Gy in single fraction, TBI ≥12 Gy fractionated, chest radiation combined with TBI, radiation combined with bleomycin, busulfan, carmustine (BCNU), or lomustine (CCNU), radiomimetic chemotherapy (e.g., doxorubicin, dactinomycin)
- Pre-morbid/Co-morbid medical conditions: Atopic history
- Health behaviors: Smoking, inhaled illicit drug use

product transfusion. Knowledge of cumulative chemotherapy dosages (eg, for anthracycline agents), or dose intensity of administration (eg, for methotrexate), also is important in estimating risk and screening frequency. This pertinent clinical information can be organized into a treatment summary that interfaces with the *COG LTFU Guidelines* to facilitate identification of potential late complications and recommended follow-up care (Fig 2). Because of the diversity and complexity of childhood, adolescent, and young adult cancer therapies, the treating oncology center represents the optimal resource for this treatment information. Furthermore, the need for ongoing, open lines of communication between the cancer center and the primary care provider is critical.

Coordination of risk-based care for childhood, adolescent, and young adult cancer survivors requires a working knowledge about cancer-related health risks and appropriate screening evaluations or access to a resource that contains this information. Often, late effects present as a distinct clinical entity (eg, growth failure, heart failure, academic underachievement, etc) remote from cancer diagnosis and treatment. The primary care physician should consistently consider the contribution of cancer and its treatment to physical and emotional health conditions presenting in survivors, use the *COG LTFU Guidelines* to identify linkages of late effects and therapeutic exposures, and consult with local pediatric oncologists and/or late effects specialists to develop a strategy for further investigation. The *COG LTFU Guidelines* represent a comprehensive resource that can be used to plan cancer survivorship care, as outlined in Fig 3. Individualized recommendations for long-term follow-up care of childhood, adolescent, and young adult cancer survivors can be customized from the *COG LTFU*

TABLE 2 Clinical and Treatment Factors Influencing Risk of Late Effects After Childhood, Adolescent, and Young Adult Cancer

Factor	Reason	Example(s)
Age at diagnosis of cancer	Age at diagnosis influences vulnerability to specific cancer treatment–related complications.	Young children experience a higher risk of neurocognitive deficits after cranial irradiation compared with adolescents.[37] Young girls, compared with older adolescents, are less vulnerable to alkylating agent–induced ovarian insufficiency because of their larger primordial follicular pool.[38]
Sex	The risk of some cancer treatment–related toxicities varies by sex.	Boys are more sensitive to gonadal injury after alkylating agents compared with girls.[39] Breast cancer risk in women treated with chest radiation is comparable to *BRCA* mutation carriers and warrants early initiation of breast cancer surveillance.[40]
Tissues and organs involved by cancer	Malignant infiltration of normal tissues may result in permanent deficits.	Survivors of central nervous system tumors may have long-term neurologic, neurosensory, or neuroendocrine late effects related to tumor location.[41] Survivors of retroperitoneal tumors (eg, Wilms tumor, neuroblastoma) experience increase risk of scoliosis.[42]
Surgery	Specific surgical procedures may be associated with increased risks for chronic symptoms or health conditions.	Sarcoma survivors treated with limb-sparing surgeries may have chronic pain or performance restrictions.[43] Survivors of Wilms tumor have an increased risk of hypertension after nephrectomy.[44]
Chemotherapeutic agents	Chemotherapeutic agents have unique organ and/or tissue toxicity profiles, many of which are dose related. Knowledge of specific chemotherapy agents received is needed to determine type and magnitude of late effects risk.	Anthracyclines are associated with increased risk of cardiomyopathy.[45] Cisplatin increases the risk of hearing loss and renal dysfunction.[46] Alkylating agents increase the risk of gonadal injury and infertility.[38]
Radiotherapy	The potential for radiation injury to normal tissues is directly related to the organs and tissues in the radiation treatment field and dose delivered.	HPA dysfunction is common after cranial radiation. HPA systems affected show relationships to dose, with growth hormone deficiency presenting at much lower dose exposure compared with gonadotropin deficiency.[47]
Hematopoietic cell transplant	In addition to risks associated with chemotherapy and radiation, survivors may experience health risks associated with immune system alterations after hematopoietic cell transplant.	Survivors who are transplant recipients have higher risks of subsequent malignancies involving epithelial and mucosal tissues.[48]
Preexisting and comorbid conditions	Common comorbid conditions can exacerbate cancer treatment–related toxicity. Management of ongoing comorbidities should be addressed during follow-up visits.	Hypertension potentiates anthracycline-associated risk for heart failure.[49] Diabetes and hypertension potentiate radiation-associated risk for stroke.[50]
Health behaviors and lifestyle	Health behaviors can mitigate or magnify risk of cancer treatment–related toxicities.	Adherence to recommended levels of moderate to vigorous physical activity reduces risk of major cardiac events and mortality in childhood cancer survivors.[51,52] Smoking increases the risk of pulmonary function deficits and subsequent malignancies.[53]
Psychosocial	Sociodemographic factors may affect survivors' access to health care and resources to prevent or remediate late effects. Premorbid and comorbid emotional health conditions are associated with adverse outcomes.	Survivors with (of those from households with) lower income and educational levels are more vulnerable to impaired health status and financial toxicity.[9,54] Survivors experiencing psychological distress are more likely to participate in health-risking behaviors (eg, tobacco, alcohol, and substance use).[55,56]
Genetics	Cancer predisposition genes as well as common genetic variants (single-nucleotide polymorphisms) are associated with increased risk of subsequent neoplasms and other treatment-related organ dysfunction.	Survivors of retinoblastoma with *RB1* mutation (all bilateral and familial cases) have an increased risk of subsequent malignant neoplasms, especially osteosarcoma.[57] Several genetic variations that may modify risk for cardiomyopathy in anthracycline-exposed survivors (eg, *SLC28A3, UGT1A6, RARG, CELF4, HAS3*) have been identified.[58]

HPA, hypothalamic-pituitary axis.

TABLE 3 Examples of 2 Survivors: Factors Contributing to Cancer-Related Morbidity After Childhood and Adolescent-Young Adult Cancer

Factor	Example 1: Leukemia	Example 2: Solid Tumor
Patient	3-y-old boy	16-y-old girl
Tumor	Acute lymphoblastic leukemia, B lineage, average risk, without CNS involvement	Embryonal rhabdomyosarcoma of the chest wall, stage II
Treatment	Antimetabolites (by mouth, IV, intrathecal), asparaginase, corticosteroids, cyclophosphamide (moderate dose), doxorubicin (low dose), vincristine	Dactinomycin, vincristine, chest radiation (36 Gy)
Potential late effects	Peripheral neuropathy; osteopenia or osteoporosis; osteonecrosis (rare for this age); cataracts (rare); hepatic dysfunction (very rare); renal insufficiency (very rare); neurocognitive deficits; leukoencephalopathy; hemorrhagic cystitis, bladder malignancy (very rare); secondary myelodysplasia or myeloid leukemia (very rare); gonadal dysfunction (rare); cardiomyopathy, congestive heart failure, arrhythmia (very rare); dental maldevelopment, periodontal disease, excessive dental caries	Peripheral neuropathy, subclavian artery disease, cardiac complications (cardiomyopathy, congestive heart failure, arrhythmia, subclinical left ventricular dysfunction, valvular disease, atherosclerotic heart disease, myocardial infarction, pericarditis, pericardial fibrosis), pulmonary complications (fibrosis, interstitial pneumonitis, restrictive or obstructive lung disease), esophageal stricture, breast tissue hypoplasia, breast cancer, scoliosis or kyphosis, shortened trunk height, secondary benign or malignant neoplasms in radiation field
Genetics and familial	Diabetes mellitus, type 2	Hypertension, early coronary artery disease
Comorbid conditions	Obesity, anxiety	Hypertension, depression
Health behaviors	Sedentary lifestyle	Smoker
Aging	Reduced bone mineral density	Cardiomyopathy

Recognition of dose-related toxicities has resulted in modification of therapies and has substantially reduced risk of some late effects. CNS, central nervous system; IV, intravenous.

Guidelines on the basis of each patient's treatment history, age, and sex into a survivorship care plan that is ideally developed by, or in coordination with, the oncology subspecialist. The survivorship care plan is a living document that is meant to be reviewed by survivors and their health care providers at least yearly and updated as new health conditions emerge and health behaviors change over time. In addition, the *COG LTFU Guidelines* provide information to assist with risk stratification, allowing the health care provider to address specific treatment-related health risks that may be magnified in individual patients because of familial or genetic predisposition, sociodemographic factors, or maladaptive health behaviors. The patient education materials, known as "health links," that accompany the *COG LTFU Guidelines*, are specifically tailored to enhance health supervision and promotion in this population by providing simplified explanations of guideline-specific topics in lay language.[15] The *COG LTFU Guidelines*, associated patient education materials, and supplemental resources to enhance guideline application, including clinical summary templates, can be downloaded from www.survivorshipguidelines.org. A Web--based platform that generates online therapeutic summaries with simultaneous output of patient-specific guidelines on the basis of exposure history, age, and sex is now accessible to institutions providing pediatric oncology follow-up care (https://cancersurvivor.passportforcare.org/).[14]

DISCUSSION AND RECOMMENDATIONS

Pediatricians and other primary care health care professionals are uniquely qualified to deliver ongoing health care to childhood, adolescent, and young adult cancer survivors, because they are already familiar with health maintenance and supervision for healthy populations and provide care for patients with complex chronic medical conditions. The concept of the medical home has been endorsed by the American Academy of Pediatrics as an effective model for coordinating the complex health care requirements of children with special needs, such as childhood cancer survivors, to provide care and preventive services that are accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective.[16] Within this framework, the pediatrician is able to view the cancer survivor in the context of the family and to assist not only the survivor but also the parents and siblings in adapting to the new normal of cancer survivorship. The focus of care for the childhood cancer survivor seen in a primary care practice is not the cancer from which the patient has now recovered but, rather, the actual and potential physical and psychosocial sequelae of cancer and its therapy and its impact on family functioning. Childhood, adolescent, and young adult cancer survivors are at a substantially increased risk of morbidity and mortality when compared with the general population.[5–10] This updated clinical report delineates recommendations that are aimed at facilitating this vulnerable population's access to high-quality survivorship.

Summary of Cancer Treatment (Abbreviated)

Demographics		
Name	Sex ☐ M ☐ F	Date of Birth

Cancer Diagnosis		
Diagnosis	Date of Diagnosis	Date Therapy Completed

Chemotherapy ☐ Yes ☐ No *If yes, provide information below*

Drug Name	Additional Information†

†**Anthracyclines**: Include cumulative dose in mg/m^2 (see section 33 of Guidelines for isotoxic dose conversion);
Carboplatin: Indicate if dose was myeloablative
Methotrexate and Cytarabine: Indicate route of administration (i.e., IV, IM, SQ, PO, IT, IO);
IV Methotrexate and Cytarabine: Indicate if "high dose" (any single dose ≥ 1000 mg/m^2) or "standard dose" (all single doses < 1000 mg/m^2)
Note: Cumulative doses, if known, should be recorded for all agents, particularly for alkylators and bleomycin.

Radiation ☐ Yes ☐ No *If yes, provide information below*

Site/Field	Total Dose* (including boost) (Gy)**

*For head/brain, neck, chest, abdomen, spine (whole, cervical, thoracic) radiation and TBI, include total doses (including boost dose, if given)
**To convert cGy or rads to Gy, divide dose by 100 (example: 2400 cGy = 2400 rads = 24 Gy)

Hematopoietic Cell Transplant ☐ Yes ☐ No *If yes, provide information below*		
Transplant Type	Autologous ☐ Yes ☐ No	Allogeneic ☐ Yes ☐ No
Chronic Graft-Versus-Host Disease (cGVHD)	Ever diagnosed? ☐ Yes ☐ No	Currently active? ☐ Yes ☐ No

Surgery ☐ Yes ☐ No *If yes, provide information below*

Procedure	Site (if applicable)	Laterality (if applicable)

Other Therapeutic Modalities ☐ Yes ☐ No *If yes, provide information below*
Did the patient receive radioiodine therapy (I-131 thyroid ablation)? ☐ Yes ☐ No
Did the patient receive systemic MIBG (in therapeutic doses)? ☐ Yes ☐ No

COG Summary of Cancer Treatment (Abbreviated Version) Version 5.0 – October 2018

FIGURE 2 Sample template for cancer treatment summary containing essential data elements necessary for generating long-term follow-up guidelines. (Reprinted with permission from Children's Oncology Group. *Long-Term Follow-Up Guidelines for Survivors of Childhood, Adolescent and Young Adult Cancers*. Version 5.0. Monrovia, CA: Children's Oncology Group; 2018. Available at: www.survivorshipguidelines.org. Accessed April 21, 2021) TBI, total body irradiation.

Recommendation 1: Primary Health Care Professionals Should Work Collaboratively With the Oncology Subspecialist to Develop and Implement the Survivorship Care Plan and Coordinate Survivorship Care

Ideally, the survivorship care plan is developed through a shared partnership that includes the primary care and oncology subspecialty providers, the survivor, and the family. Community providers can request a cancer treatment summary and survivorship care plan from the oncology center if this is not provided at the time that the survivor transitions back to the primary care setting. If a survivorship care plan is not provided by the primary oncology team, COG-affiliated subspecialty survivorship clinics can be consulted for assistance in coordinating survivorship care.[17] In addition to the *COG LTFU Guideline* recommendations for late effects screening, the ideal survivorship care plan delineates provider(s) who will be coordinating the indicated screening evaluations and identifies provider(s) responsible for communicating and explaining the results to the patient and/or caregivers.

- Request a cancer treatment summary and survivorship care plan from the survivors' oncology team if possible.
- Request medical records to organize a cancer treatment summary and survivorship care plan if a care plan is not provided by the oncology team.
- Use the summary of cancer treatment template at www.survivorshipguidelines.org or https://cancersurvivor.passportforcare.org/ to develop the survivorship care plan.
- Identify patient (eg, age at diagnosis, sex), cancer (eg, histology, involved organs and/or tissues), and treatment (surgery, chemotherapy, radiotherapy, hematopoietic cell transplant) details that may influence the risk of late effects.
- Consult the *COG LTFU Guidelines* at www.survivorshipguidelines.org to determine health risks associated with specific exposures and recommended health screening. Use the bookmark feature to identify the guideline sections pertinent to your survivor.
- Consider patient- and cancer treatment–related factors, preexisting and/or comorbid health conditions, and health behaviors, as appropriate, that may increase risk listed under "Additional Information" of each guideline section.
- Use the *COG LTFU Guidelines* health links and other educational resources listed under "Further Considerations."
- Address psychosocial factors that can affect access to health care and resources to prevent or remediate late effects.
- Contact an established long-term follow-up childhood cancer survivor program for assistance in managing complex survivorship-related needs and identifying survivorship resources. COG-affiliated subspecialty survivorship clinics are available at https://cogmembers.org/public/lateeffects/default.aspx.

FIGURE 3 How to use the *COG LTFU Guidelines* to plan cancer survivorship care.

Recommendation 2: The *COG LTFU Guidelines* Should Be Used to Guide the Development of an Individualized Follow-up Plan (Survivorship Care Plan) Based on the Childhood, Adolescent, or Young Adult Survivor's Specific Cancer Treatment and Risk of Late Complications

Although late treatment effects can be anticipated in many cases on the basis of therapeutic exposures, the risk to an individual patient is modified by multiple factors. The patient with cancer may present with premorbid health conditions that influence tolerance to therapy and increase the risk of treatment-related toxicity. Cancer-related factors, including histology, tumor site, and tumor biology and/or response, often dictate treatment modality and intensity. Patient-related factors, such as age at diagnosis and sex, may affect the risk of several treatment-related complications. Sociodemographic factors, such as household income, educational attainment, and socioeconomic status, often influence access to health insurance, remedial services, and appropriate risk-based health care. Organ senescence in aging survivors may accelerate presentation of age-related health conditions in survivors with subclinical organ injury or dysfunction resulting from cancer treatment. Genetic or familial characteristics may also enhance susceptibility to treatment-related complications. Problems experienced during and after treatment may further increase morbidity. Health behaviors, including tobacco and alcohol use, sun exposure, and dietary and exercise habits, may increase the risk of specific therapy-related complications. The *COG LTFU Guidelines* can assist the physician in maintaining a balance between overscreening (which could potentially cause undue fear of unlikely but remotely plausible complications as well as higher medical costs resulting from unnecessary screening) and underscreening (which could miss potentially life-threatening complications, thus resulting in lost opportunities for early intervention that could minimize morbidity).

Recommendation 3: The Survivorship Care Plan Should Include Screening for Potential Adverse Medical and Psychosocial Effects of the Cancer Experience

The follow-up evaluations of childhood, adolescent, and young adult cancer survivors should be individualized on the basis of their treatment history and may include screening for such potential complications as thyroid or cardiac dysfunction, second malignant neoplasms, neurocognitive difficulties, and many others.[13] In addition, providers should be mindful of the psychosocial late

effects experienced by youth treated for cancer, particularly those that may affect educational and vocational progress, because provider advocacy and intervention can facilitate survivor access to remedial resources and programs in 504 and individual education plans and vocational training.[18] Likewise, because emotional health and family functioning may be affected by the cancer experience, proactive assessment of and referral to mental health services are important to optimize the quality of survivorship. Finally, personalized risk assessment would not be complete without consideration of socioeconomic and community factors that may affect access to survivorship resources and health care.

Recommendation 4: The Survivorship Care Plan Should Address the Contribution of Comorbid Health Conditions, Familial and Genetic Factors, and Health Behaviors That Affect the Risk of Chronic Disease and Provide Interventions and Resources to Remediate and Prevent Late Effects of Cancer and Promote Healthy Lifestyle Behaviors

In addition to screening for late effects predisposed by previous therapeutic exposures, promotion of physical and mental health and well-being as part of a healthy lifestyle is an important aspect of long-term follow-up care in this population. Numerous investigations have shown that survivors of childhood, adolescent, and young adult cancer have a high rate of chronic health conditions when followed long-term,[6,8] yet many lack awareness of their treatment-related health risks.[19–21] For this reason, it is recommended that health care professionals provide anticipatory guidance regarding health promotion and disease prevention aimed at minimizing the risk of future morbidity and mortality attributable to chronic physical and mental health conditions. For example, counseling survivors who are at risk for obesity, cardiovascular disease, and osteoporosis about the importance of adhering to healthful dietary guidelines, limiting sedentary lifestyle with or without screen time, and having regular physical activity is important. Education about cancer- and disease-prevention benefits offered through vaccination can also reduce health risks.

Recommendation 5: Primary Health Care Professionals Should Work Collaboratively With the Oncology Subspecialist to Educate Survivors and Their Families About Cancer Treatment–Related Health Risks, Recommended Health Screening, and Methods for Risk Reduction

Adolescent and young adult survivors need appropriate knowledge, skills, and opportunities to learn and make decisions about their own health maintenance needs, their potential physical and mental health risks, recommended health screening related to these risks, the impact of health behaviors on physical and mental health risks, and strategies to reduce health risks. Collaboration between the oncology and primary care teams can help to ensure that survivors' educational needs are addressed. Innovative electronic and mobile health platforms represent evolving technologies that can be leveraged to educate and empower survivors preparing for health care transitions by promoting self-management of chronic health conditions and connecting them with survivorship communities and resources.[22] The *COG LTFU Guidelines* can be used as a resource to facilitate targeted education regarding cancer and treatment-related health risks and health promotion. The *COG LTFU Guideline* health links (available at www.survivorshipguidelines.org) can be printed for distribution in the primary care office setting and are available for viewing by patients and their caregivers on the Internet.[15] In this process, it is important for health care professionals to be aware that some survivors, given their young age at diagnosis, may not remember their cancer diagnosis or the treatment that they received or may not have been told about their cancer history.[23–25]

Recommendation 6: Primary Health Care Professionals Should Work Collaboratively With the Oncology Subspecialist to Prepare Survivors and Their Families for Health Care Transitions

Ensuring a smooth transition from pediatric to adult-oriented health care services poses additional challenges in the care of childhood cancer survivors as they age out of the pediatric health care system. Because adults treated for childhood cancer represent a rare population in primary care practices, practical and educational efforts of clinicians may be focused on more prevalent primary care issues. Consequently, family physicians, internists, practitioners trained in internal medicine and pediatrics, and advanced practice providers, who ultimately assume care of most adults treated for childhood cancer, endorse low comfort levels and a desire for resources and guidance in managing survivors.[26,27] These data underscore the importance of communication between oncology and primary care providers in health care transition planning. Pretransition planning is a critical element in the successful transition from pediatric to adult-oriented health care for all adolescents and young adults with special health care needs, including cancer survivors. The medical home model provides a strong foundation for this planning.[28] The updated American Academy of Pediatrics clinical report "Supporting the Health Care

Transition From Adolescence to Adulthood in the Medical Home" emphasizes the critical role of adult care clinicians in accepting and partnering with young adults to optimize health care transitions.[29] In addition, the report provides practical guidance on the key elements of transition planning and implementation for medically vulnerable populations. For childhood cancer survivors, a pretransition plan ideally outlines the roles of the patient, family, subspecialty, and community health care providers in the ongoing care of the survivor to ensure a successful transition. Importantly, in this process, providers should respect the evolving autonomy and privacy concerns of adolescents and young adults in health care discussions and decision-making, particularly related to sexual and reproductive health, which may be adversely affected by the cancer experience in some survivors.[30,31]

Recommendation 7: Primary Health Care Professionals Should Work Collaboratively With the Oncology Subspecialist to Educate Survivors and Their Families About Resources to Facilitate Their Access to Survivorship Care

Laws that extend medical coverage into young adulthood can facilitate survivors' access to timely, high-quality, and affordable survivorship care.[32] This is particularly relevant because survivors experience increased risk for multimorbidity as they age, and health conditions often present at a younger age at onset compared with individuals who have not had cancer. For example, primary care providers may not be aware of the need for early initiation of breast cancer surveillance among young adult women treated with chest radiation for childhood cancer. Delineating this risk in the survivorship care plan and providing appropriate letters of medical necessity can facilitate awareness by providers and insurance coverage of recommended surveillance imaging.[33] Finally, considering research demonstrating that a substantial proportion of young adult survivors are uninsured or underinsured, transition planning should identify community resources to address medical needs, including emotional health and rehabilitation services. Payers should facilitate communication among providers in the design of their provider networks and by adequate payment for care coordination.[34]

SUMMARY

Given the high incidence of late effects experienced by cancer survivors, individuals treated for cancer during childhood, adolescence, or young adulthood require long-term follow-up care from knowledgeable providers so that their care is appropriately tailored to their specific treatment-related risk factors. Models of survivorship care vary substantially across clinical settings on the basis of resource availability. Because multidisciplinary late effects clinics are not consistently accessible to or used by cancer survivors, pediatricians and other primary care providers represent critical participants in delivery of survivorship care.[35,36] The *COG LTFU Guidelines* provide a readily accessible resource to address knowledge deficits related to health risks associated with treatment of childhood, adolescent, or young adult cancer. Availability of this resource is particularly important as the population of long-term survivors continues to increase as a result of the effectiveness of contemporary treatment approaches.

Ultimately, the goal of this clinical report from the American Academy of Pediatrics is to increase the awareness of general pediatricians and other primary health care professionals regarding the readily available resource of the *COG LTFU Guidelines* and the ability to consult with multidisciplinary long-term follow-up clinics for childhood, adolescent, and young adult cancer survivors. These guidelines can, in turn, be used to develop a comprehensive yet individualized survivorship care plan for each cancer survivor who can be supported to work toward a planned transition to adult health care providers in primary and specialty care.

The survivorship care plan is a road map for primary health care professionals for providing risk-based long-term follow-up care in the community setting. Ongoing communication between the cancer center and the primary care provider is the cornerstone for providing high-quality care to this vulnerable patient population.

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics

DEDICATED TO THE HEALTH OF ALL CHILDREN®

Maltreatment of Children With Disabilities

Lori A. Legano, MD, FAAP,[a] Larry W. Desch, MD, FAAP,[b] Stephen A. Messner, MD, FAAP,[c] Sheila Idzerda, MD, FAAP,[d] Emalee G. Flaherty, MD, FAAP,[e] COUNCIL ON CHILD ABUSE AND NEGLECT, COUNCIL ON CHILDREN WITH DISABILITIES

Over the past decade, there have been widespread efforts to raise awareness about maltreatment of children. Pediatric providers have received education about factors that make a child more vulnerable to being abused and neglected. The purpose of this clinical report is to ensure that children with disabilities are recognized as a population at increased risk for maltreatment. This report updates the 2007 American Academy of Pediatrics clinical report "Maltreatment of Children With Disabilities." Since 2007, new information has expanded our understanding of the incidence of abuse in this vulnerable population. There is now information about which children with disabilities are at greatest risk for maltreatment because not all disabling conditions confer the same risks of abuse or neglect. This updated report will serve as a resource for pediatricians and others who care for children with disabilities and offers guidance on risks for subpopulations of children with disabilities who are at particularly high risk of abuse and neglect. The report will also discuss ways in which the medical home can aid in early identification and intervene when abuse and neglect are suspected. It will also describe community resources and preventive strategies that may reduce the risk of abuse and neglect.

INTRODUCTION

The maltreatment of children, including those with disabilities, is a critical public health issue. For the purposes of this report, children with disabilities include the full spectrum of children and adolescents with any significant impairment in any area of motor, sensory, social, communicative, cognitive, or emotional functioning. Children and youth with special health care needs is a broader group that shares some of the same risks as children with disabilities. These children have chronic medical issues that may cause impairment and, as a group, require significantly more health care than typically developing children.

Current data on incidence and prevalence of maltreatment in children with disabilities are limited by varying definitions of disability and lack of uniform methods of classifying maltreatment. There is concern that the incidence of child abuse and neglect is underreported in part because many children with disabilities have communication difficulties and cannot directly report problems.[1,2] Nonetheless, children with disabilities and special health care needs are at increased risk of child maltreatment. This report updates the previous clinical report published in 2007, "Assessment of Maltreatment of Children With Disabilities."[1]

The US Children's Bureau reported that an estimated 678 000 children were determined to be victims of abuse or neglect in 2018.[3] Three-fifths (60.8%) of child victims experienced neglect, 10.7% were physically abused, and 7.0% were sexually abused; 15.5% of these children suffered from 2 or more maltreatment types.[3] The 2010 reauthorization of the Child Abuse Prevention and Treatment Act (CAPTA) improved the data collection from states on children with disabilities by mandating that states report the number of children younger than 3 years who are involved in a substantiated case of child maltreatment and are eligible to be referred for early intervention services and the number of children who were actually referred for those services.[4] It did not require collecting information regarding types of disabilities or the number of children with disabilities who are older than 3 years when they enter the child welfare system.[4]

On the basis of national data from 2015, child victims with a disability accounted for 14.1% of all victims of abuse and neglect.[4] In that report, children with the following conditions were considered to have a disability: intellectual disability (ID), severe emotional disturbance, visual or hearing impairment, learning disability, physical disability, behavior problem, or a few other chronic medical conditions. It was believed that children with such conditions are undercounted because not every child received a clinical diagnostic assessment when child maltreatment was suspected. A recent study of the data from the National Survey of Child and Adolescent Well-Being II, which included children older than 3 years, found that nearly one-half of children investigated by child protective services (CPS) were not typically developing.[5]

Child abuse and neglect is reported in 3% to 10% of the population with disabilities.[6–10] The rate of child abuse and neglect is at least 3 times higher in children with disabilities than in the typically developing population.[11] In a recent study by the Federal Bureau of Justice Statistics, during the period from 2011 to 2015, among all people older than 12 years who had disabilities, people between 12 and 15 years of age had the highest rate of violent victimization.[8]

Using data from the National Child Abuse and Neglect Data System, Kistin et al[12] evaluated the incidence and timing of rereferral to CPS, substantiated maltreatment, determined foster care placement for children who had been reported to CPS and had unsubstantiated neglect, and compared typically developing children and children with disabilities. Children with disabilities were re-referred to CPS more frequently, were found to have been abused more frequently, and were more often subsequently placed in foster care.[12] Once placed in foster care, children with ID were more likely to experience placement instability[13] and were more likely to have adoption disruption and less likely to be reunified with a parent or other family member.[13]

A systematic review of violence against children with disabilities revealed that, overall, children with disabilities are more likely to be victims of violence than their peers without disabilities. However, the authors of that review reported limitations in the literature because of a lack of well-designed research studies, with poor standards of measurement of disability and violence and insufficient exploration about whether violence preceded the disability.[11]

Child maltreatment may result in the development of disabilities, which in turn can precipitate further abuse. Abusive head trauma, for example, is known to cause disabilities in children.[14] The majority of survivors of abusive head trauma have developmental delays, seizures, motor impairments, feeding difficulties, and later behavioral and educational dysfunction, with only 28% having no impairment.[15] Vision loss can result from occipital cortical injury and optic nerve injury.[16] Neglect is associated with short-term and long-term effects on children's cognitive, socioemotional, and behavioral development.[17,18] Neglect that occurs early in life can have more profound effects on development.

Injury from abuse is augmented by the impact it has on the cortisol stress response and consequent physiologic impact. Adverse childhood experiences, including child abuse and neglect, cause physiologic disruptions that can persist into adulthood and lead to lifelong poor physical and mental health.[19] Exposure to traumatic events is associated with significant negative effects on long-term cognitive development, such as IQ scores, language development, and academic achievement.[20] Specifically, witnessing intimate partner violence in early childhood, particularly during the first 2 years of life, is associated with decreased cognitive scores later in childhood.[21]

FACTORS THAT INCREASE THE RISK OF CHILD ABUSE AND NEGLECT

In general, the causes of abuse and neglect of children with disabilities are the same as those for all children; however, several elements may increase the risk of abuse for children with disabilities. Children with chronic illnesses or disabilities sometimes can place higher emotional, physical, economic, and social demands on their families.[22] The financial stress of raising a child with disabilities is often high, and this contributes significantly to family stress.[23,24] Other studies have found that families of children with disabilities have significantly more out-of-pocket costs for health care expenditures.[24,25] Caregivers may feel more overwhelmed and unable to cope with the care and supervision responsibilities that are required.[25] Lack of respite or other breaks in child care responsibilities for caregivers may contribute to an increased risk of abuse and neglect in children with disabilities. Neglect, the most common form of child maltreatment, is more prevalent in children with disabilities than in children without disabilities.[7] The complex needs of children with disabilities, in both special health care and educational needs, may result in the failure of the child to receive essential medications, therapies, and appropriate educational placement.[24,26]

A substance use disorder in the mother is a risk factor for child maltreatment[27] and may be the cause of the child's disability. Fetal alcohol spectrum disorder (FASD) is a classic example. The use of alcohol or other substances during pregnancy can cause a range of lifelong physical and behavioral disabilities and IDs.[28] Children with FASD often have learning problems and speech and language issues and are typically impulsive, lack focus, and have poor judgment. These problems can be extremely frustrating for any caregiver of a child with FASD. Parents with ongoing substance use disorders may also be less able to handle their children's challenging behaviors and be more punitive to their children.[29]

Parenting a child with disabilities is often challenging. Some children with disabilities may not respond to traditional means of reinforcement, and sometimes their behaviors, such as aggressiveness, noncompliance, and communication problems, can become frustrating, thus increasing caregiver stress.[30] These behavioral challenges can increase the risk of physical abuse by children's caregivers.[26]

Parents of a child with a disability may also overestimate their child's capabilities. In one study from the United States, parents of children with disabilities sometimes held unrealistically high expectations for their children.[9] Unrealistic expectations were also associated with a decreased degree of empathetic awareness of their child's limitations. Parents of children with intellectual or communication problems may sometimes turn to inappropriate physical punishment because of frustration about what they perceive as stubbornness or intentional failure to respond to verbal guidance.[31] Inappropriate expectations and ignorance of challenges a child with a disability might face can be linked to a higher risk for maltreatment. Pediatric providers can intervene by providing reasonable expectations for parents regarding their children with disabilities.[9] Parents need information and support to understand their child's abilities and challenges. They also need knowledge about proper strategies to use that are appropriate for the disability-related problems and the developmental status of their child.[25]

Although the use of aversive procedures and restraints for children who have disabilities has fortunately been diminishing, in part because of legislative changes (eg, modifications of the Individuals with Disabilities Education Act [Pub L No. 108-446 (2004)]), these practices are still sometimes used in homes, schools, programs, nursing homes, group homes, and other institutions.[32] Aversive techniques are procedures that use painful or unpleasant stimuli (such as biting the child, administering a noxious electric stimulus, or applying hot sauce to mucosal surfaces) to modify a behavior, and these techniques are always unacceptable or inappropriate. Restraints are physical measures (such as tie-downs or prolonged seclusion) used to prevent something physical from happening or for punishment. Physical restraints include forced holding, a technique that has been repudiated as being harmful.[33]

State laws are often unclear, contradictory, and varied regarding aversive and restraint techniques and do not always consider the techniques maltreatment.[34] Pediatricians and others can find additional information about the problems occurring from the use of aversive procedures or the use of restraints from the Web site Stop Hurting Kids (http://stophurtingkids.com/resources/). Over the past 20 years, research has demonstrated the effectiveness of alternative measures, commonly called "positive behavioral supports," to change behavior.[9] Pediatricians are encouraged to advocate for this approach. Information about positive behavioral support guidelines is available from a US Department of Education-funded program, the Technical Assistance Center on Positive Behavioral Interventions and Supports, at www.pbis.org, as well as other national and international programs. The American Academy of Child and Adolescent Psychiatry also provides

guidance on this subject (https://www.aacap.org).

The presence of multiple caregivers can either increase or decrease the risk of abuse of children with disabilities. Children with disabilities who require multiple caregivers or providers may have contact with numerous individuals, thereby increasing the opportunity for abuse. However, advantages to having a large number of caregivers are that there are more individuals who may detect the injuries or signs of abuse, and the additional assistance may actually decrease the amount of stress placed on the primary caregivers. Risk may be minimized by careful screening and selection of caregivers, sporadic and unscheduled monitoring of care, and recognizing that any child may become a victim of child abuse and neglect.

Children with disabilities may be unintentionally conditioned to comply with authority, which could result in them failing to recognize abusive behaviors as maltreatment.[35] Children with disabilities are often perceived as easy targets because their intellectual limitations may prevent them from being able to discern the experience as abuse and their impaired communication abilities may prevent them from disclosing abuse. Because some forms of therapy may be painful (eg, injections or manipulation as part of physical therapy), a child may not be able to differentiate appropriate pain from inappropriate pain.

ASSOCIATION BETWEEN DISABILITY TYPE AND FORM OF ABUSE

Recent research has evaluated how differences in risk of abuse and neglect correlated with the type and severity of the child's disability. The World Health Organization describes disabilities by the domains of function that are affected (ie, cognition, mobility, self-care, getting along, life activities, and participation).[36] The most severely affected children are at a lower risk of maltreatment than mobile, verbal children who are still delayed, especially those with cognitive disabilities.[37] Children who are nonverbal or hearing impaired are more likely than others to experience neglect or sexual abuse.[4]

In an Australian study, researchers examined the relationship between different types of disabilities (eg, Down syndrome, autism) and the rate of substantiated maltreatment allegations.[10] The authors found that children with ID, mental or behavioral problems, or conduct disorder had an increased risk of an abuse allegation and for a substantiated allegation. In contrast, children with autism had a lower risk than children with Down syndrome, and those with birth defects or cerebral palsy had the same risk as children without disability after adjusting for child, family, and neighborhood risk factors. The type of abuse was not specified.

