Decreased morbidity (ie, pressure ulcers, infections, overweight and obesity, etc)
Improved bone health
Improved motor coordination
Improved attention and focus
Decreased maladaptive behaviors
Barriers to participation
False belief: no programs for this population
False belief: participation is unsafe or too risky
False belief: rules of sports too hard to learn or cannot be adapted to accommodate CWD
Low physical literacy
Lack of transportation to and from activities
Lack of needed supervision or expertise
Extra cost and time commitment
Facilitators to participation
Preparticipation evaluations to maximize safety with appropriate accommodations
Organized sports that are focused on fun over competition
Clinicians, physical education teachers, and coaches who create physical activity prescriptions and recognize individual needs
Adaptations such as longer rest periods, lower coach to athlete ratios, copious positive feedback, and close monitoring for symptoms of fatigue or injury

Reproduced with permission from: American Academy of Pediatrics. Athletes with a disability. In: Bernhardt DT, Roberts WO, eds. *PPE: Preparticipation Physical Evaluation.* 5th ed. Itasca, IL: American Academy of Pediatrics; 2019:185

addressing barriers to physical activity, CWD often fill leisure time with sedentary screen-based activities.[18,58] Frequently identified barriers to participation of CWD in sports and physical activity are the child's functional limitations, negative self-perceptions, high cost, lack of accessible facilities, lack of nearby facilities or programs, and lack of providers with adaptive recreation expertise.[10,59–62] In addition, many individuals with disabilities are still, to a large extent, socially segregated and experience negative societal stereotypes and low performance expectations, providing them with limited opportunities for participation in group-based physical activities.[57,60,63] Some CWD may be discouraged to participate by an implicit societal bias that favors competitiveness and winning over participation for the sake of fun, enjoyment, and inclusion. When CWD do attempt to participate in sports, they are also more likely to be bullied by their peers[64,65]; this is especially true for CWD with obesity, who may experience additional weight-bias stigmatization. Primary care providers who have longitudinal and trusting relationships with CWD and their families can be positive role models and use nonjudgmental language and motivational interviewing to identify short-term goals and strategies related to eating and physical activity.[66] With negative experiences and lack of opportunities, support, or encouragement, some CWD may become disinterested or discouraged to participate. Older children and adolescents with disabilities may lose self-confidence to participate as skill gaps between them and their typically developing peers widen and sports become more competitive. Through required physical education services of a child's Individualized Education Program (IEP), schools can develop goals to address deficits in fundamental movement skills to foster physical literacy. However, most CWD take general physical education classes, and although physical education teachers may make accommodations for some, budget constraints and lack of training are cited as barriers to participation.[67,68] Pediatricians, other professionals, and parents may also overestimate the risk of injury during physical activity, although involvement in sports has been shown to be reasonably safe for CWD; one recent study found a lower risk of injury in CWD after controlling for personal and environmental factors.[60,69–71] Nevertheless, parents of CWD are justified in desiring high-quality, accessible, and safe adaptive recreation programs, yet they report marked variation in recreational activity availability, long waiting lists for adaptive programs, absence of suitable transport to these facilities, a reduced number of skilled instructors to run these programs, and poor advertisement of programs in the community.[60,61] Likewise, pediatricians may be unaware of adaptive recreation opportunities within the community or of the family's interest in pursuing these opportunities.[72]

Overall, misconceptions and attitudinal barriers at the level of the individual, family, and community need to be addressed to integrate children of all abilities into recreational and physical activities. Pediatricians can help families and children balance the benefits of participation with the potential risks, recognizing that historically, being "too safe" and assuming that CWD "can't do that," has been a persistent barrier to participation.

FACILITATORS TO PARTICIPATION

The combined efforts of well-informed health care providers, parents, educators, coaches, and others are needed to ensure and promote the participation of all children in sports, recreation, and physical activity (Table 1). Health care providers can facilitate

participation by asking about current levels of activity and using tools, such as a physical activity vital sign (PAVS) in the electronic health record, to start the conversation about physical activity during visits.[23] The PAVS consists of 2 screening questions that are used to assess how many days per week the individual engages in physical activity that is moderate (causes the child or youth to sweat a little and breathe harder, such as bike riding or playground activities) to vigorous (causes the child or youth to sweat and be out of breath, such as running or swimming) and how many minutes this level of physical activity is maintained. Use of the PAVS has been associated with a greater likelihood of physician exercise counseling and improved metabolic outcomes in adults.[73] Clinicians can then create "physical activity prescriptions" for CWD with goals for participation and referrals to specific programs or resources that are based on baseline physical activity, preferred activities, functional limitations that may require adaptation of the activity and preparticipatory planning, and the evidence base of the physical activity regarding risks and benefits.[23] Providers can explore the child and family's beliefs and attitudes about physical activity through motivational interviewing and arrive at a treatment plan through shared decision-making (Appendix 1).[27,74] Lastly, by their own commitment to physical activity, health care providers can serve as role models for CWD and their families. For example, pediatricians with self-reported higher levels of fitness are more likely to discuss physical activity during health supervision visits.[75]

To facilitate participation, providers can refer CWD to specialized adaptive programs staffed by recreational, physical, or occupational therapists that create a safe and fun recreational environment while allowing coordination with the primary care provider if medical concerns occur.[76] Specifically, health care providers and care coordinators within practices can partner with local adaptive recreational programs that address traditional barriers to participation (time, cost, transportation) and share this information with families. For example, many city and county parks and recreation departments offer low-cost adaptive recreation opportunities for CWD, and some adaptive recreational programs offer scholarships and provide transportation to and from activities. Therapists and coaches at specialized adaptive recreation programs facilitate participation for CWD by having lower participant to coach or instructor ratios (fewer than 4 participants for each coach), using positive feedback, and individualizing activities to the preferences of each participant.[77]

Lastly, providers can work with local and state public health agencies to promote physical activity to create and strengthen recreational programs for CWD. The Title V Maternal and Child Health Services Block Grant Program has a National Performance Measure on physical activity, with only 25% of CYSHCN with more complex health needs meeting the measure of being physically active at least 60 minutes per day.[78] At the federal level, the Centers for Disease Control and Prevention funds and supports 2 national centers on disability: Special Olympics and the National Center on Health, Physical Activity and Disability. These centers identify and expand physical activity programs, provide training for professionals, and provide data to establish best practices.[79]

Parents, caregivers, and peers are important facilitators of physical activity for CWD. Parents who believe in the benefits of physical activity report higher levels of activity in their CWD.[70] In one study, CWD whose parents were physically active at least 3 hours per week were 4.2 times as likely to be physically active compared with those whose parents were less active.[80] Therefore, an important message from pediatric health care providers to parents of CWD is to prioritize their own physical activity and to include CWD in family recreational activities.[81] Additionally, CWD are too often left behind regarding organized sports participation despite the clear benefit of participation for CWD. Parents can advocate for and support organized sports that encourage inclusion and focus on fun instead of winning, such as Special Olympics, because these are important influencers of sustained participation by CWD.[65] In addition, peer-mediated interventions to facilitate play skills and foster inclusion and acceptance of CWD by modeling behaviors can be an effective counterbalance to the barrier of systematic exclusion that has (in the past) resulted in opportunities for bullying behaviors.[82,83]

The American Heart Association has called for schools to play a central role in ensuring all students participate in enough physical activity to develop healthy lifestyles.[84] With only 24% of CWD engaging in 60 minutes of physical activity daily, schools can help a greater proportion reach this level of activity.[85] The Centers for Disease Control and Prevention recommends that a substantial percentage of students' overall physical activity should be obtained through school physical education. The right of CWD to participate in physical activity and sports in school is rooted in several federal laws. The

IDEA mandates free, appropriate public education in the least restrictive environment, and Section 504 of the Rehabilitation Act of 1973 requires that no individual shall be excluded because of disability in programs that receive federal funds.[86] Physical education is a federally mandated component of special education services, including the promotion of physical fitness, fundamental movement skills, and skills in individual and group games and sports.[67] However, many school districts allow exemption from physical education requirements for students with cognitive and other disabilities.[87] Physical education curricula for CWD can promote enjoyment of movement and skill development that can be incorporated before, during, and after school hours.[88] Pediatric providers and parents can partner with the educational team to include physical activity goals in progress metrics within a child's IEP to facilitate participation in physical activity at school.[86] Physical activity can be accurately measured for CWD through subjective and objective measures.[89] Adaptive physical education teachers can address physical activity goals by modifying recreational programs to accommodate the motor skills, muscle strength, and fitness of each child. Strategies physical education teachers use to accommodate CWD may include simplified instruction, additional skill modeling, peer teaching, equipment modification, and coordinating activities with a special education teacher.[68] Beyond physical education, the Comprehensive School Physical Activity Program developed by the Centers for Disease Control and Prevention and the Society of Health and Physical Educators, is a framework to capture all opportunities for school-based physical activity for CWD.[90] School nurses can coordinate with pediatricians in developing and implementing health care plans that promote safe participation in physical activity.[91] School-based physical activity programs, such as recess or physical education, that are focused on fun and enjoyment are strongly associated with daily physical activity in CWD.[88]

PREPARTICIPATION CONSIDERATIONS

It is important that all CWD participate in activity-related recreational programs while minimizing risks of illness or injury. Well-designed programs can target fundamental movement skills (throwing, catching, kicking, jumping, running, hopping, balance), flexibility, cardiorespiratory endurance, and muscular strength while maximizing enjoyment and safety. Rather than being excluded from sports participation, all children can be empowered to take part with a can-do attitude, enjoying the dignity of taking acceptable risk during participation just as individuals without disabilities are allowed to do. It is also important to involve parents and caregivers early and often in discussions of the importance of participation in sports, recreation, and physical activity for CWD.

A first step toward regular physical activity of all children, including CWD, is achieving physical literacy, which is the "the ability, confidence, and desire to be physically active for life."[92] For children with typical development, fundamental movement skills emerge in early childhood after the attainment of gross and fine motor milestones in infancy. Later in childhood, provided the child has opportunities to engage regularly in active play and physical activity throughout the day, additional competences are gained in coordination, balance, running, kicking, throwing, and catching.[23] The attainment of these fundamental movement skills influences physical literacy, is a strong predictor of future physical activity levels of children, and is linked to improvement in cardiovascular fitness scores and BMI.[93] Thus, CWD who have decreased gross motor function or other developmental delays may lack fundamental movement skills, may have low physical literacy, and are subsequently at risk for developing a low preference for physical activity during childhood and later in life.[23,94] Physical literacy assessments by health care providers are essential to allow early identification of any deficits.[95] Physical literacy assessments for all children begin in early childhood and encompass surveillance and screening for motor delay and exploring the child and family's knowledge, motivation, and feelings related to physical activity and movement.[23,96,97] Figure 3 provides an adaptation of the ICF framework for pediatricians to use in assessing physical literacy and promoting physical activity in CWD.[7] For CWD who have motor delays, referrals to exercise-related specialists (physical therapist, physical medicine and rehabilitation physician, recreation therapist, sports medicine physician) for structured programming may help to maximize the child's potential in developing fundamental movement skills, which in turn may foster confidence and desire to participate in sports and recreation.[98,99] Furthermore, young CWD can be given the same opportunities as other children to participate in free play and recess to develop fundamental movement skills and to foster the notion that physical activity is fun.[100,101] One such program to include students with autism with typically developing peers during recess activities led to improvements in peer engagement.[102]

How Much Physical Activity to Recommend?

All children, including CWD, are encouraged to strive to follow

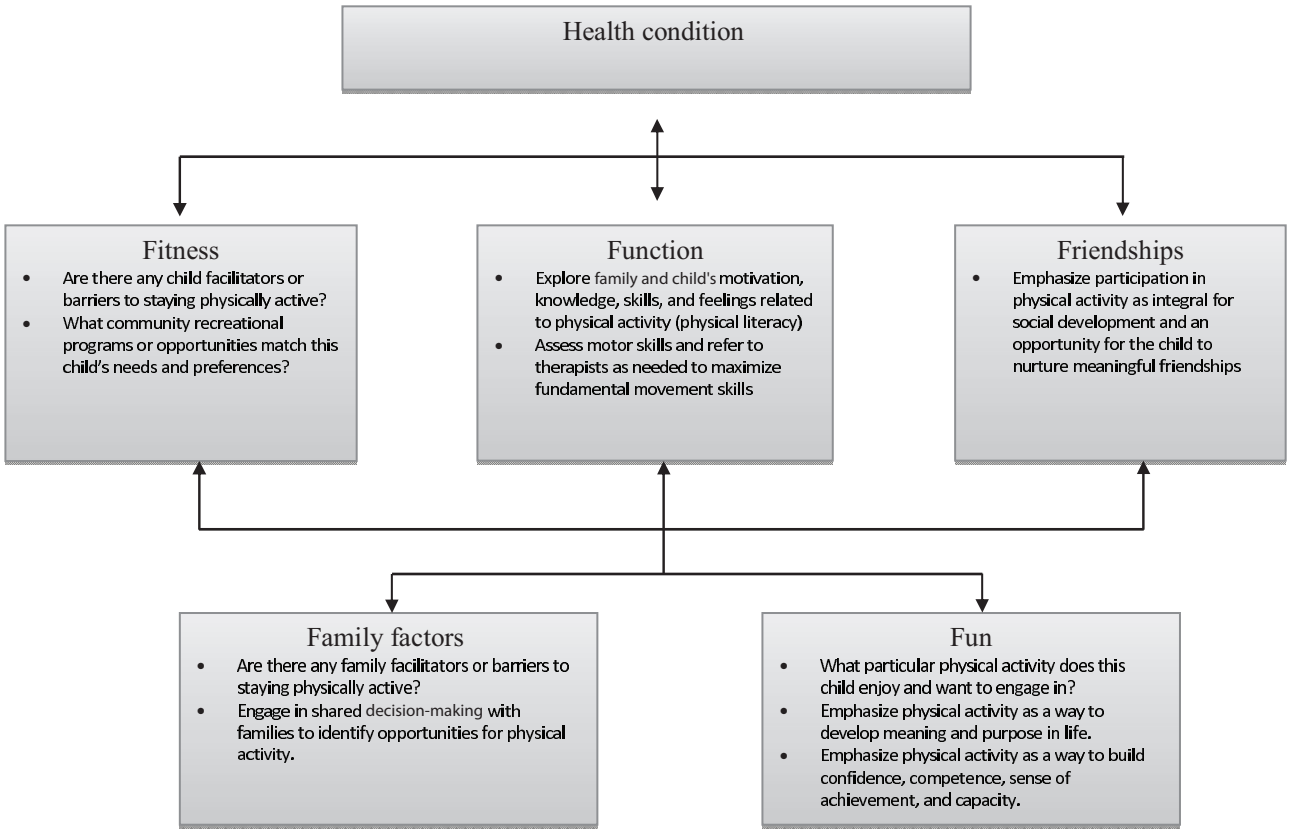

FIGURE 3 Adaptation of the International Classification of Function as a framework of assessing physical literacy and promoting participation of CWD in sports, recreation, and physical activity.[7] Adapted from World Health Organization. *Towards a Common Language for Functioning, Disability and Health*. Geneva, Switzerland: World Health Organization; 2002:9.

guidelines established by the 2018 Physical Activity Guidelines Advisory Committee, which recommends that children and adolescents (6–17 years) take part in at least 60 minutes of moderate to vigorous physical activity daily as well as in bone and muscle strengthening activities at least 3 days a week.[103] Parents of infants are encouraged to keep them active several times a day through interactive floor-based play, and parents of preschool-aged children (3–5 years) are encouraged to have their children accumulate at least 3 hours of light- to moderate-intensity activity throughout the day to develop movement skills.[23,104–106] For CWD, some modifications may be required to the frequency, intensity, and/or duration of physical activity. Goals need to be realistic, with an emphasis on encouraging children and families to do whatever they can through a gradual exploration of increases in time, intensity, and duration.[104] By asking CWD and their families about usual weekly duration and intensity of physical activity, health care providers can adapt physical activity guidelines to accommodate for neuromuscular deficits and cardiorespiratory profiles associated with specific conditions.