In another study from South Carolina, researchers examined the relationship between autism spectrum disorder (ASD) and ID and child maltreatment.[38] There were higher odds of reported and substantiated maltreatment among children with ASD only, ASD plus ID, and ID only, compared with a control group after controlling for sociodemographic factors. In a 2018 study from Tennessee, children with ASD had more referrals to a child abuse hotline than those without ASD, although substantiation rates were similar between the 2 groups.[39] In a 2018 study using data from the National Survey of Child and Adolescent Well-Being II data, children with multiple developmental delays were more likely to have recurrence of child abuse reporting.[40]

Physical Abuse

Sullivan and Knutson found that children with a disability were 3.79 times more likely to be physically abused than those without a disability.[41] Helton and Cross[37] also found that there is an association between disability and physical abuse. Rather than comparing children on the basis of diagnosis, they compared children on the basis of their level of functioning. The highest rates of physical abuse were in children with mild cognitive disabilities and no motor disability. Paradoxically, children whose disabilities are less severe are more likely to be the victims of physical abuse. These authors stated,

> "Conceptually, we can hypothesize that children with minor impairment are at greater risk because they have a complicated mix of dysfunctionality and functionality. Their dysfunctionality increases the probability that they will act in a way that elicits a negative reaction from parents, while their functionality increases their parents' expectations of them and increase their ability to take actions that may frustrate their parents."[37]

Harsh discipline, whether physical or verbal, can negatively affect children emotionally. Therefore, it is important to counsel parents of children with and without special needs about methods of discipline specifically as they relate to the developmental level of their child.[42]

Neglect

In their study, Van Horne et al followed the risks of substantiated maltreatment in a cohort of children younger than 2 years with cleft lip and palate, Down syndrome, and spina bifida. In this study, the authors found that, although children with Down syndrome had the same rate of overall substantiated maltreatment as typically developing peers, children with cleft lip and palate and spina bifida had 2 times the rate of maltreatment. However, the risk of medical neglect was significantly greater among all 3 birth defect groups than in the unaffected group of children. The medical complexity of these children may account for the

increase in medical neglect.[7] In a follow-up study by Van Horne et al[43] on children aged 2 to 10 years with the same disabilities, children with cleft lip and palate, Down syndrome, and spina bifida all had a higher rate of medical neglect compared with children who were unaffected. In a study by McDonnell et al,[38] children with ASD alone, ASD plus ID, and ID alone were found to be at greater risk of physical neglect. Children with disabilities and unsubstantiated referrals for neglect experienced future maltreatment sooner and more often than other children.[12]

Sexual Abuse

In addition to physical abuse and neglect, children with disabilities are at an increased risk for being sexually abused.[41,44] Caldas and Bensy[44] studied children aged 6 to 17 years in the school setting and examined types of abuse, profiles of the victims of abuse, and profiles of the abusers. They found that children with disabilities are at 3 times the risk of sexual abuse compared with typically developing peers. The children with the greatest risk of abuse were children who had special education classroom supports. One-half of these abused children were victimized by peers, and one-half were victimized by school personnel. In a 2007 study from Israel, researchers found that children with disabilities were more likely to suffer more severe forms of sexual abuse.[45]

Multiple factors have been found to contribute to this increased rate of sexual abuse in children with disabilities, including the increased number of caregivers that children with disabilities encounter and limited access to information and training on personal safety and sexual abuse prevention.[44,46] Parents support education on human sexuality but are uncertain of how this topic should be presented to their child with IDs or communicative or motor disabilities.[47]

It is also important to recognize that health care providers have been implicated in sexual abuse of children with disabilities.[48] Data about the incidence and prevalence of sexual abuse by health care providers are sparse and do not allow a thorough analysis of the incidence of the types of abuse or the types of perpetrators because the terms "health care provider" or "health care worker" encompass many subgroups, including physicians, nurses, and therapists. Given the increased number of health care providers that children with disabilities routinely encounter, it is essential that the prohibition of sexual abuse and exploitation be discussed and taught during the training of all health care providers. The 2011 American Academy of Pediatrics (AAP) policy statement "Protecting Children From Sexual Abuse by Health Care Providers" is an excellent resource to help with this training.[48]

Emotional Abuse

In a study from the United Kingdom, children with conduct disorder, nonconduct psychological disorders, or speech and language difficulties were associated with a higher likelihood of child protection registration for emotional abuse.[49] Children with a psychiatric diagnosis are at higher risk for psychological maltreatment and emotional abuse.[50] In a study from Turkey, children with attention-deficit/hyperactivity disorder (ADHD) were found to have higher rates of emotional abuse than controls.[51] In a retrospective study of adults with and without ADHD, adults with ADHD reported higher rates of emotional abuse experienced as children when compared with adults who did not have ADHD.[52]

PEDIATRICIAN'S ROLE

Pediatricians and other health care providers need to be actively involved in the prevention, identification, and assessment of possible maltreatment of children with disabilities. Recognizing that these children are at a much higher risk is essential. It is important to assess whether immunizations and other well-child care are up to date and to ensure that necessary appointments with specialists or for illness or injuries are kept. Many children with disabilities have a team of professionals (including but not limited to teachers, paraprofessionals, and medical providers) who regularly interact with them and have direct knowledge about the limitations, abilities, and behaviors of that individual child. By working closely with these professionals, the pediatrician can gather additional insight into any concerns about maltreatment and use this information to guide the medical evaluation.

Pediatricians and other health care providers play a key role in evaluating and documenting medical conditions that may or may not predispose children with disabilities to injury. For example, documenting the presence of, or a risk for, osteopenia, is helpful in assessing fractures that may occur later. Self-injurious behaviors, such as headbanging and self-scratching, can elicit a CPS referral.[53] Careful and thorough documentation is often key in making a determination about whether an injury is consistent with abuse or is a result of self-injurious behavior. Health care providers can document abnormal physical examination findings, observed behaviors, and reported behaviors to establish the problem list for children with disabilities. Many electronic health records now have the capability to add digital photographs and "for your information" flags and alerts to the charts that can aid in assessing future injuries or changes in behavior based on preexisting conditions. This documentation is

useful for collaboration with in-hospital providers, such as emergency medicine providers, hospitalists, and critical care providers who may also be part of the system of care for children with disabilities who are victims of abuse and neglect.

If abuse or neglect is suspected after a careful assessment, a report must be made to the appropriate CPS agency.[54] Collaboration with a multidisciplinary child abuse team or child abuse pediatrician can provide both technical assistance in the evaluation and guidance with the reporting process. Pediatricians may also need to educate CPS about medical findings to assist with the investigation by CPS. Careful consideration should be given regarding whether the evaluation is best completed in the outpatient versus inpatient setting. There are advantages and disadvantages to both; however, the safety of the child needs to be kept at the forefront in the decision-making process. If there are reports of self-injurious behavior that have not previously been documented or observed by a third party, an inpatient evaluation should be considered to observe the child's behaviors as part of the full medical evaluation.

Appropriate medical treatment can be provided for any identified injuries, infections, or other conditions. Each case of abuse or neglect that is clinically confirmed or strongly suspected requires a multidisciplinary treatment plan. Behavioral health referrals to clinicians experienced with caring for children with disabilities needs to be considered as part of the treatment plan. Evidence-based trauma therapy is available for children with disabilities, although this type of specific therapy may not be available in all communities (https://www.nctsn.org/resources/facts-traumatic-stress-and-children-developmental-disabilities).

Pediatricians are responsible for the transition of care to adult physicians but may continue to manage patients beyond their 18th birthday when they are no longer minors. When patients enter adulthood, abuse concerns are then referred to adult protective services. Pediatricians can familiarize themselves with adult protective services in their state.

Prevention

Support and assistance with parenting skills are often needed by families, and the need is greater for families with children and youth with special health care needs or disabilities. Pediatricians, as trusted family advisors, can acknowledge family needs, provide encouragement, and address parents' physical, social, and mental health needs.[55] They can present disability-specific injury prevention guidelines to help the family minimize injury.[56] The availability of parent support groups, respite care, and home health services should be explored, and referrals may be made when appropriate. Pediatricians can learn about services for parents of children with disabilities, such as respite and medical waiver subsidies and programs specific to each state and how to qualify for such funds.[57] Table 1 lists some resources for families of children with disabilities.

During each health supervision encounter, pediatric providers can address the medical, social, economic, behavioral, and psychological needs of the child and the family. Proactively addressing discipline concerns and encouraging positive parenting are especially needed in this population.[58] The AAP published a report strongly discouraging spanking and providing alternative discipline practices.[42] It is helpful to recognize and support child and family strengths at each encounter.[55] The AAP provides several resources for positive parenting (eg, www.healthychildren.org[59]; *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*, Fourth Edition[60]; and Connected Kids[61]). Pediatricians can share other positive parenting resources with families as well, such as the Centers for Disease Control and Prevention's Essentials for Parenting Toddlers and Preschoolers (http://www.cdc.gov/parents/essentials/overview.html).

All children, with or without disabilities, benefit from a medical home consisting of a health care professional who is readily accessible to the family to answer questions, help coordinate care, and discuss concerns.[62] A medical home may incorporate other professionals, including social workers, to help with accessing resources. The medical home can also collaborate with

TABLE 1 Resources for Families of Children With Disabilities

	Resources
Financial	Supplemental Security Income (SSI), Special Supplemental Nutrition Program for Women, Infants, and Children (WIC), Medicaid waiver, therapist fees, Title V maternal and child health services programs for children and youth with special health care needs
Respite or extended care	Respite centers, baby-sitting, after-school programs, emergency respite, residential supports
Specialized medical needs	In-home nursing services, durable medical equipment
Emotional support	Support groups, counseling services for families, family-to-family health information centers
Educational support	IFSPs, IEPs, special education teachers and paraprofessionals
Recreational opportunities	Camps, after-school recreation, sports

IEP, Individualized Education Program; IFSP, Individualized Family Service Plan.

partners from other disciplines, including education, child care, mental health, and faith-based organizations. While working with families of children with disabilities, health care providers can educate and encourage them to work with community agencies that provide the resources and services they need to improve the child's care and the family's coping. Child abuse prevention, including indicators of abuse, can be discussed with parents and caregivers, especially those dealing with children with disabilities, and taking into account the family's language and culture.[55]

Education

In-service training for CPS and adult protective service workers, law enforcement professionals, health care professionals, child care providers, early childhood educators, teachers, and judges is crucial, and protocols are necessary for the identification, reporting, and referral of all cases of suspected child maltreatment in all schools, programs, and institutional settings. Experts in either child maltreatment or childhood disabilities can assist with this educational endeavor. General pediatricians can help local school districts with training in positive behavioral interventions and supports.[32] Education on risk factors for maltreatment of children with disabilities is important.

Pediatricians can be important role models to parents, trainees, and others. Pediatricians and other health care providers who provide care for children with disabilities can avoid using physical restraints during procedures for these children. Often, taking the time to explain procedures in terms appropriate to developmental level or other ways to prepare a child can make restraints unnecessary except in situations when children are dangerous to themselves or others. Even when some types of restraints are needed, such as to prevent a child from scratching at newly repaired lacerations, such restraints should be as comfortable and as minimal as possible and used for the shortest time feasible. Pediatricians can also be flexible about performing procedures, such as delaying blood draws that are not essential.

Pediatricians may also assist in education about child abuse to peers, residents, medical students, and other health care students. All health care professionals need adequate training to monitor children with disabilities for signs of abuse and neglect and to screen suspected victims of child maltreatment for possible delays or disabilities.[63]

Advocacy

The pediatrician, in providing the medical home and acting as the patient's and family's advocate, may review care that is provided by various agencies and resources. Much of this advocacy effort can be performed by coordinating efforts and ensuring that recommendations are implemented.[57] By providing prevention-based continuity of care, additional patient needs, such as changes in services, can be expediently identified and resolved.

Pediatricians play an important advocacy role in their relationships with various governmental and nongovernmental agencies. AAP chapters can also have an influential role in these arenas. State, educational, social, foster care, financial, and health care systems often function in isolation from each other, with little coordination or communication.[35] Foster children with disabilities and their foster parents, for example, often suffer from lack of adequate support systems.[1] Community involvement can often lead to the development of needed resources, including child care and respite services for families with a child with a special health care need.[6] Pediatricians can advocate for the caregivers to receive financial support to access services, such as respite. Communication with schools and other systems with which families interact is another avenue to increase the awareness of the needs of children who have disabilities and/or special health care needs.

As child advocates, pediatricians are in an ideal position to influence public policy by sharing information and giving educational presentations on child maltreatment and the needs of children with disabilities. There can be advocacy for training in recognizing both abuse and findings that mimic abuse for providers of children with disabilities. Pediatricians can advocate for state policies that mandate CPS agencies to gather disability information on child maltreatment cases. Pediatricians can emphasize the devastating costs of child maltreatment to legislators, policy makers, and the public. Pediatricians can advocate for state Medicaid programs to provide prompt automatic Medicaid eligibility at enrollment in foster care, including kinship care. Pediatricians can also advocate for health care not to be disrupted if a child with disabilities is placed into Medicaid managed-care plans that do not have the child's existing specialists in network. Pediatricians can also advocate for proper coverage in both private and public insurance plans. In the case of primary care, there should be a time-limited presumptive authorization extended to a current primary care provider for well visits and timely immunization visits. Pediatricians can advocate that Medicaid programs pay for services necessary for the effective transition of care when there must be a change in specialty providers. Pediatricians can also advocate for screening procedures for potential employees in educational, recreational, and residential settings to help ensure the safety of all children in their care.[32]

SUMMARY

Children with disabilities are a vulnerable population at increased risk of child abuse and neglect and, therefore, merit special attention to reduce this risk. Children with milder forms of disability are at higher risk of abuse and neglect than more profoundly affected children.

Certain types of disabilities are associated with different forms of abuse. Children with behavioral difficulties are at a greater risk for physical abuse. Children who are nonverbal or hearing impaired are more likely to experience neglect or sexual abuse. Children with multiple developmental delays are more at risk for recurrence of child abuse reporting. Conduct disorder, nonconduct psychological disorders, speech and language difficulties, and ADHD are associated with emotional abuse.

Addressing financial struggles, family stress, and the long-term needs of these children can reduce the risk of child abuse and neglect. Pediatricians are a unique resource to children with disabilities through the medical home model and in multidisciplinary teams.

GUIDANCE FOR PEDIATRICIANS

1. Recognize signs and symptoms of child maltreatment in all children and adolescents, including those with disabilities, and understand mandatory, state-specific reporting requirements for child and adult protective services.
2. Use each medical visit as an opportunity to assess family well-being.
3. Understand that families of children with disabilities benefit from assistance in addressing their child's abilities and needs. Provide reasonable expectations for parents regarding their children with disabilities and be prepared to offer concrete suggestions about how to respond to common developmentally based challenges for the child with a disability.
4. Refer families of children with disabilities to available community resources and agencies that provide necessary services designed to aid children with disabilities and their families.
5. Structure discussions about appropriate discipline within well-child visits for the child with a disability. Parents may be uncertain as to how to deal with discipline, especially for children who are verbal but developmentally delayed, so provide guidance on positive parenting. Consider referring these families to specialists with expertise in parenting skills for children with disabilities.
6. Be actively involved with both educational and medical treatment plans developed for children with disabilities and participate in collaborative team approaches.
7. Advocate at the state and local level for system changes that support at-risk children and those with disabilities and their families.

SUGGESTED RESOURCES

A Call to Action: Ending Crimes of Violence against Children and Adults with Disabilities: this report includes recommendations on policy, surveillance systems and data collection, violence prevention, intervention, and research needs. DEDICATED TO THE HEALTH OF ALL CHILDREN®

Management Principles for Acute Illness in Patients With Medium-Chain Acyl-Coenzyme A Dehydrogenase Deficiency

Tracy L. McGregor, MD,[a] Susan A. Berry, MD, FAAP,[b] Katrina M. Dipple, MD, PhD, FAAP,[c] Rizwan Hamid, MD, PhD, FAAP,[d] COUNCIL ON GENETICS

Medium-chain acyl-coenzyme A dehydrogenase deficiency (MCADD) is a fatty acid oxidation disorder in which the patient is unable to break down fats to produce energy. This disorder places children at risk for metabolic decompensation during periods of stress, such as routine childhood illnesses. The intent of this clinical report is to provide pediatricians with additional information regarding the acute clinical care of patients with MCADD. Although each patient with MCADD will still be expected to have a primary metabolic physician, the involvement of the primary care provider is crucial as well. Appropriate treatment of children with MCADD can lead to avoidance of morbidity and mortality.

DISEASE DESCRIPTION

Medium-chain acyl-coenzyme A dehydrogenase deficiency (MCADD) is a fatty acid oxidation disorder in which the patient is unable to break down fats to produce energy.[1,2] MCADD is inherited as an autosomal recessive disorder resulting from homozygous or compound heterozygous mutations in the *ACADM* gene.[3] The incidence of MCADD in the United States is between 1:13 000 and 1:19 000.[4,5] Screening for MCADD is now included in all US newborn screening programs.[6] Medium-chain acyl-coenzyme A dehydrogenase is 1 of 4 mitochondrial enzymes that perform the initial steps in fatty acid β-oxidation, resulting in the generation of ketone bodies. Ketone bodies provide a crucial source of energy, particularly for the brain, once hepatic glycogen stores are depleted. During periods of routine childhood illness, when a child develops a negative caloric balance because of a combination of inadequate intake and increased metabolic demand, a biochemically unaffected child will first use stored hepatic glycogen then switch to fatty acid oxidation for

production of ketones as a source of energy. Children with MCADD cannot make this switch when they have exhausted their glucose and glycogen stores. Many of the presenting symptoms of MCADD, such as vomiting, irritability, lethargy, and seizures, are attributable to the ensuing hypoketotic hypoglycemia. If not treated properly and promptly, symptoms can progress relatively rapidly to coma and death.

Children with MCADD may appear normal at birth and classically present with symptoms between 2 months and 2 years of age. However, severe presentations in neonates during the first week of life and at older ages have also been seen.[7–9] The classic presentation of MCADD usually occurs during a routine childhood illness, particularly gastroenteritis. The associated feeding intolerance, secondary to decreased desire for oral intake, paired with emesis can lead to the critical risk factor of prolonged fasting. Some children also present during weaning from nighttime feedings because they are unable to tolerate the longer periods of fasting between feedings. Before inclusion of MCADD in newborn screening panels, up to 18% of patients could have a fatal outcome after the disease is revealed with their first routine childhood illness.[7,10] MCADD is now included in the newborn screening panels in all states.[6] By testing for MCADD in newborn screening programs, providers can institute appropriate avoidance of fasting in affected patients so that catastrophic outcomes can be avoided. Further guidance regarding the evaluation of abnormal newborn screen results can be found on the American College of Medical Genetics and Genomics Web site (https://www.acmg.net).

ACUTE MANAGEMENT

At-home Care

Many children with MCADD have a metabolic specialist primarily responsible for the care of their condition. Parents are instructed to monitor the child carefully, especially during periods of illness. Symptoms that should prompt concern include decreased oral intake, increased sleepiness, decreased activity, and vomiting. Some metabolic specialists institute a home glucose monitoring plan that includes checking glucose concentrations during periods of illness and whenever hypoglycemic symptoms are suspected. Other specialists prefer that patients present for evaluation when there are illnesses or circumstances that may prompt hypoglycemia. At-home care for a patient with MCADD may be possible as long as the child can tolerate adequate oral intake to prevent hypoglycemia, but caregivers should only attempt to do so in consultation with the patient's metabolic specialist. Rehydration solutions intended to replace fluid and electrolytes during periods of diarrhea and vomiting do not contain enough sugar to maintain blood glucose concentrations in a patient with MCADD; better choices for children no longer consuming infant formula or human milk are drinks that contain higher concentrations of sugar, such as juice or sports drinks.

For some patients, the metabolic specialist will prescribe bedtime doses of raw cornstarch, a complex carbohydrate that breaks down slowly, releasing glucose for an extended period of time. However, in the face of an illness that increases metabolic demand, cornstarch alone may not be sufficient to prevent overnight hypoglycemia. Pediatric health care providers and parents should be cautious and conservative when assessing a patient with MCADD. The pediatric health care provider should pay particular attention to the parent or caregiver's assessment of mental status in a child of any age. A mild decrease in activity level or attentiveness or a behavior unusual to the caregiver may be an early signal of an MCADD exacerbation, which can progress rapidly to seizures, coma, or death.

Emergency Care

It is recommended that a child with a known diagnosis of MCADD be brought to the emergency department (ED) for supplemental glucose administration early in the course of an illness to prevent development or progression of an MCADD exacerbation. This is particularly important when regular oral intake cannot be guaranteed or when parents or caregivers are unsure of the severity of symptoms. Patients and their families are typically given a sick letter or emergency letter written by the child's metabolic specialist to present at the time of arrival in the ED. Patients may also wear a medical alert bracelet or necklace to notify medical personnel of their condition. Patients and parents or caregivers are advised to carry a copy of the emergency letter with them for unexpected illnesses while away from home and are also advised to share it with the child's primary care provider. This letter usually also contains useful information for any health care provider who is planning an elective procedure. At a minimum, this letter provides direct care instructions for the ED and contact information for the metabolic specialist or provider. The metabolic specialist should be notified promptly about a patient's visit to the ED, even if the result of the ED evaluation is negative and the patient appears well and suitable for discharge from the hospital.

It cannot be stressed enough that at the time of arrival to the ED, patients with MCADD require immediate triage and medical attention. If required to wait their turn, the illness may progress to life-threatening stages in the interim, even with a brief wait. The patient should be evaluated rapidly for signs and

symptoms of hypoglycemia, including mental status changes. Patients with hypoglycemia on presentation should be treated on the basis of the severity of hypoglycemia. The most critical aspect of management of patients with MCADD is the provision of glucose, either orally or intravenously, as soon as possible, especially if there are any concerns about mental status changes. If the glucose concentrations are at or just above the normal range, the patient is not symptomatic, and the patient can tolerate sustained oral intake, then the provision of simple carbohydrates by mouth may be enough to maintain a normal blood glucose concentration. If the determination is made to discharge such a patient from the hospital rather than admit, the health care provider needs to educate the patient and/or caregivers of the signs or symptoms that should prompt a return visit to the ED. These signs include decreased mental status, decreased oral intake due to refusal or emesis, dehydration, prolonged illness, signs or symptoms of hypoglycemia, and increased caregiver concern. Follow-up arrangements with the patient's primary metabolic specialist should be made before discharge from the ED.

Many providers recommend placement of an intravenous (IV) catheter for administration of dextrose fluids at presentation to the ED, even before the examination or laboratory evaluation. If a patient with MCADD presents with a blood glucose concentration below normal range or has symptoms of hypoglycemia, then it is critical than an IV catheter be placed immediately for the administration of dextrose-containing fluids, regardless of the patient's tolerance for oral intake. A symptomatic patient with MCADD should have acute hypoglycemia treated with a bolus of 0.25 mg/kg dextrose, up to 25 g. Once euglycemia is restored, then continuous infusion of fluids containing glucose should be established. Dextrose 10% in water without any added salts is too hypotonic for continuous infusion. For children who are younger than 12 months, dextrose 10% in one-quarter–normal saline is recommended. For children who are older, dextrose 10% in half-normal saline may be administered. The rate of delivery should be at least 1.5 times that of maintenance fluids, as calculated by weight or body surface area, to accomplish a glucose infusion rate (GIR) of 10 mg/kg per minute, which is achieved by delivering dextrose 10% at this rate.[11] If the patient is experiencing rhabdomyolysis, then IV fluids with at least a 10% dextrose solution should be administered at 2 times the maintenance rate. Dextrose 5% fluids should not be used routinely in patients with MCADD, but if IV fluids with at least a 10% dextrose solution are not immediately available, dextrose 5% in half-normal saline, infused at 2 times the maintenance rate, can be used to bridge for a brief period of time until the appropriate IV fluids with a higher dextrose solution are available from the pharmacy. Once available, the patient should immediately be changed to the higher dextrose concentration to provide the desired GIR.

A thorough physical examination and clinical evaluation should be conducted to identify the source of the precipitating illness. Uncomplicated infections typical of childhood, such as otitis media, pharyngitis, or gastroenteritis, may trigger a metabolic exacerbation. If an etiology is identified, it should be appropriately treated to decrease the intensity or duration of the underlying illness. In addition to an immediate bedside glucose check, patients with MCADD may need additional laboratory evaluation in the ED. Severity of MCADD exacerbation can be assessed with a blood glucose and blood gas analysis. Additional laboratory assessments that may elucidate the triggering illness include a complete blood cell count with differential, serum chemistries, liver enzyme tests, blood cultures, and a urinalysis. Alcohol consumption may be a factor in adolescents because alcohol intoxication, particularly binge drinking, has been reported to trigger metabolic exacerbations in patients with MCADD.[12]

While the patient is maintained on IV fluids with at least a 10% dextrose solution and a GIR of at least 10 mg/kg per minute,[11] bedside glucose checks are unnecessary because this level of dextrose infusion is sufficient to prevent hypoglycemia in the absence of additional risk factors or interrupted administration. Patients who are prescribed uncooked cornstarch therapy at bedtime on a routine basis do not need cornstarch administration continued while receiving fluids with a GIR of at least 10 mg/kg per minute. A continuous infusion at this GIR will prevent overnight hypoglycemia. New treatment with uncooked cornstarch should be initiated by a metabolic health care provider and dietitian.

If a patient with MCADD also has signs and symptoms of dehydration at presentation, the delivery of dextrose-containing fluids should not be delayed to administer a normal saline bolus. If the IV catheter is of sufficient caliber, the fluid bolus can either be administered concurrently in the same IV line as the dextrose-containing fluids or through a separate IV line. If IV access cannot be initiated promptly and the child has appropriate mental status for enteral intake, then oral intake can be encouraged with carbohydrate-containing beverages, such as sports drinks, fruit juice, or nondiet sodas for older children and formula or human milk for infants. Antiemetics should be considered for those with persistent emesis to allow for increased enteral intake. It should be noted that children with MCADD should never be given formulas

enriched with medium-chain triglyceride oil, such as those often used in patients with abnormal bile secretion, pancreatic failure, or prematurity, because of their inability to process these fatty acids. If the child refuses oral intake or has recurrent emesis and IV access still cannot be established, then placement of a nasogastric or nasojejunal tube can be considered for continuous infusion of carbohydrate-rich fluids.

During the acute phase of an MCADD exacerbation, reliable parenteral access is indicated. If a patient with MCADD who has been receiving IV fluids with at least a 10% dextrose solution loses IV access, the IV should be replaced, unless the patient is ready for discharge. The approach of decreasing the IV infusion rate and monitoring for adequate intake should be avoided unless the child has already demonstrated substantial improvement. Likewise, avoid reducing the GIR by reducing the rate of fluid infusion in an attempt to encourage oral intake, especially in young children who do not understand the intent or the consequences if adequate oral intake does not follow. When a child has reached approximately three-quarters of their typical home intake without recurrent emesis, then the rate of the IV infusion can be decreased.

The use of L-carnitine therapy during acute and chronic management of MCADD remains controversial. The logic behind the use of L-carnitine supplementation is that excess acylcarnitines generated as a result of MCADD may bind free carnitine and be excreted by kidneys, leading to secondary carnitine deficiency. Given carnitine's role in the transfer of long-chain fatty acids across the inner mitochondrial membrane for subsequent β-oxidation, a deficiency in carnitine could lead to abnormalities in fatty acid oxidation.[13,14] Some authors recommend oral supplementation with 100 mg/kg per day of carnitine to correct the potential of secondary carnitine deficiency and to enhance the elimination of toxic metabolites.[15] Others recommend monitoring carnitine levels and only supplementing when they are low. Studies evaluating exercise intolerance and response to fasting challenges have been contradictory.[16–18] Importantly, carnitine supplementation is associated with significant long-term cost and mild side effects (nausea, diarrhea, abdominal pain, and a fishy odor).[17] If patients with MCADD present for care of an acute episode, the guidance provided in their sick letter or emergency letter should be followed (ie, if patients are on a long-term carnitine regimen, then they should continue on carnitine in the ED). If a letter is not available, the pediatrician should ask the parents if their child is on routine carnitine supplementation. If possible, the child's metabolic specialist should also be contacted for further instruction regarding L-carnitine therapy during the acute MCADD exacerbation.

Perioperative Management of a Patient With MCADD

Patients with MCADD are at risk for hypoglycemia if oral intake is withheld for a prolonged period before or after surgery. For elective surgical procedures, patients should be able to tolerate oral intake of clear glucose-containing fluids up to 4 hours before surgery. In a patient with MCADD, IV administration of fluids with at least a 10% dextrose solution should be started when oral intake is discontinued. Similar to an episode of acute metabolic exacerbation, IV fluids with at least a 10% dextrose solution should be infused at a rate at least 1.5 times that of maintenance to provide a GIR of 10 mg/kg per minute. Metabolic support with IV fluids with at least a 10% dextrose solution should continue through the surgery and during the recovery phase until the patient can consume an adequate oral intake. For otherwise routine procedures, such as a tonsillectomy and adenoidectomy, this may require an overnight admission if the child is unable or unwilling to eat and drink because of postoperative pain.

Trauma Management of a Patient With MCADD

A patient with MCADD with injury requires careful management to prevent acute metabolic decompensation. Injury can increase metabolic demands while also resulting in decreased oral intake because of altered mental status or pain. IV fluids with at least a 10% dextrose solution should be started if there are any signs or symptoms of hypoglycemia. Additionally, if the patient cannot immediately resume a regular diet because of mental status, assessments, or procedures, then IV fluids with at least a 10% dextrose solution will be required at 1.5 times the maintenance rate until typical oral intake is resumed.

CONCLUSIONS

Patients with MCADD who have not suffered any sequelae from their disease may present with acute illnesses or injuries similar to other patients. However, because of their interrupted metabolic pathway, they are at risk for acute metabolic decompensation during times of increased metabolic demand or decreased caloric intake. Supporting these patients with IV fluids with at least a 10% dextrose solution at 1.5 times the maintenance rate can avert the risk of hypoglycemia and prevent catastrophic outcomes.

Preventing Childhood Toxic Stress: Partnering With Families and Communities to Promote Relational Health

Andrew Garner, MD, PhD, FAAP,[a,b] Michael Yogman, MD, FAAP[c,d]
COMMITTEE ON PSYCHOSOCIAL ASPECTS OF CHILD AND FAMILY HEALTH, SECTION ON DEVELOPMENTAL AND BEHAVIORAL PEDIATRICS, COUNCIL ON EARLY CHILDHOOD

By focusing on the safe, stable, and nurturing relationships (SSNRs) that buffer adversity and build resilience, pediatric care is on the cusp of a paradigm shift that could reprioritize clinical activities, rewrite research agendas, and realign our collective advocacy. Driving this transformation are advances in developmental sciences as they inform a deeper understanding of how early life experiences, both nurturing and adverse, are biologically embedded and influence outcomes in health, education, and economic stability across the life span. This revised policy statement on childhood toxic stress acknowledges a spectrum of potential adversities and reaffirms the benefits of an ecobiodevelopmental model for understanding the childhood origins of adult-manifested disease and wellness. It also endorses a paradigm shift toward relational health because SSNRs not only buffer childhood adversity when it occurs but also promote the capacities needed to be resilient in the future. To translate this relational health framework into clinical practice, generative research, and public policy, the entire pediatric community needs to adopt a public health approach that builds relational health by partnering with families and communities. This public health approach to relational health needs to be integrated both vertically (by including primary, secondary, and tertiary preventions) and horizontally (by including public service sectors beyond health care). The American Academy of Pediatrics asserts that SSNRs are biological necessities for all children because they mitigate childhood toxic stress responses and proactively build resilience by fostering the adaptive skills needed to cope with future adversity in a healthy manner.

In order to develop normally, a child requires progressively more complex joint activity with one or more adults who have an irrational emotional relationship with the child. Someone's got to be crazy about that kid. That's number one. First, last and always.

Urie Bronfenbrenner[1]

INTRODUCTION

The term "toxic stress" refers to a wide array of biological changes that occur at the molecular, cellular, and behavioral levels when there is prolonged or significant adversity in the absence of mitigating social-emotional buffers.[2] Whether those adversity-induced changes are considered adaptive and health-promoting or maladaptive and "toxic" depends on the context. For example, in an abusive context, biological changes, such as the methylation of the glucocorticoid receptor gene,[3–5] an increase in the size or activity of the amygdala,[6–8] and a hypersensitivity to potentially threatening cues[9] could be considered adaptive, at least initially, because those changes might promote survival in a threatening environment. But those same biological changes could prove to be maladaptive, toxic, and health harming over time.[10,11]

This toxic stress framework is powerful, because it taps into a rich and increasingly sophisticated literature describing how early childhood experiences are biologically embedded and influence developmental outcomes across the life course.[12–14] This was the focus of the original technical report on toxic stress from the American Academy of Pediatrics (AAP) in 2012.[2] Current threats to child well-being and long-term health, such as widening economic inequities, deeply embedded structural racism, the separation of immigrant children from their parents, and a socially isolating global pandemic, make the toxic stress framework as relevant as ever.

That said, the toxic stress framework is a problem-focused model because it is focused on what happens biologically in the absence of mitigating social and emotional buffers. Conversely, a solution-focused approach would focus on relational health[15] (see the Appendix for a glossary of terms, concepts, and abbreviations) by promoting the safe, stable, and nurturing relationships (SSNRs) that turn off the body's stress machinery in a timely manner.[1,16,17] Even more importantly, a strengths-based, relational health framework leverages those SSNRs to proactively promote the skills needed to respond to future adversity in a healthy, adaptive manner.[16,18,19] The power of relational health is that it not only buffers adversity when it occurs but also proactively promotes future resilience. The toxic stress framework may help to define many of our most intractable problems at a biological level, but a relational health framework helps to define the much-needed solutions at the individual, familial, and community levels (see Table 1).

This revised policy statement on childhood toxic stress builds on the 2012 policy statement[12] and technical report[2] by:

- Acknowledging that a spectrum of adversity exists, from discrete, threatening events (such as abuse, bullying, or disasters) to ongoing, chronic hardships (such as poverty, racism, social isolation, or neglect). These varied adversities share the potential to trigger toxic stress responses and inhibit the formation of SSNRs.
- Reaffirming an ecobiodevelopmental framework[2] because early childhood experiences, both adverse and nurturing, are biologically embedded and influence the development of both disease and wellness later in life.
- Asserting that adults with core life skills are essential, not only to form and maintain SSNRs with children but also to scaffold and develop the basic social and emotional skills that enable children to be resilient and flourish despite adversity. A multigenerational perspective is fundamental.
- Promoting a public health approach that not only prevents, mitigates, and treats toxic stress but, more importantly, proactively promotes, reduces barriers to, and repairs relational health (the capacity to develop and maintain SSNRs with others).
- Emphasizing that the vertical integration of this public health approach or the layering of primary, secondary, and tertiary preventions and/or interventions is necessary because the heterogeneity of responses to adversity seen at the population level will need to be addressed through a menu of programs that are layered and matched to specific levels of individual need (universal preventions, plus targeted interventions for those at risk, plus indicated therapies for those with symptoms or diagnoses).
- Proposing that the public health approach also be integrated horizontally across multiple public service sectors (eg, health care, behavioral health, education, social services, justice, and faith communities) because SSNRs are promoted in safe, stable, and nurturing families that have access to safe, stable, and nurturing communities with a wide range of resources and services.

This policy statement asserts that to move forward (to proactively build

TABLE 1 A Comparison of the Toxic Stress and Relational Health Frameworks

	Toxic Stress	Relational Health
Definition	Toxic stress refers to the biological processes that occur after the extreme or prolonged activation of the body's stress response systems in the absence of SSNRs.	Relational health refers to the capacity to develop and sustain SSNRs, which in turn prevent the extreme or prolonged activation of the body's stress response systems.
Contribution	Toxic stress explains how a wide range of ACEs become biologically embedded and alter life-course trajectories in a negative manner.	Relational health explains how SSNRs buffer adversity and promote the skills needed to be resilient in the future.
Approach to clinical care	Toxic stress is a deficits-based approach because it is focused on the problem: those biological processes triggered by significant adversity in the absence of SSNRs.	Relational health is a strengths-based approach because it is focused on solutions: those individual, family, and community capacities that promote SSNRs, buffer adversity, and build resilience.
Primary preventions in the framework	Primary preventions in the toxic stress framework are focused on how to prevent the wide array of adversities that might precipitate a toxic stress response.	Primary preventions in the relational health framework are focused on how to universally promote the development and maintenance of SSNRs.
Secondary preventions in the framework	Secondary preventions in the toxic stress framework are focused on identifying individuals at high risk for poor outcomes resulting from toxic stress responses by using population-based risk factors (eg, ACE scores) or emerging biomarkers (eg, methylation patterns).	Secondary preventions in the relational health framework are focused on identifying the potential individual, family, and community barriers to SSNRs by developing respectful and caring therapeutic relationships with patients, families, and communities.
Tertiary preventions in the framework	Tertiary preventions in the toxic stress framework are focused on the evidence-based practices that treat toxic stress-related morbidities such as anxiety, depression, oppositional defiant disorder, posttraumatic stress disorder, and substance abuse disorder.	Tertiary preventions in the relational health framework are focused on the evidence-based practices such as ABC, CPP, or PCIT that repair strained relationships and assist them in becoming more safe, stable, and nurturing.
Summary	Toxic stress defines the problem. Toxic stress explains how many of our society's most intractable problems (disparities in health, education, and economic stability) are rooted in our shared biology but divergent experiences and opportunities.	Relational health defines the solution. Relational health explains how the individual, family, and community capacities that support the development and maintenance of SSNRs also buffer adversity and build resilience across the life course.

not only the healthy, happy children of today but also the well-regulated parents and productive citizens of the future) family-centered pediatric medical homes (FCPMHs) (see the Appendix for a detailed description) need to universally promote relational health. SSNRs not only buffer adversity when it occurs but also proactively build the foundational social and emotional skills that lead to resilience in the face of future adversity. Although pediatric and early childhood professionals have long recognized the parent-child relationship as foundational,[20–22] the elemental nature of relational health is not reflected in much of our current training, research, practice, and advocacy. To prevent childhood toxic stress responses and support optimal development across the life span, the promotion of relational health needs to become an integral component of pediatric care and a primary objective for pediatric research and advocacy.

A SPECTRUM OF ADVERSITY

The previous policy statement[12] and technical report[2] on childhood toxic stress noted the 10 adverse childhood experiences (ACEs) studied in the landmark ACEs Study that began in the 1990s: physical, emotional, or sexual abuse; physical or emotional neglect; problematic parental substance misuse; parental mental illness; parental separation or divorce; intimate partner violence; and an incarcerated house member.[23] These adversities are associated with a wide array of negative outcomes in a dose-dependent manner, such that the higher the ACE score (1 point for each category experienced before the age of 18 years), the higher the risk for unhealthy behaviors such as tobacco, alcohol, and other substance use; risky sexual behaviors; and obesity.[23,24] Dose-dependent relationships have also

been found between ACE scores and several of the leading causes of adult morbidity and mortality,[23,24] including cardiovascular disease,[25] lung disease,[26] liver disease,[27] mental illness,[28] and cancer.[29]

These well-established associations between ACEs and poor health outcomes decades later highlight the importance of understanding the biological mechanisms that allow adversity in childhood to "get under the skin" and to negatively impact life-course trajectories.[30–36] As discussed in the 2012 AAP technical report,[2] toxic stress responses, in which the physiologic stress response to adversity is large, chronic, and unmitigated by social-emotional buffers, are one such mechanism. Toxic stress responses are known to alter multiple systems that interact in a reciprocal and dynamic manner: genomic function, brain structure and connectivity, metabolism, neuroendocrine-immune function, the inflammatory cascade, and the microbiome.[13,14] Toxic stress-induced alterations also influence the adoption of maladaptive coping behaviors decades later.[37–40]

Several researchers have noted that many other experiences in childhood are also associated with poor outcomes later in life, and these include being raised in poverty,[41] left homeless,[42–44] exposed to neighborhood violence,[45–47] subjected to racism,[48–50] bullied,[51,52] or punished harshly.[53] This finding suggests that there is a wide spectrum of adversity that runs from discrete, threatening events (such as being abused, bullied, or exposed to disasters or other forms of violence) to ongoing, chronic life conditions (such as exposure to parental mental illness, racism, poverty, neglect, family separation or a placement in foster care, and environmental toxins or air pollution; unrelenting anxiety about a global pandemic, climate change, or deportation; or social rejection because of one's sexual orientation or gender identity). Although children experiencing discrete catastrophic events such as abuse are at a high risk for toxic stress responses, epidemiology suggests that the largest number of children at risk for toxic stress responses are those affected by ongoing chronic life conditions such as neglect.[54,55] This finding suggests that although interventions targeting children with acute threats are needed urgently (eg, efforts preventing physical abuse, child trafficking, and gun violence), those interventions alone will almost certainly miss large segments of the population (eg, those experiencing the threats of parental mental illness, racism, poverty, social isolation) who may also develop toxic stress responses and their associated poor outcomes. To minimize the burden of toxic stress responses at the population level, the entire pediatric community needs to identify and address not only the acute threats to child wellness such as abuse and physical violence but also the ongoing, chronic life conditions such as racism, poverty, and isolation that are rooted in deep-seated social constructs, societal inequities (including those within the health care system), and public policies that inhibit social cohesion, equity, and relational health. Acute threats to childhood wellness such as abuse need to be taken seriously; similar attention should be given to the social inequities and ongoing, chronic life conditions that similarly imperil a child's biological wellness and life-course trajectory.

This wide spectrum of adversity underscores the fact that ACE scores and other epidemiologically derived risk factors at the population level are not valid or reliable predictors of outcomes at the individual level.[56] Toxic stress, by contrast, refers to an individual's physiologic response to these adversities, and biomarkers of this physiologic response have the potential to be more sensitive and specific measures of experienced adversity at the individual level.[37] Validated biomarkers also offer transformational potential as measures of responsiveness to specific interventions.[37,57] With these applications in mind, the pediatric research community is hoping to develop clinic-friendly, noninvasive biomarkers for different forms and degrees of adversity.

Finally, the diverse conditions included in a broader spectrum of adversity make the formation of SSNRs more difficult. Consequently, the challenge is not only to prevent a broad spectrum of adversities from occurring but also to prevent them from becoming barriers to the SSNRs that allow individuals from across the spectrum of adversity to be resilient and flourish despite the adversity.[17,58,59]

An important consideration across many harmed and exploited communities (such as American Indian or Alaska Native populations) is the accumulation of toxic stress responses across generations, sometimes referred to as historical trauma.[60] Although higher levels of historical trauma are associated with poorer health outcomes, the science underlying these associations is only now being studied rigorously.[61] A detailed discussion of historical trauma and the special needs of these communities is beyond the scope of this policy statement, but the layered, integrated public health approaches presented here to prevent childhood toxic stress and promote relational health might inform efforts to address historical trauma as well.

THE ECOBIODEVELOPMENTAL MODEL OF DISEASE AND WELLNESS

Fortunately, adversity in childhood is only half the story, as positive experiences in childhood are associated with improved outcomes later in life. For example, positive relational experiences, such as engaged, responsive caregivers,[59,62–65] shared children's book reading,[66–68] access to quality early childhood education,[69–71] and opportunities for developmentally appropriate play with others[66,72–74] are associated with positive impacts on learning, behavior, and health. Early childhood experiences, both adverse and positive, appear to be biologically embedded and influence both disease and wellness across the life course.[30] The ecobiodevelopmental model of disease and wellness explains how the ongoing but cumulative and reciprocal dance between ecology and biology leads to changes at the molecular (eg, methylation patterns), cellular (eg, brain connectivity patterns), and behavioral levels (eg, tobacco, alcohol, or other substance use).[2,17] These changes are either adaptive or maladaptive depending on the context, and they are either benefits or risks to future health, academic success, and economic productivity.[75]

For example, significant adversity in the last trimester of pregnancy is associated with methylation of the child's glucocorticoid receptor gene.[76] In adults, the methylation of this gene is associated with the expression of fewer glucocorticoid receptors in the brain.[5] Because cortisol downregulates its own production via negative feedback loops in the brain that use glucocorticoid receptors, children with fewer glucocorticoid receptors would be expected to have higher cortisol levels and be more irritable and harder to console.[77] These changes could be considered adaptive and beneficial in the short-term because they might prepare the newborn infant for a stressful world in which the infant may need to be more vocal to have his or her needs met. But these same changes could be considered maladaptive over time because the higher cortisol levels could impair learning, and the infant's irritability could impair the formation of a strong parental bond with the infant. Conversely, early supports that allow new mothers more opportunities to bond with, breastfeed, and simply stroke their children are associated with decreases in the methylation of the glucocorticoid receptor gene, perhaps allowing infants to downregulate their stress responses more effectively.[78,79] This finding is one of the most significant predictions of the ecobiodevelopmental model: the biological mechanisms that underlie the embedding of significant childhood adversity may also underlie the embedding of positive relational experiences in childhood. The challenge, then, is not only to prevent adversity but also (for mothers, fathers, and other engaged adults) to actively promote positive relational experiences throughout infancy and childhood.

COMPONENTS OF A PUBLIC HEALTH APPROACH TO TOXIC STRESS

The ecobiodevelopmental model suggests that, to improve the likelihood of positive developmental outcomes across the life span, efforts should be made to improve the salient features of the child's environment. Changing all of the potentially salient features of a child's environment cannot be reduced to a single intervention or program, so there will be no singular panacea when it comes to addressing childhood toxic stress responses. Rather, an integrated public health approach (see Fig 1) is needed to support all children, including those with delays in development and special health care needs.[80–82] The foundation for any public health approach is universal primary prevention. In the case of toxic stress responses, universal primary prevention means trying to prevent the precipitants of toxic stress responses (eg, advocating to address the spectrum of adversities discussed above) as well as promote healthy, adaptive responses to adversity through the provision of social supports that nurture the development of foundational resilience skills (such as task persistence, curiosity, and self-regulation).[16,19,59,83]

For children at higher risk for toxic stress responses, targeted secondary interventions with tiered services (eg, HealthySteps[84,85]) may be needed. Children with known adversity but no overt symptoms,[18] children with parents who experienced significant adversity as a child,[86] and families struggling with the social determinants of health (SDoHs) (eg, poverty leading to food or housing insecurity,[87,88] language barriers, or acculturation leading to conflicts within immigrant families[89]) may benefit from an array of interventions that mitigate specific risk factors. For example, the AAP currently recommends screening parents for postpartum depression[90] and food insecurity.[87,88] Similarly, when clinical markers for an individual child's biological sensitivity to context[91–94] (see the Appendix for a glossary of terms, concepts, and abbreviations) are available, children of high (versus low) sensitivity may also benefit from different types of interventions.[95] In concordance with a layered public health approach, these various targeted interventions will

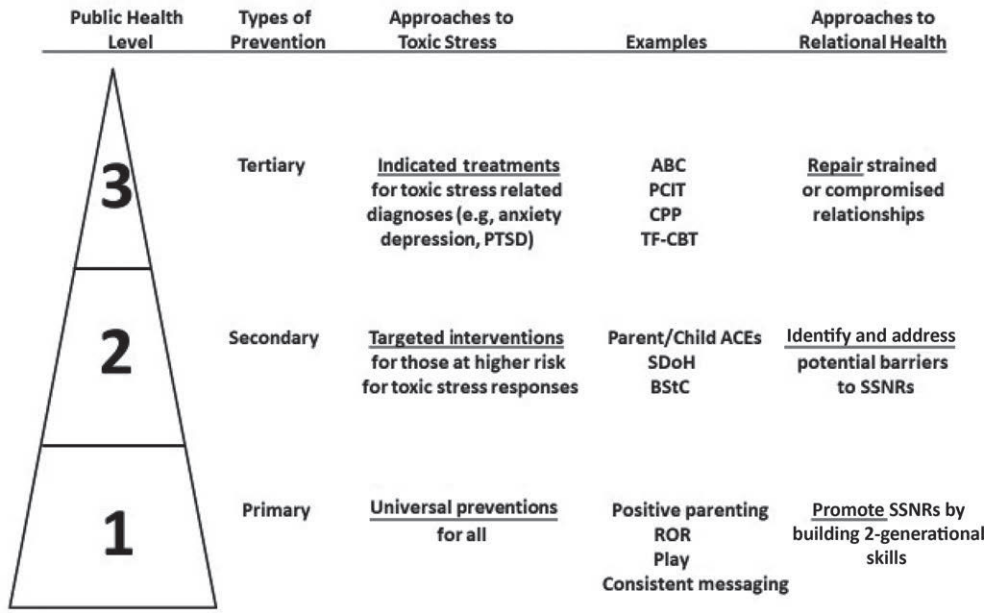

FIGURE 1 A public health approach to prevent childhood toxic stress is a public health approach to promote relational health. Many of the components of a public health approach to prevent, mitigate, and treat toxic stress responses (see examples) are also components of a public health approach to promote, identify barriers to, and repair SSNRs. The examples provided are illustrative and not intended to be comprehensive or exhaustive. See the Appendix for full descriptions of the abbreviations. BStC, biological sensitivity to context; PTSD, posttraumatic stress disorder. Adapted with permission from Garner AS, Saul RA. Thinking Developmentally: Nurturing Wellness in Childhood to Promote Lifelong Health. Itasca, IL: American Academy of Pediatrics; 2018

supplement but not replace the universal primary preventions.

For children who are symptomatic or meet criteria for toxic stress-related diagnoses (eg, anxiety, oppositional defiant disorder, or posttraumatic stress), indicated, evidence-based therapies are needed. For younger children, these therapies may include attachment and biobehavioral catch-up (ABC),[96–98] parent-child interaction therapy (PCIT),[99–102] and child-parent psychotherapy (CPP).[103–105] For older children, trauma-focused cognitive-behavioral therapy (TF-CBT) may be beneficial.[106,107] The effectiveness of these evidence-based therapies may be reduced if targeted interventions are not used to address emerging areas of risk or if universal primary preventions are not applied as well.[59,108] A layered public health approach mirrors the concept of proportionate universalism (see the Appendix for a glossary of terms, concepts, and abbreviations), in which the delivery of universal services is at a scale and intensity that is proportionate to the degree of need.[109–112] For example, if access to healthy foods is a universal objective, a proportionate response would recognize that some families may only need education about which foods are healthy, whereas some may need education about healthy foods and additional financial resources to purchase those healthy foods, and still others may require education about healthy foods, additional financial resources, and access and/or transportation to stores that sell healthy foods.

THE EMERGING SCIENCE OF RELATIONAL HEALTH

The concept of childhood toxic stress taps into a rich literature on the biology of adversity and explains the danger in overlooking significant adversity in childhood. To move forward (to proactively build healthy, resilient children), the pediatric community needs to embrace the concept of relational health.[15] Relational health refers to the ability to form and maintain SSNRs, as these are potent antidotes for childhood adversity and toxic stress responses.[57,113] Not only do SSNRs buffer adversity and turn potentially toxic stress responses into tolerable or positive responses, but they are also the primary vehicle for building the foundational resilience skills that allow children to cope with future adversity in an adaptive, healthy manner.[16,17] These findings highlight the need for multigenerational approaches that support parents and adults as they, in turn, provide the SSNRs that all children need to flourish.

Developmental science is only beginning to understand the way relational health buffers adversity and builds resilience, but emerging data suggest that responsive interactions between children and engaged, attuned adults are

paramount.[1,16,114,115] Not only are infants programmed to connect socially and emotionally with adult caregivers,[116] but the brains of parents of newborn infants appear to be reprogrammed to connect with their infants.[117] Imaging studies of new parents demonstrate changes in several major brain circuits, including a reward circuit, social information circuit, and emotional regulation circuit.[117,118] The reward circuit includes the striatum, ventral tegmental area, anterior cingulated cortex, and prefrontal cortex, where dopamine and rising levels of oxytocin interact to make social interactions more rewarding, thereby encouraging more parental engagement in infant care.[118,119] The social information circuit includes structures such as the anterior insula, inferior frontal gyrus, superior temporal gyrus, and supplemental motor area, which support internal representations of what others may be experiencing and more empathic responses to infant behaviors.[118,119] Finally, the emotional regulation circuit includes the amygdala, superior temporal sulcus, temporoparietal junction, and prefrontal cortex, which promote social cognition and a downregulation of the stress response.[118,119] The convergent conclusion from these preliminary imaging studies of the parental brain is clear: much like the infant brain, the parental brain is programmed to connect.

Recent research suggests that this dyadic need to connect promotes the development of biobehavioral synchrony between parents and infants.[119,120] Feldman[119] states, "Such coordination is observed across four systems: the matching of nonverbal behavior; the coupling of heart rhythms and autonomic function; the coordination of hormone release [eg, oxytocin following contact with both mothers and fathers]; and brain to brain synchrony [eg, coordinated brain oscillation in alpha and gamma rhythms]." Because the human brain is so immature at birth, the infant is dependent on this biobehavioral synchrony not only for survival but also for laying the foundation for future self-regulation and social-emotional skills. One expert has written that "this synchronous biobehavioral matrix builds the child's lifelong capacity for intimacy, socio-affective skills, adaptation to the social group, and the ability to use social relationships to manage stress."[117] Early relational experiences with engaged and attuned adults have a profound influence on early brain and child development.

LINKS BETWEEN RELATIONAL HEALTH AND RESILIENCE

The importance of engaged and attuned adults does not end in the newborn period. In fact, there is increasing evidence that strong social-emotional supports, such as high family resilience and connection and the provision of positive childhood relational experiences, are associated with children who are resilient and flourish despite their level of adversity.[59,121] This finding has renewed interest in defining the critical elements that children, families, and communities need to thrive despite adversity.[18,19,65,122–124] Resilience, for example, is now understood to be the manifestation of capacities, resources, or skills that allow some children, families, and communities to respond to adversity in a healthy, adaptive manner.[16,83,124] At the child level, foundational capabilities (such as social skills, emotional regulation, language, and executive functions like impulse inhibition, working memory, cognitive flexibility, abstract thought, planning, and problem solving) are the building blocks of resilience and need to be modeled, taught, learned, practiced, reinforced, and celebrated.[16] A recent literature review identified 5 modifiable resilience factors relevant to clinical pediatric care: (1) "addressing maternal mental health problems"; (2) "encouraging responsive, nurturing parenting"; (3) "building positive appraisal styles and executive function skills"; (4) "teaching children self-care skills and routines"; and (5) "using trauma-focused interventions and educating families about trauma."[83] The emphasis on building new skills underscores the AAP's concern that excessive screen time might limit opportunities to develop more adaptive and generalizable skills.[125]

Flourishing despite adversity is another construct that has been studied. Three indicators of flourishing are amenable to parental report and are rough markers of executive function: (1) "the child shows interest and curiosity in learning new things," (2) "the child works to finish tasks he or she starts," and (3) "the child stays calm and in control when faced with a challenge."[59] In analyses of data from the 2016–2017 National Survey of Children's Health, "the prevalence of flourishing children increased in a graded fashion with increasing levels of family resilience and connection."[59] In fact, a higher percentage of children with high adversity (ACE scores 4–9) but high family connection and resilience were flourishing (30.5%) than children with low adversity (ACE score of 0) but low family resilience and connection (26.8%).[59] Approaches to minimizing toxic stress that only look at measures of adversity (such as ACE scores or biomarkers) will miss out on opportunities to support the relational health that promotes

flourishing despite adversity. Measures of both resilience and "flourishing despite adversity" suggest that much more can be done to build the SSNRs and overall relational health that buffers adversity and builds both the skills and contexts necessary for children to thrive. The Healthy Outcomes From Positive Experiences framework promotes relational health through positive childhood experiences, such as "being in nurturing, supportive relationships; living, developing, playing, and learning in safe, stable, protective, and equitable environments; having opportunities for constructive social engagement and connectedness; and learning social and emotional competencies."[126,127]

A PUBLIC HEALTH APPROACH TO BUILD RELATIONAL HEALTH

Applying a public health approach to the promotion of relational health (see Fig 1) reveals that many of the universal primary preventions for toxic stress are also effective means of promoting the development of SSNRs (eg, positive parenting styles, developmentally appropriate play with others,[66,73,74,128] and shared reading[129,130]). Similarly, many of the risk factors for toxic stress responses that are the targets of secondary interventions are also potential barriers to the development of SSNRs that need to be identified and addressed (eg, child ACE scores, parent ACE scores, SDoHs, or even a strong biological sensitivity to context). Finally, many of the indicated treatments for children who are symptomatic as a result of toxic stress are programs that focus on repairing strained or compromised relationships (eg, ABC, PCIT, CPP, and TF-CBT). In short, a public health approach to prevent childhood toxic stress is a public health approach to promote relational health.

Vertical Integration to Match Levels of Need With Specific Interventions

Emerging data supporting a biological sensitivity to context (see the Appendix for a glossary of terms, concepts, and abbreviations) begin to explain heterogeneous responses to both adversity and interventions at the population level.[92,131–136] Consequently, there is an urgent need for a battery of biological, behavioral, and contextual markers that might better stratify both the risks and predicted responsiveness to interventions at the individual level.[37] FCPMHs (see the Appendix for a detailed description) are well placed to begin matching levels of need with specific types of interventions, a process known as vertical integration.[82]

Public health approaches are vertically integrated when they are founded on universal primary preventions (eg, promoting family resilience and connection and positive childhood experiences), with tiered, targeted interventions (eg, addressing SDoHs) and indicated treatments (eg, PCIT) being layered on this foundation, depending on the specific needs of the particular child, family, or community. This emphasis on universal primary preventions is congruent with the fact that more children are mentally and socially well and flourish as adults, regardless of their level of childhood adversity, if they also are afforded positive relational experiences and high family resilience and connection during childhood.[59,121] Relational health includes more than "nurturing" in its traditional, spoken sense (eg, verbal warmth or responsivity); it also includes the activities that support the relationship more broadly (eg, reading aloud and a prescription to play), and research has documented that nurturing words and actions are inextricably linked.[137] Although there are both practice-based (eg, Reach Out and Read [ROR],[129,138,139] the Video Interaction Project [VIP],[66,72] HealthySteps[84,85]) and community-based programs (eg, positive parenting programs,[140,141] home visiting programs,[142,143] quality early child care settings[69,71]) that promote these early positive relational experiences, they are not funded at levels that would make them universally accessible. More importantly, they are rarely integrated vertically with other programs that layer on additional efforts to address barriers to relational health (eg, SDoHs) or already strained or compromised relationships (eg, PCIT) when needed. A vertically integrated public health approach acknowledges that universal primary preventions are absolutely necessary yet insufficient to promote relational health.

For children deemed to be at high risk for toxic stress responses, potential barriers to relational health need to be identified and addressed through team-based care[144] and collaborative community partnerships (eg, food banks,[145,146] medical-legal partnerships[147]). These additional interventions are supplemental to and do not replace universal primary preventions. Similarly, symptomatic children need to be referred to evidence-based treatment programs (eg, ABC, PCIT, CPP, TF-CBT), but these are supplemental to and do not replace either targeted interventions for potential barriers to SSNRs or the aforementioned universal primary preventions. Efforts to repair strained or compromised relationships are likely to be more effective if other potential barriers to SSNRs are being addressed (eg, parental mental illness and basic needs) and additional efforts are being made to actively promote

SSNRs (eg, the provision of developmentally appropriate play).

Horizontal Integration Across Sectors at the Community Level

A public health approach to promoting relational health should also be integrated horizontally (or across sectors) at the local level.[81,82,148] SSNRs are easier to form when safe, stable, and nurturing families are able to live in safe, stable, and nurturing communities.[124,149,150] The FCPMH is ideally placed to educate families about what a safe, stable, and nurturing family environment looks like for a child, but doing so will require changes at the provider and practice levels (see Table 2). However, FCPMHs are also called to advocate for policies at the federal, state, and local levels that promote safe, stable, and nurturing communities. In doing so, FCPMHs become the anchor for "medical neighborhoods,"[149] in which community resources across multiple sectors (eg, health, education, justice, social services, faith communities, and businesses) collaborate not only to address barriers to SSNRs (such as home visiting programs,[142] HealthySteps,[150,151] medical-legal partnerships,[147] coordinated responses to disasters,[152,153] and efforts to promote access to healthy foods, safe housing, potable water, and clean air) but also to advocate for public policies (such as paid parental leave,[154,155] income support,[87,88] restorative justice,[156–158] and implementation of the Family First Prevention Services Act) that intentionally and actively foster SSNRs (Table 2).[149,159–161]

THE CENTRALITY OF RELATIONSHIPS IN PEDIATRIC CARE

A public health approach to relational health is built on the SSNRs that buffer adversity and build resilience. Such an approach will require pediatricians, other pediatric health care professionals, and FCPMHs in general to partner with families and communities in practical and innovative ways to universally promote SSNRs, address potential barriers to SSNRs in a targeted manner, and afford indicated treatments that repair relationships that have been strained or compromised (see Table 2). But underlying this approach are 2 fundamental assumptions. The first is that pediatric providers will have the financial supports needed to expand their capacity for developing respectful, continuous, trusted, and nurturing relationships with both the patients and caregivers of the patients who they serve. Without strong therapeutic alliances with patients, caregivers, and families, few of the recommended universal primary preventions will be implemented, few of the targeted interventions will be used, and few of the indicated treatments will be sought. To promote SSNRs at the practice level, both financial incentives (eg, payment reforms) and enhanced training needs to be provided.[162,163] Pediatric providers should be afforded the following: (1) sufficient time with patients and families, (2) the benefit of long-term continuity with patients and families, and (3) opportunities to learn about and practice the interpersonal and communication skills needed to form respectful, trusted, and collaborative therapeutic relationships.[162] For parents to trust, pediatric providers need to listen and understand parental concerns and beliefs before making recommendations. Communication could be further enhanced by cultural humility,[164,165] implicit bias training,[166–171] a more diverse health care team (eg, providing families and patients the opportunity to seeing themselves reflected in the sex, ethnicity, and cultural backgrounds of the team members), and access to professional interpreters. In the end, the ability of the FCPMH to leverage change within the family context is entirely dependent on the capacity of the pediatric providers to form strong therapeutic relationships with the patients, caregivers, and families.

The second assumption is that the FCPMH will have the capacity to form working relationships with a wide array of community partners. The FCPMH alone cannot leverage significant change within the community context. Changing community contexts will require healthy, trusting, and robust partnerships with a wide array of local community partners from multiple sectors (education, social services, and businesses), not only to facilitate family access to the requisite community interventions but also to coordinate effective advocacy campaigns to secure both those interventions and family-friendly public policies. Simply put, successfully implementing a public health approach that prevents childhood toxic stress and promotes SSNRs will require FCPMHs to put relational health at the center of everything they do.[172]

ACKNOWLEDGING THE ROLE AND TOLL OF SOCIAL ISOLATION

There is an emerging evidence base that social isolation is on the rise and detrimental to both individual[173] and community health.[174] Social scientists have documented the fragmentation of society at the community level[175] as well as its negative impact on how communities view their collective stewardship of their most treasured resource: their children.[176] Psychologists have decried a "crisis of connection" and point to a culture that values the self over relationships and individual

TABLE 2 Implementing a Public Health Approach to Relational Health Will Require Changes at the Provider, Practice, and Community Levels, as Well as Horizontal Integration Across Sectors

Types of Prevention	Approaches to Relational Health	Examples at the Provider Level	Examples at the Practice Level	Examples at the Community Level
Tertiary	Repair strained or compromised relationships	Build the therapeutic alliance; employ a common-factors approach; explain behavioral responses to stress; endorse referral resources.	Colocate counseling services (warm handoffs); facilitate, track, and follow-up on referrals offered.	Embrace restorative justice and social inclusion (over punitive measures and exclusion).
Secondary	Identify and address potential barriers to SSNRs	Build the therapeutic alliance; surveil for possible barriers to SSNRs; champion screening at practice level; endorse referral resources.	Universal screening for prevalent barriers seen in that practice; facilitate, track, and follow-up on referrals offered.	Identify and address sources of inequity, isolation, and social discord (poverty and racism).
Primary	Promote SSNRs by building 2-generational relational skills	Build the therapeutic alliance; promote positive parenting; encourage developmentally appropriate play.	Provide or support positive parenting classes; participate in ROR, VIP, and other programs that support the dyad.	Implement home visiting; support extended family medical leave.

See the Appendix for full descriptions of the abbreviations.

successes over the general welfare, leading to declining levels of empathy and trust.[177] Epidemiologists have demonstrated that an individual's degree of social isolation is a powerful predictor of mortality, much like traditional clinical risk factors (eg, obesity or hypertension) or ACE scores.[178] Both epidemiologists and economists have pointed to increasing levels of inequity as correlating with poorer levels of overall health for both the impoverished and the wealthy.[174] Finally, physiologists have long known that social deprivation in childhood alters the programming of the body's stress response.[179,180]

Taken together, these diverse lines of inquiry suggest that it may not actually be the wide spectrum of childhood adversity that drives poor outcomes but the degree to which that adversity drives shame, guilt, anger, alienation, disenfranchisement, and degree of social isolation.[181,182] If so, the proposed public health approach toward the promotion of SSNRs is needed, not only to buffer adversity and promote resilience but also to begin bridging political, religious, economic, geographic, identity-based, and ideological divides that increase social isolation, encourage tribalism, diminish empathy, and, ultimately, drive poor outcomes in the medical, educational, social service, and justice systems.

For many resource-poor families and older children, overall relational health is dependent not only on dyadic serve and return interactions with family members but also on trusted, SSNRs with others in the community through interactions at the medical clinic, school, recreation leagues, faith-based and civic organizations, community improvement efforts, and employment opportunities. Along

these lines, the Aspen Institute has created the Social Fabric Project to incentivize local projects that prioritize the building of relationships and community connections over a focus on self-absorption and hyperindividualism.[183] Similarly, more attention could be given to the built environment and need for public green spaces, such as parks, to promote social cohesion and a sense of community belonging.[184,185]

Finally, it should be noted that public health mandates to maintain "social distancing" during the coronavirus pandemic actually refer to physical distancing and are not intended to further isolate, alienate, or disenfranchise already vulnerable populations. If nothing else, pandemic-mandated stay-at-home orders should increase our collective awareness of the distress associated with being socially isolated or vulnerable. The coronavirus pandemic has highlighted the urgent need to provide all children with the SSNRs that buffer unexpected adversities and build the skills necessary to be resilient.

A RENEWED COMMITMENT TO SCIENCE-BASED POLICY FORMATION

In the decade since the first AAP policy statement and technical report on childhood toxic stress were published, even more evidence has accumulated that:

1. "What happens in childhood does not stay in childhood."[186,187] Adverse experiences in childhood are not destiny, but for many children, significant adversity bends life-course trajectories for the worse.
2. In the absence of SSNRs, many different forms of childhood adversity (from catastrophic episodes of abuse or violence to chronic conditions, such as exposure to racism, poverty, and/or neglect) can lead to toxic stress responses that result in changes at the molecular, cellular, and behavioral levels and negatively impact outcomes in health, education, and economic productivity.
3. Individual variation in biological sensitivity to context (see the Appendix for a glossary of terms, concepts, and abbreviations) contributes to heterogeneity in both responses to adversity and responses to interventions. This has important implications for how we nurture and fulfill the potential of all children, not just those who are relatively less sensitive to their contexts and appear to be relatively more resilient despite adversity.
4. In the presence of SSNRs, a limited degree of childhood adversity (eg, normative childhood frustrations and setbacks) can lead to the positive stress responses that build the rudiments of resilience: a set of social and emotional skills that allow children to adapt to future adversity in a healthy manner.
5. Relational health, in the form of at least one SSNR, is a universal, biological imperative for children to fulfill their potential; to be healthy and resilient; to be successful academically, economically, and socially; and, perhaps most importantly, to be the caregivers that value and build SSNRs with subsequent generations.

Society is currently trending toward division, marginalization, alienation, and social isolation.[177] In opposing this trend and calling for a public health approach that builds SSNRs, the AAP is working to translate the latest developmental science into practices and public policies (see Table 2) that build healthy, resilient children. With almost a century of service to children, families, and communities, the field of pediatrics has made critical contributions at the interface of science and public policy. Be it child labor laws, federal grants to states to promote maternal-child health, support for paid parental leave after childbirth, required immunizations to attend school, the use of car safety seats, the adoption of children by same-sex parents, the harms of corporal punishment, the safe storage of firearms, the care of immigrant children in federal custody, the negative effect of toxins and global warming on child health, or the importance of nutrition and income support for healthy families, pediatric professionals have been a powerful force for bringing a scientifically grounded, evidence-based perspective to public debates. The AAP remains committed to respond when empirical evidence and the latest developmental science shine new light on the issues and trends of the day. Simply put, public policies, social constructs, and societal norms that divide, marginalize, alienate, and isolate are clear threats to the well-being of all children. The commitment of the AAP to the well-being of all children requires that it not only address a wide spectrum of adversities but, also, that it speak against public policies, social constructs, and societal norms that perpetuate the ongoing, chronic precipitants of toxic stress responses such as poverty[87,88] and racism[166] and for public policies that promote relational health, inclusion, and equity.[111,188–191]

APPLICATION OF SCIENCE-BASED PRINCIPLES TO STRENGTHEN PEDIATRIC PRACTICE

Drawing on a framework produced by the Center on the Developing Child at Harvard University,[192] this policy statement highlights the following 3 science-informed principles to prevent toxic stress

responses and to build healthy, resilient children.

Support Nurturing Relationships

Of the 3 principles, this is the one that aligns most clearly with the core functions of the FCPMH and is, therefore, the primary focus of this policy statement. The use of trusted, supportive relationships within the FCPMH to promote the relational health of families is an emerging focal point for pediatric clinical research, and pediatric primary care is increasingly seen as a venue for fostering social-emotional health.[193,194] These universal primary prevention strategies form the base of the public health pyramid (Fig 1 and Table 2), but additional, layered interventions that recognize and address child-level (eg, delays in development and a biological sensitivity to context), family-level (eg, poverty and parent mental illness), and community-level (eg, racism and violence) barriers to SSNRs may also be required for some families, whereas others will need even more intensive, evidence-based treatments (eg, ABC, PCIT, CPP, TF-CBT) to repair relationships that are already strained or compromised. The buffering and skill-building roles of responsive relationships are biologically embedded, and they are essential promoters of healthy development.[59] Existing AAP reports on managing perinatal depression,[90] supporting grieving children,[195] fostering male caregiver engagement,[196] partnering with home visiting programs,[142] encouraging developmentally appropriate play,[74,197] discouraging screen time,[125] and promoting shared-book reading[67,68] include additional recommendations on ways primary care pediatricians might promote SSNRs.

Reduce External Sources of Stress on Families

This principle points to the potential benefits of addressing stressors from across the spectrum of adversity, including those that might have been considered well beyond the scope of traditional pediatric practice in the past. Poverty, food insecurity, housing insecurity, racism, community violence, discrimination, alienation, disenfranchisement, and social isolation are examples that impose significant hardships on families and become potential barriers to developing SSNRs. FCPMHs could work to reduce these barriers by partnering with their AAP chapter, local organizations (such as schools, businesses, and faith-based organizations), and other community assets (including parents, extended family, child care providers, community health workers, and patients) to form medical neighborhoods[149,159,161] that work collaboratively to address the SDoHs while also advocating for policies that support safe, stable, and nurturing families and communities. For example, expanding family leave policies[154] could reduce family stress and promote positive childhood experiences. Similarly, advocating for a Health in All Policies approach could advance health equity and minimize family and community distress by addressing the underlying economic inequities.[198–200] The commitment of the AAP to decreasing family stress is manifest in many of its official statements, including poverty,[87,88] racism,[166] maternal depression,[90] disasters,[152,153] father engagement,[196] home visiting,[142] and the importance of play.[74,197]

Strengthening Core Life Skills

The strengthening of core life skills (eg, executive function and self-regulation) is needed for families and communities to provide well-regulated, nurturing environments. Although intensive, capacity-building efforts for parents and other caregivers with limited executive function skills is beyond the scope of most pediatric settings, providing information and support around basic child-rearing practices and establishing daily routines is a cornerstone of traditional primary care. Caregivers with core life skills are essential for the development of executive function and self-regulation skills in their children. The guidelines on parent education and support in *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents* (4th edition) is a starting point for all families,[201] but there is a need to provide more effective, individualized, evidence-based parenting supports (eg, ROR, HealthySteps, VIP) beyond simply providing information about child development. Integrated behavioral health services as part of the FCPMH team might be the next layer for parents who need additional assistance (eg, parental depression), and the need for more intensive skill building (eg, PCIT) for some parents becomes yet another focus for collaboration with key services within the community (eg, ABC, PCIT, CPP, and TF-CBT). Understanding, practicing, and reinforcing executive functions and self-regulation skills (eg, managing strong emotions, ensuring adequate sleep, and getting regular exercise) is essential because all caregivers need these skills to create the kinds of environments in which children thrive.[16,37,59] Whether an adult coaching or skill-building component is incorporated within a FCPMH or connected to it in a collaborative manner, the essential role that these programs play in promoting the healthy development of children is clear, especially for those who are the most disadvantaged.[1,16]

Realizing the full impact of these principles within primary care practice, however, will also require fundamental changes in medical education and payment models. To usher in these fundamental reforms, more pediatricians will need to assume leadership positions outside the realm of clinical care.[202,203] In addition, pediatric training programs will need to educate residents about the ecobiodevelopmental model, train them on how to develop strong therapeutic relationships with parents and caregivers, teach them how to model nurturing and affirming interactions with children of all ages, train them how to encourage caregivers to have positive relational experiences with children of all ages, prepare them to work as part of interdisciplinary teams[144,150] (eg, integrated with behavioral health and social service professionals), educate them on how to develop collaborative partnerships with community referral resources, and encourage them to become vocal advocates for public policies that promote safe, stable, and nurturing families and communities.

Foremost on the advocacy agenda will be the need for serious payment reforms that consider the complexity of care attributable to adverse family and community contexts and include financial supports that incentivize families to engage with an FCPMH.[204] Payment reforms need to be sufficient to allow FCPMHs to spend more time with families, function as interdisciplinary teams, integrate into their community's initiatives and services to support children and families (horizontal integration), and anchor medical neighborhoods that not only foster wellness in childhood but promote positive outcomes across the life span.

SUMMARY AND RECOMMENDATIONS

Preventing childhood toxic stress responses, promoting resilience, and optimizing development will require that all children be afforded the SSNRs that buffer a wide range of adversities and build the foundational skills needed to cope with future adversity in an adaptive, health-promoting manner. The 3 principles described above, each of which is grounded in the research literature, provide a science-based framework for developing innovative strategies to promote SSNRs at the dyadic level, family level, and community level. Translating these principles into pediatric practice will require FCPMHs to:

1. Understand the toxic stress framework, which explains how many of our society's most intractable problems, such as disparities in health, education, and economic stability, are rooted in our shared biology but divergent experiences and opportunities (see Table 1).
2. Understand the relational health framework, which explains how the individual, family, and community capacities that support the development and maintenance of SSNRs also buffer adversity and build resilience across the life course (see Table 1).
3. Foster strong, trusted, respectful, and supportive relationships with patients and their families to encourage the acceptance of individualized prevention, intervention, and treatment strategies. Doing so will require all health professionals to address their implicit biases, develop cultural humility, and provide culturally competent recommendations.
4. Foster strong, trusted, respectful, and effective collaborations with the community partners who are well-positioned to provide the individualized prevention, intervention, and treatment strategies.
5. Acknowledge that a wide range of adversities, from discrete, threatening events to ongoing, chronic life conditions, share the potential to trigger toxic stress responses and inhibit the formation of SSNRs.
6. Embrace an ecobiodevelopmental model for understanding how both adverse and positive relational experiences in childhood become biologically embedded and impact both negative and positive outcomes across the life course.
7. Move beyond singular, panacea programs toward a layering of interventions that are integrated, both vertically and horizontally, into the local public health efforts to promote safe, stable, and nurturing communities, families, and relationships.
8. Employ a vertically integrated public health approach to promote relational health that is founded on universal primary preventions (such as positive parenting programs, ROR, and developmentally appropriate play) but also offers more precise screening for relational health barriers (such as maternal depression, food insecurity, or exposure to racism) as well as indicated treatments to repair strained or compromised relationships (such as ABC, CPP, PCIT, and TF-CBT).
9. Become hubs for medical neighborhoods, horizontally integrating a wide array of local efforts and early childhood initiatives that not only support families with resources and programs but also advocate for

the public policies that promote safe, stable, and nurturing families and communities.