The Preparticipation Evaluation: Special Concerns for CWD

Families of CWD will sometimes schedule mandatory preparticipation physical evaluations or recommended health supervision visits. In either case, these visits allow opportunities for families and providers to discuss medical and psychosocial issues that are relevant for participation in physical activity. The concepts of self-determination and shared decision-making have emerged as important themes in the care of CWD.[27] Discussions with children and families may start with a query about the child's current level of physical activity and the importance the family and child place on being physically active. Families of CWD may experience high levels of day-to-day stress and may consider time for physical activity a lower priority. Using behavioral techniques, such as motivational interviewing, providers can explore the family's beliefs and develop achievable physical activity goals. Once the wishes of the child and family are known, conditions that may interfere with participation or predispose the child to injury can be collaboratively discussed between the child, family, provider, and other treatment team members.

The child's current health status and functional ability, demands of the sport (including level of competition), and whether the sport can be modified with protective or adaptive equipment to allow for safer participation are important considerations. Given the complexity, the preparticipation evaluation for CWD may not occur in the context of a single office visit but rather over a period of time with the assistance of care coordination from the primary care medical home to obtain input from the child's multidisciplinary team, which may include subspecialists such as physical medicine and rehabilitation or sports medicine physicians; school nurses, coaches, and physical education teachers; and recreation, physical, and occupational therapists. Ideally, members of the multidisciplinary team can periodically reassess CWD to update treatment plans, including recommendations about sport participation, adaptations, and any restrictions deemed necessary.

The goal of the preparticipation evaluation is to review the desired activities of the child and family and the current state of disability-specific and co-occurring conditions to provide an appropriate menu of activities and potential accommodations or precautions that may be needed. Tables 2 and 3 show elements of a preparticipation history and physical examination that can be used for CWD. For example, children with physical disabilities, such as cerebral palsy, may have decreased flexibility with joint contractures, muscle strength imbalances, and lack of motor control, coordination, and equilibrium, which may increase the risk of lower extremity overuse injuries, strains, and sprains. If a child with cerebral palsy wishes to play baseball and there are limitations in skills (catching, throwing, and using a bat), it may be advisable to consider ways to adapt the sport or the child's participation to prevent injury to the athlete or other participants.[107] Children with neurologic conditions who use wheelchairs for ambulation are at higher risk of upper extremity overuse injuries, peripheral nerve entrapment (eg, carpal tunnel syndrome), and pressure sores affecting the sacrum and ischial tuberosities.[108] The preparticipation evaluation presents an opportunity to screen for skin ulcerations and, when present, initiate appropriate treatment before sports participation.[109,110] Inspecting the adaptive or medical equipment used by CWD participating in sport so that braces are appropriately fitted and sports wheelchairs are in proper working order promotes optimum performance and injury prevention. Families can be encouraged to bring all equipment used during physical activity to the preparticipation visit so that these assessments can be conducted. If needed, referrals to exercise-related subspecialists (physical therapist, physical medicine and rehabilitation physician, recreation therapist, sports medicine physician) can be made for equipment adjustments or other equipment concerns.

The preparticipation evaluation also allows for the provision of anticipatory guidance that promotes safe participation for children with physical disabilities. For example, athletes with spinal cord pathology above the sixth thoracic level may develop autonomic dysreflexia, which is excessive and uncontrolled sympathetic nervous system output. This condition, which can be life-threatening, may be triggered by bladder infections, sunburns, and other stimuli or may be self-induced by an act such as occluding a bladder catheter in an attempt to improve sport performance (also known as "boosting"). Autonomic dysreflexia may present with symptoms and signs such as headache, high blood pressure, or bradycardia, and these symptoms prompt immediate removal of the precipitating factor and prompt medical care.[107] Children with spinal cord injuries and cerebral palsy are also at risk for abnormal thermoregulation and exertional heat illness resulting from impaired sweating and control of peripheral blood flow as well the use of certain medications (such as those with anticholinergic properties).[107,111] As is the current practice for most adaptive and therapeutic sports organizations, coaches can modify the activity as needed, provide frequent breaks of appropriate duration, have ready access to fluids, and use appropriate clothing and equipment, which can mitigate this risk.[107,111,112]

Children with developmental disabilities also benefit from preparticipation planning and anticipatory guidance. For example, children with autism may have apraxia and motor coordination deficits, increasing the risk for injuries.[113] This risk can be managed by adaptations to the activity or the equipment or with additional neuromotor training to develop kinesthetic awareness.[114] Children with intellectual disability may have lower muscle strength, balance, flexibility, and endurance and may benefit from exercise that is of lower intensity as well as preparatory conditioning, such as resistance training, to reduce the risk of injury.[108] Children with Down syndrome are at slight increased risk of symptomatic atlantoaxial instability (AAI). Neurologic manifestations of AAI with cervical cord myelopathy include significant neck pain, radicular pain, weakness, spasticity or change in tone, gait difficulties, hyperreflexia, and change in bowel or bladder function or other signs or symptoms of myelopathy. In the

TABLE 2 Elements of a History During Preparticipation Evaluation for CWD

History	Comments
Is there a history of seizures?	Children with uncontrolled seizures or implantable devises (eg, ventriculoperitoneal shunt, vagal nerve stimulator) may benefit from consultation with a neurologist or neurosurgeon, respectively, to assist with medical eligibility. Although there is no universal exclusion for participation in contact sports for children with epilepsy, some families may choose to avoid sports in which seizure activity would pose risk to self or others (eg, archery, riflery, weightlifting, and sports that involve heights). There are considerations related to prevention of drowning in children with epilepsy who swim.[118] In addition, some antiepilepsy drugs can impair normal sweating.
Is there a history or concern for hearing or vision loss?	Boxing and full-contact martial arts are not recommended for functionally one-eyed athletes.[119] Visually asymptomatic CWD are encouraged to have a vision screening based on the *Bright Futures* periodicity table. Those with ocular signs or symptoms are recommended to have a complete examination by a pediatric ophthalmologist.[120]
Is there a history or concern for cardiopulmonary disease?	Children with stage 2 hypertension are recommended to refrain from high-static sports (weightlifting, gymnastics). Children with congenital heart disease, structural heart disease, and dysrhythmias are encouraged to have consultation with a cardiologist.[119]
Is there history of symptomatic AAI?	Children with symptomatic AAI may report or demonstrate fatigue, gait abnormalities, neck pain, limited neck range of motion, changes in coordination, spasticity, hyperreflexia, clonus, or extensor-plantar reflex. Parents can be advised that participation in contact sports, such as football, soccer, and gymnastics, places children at risk for spinal cord injury.[115]
Is there a history of heat stroke or heat exhaustion?	Thermoregulation in children with spinal cord injuries can be impaired because of skeletal muscle paralysis (impaired shivering and reduced ability to produce heat) and a loss of autonomic nervous system control (impaired sweating and vasodilation to dissipate heat). Athletes who have a history of heat illness are more at risk to develop the condition again.
Is there a history of fractures or dislocations?	Ligamentous laxity and joint hypermobility are more common in some disabilities, such as Down syndrome and Ehlers-Danlos syndrome. Children with obesity, those with osteogenesis imperfecta, and athletes in wheelchairs may have reduced bone mineral density with increased fracture risk.
Are there adaptive devices used during sports participation?	Health care providers are encouraged to be aware of the child's need for adaptive equipment. Athletes using wheelchairs are at increased risk for shoulder and wrist injuries and upper extremity peripheral nerve entrapment syndrome.
Is there a need for bladder catheterization?	Athletes with spinal cord injuries or other neurologic conditions may have neurogenic bladder and need an indwelling catheter or require intermittent catheterization.
Is there a history of pressure sores or ulcers?	Children who use wheelchairs are prone to pressure ulcers over the sacrum and ischial tuberosities.
What medications is the child taking?	Medications used for pain and bladder dysfunction can interfere with the normal sweating response; medications that alter QT intervals also may require special assessments.
Is there a history of autonomic dysreflexia?	Autonomic dysreflexia is acute onset of excessive, unregulated sympathetic output that can occur in children with spinal cord injuries at or above the sixth thoracic spinal cord level. This condition may occur spontaneously or may be self-induced (boosting) in an attempt to improve performance.[121]

Adapted from American Academy of Pediatrics. Athletes with a disability. In: Bernhardt DT, Roberts WO, eds. *PPE: Preparticipation Physical Evaluation.* 5th ed. Itasca, IL: American Academy of Pediatrics; 2019:182–183.

absence of myelopathic signs and symptoms during the preparticipation evaluation, routine radiographic evaluation of the cervical spine is not recommended.

Children and youth with Down syndrome can be encouraged to participate in activities they enjoy, although contact sports, such as football, soccer, and gymnastics, may place them at increased risk of spinal cord injury.[115]

As the above examples illustrate, for each child and youth with a

TABLE 3 Elements of a Physical Examination During Preparticipation Evaluation for CWD

Physical Examination Components	Items to Screen
Ocular	Decreased visual acuity
	Ocular health
	Strabismus
	Abnormalities in ocular appearance
Cardiovascular	Cardiovascular heart disease
	Hypertension
Neurologic	Peripheral neuropathies
	Inadequate motor control
	Inadequate coordination and balance
	Clonus
	Impaired hand-eye coordination
	Sensory dysfunction
	AAI
	Hyperreflexia
	Ataxia
	Muscle weakness
	Spasticity
	Upper motor neuron and posterior column signs and symptoms
Dermatologic	Abrasions
	Lacerations
	Blisters
	Pressure ulcers
	Rashes
Musculoskeletal	Limited neck range of motion
	AAI
	Torticollis
	Decreased flexibility, often with contractures; decreased strength; and muscle strength imbalance
	Wrist and elbow extensor tendinitis in athletes using wheelchairs
	Rotator cuff tendinitis and impingement in athletes using wheelchairs
	Pelvic dysfunction caused by lower extremity prosthetic device causing unequal leg lengths

disability, pediatricians can review condition-specific information, current medications, and other individualized aspects of the history to offer recommendations that promote safe participation. Concerns or questions that arise during the preparticipation visit can be addressed through consultation with a sports medicine or physical medicine and rehabilitation physician, who can provide additional guidance. Although a comprehensive review of preparticipation considerations is beyond the scope of this report, health care providers are encouraged to refer to the publication *PPE: Preparticipation Physical Evaluation, Fifth Edition*, which has a chapter titled "Athletes with Disability." A supplemental history form for athletes with a disability and a Special Olympics medical form are available for download at https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Pages/PPE.aspx or in Supplemental Fig 4.[116]

RECOMMENDATIONS

Pediatricians can promote participation of children and adolescents with disabilities in sports, recreation, and physical activity in the following ways:

1. Assess motor development, physical literacy, and physical activity levels at all health supervision visits with CWD.
    a. Adding a PAVS to visits can help start conversations about physical activity with CWD and their families.

Communicate the physical, beha-vioral, cognitive, and social-emotional benefits of participation in sports, recreation, and physical activity to CWD and their caregivers (Table 1).

- a. Promotion of physical activity is a *Bright Futures* key health promotion theme to be aware of in each stage of child development.[24]

Health care providers can make a difference when they agree to "take the pledge" to talk to their patients about physical activity (https://www.nchpad.org/pledge/doctalk).
Encourage parents to be physically active and encourage inclusion of CWD in family recreational activities.
Recognize, identify, and address barriers to participation at the individual, family, community, and societal levels to increase the opportunities for CWD to be physically active (Table 1).

- a. Refer CWD to local adaptive and therapeutic recreation programs that decrease the barriers to participation. If there is limited access to local programs, home-based programs with adapted exercises and movements can be recommended. Free-to-access videos are available through the National Center on Health, Physical Activity and Disability (https://www.nchpad.org/Videos).

Pediatricians can partner with families, schools, and community organizations in advocating for safe, affordable, accessible, and inclusive recreational programs for CWD to reduce disparities in participation in physical activity;
Encourage participation by discu-ssing physical activity goals with CWD and their families and

partnering with interdisciplinary team members to develop physical activity prescriptions that can be incorporated within an after-visit summary within the electronic medical record. If a handwritten paper note is preferred, a free physical activity prescription pad is available through the Americans with Disabilities Fund at http://foundationforpmr.org/old/physicians/diagnostic-population/rx-for-exercise-pediatrics-new/.

a. Participation in recreation, sports, and physical activity has inherent risk for all. Rather than exclusion from sports participation, pediatricians can encourage CWD to adopt a can-do attitude, enjoying the dignity of taking acceptable risk during participation just as individuals without disabilities are allowed to do.

While striving to meet the 2018 Physical Activity Guidelines Advisory Committee recommendations for physical activity, some CWD will require modifications to the frequency, intensity, and/or duration of physical activity. Realistic goals can be based on gradual increases in baseline duration and intensity of physical activity.

Perform preparticipation evaluations for CWD, in collaboration with the child, family, pediatric specialists, and therapists, leading to opportunities to participate in sports and recreational activities with appropriate adaptation to minimize risk of injury (Tables 2 and 3).

a. Encourage families to bring ada-ptive equipment used during physical activity to visits to assess need for adjustments or referrals.