10. Advocate that health systems, payers, and policy makers at all levels of government align incentives and provide funding to promote the universal primary prevention work discussed in this policy statement. FCPMHs are well-suited and even inclined to support the formation and maintenance of SSNRs as outlined in this policy statement, but they are not currently funded to do so.[205]

Finally, to develop the physician leadership for the FCPMHs of the future, pediatric training programs will need to:

1. Educate residents about the ecobiodevelopmental model and the implications for not only health care but education, juvenile justice, and public policy.
2. Provide longitudinal experiences that train residents on how to develop strong, trusted, respectful, and supportive relationships with parents and caregivers. Doing so will require all trainees to address their implicit biases, develop cultural humility, and provide culturally competent recommendations.
3. Teach residents how to identify and develop collaborative relationships with the local referral resources and early childhood initiatives in their communities.
4. Prepare residents to work as part of the interdisciplinary teams[144] that transform FCPMHs into hubs for medical neighborhoods.[161]
5. Educate residents about the many different facets of a fractured early childhood system of care (eg, Medicaid, Individuals with Disabilities Education Act Parts C and B, Child Care and Development Block Grants, Head Start, etc), as there is little collaboration or communication between the systems, funders, and programs that address child health, out-of-home child care, education, special education, protective services, or public health. Trainees need to understand all of these many facets so they are prepared to be effective advocates for their patients and families.
6. Encourage them to become leaders in interdisciplinary early childhood systems work and vocal advocates for public policies that promote positive relational experiences in safe, stable, and nurturing families and communities.

APPENDIX

Glossary of Terms, Concepts, and Abbreviations

ABC

Acronym for Attachment and Biobehavioral Catch-up; ABC is an evidence-based program of interventions to assist foster parents in nurturing children who have experienced disruptions in care.

ACEs

Acronym for adverse childhood experiences. In the original ACE Study, 10 categories of adversity were examined: emotional, physical, and sexual abuse; 5 measures of household dysfunction, including the mother being treated violently (intimate partner violence), household substance abuse, household mental illness, parental separation or divorce, and incarcerated household member; and emotional or physical neglect. Other investigators have applied the term ACEs to additional adversities known to affect child health, such as poverty, neighborhood violence, and exposure to racism. Although this term is frequently used to refer to the child's experiences (child ACEs), it has also been applied to the adversities that parents experienced during their own childhoods (parental ACEs).

ACE Score

The ACE score is the sum of the 10 original categories of ACEs experienced before the 18th birthday. To determine an individual's ACE score, see http://acestoohigh.com/got-your-ace-score.

Biobehavioral Synchrony

Biobehavioral synchrony refers to the matching of nonverbal behaviors (eg, eye contact), coupling autonomic functions (eg, heart rate), coordination of hormone release (eg, oxytocin), and alignment of brainwaves between a parent and an infant.

Biological Sensitivity to Context

Biological sensitivity to context is a theory with emerging evidence "that children differ in their susceptibility to environmental influence in a 'for better and for worse' manner, depending on their psychobiologic reactivity to stress." As a consequence, "the very characteristics that are often thought of as children's frailties (eg, high stress reactivity) can also be their strengths, given the right context."*,[91,131,134,206]

Common-Factors Approach

The common factors are communication skills that help to build a therapeutic alliance (the bond felt between the clinician and

**The quoted material in this entry is from Ellis BJ. Biological Sensitivity to Context/Adaptive Calibration Model. University of Utah, Department of Psychology, College of Social & Behavioral Science. Available at: https://psych.utah.edu/research/labs/biological-sensitivity.php.*

patient and/or family, a powerful factor in facilitating emotional and psychological healing), which, in turn, increases the patient and/or family's optimism, feelings of well-being, and willingness to work toward improved health. Other common-factors techniques target feelings of anger, ambivalence, and hopelessness, family conflicts, and barriers to behavior change and help seeking. Still other techniques keep the discussion focused, practical, and organized. These techniques come from family therapy, cognitive therapy, motivational interviewing, family engagement, family-focused pediatrics, and solution-focused therapy. They have been proven useful and effective in addressing mental health symptoms in pediatrics across the age spectrum (as per the AAP policy statement on mental health competencies in pediatric care).

CPP

Acronym for child-parent psychotherapy; CPP is an evidence-based, psychoanalytic approach for treating dysfunctional parent-child relationships based on the theory that the parent has unresolved conflicts with previous relationships.

Ecobiodevelopmental

The ecobiodevelopmental framework asserts that the ecology becomes biologically embedded, and there is an ongoing but cumulative dance between the ecology and the biology that drives development over the life span.

Executive Functions

Executive functions are the cognitive skills needed to control behavior and attain goals. Executive functions are core life skills, and they include capacities like impulse inhibition, working memory, cognitive flexibility, abstract thought, planning, and problem solving.

FCPMH

Acronym for the family-centered pediatric medical home; in an FCPMH, the pediatrician leads an interdisciplinary team of professionals providing care that is:

- family-centered: the family is recognized and acknowledged as the primary caregiver and support for the child, ensuring that all medical decisions are made in true partnership with the family;
- accessible: care is easy for the child and family to obtain, including geographic access and insurance accommodation;
- continuous: the same primary care clinician cares for the child from infancy through young adulthood, providing assistance and support to transition to adult care;
- comprehensive: preventive, primary, and specialty care are provided to the child and family;
- coordinated: a care plan is created in partnership with the family and communicated with all health care clinicians and necessary community agencies and organizations;
- compassionate: genuine concern for the well-being of a child and family are emphasized and addressed; and
- culturally effective: the family and child's culture, language, beliefs, and traditions are recognized, valued, and respected.

An FCPMH is not a building or place; it extends beyond the walls of a clinical practice. A medical home builds partnerships with clinical specialists, families, and community resources. The medical home recognizes the family as a constant in a child's life and emphasizes partnership between health care professionals and families (as per the National Resource Center for the Patient/Family-Centered Medical Home at the AAP).

If properly funded, FCPHMs are well placed to implement the following functions:

- screening for behavioral and developmental risk factors and diagnoses, including mental health conditions, developmental delays, SDoHs, and family-level risk and resilience factors;
- care coordination, linking families to community-based supports to address SDoHs, parenting concerns, developmental delays, and behavioral and mental health concerns;
- integrated behavioral health and family support services through colocated, interdisciplinary teams that include case management, behavioral health services, and positive parenting programs;
- preventive and dyadic mental health services that do not requiring a psychiatric diagnosis code for payment, thereby enabling the deployment of primary and secondary prevention strategies before the emergence of behavioral or medical disorders;
- enhanced payment for prolonged medical visits, allowing for more patient-centered communication, interdisciplinary care, and development of therapeutic alliances; and
- ancillary support services (interpretation, telemedicine, transportation, etc) enabling youth with special health care needs to access the many layers of support that they frequently require.

HealthySteps

HealthySteps is an evidence-based, interdisciplinary pediatric primary care program that promotes positive parenting and healthy development for infants and toddlers, with an emphasis on families living in low-income communities. HealthySteps uses a tiered approach to match services with the level of need, and the core components include: (1) child development social-emotional, and behavioral screening, (2) screening for family needs, (3) child development support line (eg, phone,

text, e-mail, and online portal), (4) child development and behavioral consultants, (5) care coordination and systems navigation, (6) positive parenting guidance and information, (7) early learning resources, and (8) ongoing, preventive team-based well-child visits.

Horizontal Integration

A public health approach that cuts across traditional silos and funding streams; a horizontally integrated public health approach also includes the educational, civic, social service, and juvenile justice systems.

Medical Neighborhood

Extends the concept of the FCPMH into the local community; in a medical neighborhood, the FCPMH or health system anchors and supports cross-sector efforts to address family needs (eg, the SDoH), promote population level wellness, and collectively advocate for needed funding and policy changes.

PCIT

Acronym for Parent-Child Interaction Therapy; PCIT is an evidence-based intervention to change the patterns of parent-child interactions to improve the parent-child relationship.

Positive Childhood Experiences

Reciprocal experiences with engaged and attuned adults (like those that occur during developmentally appropriate play) that build SSNRs; they are warm, affirming, and inclusive, and they promote early relational health.

Relational Health

The capacity to develop and maintain SSNRs with others; relational health is an important predictor of wellness across the life span.

Resilience

The capacity to respond to adversity in a healthy, adaptive manner; resilience is the manifestation of skills (eg, social skills, emotional regulation, language, and executive functions) that can be modeled, taught, learned, practiced, and reinforced.

Restorative Justice

Refers to efforts to repair the harm that occurs with unjust behaviors, as opposed to retributive or punitive justice, which simply punishes those who have acted unjustly. Typically, restorative justice allows the victims and the offenders to mediate a restitution agreement that is satisfactory to both parties. In this way, the victims play an active role in communicating with and understanding the offenders, and the offenders have the chance to take responsibility for their actions, identify steps that might prevent offending behaviors in the future, and redeem themselves in the eyes of the victims and community (as per Garner and Saul[17])

ROR

Acronym for Reach Out and Read; ROR is a nonprofit organization and early literacy program. ROR provides age appropriate books and encourages parents to regularly read to and interact with their children to support school readiness and healthy parent-child relationships.

SDoHs

Acronym for the social determinants of health; SDoHs refer to conditions where people live, learn, work, and play (like socioeconomic status, social capital, or exposure to discrimination or community violence) that are known to affect health outcomes across the life span.

SSNRs

Acronym for safe, stable, and nurturing relationships; these allow the child to feel protected, connected, and competent.

TF-CBT

Acronym for Trauma-Focused Cognitive Behavioral Therapy; TF-CBT is an evidence-based, manualized, skills-based therapy that allows parents and children to better process emotions and thoughts related to traumatic experiences.

Toxic Stress

The biological response to frequent, prolonged, or severe adversities in the absence of at least one safe stable and nurturing relationship; these biological responses might be beneficial or adaptive initially, but they often become health harming or maladaptive or "toxic" over time or in different contexts.

Vertical Integration

A public health approach that includes primary universal preventions to promote wellness (like promoting positive parenting practices), secondary targeted interventions for those deemed to be at risk for poor outcomes (like using biomarkers both to identify those at higher risk and to monitor the effectiveness of various interventions), and tertiary evidence-based treatments for the symptomatic (like referring to providers trained in TF-CBT).

VIP

Acronym for the Video Interaction Project; VIP uses video-taped interactions of parent-child dyads to teach parents how to be more engaged, attuned, and responsive to their child's developing behaviors.

ACKNOWLEDGMENTS

Drs Garner and Yogman gratefully acknowledge the contributions of Dr Shonkoff to early drafts of this article.

Preventing Home Medication Administration Errors

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Preventing Home Medication Administration Errors

H. Shonna Yin, MD, MSc, FAAP,[a] Daniel R. Neuspiel, MD, MPH, FAAP,[b] Ian M. Paul, MD, MSc, FAAP,[c]
COUNCIL ON QUALITY IMPROVEMENT AND PATIENT SAFETY, COMMITTEE ON DRUGS

Medication administration errors that take place in the home are common, especially when liquid preparations are used and complex medication schedules with multiple medications are involved; children with chronic conditions are disproportionately affected. Parents and other caregivers with low health literacy and/or limited English proficiency are at higher risk for making errors in administering medications to children in their care. Recommended strategies to reduce home medication errors relate to provider prescribing practices; health literacy–informed verbal counseling strategies (eg, teachback and showback) and written patient education materials (eg, pictographic information) for patients and/or caregivers across settings (inpatient, outpatient, emergency care, pharmacy); dosing-tool provision for liquid medication measurement; review of medication lists with patients and/or caregivers (medication reconciliation) that includes prescription and over-the-counter medications, as well as vitamins and supplements; leveraging the medical home; engaging adolescents and their adult caregivers; training of providers; safe disposal of medications; regulations related to medication dosing tools, labeling, packaging, and informational materials; use of electronic health records and other technologies; and research to identify novel ways to support safe home medication administration.

BACKGROUND

Errors in pediatric medication administration in the home environment are common[1–3] and can result in serious consequences.[4–6] These errors include dosing mistakes (both underdosing and overdosing), errors in frequency or duration of dosing (including missed doses), administration of incorrect medications or formulations, wrong route of administration, incorrect preparation or storage, and use of expired medications.[2–4,7–9] Many root causes have been identified that may contribute to errors,

including provider prescribing practices,[10–12] pharmacy dispensing practices,[6,13] confusing measurement units and dosing tools for liquid medications,[14–19] involvement of more than one caregiver,[5,9] and health literacy and language barriers.[17,20–24] This policy statement reviews this information and recommends strategies to reduce the incidence of pediatric medication administration errors at home, including those involving prescription and over-the-counter (OTC) medications, as well as vitamins and supplements.

STATEMENT OF PROBLEM

More than half of children in the United States take 1 medication or more each week,[25] and caregivers commonly make errors in administering medications to children.[2,3,19,26] One study showed that nearly half of caregivers gave a dose of medication that deviated more than 20% from what was prescribed after their child was discharged from the emergency department of a public hospital; 1 in 4 caregivers gave a dose that deviated by more than 40%.[3] A second study in a similar setting found comparable rates.[19] In another study, more than half of caregivers gave doses of OTC medications outside of the recommended range for their child.[26] Although for the majority of commonly used medications, a single dosing error is unlikely to cause a clinically significant injury, persistent errors across multiple doses raise concerns for harm. OTC medications as well as vitamins and supplements are widely used and are perceived to be safe by many caregivers[25,27–32] but may cause serious harm when used incorrectly.[5,33–36] Regimen-related factors, involving multiple medications[37–39] or requirements for more frequent administration (eg, 3 times a day instead of 1 time a day), are associated with more errors.[40,41] Regimens in which acetaminophen and ibuprofen are given continuously in an alternating fashion are also difficult to follow and prone to error,[42–44] unless explicit instructions and/or charts are clearly provided to support understanding. Other regimen-related factors that place children at risk for errors include scenarios involving liquid medications or other special preparations (eg, granules that need to be mixed with food),[1,45] situations in which a combination of single and multiple ingredient prescription and OTC medications are given (in which confusion between generic and brand names may result in families being unaware that a child is being given medications with overlapping active ingredients),[22,46,47] when medications are available in more than one concentration and/or formulation,[22,48,49] or when medications with narrow therapeutic windows are involved.[50–52] Home medication errors are of particular concern in the management of children with chronic conditions and special needs, such as cancer, sickle cell disease, epilepsy, and autism, as these children are often prescribed multiple medications or medications that have complex administration instructions, and there is an increased potential for harm when errors occur.[9,53–58] Medication administration in pediatrics is also challenging as more than one caregiver may be involved in the care of a child and more than one child in a family may be taking medications.[9,59] Confusion about whether a medication has already been given can lead to double dosing or missed doses of medicines; miscommunication between caregivers has contributed to cases of significant pediatric morbidity.[5] Adolescents with less caregiver supervision may also have more frequent home medication errors, particularly when their prescriptions are for conditions treated confidentially, without caregiver knowledge, such as sexually transmitted infections.[59–63] In the outpatient pediatric setting, medication administration errors are believed to account for the majority of preventable pediatric adverse drug events.[37,64]

IMPACT OF HEALTH CARE PROVIDER PRESCRIBING AND PHARMACY DISPENSING PRACTICES

Health care provider prescribing practices contribute to medication errors; providers can prescribe in ways that can make medication administration by caregivers and patients easier or more complex. Missing or unclear information (eg, related to route, frequency, duration, indication) can affect the understandability of medication instructions.[10,65] In addition, providers may not follow safe prescribing practices recommended by The Joint Commission, resulting in caregiver confusion; The Joint Commission standards apply to both inpatient and outpatient settings and recommend inclusion of leading zeros (eg, 0.X), avoidance of trailing zeros (eg, X.0), and avoidance of confusing abbreviations that may not be familiar to families, such as U (unit) and QD (daily), when prescriptions are ordered.[66] Because pediatric providers often rely on weight-based dosing and may prescribe in milligrams (mg), which may lead to complex dose amounts (eg, 4.8 mL) prescribed when milligrams are converted to milliliters, rather than simpler and easier-to-measure doses rounded to a whole number (eg, 5 mL).[67,68] Pediatric providers may also use multiple units of measurement in their instructions[18,19] and may believe that caregivers are more comfortable with instructions using teaspoon or tablespoon terms.[69]

Limitations in the functionality of electronic health record (EHR) systems may further contribute to these issues by not allowing rounding or by defaulting to instructions that use multiple units.[67,70,71] Providers who have not performed a thorough medication review or reconciliation process may also not be aware of all the medications a child is taking and whether caregivers are administering medications correctly, including avoiding giving medications that interact; the medical home model seeks to prevent this by having a coordinating health care provider with oversight over all medications for an individual patient.[72] Providers can simplify medication regimens by avoiding prescribing medications that are not essential as well as deprescribing, or discontinuing, unnecessary medications.[73]

Pharmacist dispensing practices may also contribute to incorrect medication administration, because dispensing practices can affect the clarity of instructions given to caregivers.[6,13] Several studies have shown that units of measurement included on prescriptions were frequently changed in the pharmacy setting (eg, one unit switched to another unit or additional unit of measure added), which can become a source of caregiver confusion, particularly if the units used as part of instructions are different from the units mentioned during medication counseling in the clinical setting.[18,19] State pharmacy regulations also allow pharmacists to fill a prescription using a different strength and/or concentration of medication than prescribed, as long as the dose in milligrams is equivalent; if pharmacists do not inform caregivers of this change, this practice can contribute to confusion.[13,74] Like providers, pharmacists also can alter the display of doses involving decimals.[13,75] Pharmacy dispensing errors have contributed to cases of significant pediatric morbidity (eg, related to changing units of measurement).[6,13] Use of pharmacy software to support safe pharmacist dispensing practices and use of a universal formulary that limits the number of medication concentrations available (including for medications requiring compounding) have been suggested as ways to decrease the potential for pharmacist dispensing error as well as caregiver administration error.[13,76] The US Food and Drug Administration (FDA)–funded Standardize 4 Safety initiative, led by the American Society of Health-System Pharmacists, seeks to create national standards around medication concentrations for intravenous and oral medications to reduce the risk of medication errors.[76]

ROLE OF HEALTH LITERACY AND LIMITED ENGLISH PROFICIENCY

For caregivers, the task of understanding how to correctly administer medications to children may be challenging from a health-literacy perspective, and advanced health-literacy skills may be required to manage complex medication regimens. Health literacy refers to an individual's ability to read, understand, and process health information for informed decision-making regarding health issues and includes the ability to navigate the health care system.[77,78] Nearly 30% of parents in the United States, or approximately 21 million US parents, have low health literacy,[79] placing them at increased risk of making medication administration errors.[17,41,79,80] Notably, only 15% of parents are considered to have proficient levels of health literacy, indicating that the majority of caregivers struggle with some health-literacy challenges.[79] Caregivers with low health literacy have greater difficulty understanding prescription and OTC labels and are more likely to use nonstandard kitchen spoons, to misunderstand active ingredient information, and to be unaware of weight-based dosing.[23,47,79–84] Among caregivers, limited health literacy has been linked to an increased odds of liquid medication dosing errors by 1.5-fold to 2.5-fold.[17,24,82,83]

Approximately 12% of US adults have limited English proficiency.[85,86] Patients with limited English proficiency are at increased risk for misunderstanding instructions and making errors, especially when the information provided is not in the language of their preference and the quality of translated instructions is poor.[21,37,86–91] Cultural factors may also affect adherence to medication regimens[22,92,93]; assessing culturally based health beliefs related to medication use can help providers understand issues that may have significant implications for how caregivers or patients understand and will act on the instructions provided. Provision of instructions in the caregiver's and/or patient's native or preferred language is considered to be an essential first step to achieving understanding of medication instructions; use of trained interpreters and certified translation experts is necessary to facilitate high-quality translation and interpretation.[94,95] Suboptimal access to high-quality medical interpretation and pharmacy label translations is common and can have important clinical consequences.[88,96–98] Notably, those with limited English proficiency are disproportionately affected by low health literacy.[24] Compared with those with low health literacy or limited English proficiency alone, caregivers with both low health literacy and limited English

proficiency are at even greater risk of medication errors.[24]

CHALLENGES FOR EFFECTIVE PROVIDER-PATIENT AND CAREGIVER COMMUNICATION IN CLINICAL AND PHARMACY SETTINGS

Communication obstacles in the clinical setting can be challenging for caregivers and patients regardless of literacy level and English proficiency, but these issues are especially difficult for those with low health literacy and limited English proficiency.[20,77,79,87,99–101] Provider counseling may be incomplete, leaving out key information, such as indication, dose, route, frequency, and duration, or may not address side effects or drug interactions.[102,103] Provider counseling may also not be explicit enough (eg, medication instructions say to give "twice a day" instead of "in the morning" and "in the afternoon") or may not be accurate (eg, "give every 8 hours" leads to the impression that a child would need to be woken up from sleep when this may not be true)[13,22]; it is best if these more explicit instructions are verbally presented to families by the provider and conveyed to the pharmacist for inclusion on the prescription. Use of a Universal Medication Schedule (UMS) approach, in which frequency information is presented by using 4 specific times of day (eg, "morning," "noon," "evening," and "bedtime" instead of as number of times per day) has been associated with improved patient understanding of medication instructions.[104,105] Lack of explicit provider counseling regarding route of administration may lead to medications inadvertently being put in the wrong location (eg, oral antibiotic for an ear infection placed in the ear canal instead of in the mouth), resulting in treatment failure.[2,22] Confusion may also result from the language used on the prescription (eg, for the instruction "once a day," Spanish-speaking families may misinterpret "once" to be "11," resulting in a serious overdose).[77,106] EHRs could be leveraged to facilitate provision of complete instructions (eg, hard stops unless information on dose, frequency, route, and duration are included) and can support provision of explicit standard dosing intervals (eg, Universal Medication Schedule [UMS] approach) as well as appropriate language translations.[104,107]

The majority of pediatric providers do not routinely use health literacy–informed "advanced counseling" strategies,[108,109] such as demonstration, drawings/pictures, or teachback/showback, even though use of these strategies has been associated with reduced caregiver dosing errors and improved understanding of medication instructions,[3,109,110] with benefits observed for families across literacy levels.[111] For patients who are being discharged from the hospital with complex medication regimens, emphasis on demonstration and showback, as part of a rooming-in process, may be beneficial for a safe transition to home.[112] Use of simulation may also be helpful for caregivers and providers to learn important aspects of medication administration and effective counseling strategies, respectively.[113–115]

Although use of written information as part of counseling has been found to be beneficial in reducing cognitive load,[116,117] health care providers often do not use written information to supplement provider verbal medication counseling.[108,118] Plain-language written instructions can give clinicians a framework for low-literacy counseling, helping to provide an easy-to-understand "script," as well as ensuring that key concepts are covered; optimally, these patient- and regimen-specific instructions would be given to families to take home and share with other caregivers.[3,119] Provision of a pictographic dosing diagram as part of written instructions, which visually illustrates the amount of medication to provide within a recommended dosing tool, has been found to be a promising strategy to enhance caregiver understanding of the appropriate dose, with benefits observed across health-literacy levels[82,120]; in 1 study, researchers found a more than fivefold reduction in dosing errors with prescribed daily dose medications with the use of a pictographic medication instruction sheet–based intervention to supplement provider verbal counseling.[3] Use of the intervention, which included a pictographic printed log to help caregivers track medication use, was also associated with an increased likelihood of families completing ≥80% of the recommended medication course.[3] Technological advances represent a promising avenue for promoting provider adoption of such tools.[67,121,122] For example, incorporation of tools into the EHR workflow could allow providers to quickly generate pictographic patient- and medication-specific low-literacy instruction sheets at the point of prescribing. Providing families with a printout of the after-visit summary allows them to have a tangible resource to refer to when they have questions about how to take medications at home; families may not be able to access this information online from home.

There are many ways EHRs could support the provision of tailored written medication instructions for pediatric patients.[67,122] For example, a typical precaution for a

drug that causes sedation is "do not drive a car or operate heavy machinery," which might be disregarded by a caregiver of a young child who would then overlook the potential risk of sedation. EHRs could automatically adjust messaging based on the age of the patient; for example, a child-focused precaution for a drug that causes sedation could be "watch your child when he or she is riding a bike, climbing stairs, or doing other activities where being awake and alert is important." In addition, EHRs could provide pediatric-centric information about the frequency or severity of adverse reactions in children because this information may differ from information targeted for adult patients.

Use of other visual modalities, as well as online and mobile technology resources, can also help support safe medication administration. Linkages to online pediatric information, as well as apps,[123] could be made more easily accessible to families seen in health care settings. Videos can also help support adherence to medication instructions.[123] Use of text messaging could also be leveraged to support caregivers in administering medications to children,[124,125] but text messaging of protected health information must comply with the Health Insurance Portability and Accountability Act of 1996.[126,127]

Because all patients and families benefit from simple, clear instructions, a "universal precautions" communications approach is generally recommended.[100,101,128,129] There is growing acceptance of the concept that health literacy is a fluid state that can be affected by stress, anxiety, and context, rather than a fixed trait.[77,129,130] It is, therefore, best to use health literacy–informed communication with all individuals.

In the pharmacy setting, caregivers often do not receive or opt out of verbal counseling from staff.[131] Prescription bottle labels may not be designed in a patient-centered manner[132–134] and may not incorporate health-literacy principles. For example, although prescription labels that include a pictographic dosing diagram have been found to be beneficial, especially for reducing large dosing errors (in 1 study, researchers found a twofold decreased odds of error with the use of text-plus-pictographic dosing instructions compared with text-only instruction[82]), use of pictographic diagrams on medication labels has not been adopted as part of standard care. Finally, written materials provided to families at the time of medication dispensing are often written at a ninth-grade reading level or higher[16,135,136]; experts recommend a sixth- to eighth- grade reading level for the average person and a fifth-grade level or below for people with low literacy.[137–139]

Empowering families during clinical and pharmacy encounters can help reduce the risk of home medication errors.[140–144] Health care providers, including pharmacists, can encourage caregivers to ask questions when they are unsure of how to give medications at home by increasing awareness that caregiver difficulty with administering medications is common and that questions are expected (eg, "It is common for caregivers to have questions about how to give these medications. What questions do you have for me?").[142,145–147] Caregiver awareness that both prescribers and pharmacists are responsible for providing information on how to administer medications safely to their child may prompt them to ask questions when they are confused.[142]

ROLE OF LIQUID FORMULATIONS IN HOME MEDICATION ERRORS IN CHILDREN

Liquid formulations of medications, on which pediatric providers rely, especially for young children and children who have feeding tubes,[13,148,149] are involved in more than 80% of pediatric home medication errors.[1] For children with feeding tubes, care is further complicated by the need to give a water flush after medication dosing to facilitate removal of any remaining medication in the tube.[148] Compared with tablets and capsules, liquid medications may be more complex to administer[1,150]; in certain contexts, switching from liquid to tablets or chewable formulation may simplify therapeutic regimens and promote adherence.[151,152] Dosing errors are easier to make with liquid formulations compared with solid-form medications, with confusion related to the measurement of liquids resulting in wide variation in dosing, ranging from large multifold overdoses to significant underdosing.[13,19,83] Overdosing medications is problematic given concerns related to drug toxicity and side effects, but underdosing can also have serious implications, including lack of therapeutic effect and symptom relief as well as potential contributions to antibiotic drug resistance.[2,4,8,80,83,153,154]

Many caregivers are unaware that use of nonstandard kitchen spoons for dose measurement should be avoided because kitchen spoons vary widely in size and shape.[14,23,155,156] Caregiver use of kitchen spoons is associated with higher rates of dosing errors[50,155,157,158]; although a teaspoon is considered to be equivalent to 5 mL, kitchen teaspoons have been found to measure between 2 and 9 mL.[159] The American Academy of Pediatrics

(AAP) has long recommended that liquid medications be measured using standard dosing tools.[14,160] A wide range of tools with standard measurement markings are available, including oral syringes, cups, dosing spoons, droppers, and measuring spoons[17]; these standard tools have calibrated markings that can be used to help caregivers measure doses accurately.[156,158,160] The FDA has recommended inclusion of a dosing tool with standard measurement markings (also called a standard dosing tool) for all OTC liquid medications.[161–163] Despite these recommendations, it is not standard practice for dosing tools to be provided in the clinical or pharmacy setting.[3,109,164] Use of health literacy–informed advanced counseling strategies (such as teachback, showback, and demonstration) has been found to be especially effective when conducted in conjunction with provision of a standard dosing tool.[109]

With prescription and OTC products, it is recommended that only the tool provided with the medication be used for administering that medication[15,162,165]; caregivers can be counseled to ask for a dosing tool at the time of medication purchase if they are not given one.[166] Colocation of dosing tools with their associated medications and storing the tool with the medication up, away, and out of sight of children can promote caregiver use of the correct tool and prevent unintentional medication ingestions.[166–169] The quality of dosing tool used has implications for correct medication measurement; some dosing tools that are designed for single or limited use have markings that rub off. Repeated use of such tools can result in hard-to-read markings that make it difficult for caregivers and/or patients to determine the right level to which to fill the tool; the US Pharmacopeia recommends the use of dosing tools with indelible markings.[170]

Caregivers vary in their ability to dose accurately with different types of standard dosing tools.[17,82,83,171,172] Dosing cups may be especially difficult to measure with; caregivers may confuse the entire cup as the dose, may not place the cup on a level surface when measuring, or may not look at the markings at eye level; markings on devices may also not be printed clearly (eg, etched versus printed).[17,166,173] Dosing cups have been associated with a more than threefold increased odds of error compared with oral syringes,[17,80,83] and the potential for multifold errors with cups is especially high with small-dose volumes.[80,82,83] Oral syringes are typically preferred by health care providers for increased accuracy in dose measurement and are generally recommended when dosing accuracy is essential[14,83]; this is especially important with medications that have a narrow therapeutic window.[50,83] Oral syringes are typically recommended for administering medication to young children, especially when small doses are involved.[83] To determine the optimal dosing tool to give to families, it is also important for providers to consider the relationship between the size of the dosing tool and the prescribed dose amount.[80,82,83] Dispensing a tool that is too large for a dose (eg, a 10-mL syringe for a 1-mL dose) increases the risk of multifold errors because there is a large amount of extra space that can be filled, resulting in overdosing.[82,173] Dispensing a tool that is too small for a dose (eg, 5-mL syringe for a 7.5-mL dose) results in the need to fill a tool multiple times, requiring the use of numeracy skills (eg, $5 + 2.5 = 7.5$ mL).[16,82,120] Dosing cups may be adequate for larger doses (eg, >10 mL), particularly for lower-risk medications with wide therapeutic margins.[82] With the growing use of electronic prescribing,[174,175] information on optimal dosing tools for prescribed medications could be automatically generated at the point of prescribing in the EHR or at the point of dispensing within pharmacy software systems, providing information to clinicians and pharmacists about which tool is best to use based on the recommended dose amount.

Confusion about units of measurement also contributes to dosing errors with liquid medicines.[13–15,19,81,176] A variety of terms, such as milliliter, teaspoon, and tablespoon, and their associated abbreviations (mL, tsp, TBSP, respectively) may be used interchangeably as part of verbal and written communication of dosing instructions and associated dosing tools; milligram (mg) may also be used.[13,15,18,19,177] Variability in the use of units is common; in 1 study, researchers found that in more than one-third of cases, medication bottle labels did not contain the same units found on the prescription,[19] and in another study, researchers found that labels and associated dosing tools included with top-selling OTC liquid medications frequently did not use consistent text for unit terms.[15] Confusion between volumetric unit terms increases the risk of multifold errors by caregivers and providers (eg, teaspoon confused for milliliter can lead to a fivefold under or overdose)[13]; confusion between volumetric and nonvolumetric terms (eg, milliliter and milligram) can also lead to confusion.[18,177] Spoon-based terms inadvertently endorse the use of nonstandard dosing tools; in 1 study, caregivers had a fourfold increased odds of choosing a kitchen spoon (ie, kitchen teaspoon or tablespoon) when teaspoon units were present on the medication label.[81] Dosing in milliliters has been associated with fewer

caregiver errors compared with dosing using spoon-based terms.[82,83] Concerns about unit-of-measurement–related errors has led the Centers for Disease Control and Prevention, via its PROTECT (Prevention of Overdoses and Treatment Errors in Children Taskforce) Initiative, to recommend milliliter-only dosing and elimination of spoon-based terms.[178] As a member of this initiative, the AAP has endorsed milliliter-only dosing, joining groups such as the American Academy of Family Physicians, American Pharmacists Association, American Association of Poison Control Centers, US Pharmacopeia, the Institute for Safe Medication Practices, and the Pediatric Pharmacy Advocacy Group.[13,14,179–181] Although people with low health literacy may especially benefit from a simpler, milliliter-only dosing system, those with low health literacy are more likely to prefer teaspoon units and perceive that a move to a milliliter-only unit system will be difficult.[182] EHR systems can be leveraged to support milliliter-only dosing (eg, limiting unit choices and defaulting to milliliter-only dosing).[14,69]

OTC MEDICATIONS

Caregivers and patients often do not receive guidance from health care providers on the use of OTC products[20]; they may not be aware that pharmacists are trained to counsel families about how to select and use OTC products and are available for consultation.[183] Caregivers and patients, therefore, often rely on their own health-literacy skills or those of family members to determine which medications to purchase and how to appropriately administer them.[20,84] Nearly 60% of US caregivers report difficulty understanding OTC labels, with 1 in 3 reporting "great" or "moderate" difficulty.[79] Many caregivers struggle to appropriately select medications, including distinguishing between different formulations or strengths, and recognizing that 2 or more medications with the same active ingredient should not be given at the same time (to avoid double dosing).[4,7,47,184] Caregivers also struggle to navigate dosing charts to determine the correct amount of medication to give to their child and fail to recognize that dosing should generally be based on child weight rather than age.[23,26,185] This issue may be especially confusing for caregivers of children who are overweight or obese.[186,187] In addition, caregivers may confuse the child's weight in kilograms versus pounds; consistent provider use and communication of weight in kilograms could reduce inadvertent caregiver dosing errors.[187,188] Dosing charts also may not include dosing information for the youngest children; for example, for children younger than 2 years, the dosing chart for acetaminophen states "ask your doctor,"[189,190] contributing to caregiver confusion.

Caregivers are frequently confused about how to correctly administer OTC cough/cold products.[84,191,192] Several issues have been specifically identified that contribute to caregiver errors with OTC cough/cold products, including confusion with age restriction information, difficulty recognizing that some cough cold medications contain multiple active ingredients (and may include an antipyretic), and confusion interpreting dosing charts.[47,192,193]

In 2008, the FDA, spurred by cases of fatalities in young children, several of which involved home administration errors by caregivers,[194–196] issued a public health advisory recommending that cough/cold products not be used in children younger than 2 years[191]; this recommendation was later voluntarily extended to children 4 years and younger by manufacturers of OTC cough/cold products.[197] Although rates of adverse events related to cough/cold medication in children have decreased after these efforts, caregivers of young children continue to use these products.[8,28,192]

MEDICATION RECONCILIATION AND THE MEDICAL HOME

Because children are often taking a combination of medications, which may include both single and multi-ingredient prescription and OTC products, as well as vitamins and other supplements, a medication reconciliation process is recommended at all relevant clinical encounters, such as when a new provider is taking over the care of a patient, when there has been a long gap between clinical encounters, or a when a new medication is being prescribed.[198–201] Caregivers may not realize that 2 medications interact or may not realize that 2 medications their child is taking contain the same active ingredients, leading to a multifold overdose.[28,47] For children with special health care needs, in particular, having a medical home with a primary care provider responsible for coordinating care among all providers is helpful for promoting a safe home medication–use environment.[72]

Review of each medication a patient is taking (to determine if the medication is being administered correctly, if the medication is still necessary, and if the administration instructions need to be updated [eg, dose adjusted to account for weight gain]) is considered an important safety practice.[100,101,202] EHRs could be used to generate medication lists for families to review and bring to provider visits to support the medication reconciliation process.[199,203] Encouraging

caregivers to bring in medications to provider visits and describe how medications are being administered can also be helpful in identifying potential errors in medication use.[100,101,198]

MEDICATION DISPOSAL

Caregivers often keep medications in their homes even after medications are expired or are no longer in use.[204,205] Having medications in the home that are no longer in use may increase the likelihood that these medications will be confused with medications in use and may lead to inadvertent administration of the wrong medication to the child that the medication was intended for or another person in the home[206]; with unused opioids in the home, there are also concerns about the abuse and diversion potential for adolescents and other adults in the home.[207] Saving leftover medicine prescribed for an acute illness for a later illness episode may lead to ineffective treatment of a child's illness because there may not be sufficient medication remaining to properly treat a subsequent illness and medication potency may be reduced for expired medications.[206,208]

Recommendations exist about how to safely dispose of medications.[209,210] Recent federal guidelines state that prescription or OTC medications are not to be flushed down the toilet or poured down a sink unless patient information material specifically states that it is safe to do so. If no disposal instructions are given as part of the medication labeling information, FDA guidelines recommend the following actions:

- Taking advantage of programs that allow the public to take unused drugs to a central location for proper disposal. Local law enforcement agencies may sponsor medicine take-back programs. City or county government household trash and recycling services may also have specific medication disposal options and guidelines.
- Transferring unused medicines to collectors registered with the Drug Enforcement Administration (DEA). The DEA website has information on how to find an authorized collector (http://www.deadiversion.usdoj.gov/drug_disposal/index.html).[211]

Pharmacies may also have drug disposal kits available for safe medication disposal in the trash or drop-off kiosks where families can dispose of unused medications.[210]

If there are no disposal instructions given on the drug label and no take-back program or disposal kits are available, medications can be thrown out in the household trash. Before throwing out medications, removal of medications from their original containers and mixing them with an undesirable substance, such as used coffee grounds, dirt, or kitty litter, is recommended (this makes the drug less appealing to children and pets and unrecognizable to people who may intentionally go through the trash seeking drugs).[210] Placement of the mixture in a sealable bag, empty can, or other container will prevent the drug from leaking or breaking out of a garbage bag.[209]

RECOMMENDATIONS

The following actions can reduce home medication administration errors:

1. Improve communication to caregivers and patients (Table 1):
   - Make medication regimens as simple as possible (eg, avoid prescribing unnecessary medications, reduce number of medications prescribed, discontinue medications when possible, reduce administration frequency, and avoid unnecessary multiingredient combination products).
   - Use appropriate dosing units (eg, use mL-only and avoid spoon-based or nonmetric units; avoid nonvolumetric units [eg, mg] in describing the dose amount).
   - Use only kilograms (kg) for child weight to reduce inadvertent mix-ups (with pounds) and potential for error.
   - Learn and use health literacy–informed verbal counseling strategies (eg, plain language, pictures/drawings, and teachback/showback) for use in clinical and pharmacy settings, including as part of hospital discharge.
   - Provide verbal counseling in the language of caregiver/patient preference, using a trained interpreter if the provider does not have fluency in the patient's preferred language.
   - Provide written patient education materials on medication use appropriate for the literacy level and languages spoken by patients and caregivers.
   - Provide a printout of the after-visit summary for families to take home and refer to for information about their medication instructions.
   - Make an extra effort to verify caregiver/patient understanding in cases involving specific higher-risk medication regimens or at-risk populations (Table 2). This includes the following:
     - Counseling caregivers about OTC medications and addressing common sources of caregiver confusion with

TABLE 1 Recommended Provider Counseling Practices to Promote Safe Home Administration of Pediatric Medications

Recommended Practice	Explanation
Provide straightforward and actionable instructions	Medication counseling conveys key instructions, including: • Medication name • Medication purpose (indication) • Dose amount • Frequency • Duration • Route of administration • Side effects Provide dose amount using milliliter units only, using the abbreviation "mL." • Avoid spoon-based units (eg, teaspoon [tsp] and tablespoon [TBSP]) • Avoid dosing in cubic centimeters (ie, cc) • Use mL units consistently in verbal and written communication Provide dose amounts that are easy to measure.: avoid fraction or decimal amounts when possible (use whole number amounts); include leading zeros if decimal amounts are used (eg, 0.X); avoid trailing zeros (eg, X.0); and avoid confusing abbreviations, such as U (unit) and QD (daily) (eg, for insulin dosing, spell out the word "unit"). • Avoid fraction or decimal amounts when possible (use whole number amounts) • Include leading zeros if decimal amounts are used (eg, 0.X) • Avoid trailing zeros (eg, X.0) • Avoid confusing abbreviations, such as U (unit) and QD (daily) (eg, for insulin dosing, spell out the word "unit") Give explicit instructions regarding timing: • Provide information on time of day (eg, in the morning and in the evening) instead of providing only frequency information (eg, 2 times a day) • Include information on explicit timing on prescriptions
Incorporate health literacy–informed counseling strategies and educational materials for caregivers as part of care provided in inpatient, outpatient, emergency care, and pharmacy settings	Use a universal precautions approach to counseling (perspective that all patients would benefit from receiving evidence-based, health literacy–informed communication strategies) Use the following health literacy–informed verbal communication strategies: • Plain, "living room" language • Demonstration (eg, for liquid medications, consider using an oral syringe to demonstrate the amount of medication the caregivers should measure out; for asthma, consider having a staff member demonstrate how to use the spacer with inhaler) • Teachback: ask caregivers to say in their own words how they will give the medication (eg, "I want to make sure I did a good job explaining to you how much medication you should give. Can you tell me how much medication you will give to Jennifer each time?") • Showback (eg, have caregiver demonstrate how much medication they plan to give each time using an oral syringe). Provide patient- and regimen-specific written instructions that can be taken home and shared with family members: • Incorporate written instructions into verbal counseling to reduce cognitive load • Use pictures and/or drawings to supplement counseling (eg, for liquid medications, provide a pictographic dosing diagram which visually shows the right amount of medication to give within a standard dosing tool) • Provide a log for caregivers to keep track of medications given and help promote adherence to the full course of medication • Written information recommended to be at a sixth- to eighth-grade reading level for the general population and a ≤5th grade reading level for patients with low literacy.
For liquid medications, promote caregiver use of standard dosing tools	• Counsel caregivers to use standard dosing tools (eg, tools with standard measurement markings, such as oral syringes, cups, dosing spoons, and droppers) and avoid the use of nonstandard kitchen spoons. • For prescribed medications, it is recommended that health care providers or pharmacists provide a standard dosing tool to caregivers to take home if no tool is provided as part of packaging (in particular, providers dispensing the medication are responsible for making sure that families have an appropriate tool to use to measure the prescribed medication). ◦ Provide oral syringes when dosing accuracy is important, especially when smaller doses are recommended (eg, <5 mL). ◦ Provide tool with the smallest size to fit the dose without the need to fill the tool multiple times for a single dose. • Warn caregivers regarding potential known pitfalls of dosing cup use.

TABLE 1 Continued

Recommended Practice	Explanation
	◦ Avoid cups for smaller doses (eg, <5 mL). ◦ Place cups on a level surface when measuring; look at markings at eye level when measuring. • Promote dosing-tool best practices. ◦ For prescription medications, use tool provided by health care provider or pharmacy for specific medication prescribed. ◦ For OTC medications, use dosing tool included in packaging. ◦ Colocation of dosing tool with prescribed medication.
Provide language concordant care	Verbal counseling and written information should be provided in the language of patient and/or family preference. • High-quality translations should be provided. • Trained/certified professional interpreters should be used.
Empower caregivers to engage in care	• Empower caregivers to ask questions. ◦ Acknowledge that many caregivers have difficulty with administering medications and that questions are expected (eg, "I just gave you a lot of information. It is common for caregivers to have questions about how to give these medications. What questions do you have for me?") • Encourage caregivers to request a dosing tool if one is not provided.
Reconcile medications at each relevant patient encounter	Conduct regular reviews of medication lists with patients and caregivers. • Systematically review each medication taken (eg, name, strength, indication, dose, frequency, and expected duration) • OTC medications, and vitamins and/or supplements, should be included.

OTC medications, including age restrictions, active ingredient information, and dosing instructions (eg, prioritization of weight versus age).

- Providing anticipatory guidance for adolescent patients to address their evolving responsibility in managing their own health care, including the responsible use of medications and review of their medication use with adult caregivers.
- Encouraging families with multiple caregivers to develop a communication strategy about medication administration to prevent overdoses and maintain correct dosing intervals.
- Encouraging families to avoid use of products that have "do not use" statements on the label that apply to their child, such as for OTC

TABLE 2 Scenarios Involving Increased Risk for Medication Error

Regimens involving:
- Medications with a narrow therapeutic window, including warfarin and tacrolimus
- "High-alert" medications (see Institute for Safe Medication Practices' High-Alert ambulatory list: https://www.ismp.org/recommendations/high-alert-medications-community-ambulatory-list)
- Complex instructions (eg, multiple medications, multiple administrations in a day, nonwhole number doses, or more than one unit of measurement used), including medications that require compounding in which standard concentrations may not exist
- Medications requiring special preparation (eg, mixing and diluting)
- OTC medications (eg, caregiver confusion related to age restrictions, active ingredient information, and dosing chart interpretation)
- Regimens involving alternating acetaminophen/ibuprofen dosing
- Cough/cold medications, especially in young children

Populations at risk:
- Children with chronic health conditions and special needs
- Multiple caregivers are involved
- More than one child in the family is taking the same medication
- Adolescents
- Caregivers/patients with low health literacy
- Caregivers/patients with limited English proficiency

cough/cold medications.

2. Encourage the use of a standardized dosing tool with all liquid medications. This may be already included in packaging or provided by the pediatric clinician or pharmacist.
   - Provide oral syringes when dosing accuracy is essential, especially when smaller doses are recommended (eg, <5 mL) and when medications are for young children.
3. Provide a dosing tool with the smallest size to fit the dose without the need for filling the instrument multiple times for a single dose.
4. Demonstrate the prescribed dose of medication by using a dosing tool and have the patient/caregiver teachback/showback the dose.
5. Counsel caregivers about colocation of dosing tool for ease of access of the tool when medications are administered; store dosing tools with medications safely (eg, up, away, and out of sight).
6. Encourage caregivers to ask for a dosing tool with all prescribed medications and to use their medication-specific tool each time.
7. If a dosing tool comes packaged with a medication, caregivers should use that tool to measure that medication.
8. On all prescriptions, it is best to do the following:
   - Include patient weight so that pharmacists can double check the dose.
9. Include indications so that pharmacists can provide a second check on the dose (some medications are dosed differently on the basis of indication or may be used off-label), except in cases that involve sensitive issues, such as psychiatric or substance use disorders.
10. Reconcile medications at all relevant patient encounters (such as when a new provider is taking over the care of a patient, when there has been a long gap between clinical encounters, or when a new medication is being prescribed) by systematically reviewing each medication being taken (eg, name, strength, indication, dose, frequency, and expected duration); OTC medications, and vitamins and supplements, should be included in this review.
    - Medication information provided to families, including at the time of discharge from both inpatient units and emergency departments, needs to include key administration information, such as medication dose, route, frequency, and duration.
11. Providers involved in discharge, from both inpatient units and emergency departments, are responsible for giving information to the patient's primary care provider such that the medication plan initiated in the hospital is appropriately executed at home. For chronic medications, information about whether the medication needs to be adjusted for weight is considered an essential piece of information.
12. Encourage caregivers to bring for review their actual medications, or a list of medications, to provider visits.
13. Providers should access educational modules and other resources for safe prescribing practices (including mL-only dosing), health literacy–informed patient education and counseling, and safe storage and administration of home medications (Table 3).
14. Professional organizations should make educational modules and other resources to promote safe home medication administration available to providers and incorporate them as part of continuing medical education and maintenance-of-certification opportunities.
15. To avoid unintentional ingestions and use of expired prescription medications, promote safe disposal of unused medications after course completion. Common household OTC medications should also be safely disposed of when expired.
16. Encourage governmental agencies and industry to adopt measures to promote home medication safety, including the following:
    - Standardization of dosing units.
17. Ensuring that appropriate dosing tools are packaged with oral liquid medications.
18. Optimization of medication labels and packaging to decrease caregiver confusion.
19. Standardization of formulations to reduce confusion between infant versus children's formulations of medications.
20. Provision of health literacy –informed patient information materials in the language of patient and/or family preference.
21. Removal of "ask your doctor" from OTC medication labels and replacement with more precise instructions when possible (eg, acetaminophen for children aged <2 years).
22. Promotion of EHR functionality that supports safe pediatric medication use (eg, automatic rounding to whole numbers for liquid medications, limitation or default to mL-only dosing, limitation to one concentration of medication, default standard dosing based on weight, explicit standard dosing intervals [eg, morning and night versus twice a day], hard stops to facilitate acquisition of a complete set of information [eg, dose, frequency, and duration], prompts about drug interactions, and provision of

information in the patient's preferred language).

23. Continued support for child-proof packaging.
24. Encourage research funding for novel ways to support safe home medication administration, including identifying strategies to evaluate and support appropriate dosing, and improve medication tracking and feedback to support caregiver and patient adherence to instructions.

Prevention of Drowning

- *Technical Report*

TECHNICAL REPORT

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Prevention of Drowning

Sarah A. Denny, MD, FAAP,[a] Linda Quan, MD, FAAP,[b] Julie Gilchrist, MD, FAAP,[c] Tracy McCallin, MD, FAAP,[d,e] Rohit Shenoi, MD, FAAP,[f] Shabana Yusuf, MD, Med, FAAP,[f] Jeffrey Weiss, MD, FAAP,[g,h] Benjamin Hoffman, MD, FAAP,[i]
COUNCIL ON INJURY, VIOLENCE, AND POISON PREVENTION

Drowning is a leading cause of injury-related death in children. In 2018, almost 900 US children younger than 20 years died of drowning. A number of strategies are available to prevent these tragedies. As educators and advocates, pediatricians can play an important role in prevention of drowning.

INTRODUCTION

Background

Drowning is the leading cause of unintentional injury–related death in US children 1 through 4 years of age and, as of 2018, has surpassed birth defects as the most common cause of death among this age group. Drowning is the third leading cause of unintentional injury–related death among US children and adolescents 5 through 19 years of age.[1] In 2018, almost 900 US children and youth under 20 years died of drowning and more than 7200 were seen at a hospital emergency department (ED) for a drowning event, with 35% of those children either hospitalized or transferred for further care.[1] Rates of drowning death vary with age, sex, and race; those at greatest risk are toddlers and male adolescents. Underlying medical conditions, such as seizures and autism, also increase risk. Fortunately, childhood unintentional drowning fatality rates have decreased steadily from 2.68 per 100 000 in 1985 to 1.09 per 100 000 in 2018. Most victims of nonfatal drowning do well, but severe long-term neurologic deficits are seen with extended submersion times, prolonged resuscitation efforts, and lack of early bystander-initiated cardiopulmonary resuscitation (CPR).[2–4]

The American Academy of Pediatrics (AAP) has revised this technical report because of new information and research regarding (1) populations at increased risk; (2) racial and sociodemographic disparities in drowning rates; (3) water competency (water safety knowledge and attitudes, basic swim skills, and response to a swimmer in trouble)[5,6]; (4) the need for close, constant, attentive, and capable adult supervision when children are in and around water as well as life

jacket use among children and adults; (5) the importance of physical barriers to prevent access to water when children are not expected to be around water; and (6) the Drowning Chain of Survival and importance of bystander CPR (Table 1).

In 2002, the World Congress on Drowning and the World Health Organization revised the definition of drowning to be "the process of experiencing respiratory impairment from submersion/immersion in liquid." Drowning outcomes are classified as death, no morbidity, or morbidity (further divided into moderately disabled, severely disabled, vegetative state/coma, and brain death). Terms such as wet, dry, near, secondary, active, passive, and silent drowning should not be used. The 2002 revised definition and classification is more consistent with other medical conditions and injuries and should help in drowning surveillance and collection of more reliable and comprehensive epidemiological information.[7]

Sociodemographic Factors

Rates of drowning vary by sociodemographic factors, such as age, sex, race and ethnicity, and the presence of neurodevelopmental disorders such as epilepsy, autism spectrum disorder (ASD), and intellectual disability. Drowning rates are reported on the basis of the population under examination, not on the basis of the group's exposure; exposure-based rates might increase disparities among groups.[8] The highest rate of drowning is in the 0- to 4-year age group (2.26 per 100 000 population), with children aged 12 to 36 months being at highest risk (3.38 per 100 000). There is a second peak incidence in adolescence (1.90 per 100 000 among boys aged 15 to 19 years), attributable largely to a high number of male drowning deaths. Approximately 75% of childhood drowning victims are boys,[1] and, after the first year of life (during which risks are often similar), boys are at greater risk of drowning than are girls at each age. Among children and preteens, drowning death is roughly twice as common in boys as in girls, but among adolescents, the rate is almost 10 times higher among boys (Table 2).[1] The higher drowning rate for boys has been explained by greater exposure to aquatic environments, overestimation of swimming ability, higher risk taking, and greater alcohol use.[9,10]

Among children aged 0 to 19 years overall, drowning rates from 2014 to 2018 are highest among Black (1.79 per 100 000) and American Indian (AI) and Alaska native (AN) (1.49 per 100 000) individuals; drowning rates are lower among white (1.06 per 100 000), Asian American and Pacific Islander (0.85 per 100 000), and Hispanic (0.82 per 100 000) individuals.[1] One analysis of 11 years of fatal drowning data among people younger than 30 years reveals that AI and AN individuals have the highest rates of fatal drowning (2.57 per 100 000), higher than both Black (1.90 per 100 000) and white (1.32 per 100 000) individuals. AI and AN individuals have the lowest drowning risk of all races and ethnicities in swimming pools but the highest in natural water settings (1.22 per 100 000 among AI and AN versus 0.63 per 100 000 among Black and 0.42 per 100 000 among white individuals). AI and AN individuals could not be included in additional analyses of race and ethnicity (eg, white, Black, Hispanic) by single year of age because of small numbers. When considering race and ethnicity as a risk factor, age dramatically influences drowning disparities. The highest rates were among children aged 1 year, with rates for white children (5.22 per 100 000) higher than those for Hispanic (4.14 per 100 000) and Black (2.98 per 100 000) children. Between the ages of 1 and 5 years, drowning rates decreased significantly for each racial and ethnic group but decreased less among Black children. However, the drowning rates for Black children were significantly higher than those for white and Hispanic children at every age from 5 years to 18 years, and this difference persisted when examining drowning in swimming pools and natural water settings. An analysis that was focused specifically on swimming pool drowning deaths in the 5- to 24-year age group demonstrated that Black males had higher drowning rates than either white or Hispanic males, even when adjustments were made for income. Although the majority of white children drowned in residential pools, Black children were more likely to die in a public pool, often at a motel or hotel.[11] In swimming pools, Black children aged 5 to 19 years were 5.5 times more likely to drown than white children of the same age.[12] With no physiologic differences to explain the difference in drowning risk, race and ethnicity are likely a proxy for social and cultural differences

TABLE 1 Key Evidence-Based Strategies

Assess all children for drowning risk on the basis of risk and age, and prioritize evidence-based strategies:
• Barriers
• Supervision
• Swim lessons
• Life jackets
• CPR

TABLE 2 Unintentional Drowning Deaths, United States, 2014–2018

	Average Annual (Crude Rate No. Deaths Per 100 000)		
Age Group, y	Boys	Girls	Total[a]
<1	19 (0.93)	17 (0.90)	36 (0.91)
1–2	175 (4.32)	93 (2.40)	269 (3.38)
3–4	104 (2.55)	41 (1.05)	145 (1.81)
0–4	298 (2.93)	152 (1.56)	450 (2.26)
5–9	95 (0.91)	36 (0.36)	131 (0.64)
10–14	71 (0.68)	27 (0.26)	98 (0.47)
15–19	205 (1.90)	21 (0.21)	226 (1.07)
0–19	670 (1.60)	236 (0.59)	906 (1.10)

between the groups. The reasons that Black children and teenagers are at higher risk of drowning have not been thoroughly studied, but poor swimming skills in both children and their parents, lack of early training, and lack of lifeguards at motel and hotel pools may be important factors.[11,13–15]

Risks related to race and ethnicity are likely related to differences in exposure, behavior, knowledge, and skills. In Ontario, Canada, African, Hispanic, and Asian people have higher age-adjusted drowning rates compared with those of European descent.[16] In a survey targeting poor children of color, approximately 57.5% of Black youth and 56.2% of Hispanic youth reported being unable to swim or being uncomfortable in the deep end of the pool. [14] Black females report fear of drowning; this negatively affects seeking swimming instruction and swimming abilities.[15] Certain religious beliefs may prevent children from taking swimming lessons because of lack of single-sex aquatic settings or type of clothing restrictions.[17] Socioeconomic disparities account for some, but not all, of the disparities. Inadequate funding for pools, swimming programs, and lifeguards, as well as the cost associated with swimming lessons, may affect water competency and community resources for low-income populations. Differences persist after controlling for socioeconomic status, cultural and historical factors, and access.[11] Finally, the role of race and ethnicity as a risk factor may vary at the local level, necessitating examination of risk at the level of individual communities.[18]

Further research is imperative to learn more about racial and ethnic disparities in drowning and guide effective prevention interventions. A study performed in Alaska to decrease injury in AN territories successfully increased the use of float coats (summer-weight coats that doubled as personal flotation devices) by using an aggressive education campaign, increased enforcement, and increased availability of float coats. This project was successful because of partnership with tribal elders in developing culturally appropriate messaging.[19] In addition, understanding the historical relationships that affect risk perception around water safety helps inform aquatic risk communication to different cultural and ethnic groups.[20] The drowning research agenda should include understanding the disparities affecting immigrants, refugees, and various ethnic and racial populations and establish evidence-based interventions to improving water competency and decreasing drowning rates in these disproportionately affected groups.

The role of socioeconomic status and income on drowning rates, independent of race, is not well known. Worldwide, drowning rates are much higher in low-income, resource-limited countries, possibly because of the increased exposure to natural bodies of water.[21,22] In contrast, a study of pool drowning conducted in California found that among children younger than 10 years, drowning rates were actually associated with higher family income and parental education. This association was attributed to increased exposure to residential swimming pools in more affluent communities.[23] In the Netherlands, individuals of ethnic minorities were more likely to drown than those of Dutch heritage, even after adjusting for age, sex, income, and urbanization.[24] Among Black males in the United States, swimming pool drowning risk remained higher even after controlling for income,[11] and among urban youth, Black children reported lower swimming ability after controlling for income.[13] Underlying reasons are not well understood but may include cultural, historical (such as segregation and lack of access), and environmental influences.

Temporal and Geographic Variation

Among all causes of unintentional injury death in the United States, drowning shows the greatest seasonal variation.[25] For drowning victims younger than 15 years, 70% of deaths occurred from May to August; the risk of drowning significantly increased (up to 69%) when the outside temperature exceeded 30°C (86°F).[26] Drowning also occurred disproportionately on Saturdays and Sundays. In 2016, in Maricopa County, Arizona, 47% of the 131 life-threatening pool-related incidents among children aged 0 to 4 years occurred on the weekend. The peak time of day was 6 PM to 8 PM, with 75% of all incidents

occurring between noon and 9 PM.[27] In another report, approximately one-half of drownings occurred between 4 PM and 6 PM, coinciding with the busiest swim times as well as distractions secondary to meal preparation.[28]

For the period 2014–2018, the 3 US states with the highest number of drowning deaths in the 0- to 19-year age group were California (419 per 100 000), Florida (489 per 100 000), and Texas (516 per 100 000). For the same age group, the states with the highest rates of drowning deaths per 100 000 population aged 0 to 19 years were Louisiana (2.3), Florida (2.1), and Mississippi (2.0). The lowest drowning death rates were reported in some of the New England and mid-Atlantic states.[25]

Setting

Age is an important determinant of drowning location. Most infants drown in bathtubs and buckets, whereas the majority of preschool-aged children drown in swimming pools. Older children and adolescents are more likely to drown in natural bodies of water. In a large national study of 1420 drowning deaths in children younger than 20 years, 47% of drownings in all age groups occurred in fresh water, 32% in artificial pools, 9% in the home (bathtubs, buckets), and 4% in salt water.[29] In a study from Washington state, natural bodies of water were the setting in 35% of drownings in the 0- to 4-year age group, 69% of the drownings in the 5- to 14-year age group, and 95% of the drownings of adolescents.[30] Similar findings were found in another study conducted in Massachusetts.[31] In contrast, for nonfatal drowning involving children and adults, 57% occurred in pools, 25% occurred in natural bodies of water, 9% occurred in bathtubs, and 8% were unspecified.[32]

Most infant drowning deaths occur in bathtubs (62%–71%) and large buckets (16%).[25,29] Almost all parents report believing a child should be at least 6 years old before being allowed to bathe alone.[33] However, approximately 15% to 30% of caregivers have reported leaving their children younger than 2 years unsupervised in the bath for a period ranging from 1 minute to slightly over 5 minutes.[34,35] In fact, in this study, 33% of parents reported leaving children younger than 2 years for a little over 1 minute and 24% for more than 2 minutes but less than 5 minutes.34 The caregivers were distracted by a phone, getting diapers or clothes for the child, or completing household chores.[34] Of note, first-time parents were less likely to leave children in the bathtub when compared with parents with an older child.[36] The association of unsupervised bathtub drowning deaths with the use of bathtub seats and rings was recognized more than 2 decades ago.[37] The bath seat and ring are designed to position the infant in a sitting position with 3 to 4 legs and suction cups at their base. Three hazard scenarios have been described with these devices: (1) the seat tipping over from suction cup failure, (2) the child becoming entrapped in leg openings that are too big, and (3) the child climbing out of the seat.[37] Additionally, infant tubs pose another risk contributing to bathtub drownings. Between January 2004 and December 2015, a total of 247 incidents were reported to the Consumer Product Safety Commission (CPSC) involving infant tubs, 31 fatal and 216 nonfatal.[38]

In a national study, 56% of drownings in children aged 0 to 4 years occurred in swimming pools, but a sizable portion (26%) occurred in fresh bodies of water (rivers, creeks, lakes, ponds, canals, and quarries).[29] In children younger than 5 years, the largest numbers of natural water drownings occur in ponds, whereas older children more commonly drown in lakes.[39]

Although children aged 5 to 14 years are slightly more likely to drown in a natural body of water than in a swimming pool, a high proportion (69%) of adolescents aged 15 to 19 years drowned in natural bodies of water.[29] More than one-half of natural water drownings occur in children younger than 14 years, and a greater proportion of these occur in urban settings with populations of more than 1 million.[39]

In-ground Pools

As opposed to open bodies of water, swimming pools have fewer drowning hazards, such as unknown depths, undefined areas, and presence of currents and waves.[12] However, swimming pools can pose a serious risk to toddlers and young children and older children who do not know how to swim. There are an estimated 6700 pool- or spa-related, hospital ED-treated, nonfatal drowning injuries and 379 pool- or spa-related fatal drownings each year involving US children younger than 15 years.[40] Of these, 75% involve children younger than 5 years. The recurring drowning scenario in pools and spas for young children includes unexpected, unsupervised access to the water. Only 17% had been last seen in or near the pool or spa before the incident and 10% had compromised or circumvented a pool or spa barrier.[40]

Pediatric swimming pool drownings occur in single-family and multifamily residences or public pools. Pediatric swimming pool drownings in single-family and multifamily residences are best predicted by the number of pools by

housing type and the number of children aged 0 to 17 years by housing type.[41] The risk of a submersion is 2.7 times higher for a child at a multifamily than a single-family residence and 28 times more likely in a swimming pool at a multifamily property than a pool at a single-family residence.[41]

Fixed and Portable Aboveground Pools

Aboveground pools can be fixed or portable. Aboveground pools can vary in size and height from small inflatable pools to larger versions that can hold thousands of gallons of water.[42] A portable pool is any movable structure intended for swimming or other water recreation, including wading pools, inflatable pools, and "soft-sided, self-rising" pools. Portable pools are increasingly popular compared with fixed aboveground pools because they can be set up and taken down or moved to another location with relative ease. Portable pools in residential settings also pose a risk of submersion-related morbidity and mortality to children.

From 2014 to 2016, there were, on average, 363 fatalities each year associated with pool or spa drownings involving children younger than 15 years. Aboveground pools accounted for 19% and portable pools accounted for 5% of these fatalities.[43]

The CPSC recommends that all pools, in-ground and aboveground, have a barrier, optimally 4-sided isolation fencing. The pool structure can serve as a barrier if the walls of the pool are high enough to meet the recommended 4-foot height for barrier fencing. Alternatively, a barrier can be mounted onto the top of the pool structure. The CPSC also recommends that, if the pool walls are not high enough, the steps or ladder leading to the pool be secured, locked, or removed or surrounded by a barrier to prevent access when the pool is not in use.[42] The American Society for Testing and Materials (ASTM) has published a standard (F 2666-16) for aboveground pools for residential use that addresses structural integrity, sanitation, electrical safety, and safety message labeling.[44]

Unfortunately, many parents do not consider fencing for an inflatable or portable pool, and such pools often fall outside of local building codes that require pool fencing. Because they contain such large amounts of water, these pools are often left filled for weeks at a time, presenting a continuous danger. The soft sides of some models allow children to lean over and easily fall into the pool headfirst. Ladders supplied with inexpensive aboveground pools generally cannot be locked to block access and are cumbersome to remove from the pools. Whether portable or fixed, children may be able to gain access to the water more easily than parents and caregivers intend. Children can enter the pool using the pool ladder (68%) or by climbing on a nearby object (20%).[45] In a study of aboveground pools, children between 42 and 54 months of age were shown to be able to climb into a pool with a 48-inch wall, even if the ladder was removed.[46]

It is important to stress that no single intervention is fully protective. Rather, multiple layers of protection are recommended. Industry is advised to develop affordable and effective products that include isolation fencing, safety covers, and alarms for portable pools. Extensive public education should stress that children can drown in portable pools. These efforts should be combined with strategies that reduce drowning risk, such as close supervision, CPR education, and methods to prevent unsupervised children from gaining access to these pools.[47]

Drain Entrapment

Entrapment and hair entanglement remain causes of injury and drowning in the pediatric population. The CPSC reported 11 victims of circulation entrapment from 2014 to 2018 (4 pool and 7 spa), including 2 fatalities, all in children aged 0 to 14 years, with the peak in the 5- to 9-year age group.[48] A circulation entrapment is defined as an entrapment involving the water circulation system of the product. Hair entanglement typically involves girls with long hair who are underwater near a suction outlet. The water flow into the drain sweeps the hair into and around the drain cover, where it becomes entangled in the holes and protrusions of the cover. Other types of entrapment involve a limb or body part. This scenario often involves a child playing with an open drain, inserting a hand or foot into the pipe, and then becoming trapped by increasing suction and resulting tissue swelling. Deaths occur from drowning.

Entrapment and entanglement can be prevented by the use of special drain covers, safety vacuum release systems (SVRSs), filter pumps with multiple drains, and a variety of other pressure-venting filter construction techniques.[49] Unfortunately, many parents and pool and spa owners are not aware of the risk of entrapment and entanglement; only 15% have installed antivortex drain covers, only 14% have multiple drain systems, and only 12% have SVRSs in their pools or spas.[50] In 2007, Congress passed the Virginia Graeme Baker Pool and Spa Safety Act, which requires drain covers, unblockable drains, and SVRSs for all public pools and spas in the United States.[51] The act markedly reduced the number of injuries and deaths attributable to drain entrapment.[52] Although the act does

not apply to private pools, residential pool owners can protect against entrapment by implementing the recommendations reflected in the legislation.

Lapses in Adult Supervision

Although poor supervision is often cited as a contributing factor for childhood drowning, especially for younger children,[18,53,54] an accepted definition for adequate supervision is lacking.[55] Supervisory behavior has been described as being composed of 3 components: proximity, attention, and continuity.[56] Attention and continuity are related to awareness, and proximity is related to the ability to intervene if needed. Proximity might be particularly important for young children and/or nonswimmers. For beginning swimmers, adequate supervision should include "touch supervision" in which the supervising adult is within arm's reach of the child so they can pull the child from the water if the child's head becomes submerged. High levels of all 3 components are likely necessary to keep children safe when around water. When children are not intended to be in or around the water, differing levels of the components may be appropriate, but the inevitable decreases in attention and proximity and lapses in continuity highlight the need for barriers to prevent water entry. It is important to note that supervision cannot replace barriers, and barriers cannot eliminate the need for supervision; they should work in conjunction with each other.

Drowning most often occurs quickly and quietly during periods of inadequate supervision. In Bangladesh, a case-control study of unintentional injury deaths among children younger than 5 years found that fatalities were 3 times more likely to occur in unsupervised children compared with matched, alive children.[22] Among 127 drowning deaths in children examined by a state's child death review teams, 38 (30%) were not in the care of an adult (4% unsupervised entirely, 25% with other children or friends, 4% at a location with lifeguards present). In deaths occurring among children younger than 5 years, teams identified inadequate supervision and isolated neglect as a factor in 68% (21 of 31) of cases.[18] When responding to an online questionnaire, parents admitted that they talked to others (38%), read (18%), ate (17%), and talked on the phone (11%) while supervising their child near water.[57] In a study of 496 drowning deaths in children younger than 14 years that were reviewed by state child death review teams, only 10% were completely unsupervised at the time of the drowning.[57] A more recent examination of national child death review data found that supervision was assessed to be lacking in 49% of incidents involving children drowning in pools. Caregivers often provided inadequate supervision because of drug or alcohol impairment, injury or illness, or distraction. Necessary supervision was noted to be lacking more often among drowning deaths involving younger children compared with older children.[54] Similarly, in an Australian study of 339 unintentional drowning deaths among children aged 0 to 14 years, coroners identified lack of supervision as a contributory factor in 72% of cases.[53]

Parental perceptions regarding necessary levels of supervision change as children progress through swim training, potentially to the detriment of the child's safety.[58,59] In a survey of parents of children aged 2 to 5 years enrolled in community swim lessons 4 times over 8 months, as parents' perceptions of their child's swim skill increased, their belief in the child's ability to keep themselves safe in the water increased and their perception regarding the need for parental supervision decreased.[59] The sociocultural norms and environment of a community can also influence parental perceptions and resultant supervisory behavior that is deemed appropriate.[60]

Alcohol

Alcohol plays a significant role in drowning risk related to boating, swimming, and supervision. A meta-analysis found that 30% to 70% of swimming and boating fatal drowning victims had a measurable blood alcohol concentration (BAC) and that 10% to 30% of these deaths could be attributed specifically to alcohol use.[61] In boating, there is evidence that the relative risk of drowning death is directly related to BAC, with a 16-fold greater risk when BAC was greater than 0.10 (100 mg/dL).[62] Boat passengers are at risk for alcohol-related drowning regardless of the alcohol use of the boat operator.[63] Most drownings associated with alcohol occur during recreational periods, over weekends, and in the afternoon. A longitudinal study showed that a decrease in regional unintentional drowning rates was associated with a decrease in deaths attributable to alcohol use.[64,65]

Alcohol may increase the risk of drowning not only by impairing judgment and performance but also through physiologic effects (eg, poor balance, impaired orientation, hypothermia) that affect survival once submersion occurs.[62] Alcohol use while boating is also significantly associated with low or no life jacket use.[66] Little information is available regarding the association of drug use and

drowning. In a 10-year retrospective study from Ohio, researchers found that only 3% of 141 accidental drowning deaths were associated with illicit drugs.[67]

Studies examining the relationship of caregiver alcohol use and unintentional childhood injury indicate that caregiver-reported number of drinks predicted decreased caregiver supervision and a higher likelihood of children sustaining injury.[68,69] Avoidance of alcohol and drug intake positively affects caregivers' prevention of and recognition and response to a child struggling to swim in water, resulting in better drowning surveillance. Alcohol and other drug use should be avoided when swimming, boating, or supervising children in and around the water. Boaters should be educated about the dangers of consuming alcohol when operating or riding in a watercraft, and authorities should enforce local Boating Under the Influence legislation.

At-Risk Populations

Certain populations are at increased risk of drowning because of behavioral, skill, or environmental factors as well as underlying medical conditions.