PPE: Preparticipation Physical Evaluation, Fifth Edition, serves as a resource for medical providers to keep athletes safe and healthy while participating in sports and includes condition-specific preparticipation considerations for athletes with disabilities.

The use of a preparticipation form can promote the documentation of relevant medical issues that can be shared with therapeutic recreation programs, schools, and coaches (Supplemental Fig 4; https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Pages/PPE.aspx).

Partner with children, parents, and educational teams to include physical activity goals and modifications in a student's IEP and advocate for school-based physical activity programs for CWD.

Be aware of and actively refer to local school and community-based organizations that offer appropriate physical activity programs and sports for CWD.

a. Local and state disability organizations, such as family-to-family health information centers and Family Voices, may have up-to-date lists of adaptive recreation programs (https://familyvoices.org/).

Web sites of national organizations, such as Special Olympics, the National Center on Health, Physical Activity and Disability, and Move United, can provide information on local activities (see Resources for Health Care Providers and Families).

Advocate at the local, state, and national levels for policies that that promote inclusion of CWD in sports, recreation, and physical activity and for surveillance systems that include CWD to track participation and access.[117]

SUMMARY AND CONCLUSIONS

Participation in free play, sports, recreational programs, and physical activity improves health, well-being, and quality of life for CWD and their families. Although more research is needed to confirm specific outcomes and benefits, particularly among individuals with higher levels of disability, clinicians should not hesitate to promote physical activity for CWD. Well-informed decisions regarding each child's participation are made through consideration of individual activity preferences, overall health status, motor skills, balance, muscle strength, bone strength, fitness level, and the availability of adaptive programs. Child, family, and societal barriers to participation continue to exist and need to be directly identified and addressed through advocacy at the local, state, and federal levels. Pediatric health care providers are urged to promote healthy, active living for CWD through physical activity, exercise, recreation, and organized sport by creating specific physical activity prescriptions suited to the child's interests and ability. The benefits are substantial not only for the children who participate but also for communities that welcome them.

APPENDIX: SAMPLE PROCESSES IN CREATING PHYSICAL ACTIVITY PRESCRIPTIONS FOR CWD

Example 1

During a health supervision visit for a 10-year-old girl with autism spectrum disorder, the clinician notes her BMI is greater than the 95th percentile. On the PAVS, the mother reports 1 day of physical activity per week for 20 minutes. When asked, the child indicates she likes playing basketball, but her mother reports that previous attempts at several team sports, including basketball, have been negative experiences. Her mother explains that the skills required, the pace of play, and the increasingly competitive aspect of the team exceeded her capability, resulting in her becoming discouraged and quitting. She has since become more involved in sedentary activities, such as video games and television viewing. Through a previous collaboration with the state parent-to-parent network, the care coordinator for the practice maintains a list of local adaptive recreational programs. The clinician informs the family of a low-cost adaptive basketball program for CWD offered by the nearby parks and recreation department. Through motivational interviewing, the child and parent agree to walk the family dog to the park 3 times per week, where she can practice basketball in addition to the twice weekly basketball activities offered through the adaptive recreation program. Her after-visit summary includes a physical activity prescription with the contact information for the program and the goals of basketball 3 times per week and walking to the park 3 times per week. At follow-up in 3 months, the child proudly shows the clinician the team photograph of her adaptive basketball team. Her PAVS has improved to 4 days of activity per week for 40 minutes. Her mother reports meeting families of other CWD through the program, which has resulted in friendships and the child wanting to enroll in other sports offered.

Example 2

A 12-year-old boy with hemiplegic cerebral palsy, intellectual disability, and attention-deficit/hyperactivity disorder is seen in follow-up. Despite taking stimulant medication, he continues to display impulsive and oppositional behaviors, especially at home. He is tripping and falling and complaining of more pain, leading to less physical activity. He previously had an ankle foot orthosis but stopped wearing it after excessive skin irritation and pain. His PAVS filled out by his mother shows 2 days of activity per week for 30 minutes. His examination shows increased right upper and lower extremity tone and hyperreflexia. His right hamstrings and gastrocnemius muscles are tight, and his right ankle does not dorsiflex past 0°. Through motivational interviewing, he expresses a desire to participate in martial arts, which his mother states he initially enjoyed before quitting because of pain. His after-visit summary includes a physical activity prescription for martial arts after consultation for further preparticipation planning with several specialists. He is referred for a physical medicine and rehabilitation consultation with the request for assistance in preparticipation planning for martial arts. In the physical medicine and rehabilitation clinic, his spasticity is treated with intramuscular botulinum toxin injections, and he is fitted with a new ankle foot orthosis. He is referred to physical therapy and has weekly sessions to address goals of improving core strength, balance, and lower extremity flexibility and to refine and reinforce his home exercise program. He visits with his primary care pediatrician regularly, often bringing the latest color belt that he has earned in karate. His mother feels that the stimulant medication, his home exercise program, and martial arts have helped with attention, focus, and quality of life.

This statement updates the recommendations of the American Academy of Pediatrics for the routine use of influenza vaccine and antiviral medications in the prevention and treatment of influenza in children during the 2021–2022 influenza season. A detailed review of the evidence supporting these recommendations is published in the accompanying technical report.[1] The American Academy of Pediatrics recommends annual influenza immunization of all children without medical contraindications, starting at 6 months of age. Influenza vaccination is an important intervention to protect vulnerable populations and reduce the burden of respiratory illnesses during circulation of severe acute respiratory syndrome coronavirus 2, which is expected to continue during the 2021–2022 influenza season. Any licensed, recommended, age-appropriate vaccine available can be administered, without preference for one product or formulation over another. Antiviral treatment of influenza with any licensed, recommended, age-appropriate influenza antiviral medication is recommended for children with suspected or confirmed influenza who are hospitalized, have severe or progressive disease, or have underlying conditions that increase their risk of complications of influenza. Antiviral treatment may be considered for any previously healthy, symptomatic outpatient not at high risk for influenza complications, in whom an influenza diagnosis is confirmed or suspected, if treatment can be initiated within 48 hours of illness onset and for children whose siblings or household contacts either are younger than 6 months or have a high-risk condition that predisposes them to complications of influenza.

T T

Children consistently have the highest attack rates of influenza in the community during seasonal influenza epidemics. Children play a pivotal role in the transmission of influenza virus infection to household and other close contacts and can experience substantial morbidity, including severe or fatal complications from influenza infection.[2] Children younger than 5

years, especially those younger than 2 years, and children with certain underlying medical conditions are at increased risk of hospitalization and complications attributable to influenza (Table 1).[2] School-aged children bear a large influenza disease burden and are more likely to seek influenza-related medical care compared with healthy adults.[2,3] Reducing influenza virus transmission among children decreases the burden of childhood influenza and transmission of influenza virus to household contacts and community members of all ages.[2,3] Influenza vaccination is particularly important during the severe acute respiratory syndrome coronavirus 2 pandemic to reduce the burden of respiratory illnesses and hospitalizations and preserve the capacity of the health care infrastructure. The American Academy of Pediatrics (AAP) recommends routine influenza vaccination and antiviral agents for the prevention and treatment of influenza in children, respectively. This policy statement summarizes updates and recommendations for the 2021–2022 influenza season. An accompanying technical report provides further detail regarding recent influenza seasons, influenza vaccine effectiveness (VE), detailed updates of inactivated influenza vaccines (IIVs) and live attenuated influenza vaccines (LAIVs), influenza vaccination coverage, vaccine implementation, and timing of vaccination and duration of protection.[1]

UPDATES FOR THE 2021–2022 INFLUENZA SEASON

1. All pediatric and adult seasonal influenza vaccines are quadrivalent. Trivalent vaccines are no longer expected to be available in the United States.
2. The composition of the influenza vaccines for 2021–2022 has been updated. The recommended influenza A(H1N1)pdm09 and A(H3N2) components of the vaccine are new for this season. The influenza B components are unchanged from the previous season.
3. The vaccine formulations available for children 6 through 35 months of age are unchanged from last season (Table 2). Afluria Quadrivalent is the only vaccine for children 6 through 35 months of age available in a dosing volume of 0.25-mL prefilled syringe. Fluzone Quadrivalent, which was previously available in a 0.25-mL and a 0.5-mL prefilled syringe, is only available in a 0.5-mL presentation for this age group. However, a 0.25-mL dose is still an approved option if drawn from a multidose vial. The presentation and approved dose for the 2 other vaccines available for this age group, Fluarix and FluLaval, is 0.5 mL.
4. The age indication for the cell culture–based IVV, Flucelvax Quadrivalent, has been extended to ages 2 years and older (previously indicated for 4 years and older), providing one more option for young children.
5. Any licensed, recommended, age-appropriate vaccine available can be administered, without preference for one product or formulation over another.
6. Children 6 months through 8 years of age who are receiving influenza vaccine for the first time, who have received only 1 dose ever before July 1, 2021, or whose

TABLE 1 People at High Risk of Influenza Complications

Children aged <5 y, and especially those aged <2 y,[a] regardless of the presence of underlying medical conditions
Adults aged ≥50 y, and especially those aged ≥65 y
Children and adults with chronic pulmonary (including asthma and cystic fibrosis), hemodynamically significant cardiovascular disease (except hypertension alone), or renal, hepatic, hematologic (including sickle cell disease and other hemoglobinopathies), or metabolic disorders (including diabetes mellitus)
Children and adults with immunosuppression attributable to any cause, including that caused by medications or by HIV infection
Children and adults with neurologic and neurodevelopment conditions (including disorders of the brain, spinal cord, peripheral nerve, and muscle, such as cerebral palsy, epilepsy, stroke, intellectual disability, moderate to severe developmental delay, muscular dystrophy, or spinal cord injury)
Children and adults with conditions that compromise respiratory function or handling of secretions (including tracheostomy and mechanical ventilation)[6]
Women who are pregnant or postpartum during the influenza season
Children and adolescents aged <19 y who are receiving long-term aspirin therapy or salicylate-containing medications (including those with Kawasaki disease and rheumatologic conditions) because of increased risk of Reye syndrome
American Indian and Alaska Native people[b]
Children and adults with obesity (ie, BMI ≥40 for adults and based on age for children)
Residents of chronic care facilities and nursing homes

Adapted from the Centers for Disease Control and Prevention. Prevention and control of seasonal influenza with vaccines: recommendations of the Advisory Committee on Immunization Practices—United States, 2021–22 influenza season. *MMWR Recomm Rep.* 2021, In press.

[a] The Centers for Disease Control and Prevention recommendations state: Although all children younger than 5 years old are considered at higher risk for complications from influenza, the highest risk is for those younger than 2 years old, with the highest hospitalization and death rates among infants younger than 6 months old.

[b] American Indian and Alaska Native (AI and AN) children have a higher rate of influenza complications.[7–10] Most at-risk AI and AN children will also qualify in other high-risk categories to receive appropriate antiviral treatment. In the setting of a shortage, AI and AN children should be prioritized to receive influenza vaccine or antiviral medications, according to local public health guidelines.

TABLE 2 Recommended Seasonal Influenza Vaccines for Different Age Groups: United States, 2021–2022 Influenza Season

Vaccine	Trade Name (Manufacturer)	Age Group	Presentation and Hemagglutinin Antigen Content (IIVs and RIV4) or Virus Count (LAIV4) per Dose for Each Antigen	Thimerosal Mercury Content (mg Hg/0.5-mL Dose)	CPT Code
Quadrivalent standard dose: egg-based vaccines					
IIV4	Afluria Quadrivalent (Seqirus)	6–35 mo	0.25-mL prefilled syringe (7.5 μg/0.25 mL)	0	90685
	Afluria Quadrivalent (Seqirus)	≥36 mo	0.5-mL prefilled syringe (15 μg/0.5 mL)	0	90686
	Afluria Quadrivalent (Seqirus)	≥6 mo	5.0-mL multidose vial[a] (15 μg/0.5 mL)	24.5	90687
	Fluarix Quadrivalent (GlaxoSmithKline)	≥6 mo	0.5-mL prefilled syringe (15 μg/0.5 mL)	0	90686
	FluLaval Quadrivalent (GlaxoSmithKline)	≥6 mo	0.5-mL prefilled syringe (15 μg/0.5 mL)	0	90686
	Fluzone Quadrivalent (Sanofi Pasteur)	≥6 mo	0.5-mL prefilled syringe (15 μg/0.5 mL) (0.25 mL no longer available)	0	90686
	Fluzone Quadrivalent (Sanofi Pasteur)	≥6 mo	0.5-mL single-dose vial (15 μg/0.5 mL)	0	90686
	Fluzone Quadrivalent (Sanofi Pasteur)	≥6 mo	5.0-mL multidose vial[a] (15 μg/0.5 mL)	25	90687
Quadrivalent standard dose: cell culture–based vaccines					
ccIIV4	Flucelvax Quadrivalent (Seqirus)	≥2 y	0.5-mL prefilled syringe (15 μg/0.5 mL)	0	90674
	Flucelvax Quadrivalent (Seqirus)	≥2 y	5.0-mL multidose vial[a] (15 μg/0.5 mL)	25	90756
Quadrivalent standard dose: egg-based with adjuvant vaccines					
aIIV4 MF-59 adjuvanted	Fluad Quadrivalent (Seqirus)	≥65 y	0.5-mL prefilled syringe ((15 μg/0.5 mL)	0	90653
Quadrivalent high dose: egg-based vaccine					
IIV4	Fluzone High Dose (Sanofi Pasteur)	≥65 y	0.7-mL prefilled syringe (60 μg/0.7 mL)	0	90662
Recombinant vaccine					
RIV4	Flublok Quadrivalent (Sanofi Pasteur)	≥18 y	0.5-mL prefilled syringe (45 μg/0.5 mL)	0	90682
Live attenuated vaccine					
LAIV4	FluMist Quadrivalent (AstraZeneca)	2–49 y	0.2-mL prefilled intranasal sprayer (Virus dose: 10 6.5–7.5 FFU/0.2 mL)	0	90672

Adapted from the Centers for Disease Control and Prevention. Prevention and control of seasonal influenza with vaccines: recommendations of the Advisory Committee on Immunization Practices (ACIP)—United States, 2021–2022 influenza season. *MMWR Recomm Rep.* 2021. In press. Table has been reformatted and updated. Implementation guidance on supply, pricing, payment, CPT coding, and liability issues can be found at www.aapredbook.org/implementation. aIIV4, quadrivalent adjuvanted inactivated influenza vaccine; ccIIV4, quadrivalent cell culture–based inactivated influenza vaccine; CPT, *Current Procedural Terminology*; FFU, fluorescent focus unit; LAIV4, quadrivalent live attenuated influenza vaccine; RIV4, quadrivalent recombinant influenza vaccine.

[a] For vaccines that include a multidose-vial presentation, a maximum of 10 doses can be drawn from a multidose vial.

vaccination status is unknown should be offered vaccination as soon as influenza vaccines become available and should receive 2 doses of vaccine 4 weeks apart, ideally by the end of October (Fig 1). Children needing only 1 dose of influenza vaccine, regardless of age, should also receive vaccination ideally by the end of October. Data available to date on waning immunity do not support delaying vaccination in children.

7. Influenza vaccine may be administered simultaneously with or any time before or after administration of the currently available novel coronavirus disease 2019 (COVID-19) vaccines. Given that it is unknown whether reactogenicity of COVID-19 vaccines will be increased with coadministration of influenza vaccine, the reactogenicity profile of the vaccines should be considered, and providers should consult the most current Advisory Committee on Immunization Practices (ACIP)/AAP guidance regarding coadministration of COVID-19 vaccines with influenza vaccines.
8. Children with acute moderate or severe COVID-19 should not receive influenza vaccine until they have recovered; children with mild illness may be vaccinated.
9. The language on contraindications for IIV and LAIV has been updated to harmonize with recommendations of the ACIP and package inserts. A documented previous severe reaction to any IIV or LAIV is a contraindication to vaccination with IIV or LAIV.
10. The importance of influenza vaccination during the severe acute respiratory syndrome coronavirus 2 pandemic is emphasized.

HIGH-RISK GROUPS IN PEDIATRICS

Children and adolescents with certain underlying medical conditions have a high risk of complications from influenza (Table 1). Although universal influenza vaccination is recommended for everyone starting at 6 months of age, emphasis should be placed in ensuring that high-risk and vulnerable children and their household contacts and caregivers receive annual influenza vaccine.

SEASONAL INFLUENZA VACCINES

The seasonal influenza vaccines licensed for children and adults for the 2021–2022 season are shown in Table 2. More than one product may be appropriate for a given patient, and vaccination should not be delayed to obtain a specific product.

All 2021–2022 seasonal influenza vaccines will be quadrivalent and contain the same influenza strains as recommended by the World Health Organization and the US Food and Drug Administration Vaccines and Related Biological Products Advisory Committee for the Northern Hemisphere.[4,5] Both influenza A(H1N1) and A(H3N2) components are different in this

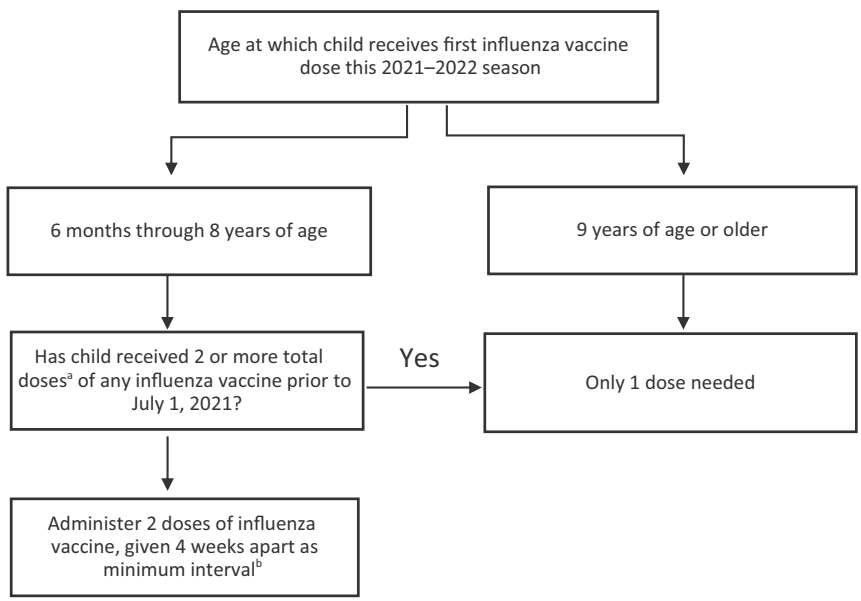

FIGURE 1 Number of 2021–2022 seasonal influenza vaccine doses for children based on age and previous vaccination history. [a] The 2 doses need not have been received during the same season or consecutive seasons. [b] Administer 2 doses based on age at receipt of the first dose of influenza vaccine during the season. Children who receive the first dose before their ninth birthday should receive 2 doses, even if they turn 9 years old during the same season.

season's vaccine. The B components are unchanged. The influenza A strains may be different for egg-based versus cell- or recombinant-based vaccines on the basis of their optimal characteristics for each platform, but all are matched to the strains expected to circulate in the 2021–2022 season.

1. Quadrivalent vaccines contain:
   a. influenza A(H1N1) component:
      i. egg-based vaccines: A/Victoria/2570/2019 (H1N1) pdm09-like virus (new this season);
      ii. cell- or recombinant-based vaccines: A/Wisconsin/588/2019 (H1N1) pdm09-like virus (new this season).
   b. Influenza A(H3N2) component:
      i. egg-based vaccines: A/Cambodia/e0826360/2020 (H3N2)-like virus (new this season);
      ii. cell- or recombinant-based vaccines: A/Cambodia/e0826360/2020 (H3N2)-like virus (new this season).
   c. B/Victoria component:
      i. all vaccines: B/Washington/02/2019-like virus (B/Victoria/2/87 lineage) (unchanged).
   d. B/Yamagata component:
      i. all vaccines: B/Phuket/3073/2013-like virus (B/Yamagata/16/88 lineage) (unchanged).
2. Trivalent vaccines do not include the B/Yamagata component (not available in United States).

INFLUENZA VACCINE RECOMMENDATIONS

1. The AAP recommends annual influenza vaccination for everyone 6 months and older, including children and adolescents, during the 2021–2022 influenza season.
2. For the 2021–2022 influenza season, the AAP recommends that any licensed influenza vaccine appropriate for age and health status can be used for influenza vaccination in children. IIV and LAIV are options for children for whom these vaccines are appropriate. This recommendation is based on review of current available data on LAIV and IIV VE. The AAP will continue to review VE data as they become available and update these recommendations if necessary.
3. The AAP does not have a preference for any influenza vaccine product over another for children who have no contraindication to influenza vaccination and for whom more than one licensed product appropriate for age and health status is available. Pediatricians should administer whichever formulation is available in their communities to achieve the highest possible coverage this influenza season.
4. Children 6 through 35 months of age may receive any licensed, age-appropriate IIV available this season, at the dose indicated for the vaccine. No product is preferred over another for this age group. Children 36 months (3 years) and older should receive a 0.5-mL dose of any available, licensed, age-appropriate vaccine.
5. The number of seasonal influenza vaccine doses recommended to be administered to children in the 2021–2022 influenza season remains unchanged and depends on the child's age at the time of the first administered dose and vaccine history (Fig 1).
6. Children 6 months through 8 years of age who are receiving influenza vaccine for the first time or who have received only 1 dose before July 1, 2021, or whose vaccination status is unknown, should receive 2 doses of influenza vaccine 4 weeks apart, ideally by the end of October, and vaccines should be offered as soon as they become available. Children needing only 1 dose of influenza vaccine, regardless of age, should also receive vaccination ideally by the end of October.
7. Influenza vaccine may be administered simultaneously with or any time before or after administration of the currently available COVID-19 vaccines. Given that it is unknown whether reactogenicity of COVID-19 vaccines will be increased with coadministration of influenza vaccine, the reactogenicity profile of the vaccines should be considered, and providers should consult the most current ACIP/AAP guidance regarding coadministration of COVID-19 vaccines with influenza vaccines.
8. Children with acute moderate or severe COVID-19 should not receive influenza vaccine until they have recovered; children with mild illness may be vaccinated.
9. Efforts should be made to ensure vaccination for children in high-risk groups (Table 1) and their contacts, unless contraindicated.
10. Product-specific contraindications must be considered when selecting the type of vaccine to administer. Children who have had an allergic reaction after a previous dose of any influenza vaccine should be evaluated by an allergist to determine if future receipt of the vaccine is appropriate.
11. Children with egg allergy can receive influenza vaccine (IIV or LAIV) without any additional precautions beyond those recommended for all vaccines.

12. Pregnant women should receive IIV at any time during pregnancy, to protect themselves and their infants, who benefit from the transplacental transfer of antibodies. Women in the postpartum period who did not receive vaccination during pregnancy should receive influenza vaccine before discharge from the hospital. Influenza vaccination during breastfeeding is safe for mothers and their infants.
13. The AAP supports mandatory vaccination of health care personnel (HCP) as a crucial element in preventing influenza and reducing health care–associated influenza infections because HCP often care for individuals at high risk for influenza-related complications.

INFLUENZA VACCINE CONTRAINDICATIONS AND PRECAUTIONS

The contraindications and precautions for the use of IIV and LAIV are described in Table 3, and further details are provided in the technical report.[1] Anaphylactic and severe allergic reactions to any influenza vaccine are contraindications to vaccination. The AAP recommends that children who have had an allergic reaction after a previous dose of any influenza vaccine should be evaluated by an allergist to determine if future receipt of the vaccine is appropriate.

INFLUENZA TREATMENT RECOMMENDATIONS

Antivirals available for the treatment and prophylaxis of influenza in children are described in Table 4.

1. Antiviral medications are important in the control of influenza but are not a substitute for influenza vaccination. Pediatricians should promptly identify patients suspected of having influenza infection for timely initiation of antiviral treatment, when indicated and based on shared decision-making between the pediatrician and child's caregiver, to reduce morbidity and mortality. Although best results are observed when the child is treated within 48 hours of symptom onset, antiviral therapy should still be considered beyond 48 hours of symptom onset in children with severe disease or those at high risk of complications.
2. Antiviral treatment should be offered as early as possible to the following individuals, regardless of influenza vaccination status:
   - Any hospitalized child with suspected or confirmed influenza disease, regardless of duration of symptoms.
   - Any child, inpatient or outpatient, with severe, complicated, or progressive illness attributable to influenza, regardless of duration of symptoms.
   - Children with influenza infection of any severity if they are at high risk of complications of influenza infection (Table 1), regardless of duration of symptoms.
3. Treatment may be considered for the following individuals:
   - Any previously healthy, symptomatic outpatient not at high risk for influenza complications, in whom influenza is confirmed or suspected on the basis of clinical judgment, if treatment can be initiated within 48 hours of illness onset.
   - Children with suspected or confirmed influenza disease whose siblings or household contacts either are younger than 6 months or have a high-risk condition that predisposes them to complications of influenza (Table 1).

INFLUENZA CHEMOPROPHYLAXIS RECOMMENDATIONS

Antiviral chemoprophylaxis is recommended after known or suspected influenza exposure in the following situations:

- For children at high risk of complications from influenza for whom influenza vaccine is contraindicated.
- For children at high risk of complications during the 2 weeks after influenza vaccination, before optimal immunity is achieved.
- For family members or HCP who are unvaccinated and are likely to have ongoing, close exposure to
  - unvaccinated children at high risk or
  - unvaccinated infants and toddlers who are younger than 24 months.
- For control of influenza outbreaks for unvaccinated staff and children in a closed institutional setting with children at high risk (eg, extended-care facilities).
- As a supplement to vaccination among children at high risk, including children who are immunocompromised and may not respond with sufficient protective immune responses after influenza vaccination.
- As postexposure antiviral chemoprophylaxis for family members and close contacts of an infected person if those people are at high risk of complications from influenza.
- For children at high risk of complications and their family members and close contacts, as well as HCP, when circulating strains of

TABLE 3 Influenza Vaccines Contraindications and Precautions

Vaccine	Contraindication	Precaution	Provider Discretion	Not Contraindications
IIV	• Anaphylaxis or severe allergic reaction to previous influenza vaccination	• History of GBS within 6 wk of previous influenza vaccination	• Defer to resolution of illness for moderate to severe febrile illness, including COVID-19	• Minor illness, with or without fever • Egg allergy
LAIV	• Anaphylaxis or severe allergic reaction to previous influenza vaccination	• History of GBS within 6 wk of previous influenza vaccination	• Defer to resolution of illness for moderate to severe febrile illness, including COVID-19	• Minor illness, with or without fever
	• Age <2 y	• Diagnosis of asthma and aged >5 y with certain chronic underlying conditions (metabolic disease, diabetes mellitus, chronic pulmonary and/or cardiac disease, renal dysfunction, or hemoglobinopathies)	• Defer to resolution of symptoms or use IIV if a patient has nasal congestion that could impede vaccine delivery	• Egg allergy
	• Age 2–4 y with asthma or history of wheezing • Cochlear implants • Active CSF leaks • Primary or acquired immunodeficiency • On immunosuppressive or immunomodulatory therapy • Anatomic or functional asplenia (including sickle cell disease) • Close contacts or caregivers of severely immunocompromised individuals • On aspirin or salicylate-containing medications • Immunization with a live-virus vaccine within the previous 4 wk, except if given the same day • Taking or have recently taken influenza antiviral medications[a] • Currently pregnant			

CSF, cerebrospinal fluid; GBS, Guillain-Barré syndrome.
[a] Until 48 h (oseltamivir, zanamivir), 5 d (peramivir), and up to 2 wk (baloxavir) after stopping the influenza antiviral therapy.

influenza virus in the community are not well matched by seasonal influenza vaccine virus strains on the basis of current data from the Centers for Disease Control and Prevention and state or local health departments.