Toddlers

For the period 2014–2018, the highest rate of drowning occurred in the 0- to 4-year age group (2.26 per 100 000 population), with children aged 12 to 36 months being at highest risk (3.38 per 100 000). Most infants drown in bathtubs and buckets, whereas the majority of preschool-aged children drown in swimming pools.[29] These children are developmentally curious and drawn to water but lack the awareness of its dangers. For instance, as many as 35% of typically developing children aged 10 to 18 months can climb into a bathtub.[70]

Therefore, the primary problem for this young age group is lack of barriers to prevent unanticipated, unsupervised access to water, including swimming pools, hot tubs and spas, bathtubs, natural bodies of water, and standing water in homes (buckets, tubs, and toilets). The CPSC found that 69% of children younger than 5 years were not expected to be at or in the pool at the time of a drowning incident.[71]

Adolescents

Older adolescents (aged 15 to 19 years) have the second-highest fatal drowning rates. In this age group, approximately one-half of all drownings occur in natural water settings.[72] In 2016, SafeKids Worldwide reported that the natural water fatal drowning rate for adolescents aged 15 to 17 years was more than 3 times higher than that for children aged 5 to 9 years and twice the rate for children younger than 5 years.[54] Adolescence is a formative period, often involving seeking high-intensity and exciting experiences and sensations.[73] During this time, adolescents are especially vulnerable to the presence of peers. The mere presence of peers promotes risk-taking activity, especially if the adolescent has experienced previous social isolation.[74] This behavioral psychology plays a role in vulnerable teenagers, especially adolescent boys of racial and ethnic minorities, in social aquatic activities. The increased risk for fatal drowning in adolescents can be attributed to several factors, including overestimation of skills, underestimation of dangerous situations, engagement in high-risk and impulsive behaviors, and substance use.[75] Alcohol remains a leading factor in drowning deaths among adolescents and adults, contributing to 30% to 70% of recreational water deaths among US adolescents and adults.[76] Providing drowning prevention anticipatory guidance to adolescents and their caregivers, especially relating to alcohol use, can help address reported low rates of water safety knowledge in this age group.[77]

Boaters

In 2019, the US Coast Guard reported 46 boating deaths in individuals aged 19 years and younger, with 59% attributed to drowning; the remainder were mostly attributable to trauma. The majority (78%) of the boating deaths in this age group occurred while riding in an open motorboat (39%) or canoe or kayak (39%). Analysis of all fatal boating incidents revealed that 70% of the operators had not had boating safety instruction, and 23% of the incidents cited alcohol as a leading factor.[78]

Most boating-related drowning deaths (86%) occur among individuals who are not wearing a life jacket.[78] In children younger than 14 years, nearly 45% of those who died in a boating-related incident were not wearing a life jacket.[57] Federal law requires life jacket use for children younger than 13 years on recreational boats in the United States. In an observational study of small boats, researchers found that 90% of children younger than 5 years wore life vests, but only 13% among those aged 14 years or older wore life vests.[79] Trends in life jacket use from 1999 to 2010 showed an increase in life jacket use across all pediatric age groups in all boat types, but only an increase among adult boaters in sailboats.[80] Another observational study of swimmers and waders in designated swim areas revealed that life jacket and other flotation device use decreased with increasing age,

with 50% of children younger than 6 years using a life jacket compared with 3% of adults.[81]

Underlying Medical Conditions

Epilepsy

Epilepsy is a known risk factor in drowning, and drowning is the most common cause of death from unintentional injury for people with epilepsy, most commonly in bathtubs.[82] Children with epilepsy have a relative risk for fatal and nonfatal drowning 7.5-fold to 10-fold higher than children without seizures.[83,84] Drowning risk is dependent on such factors as age, severity of illness, degree of exposure to water, and level of supervision.[83–85]

Despite this drowning risk, water-based activities such as swimming can be safe for children with epilepsy, especially for those with well-controlled seizures (as defined by the child's neurologist). Many children with epilepsy learn to swim (and can do so safely), and some children with epilepsy swim competitively. Children with poorly controlled seizures (as defined by the child's neurologist) might be safest with one-to-one direct supervision (ie, constantly attentive and ready to quickly intervene) during water-based activities. Bathtubs and shallow water can present a hazard for any child with epilepsy, and showers are preferred over baths when age appropriate.[17]

Parents of children with poorly controlled seizure disorders should have a discussion with their child's neurologist or pediatrician before any swim activity. Whenever possible, children with epilepsy should also consider swimming only at locations where there is a lifeguard to add a layer of protection to their one-to-one supervision.

Autism

Children with ASD are at increased risk of drowning. A 2017 study revealed that unintentional injury deaths were nearly 3 times as likely for all individuals with ASD compared with the general population.[86] This excess risk was particularly high for children with greater degrees of intellectual disability[87] and for those younger than 15 years, who were reportedly 40 times more likely to die of injury.[86] Drowning, specifically, is a leading cause of unintentional injury deaths among children with ASD.[86] Wandering was the most commonly reported behavior leading to drowning, accounting for nearly 74% of fatal drowning incidents among children with ASD.[88] It has been proposed that swimming lessons be provided to children after the diagnosis of ASD is made.[86] A small pilot study of an 8-hour aquatic group therapy program demonstrated a statistically significant increase in water safety skills among children with ASD.[89] However, swimming instruction alone may not confer the necessary ability to transfer learned skills from one water setting to another. Supervision and barriers with alarms are critical layers of protection against drowning for children with ASD and other disabilities. Additionally, removal of enticing toys from the pool area when the pool is not in use is advised. The National Autism Association's Big Red Safety Box[90] is a resource that aids in development of a safety plan for public places where there is a handoff of supervision so that children with ASD and other disabilities do not wander off.

Attention-Deficit/Hyperactivity Disorder

Although it has not been specifically examined, children with a diagnosis of attention-deficit/hyperactivity disorder (ADHD) may have an increased risk of drowning related to increased risk taking and impulsivity. Studies suggest a strong association between ADHD and risk of all unintentional injuries.[91,92] Studies have demonstrated a reduction in unintentional injury risk among those children diagnosed with ADHD who are being treated with medication.[92,93]

Other Neurologic Diagnoses

For children with neuromuscular junction and muscle diseases or peripheral neuropathies, risk of participation in water-based activities may depend on the degree of fatigability and whether the disease is rapidly degenerative. If engaging in water-based activities, consultation with the child's neurologist and one-to-one adult supervision (ie, constantly attentive and ready to quickly intervene) is advised. Children with movement disorders, hemiplegia or diplegia (eg, cerebral palsy, stroke), white matter diseases (eg, adrenoleukodystrophy), and neuroimmunological disorders (eg, multiple sclerosis), have varied effects of the diseases on water safety and may have individualized capabilities. Therefore, consultation with a child's neurologist is advised regarding participation in water-based activities. Children with implantable devices (eg, ventriculoperitoneal shunts, vagus nerve stimulators) are also advised to consult their neurosurgeon about water safety.

Cardiac Arrhythmias

Exertion while swimming can trigger arrhythmia among individuals with long QT syndrome.[94] Although the condition is rare and such cases represent a small percentage of drownings, long QT syndrome should be considered as a possible cause for unexplained submersion injuries among proficient swimmers in low-risk

settings. Additionally, Brugada syndrome and catecholaminergic polymorphic ventricular tachycardia may also lead to increased risk.[95] This increased drowning risk underscores the need to counsel on the importance of close supervision for any child or adolescent with these conditions when in or around water.

Interventions

In the Haddon matrix of injury prevention, safety interventions are aimed at changing the environment, the individual at risk, or the agent of injury (in this case, water). For drowning prevention, the environment and the individual are the prime targets (Table 3). Experts generally recommend multiple layers of protection be used to prevent drowning because no single strategy is likely to prevent all submersion deaths and injuries. Such layers might include environmental changes, such as adult supervision, antientrapment and antientanglement measures, pool fencing, pool covers, water entry alarms, lifeguards, and CPR training. Additional prevention layers focused on the individual would include strategies such as swimming and survival skills training and use of life jackets. A concise list of recommendations can be found in the AAP policy statement "Prevention of Drowning."[96]

Adult Supervision

Close, attentive, and constant supervision of young children when they are in or around any body of water is an essential preventive strategy.[18,53] Appropriate supervision also includes examination of any unfamiliar environment for water hazards (eg, unfenced pool or pond) and prevention measures (eg, doors locked, gates closed). Adequate supervision should include being capable of recognizing and responding appropriately to a swimmer in distress. Diligent supervision, along with other measures, may be increasingly important among children with conditions that increase drowning risks, such as ASD or seizures, as noted above. Additionally, supervision is paramount in environments where barrier fencing is not possible.

Unfortunately, parents and caregivers may have misperceptions about what drowning looks like and how to appropriately supervise children.[54,97] In a survey of 1003 parents of children aged 0 to 12 years with access to a pool, researchers found that 48% of parents mistakenly believed they would be able to hear splashing or crying if their child was in trouble in the water, 56% believed that a lifeguard, if present, is the primary person responsible for supervising their child, and 32% reported leaving their child entirely unsupervised in a pool for 2 minutes or longer.[54]

Because young children who fall into water often make no noise and can be hard to see below the water surface, proper care of a young nonswimmer or beginning swimmer requires the supervising adult to be constantly attentive, in close proximity (ie, within arm's reach) and prepared to intervene. To stress the importance of supervision, as part of a water safety program, some communities promote "water watchers," encouraging a designated adult (identified with a hat or lanyard) to be responsible for constant supervision without engaging in any distracting activities.[39] However, these programs have not been evaluated. In an attempt to improve parental supervisory behaviors at public pools, an educational program (Keep Watch @ Public Pools) was piloted in Melbourne, Australia. At intervention pools, researchers observed improved attention, proximity, and preparedness among parents of children aged 6 to 10 years but no significant changes among parents of younger or older swimmers.[98]

Appropriate adult supervision for children around water is close, constant, competent, and attentive. In addition, supervisors need to know what a distressed swimmer looks like and how to safely intervene if needed. Development and evaluation of effective water safety education for parents are still needed.

Antientrapment and Antientanglement Measures

Entrapment and entanglement prevention measures include use of special drain covers, SVRSs, filter pumps with multiple drains, and a variety of other pressure-venting filter construction techniques.[49] Although such devices are required in commercial pools, they are often not required in residential pools.[47] Residential pool owners should be educated to include these effective safety measures.

Pool Fencing

Pool fencing is one of the most important prevention strategies to decrease the risk of drowning in swimming pools when children are not supposed to have access to the water. Compared with no fencing, installation of 4-sided fencing that isolates the pool from the house and yard has been demonstrated to decrease the number of pool immersion injuries among young children by more than 50%.[99–101] A Cochrane meta-analysis of available studies found that the odds ratio for a drowning in a fenced versus an unfenced pool was 0.27 (95% confidence interval [CI]: 0.16–0.47). In this analysis, 4-sided fencing

TABLE 3 Haddon Matrix for Drowning Prevention Strategies With Associated Levels of Evidence

	Personal	Equipment	Physical Environment	Social Environment
Pre-event	Provide close, constant, attentive supervision of children and poor swimmers[a]	Install 4-sided fencing that completely isolates the pool from the house and yard[b]	Swim where there are lifeguards[a]	Mandate 4-sided residential pool fencing[b]
	Evaluate preexisting health condition[c]	Install self-closing and latching gates[b]	Attend to warning signage[c]	Mandate life jacket wear[b]
	Develop water competency, including swim ability[a]	Wear life jackets[b]	Swim at designated swim sites[c]	Adopt the Model Aquatic Health Code[c]
	Know how to choose and fit a life jacket[c]	Install compliant pool drains[a]	Remove toys from pools when not in use to reduce temptation for children to enter the pool[c]	Increase availability of lifeguards[a]
	Avoid substance use[a]	Install door locks[c]	Empty water buckets and wading pools[c]	Increase access to affordable and culturally compatible swim lessons[c]
	Know the water's hazards and conditions[c]	Enclosures for natural bodies of water[c]	Lakefront slope gradient[d]	Close high-risk waters during high-risk times[d]
	Swim at a designated swim site[d]	Promote life jacket loaner programs[c]		Develop designated natural water swim sites[d]
	Learn CPR[b]	Role model life jacket use by adults[a]		Enforce Boating Under the Influence laws[b]
	Take a boater education course[c]	Make rescue devices available at swim sites[c]		
	—	Provide ability to call for help[b]		
	—	Ensure functional watercraft[c]		
Event	Water survival skills[c]	Rescue device available[c]	Lifeguard or bystander response[b]	Emergency Medical System[b]
Postevent	—	AED[c]	Early bystander CPR[b]	Advanced medical care[c]
	—	Rescue equipment[c]	EMS response[b]	

[a] Trials or diagnostic studies with minor limitations; consistent findings from multiple observational studies.
[b] Well-designed and conducted trials, meta-analyses on applicable populations.
[c] Expert opinion, case reports, reasoning from first principles.
[d] Single or few observational studies or multiple studies with inconsistent findings or major limitations.

(which isolates the pool from the house and yard) was superior to 3-sided fencing (which allows direct access to the pool from the house) with an odds ratio of 0.17 (95% CI: 0.07–0.44).[101] In an Australian study, researchers found that the risk of a child drowning in a pool with 3-sided fencing was almost twice that seen in pools with 4-sided fencing (incidence rate ratio, 1.78; 95% CI: 1.40–1.79).[28]

Unfortunately, laws and ordinances regarding pool fencing may have dangerous loopholes. The Virginia Graeme Baker Pool and Spa Safety Act defined minimum state law requirements as "the enclosure of all outdoor residential pools and spas by barriers to entry that will effectively prevent small children from gaining unsupervised and unfettered access to the pool or spa."[51] Three-sided fencing with self-locking or alarming doors between the house and pool area are often considered acceptable, and, in some locales, pool covers can substitute for a fence. Often, a fence law pertains only to new pool construction or to homes in which a young child is actually living at the time of the pool installation. Furthermore, in the United States, pool fences are rarely inspected and ordinances are often not enforced. In a recent Australian study, researchers found that government inspections raised the rate of compliance with pool fencing laws from approximately 50% to 97%.[102] Another study from Australia revealed that in the 5 years after enactment of legislation to improve the effectiveness of pool fencing, the number of private swimming pool drowning deaths halved.[103]

Children's ability to climb fences varies with the type of fence. In one study, chain-link fences were easily scaled by children, whereas ornamental iron bar fences proved more difficult to climb.[104] Fences should be at least 4 feet high, and no opening under the fence should be more than 4 inches (some building codes require a 5-foot fence and a maximum fence-to-ground

distance of only 2 inches). Vertical members of the fence should be less than 4 inches apart to keep a child from squeezing through, and there should be no foot- or handholds that could help a young child climb the fence. The fence should not prevent a clear view of the pool. Gates should be self-closing and self-latching, with the latch placed at least 54 inches above the bottom of the gate. The gate should open away from the pool (so that it will not open if leaned on) and should be checked often to ensure good working order. Pool gate alarms may provide additional protection, but no research exists on their efficacy. Detailed guidelines for safety barriers for home pools are available online from the CPSC,[42] but homeowners must also be aware of local laws and building codes regarding pool fence construction and after installation continue to check the fence and gate's integrity.

Pool Covers

Retractable pool covers and pool nets capable of holding the weight of a child have been advertised as effective barriers for drowning prevention. Because these covers must be removed and replaced each time the pool is used, they are less likely to be effective. Active interventions requiring an action each time they are to be used are proven to be less effective than passive interventions, which are always in effect.[105,106] The CPSC states that power safety covers can be installed on pools to serve as a security barrier, especially if the pool is not completely separated from the house and the yard by a fence.[42] However, there is currently no evidence to support this recommendation, and pool covers may impart a false sense of security. Because there are no studies regarding the efficacy of pool covers, they cannot be recommended as a substitute for isolation fencing.

On the contrary, some types of pool covers actually present a hazard for children. In 1980, the CPSC issued a warning about solar pool covers that are designed to keep the water warm and minimize pool chemical and water evaporation. When children try to walk on or remove these thin sheets of plastic, they can drown when they become entangled in the cover or hidden from view.[107] Additionally, even weight-bearing pool covers can make it difficult to see beneath them, potentially concealing a drowning victim.

Alarms

Pool Alarms

The CPSC has evaluated the performance of surface, subsurface, and wristband pool alarms. Several of these alarms functioned properly; however, the report concluded that alarms "should not be relied on as a substitute for supervision or a barrier completely surrounding the pool." No study has demonstrated whether pool alarms prevent drowning.[108] Additional research is needed to evaluate the efficacy of pool alarms, door alarms, and pool covers in the prevention of drowning.

Door Alarms

Many homes with pools, including private residences and homes used as vacation rentals, have doors that open directly into the pool area. It is important that all homes with pools have security measures in place so that children cannot enter the pool area unsupervised. Door alarms are one way to alert that the child has gained access to the pool area. The CPSC recommends that door alarms sound for at least 30 seconds within 7 seconds of the door opening, that the alarm be loud and distinct from other sounds in the house, and that the alarm have an automatic reset feature.[42] Effectiveness of door alarms has not been studied, and they should only be used as an adjunct to other proven layers of protection against drowning.

Lifeguards

Although no formal scientific study has quantified the value of lifeguards, anecdotal reports indicate that drowning rates are lower when lifeguards are present.[109] The United States Lifesaving Association (USLA) reports that more than 75% of drownings at USLA sites occurred at times when the beaches were unguarded, and the estimate that a person will die by drowning while protected by USLA-affiliated lifeguards is 1 in 18 million.[110] In addition to rescue efforts, lifeguards serve to make beaches safer by monitoring the aquatic environment, enforcing rules and regulations, and educating beachgoers about safety and injury prevention. Lifeguards most often perform prevention activities (54.8%), with rescues representing only 1.9% of lifeguard interventions.[111] Studies indicate that lifeguards are cost-effective[112,113] and reduce situations likely to end in injury or drowning.[109] Those choosing to swim in natural bodies of water or other sites accessible to the public should swim in designated swim areas with lifeguards present.

Although lifeguards are an important layer of protection against drowning, they are only one part of a multilayered approach. A study examining fatalities in lifeguarded US swimming pools found that, in fatal incidents, swimmers and pool bystanders were twice as likely to identify the submersion victim as were lifeguards.[114] A survey found that 20% of parents interviewed thought that the lifeguard was the main person responsible for supervising

their child while in the water, leading to a false sense of security and a resultant lack of parental supervision.[57] Nevertheless, trained, professional lifeguards provide a significant layer of protection to swimmers, especially through trained rescue and resuscitation in the event of a significant submersion. However, lifeguards do not take the place of caregiver supervision.

Bystander CPR

Immediate resuscitation at the submersion site, even before the arrival of emergency medical services (EMS) personnel, is the most effective means to improve outcomes in the event of a submersion incident.[2,3] Prompt initiation of bystander CPR and activation of prehospital advanced cardiac life support for the pediatric submersion victim have the greatest effects on survival and significantly improved neurologic prognosis.[4,115]

Although the Centers for Disease Control and Prevention recommends all caregivers and supervisors of children be trained in CPR,[32] several strategies can increase first response skills, including rescue and infant and child CPR training for caregivers of at-risk drowning populations. A video on drowning risk, pool fencing, and CPR shown to pregnant pool owners increased their likelihood of obtaining CPR instruction compared with those not shown the video.[116] Another study, the American Heart Association's "Child CPR Anytime," a 25-minute CPR instruction given to parents while their children were in a community swim lesson, led to significant sustained improvement in parental knowledge and confidence in performing CPR.[117]

Drowning can be described as a continuum, with an initial phase of respiratory arrest but intact circulation that will progress to cardiac arrest if hypoxia persists. In the first stage of the drowning continuum (ie, after a witnessed or brief submersion), rescue breathing to provide effective ventilation of the victim may be sufficient if circulation remains intact. As the drowning victim progresses from respiratory arrest to cardiac arrest (no palpable pulse), resuscitation using the compressions-airway-breathing sequence is initiated. "Hands-only" CPR is not appropriate for drowning victims because hypoxia is almost exclusively the cause of cardiac arrest resulting from drowning.[118] In a recent study on bystander CPR after drowning, resuscitation of victims aged 5 to15 years using compression and ventilation CPR was statistically significantly associated with neurologically favorable survival and survival to hospital discharge compared with compression-only CPR.[119]

Automated external defibrillator (AED) use may not be beneficial in resuscitation of the drowning victim as opposed to other etiologies of cardiac arrest. In a recent study, application of an AED before the arrival of EMS, even for patients found to have a shockable rhythm, was associated with decreased likelihood of favorable neurologic outcome.[115] Authors postulated that lay rescuers may have prioritized AED application over ventilation provided by CPR or had prolonged resuscitation duration until arrival of EMS.[115] The Heimlich maneuver is not recommended because positive-pressure ventilation by mouth or mask will accomplish adequate oxygenation without the delay caused by performing the Heimlich maneuver.[108] Current American Heart Association guidelines recommend that drowning victims who require any form of resuscitation (including only rescue breaths) be transported to the ED for evaluation and monitoring, even if they appear alert with effective cardiopulmonary function at the scene.[120]

Swimming Lessons, Water Survival Training, and Water Competency

All children should eventually learn to swim. Swim skill and water competency may be the most important drowning prevention measures in natural water settings because fencing and lifeguarding may be impractical in these settings. The position of the AAP has focused on the child being "developmentally ready" for formal swimming lessons. Developmental readiness for swim lessons is multifaceted; the determinant of readiness is not the child's age but the confluence of physical, social, behavioral and emotional, and cognitive skills balanced against the environmental risks of drowning.

It has been demonstrated that children aged 2–4 years can acquire the motor skills for swimming and that most children aged 4.5 years are developmentally ready to do so; by 5 or 6 years of age, most can master the front crawl.[121–123] Subsequently, Brenner et al revealed the preschool age group experienced a reduction in fatal drowning risk if they had had swim lessons,[124] as did Yang et al in a study of Chinese preschoolers.[125] School-aged children in the Bangladesh SwimSafe Program were demonstrated to have significantly decreased drowning rates.[126]

Before a case-control study of swimming lessons,[124] concerns about early swim lessons were based on the fear that swim lessons might increase drowning risk,[127] with the premise that parents whose children were in swim programs would have a false sense of security, resulting in inadequate supervision around water. Several studies have shown that parents of small children enrolled in swimming lessons were more likely to endorse the statements "swimming lessons are the best way to prevent drowning,"

"toddlers can learn to save themselves if they fall into water," and "it is better to develop swimming ability rather than rely on adult supervision."[128,129] When these parents were given a targeted educational program to reverse misconceptions about toddler water safety or given feedback about their child's progress or stories of close calls, they were more likely to agree that their child required more, not less, supervision and more likely to disagree that swimming lessons were the best way to prevent drowning.[58,128] Thus, swim lessons should include parental training to improve the parents' understanding of their child's actual swimming abilities and continued risk.

The American Red Cross Scientific Advisory Council defines basic swim skills as the following: ability to enter the water, surface, turn around, propel oneself for at least 25 yards, and then exit the water.[129] It is important to recognize that performance of these water survival skills, usually learned in a pool, is affected by the aquatic environment (water temperature, movement, depth, clothing, distance), for which a person may be unprepared. Demonstration of skills in one aquatic environment may not transfer to another. Effective swim lessons should provide repeated and progressively more experiential training, including swimming in clothes, swimming in life jackets, falling in, and self-rescue. Consequently, achieving basic swim skills requires multiple sessions of lessons. Thus, parents need to be aware of their child's progress and keep their child in lessons until basic water competency skills are achieved. More research is needed to determine which types of swim instruction and water survival skills training are most effective in preventing drowning in children of all ages.

The international drowning prevention community has begun to expand the concept of water competency to include needed skills, knowledge, and behaviors.[5] In addition to basic swim skills, water competency should include knowledge of local hazards in the aquatic environment, risk judgment and self-assessment of abilities, and recognition and response to a person in distress in the water, including safe rescue and CPR.[5] Thus, acquisition of water competency is a protracted process that involves learning in conjunction with developmental maturation and physical skill sets by the child.

Barriers to swim lessons and water competency are more commonly based in cultural norms, economics, and access. Black communities have reported a legacy of reluctance to engage in swimming related to long-standing segregation and exclusion from public pools.[130] Vietnamese immigrant families reported that pool environments are alien and cold and recreational swimming is not valued.[131] Clothing that protects modesty may not be allowed in some pools, and, for some religious and ethnic groups, single-sex aquatic settings are required.[17] In addition, the multiple swim sessions required to achieve basic water competency can be costly, and access to affordable, convenient, and culturally appropriate swim lessons may be limited. Moreover, decreased municipal funding for swimming pools and lifeguards has worsened access to swimming lessons and safe water recreation in many communities. These barriers can, and should, be addressed through community-based programs targeting high-risk groups by providing free or low-cost swim lessons, developing special programs and changing pool policies, using language and culturally appropriate instructors to deliver water safety classes, and working with health care clinics and places of worship to refer families to swim programs.[17,132]

Although early instruction may be beneficial, there are currently no data to support a recommendation for infant swim lessons. Aquatic programs for young children (especially those younger than 1 year) pose some medical concerns, and initiation of a swim program should be discussed between an infant's caregiver and pediatrician. These include the risk of gastrointestinal tract infections, dermatitis, and acute respiratory illness that result from exposure to infectious agents and pool chemicals. Hyponatremia from ingesting water and hypothermia are also health risks to the infant.[133] Fortunately, medical problems from swimming are rare, treatable, and preventable events.[134,135] The World Aquatic Babies and Children Network has published guidelines for the operation of aquatic programs for children younger than 3 years. The guidelines recommend (1) required parental involvement, (2) a fun atmosphere with one-on-one teaching, (3) qualified teachers, (4) warm water to prevent hypothermia, (5) maintenance of water purity, and (6) a limited number of submersions to prevent water ingestion and hyponatremia.[136] The American Red Cross has resources for choosing a swim program.[137]

Multiple studies have found that exposure to chlorination byproducts in swimming pools can damage respiratory epithelium and can result in a child's predisposition to asthma and bronchitis and other allergic conditions.[138–142] However, a longitudinal study of children from birth to age 7 to 10 years revealed no increased risk of respiratory symptoms, allergy, or asthma among those with chronic but

noncompetitive swimming pool exposure. In fact, their lung function was better.[141]

The AAP supports swimming lessons for children older than 1 year. Swim lessons are increasingly available for children with various disabilities, including autism, or other health conditions. A parent's decision about when to initiate swimming lessons must be individualized on the basis of a variety of factors, such as frequency of exposure to water, health concerns, emotional maturity, and physical limitations, while considering that toddlers aged 12 to 36 months are at highest risk of drowning. It must be stressed that swimming lessons, in isolation, will not drown-proof a child. The goal of swim lessons is to reduce the risk of drowning but also to promote and prepare for parent-child activities, exercise, fun, and enjoyment of the long process of acquiring aquatic learning and water competency. Swim ability must be considered as only one part of water competency and of a multilayered protection plan involving effective pool barriers, constant and capable supervision, life jacket use, and lifeguards. Parents and guardians of children should become an integral component of aquatic programs to facilitate and continue development of their child's water competence.

Importantly, parental acquisition of water competency knowledge and behaviors are critical to reinforce and promote the child's water competency. Because parents and caregivers are usually the most immediate layer of protection, they need to learn key physical skill sets, too. Untrained rescuers, such as a parent or bystander, often die when they enter the water to attempt the rescue of a drowning victim.[143–145] Even a small child can drown an untrained rescuer. Sometimes the primary drowning victim survives, whereas the intended rescuer, often a male relative, fatally drowns; other times, both die.[144] Because rescuer safety must be the priority, only people trained in the advanced skills of water rescue should enter the water. Safer rescue techniques should be taught to children and their parents as a part of comprehensive water safety training during swim lessons.[146] These techniques involve reaching with an object or throwing something that floats to avoid water entry ("Reach, throw, or row; don't go"). Safe rescue of a drowning person requires knowing one's limitations, risks, and training to avoid putting oneself at risk.

Life Jackets

Life jackets prevent drowning by keeping the airway out of the water when the user is immersed. Life jacket requirements for boaters have been promoted by the US Coast Guard and watersports organizations. Life jackets prevent drowning deaths; the use of an approved life jacket decreased boat-related drowning morbidity and mortality by 50%.[147,148] Unfortunately, their use remains low; US Coast Guard boating statistics from 2017 indicate that in only 15.5% of fatal drownings among all ages, the victims were wearing a life jacket.[78] However, in the past 10 years, life jacket use among children and teenagers younger than 18 years in boats has increased from 56% to 65% nationally. Reasons commonly cited for not wearing a life jacket include beliefs that drowning risk is low; that life jackets restrict movement, are uncomfortable, or are unattractive; and that wearing a life jacket is a sign of fear or inexperience.[66] Recent changes in life jacket design address some of these concerns. Parents of children who do not always wear life jackets report reasons including the following: (1) the parent is in close proximity to the child, (2) a life jacket for the child is onboard in case of emergency, and/or (3) the child has good swimming skills.[57] Importantly, many drowning incident reports include parents who drown while attempting to help their child.[143,145]

Life jacket use has expanded beyond boating; they are increasingly used for children who are weak swimmers or nonswimmers when near or in the water wading or swimming. In one recent study, 50% of children younger than 5 years wore one when in the water at designated natural water swim sites.[81] Although anecdotal reports remain the only evidence supporting the effectiveness of life jackets for preventing drowning when swimming, the means of protection would be similar by keeping the airway out of the water.

Legislation is the most effective way to increase life jacket use, leading to 90% to 95% compliance among specific groups, such as children, people on personal watercraft, and those in activities such as water skiing.[149] Moreover, local ordinances requiring life jacket use by those near or in the water of specific high-risk waterways have led to observed increases in life jacket wear.[150] Parental modeling[148] and educational campaigns[151] can both increase life jacket use among children and teenagers in boats. Life jacket loaner programs at swimming and boating sites increase access to life jackets, often at no cost, and allow a family to choose to recreate at a safer site. Some states now require camps and other venues to provide life jackets for swimmer use.[152]

To decrease consumer confusion and increase wear, standardization of life jacket wear requirements is needed. Many states that share

bodies of natural water have different laws. Few states mandate life jacket use among boating teenagers; only Louisiana requires use for those younger than 17 years.[153] Using a risk reduction approach, state life jacket laws should include adolescents, the highest risk age group, and address small vessels, including paddle craft.

Newer life jackets address some of the barriers to their use. Inflatable life jackets are light and not bulky but are only for those aged ≥16 years, are costly, and require replacement of the inflating carbon dioxide cylinder. US Coast Guard–approved life jackets now include a model similar to the inflatable arm floats popular among preschoolers because it facilitates floating (eg, the Puddle Jumper). Parents need to check that any life jacket fits appropriately and is US Coast Guard approved because there are many similar products that do not meet safety requirements. It is important to recognize that air-filled swimming aids (such as inflatable armbands) are toys that can deflate or slip off and should not be used in place of life jackets. Information about infant and child life jackets for a variety of aquatic situations is available online from the US Coast Guard.[154]

Boating Safety

Preventing boating-related injuries and deaths requires good boat maintenance and function and safe and sober operators and passengers. Parents can teach boating and water safety to their children and prohibit alcohol use during recreational water activities. They can check that the boat operator has had boater education, does not use or allow drug or alcohol intake while boating, has appropriately sized US Coast Guard–approved life jackets available for each passenger per federal law, and will both wear a life jacket and require children to wear them.

Multiple studies using different methodologies consistently show that life jackets decrease boating-related injuries and deaths by 50%.[148] In a matched cohort control study of all boating deaths reported to the US Coast Guard, boaters who wore life jackets had 50% lower death rates compared with those who did not in the same boat.[147] In Australia, a mandatory life jacket law increased life jacket wear and also decreased boating drowning deaths by 50%.[155]

In contrast to boating requirements, all states mandate that all people wear a life jacket when on a personal watercraft or when being towed behind a boat, such as water skiing or water boarding. Life jacket wear rates among people of all ages participating in these activities are greater than 90%.[156] A national law requires that every boat has available an appropriately sized life jacket for each passenger.[153] Almost all states require children to wear a life jacket when in boats; however, the mandated upper age varies from 5 to 16 years.[153] For states lacking life jacket laws, federal law mandates life jackets be worn by children younger than 13 years on a moving boat.[153] These mandates explain why national wear rates have increased since 1999 only among pediatric age groups, including teenagers. In 2017, wear rates were 94% in children younger than 5 years, 87% in those 6 to 12 years, and 46.5% in those 13 to 17 years.[156] In contrast, despite continued efforts and recommendations by multiple organizations to promote life jacket use while boating, wear rates among adult motor boaters, the largest group of boaters, remain stagnant and low.

Boaters' life jacket wear increases when mandated[149,150,155]; the higher rates observed among teenagers, even when not mandated, may be spillover effects from pediatric laws. Wear rates also increase with adult modeling; in Washington state, if even 1 adult in the boat wore a life jacket, the likelihood of adolescent use rose to 81.4%, compared with only 36.1% of adolescents accompanied by adults not wearing a life jacket.[149]

Drowning Chain of Survival

The Drowning Chain of Survival (Fig 1) refers to a series of steps that, when enacted, attempt to reduce mortality associated with drowning. The steps of the chain are the following: Prevent drowning, recognize distress, provide flotation, remove from water, and provide care as needed. The chain starts with prevention, the most important and effective step to reducing morbidity and mortality from drowning.[157] The subsequent steps of the Drowning Chain of Survival differ uniquely from the Cardiac Arrest Chain of Survival because of the water environment; flotation is needed to keep the victim's airway out of the water and to facilitate getting them to land. The drowning time line (Fig 2) shows the different levels of actions and interventions chronologically that could interrupt each sequence of the drowning process once drowning begins.[158] These interventions may be used by the drowning victim who has swim skills to self-rescue or the parent or lifeguard who needs to recognize the child in trouble, initiate a safe rescue, and provide CPR. The time line shows that rescue and resuscitation of a drowning victim must occur within minutes to save lives. It also shows that the lay rescuers' efforts should take place out of the water to prevent the rescuer from risk of also drowning.[143,144] Moreover, it

FIGURE 1 Drowning chain of survival. Adapted from Szpilman D, Webber J, Quan L, et al. Creating a drowning chain of survival. Resuscitation. 2014;85(9):1151.

underscores the critically time-sensitive role of the parent or supervising adult in preventing a drowning and stopping it from becoming a fatality.

Outcome Predictors

The clinical outcome for pediatric drowning victims can be difficult to predict and depends on multiple factors.[159] Prognosis is ultimately dependent on the extent of cerebral hypoxia and resultant cerebral damage incurred during the initial drowning event and retrieval from the water.[160] Good outcomes (survival with no neurologic sequelae) are increased with submersion durations of less than 6 minutes and EMS response times of less than 10 minutes,[161] which can be facilitated by early rescue and initiation of bystander CPR.[2,115] The Submersion Score, a compilation of clinical signs, has identified pediatric patients at low risk for injury after significant submersion.[162] In addition, a recent study identified that low-risk patients had normal vital signs and pulse oximetry at the time of arrival to the ED.[163] Despite the common belief that young age is protective, a meta-analysis found that young age did not correlate with better outcome.[161]

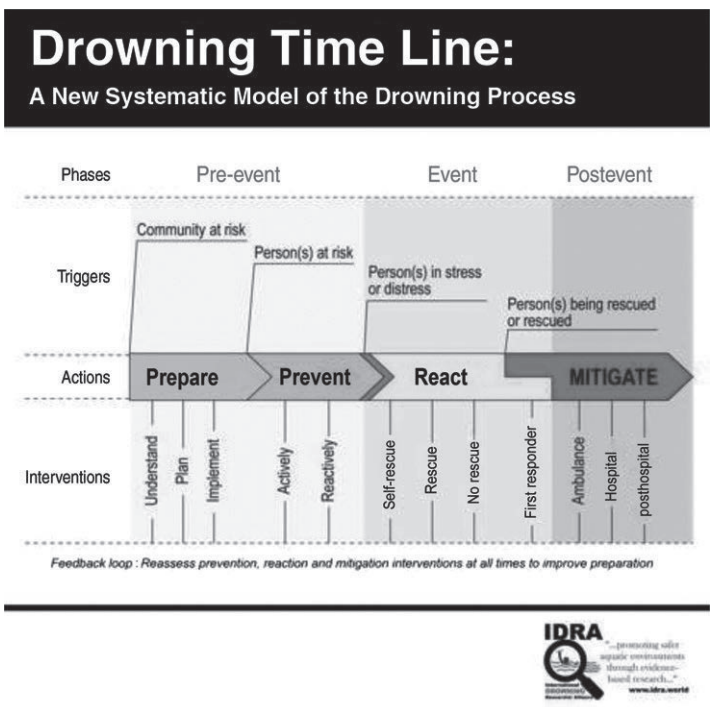

FIGURE 2 Drowning time line. Adapted from Szpilman D, Tipton M, Sempsrott J, et al. Drowning time-line: a new systematic model of the drowning process. Am J Emerg Med. 2016;34(11):2225.

The strongest predictor of poor outcome (death or survival with moderate or severe neurologic sequelae) appears to be increased submersion duration of 6 minutes or longer, with a low likelihood of good outcome after submersion greater than 10 minutes.[118,161] In a recent study on childhood swimming pool submersions, poor outcome was associated with submersions 5 minutes or longer in duration and those occurring on weekdays (possibly because events held at multiresident pools have a higher chance of bystander rescue on weekends).[164] The highest risk ratio in a recent systematic review and meta-analysis was submersion of 15 to 25 minutes' duration, with those longer than 25 minutes being invariably fatal.[161]

In addition to submersion duration, poor outcome predictors include additional prehospital factors (duration of apnea), initial ED presentation (fixed and dilated pupils, bradycardia or asystole, hypothermia, Glasgow coma scale score <5, prolonged CPR duration), and other hospital course determinants (intubation and use of inotropes); however, none are absolutely predictive of outcome.[159,165] Current evidence has not found a protective

effect of colder water temperatures for drowning victims, and hypothermia does not improve chances of survival.[95,161,166] Although acidemia on blood gas analysis (as a surrogate for respiratory failure with hypoxia) and hyperkalemia may suggest poor prognosis, there are insufficient data to adequately predict poor outcome for patients with these laboratory findings.[95]

The majority of pediatric nonfatal drowning victims have a good outcome without neurologic sequelae; however, some survivors may have significant long-term neurologic deficits. Children whose submersion duration exceeded 10 minutes had a significantly poorer health-related quality of life than those who were submerged for shorter durations.[167] Patients admitted to the hospital who demonstrated no neurologic improvement at 48 hours had a poor prognosis.[95] Factors independently associated with higher long-term mortality risk for survivors of nonfatal drownings include age 5 to 15 years and severe neurologic impairment at discharge.[168] Ultimately, because in-hospital treatment has not been demonstrated to improve drowning outcomes,[64] prevention of drowning incidents is critical.

Policy Statement

Advice pediatricians may provide to parents and recommendations for advocacy at the community level is available in the accompanying policy statement.[96]

This clinical report updates a 2006 report from the American Academy of Pediatrics titled "Sexuality of Children and Adolescents With Developmental Disabilities." The development of a healthy sexuality best occurs through appropriate education, absence of coercion and violence, and developmental acquisition of skills to navigate feelings, desires, relationships, and social pressures. Pediatric health care providers are important resources for anticipatory guidance and education for all children and youth as they understand their changing bodies, feelings, and behaviors. Yet, youth with disabilities and their families report inadequate education and guidance from pediatricians regarding sexual health development. In the decade since the original clinical report was published, there have been many advancements in the understanding and care of children and youth with disabilities, in part because of an increased prevalence and breadth of autism spectrum disorder as well as an increased longevity of individuals with medically complex and severely disabling conditions. During this same time frame, sexual education in US public schools has diminished, and there is emerging evidence that the attitudes and beliefs of all youth (with and without disability) about sex and sexuality are being formed through media rather than formal education or parent and/or health care provider sources. This report aims to provide the pediatric health care provider with resources and tools for clinical practice to address the sexual development of children and youth with disabilities. The report emphasizes strategies to promote competence in achieving a healthy sexuality regardless of physical, cognitive, or socioemotional limitations.

INTRODUCTION

As stated by the World Health Organization, "Sexual health is a state of physical, emotional, mental and social well-being in relation to sexuality … Sexual health requires a positive and respectful approach to sexuality and sexual relationships, as well as to the possibility of having pleasurable and safe sexual experiences, free of coercion, discrimination, and violence."[1] One's sexuality is experienced through one's thoughts and desires; attitudes, beliefs, and values; and actions, behaviors, and relationships.[1] Developing healthy sexuality is important for all individuals and depends, in part, on having evidenced-based and evidence-informed information to formulate attitudes and beliefs about sexual orientation, gender identity, relationships, and intimacy.[2–4] It is well known that sexual satisfaction and intimacy are directly related to quality of life,[5] and, thus, pediatric health care providers are encouraged to address the sexual health and education needs of their patients as they grow and develop to promote their patients' competence in achieving a healthy sexuality. Generally speaking, pediatric health care providers are an important resource for sexual education and counseling for children, adolescents, and young adults as well as for parents seeking anticipatory guidance.[6] Pediatric health care providers can help patients and their parents/caregivers understand their changing feelings, their changing bodies, their desires for relationships, and how to avoid risky sexual situations.[6] As is true for everyone, it is important that individuals with disabilities be provided experiences to acquire developmentally appropriate, relevant, and accurate sexual health knowledge to become competent. Youth with disabilities need regular opportunities to develop and use skills for negotiating sexual desire, intimacy, and activity that supports healthy sexuality while limiting negative outcomes of sexual activity (such as sexually transmitted infections [STIs], unintended pregnancy or sexual coercion, violence, abuse, or exploitation) regardless of their intellectual capacity. Culturally responsive pediatric health care should include sexual health as a focus for all children and adolescents, including those with disabilities, and actively involve parents and caregivers, while respecting the youth's autonomy and rights to privacy.[2]

THE SEXUAL HEALTH NEEDS OF CHILDREN AND YOUTH WITH DISABILITIES

Children with disabilities are a growing subset of children with diverse needs that affect their functioning, health, and well-being. More than 10 million children in the United States have health conditions that moderately or consistently affect their daily activities at least some of the time.[7] This means that most pediatric primary care providers routinely care for children and youth with a broad range of developmental and acquired health conditions that affect their ability to function as children typically do or require special services such as Individualized Education Programs at school.[8] Disabilities experienced in childhood may be primarily physical in nature or associated with intellectual and/or social-communication impairments or may involve co-occurring conditions. The associated health condition or etiology of the disability or disabilities, the severity of the disability or disabilities, and what aspects of functioning are affected all influence how sexuality is addressed in the clinical setting.

Developing a healthy sexuality is a complex process for all children and youth, especially those with disabilities. Sexual development is not just physiologic changes of a person's body but is a key part of social competency and should be considered in the context of basic human desires for connectedness and intimacy, beliefs, values, and aspirations. Sociosexual development is an essential part of growing up, and emphasis on this aspect of development is especially important for individuals with disabilities as they navigate changing bodies, expectations, and desires.[9] Individuals with all types of disabilities may have to negotiate varying and unique reproductive capacity and sexual intimacy issues, yet they routinely experience inadequate education and opportunities to develop competence.[10,11] Ample research indicates people with disabilities receive substandard sexual education and reproductive health care.[12–15] Families and/or caregivers of children with disabilities may be reluctant or feel that they are not empowered to acknowledge their child's potential as a sexual individual and may shelter them from the routine presexual social experiences of other children and underestimate their interest in sex and their risk for exploitation.[10,16] Helping families and/or caregivers understand their children's sexual development and how to support it may require additional time and counseling to address expectations of all involved around appropriate independence and autonomy through shared decision-making strategies.[17] In addition, children with disabilities are often limited in social participation and social networks outside of school,[10,18] which offer typical social experiences that form the developmental framework toward understanding one's own individual sexuality, interests, and behaviors. The lack of understanding about how disability affects sexual expression likely influences health care providers' willingness to

address it, as does the more general stigmatization of people with disabilities as nonsexual beings.[19]

Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition, provides the foundation for pediatric health care providers to promote healthy sexual development.[20] Care and education should be delivered through a longitudinal, developmentally appropriate, culturally respectful relationship between health care providers and their patients and families, caregivers, and educators.[20] In the last 10 years, sexuality education resources specifically designed for individuals with specific health conditions have emerged (Table 1).[21] Routine health maintenance and chronic health care visits, including health care

transition preparation visits, afford opportunities for the pediatric health care provider to gather information, give guidance, provide education, and be a resource regarding sexuality for children and adolescents with disabilities as they develop their skills and competence.[6,20,22] Pediatric health care providers can introduce issues of psychosexual development to families and caregivers and their children in early childhood and have discussions at health maintenance visits throughout childhood, adolescence, and young adulthood.[2] Doing so, on a routine basis, helps normalize the topic and helps reinforce understanding. The education should go beyond the basics of anatomy and physiology of puberty and reproduction to incorporate education about gender identity, sexual orientation, interpersonal relationships, intimacy, the types of sexual expression, and body image.[23,24] Culturally responsive care recognizes that sexuality is influenced by personal and environmental factors, such as religion or ethnic background.[2] It is essential for developmentally appropriate sexuality education to start early in childhood, with families and/or caregivers and primary care providers helping young children to develop a safe, healthy, and positive attitude toward themselves and others. This healthy and safe attitude includes understanding respect, consent, and relationship building.[25]

ADDRESSING PUBERTAL DEVELOPMENT IN CHILDREN WITH DISABILITIES

Like any child, a child with disabilities may feel anxious and unhappy about how their body is changing during puberty. The timing of onset of puberty (Table 2) in a child with disabilities may be different from that of a typically developing child.[26] Some patients with severe nutritional issues may be late to go through puberty because of failure to thrive and low BMI and may achieve menarche late or have sparse menses that start at an older age than typical. Patients with certain genetic disorders or conditions associated with chromosome abnormalities[27] may require hormonal treatment to enter and proceed through puberty.

Conversely, patients with certain neurologic disorders, including myelomeningocele or hydrocephalus, have a greater chance of early adrenarche and pubarche, and girls may achieve menarche at younger than 10 years (Table 2).[28] Central precocious puberty is defined as the full activation of the hypothalamic-pituitary-gonadal axis before 8 years of age in genetic girls and before 9 years of age in genetic boys.[29,30] Central precocious puberty is more common in children with fragile X syndrome, congenital brain malformations, and a history of birth asphyxia, meningitis, or other acquired brain injury.[31]

Menstrual Manipulation and/or Suppression

Although menstruation is often not a barrier to care and well-being, there are a number of concerns that face the primary caregivers of individuals with disabilities once they achieve menarche.[32] These concerns may include hygiene issues (especially for individuals who cannot use a toilet independently), worsening seizures, worsening cyclical behavioral problems, discomfort for the child or adolescent (including breast tenderness and headaches), difficulty for a caregiver who is not comfortable dealing with menses, and difficulty coping at school.[33,34] Menstrual hygiene issues can be introduced early in puberty, even before menarche, and with caregiver shared decision-making, providers can help identify ways to foster independence and teach individuals with disabilities how to manage their menses or seek appropriate help, such as from the school nurse. It is important for caregivers to understand that amenorrhea is often not achieved immediately but that menstrual manipulation may be used to induce amenorrhea, better regulate cycles, or decrease the amount or duration of menstrual flow and minimize menstrual pain and/or dysmenorrhea.[35] Providers interested in understanding the myriad available options are encouraged to review the clinical report from the American Academy of Pediatrics (AAP) and the North American Society for Pediatric and

TABLE 2 Common Differences of Timing of Puberty in Patients with Disabilities

Early-Onset Puberty	Typical Puberty	Delayed Puberty
Congenital brain malformations	Varies by family, ethnic, and racial groups	Severe nutritional deficiency
Hydrocephalus	Attention-deficit/hyperactivity disorder	Hormonal abnormalities
Neural tube defects; myelomeningocele	Children with ASD with typical growth	Sex chromosome abnormalities
Epilepsy	Other behavioral and mental health issues	Chromosome abnormalities (ie, trisomy 21)
Severe cognitive disabilities	Mild and moderate cognitive disabilities	Complex disabilities
Brain injuries		Psychiatric medications causing high prolactin
Some genetic conditions such as fragile X, neurofibromatosis 1, tuberous sclerosis, and McCune-Albright syndrome		

Adolescent Gynecology, "Menstrual Management for Adolescents With Disabilities."[32] Surgical options for menstrual suppression are rarely indicated. Menstrual suppression before menarche and endometrial ablation are not recommended.[36] Permanent decisions regarding sterilization have ethical, legal, and medical implications, vary by state, and are beyond the scope of this report. There are also important ethical issues to consider such as patient autonomy and independent decision-making, separate from caregiver issues related to menstrual manipulation in general.[37] Having a conversation and physical examination performed in a confidential manner with appropriate chaperoning and consenting and the caregiver excused from the room is an important practice, especially for those patients with physical disabilities alone or cognitive disabilities requiring limited supports (mild intellectual disability). A confidential examination provides an opportunity to assess the individual's sexual health knowledge and risks or history of abuse or coercion.[6,35] Addressing menstruation can also foster a discussion regarding sexual activity, the risk of sexual victimization, and the need to prevent STIs and pregnancy.

STI and Pregnancy Prevention

Although individuals with disabilities may be delayed, compared with their peers, in terms of first sexual encounters, they are more likely to engage in unsafe sex practices, which is especially true for those with mild disabilities.[38,39] Some youth, such as youth with attention-deficit/hyperactivity disorder, are more likely than their peers to engage in sexual activity earlier and also engage in unsafe sex practices.[40,41] All sexually active adolescents are at risk for STIs, including HIV, and, therefore, should be counseled about how to reduce their risks, including the use of barrier protection, in addition to long-acting reversible contraception, as appropriate.[2,6,42–44] Sexual minority youth often do not receive counseling appropriate for their sexuality; therefore, the pediatric health care provider should tailor counseling on the basis of the youth's specific needs when possible.[45] Providers should encourage and facilitate family-child communication about sexual health and confidentially ensure that any sexual activity is consensual for the youth.[6,45] Confidential family planning services and sexual health care should be made available to adolescents in accordance with legal obligations.[2,27,32,46] Effective counseling is characterized by compassion, respect, a nonjudgmental attitude, and using open-ended questions.[47] Shared decision-making strategies can be employed to enhance the autonomy of the individual with disabilities and can help ensure that all voices are heard during the decision-making process.[17]

Human Papillomavirus Vaccine

Vaccination against human papillomavirus (HPV) has become one of the most successful vaccination programs, not only to prevent this STI but also to significantly reduce certain cancers. Because of the efficacy and safety of the HPV vaccine, all pediatric patients, including those with disabilities, should receive a full course of this vaccine.[48,49] Patients with a history of sexual abuse or violence should receive the HPV series starting at 9 years of age.[50]

Counseling Regarding Genetic Reproductive Risks

Many patients with disabilities may have an underlying genetic disorder as their primary diagnosis, which carries a recurrence risk.[51] Often, the diagnosis is made during infancy or early childhood and communicated with the family, but it is common that the diagnosis and recurrence risk may never have been formally discussed with the patient as he or she approaches reproductive age. Part of caring for patients with genetic disorders as they reach an age in which they may become sexually active or pregnant is to make sure that patients receive appropriate genetic counseling (such as with a genetic counselor) to understand contraception options and their reproductive risks.[52] Table 3 lists reproductive risks for some common genetic disorders. Extensive information regarding trisomy 21 is available in the health supervision guidance from the AAP.[53] There are thousands of genetic conditions that may be associated with disabilities for which the pediatric health care provider can find additional condition-specific information by searching https://ghr.nlm.nih.gov/condition. In addition, youth with disabilities may be taking medications that alter sexual function or have teratogenic effects. Screening and counseling regarding medication adverse effects are important aspects of ensuring optimal sexual and reproductive health.

ADDRESSING THE RISKS OF SEXUAL ABUSE AGAINST CHILDREN AND YOUTH WITH DISABILITIES

Children with disabilities of all types are nearly 3 times as likely as those without disabilities to be sexually abused, and the risks are increased further for children with intellectual disabilities.[54] Although overall lifetime sexual violence victimization is low for men, men with disabilities have 3 times higher rates of victimization than men without disabilities do (13.8% vs 3.7%, respectively).[55] Nearly 25% of

TABLE 3 Reproductive Risks in Common Genetic Disorders

Genetic Disorder	Reproductive Risks
Autosomal dominant disorders	
Achondroplasia: most common form of skeletal dysplasia caused by a mutation in FGFR3	A person with achondroplasia whose partner has normal stature has a 50% chance of having a child with achondroplasia. A pregnant woman with achondroplasia may have difficulty carrying the fetus to term.
	If both genetic parents have achondroplasia, there is a 25% chance of having an infant with a lethal disorder who has 2 copies of the FGFR3 mutation.
Deletion of 22q11: common, with wide spectrum of presentation including intellectual disabilities, mental health issues, congenital heart disease, immunodeficiency, and hypoparathyroidism (formerly called DiGeorge syndrome)	A parent with mild learning problems or mental health issues can have a child with more complex birth defects and severe developmental problems.
	Chromosomal abnormalities, such as microdeletions, are passed on in an autosomal dominant pattern and may have variable severity of the phenotype from one generation to the next.
OI: most forms of brittle bone disease are caused by mutations in COL1A1 or COL1A2.	Confirmation of the diagnosis of OI can now be made with DNA analysis in blood.
	Most severe cases of OI arise from de novo mutations, but patients with milder forms of OI have a 50% chance of passing on their mutation in each pregnancy. There are more rare forms of OI caused by autosomal recessive genes with a 25% recurrence risk.
EDS: there are now 14 types of EDS	The hypermobile type is the most common with an estimated incidence of 1:5000. The genes for this type are unknown. This type can be associated with gastrointestinal tract issues, immunologic changes, dysautonomia, pelvic floor dysfunction, prolapse of the rectum and/or uterine prolapse, and chronic pain and disability.
	The vascular form of EDS can be associated with severe, life-threatening issues including arterial rupture, intestinal rupture, and uterine rupture in pregnancy.
Autosomal recessive disorders	A history of consanguinity increases the chances of having a partner who carries mutations in the same gene.
	Genetic boys with cystic fibrosis are sterile.
	Patients of certain ethnic backgrounds have a higher carrier rate of having mutations in autosomal recessive disorders; there are now next-generation sequencing panels that screen for carriers of certain disorders so that patients can receive genetic counseling regarding their recurrence risks.
	Many patients with autosomal recessive disorders have more severe disabilities and are less likely to procreate.
X-linked disorders	Females who are carriers of FMR1, which causes fragile X syndrome, have an increased risk of premature ovarian failure. The maternal grandfather may develop a condition that mimics Parkinson disease, called FRAXTAS.
	The severity of symptoms in female carriers of X-linked disorders may be affected by skewed X-inactivation.
	A female carrying a mutation in an X-linked gene (eg, fragile X syndrome) may be normal or have just a mild phenotype but has a risk of having a male child with more severe issues.
Mitochondrial disorders	Mitochondrial disorders may be caused by mutations in mitochondrial DNA, in which case they are maternally inherited, or may be caused by mutations in autosomal genes, in which case they are usually autosomal recessively inherited.
	Maternally inherited mitochondrial disorders are generally passed on to all children in the sibship, although the severity of issues may vary from one sibling to another.
Multifactorial disorders	
NTDs are common birth defects with an increased recurrence risk within families	Patients with NTDs have an ~5% chance of having a child with an NTD.
	Siblings of patients with NTDs, parents, aunts, uncles, etc, also have an increased risk.
	Folate, 4 mg/kg per day, taken 3 mo before conception and through the first trimester, can decrease (but not eliminate) this risk.
	Certain ethnic groups (including people of English and/or Irish, Hispanic, and Chinese descent) have an increased risk of having a child with an NTD and might also consider taking folate prophylactically, even without a family history.
Other	Some disorders are caused by multiple factors including genes that may not be known, teratogens such as alcohol, or nutritional factors such as low folate. Recently available genetic tests including next-generation sequencing panels have helped make specific diagnoses in patients with rare disorders.

COL1A1, collagen type I alpha 1; COL1A2, collagen type I alpha 2; EDS, Ehlers-Danlos syndrome; FGFR3, fibroblast growth factor receptor 3; FRAXTAS, fragile X-associated tremor/ataxia syndrome; NTD, neural tube defect; OI, osteogenesis imperfecta.

adolescent women, regardless of disability status, report being victims of sexual abuse and/or assault.[56] In a cross-sectional survey of 101 students with disabilities from a large northeastern public university, 22% reported some form of abuse over the last year, and nearly 62% ($n = 63$) had experienced some form of physical or sexual abuse before the age of 17.[57] Of those who were abused in the past year, 40% reported little or no knowledge of abuse-related resources, and only 27% reported the incident.[57] Compared with respondents without disabilities, young women with physical disabilities had a higher odds of being a victim of rape (odds ratio: 1.49; 95% confidence interval: 1.06–2.08).[58] Perpetrators of sexual violence against people with disabilities often know their victims well. Nearly one-third of perpetrators of sexual abuse are family members or acquaintances, and an additional 44% of assailants had a care-provider relationship with their victims.[55]

Children and youth with disabilities are more vulnerable to sexual victimization, likely because of a variety of factors depending on the type of disability, including a decreased ability to resist an attack, a desire to please the other person without a full understanding of the circumstances, dependence on others for aspects of care and decision-making, limited communication skills, and increased tolerance of physical intrusion, among others.[55] For example, some individuals with intellectual disability may lack the decision-making capacity, ability to consent, and skills necessary to develop healthy relationships, which can be associated with sexual exploitation, abuse, or coercion.[59,60] Given the increased risk of sexual abuse, coercion, and assault, the pediatric provider is encouraged to surveil often, in developmentally appropriate ways, and provide resources when a concern is raised.[2,55,61] As is the case for all children, health care providers are mandated reporters, and reporting should occur to the appropriate authorities[61,62] If the youth with disabilities is 18 years or older, reports should be made to adult protective services. In addition, children with disabilities may have been placed in foster care because of sexual abuse; therefore, the pediatric health care provider is encouraged to screen for a history of sexual violence for this population. Specific AAP policies on sexual abuse, coercion, and assault as they relate to children with disabilities can be found in Table 4.

TYPICAL AND PROBLEM SEXUAL BEHAVIORS

There are a wide range of typical and developmentally appropriate child and adolescent sexual behaviors that provide teachable moments for health care providers and families, especially during early development.[63] For example, when a preschooler undresses in the classroom, an adult can comment, "undressing is what we do privately before taking a bath, not in front of our friends at school." Children with developmental disabilities, including autism spectrum disorder (ASD), may extend the ages of typical sexual exploration. Providers need to consider social, cultural, religious, familial, and medical contexts for typical and problem behaviors. It is important to be able to differentiate signs of expected and/or typical versus atypical, aberrant, or problem sexual behaviors in children with disabilities and provide appropriate education and counseling on the topic.

Typical behaviors in early development, which may be seen in older children who have developmental disabilities, include general sexual curiosity, masturbation, an interest in peer or sibling genitals, standing or sitting too close, trying to view adult nudity, and sometimes crude mimicking of movements associated with sexual acts. These are separated from uncommon and rarely typical behaviors, regardless of cognitive ability, such as explicit imitation of sexual acts, asking peers or adults to engage in sexual activities, insertion of objects into genitals, activity with children who are more than 4 years apart, and frequent sexual behaviors that are resistant to distraction.[63,64] Atypical behaviors at any age or developmental level include sexual behaviors that result in distress or pain, are associated with physical aggression or coercion, or become persistent and resistant to redirection. Sorting out behaviors that involve sexual offense from those that are problem behaviors and challenging to self or others can help determine the acuity and degree of intervention.[31] Regardless, challenging sexualized behaviors associated with developmental disabilities or acquired disorders such as brain injury require assessment of the reason for the behavior. Families and/or caregivers and the clinicians can work with schools, behavioral analysts, and/or psychologists to obtain a functional behavior assessment and customize behavioral interventions.[31,65]

Problem or inappropriate sexual behaviors, such as public masturbation and nonconsensual groping, are exhibited more commonly in children and adolescents with disabilities, specifically developmental disabilities, and may be the most problematic in those with ASD.[65] Core deficits in social reciprocity, communication, and sensory

processing likely contribute to poor adherence to sociosexual norms, as well a limited understanding of the consequences of sexual behavior. In a recent survey of both parents and youth, 29% of young adults with ASD experienced challenging sexualized behaviors, most commonly masturbation in public.[66] When parents of children and youth with ASD, Down syndrome, and typical development were interviewed, those with ASD had significantly more trouble in multiple domains of sexual functioning, including social behavior, privacy awareness, sex education, sexual behavior, and parental concerns.[67] Improving sociosexual education can help prevent or minimize many of these behaviors and should begin at a young age.[68] Health care providers, educators, and family members and caregivers can work collaboratively toward extinguishing problem behaviors and use reminders, distractions, or replacement with socially appropriate gestures or places. Specific resources to address problem behaviors can be found in Table 5.

SEXUALITY AND ADOLESCENTS WITH ASD

Adulthood is a highly social construct. Negotiating the transition to adulthood from supervised, structured home and school settings can be challenging for all adolescents, especially for individuals with ASD.[69–71] It is not surprising that the core deficits of ASD, including difficulty with social reciprocity and pragmatic communication, complicate experiences and relationships of youth with ASD, compared with their typical or cognitively delayed peers.[67,72] Although youth and adults with ASD did not significantly differ from their counterparts without ASD in their knowledge of sexual language and interest in sexual experiences,[72,73] more than a dozen studies including direct report by individuals with ASD

TABLE 5 Resources for Problem Behaviors

Problem Behavior	Resources
Excessive or public masturbation	Suggested conversation: "Today, we discussed that masturbation is a normal behavior. Excessive and/or inappropriate masturbation is often difficult to control because it can be a self-reinforcing behavior. We discussed that although inappropriate masturbation, such as public masturbation, may not completely go away, your child can learn to be redirected to perform the behavior in private. The key to approaching this is to ensure that your child both has a personal space and that he or she understands the appropriate place for private behaviors. Recommend using a schedule or timer to set boundaries for these behaviors." Specific protocols for minimizing excessive public masturbation include interrupting the behavior, reminding the person of appropriate time and place, redirection, and allowing masturbation in private. Often, working with a behavior therapist who can offer applied behavior analysis is recommended. Resources: Kate E. Reynolds books: *Things Tom Likes: A Book About Sexuality and Masturbation for Boys and Young Men with Autism and Related Conditions* (2015) and *Things Ellie Likes: A Book About Sexuality and Masturbation for Girls and Young Women with Autism and Related Conditions* (2015).
Inappropriate interactions (stalking), touching, or romantic gestures	Through the Individualized Education Program, request a functional behavior assessment and a behavior intervention plan for positive supports such as a social skills group, scripting, video modeling and feedback, self-management, and rule governed behaviors. Resource: Teaching Moment: Teaching Your Kids Appropriate and Inappropriate Touching (https://www.northshore.org/healthy-you/teaching-your-kids-appropriate-touching/).
Using public restrooms	Resources: Kate E Reynolds books: *Tom Needs to Go: A Book About How to Use Public Toilets Safely for Boys and Young Men with Autism and Related Conditions* (2015) and *Ellie Needs to Go: A Book About How to Use Public Toilets Safely for Girls and Young Women with Autism and Related Conditions* (2015).

indicate lower levels of sexual knowledge (including understanding of privacy norms) decreased social opportunities, and increased social anxiety and vulnerability.[66,74,75] In addition, at a population level, teenagers and young adults with ASD without an intellectual disability have greater diversity in sexual orientation and gender identity, compared with typically developing peers, which they state can be confusing.[76] As understanding of sexual knowledge and health differences between individuals with ASD increases, there are new opportunities to individualize safety and sex education to understand sexual orientation and prevent socially isolating problem sexual behaviors, sexual coercion, and abuse.[74] Typical sex education may not be sufficient for people with ASD, and specific methods and curricula are necessary to match their needs (Table 1).[77] An enhancement of clinical services and additional research is needed to ensure people with ASD have their informational needs met and are able to achieve a healthy sexuality.[78]

SEXUALITY AND ADOLESCENTS WITH SPINA BIFIDA OR A SPINAL CORD INJURY

Individuals with spina bifida or a spinal cord injury have some amount of lower extremity paralysis and also tend to have a neurogenic bowel and bladder as well as loss of nerve signals to their sex organs. The neurologic consequences of spinal cord injury and spina bifida can alter sexual and reproductive experiences for people with these conditions, affect confidence and self-esteem, and hinder relationship building.[12,79–81] Although many youth with spina bifida do not understand their reproductive potential, women with spinal cord injury or spina bifida tend to have normal fertility but require high-risk obstetric care before and during their pregnancies.[12,82] Many women with spinal cord injury or spina bifida, when sexually aroused, do not have full vulvar engorgement or vaginal lubrication, making penetration difficult or painful.[83] Some women with these conditions are able to experience orgasms.[82] Men with spina bifida or spinal cord injury tend to have altered fertility.[84] In addition, the performance of sexual intercourse may be hindered by erectile dysfunction, including an inability to achieve or maintain an erection for

penetration and retrograde, absent, or incomplete ejaculation.[79,85] For both men and women with these conditions, engaging in sexual activity may be complicated by incontinence from neurogenic bowel or bladder.[86,87] Both men and women may be counseled to catheterize their bladders before and after sexual activity.[83] Men who have retrograde ejaculation often need to flush their bladders after sex to remove semen from the bladder.[88] Sexual education and guidance should be tailored to the individual's needs and should consider the cognitive and physical capabilities of the individual.[86] Many people with spina bifida also commonly have learning disabilities and other cognitive problems.[89] People with spina bifida also need to be counseled about the use of nonlatex condoms because of the risk of latex allergies in this population.

SEXUALITY AND HEALTH CARE TRANSITION

Viewing sexuality as a normative part of adolescence in people with disabilities, including ASD, is conceptually new, compared with long-standing myths of universal asexuality and limited sexual experiences.[72,75] The 2018 AAP clinical report, "Supporting the Health Care Transition From Adolescence to Adulthood in the Medical Home," provides a strong framework for primary care providers to longitudinally promote and integrate healthy sexuality for all youth, both with and without disabilities, from understanding pubertal changes and gender identity to experiencing sexual feelings and understanding sexual orientation to ultimately exploring and developing capacity for intimacy and reproduction.[22] This ongoing longitudinal relationship, similar to that for typically developing youth, includes confidential conversations, appropriate genital examinations, openness to sexual and gender diversity and individual and family preferences, and, if needed, sensitive reporting of sexual abuse or violence.[90] As opportunities for employment, postsecondary education, and community living increase for a large portion of the population with disabilities, it is imperative to prepare and support them in their sociosexual self-efficacy, safety, and well-being.

THE PEDIATRIC HEALTH CARE PROVIDER'S ROLE

Pediatric health care providers play a crucial and longitudinal role in the development of healthy sexuality of children and youth with disabilities. The unique relationship with the patient and family over time allows the pediatric health care provider to discuss and promote important social and sexual skills at an individualized pace appropriate for each patient.

- Pediatric health care providers can examine and adjust or reinforce their knowledge, beliefs, and attitudes about sexuality and gender identity to ensure their own behavior reflects inclusivity and autonomy of all their patients, especially children and adolescents with disabilities; all people have the right to develop relationships, exercise choice and autonomy, and receive education to promote a healthy sexuality, regardless of sexual orientation or gender identity. Communication that is open and respectful can help develop trust and foster shared decision-making.
- At the earliest ages, including preschoolers, pediatric health care providers are encouraged to discuss appropriate "private" versus "public" behaviors. Pediatric health care providers can help children with disabilities and their families understand boundaries and the concept of body ownership and consent. Explaining "good touch," "bad touch," and "necessary touch" can help children frame their understanding of appropriate and inappropriate circumstances and situations. Using anatomically correct language for body parts at young ages helps children to understand their bodies in a positive, healthy way and offers children a way to express healthy sexuality.
- By at least 8 or 9 years of age, pediatric health care providers should begin to discuss puberty and may need to do so sooner if the child is at risk for precocious puberty. Discussing puberty, preparing children and families, and offering additional materials (separate from school curriculum; Table 1) to review in a quiet comfortable place such as the home allows for questions, clarification, and anticipatory guidance for supports in hygiene and normalization of experiences.
- As with all adolescents, pediatric health care providers are encouraged to offer youth with disabilities an opportunity to speak with their provider confidentially during a visit. This allows youth to express their thoughts and experiences and ask questions. This is especially important for youth who are discovering their nonbinary gender identity or nonheterosexual sexual orientation. The pediatric health care provider's office should be a safe place to discuss these issues for all youth, including those with disabilities.
- Pediatric health care providers have opportunities with families and caregivers to introduce topics such as healthy sexual development and exploration while limiting risk of harm. Encouraging coeducational supervised group activities to include individuals with disabilities in typical teenager interactions often is best received by families and caregivers as anticipatory guidance by their trusted

provider. This is also a good time to encourage families and caregivers to be a primary source of sexual education for their children. There are many resources available, including those listed in Table 1. Pediatric health care providers can partner with families and caregivers who may feel uncomfortable addressing sexual health through a shared decision-making process that is culturally responsive and elevates the rights of children with disabilities to gain knowledge and understanding regarding their developing sexuality.

- Pediatric health care providers are the best resource to counsel all youth, including youth with disabilities, regarding the prevention of STIs and unwanted pregnancy as well as the benefits of HPV vaccination.
- Pediatric health care providers can help youth with disabilities procure contraceptives in a confidential manner, with adherence to informed consent rules.
- Pediatric health care providers can screen for STIs or ensure that appropriate referrals are in place (eg, gynecology or urology) for routine screening as part of their role in providing care in a medical home.
- Pediatric health care providers are well suited to provide families with resources to help them address problematic or inappropriate sexual behaviors (Table 5).
- Pediatric health care providers can partner with schools to ensure that children with disabilities have access to a developmentally appropriate sexual education that includes knowledge building around sexual victimization, safer sex practices, consent, and respect through their Individualized Education Programs or as part of the typical curriculum.
- Pediatric health care providers may need to offer education to schools regarding the high risk of sexual victimization for children with disabilities, how best to prevent it, and how to identify it if it occurs.
- Pediatric health care providers are vigilant about the knowledge that children and youth with disabilities are at an increased risk for sexual abuse and assault and can help families understand this risk. Asking about unwanted or coercive interactions and monitoring for emotional disturbance that may indicate sexual abuse or coercion can happen at every visit. If concerns arise, ensuring that proper reporting occurs and follow-up care is delivered is a role pediatric health care providers are trained to provide.

Pediatric health care providers are encouraged to approach sexual education and guidance individually for children and youth with disabilities, taking into account their patient's developmental trajectory and understanding the functional limitations of health conditions that can affect the development of healthy sexuality. Numerous other AAP reports can help inform the pediatric health provider on the topic of sexuality (Table 4). Framing healthy sexuality through a "competence lens" helps providers recognize the strengths and challenges for each individual patient. To be competent at something, an individual must have sufficient knowledge and skills to engage in action. Although there may be barriers to the development of skills needed for healthy sexuality in individuals with disabilities, it is important to prioritize ongoing skill development, compensatory strategies, and opportunities for autonomy and self-actualization.

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Promoting Human Milk and Breastfeeding for the Very Low Birth Weight Infant

Margaret G. Parker, MD, MPH,[a] Lisa M. Stellwagen, MD,[b,c] Lawrence Noble, MD,[d,e] Jae H. Kim, MD, PhD,[f] Brenda B. Poindexter, MD,[g] Karen M. Puopolo, MD, PhD,[h] SECTION ON BREASTFEEDING, COMMITTEE ON NUTRITION, COMMITTEE ON FETUS AND NEWBORN

Provision of mother's own milk for hospitalized very low birth weight (VLBW) (≤1500 g) infants in the NICU provides short- and long-term health benefits. Mother's own milk, appropriately fortified, is the optimal nutrition source for VLBW infants. Every mother should receive information about the critical importance of mother's own milk to the health of a VLBW infant. Pasteurized human donor milk is recommended when mother's own milk is not available or sufficient. Neonatal health care providers can support lactation in the NICU and potentially reduce disparities in the provision of mother's own milk by providing institutional supports for early and frequent milk expression and by promoting skin-to-skin contact and direct breastfeeding, when appropriate. Promotion of human milk and breastfeeding for VLBW infants requires multidisciplinary and system-wide adoption of lactation support practices.

STATEMENT OF PROBLEM

Provision of mother's own milk for hospitalized very low birth weight (VLBW) (≤1500 g) infants in the NICU provides short- and long-term health benefits. Mothers of very preterm infants face many challenges in the provision of breast milk. The goal of this clinical report is to provide neonatal clinicians up-to-date information regarding NICU lactation support for mothers of VLBW infants.

BACKGROUND INFORMATION

Epidemiology

National data from more than 800 NICUs that participate in the Vermont xford Network Quality Collaborative showed that provision of human milk at discharge among VLBW infants has increased from 44 in 008 to 5 in 017, but disparities persist according to maternal race and ethnicity and US census region.[1] Human milk provision is lowest among non-Hispanic Black and American Indian/Alaska Native populations and within the southern region of the United States (Fig 1). Currently, there is no mechanism for national surveillance of hospital-based practices known to support breastfeeding among VLBW infants, although such surveillance has been conducted intermittently at the state ' or individual NICU level.[4–7] Hereafter, breast milk terminology is used according to definitions in Table 1.

Health Outcomes

Mother's own milk contains macronutrients and micronutrients as well as active biological components, including immunoglobulins, cytokines, growth factors, hormones, antimicrobial agents, immune cells, stem cells, and prebiotic oligosaccharides.[8] A substantial portion of the breast milk microbiome comprises probiotic bacteria.[9] Mother's own milk has been associated with multiple health benefits for VLBW infants, including lower incidences of necrotizing enterocolitis (NEC), late-onset sepsis, chronic lung disease, retinopathy of prematurity, and neurodevelopmental impairment (Tables and). Generally, higher doses of mother's own milk are associated with increased health benefits; however, exposures of human milk are highly variable among studies (Table) and there is a paucity of data comparing infants exclusively fed mother's own milk, pasteurized donor milk, or preterm formula.

Pasteurized donor milk is recommended for VLBW infants when mother's own milk is not available[10]; however, pasteurization, freeze-thaw cycles, multiple container changes, and prolonged storage times required for donor milk processing reduce bioactivity.[11] When provided as an exclusive diet or in combination with mother's own milk feeding, pasteurized donor milk is protective against NEC but does not appear to confer the additional health benefits that have been reported with mother's own milk, such as reduction in late-onset sepsis or improvements in neurodevelopment.[1] Pasteurized donor milk may be considered a "bridge" until a full supply of mother's own milk is available.

Although the benefits of a human milk-based diet for preterm infants are established, studies examining the impact of an exclusive human milk diet on the risk of NEC versus a diet with any bovine components (preterm formula or bovine-derived human milk fortifier HMF) have had mixed results (Table). Several randomized control trials (RCTs) and observational studies reported reductions in NEC when very preterm infants received an exclusive human milk diet versus a diet with any bovine formula or bovine-derived HMF.[1 –16] These data are countered by the largest RCT of an exclusive human milk diet of 1 7 infants with birth weight <1 50 g who received bovine- versus human-derived HMF as a supplement to mother's own milk or pasteurized donor milk, which found no difference between groups in feeding tolerance or NEC.[17] Studies comparing human-derived HMF with hydrolyzed bovine protein HMF are not available at the time of this report.