TABLE 4 Recommended Dosage and Schedule of Influenza Antiviral Medications for Treatment and Chemoprophylaxis in Children for the 2021–2022 Influenza Season: United States

Medication	Treatment	Chemoprophylaxis[a]
Oseltamivir[b]		
Adults	75 mg, twice daily for 5 d	75 mg, once daily for 10 d
Children ≥12 mo (based on body wt)	Duration in all groups is 5 d	Duration in all groups is 10 d
≤15 kg (≤33 lb)	30 mg, twice daily	30 mg, once daily
>15 kg–23 kg (>33 lb–51 lb)	45 mg, twice daily	45 mg, once daily
>23 kg–40 kg (>51 lb–88 lb)	60 mg, twice daily	60 mg, once daily
>40 kg (>88 lb)	75 mg, twice daily	75 mg, once daily
Infants 9–11 mo[c]	3.5 mg/kg per dose, twice daily	3.5 mg/kg per dose, once daily
Term infants 0–8 mo[c]	3 mg/kg per dose, twice daily	3 mg/kg per dose, once daily for infants 3–8 mo. Not recommended for infants aged <3 mo because of limited safety and efficacy data in this age group
Preterm infants[d]		
<38 wk postmenstrual age	1.0 mg/kg per dose, twice daily	—
38 through 40 wk postmenstrual age	1.5 mg/kg per dose, twice daily	—
>40 wk postmenstrual age	3.0 mg/kg per dose, twice daily	—
Zanamivir[e]		
Adults	10 mg (two 5-mg inhalations), twice daily for 5 d	10 mg (two 5-mg inhalations), once daily for 10 d
Children		
≥7 y for treatment	10 mg (two 5-mg inhalations), twice daily for 5 d	10 mg (two 5-mg inhalations), twice daily for 10 d
≥5 y for chemoprophylaxis	10 mg (two 5-mg inhalations), twice daily for 5 d	10 mg (two 5-mg inhalations), twice daily for 10 d
Peramivir		
Adults	One 600-mg intravenous infusion, given over 15–30 min	Not recommended
Children (2–12 y)	One 12-mg/kg dose, up to 600-mg maximum, via intravenous infusion for 15–30 min	Not recommended
Children (13–17 y)	One 600-mg dose, via intravenous infusion for 15–30 min	Not recommended
Baloxavir		
People aged ≥12 y who weigh >40 kg	40–80 kg: one 40-mg dose, orally ≥80 kg: one 80-mg dose, orally	40–80 kg: one 40-mg dose, orally ≥80 kg: one 80-mg dose, orally

Adapted from the 2018 Infectious Diseases Society of America guidelines[11] and https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm. —, not applicable.

[a] Centers for Disease Control and Prevent recommends routine chemoprophylaxis with oseltamivir or zanamivir for 7 days, 10 days only if part of institutional outbreak (https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm).

[b] The duration of treatment with oseltamivir is 5 days. Oseltamivir is administered orally without regard to meals, although administration with meals may improve gastrointestinal tolerability. Oseltamivir is available as Tamiflu in 30-mg, 45-mg, and 75-mg capsules and as a powder for oral suspension that is reconstituted to provide a final concentration of 6 mg/mL. For the 6-mg/mL suspension, a 30-mg dose is given with 5 mL of oral suspension, a 45-mg dose is given with 7.5 mL oral suspension, a 60-mg dose is given with 10 mL oral suspension, and a 75-mg dose is given with 12.5 mL oral suspension. If the commercially manufactured oral suspension is not available, a suspension can be compounded by retail pharmacies (final concentration also 6 mg/mL), based on instructions contained in the package label. In patients with renal insufficiency, the dose should be adjusted on the basis of creatinine clearance. For treatment of patients with creatinine clearance 10–30 mL/min: 75 mg, once daily for 5 days. For chemoprophylaxis of patients with creatinine clearance 10–30 mL/min: 30 mg, once daily for 10 days after exposure or 75 mg, once every other day for 10 days after exposure (5 doses). See https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm and Infectious Diseases Society of America guidelines.[11]

[c] Approved by the US Food and Drug Administration for children as young as 2 weeks of age. Given preliminary pharmacokinetic data and limited safety data, oseltamivir can be used to treat influenza in both term and preterm infants from birth because benefits of therapy are likely to outweigh possible risks of treatment. Of note, the Center for Disease Control and Prevention recommends a 3 mg/kg/dose, twice daily, for all infants <12 months old; the Infectious Diseases Society of America guidelines[11] include both AAP and Center for Disease Control and Prevention recommendations.

[d] Oseltamivir dosing for preterm infants. The weight-based dosing recommendation for preterm infants is lower than that for term infants. Preterm infants may have lower clearance of oseltamivir because of immature renal function, and doses recommended for term infants may lead to high drug concentrations in this age group. Limited data from the National Institute of Allergy and Infectious Diseases Collaborative Antiviral Study Group provide the basis for dosing preterm infants by using their postmenstrual age (gestational age + chronological age). For extremely preterm infants (aged <28 wks), please consult a pediatric infectious disease physician.

[e] The duration of treatment with zanamivir is 5 days. Zanamivir is administered by inhalation by using a proprietary "Diskhaler" device distributed together with the medication. Zanamivir is a dry powder, not an aerosol, and should not be administered by using nebulizers, ventilators, or other devices typically used for administering medications in aerosolized solutions. Zanamivir is not recommended for people with chronic respiratory diseases, such as asthma or chronic obstructive pulmonary disease, which increase the risk of bronchospasm.

ABBREVIATIONS

TECHNICAL REPORT

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Recommendations for Prevention and Control of Influenza in Children, 2021–2022

COMMITTEE ON INFECTIOUS DISEASES

This technical report accompanies the recommendations of the American Academy of Pediatrics for the routine use of the influenza vaccine and antiviral medications in the prevention and treatment of influenza in children during the 2021–2022 season. Influenza vaccination is an important intervention to protect vulnerable populations and reduce the burden of respiratory illnesses during circulation of severe acute respiratory syndrome coronavirus 2, which is expected to continue during this influenza season. In this technical report, we summarize recent influenza seasons, morbidity and mortality in children, vaccine effectiveness, vaccination coverage, and detailed guidance on storage, administration, and implementation. We also provide background on inactivated and live attenuated influenza vaccine recommendations, vaccination during pregnancy and breastfeeding, diagnostic testing, and antiviral medications for treatment and chemoprophylaxis.

INTRODUCTION

This technical report accompanies the recommendations of the American Academy of Pediatrics (AAP) for the routine use of influenza vaccine and antiviral medications in the prevention and treatment of influenza in children during the 2021–2022 season.[1]

SUMMARY OF RECENT INFLUENZA SEASONS IN THE UNITED STATES

2017–2018, 2018–2019, and 2019–2020 Influenza Seasons

The 2017–2018 influenza season was the first season classified as a high-severity season for all age groups, with high levels of outpatient clinic and emergency department visits for influenzalike illness, high rates of influenza-related hospitalization, and high mortality.[2–4] Influenza A (H3N2) predominated early, followed by a second wave of

influenza B/Yamagata from March 2018 onward. Although hospitalization rates for children did not exceed those reported during the 2009 pandemic, they did surpass rates reported in previous high-severity A(H3N2)-predominant seasons. Excluding the 2009 pandemic, the 188 pediatric deaths reported during the 2017–2018 season (approximately half of which occurred in otherwise healthy children) were the highest reported since influenza-associated pediatric mortality became a nationally notifiable condition in 2004.[2–4] Among pediatric deaths of children 6 months and older who were eligible for vaccination and for whom vaccination status was known, approximately 80% had not received the influenza vaccine during the 2017–2018 season.[2] Influenza vaccine effectiveness (VE) for the 2017–2018 season in children is shown in Table 1.[3]

The 2018–2019 influenza season was the longest-lasting season reported in the United States in the past decade, with elevated levels of influenzalike illness activity for a total duration of 21 consecutive weeks (compared with an average duration of 16 weeks).[5] Variations in circulating strains affected vaccine efficacy. Influenza A(H1N1)pdm09 viruses predominated from October to mid-February, and influenza A(H3N2) viruses were identified more frequently from February to May. Influenza B (B/Victoria lineage predominant) represented approximately 5% of circulating strains. Most characterized influenza A(H3N2) viruses were antigenically distinct from the A(H3N2) component of the 2018–2019 vaccine. The vaccine's A(H3N2) virus belonged to subclade 3C.2a1. Cocirculation of multiple genetically diverse subclades of A(H3N2) was documented. Circulating viruses identified belonged to subclade 3C.2a1 or clade 3C.3a, with 3C.3a viruses accounting for >70% of the A(H3N2) viruses in the United States. This likely contributed to an overall lower VE against influenza A(H3N2) this season, despite achieving the highest vaccination coverage reported in the last decade in children (62.6% overall) (Table 1, Fig 1).[5,6]

The 2018–2019 season was of moderate severity, with similar hospitalization rates in children as during the 2017–2018 season (71 per 100 000 among children 0–4 years old and 20.4 per 100 000 among children 5–17 years old), which were higher than those observed in previous seasons from 2013–2014 to 2016–2017.[5] Among 1132 children hospitalized with influenza and for whom data were available, 55% had at least 1 underlying medical condition; the most commonly reported underlying conditions were asthma or reactive airway disease (26%), neurologic disorders (15.6%), and obesity (11.6%).[7] A total of 144 influenza-associated pediatric deaths were reported.

The 2019–2020 influenza season was unusual and complicated by the

Influenza B/ amagata			
Overall all ages	48 (39 to 55)	Not reported	NA
mo to 8 y	77 (49 to 90)	Not reported	NA
9 17 y	28 (1 to 48)	Not reported	NA

VE is estimated as 100 (1 – odds ratio ratio of the odds of being vaccinated among outpatients with influenza-positive test results on the CDC's real-time reverse transcriptase polymerase chain reaction to the odds of being vaccinated among outpatients with influenza-negative test results); odds ratios were estimated by using logistic regression. Adjusted for study site, age group, sex, race and/or ethnicity, self-rated general health, number of days from illness onset to enrollment, and month of illness using logistic regression. NA, not applicable.

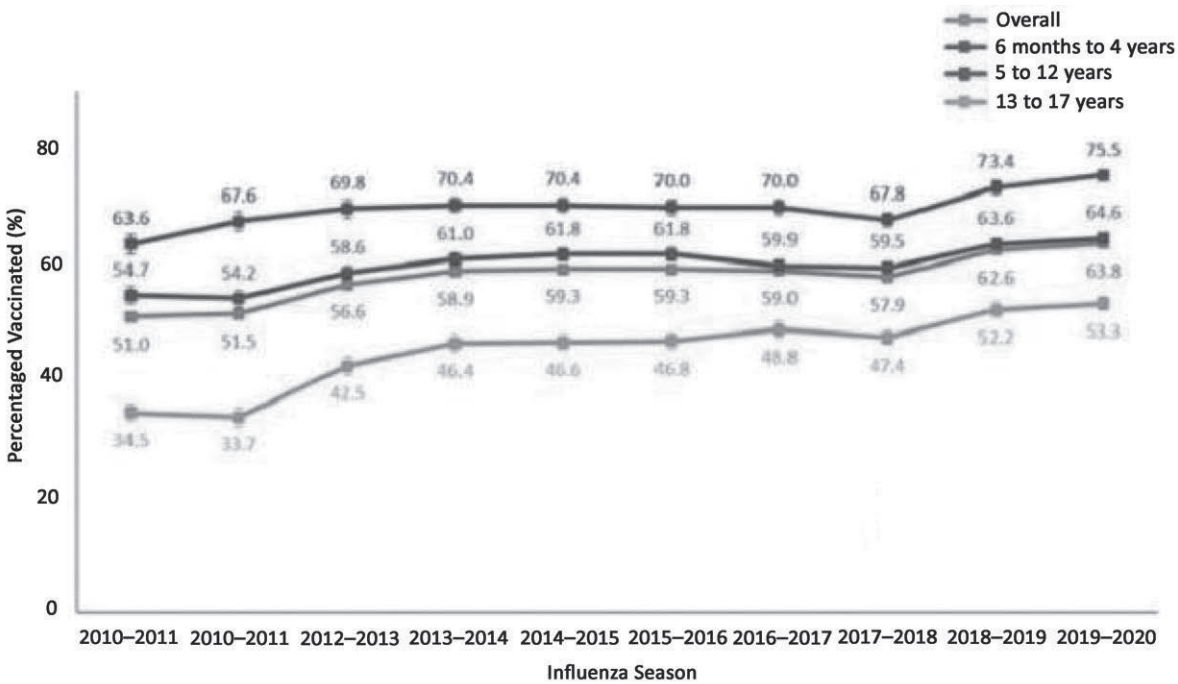

FIGURE 1 Influenza vaccination coverage in children 6 months to 17 years of age in the United States, 2010–2020. Error bars represent 95 CIs around the estimates. Adapted from Centers for Disease Control and Prevention. Flu vaccination coverage, United States, 2019–20 influenza season. Available at https //www.cdc.gov/flu/fluvaxview/coverage-1920estimates.htm ref10. Accessed uly 12, 2021; and National Immunization Survey-Flu (NIS-Flu) (https //www.cdc.gov/vaccines/imzmanagers/nis/about.html).

emergence of the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) pandemic in early 2020. Influenza activity began early in October 2019, continuing through mid-March 2020, with an abrupt decline after the implementation of social distancing measures for mitigation of the SARS-CoV-2 pandemic. Although influenza B/Victoria viruses predominated early in the season, influenza A(H1N1)pdm09 viruses were the most predominant circulating strain. Influenza A(H3N2) and the B/Yamagata lineage represented approximately 4.1% and 0.8% of circulating strains, respectively. A majority of characterized influenza A(H1N1)pdm09 (82.5%) and influenza B/Victoria (59.7%) viruses were antigenically similar to the viruses included in the 2019–2020 influenza vaccine. Less than half (46.5%) of influenza A(H3N2) viruses were antigenically similar to the A(H3N2) component of the 2019–2020 vaccine. During this season, the predominant A(H3N2) circulating clade was 3C.2a, subclade 3C.2a1, with cocirculation of a small proportion of 3C.3a, in contrast to the 2018–2019 season, when 3C.3a strains predominated. Estimates of the effectiveness of the 2019–2020 seasonal influenza vaccines against medically attended influenza illness from the US Flu VE Network are shown in Table 1.[8] Susceptibility to available antiviral agents remained greater than 99% for all circulating strains, but 0.5% of A(H1N1)pdm09 isolates tested by the Centers for Disease Control and Prevention (CDC) exhibited substantially reduced inhibition to oseltamivir and peramivir. Reduced susceptibility to baloxavir has not been reported in the United States to date.[9]

The 2019–2020 season was of moderate severity, although 3 peaks of influenzalike illness activity and the highest hospitalization rates in children, 68.2 per 100 000 population overall, were reported this season. The first peak of activity occurred in early January, likely associated with influenza B circulation; the second peak occurred in February, when influenza A(H1N1)pdm09 became predominant; and the third peak in March was associated with cocirculation of influenza and SARS-CoV-2. The CDC now has a separate surveillance report for novel coronavirus disease 2019 (COVID-19)–like illness.[10] The cumulative influenza hospitalization rates per 100 000 population were 92.3 among children 0 to 4 years old and 23.5 among children 5 to 17 years old. Hospitalization rates in children 0 to 4 years old were higher than those seen for this age group during the 2009 influenza pandemic, higher than the rate in adults 50 to 64 years old this season (89.4 per 100 000), and the highest

on record for this age group. Among children hospitalized with influenza and for whom data were available, 48.6% had no recorded underlying condition and 42.9% had at least 1 underlying medical condition; the most commonly reported underlying conditions were asthma or reactive airway disease (22.1%), neurologic disorders (17.5%), and obesity (12%).

There were 199 laboratory-confirmed influenza-associated pediatric deaths. Most (62.2%) of those children died after being admitted to the hospital. The median age of the pediatric deaths was 6.1 years (range, 2 months to 17 years). Seventy-seven of the pediatric deaths were associated with influenza A viruses, and 122 were associated with influenza B viruses. Among the 183 children with a known medical history, 42.6% of deaths occurred in children who had at least 1 underlying medical condition recognized by the Advisory Committee on Immunization Practices (ACIP) to increase the risk of influenza-attributable disease severity. Therefore, most (57.4%) had no known underlying medical conditions. The majority of the deaths occurred in children 2 to 12 years of age: 6.0% were younger than 6 months, 17.1% were 6 to 23 months of age, 20.6% were 2 to 4 years of age, 36.2% were 5 to 11 years of age, and 20.1% were 12 to 17 years of age. Among 72 children who died and were tested, 50% had a bacterial coinfection. Among 141 children who were 6 months or older at the time of illness onset, and therefore would have been eligible for influenza vaccination and for whom vaccination status was known, most (74%) were unvaccinated. Only 37 (26%) had received at least 1 dose of the influenza vaccine (30 had complete vaccination, and 7 had received 1 of 2 ACIP-recommended doses).

2020–2021 Influenza Season

The 2020–2021 influenza season was substantially and unusually mild, likely because of the circulation of SARS-CoV-2 and the implementation of pandemic mitigation measures. The circulation of influenza viruses was low, without a typical seasonal peak. From September 2020 to May 22, 2021, $<$0.2% of specimens tested were positive for influenza. Among public laboratory isolates, both influenza A (61.4%) and B (38.9%) viruses had been isolated. Among influenza A strains, 52.2% were influenza A(H3N2), 45% were A(H1N1)pdm09, and 2.5% were H3N2v. Furthermore, 1 human infection with a novel influenza A(H1N2) virus variant (A(H1N2)v) was reported in a child who recovered from the illness. This is the first influenza A(H1N2)v virus identified in the United States. Among influenza B strains, both Victoria (60%) and Yamagata (40%) lineages were reported. VE data could not be obtained because of low virus circulation. However, the A(H1N1)pdm09, A(H3N2), and B/Victoria strains that were genetically characterized were similar to the strains included in the vaccine. No antiviral resistance was observed among tested isolates.

The hospitalization rate during the 2020–2021 influenza season (0.8 per 100 000) is the lowest reported since routine data collection began in 2005 by the CDC. As a reference, the end-of-season hospitalization rate was only one-tenth of the previous lowest-severity season in 2011–2012. As such, age-specific hospitalization rates and rates by patient characteristics, including underlying medical conditions, are not available. The overall pneumonia, influenza, and/or COVID-19 mortality observed this season was attributable primarily to COVID-19 and not influenza. No influenza-associated pediatric deaths were identified from this past season. One influenza-associated pediatric death that occurred in January 2020 was reported during the 2020–2021 season.

INFLUENZA MORBIDITY AND MORTALITY IN CHILDREN

Influenza viruses are a common cause of acute lower respiratory tract infection (ALRTI) in children. Pediatric hospitalizations and deaths caused by influenza can be substantial. A recent study estimated that globally, influenza virus accounts for 7% of all ALRTIs, 5% of ALRTI hospitalizations, and 4% of ALRTI deaths in children younger than 5 years.[11] In the United States, the rates of influenza-associated hospitalization for children younger than 5 years consistently exceed the rates for children 5 to 17 years of age, and during the 2019–2020 season, they exceeded the hospitalization rates of adults 50 to 64 years of age.[7] Children 5 to 17 years of age also experienced higher than usual hospitalization rates during the 2019–2020 season. The impact of the anticipated SARS-CoV-2 cocirculation with influenza in the 2021–2022 season is unknown at this time. It is, therefore, particularly important that children are protected against influenza through timely vaccination in the 2021–2022 influenza season.

HIGH-RISK GROUPS IN PEDIATRICS

Children and adolescents with certain underlying medical conditions have a high risk of complications from influenza (Table 2). In addition, influenza vaccination is particularly important in African American and Hispanic/Latinx populations who have been identified as having higher rates of

TABLE 2

People at High Risk of Influenza Complications
Children <5 y, and especially those <2 y,[a] regardless of the presence of underlying medical conditions
Adults ≥50 y, and especially those ≥65 y
Children and adults with chronic pulmonary disease (including asthma and cystic fibrosis); hemodynamically significant cardiovascular disease (except hypertension alone); or renal, hepatic, hematologic (including sickle cell disease and other hemoglobinopathies), or metabolic disorders (including diabetes mellitus)
Children and adults with immunosuppression attributable to any cause, including that caused by medications or by HIV infection
Children and adults with neurologic and neurodevelopment conditions (including disorders of the brain, spinal cord, peripheral nerve, and muscle, such as cerebral palsy, epilepsy, stroke, intellectual disability, moderate to severe developmental delay, muscular dystrophy, or spinal cord injury)
Children and adults with conditions that compromise respiratory function or handling of secretions (including tracheostomy and mechanical ventilation)[124]
Women who are pregnant or post partum during the influenza season
Children and adolescents <19 y who are receiving long-term aspirin therapy or salicylate-containing medications (including those with Kawasaki disease and rheumatologic conditions) because of increased risk of Reye syndrome
American Indian/Alaska Native people[b]
Children and adults with obesity (ie, BMI ≥40 for adults and based on age for children)
Residents of chronic care facilities and nursing homes

Adapted from Grohskopf LA, Alyanak E, Ferdinands JM, et al. Prevention and control of seasonal influenza with vaccines: recommendations of the Advisory Committee on Immunization Practices—United States, 2021–22 influenza season. *MMWR Recomm Rep.* 2021;70(5):1–28

[a] The CDC recommendations state that although all children younger than 5 y old are considered at higher risk for complications from influenza, the highest risk is for those younger than 2 y old, with the highest hospitalization and death rates among infants younger than 6 mo old.

[b] American Indian/Alaska Native (AI/AN) children have higher rate of influenza complications.[125–128] Most at-risk AI/AN children will also qualify in other high-risk categories to receive appropriate antiviral treatment. In the setting of a shortage, AI/AN children should be prioritized to receive influenza vaccine or antiviral medications according to local public health guidelines.

hospitalization from influenza and being more vulnerable to COVID-19.[12] Although universal influenza vaccination is recommended for everyone starting at 6 months of age, emphasis should be placed on ensuring that people in high-risk groups and their household contacts and caregivers receive the annual influenza vaccine.

EFFECTIVENESS OF INFLUENZA VACCINATION ON HOSPITALIZATION AND MORTALITY

Several studies demonstrated that influenza vaccination effectively decreased hospitalization in children in places where universal pediatric immunization was implemented. In a study conducted by the US New Vaccine Surveillance Network in 2015–2016, among 1653 children enrolled from 7 pediatric hospitals, the adjusted VE in children with complete influenza immunization against any influenza-associated hospitalization was 56% (95% confidence interval [CI], 34% to 71%), 68% (95% CI, 36% to 84%) against A(H1N1)pdm09, and 44% (95% CI, −1% to 69%) against B viruses.[13] A study in children 6 months to 8 years of age conducted in Israel over 3 influenza seasons from 2015 to 2017 demonstrated that over all seasons, fully vaccinated children had a VE against hospitalization of 53.9% (95% CI, 38.6% to 68.3%), whereas partial vaccination was not effective (25.6%; 95% CI, −3% to 47%).[14] In this study, a VE against hospitalization as high as 60% to 80% was observed when circulating and vaccine influenza A and B strains matched. After establishing free vaccination for preschool-aged children and children at risk because of comorbid medical conditions in Australia in 2018, VE of the influenza vaccine in preventing influenza hospitalization was estimated to be 78.8% (95% CI, 66.9% to 86.4%).[15] In the United Kingdom, during the 2018–2019 season, the overall adjusted VE against influenza-confirmed hospitalization was reported to be 53% (95% CI, 33.3% to 66.8%), with protection varying by strain. Protection was 63.5% (95% CI, 34.4% to 79.7%) against influenza A(H1N1)pdm09, but there was no protection against influenza A(H3N2).[16] Finally, in a systematic review and meta-analysis of 28 studies, Kalligeros et al[17] concluded that the influenza vaccine offered significant protection against any type of influenza-related hospitalization in children 6 months to 17 years of age, with a VE of 57.5% (95% CI, 54.8% to 65.5%). Strain-specific VE was higher for influenza A(H1N1)pdm09 (75.1%; 95% CI, 54.8% to 93.3%) and influenza B (50.9%; 95% CI, 41.7% to 59.9%), compared with influenza A(H3N2) (40.8%; 95% CI, 25.6% to 55.9%). As expected, children who were fully vaccinated were better protected (VE 61.8%; 95% CI, 54.4% to 69.1%) compared with those who were partially vaccinated (VE 33.91%; 95% CI, 21.1% to 46.7%). Notably, VE was higher in children younger than 5 years (61.7%; 95% CI, 49.3% to 74.1%) than in children 6 to 17 years of age (54.4%; 95% CI, 35.1% to 73.6%). In the United States, the CDC estimated that during the 2018–2019 season, influenza vaccination prevented 20% of projected hospitalizations associated with infection with the A(H1N1)pdm09 virus among

children 5 to 17 years of age and 43% among children 6 months to 4 years of age.[18]

Historically, up to 80% of influenza-associated pediatric deaths have occurred in unvaccinated children 6 months and older. Influenza vaccination is associated with reduced risk of laboratory-confirmed influenza-related pediatric death.[19] In one case-cohort analysis comparing vaccination uptake in laboratory-confirmed influenza-associated pediatric deaths to estimated vaccination coverage among pediatric cohorts in the United States from 2010 to 2014, Flannery et al[19] found that only 26% of children had received the vaccine before illness onset, compared to an average vaccination coverage of 48%. Overall VE against influenza-associated death in children was 65% (95% CI, 54% to 74%). More than half of children in this study who died of influenza had ≥1 underlying medical condition associated with increased risk of severe influenza-related complications; only 1 in 3 of these at-risk children had been vaccinated; yet VE against death in children with underlying conditions was 51% (95% CI, 31% to 67%). Similarly, influenza vaccination reduces by three-quarters the risk of severe life-threatening laboratory-confirmed influenza in children requiring admission to the ICU.[20] The influenza virus type might also affect the severity of disease. In a study of hospitalizations for influenza A versus B, the odds of mortality were significantly greater with influenza B than with influenza A and were not entirely explained by underlying health conditions.[21]

SEASONAL INFLUENZA VACCINES

The seasonal influenza vaccines licensed for children and adults for the 2021–2022 season are shown in Table 3. More than one product may be appropriate for a given patient, and vaccination should not be delayed to obtain a specific product.

All 2021–2022 seasonal influenza vaccines will be quadrivalent and contain the same influenza strains as recommended by the World Health Organization (WHO) and the US Food and Drug Administration's (FDA's) Vaccines and Related Biological Products Advisory Committee for the Northern Hemisphere.[22] Both influenza A(H1N1) and A(H3N2) components are different in this season's vaccine. The B components are unchanged. The influenza A strains may be different for egg-based versus cell- or recombinant-based vaccines on the basis of their optimal characteristics for each platform, but all are matched to the strains expected to circulate in the 2021–2022 season.

1. Quadrivalent vaccines contain the following:
   a. influenza A(H1N1) component:
      i. egg-based vaccines: A/Victoria/2570/2019 (H1N1) pdm09-like virus (new this season); and
      ii. cell- or recombinant-based vaccines: A/Wisconsin/588/2019 (H1N1) pdm09-like virus (new this season);
   b. influenza A(H3N2) component:
      i. egg-based vaccines: A/Cambodia/e0826360/2020 (H3N2)-like virus (new this season); and
      ii. cell- or recombinant-based vaccines: A/Cambodia/e0826360/2020 (H3N2)-like virus (new this season);
   c. B/Victoria component:
      i. all vaccines: B/Washington/02/2019-like virus (B/Victoria/2/87 lineage) (unchanged); and
   d. B/Yamagata component:
      i. all vaccines: B/Phuket/3073/2013-like virus (B/Yamagata/16/88 lineage) (unchanged).
2. Trivalent vaccines do not include the B/Yamagata component (not available in United States).

Inactivated Influenza Vaccine

For the 2021–2022 season, all licensed inactivated influenza vaccines (IIVs) for children and adults in the United States are quadrivalent vaccines, with specific age indications for available formulations (Table 3). Among vaccines available for children, 4 are egg based (seed strains grown in eggs) and 1 is cell culture based (seed strains grown in Madin-Darby canine kidney cells). All inactivated egg-based vaccines (Afluria Quadrivalent, Fluarix Quadrivalent, Flulaval Quadrivalent, and Fluzone Quadrivalent) are licensed for children 6 months and older and are available in single-dose, thimerosal-free, prefilled syringes. The only pediatric cell culture–based vaccine (Flucelvax Quadrivalent) is now licensed for children 2 years and older.[23] The extension of the age indication down from 4 years to 2 years of age in March 2021 was based on data from a randomized double-blind clinical efficacy study conducted among children 2 to 18 years of age over 3 seasons (2017 in the Southern Hemisphere and 2017–2018 and 2018–2019 in the Northern Hemisphere), in which Flucelvax Quadrivalent demonstrated efficacy against laboratory-confirmed influenza illness of 54.6% (95% CI, 45.7% to 62.1%), compared with a control vaccine (meningococcal serogroup ACWY conjugate vaccine).[24]

A quadrivalent recombinant baculovirus-expressed hemagglutinin influenza vaccine (quadrivalent recombinant influenza vaccine [RIV4]) (Flublok

TABLE 3 Recommended Seasonal Influenza Vaccines for Different Age Groups: United States, 2021–2022 Influenza Season

Vaccine	Trade Name (Manufacturer)	Age Group	Presentation and Hemagglutinin Antigen Content (IIVs and RIV4) or Virus Count (LAIV4) per Dose for Each Antigen	Thimerosal Mercury Content, µg Hg/0.5-mL Dose	CPT Code
Quadrivalent standard dose: egg-based vaccines					
IIV4	Afluria Quadrivalent (Seqirus)	6–35 mo	0.25-mL prefilled syringe (7.5 µg/0.25 mL)	0	90685

Prevention and control of seasonal influenza with vaccines: recommendations of the Advisory Committee on Immunization Practices—United States, 2021–22 influenza season. *MMWR Recomm Rep.* 2021;70(5):1–28. The implementation guidance on supply, pricing, payment, CPT coding, and liability issues can be found at www.aapredbook.org/implementation. aIIV4, quadrivalent adjuvanted inactivated influenza vaccine; ccIIV4, quadrivalent cell culture–based inactivated influenza vaccine; CPT, *Current Procedural Terminology*; FFU, fluorescent focus unit; —, not applicable.