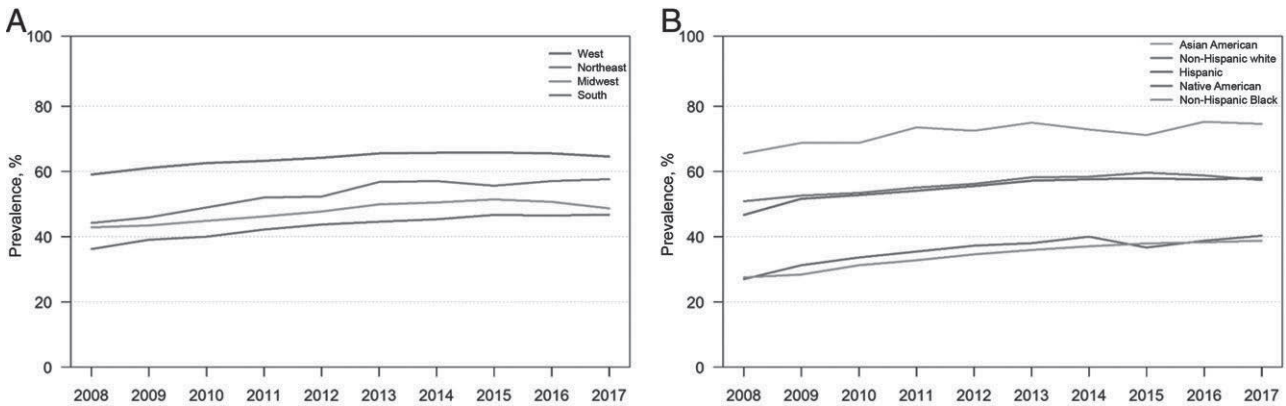

FIGURE 1 Any human milk at discharge among VLBW infants in the United States, 2008–2017. A, Any human milk at discharge among VLBW infants according to US region. B, any human milk at discharge according to maternal race/ethnicity. Adapted with permission from Parker et al.[1]

TABLE 1 Breast Milk Terms

Term	Definition
Mother's own milk	Milk from an infant's own mother
Pasteurized donor milk	Breast milk donated to a milk bank and pasteurized to eliminate pathogens
Informally shared milk	Unpasteurized milk from another infant's mother
Human milk	Mother's own milk or pasteurized donor milk
Bovine-derived HMF	Cow's milk protein based nutritional fortifier for human milk
Human-derived HMF	Human milk protein based nutritional fortifier for human milk
Exclusive human milk diet	Mother's own milk or pasteurized donor milk with a human-derived HMF

LACTATION CARE FOR THE VLBW INFANT

Institutional Lactation Supports

Mothers of very preterm infants are more likely to initiate lactation compared with mothers of term infants,[18] yet many of these mothers do not meet their intended feeding goals.[19] Mothers of VLBW infants face several challenges, including (1) preexisting and pregnancy-related medical morbidities that may contribute to delayed lactogenesis and/or reduced milk production[20–22]; (2) prolonged mother–infant separation; (3) dependence on pumping to maintain milk production, rather than direct breastfeeding; and (4) competing demands on their time that impede frequent milk expression and NICU visitation, such as requirements to return to work and care for other children and family members, among other factors.[23,24] Multidisciplinary NICU teams can play a critical role in ongoing lactation support by providing education, institutional supports for milk provision, and medical practices that support lactation.[4,5,25,26]

Lactation Education and Consultation

Family education has been shown to increase breastfeeding intent and reduce maternal anxiety.[27–30] Staff lactation education increases staff knowledge about breastfeeding and changes attitudes toward the use of human milk among preterm infants.[31] Readily available lactation consultants with NICU expertise improves maternal support in lacation.[25,32] However, bedside nurses also provide significant lactation education and education reinforcement.[4] Family education may include information on the health benefits of mother's own milk for VLBW infants, the need for early and frequent milk expression, the role of skin-to-skin contact (SSC), nonnutritive suckling and direct breastfeeding when physiologically appropriate, and technical information on proper milk handling, storage, and transport. NICU staff need familiarity with the technical skills of hand expression, pumping, and stepwise progression from enteral tube to oral feedings at the breast.[25,32] Family-centered care models promote family integration in medical care and improve duration of lactation.[33,34]

Milk Expression: Timing, Frequency, and Modality

Initiating milk expression soon after birth is important to stimulate milk production and provide early feedings with beneficial effects on the VLBW infant[35]; however, the optimal timing is unclear. A multisite observational study of 1157 mother-VLBW dyads found that first milk expression within 8 hours after birth predicted the highest likelihood of lactation until hospital discharge.[36] An RCT of 180 mothers who first expressed milk 1 to 60 minutes, 61 to 180 minutes, and 181 to 360 minutes after birth found no difference in lactation at 6 weeks or mother's milk feeding at discharge but found a greater volume of milk production over the first 6 weeks within the group expressing milk at 181 to 360 minutes.[35] It remains unclear whether hand expression or use of a breast pump is best for initial milk expression. One study of 11 mothers reported that hand expression in the first 48 hours was superior,[36] but a larger RCT of hand expression versus pumping for the first 7 days after birth reported that pumping was superior.[37]

Frequent milk expression is associated with a longer duration of milk production and greater milk volumes throughout the NICU hospitalization in observational studies[38–43]; however, the optimal frequency of milk expression is difficult to ascertain because studies differ in pumping frequency cut-points ($\geq$4 to 7 times per day).[38–44] Frequent milk expression is needed to maintain ongoing milk supply. Milk production $\geq$500 mL per day by day 14 after birth has been shown to predict a longer duration of milk production during the NICU hospitalization among mothers of VLBW infants.[42,43] Mothers should pump with an effective and efficient double electric breast pump at home and in the hospital when possible because these pumps are superior to manual pumps.[37,45,46] It is useful

TABLE 2 Dose-Response Studies Examining Health Benefits of Human Milk for VLBW Infants

		Outcomes					
Study	Exposure	NEC	Late-Onset Sepsis	Chronic Lung Disease	Retinopathy of Prematurity	Neurodevelopment	Hospital Growth

DM, donor milk; HM, human milk (combination of mother's milk and donor milk); MM, mother's milk; PF, preterm formula; —, not applicable.

for mothers to be trained in pump use by hospital staff before they are discharged, helping them navigate common technical issues such as suction strength, pain with pumping, and proper flange fit. Mothers may be encouraged to pump at the infants' bedside with accommodations to protect privacy, because greater milk volumes have been reported when mothers pump in close contact with their infants[47]; however, the design of certain centers may mean that a central lactation room is more comfortable for some women. A single-center observational study showed increased milk volume among mothers of infants born at <31 weeks' gestation after training in hand expression while pumping (ie, "hands on pumping"), but this finding has not been examined in an RCT.[39] Mothers need training in appropriate techniques for milk storage and transport and to be provided with rigid, food-grade

TABLE 3 RCTs Examining Health Benefits of Human Milk for VLBW Infants

			Outcomes						
Study	Intervention	Control	NEC	Late-Onset Sepsis	Feeding Tolerance	Chronic Lung Disease	Retinopathy of Prematurity	Neurodevelopment	Hospital Growth
RCT of PF versus DM as a supplement to MM									
Schanler et al, 2005 ($n = 243$)[144]	MM + PF and MM + DM	MM	No difference	Favors MM	—	—	—	—	Varied[a]
RCTs of exclusive human milk versus not									
Cristofalo et al, 2013 ($n = 43$)[14]	DM + human HMF	PF + bovine HMF (powder)	Favors DM + human HMF	No difference	Favors DM + human HMF	—	No difference	—	Favors PF + bovine HMF
Sullivan et al, 2010 ($n = 207$)[15]	Exclusive HM (MM + DM + human HMF)	MM + PF + bovine HMF (powder)	Favors exclusive HM	No difference	No difference	No difference	No difference	—	No difference
Corpeleijn et al, 2016 ($n = 373$)[145]	MM + DM[b]	MM + PF[b]	No difference	No difference	—	No difference	No difference	—	—
O'Connor et al, 2016 ($n = 363$)[146]	MM + DM + bovine HMF (powder)	MM + PF + bovine HMF (powder)	Favors MM + DM + bovine HMF	No difference	—	No difference	No difference	No difference	No difference
RCTs of exclusive human milk examining fortifier types									
Moya[c,d] et al, 2012 ($n = 150$)[84]	MM + DM + bovine HMF (powder)	MM + DM + bovine HMF (liquid)	—	—	—	—	—	—	Favors bovine liquid HMF
Kim[c,e] et al, 2015 ($n = 147$)[82]	MM + DM + bovine HMF (powder)	MM + DM + bovine HMF (liquid)	—	—	No difference	—	—	—	No difference
O'Connor et al, 2018 ($n = 127$)[17]	MM + DM + human HMF	MM + DM + bovine HMF (powder)	No difference	No difference	No difference	No difference	Favors human HMF	—	No difference

DM, donor milk; MM, mother's milk; —, not applicable.

[a] Regarding wt gain, MM only was favorable over MM + DM; Regarding length gain, combined MM + PF and MM + was favorable over MM only.

[b] Intervention delivered in first 10 d of hospitalization before fortifier introduction.

[c] In this trial, intact protein was used for the powder fortifier and hydrolyzed protein was used for the liquid fortifier.

[d] In this trial, the powder HMF had 2.6 g per 100 mL and the liquid HMF had 3.2 g per 100 mL.

[e] In this trial, the powder HMF had 3 g per 100 mL and the liquid HMF had 3.6 g per 100 mL.

human milk collection containers.[32,48] Individualized plans for milk production after maternal hospital discharge may be developed with staff and lactation consultants.

NICU Practices Supporting Lactation

Recent reviews of studies examining SSC among mother-VLBW infant dyads found a positive effect of SSC on duration of mother's own milk production[49] as well as other important neonatal outcomes.[50] Early SSC has been associated with changes to the oral infant microbiome,[51] which may have implications for immune health. A previous American Academy of Pediatrics report provides guidance for SSC.[52] Family members can be encouraged to engage in SSC as often as possible and for as long as desired, depending on the infant's clinical condition. SSC can be safely performed among ventilated infants, infants receiving continuous positive airway pressure, and infants with securely placed central catheters. Facilitation of SSC may require the help of multiple hospital providers, including respiratory therapists. Continuous cardiovascular monitoring and monitoring for correct head positioning to maintain airway patency is needed.

Oral colostrum care consists of placing small amounts of colostrum on the infant buccal mucosa, often in the first hours after birth before beginning enteral feeding. Most mothers are able to provide colostrum for this purpose, even if the mother herself is significantly ill. Research in this area is emerging; a recent Cochrane meta-analysis of 6 small studies reported that oral colostrum care was associated with reduced days to enteral feedings (mean difference: −2.58 [95% confidence interval: −4.01 to −1.14]) but was not associated with reduction of NEC, late-onset sepsis, or mortality.[53] No adverse effects have been reported.[53] Research has not yet examined the impact of oral colostrum care in mother's own milk provision or family engagement later in the NICU hospitalization.

Transition to Direct Breastfeeding

Observational studies demonstrate that initial oral feedings at the breast, more frequent breastfeeding episodes, and earlier gestational age at the time of first breastfeeding attempt are associated with longer duration of breastfeeding during the hospital and postdischarge time periods.[54–58] Despite these potential benefits, significant barriers impede breastfeeding in the NICU, such as prolonged immature oromotor coordination, mother-infant separation, and the need for fortification of mother's own milk to optimize growth. Mothers can be encouraged to begin oral feeding at the breast as soon as the infant shows physiologic readiness (ie, feeding cues), and the infant's level of respiratory support allows for oral feeding. Oral feedings at the breast have been studied as early as 31 to 33 weeks' postmenstrual age.[54,55,57–59] Direct breastfeeding can occur as often as the infant's condition and mother's presence allows. Pre- and post-breastfeeding weight measurements may be used to monitor milk transfer.[60,61]

Multidisciplinary Team–Based Approaches

Multidisciplinary teams, including nursing, lactation, physicians, dietitians, and feeding therapists may best support lactating mothers.[4] Structured local and statewide quality improvement initiatives focused on adoption of hospital lactation support practices by multidisciplinary teams have successfully increased lactation rates.[3] Facilitators of effective multidisciplinary NICU lactation support teams include the following: consistent communication to families and among hospital staff members, physician buy-in, integration of lactation support practices into daily workflow, and ongoing data-driven feedback.[4,62]

Health Equity

Racial and ethnic disparities in the provision of mother's milk and pasteurized donor milk for VLBW infants are well-described; human milk use is lower among VLBW infants with non-Hispanic Black mothers, compared with those with non-Hispanic White mothers.[1,43,63,64] In addition to adherence to evidenced-based breastfeeding support practices described above for all mothers, several additional approaches have been shown to reduce Black and White disparities in breastfeeding in the NICU setting, including peer-counselor programs and support groups,[65,66] assistance with breast pump acquisition,[67] and transportation for mothers to visit the hospital.[28,30,64]

Growth and Fortification Needs for Human Milk–Fed VLBW Infants

The nutritional objective for hospitalized preterm infants is to match the fetal accretion of nutrients; nonetheless, poor growth continues to affect the majority of hospitalized VLBW infants.[68,69] Nutritional requirements cannot be met with human milk alone in the volumes of milk that are generally tolerated by VLBW infants because requirements exceed those of healthy term newborn infants in protein, energy, fatty acids, minerals, and micronutrients.[70] Multinutrient fortifiers are, therefore, added to human milk–fed to hospitalized VLBW infants.[71] It may be helpful to provide mothers with information on the use of HMFs, emphasizing the critical role of human milk despite

the need for fortification to optimize growth and development.

The macronutrient composition of preterm, term, and pasteurized donor milk is variable (Fig 2),[72–76] as are the needs of individual infants, and therefore, routine growth and nutrition monitoring is needed. Generally, the milk of mothers of preterm infants has higher protein content than the milk of mothers of term infants until about 10 to 12 weeks after birth[75] but still contains less than what is recommended for preterm infants (Fig 2).[70] The macronutrient content of pasteurized donor milk is often lower than that of milk provided by mothers of preterm infants,[74] such that infants supplemented with pasteurized donor milk, even with the addition of fortifiers, have a greater risk of growth failure.[77] Holder pasteurization used for donor milk processing results in a loss of lipase activity,[78] which reduces fat digestibility, which further adds to the risk of poor growth. Retort processing, another pasteurization method used to make shelf-stable donor milk, has been shown to significantly reduce lysozyme and secretory immunoglobulin A.[79] Overall, pasteurized donor milk is nutritionally suboptimal to a mother's own milk, reinforcing the importance of supporting mothers in maximal lactation.

Bovine- and human-derived HMFs are commercially available and vary in macronutrient content and degree to which proteins are hydrolyzed.[80–82] Bovine HMFs exist in powdered and liquid forms. In the United States, there has been a transition to use of liquid fortifier because of reports of bacterial contamination of infant formula powder and transmission of *Cronobacter (Enterobacter) sakazakii* during the hospital time period.[83] The liquid forms are supplied in sterile, single-use aliquots. Newer bovine HMFs provide hydrolyzed protein at higher protein concentrations than previous powder HMFs with intact proteins, which has been associated with improved growth.[80,84] Bovine liquid HMFs may be acidified as part of the sterilization process. A trial comparing acidified to nonacidified liquid HMFs showed similar growth but increased transient metabolic acidosis among VLBW infants receiving acidified liquid HMFs.[85] Optimal timing of fortification remains unclear, but several recent RCTs of fortification at feeding volumes less than 80 mL/kg per day showed no associations with feeding intolerance or NEC.[15,86,87] Adjustable fortification algorithms based on markers such as serum urea nitrogen may improve growth.[88,89] Rapid point-of-care milk analyzers that measure the macronutrient content of milk to facilitate individualized fortification strategies are emerging and have become available for clinical use.[90]

HUMAN MILK SAFETY

Milk Preparation and Storage

NICUs should optimally have institutional protocols and parent education addressing breast pump and pump kit cleaning as well as milk storage, handling, and transportation practices.[48,91,92] Guidelines for milk storage are provided in Table 4.[92–96] Fresh milk feedings maximize bioactive properties that are decreased with freezing.[97–99] Errors in administration of milk (feeding milk to an infant from an unrelated mother) are well-documented, and NICUs are best served by clear site-specific protocols for decreasing the risk of such errors. Two-provider verification as well as the use of systems similar to electronic medication administration bar coding are possible practices for preventing milk misadministration.[100,101] The Centers for Disease Control and Prevention provides guidance for instances when milk

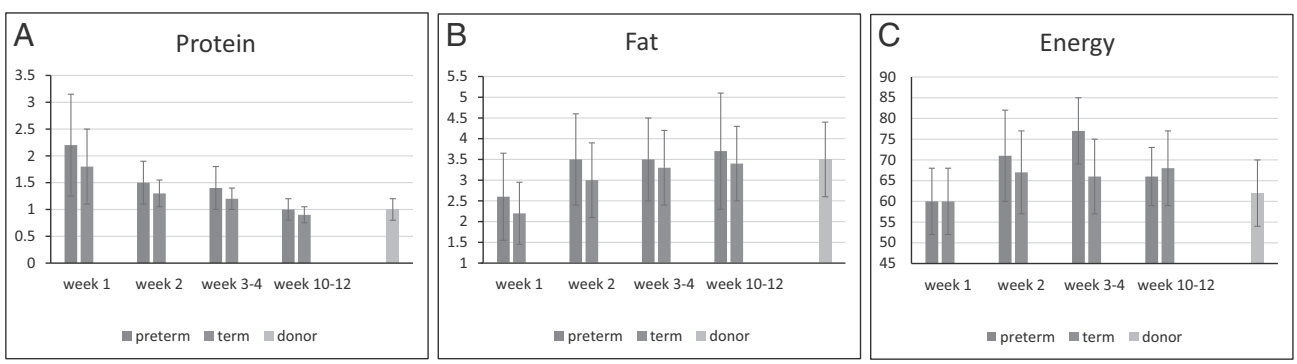

FIGURE 2 Comparison of macronutrient content of preterm, term, and pasteurized donor milk. Error bars indicated 1 SD. A, Protein content (g per 100 mL). B, Fat (g per 100 mL). C, Energy content (kcal per 100 mL). Preterm and term milk results modified from Gidrewicz et al.[75] Donor milk results modified from the mature donor milk category (milk from mothers obtained 4 to 52 weeks after birth) from John et al.[76]

misadministration has occurred (https://www.cdc.gov/breastfeeding/recommendations/other_mothers_milk.htm).[102] Temperature-controlled milk warmers can be used to facilitate safe warming practices.[48]

Informal Milk Sharing

Informal milk sharing is the noncommercial sharing of human milk between mothers for the purpose of infant feeding. This practice is increasing in the United States.[103] Health care providers may choose to discourage families from direct milk sharing and the purchase of human milk from Internet-based sources. Both practices are associated with risks of bacterial or viral contamination of nonpasteurized milk and the possibility of exposure to medications and other substances.[10,104] Informal milk sharing may involve suboptimal milk handling and storage practices that may increase the likelihood of bacterial contamination.[103] Despite counseling, some mothers of VLBW infants will continue to plan on informal milk sharing; mothers are encouraged to discuss this openly with the infant's care team. Some institutions require parents to sign informed consent for hospital use of informally shared milk to document knowledge of the associated risks.

Contraindications

Contraindications to breastfeeding are described in detail in previous American Academy of Pediatrics publications related to breastfeeding.[104–107] Providers may use LactMed, a Web-based information source published by the National Library of Medicine and National Institutes of Health,[108] or other valid published sources of guidance in counseling mothers in provision of mother's own milk when receiving medications. Generally, studies examining effects of maternal medications in mother's own milk have not been performed among VLBW infants; thus, providers must weigh the risks of exposure to maternal medications with the benefits of the mother's own milk in clinical decision-making.

Cytomegalovirus

Cytomegalovirus (CMV) is a ubiquitous double-stranded DNA virus with which 60% to 70% of American women are infected before pregnancy.[109] Most CMV immunoglobulin G–positive women shed the virus in breast milk during lactation. Mother's own milk is the primary source of CMV transmission among term newborn infants, and nearly all term infants who acquire CMV during breastfeeding are infected without signs of illness.[110] In contrast, postnatally acquired cytomegalovirus (pCMV) infection in preterm infants can be associated with a sepsis-like illness, increased morbidity, and, rarely, mortality.[111–113] Manifestations of pCMV infection can include apnea, pneumonitis, leukopenia, thrombocytopenia, hepatitis, cholestasis, and colitis.[114] Health care providers caring for VLBW infants fed mother's own milk and presenting with signs suggestive of late-onset sepsis may consider CMV testing as well as evaluation for bacterial infection. The freeze-thawing cycle has been shown to reduce, but not eliminate, the viral load of CMV in mother's own milk[115] and is associated with loss of bioactive components.[97–99] A recent meta-analysis estimated that rates of postnatally acquired CMV infection from consumption of mother's own milk was 19% (11% to 32%) for asymptomatic CMV infection and 4% (2% to 7%) for CMV sepsis-like syndrome.[112] Although the overall rate of acquiring pCMV is decreased among infants fed frozen mother's own milk (13% [7% to 24%]), freezing is not associated with a decreased risk of CMV sepsis-like syndrome (5% [2% to 12%]), suggesting that minimal viral exposure is required to infect the extremely low birth weight infants at the highest risk for symptomatic pCMV sepsis-like syndrome.[112] Two studies have found higher rates of bronchopulmonary dysplasia among VLBW infants with pCMV infection.[114,116] The long-term neurodevelopmental effect of breast milk–acquired pCMV among VLBW infants is unclear, with some studies finding no effect on neurodevelopment and several others attributing varying degrees of cognitive delay to pCMV infection.[117–124] Additional studies are needed to determine the relative impact of breast milk–acquired pCMV infection, given the many

TABLE 4 Maximum Human Milk NICU Storage Recommendations

Environment	Temperature	Freshly Expressed Mother's Milk	Frozen Mother's Milk	Frozen Pasteurized Donor Milk
Room temperature	60° 85°F or 16° 29°C	4 h	4 h[a]	4 h[a]
Refrigerator	39°F or 4°C	96 h	48 h[a,b]	48 h[a]
Freezer (2 door refrigerator and freezer)	0°F or −18°C	9 mo	9 mo	6 8 mo[c]
Deep freezer	0°F or −18°C	12 mo	12 mo	6 12 mo[c]

benefits of mother's own milk among VLBW infants, particularly for decreasing the risk of NEC. At the current time, evidence is insufficient to support withholding mother's own milk because of the risk of pCMV.

Discharge Planning

Postdischarge plans must be individualized to consider the mother's goals for breastfeeding, bottle-feeding with expressed milk, and/or formula as well as the infant's growth status and anticipated need for postdischarge milk fortification. It is optimal for health insurers to provide coverage for lactation support to mothers who continue to provide breast milk after the VLBW infant is discharged from the hospital. More than one-half of VLBW infants have extrauterine growth failure (weight for gestational age: less than 10th percentile) at discharge.[68] Postdischarge fortification may be considered among these infants. However, current evidence supporting the use of postdischarge fortification among VLBW infants fed mother's own milk is limited. In one small RCT ($n = 39$), researchers examined fortification of half of mother's own milk feedings for 12 weeks versus no fortification and found improved growth outcomes and bone mineral content in the fortification group,[125] and another larger Danish RCT found no growth benefit among very preterm infants who received less fortification (1 fortified mother's own milk feeding per day) versus no fortification.[126] Neither study showed differences in neurodevelopment. The duration and dose of postdischarge fortification to optimize postdischarge growth and neurodevelopment among former VLBW infants fed human milk requires further study. When developing postdischarge feeding plans, the NICU team should optimally balance the need for fortification (on the basis of existing evidence and the individual infant's nutritional and growth status) with the mother's breastfeeding goals. The logistic challenges of expressing and fortifying milk in the home environment should also be considered. It is helpful to communicate postdischarge lactation and nutrition plans to the infant's outpatient pediatric providers.

Summary

Mother's own milk is the normative standard for VLBW infant nutrition and is associated with multiple health benefits. Neonatal staff and health care providers caring for VLBW infants and their mothers play a critical role in advocating and supporting mothers in NICU lactation.

Key Points

1. Human milk is the optimal nutrition for VLBW infants and decreases the risk of significant complications of prematurity, most notably, NEC. Pasteurized donor milk feeding is recommended when mother's own milk is not available, is insufficient, or is contraindicated.
2. Culturally appropriate information on lactation and the health benefits of human milk should be provided to families of VLBW infants.
3. NICU care for VLBW infants includes determination and support of maternal lactation goals. Lactation consultation with expertise in the needs of preterm infants is an integral part of VLBW NICU care.
4. Racial and ethnic disparities in the provision of mother's own milk and pasteurized donor milk for VLBW infants exist and may be best addressed with center-specific efforts to identify and mitigate local disparities.
5. Effective and efficient double electric breast pumps for mothers of VLBW infants will maximally support mothers in milk expression at the hospital and at home.
6. Because of the need for early and frequent milk expression to maintain milk supply, technical assistance in early milk expression should be available to mothers within 6 to 8 hours of birth of any VLBW infant.
7. Mothers should be encouraged to express their milk as often as needed to maintain a milk supply for their infant(s), ideally every 3 to 4 hours.
8. Written protocols and maternal education addressing milk collection, storage, and transport will optimize infant feeding safety.
9. Centers may encourage and support families in SSC, nonnutritive suckling, and direct breastfeeding, when appropriate to the infant's medical condition.
10. Human milk frequently requires fortification to meet the nutritional needs of VLBW infants. Centers may provide mothers with information on the rationale for and the content of HMFs.
11. CMV infection can be acquired through mother's own milk feeding. Current evidence is insufficient to support withholding mother's own milk solely on the basis of this risk.
12. NICU discharge planning optimally includes defined feeding plans that consider and address the mother's breastfeeding goals in conjunction with the infant's need for milk fortification.

Promoting the Participation of Children and Adolescents With Disabilities in Sports, Recreation, and Physical Activity

Paul S. Carbone, MD, FAAP,[a] Peter J. Smith, MD, MA, FAAP,[b] Charron Lewis, MD, FAAP,[c] Claire LeBlanc, MD, FAAP,[d]
COUNCIL ON CHILDREN WITH DISABILITIES, COUNCIL ON SPORTS MEDICINE AND FITNESS

The benefits of physical activity are likely universal for all children, including children and adolescents with disabilities (CWD). The participation of CWD in physical activity, including adaptive or therapeutic sports and recreation, promotes inclusion, minimizes deconditioning, optimizes physical functioning, improves mental health as well as academic achievement, and enhances overall well-being. Despite these benefits, CWD face barriers to participation and have lower levels of fitness, reduced rates of participation, and a higher prevalence of overweight and obesity compared with typically developing peers. Pediatricians and caregivers may overestimate the risks or overlook the benefits of physical activity in CWD, which further limits participation. Preparticipation evaluations often include assessment of health status, functional capacity, individual activity preferences, availability of appropriate programs, and safety precautions. Given the complexity, the preparticipation evaluation for CWD may not occur in the context of a single office visit but rather over a period of time with input from the child's multidisciplinary team (physicians, coaches, physical education teachers, school nurses, adaptive recreation specialists, physical and occupational therapists, and others). Some CWD may desire to participate in organized sports to experience the challenge of competition, and others may prefer recreational activities for enjoyment. To reach the goal of inclusion in appropriate physical activities for all children with disabilities, child, family, financial, and societal barriers to participation need to be identified and addressed. Health care providers can facilitate participation by encouraging physical activity among CWD and their families during visits. Health care providers can create "physical activity prescriptions" for CWD on the basis of the child's preferred activities, functional status, need for adaptation of the activity and the recreational opportunities available in the community. This clinical report discusses the

importance of participation in sports, recreation, and physical activity for CWD and offers practical suggestions to health care providers.

GLOSSARY OF TERMS

- Children and youth with special health care needs (CYSHCN) are "children who have or are at increased risk for a chronic physical, developmental, behavioral or emotional condition and who also require health and related services of a type or amount beyond that required by children generally."[1] In the United States, 19% of children have a special health care need.[2] CYSHCN are a diverse group of children, ranging from children with chronic conditions, to those with medical complexity, to children with cognitive, behavioral, or emotional conditions. The term CYSHCN includes children with disabilities (CWD) and children with medical complexity, whom are described below and shown in Fig 1.
- CWD are defined under the Individuals with Disabilities Education Act (IDEA) as children with intellectual disabilities, hearing impairments (including deafness), speech or language impairments, visual impairments (including blindness), serious emotional disturbance, orthopedic impairments, autism spectrum disorder, traumatic brain injury, other health impairments, or specific learning disabilities and who, by reason thereof, need special education and related services.[3] Although not part of the IDEA definition, the World Health Organization International Classification of Functioning, Disability and Health (ICF) framework provides an important alternative framework for disability because of its emphasis on body function, pursuit of meaningful activities, and community participation as primary determinates of the health of individuals rather than emphasis on any particular diagnosis or deficit (Fig 2).[4]
- Children with medical complexity have multiple significant chronic health problems resulting in functional limitations, high health care service needs, and often the need for or use of medical technology.[5] An example of a child with medical complexity is one with a genetic syndrome with an associated congenital heart defect, difficulty swallowing, cerebral palsy, and a urologic condition. This child would typically require the care of a primary care physician; multiple pediatric medical subspecialists or pediatric surgical specialists, home nurses, and rehabilitative and habilitative therapists; community-based services; extensive pharmaceutical therapies; special attention to his or her nutritional needs and growth; and durable medical equipment to maintain health, maximize development, and promote function.
- Participation, defined by the ICF, is the nature and extent of a person's involvement in desired activities, such as recreation, leisure activities, and community life. The ICF also emphasizes the interconnection of contextual factors, environmental and personal, that can have profound influences on participation. For example, finding out what recreational activities are enjoyable and fun for CWD (personal factors) and supporting families (environmental factors) can foster increased community participation and bolster overall health.[6,7]
- Physical activity refers to any body movement produced by skeletal muscles that requires energy expenditure.[8]
- Exercise is planned, structured, and repetitive physical activity that aims to improve or maintain one or more component of physical fitness.[8] Exercise may be subdivided into aerobic (cardiovascular endurance), flexibility (increase muscle and joint range of motion), anaerobic (resistance training), and high-impact weight-bearing exercise (that promotes bone health).[8]

INTRODUCTION

International efforts to promote the well-being of CWD through participation in exercise, sports, recreation, and physical activities began with the first competitive sporting event for individuals with disabilities in 1948, followed by the first Paralympics competition in 1960. Special Olympics was established in 1968 and is now the largest recreational program for children and adults with intellectual disabilities, with 5.5 million athletes in 1930 countries.[9] Despite the success of these programs, opportunities for CWD to participate in physical activity, exercise, or competitive sports remain limited, and they are less likely to participate compared with their peers without disabilities.[10–12] In the absence of such opportunities and the encouragement to participate, many CWD engage in more sedentary and solitary activities, leading to a higher prevalence of overweight and obesity, lower levels of cardiorespiratory fitness, and increasing social isolation.[13–19] Taking part in physical activity through recreation and sport provides CWD the opportunity to achieve better physical and mental health, develop skills and competencies, express creativity, form friendships, and improve quality of life.[20–23] Thus, the American Academy of Pediatrics *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition*, includes promotion of physical activity as a key health promotion theme and includes recommendations for health care providers to help CYSHCN and their families identify appropriate and enjoyable activities and implement adaptations based on need and ability.[24]

This clinical report discusses the importance of physical activity for CWD, reviews potential barriers to inclusion, and offers practical solutions for clinicians to facilitate participation. Of note, the terms CYSHCN, CWD, and children with medical complexity are overlapping (Fig 1). This clinical report focuses on the needs of CWD, but many of the comments and recommendations apply also to the larger group of CYSHCN. However, not all points or problems apply equally to the diverse subgroups of CWD. For example, some recommendations may apply more to children with physical impairments or children with cognitive or behavioral impairments. Furthermore, the subgroups within CWD are also overlapping and can shift over time, such as the case in which a child with primary motor impairments as a young child might be more impacted by cognitive or behavioral impairments as an adolescent (Fig 1). Regardless of the subgroup, CYSHCN and all children with different abilities are at risk for being "left out," which can adversely affect wellness, community integration, and full actualization of their individuality. Although it is hoped that children with and without disabilities engage in physical activity together, there will be times when CWD and their families opt for adaptive programs that are focused specifically on their needs. It must also be noted that there is a heterogeneity of adaptive recreation and sports programs, varying both by the type of primary impairment they are focused on and by the competitive levels of the programs. For example, Paralympians are high-performance competitive athletes who generally self-identify as primarily having physical or visual impairments, whereas Special Olympians are often individuals with intellectual and developmental disabilities who compete in many different sports at various competitive levels.[9,25] There are also sports programs for people with hearing impairments, with the most elite being the Deaflympics.[26] Although adaptive recreation programs have existed for more than 50 years, recently there has been accelerated growth in the number of programs, especially those with a primary purpose of fostering physical activity in a noncompetitive, fun environment. Whatever the activity or the level of competition, health care providers can engage in shared decision-making with CWD and their families with the goal of pursuing appropriate opportunities for physical activity.[27]

BENEFITS OF PARTICIPATION IN PHYSICAL ACTIVITIES

The benefits of physical activity are likely universal for all children, including those with disabilities. CWD are underrepresented in exercise intervention research, resulting in a limited understanding of how research involving children without disabilities can be translated into guidance for physical activity programs for CWD. The limited research conducted to date points to at least short-term benefits for CWD, such as improvements in aerobic capacity, muscular strength, physical and cognitive function, body weight and composition, social skills, relationships, and psychological well-being.[28–30] Although many studies of exercise interventions for children with physical disabilities have small sample sizes and lack randomization, they support safe participation and improvements in fitness and well-being.[31] Several studies rated from moderate- to high-quality show that children and youth with physical disabilities who participate in physical activity programs improve their locomotor performance and skills, object control, social skills, peer interactions, and self-confidence.[29] One randomized trial of an 8-month weight-bearing physical activity program for children with cerebral palsy showed improvements in bone mineral density.[32] In some CWD, exercise interventions may even be able to slow disease progression. For example, in 2 randomized trials of assisted bicycle and upper extremity training, functional motor deterioration slowed in boys with Duchenne muscular dystrophy.[33,34] Ambulatory children with spina bifida can also increase their walking speed and cardiorespiratory fitness with treadmill training programs.[35] Thus, *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition*, includes recommendations for health care providers to help CYSHCN and their families identify appropriate and enjoyable physical activities and implement adaptations on the basis of their needs and abilities.

Physical activity also has benefits for children with primarily cognitive and behavioral disabilities. Children with autism spectrum disorder (hereafter referred to as autism), who are more likely to be diagnosed with overweight or obesity, have this risk attenuated with regular physical activity and sports participation.[36] Short periods of walking or running before educational sessions also help children with autism increase the proportion of correct academic responses and work tasks completed in school settings.[37,38] Other exercise interventions for children with autism, such as horseback riding, martial arts, swimming, yoga, or dance, can result in better social responsiveness and decreased irritability, stereotypical behavior, and hyperactivity.[39–43] Although stimulant medication is the mainstay in addressing core symptoms for children with attention-deficit/hyperactivity disorder, aerobic exercise offers a safe and widely beneficial adjunct in decreasing hyperactivity and improving attention and executive function.[44] Youth with intellectual disability who are overweight or obese benefit from participating in an integrative training program, with improved cardiorespiratory fitness, balance, muscle strength, and endurance as well as lower BMI.[45] Adolescents and adults with Down syndrome who receive individualized progressive resistance training over 10 weeks have increased muscular strength and become more physically active.[46]

Beyond the physiologic benefits, regular physical activity, recreation, and sports participation are associated with both psychosocial well-being and quality of life of CWD as well as with improving academic achievements.[21] For example, participants in Special Olympics show heightened self-esteem, perceived physical competence, and peer acceptance when compared with nonparticipants.[47] Physically active individuals with cerebral palsy experience higher quality of life and happiness compared with those who are less active.[20] Children with autism who have higher levels of participation in organized activities, including sports, have better social-emotional adjustment as well as reduced loneliness and depression.[48,49] Children with muscular dystrophies who participate in physical activities, such as swimming, benefit by cultivation of friendships, increased self-confidence, and enjoyment.[50] Children with hearing impairment who participated in a 3-month ice skating program were found by their parents to have improvements in self-esteem, behavior, and sleep quality.[51]

Despite the physical, behavioral, cognitive, and psychosocial benefits of physical activity for CWD, the incorporation of physical activity is often prioritized below other interventions in treatment planning.[49] Yet, as the above examples illustrate, inclusion of physical activity into treatment plans allows CWD real-world and enjoyable opportunities to work on motor, communication, and social skill goals identified in traditional therapies, such as physical, speech, and occupational therapy.

BARRIERS TO PARTICIPATION

Despite the potential benefits, CWD participate in sports, recreation, and physical activity less than children without disabilities, and they experience barriers to participation that go beyond the functional limitations associated with their disabilities (Table 1).[52–57] Without

TABLE 1 Benefits, Barriers, and Considerations for Participation in Sports by CWD

Benefits of participation
Improved wellness
Increased community integration
Improved muscle strength
Improved fundamental movement skills
Enhanced psychosocial well-being
Increased cardiorespiratory fitness