[a] For vaccines that include a multidose vial presentation, a maximum of 10 doses can be drawn from a multidose vial.

Quadrivalent) is licensed only for people 18 years and older. A high-dose quadrivalent inactivated influenza vaccine (IIV4) (Fluzone High-Dose Quadrivalent) containing 4 times the amount of antigen for each virus strain compared with the standard-dose vaccines is licensed only for people 65 years and older. The quadrivalent MF-59 adjuvanted inactivated vaccine (Fluad Quadrivalent) was licensed for people 65 years and older in February 2020.[23] Adjuvants may be included in a vaccine to elicit a more robust immune response, which could lead to a reduction in the number of doses required for children. In one pediatric study, the relative vaccine efficacy of an MF-59 adjuvanted influenza vaccine was significantly greater than that of a nonadjuvanted vaccine in the 6- to 23-month age group.[25] Adjuvanted seasonal influenza vaccines are not licensed for children in the United States.

Children 36 months (3 years) and older can receive any age-appropriate licensed IIV, administered at a 0.5-mL dose containing 15 μg of hemagglutinin (HA) from each strain. Children 6 to 35 months of age may receive any age-appropriate licensed IIV without preference for one product over another. Several vaccines have been licensed for children 6 to 35 months of age since 2017 (Table 3). All are quadrivalent, but the dose volume, and therefore the antigen content, may vary among different IIV products. In addition to a 0.25-mL (7.5 μg of HA per vaccine virus) Fluzone Quadrivalent vaccine, a 0.5-mL formulation of Fluzone Quadrivalent containing 15 μg of HA per vaccine virus per dose was licensed in January 2019 after these 2 formulations were shown to have comparable safety and immunogenicity in a single randomized multicenter study.[26–28] Only the 0.5-mL Fluzone prefilled syringe will be available this season. In addition, 2 other vaccines, Fluarix Quadrivalent[29] and FluLaval Quadrivalent,[30] are licensed at a 0.5-mL dose in children 6 to 35 months of age. These 2 vaccines do not have a 0.25-mL dose formulation. Afluria Quadrivalent is the only pediatric vaccine that has a 0.25-mL presentation for children 6 to 35 months of age. Afluria 0.5 mL is licensed for children 3 years and older only.[31]

Given that different formulations of IIV for children 6 to 35 months of age are available, care should be taken to administer the appropriate volume and dose for each product. In each instance, the recommended volume may be administered from an appropriate prefilled syringe, a single-dose vial, or a multidose vial, as supplied by the manufacturer. For vaccines that include a multidose vial presentation, a maximum of 10 doses can be drawn from a multidose vial. Importantly, dose volume is different from the number of doses needed to complete vaccination. Children 6 months to 8 years of age who require 2 doses of the vaccine for the 2021–2022 season should receive 2 separate doses at the recommended dose volume specified for each product.

IIVs are well tolerated in children and can be used in healthy children as well as those with underlying chronic medical conditions. CDC best practice guidelines should be followed for administration (https://www.cdc.gov/vaccines/hcp/acip-recs/general-recs/). The most common injection site adverse reactions after administration of IIV in children are injection site pain, redness, and swelling. The most common systemic adverse events are drowsiness, irritability, loss of appetite, fatigue, muscle aches, headache, arthralgia, and gastrointestinal tract symptoms.

IIVs can be administered concomitantly with other inactivated or live vaccines.[32–36] The influenza vaccine may be administered simultaneously or at any time before or after administration of the currently available COVID-19 vaccines.[37] In general, although data are not available for concomitant administration of COVID-19 with other vaccines in children, extensive experience with non-COVID-19 vaccines has demonstrated that immunogenicity and adverse event profiles are generally similar when vaccines are administered simultaneously as when they are administered alone. Furthermore, concomitant administration with the influenza vaccine is being evaluated in adults (unpublished observations presented at ACIP Influenza Workgroup meeting, February 2, 2021), and data in children are anticipated to inform recommendations. Given that it is unknown whether reactogenicity of COVID-19 vaccines will be increased with coadministration of the influenza vaccine, the reactogenicity profile of the vaccines should be considered, and providers should consult the most current ACIP and AAP guidance regarding coadministration of COVID-19 vaccines with influenza vaccines.[38] Overall, the benefits of timely vaccination with same-day administration of IIV and other recommended vaccines outweigh the risk of potential reactogenicity in children.

Thimerosal-containing vaccines are not associated with an increased risk of autism spectrum disorder in children. Thimerosal from vaccines has not been linked to any neurologic condition. The AAP supports the current WHO recommendations for use of

thimerosal as a preservative in multiuse vials in the global vaccine supply.[39] Despite the lack of evidence of harm, some states have legislation restricting the use of vaccines that contain even trace amounts of thimerosal. The benefits of protecting children against the known risks of influenza are clear. Therefore, to the extent permitted by state law, children should receive any available formulation of IIVs rather than delaying vaccination while waiting for reduced thimerosal-content or thimerosal-free vaccines. IIV formulations that are free of even trace amounts of thimerosal are widely available (Table 3).

Live Attenuated (Intranasal) Influenza Vaccine

The intranasal live attenuated influenza vaccine (LAIV) was initially licensed in the United States in 2003 for people 5 to 49 years of age as a trivalent formulation (trivalent live attenuated influenza vaccine [LAIV3]), and the approved age group was extended to 2 years of age in 2007. The quadrivalent formulation (quadrivalent live attenuated influenza vaccine [LAIV4]), licensed in 2012, was first available during the 2013–2014 influenza season, replacing the LAIV3.

The CDC conducted a systematic review of published studies evaluating the effectiveness of the LAIV3 and LAIV4 in children from the 2010–2011 to the 2016–2017 influenza seasons, including data from US and European studies.[40] The data suggested that the effectiveness of the LAIV3 or LAIV4 for the influenza A(H1N1)pdm09 strain was lower than that of the IIV in children 2 to 17 years of age. The LAIV was similarly effective against influenza B and A/H3N2 strains in some age groups compared with the IIV. The LAIV was not recommended by the CDC or AAP for use in children during the 2016–2017 and 2017–2018 seasons, given concerns about its effectiveness against A(H1N1)pdm09. For the 2017–2018 season, a new A(H1N1)pdm09-like virus strain (A/Slovenia/2903/2015) was included in the LAIV4, replacing the previous A/Bolivia/559/2013 strain. A study conducted by the LAIV4 manufacturer evaluated viral shedding and immunogenicity associated with the LAIV4 formulation containing the new A(H1N1) pdm09-like virus among US children 24 to 48 months of age.[41] Shedding and immunogenicity data suggested that the new influenza A(H1N1)pdm09-like virus included in its latest formulation had improved replicative fitness over previous LAIV4 influenza A(H1N1)pdm09-like virus strains, resulting in an improved immune response comparable to that of the LAIV3 available before the 2009 pandemic. Shedding and replicative fitness are not known to correlate with efficacy, and no published effectiveness estimates for this revised formulation of the vaccine against influenza A(H1N1)pdm09 viruses were available before the start of the 2018–2019 influenza season because influenza A(H3N2) and influenza B viruses predominated during the 2017–2018 Northern Hemisphere season. Therefore, for the 2018–2019 influenza season, the AAP recommended the IIV4 or trivalent inactivated influenza vaccine as the primary choice for influenza vaccination in children, with LAIV4 use reserved for children who would not otherwise receive an influenza vaccine and for whom LAIV use was appropriate for age (2 years and older) and health status (ie, healthy, without any underlying chronic medical condition).

In February 2019, the AAP Committee on Infectious Diseases reviewed available data on influenza epidemiology and VE for the 2018–2019 season and agreed that harmonizing recommendations between the AAP and CDC for the use of LAIVs in the 2019–2020 season was appropriate. After the February 2020 ACIP meeting, the AAP Committee on Infectious Diseases reviewed available epidemiological and effectiveness data for the previous and current seasons to inform recommendations for the 2020–2021 season. Despite the early circulation of A(H1N1)pdm09 during the 2018–2019 season and its predominance during the 2019–2020 season, low use of the LAIV4 in the US population has limited the evaluation of product-specific VE, and no additional US data on VE for the LAIV4 are available. Although the proportion of the LAIV used for vaccination is unknown, interim overall VE (not specific to a type of vaccine) for the 2019–2020 influenza season showed reassuring protection in children against circulating influenza A and B strains (Table 1).[42] Furthermore, influenza vaccine coverage rates in children were stable until the COVID-19 pandemic.[6] In European surveillance networks where uninterrupted use of the LAIV has continued from the 2016–2017 to the 2019–2020 seasons, the United Kingdom was the only country to report final VE against medically attended influenza for the 2018–2019 season. In children 2 to 17 years of age, the reported VE was 49.9% (95% CI, −14.3% to 78.0%) for A(H1N1)pdm09 and 27.1% (95% CI, −130.5% to 77%) for A(H3N2).[43] The final adjusted VE in the United States (where mostly the IIV was used) for 2018–2019 against A(H1N1)pdm09 was 59% (95% CI, 47% to 69%) for children 6 months to 8 years of age but only 24% (95% CI, −18% to 51%) for children 9 to 17 years of age. The

reported US VE was 24% (95% CI, 1% to 42%) in children 6 months to 8 years of age and 3% (95% CI, −30% to 28%) in children 9 to 17 years of age for A(H3N2).[44] Direct comparisons cannot be made given differences in reporting of VE for various age groups. Other countries that use the LAIV (Canada, Finland) have not reported LAIV4-specific VE in the past several seasons. Small case numbers and low LAIV use may also limit accurate VE calculations in these countries. In general, as long as use of the LAIV is low relative to the IIV, it will be difficult to estimate LAIV VE accurately. Furthermore, important variability in VE against all strains is reported for both the IIV and LAIV.

Influenza VE varies from season to season and is affected by many factors, including age and health status of the recipient, influenza type and subtype, existing immunity from previous infection or vaccination, and degree of antigenic match between vaccine and circulating virus strains. It is possible that VE also differs among individual vaccine products; however, product-specific comparative effectiveness data are lacking for most vaccines. Additional experience over multiple influenza seasons will help to determine optimal use of the available vaccine formulations in children. The AAP will continue to monitor annual influenza surveillance and VE reports to update influenza vaccine recommendations if necessary.

The most commonly reported reactions of the LAIV4 in children are runny nose or nasal congestion, headache, decreased activity or lethargy, and sore throat. The LAIV4 may be administered simultaneously with other inactivated or live vaccines, but if not given simultaneously, it is recommended that administration of other live vaccines is separated by a 4-week interval from LAIV4 vaccination.

LAIV and Immunocompromised Hosts

The IIV is the vaccine of choice for anyone in close contact with a subset of severely immunocompromised people (ie, those requiring a protected environment). The IIV is preferred over the LAIV for contacts of severely immunocompromised people because of a theoretical risk of infection attributable to LAIV strains in an immunocompromised contact of an LAIV-immunized person. Available data indicate a low risk of transmission of the virus from both children and adults vaccinated with the LAIV. Health care personnel (HCP) immunized with the LAIV may continue to work in most units of a hospital, including the NICU and general oncology ward, using standard infection-control techniques. As a precautionary measure, people recently vaccinated with the LAIV should restrict contact with severely immunocompromised patients for 7 days after immunization, although there have been no reports of LAIV transmission from a vaccinated person to an immunocompromised person. In the theoretical scenario in which symptomatic LAIV infection develops in an immunocompromised host, LAIV strains are susceptible to antiviral medications.

INFLUENZA VACCINE CONTRAINDICATIONS AND PRECAUTIONS

Anaphylactic and severe allergic reactions to any influenza vaccine are contraindications to vaccination. The AAP recommends that children who have had an allergic reaction after a previous dose of any influenza vaccine should be evaluated by an allergist to determine if future receipt of the vaccine is appropriate.

Minor illnesses, with or without fever, are not contraindications to the use of influenza vaccines, including among children with mild upper respiratory infection symptoms or allergic rhinitis. In children with a moderate to severe febrile illness (eg, high fever, active infection, requiring hospitalization), on the basis of the judgment of the clinician, vaccination should be deferred until resolution of the illness. Children with confirmed COVID-19 can receive the influenza vaccine when the acute illness has resolved and/or illness is mild. Children with an amount of nasal congestion that would notably impede vaccine delivery into the nasopharyngeal mucosa should have the LAIV deferred until resolution or may receive the IIV.

A precaution for vaccination is a condition in a recipient that might increase the risk or seriousness of a possible vaccine-related adverse reaction. A precaution also may exist for conditions that might compromise the ability of the host to develop immunity after vaccination. Vaccination may be recommended in the presence of a precaution if the benefit of protection from the vaccine outweighs the potential risks.

A history of Guillain-Barré syndrome (GBS) after influenza vaccination is considered a precaution for the administration of influenza vaccines. GBS is rare, especially in children, and there is a lack of evidence on risk of GBS after influenza vaccination in children. Nonetheless, regardless of age, a history of GBS <6 weeks after a previous dose of the influenza vaccine is a precaution for administration of the influenza vaccine. GBS may occur after influenza infection. The benefits of influenza vaccination might

outweigh the risks for certain people who have a history of GBS (particularly if not associated with previous influenza vaccination) and who also are at high risk for severe complications from influenza.

Specific precautions for the LAIV include a diagnosis of asthma in children 5 years and older and the presence of certain chronic underlying medical conditions, including metabolic disease, diabetes mellitus, other chronic disorders of the pulmonary or cardiovascular systems, renal dysfunction, or hemoglobinopathies. Because the safety of the LAIV has not been definitively established in these situations, the IIV should be considered, and vaccination should not be delayed in these high-risk groups. People who should not receive the LAIV are listed below.

People in whom the LAIV is contraindicated include the following:

- children younger than 2 years;
- children 2 to 4 years of age with a diagnosis of asthma or a history of recurrent wheezing or a medically attended wheezing episode in the previous 12 months because of the potential for increased wheezing after immunization; in this age range, many children have a history of wheezing with respiratory tract illnesses and are eventually diagnosed with asthma;
- children with cochlear implants or active cerebrospinal fluid leaks;
- children who have a known or suspected primary or acquired immunodeficiency or who are receiving immunosuppressive or immunomodulatory therapies;
- children with anatomic or functional asplenia, including from sickle cell disease;
- close contacts and caregivers of those who are severely immunocompromised and require a protected environment;
- children and adolescents receiving aspirin or salicylate-containing medications;
- children who have received other live-virus vaccines within the previous 4 weeks (except for the rotavirus vaccine); however, the LAIV can be administered on the same day with other live-virus vaccines if necessary;
- children taking an influenza antiviral medication until 48 hours (oseltamivir, zanamivir), 5 days (peramivir), or 2 weeks (baloxavir) after stopping the influenza antiviral therapy; if a child recently received the LAIV but has an influenza illness for which antiviral agents are appropriate, the antiviral agents should be given; if antiviral agents are necessary for treatment within 2 weeks of LAIV immunization, reimmunization or administration of IIV is indicated because of the potential effects of antiviral medications on LAIV replication and immunogenicity; and
- pregnant women.

INFLUENZA VACCINES AND EGG ALLERGY

There is strong evidence that individuals with egg allergies can safely receive the influenza vaccine without any additional precautions beyond those recommended for any vaccine.[45,46] The presence of an egg allergy in an individual is not a contraindication to receive the IIV or LAIV. Vaccine recipients with egg allergies are at no greater risk for a systemic allergic reaction than those without egg allergies. Therefore, precautions, such as choice of a particular vaccine, special observation periods, or restriction of administration to particular medical settings, are not warranted and constitute an unnecessary barrier to immunization. It is not necessary to inquire about an egg allergy before the administration of any influenza vaccine, including on screening forms. Routine prevaccination questions regarding anaphylaxis after receipt of any vaccine are appropriate. Standard vaccination practice for all vaccines in children should include the ability to respond to rare acute hypersensitivity reactions. Children who have had a previous allergic reaction to the influenza vaccine should be evaluated by an allergist to determine if future receipt of the vaccine is appropriate.

INFLUENZA VACCINES DURING PREGNANCY AND BREASTFEEDING

The influenza vaccine is recommended by the ACIP, the American College of Obstetrics and Gynecology, and the American Academy of Family Physicians for all women during any trimester of gestation for the protection of mothers against influenza and its complications.[23,47] Substantial evidence has accumulated regarding the efficacy of maternal influenza immunization in preventing laboratory-confirmed influenza disease and its complications in both mothers and their infants in the first 2 to 6 months of life.[47–52] Pregnant women who are immunized against influenza at any time during their pregnancy provide protection to their infants during their first 6 months of life, when they are too young to receive the influenza vaccine themselves, through transplacental passage of antibodies.[49–57] Infants born to women who receive influenza vaccination during pregnancy have been shown to have a risk reduction of up to 72% (95% CI, 39% to 87%) for laboratory-confirmed influenza hospitalization in the first few months of life.[55]

It is safe to administer the IIV to pregnant women during any trimester of gestation and post partum. Any licensed, recommended, and age-appropriate influenza vaccine may be used, although experience with the use of the RIV4 in pregnant women is limited. The LAIV is contraindicated during pregnancy. Data on the safety of influenza vaccination at any time during pregnancy continues to support the safety of influenza immunization during pregnancy.[47,49–54,58] In a 5-year retrospective cohort study from 2003 to 2008 with more than 10 000 women, influenza vaccination in the first trimester was not associated with an increase in the rates of major congenital malformations.[59] Similarly, a systematic review and meta-analysis of studies of congenital anomalies after vaccination during pregnancy, including data from 15 studies (14 cohort studies and 1 case-control study), did not show any association between congenital defects and influenza vaccination in any trimester, including the first trimester of gestation.[60] Assessments of any association with influenza vaccination and preterm birth and infants small for gestational age have yielded inconsistent results, with most studies reporting a protective effect or no association against these outcomes.[61,62] The authors of a cohort study from the Vaccines and Medications in Pregnancy Surveillance System of vaccine exposure during the 2010–2011 to 2013–2014 influenza seasons found no significant association of spontaneous abortion with influenza vaccine exposure in the first trimester or within the first 20 weeks' gestation.[63] One observational Vaccine Safety Datalink study conducted during the 2010–2011 and 2011–2012 influenza seasons indicated an association between receipt of the IIV containing H1N1pdm09 and risk of spontaneous abortion when an H1N1pdm09-containing vaccine had also been received the previous season.[64] A follow-up study conducted by the same investigators with a larger population and stricter outcome measures did not show this association and further supported the safety of the influenza vaccine during pregnancy.[65]

Women in the postpartum period who did not receive influenza vaccination during pregnancy should be encouraged to discuss receiving the influenza vaccine before discharge from the hospital with their obstetrician, family physician, nurse midwife, or other trusted provider. Women who traditionally experience barriers to preventive care (eg, women who do not qualify for Medicaid) should be offered vaccination before hospital discharge or offered information in their preferred language about free vaccine clinics. Vaccination during breastfeeding is safe for mothers and their infants.

Breastfeeding is strongly recommended to protect infants against influenza viruses by activating innate antiviral mechanisms, specifically type 1 interferons. Human milk from mothers vaccinated during the third trimester also contains higher levels of influenza-specific immunoglobulin A.[66] Greater exclusivity of breastfeeding in the first 6 months of life decreases the episodes of respiratory illness with fever in infants of vaccinated mothers. For infants born to mothers with confirmed influenza illness at delivery, breastfeeding is encouraged, and guidance on breastfeeding practices can be found at https://www.cdc.gov/breastfeeding/breastfeeding-special-circumstances/maternal-or-infant-illnesses/influenza.html and at https://www.cdc.gov/flu/professionals/infectioncontrol/peri-post-settings.htm. Breastfeeding should be encouraged even if the mother or infant has influenza illness. The mother should pump and feed expressed milk if she or her infant is too sick to breastfeed. If the breastfeeding mother requires antiviral agents, treatment with oral oseltamivir is preferred. The CDC does not recommend use of baloxavir for treatment of pregnant women or breastfeeding mothers. There are no available efficacy or safety data in pregnant women, and there are no available data on the presence of baloxavir in human milk, the effects on the breastfed infant, or the effects on milk production.

VACCINE STORAGE AND ADMINISTRATION

The AAP storage and handling tip sheet provides resources for practices to develop comprehensive vaccine management protocols to keep the temperature for vaccine storage constant during a power failure or other disaster.[67] The AAP recommends the development of a written disaster plan for all practice settings. During the COVID-19 pandemic, the AAP recommends that influenza vaccine administration follow CDC guidance for administration of immunizations (https://www.cdc.gov/vaccines/pandemic-guidance/index.html). Vaccination in the medical home is ideal to ensure that pediatric patients receive other vaccinations and routine care in a timely manner and receive catch-up immunizations if delays have occurred because of the pandemic. In general, infection-prevention measures should be in place for all patient encounters, including screening for symptoms, physical distancing, respiratory and hand hygiene, and surface decontamination. In

addition to standard precautions and hand hygiene, during the COVID-19 pandemic, it is recommended that vaccine administrators wear a surgical face mask (not N95 or respirator) at all times and eye protection if the level of community spread is moderate or elevated.[68] Administration of the LAIV intranasally is not an aerosol-generating procedure; however, vaccine administrators are advised to wear gloves when administering the LAIV given the potential for contact with respiratory secretions. Gloves used for intranasal or intramuscular vaccine administration should be changed with every patient. Gowns are not required.

IIVs

IIVs for intramuscular injection are shipped and stored at 2°C to 8°C (36°F–46°F); vaccines that are inadvertently frozen should not be used. These vaccines are administered intramuscularly into the anterolateral thigh of infants and young children and into the deltoid muscle of older children and adults. Given that various IIVs are available, careful attention should be paid to ensure that each product is used according to its approved age indication, dosing, and volume of administration (Table 3). A 0.5-mL unit dose of any IIV should not be split into 2 separate 0.25-mL doses. If a lower dose than recommended is inadvertently administered to a child 36 months or older (eg, 0.25 mL), an additional 0.25-mL dose should be administered to provide a full dose of 0.5 mL as soon as possible. The total number of full doses appropriate for age should be administered. If a child is inadvertently vaccinated with a formulation only approved for adults, the dose should be counted as valid.

LAIV

The cold-adapted, temperature-sensitive LAIV4 formulation is shipped and stored at 2°C to 8°C (35°F–46°F) and administered intranasally in a prefilled single-use sprayer containing 0.2 mL of the vaccine. A removable dose-divider clip is attached to the sprayer to facilitate administration of 0.1 mL separately into each nostril. If the child sneezes immediately after administration, the dose should not be repeated.

TIMING OF VACCINATION AND DURATION OF PROTECTION

Although peak influenza activity in the United States tends to occur from January to March, influenza can circulate from early fall (October) to late spring (May), with one or more disease peaks. This pattern of circulation was substantially altered during the COVID-19 pandemic. Predicting the onset and duration or the severity of the influenza season with accuracy is impossible. It is also challenging to balance public health strategies needed to achieve high vaccination coverage with achieving optimal individual immunity for protection against influenza at the peak of seasonal activity, knowing that the duration of immunity after vaccination can wane over time. Initiation of influenza vaccination before influenza is circulating in the community and continuing to vaccinate throughout the influenza season are important components of an effective influenza vaccination strategy.

Complete influenza vaccination by the end of October is recommended by the CDC and AAP. Children who need 2 doses of the vaccine should receive their first dose as soon as possible when the vaccine becomes available, to allow sufficient time for receipt of the second dose ≥4 weeks after the first, before the onset of the influenza season. Children who require only 1 dose of the influenza vaccine should also ideally be vaccinated by the end of October. Recent data in adults suggest that early vaccination (July or August) might be associated with suboptimal immunity before the end of the influenza season, and the CDC now discourages vaccination in the summer months, particularly among older adults.[37]

Although the evidence is limited in children, recent reports raise the possibility that early vaccination might contribute to reduced protection later in the influenza season.[69–80] In these studies, VE decreased within a single influenza season, and this decrease was correlated with increasing time after vaccination. However, this decay in VE was not consistent across different age groups and varied by season and virus subtypes. In some studies, waning VE was more evident among older adults and younger children[72,74] and with influenza A(H3N2) viruses more than influenza A(H1N1) or B viruses.[73,76,78] A multiseason analysis from the US Flu VE Network found that VE declined by approximately 7% per month for influenza A (H3N2) and influenza B and by 6% to 11% per month for influenza A (H1N1)pdm09 in individuals 9 years and older.[71] VE remained greater than 0 for at least 5 to 6 months after vaccination. A more recent study of children older than 2 years also found evidence of declining VE, with an odds ratio increasing approximately 16% with each additional 28 days from vaccine administration.[77] Another study evaluating VE from the 2011–2012 to the 2013–2014 influenza seasons demonstrated 54% to 67% protection from 0 to 180 days after vaccination.[75] Finally, a multiseason study in Europe from 2011–2012 to 2014–2015 showed a

steady decline in VE down to 0% protection by 111 days after vaccination.[76]

Further evaluation is needed before any policy change in timing of influenza administration in children is made. An early onset of the influenza season is a concern when considering delaying vaccination. Until there are definitive data demonstrating waning immunity influences VE in children, administration of the influenza vaccine should not be delayed to a later date because this increases the likelihood of missing influenza vaccination altogether.[81] Providers may continue to offer vaccination as long as influenza is circulating and until June 30 of each year, when the seasonal influenza vaccine expires, because the duration of influenza circulation is unpredictable. Furthermore, a person may experience more than 1 influenza infection during a given season because of the various cocirculating strains. Although influenza activity in the United States is typically low during the summer, influenza cases and outbreaks can occur, particularly among international travelers, who may be exposed to influenza year-round, depending on the destination.

VACCINE IMPLEMENTATION

The AAP Partnership for Policy Implementation has developed a series of definitions using accepted health information technology standards to assist in the implementation of vaccine recommendations in computer systems and quality measurement efforts. This document is available at https://www.aap.org/enus/professional-resources/quality-improvement/Pages/Partnership-for-Policy-Implementation.aspx. In addition, the AAP has developed implementation guidance on supply, payment, coding, and liability issues; these documents can be found at https://www.aap.org/en/patient-care-pages-in-progress/influenza/managing-influenzavaccination-in-your-practice/. The committee supports adequate payment from public and private payers for the vaccine product and administration in the pediatric population. Information on preparing your practice to administerinfluenza vaccines during the COVID-19 pandemic can be found at https://services.aap.org/en/pages/2019-novel-coronaviruscovid-19-infections/help-for-pediatricians/preparing-for-flu-season/. HCP, influenza campaign organizers, and public health agencies are encouraged to collaborate to develop improved strategies for planning, distribution, communication, and administration of vaccines. For example, pediatricians can play a key role in educating and assisting early childhood education centers and schools in educating parents on the importance of influenza immunization. Resources for effective communication and messaging strategies, including promoting vaccinations and providing resources for pediatricians to communicate with patients, families, and the communities they serve, are available on the AAP Web site (https://services.aap.org/en/news-room/campaigns-and-toolkits/immunizations and https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/immunizations/Influenza-Implementation-Guidance/Pages/Patient-Family-and-Community.aspx).

Pediatricians and other pediatric health care providers should plan to make the influenza vaccine easily accessible for all children. Examples include sending alerts to families that vaccine is available (eg, e-mails, texts, letters, patient portals, practice-specific Web sites, or social media platforms); creating walk-in influenza vaccination clinics; extending hours beyond routine times during peak vaccination periods; administering the influenza vaccine during both well-child examinations and sick visits as well as in hospitalized patients, especially those at high risk of influenza complications, before hospital discharge (unless medically contraindicated); implementing standing orders for influenza vaccination; considering how to immunize parents, adult caregivers, and siblings (see risk management guidance associated with adult immunizations in ref 85) at the same time as children; and working with other institutions (eg, schools, child care programs, local public health departments, and religious organizations) or alternative care sites, such as pharmacies and hospital emergency departments, to expand venues for administering the vaccine. If a child receives the influenza vaccine outside his or her medical home, such as at a pharmacy, retail-based clinic, or another practice setting, appropriate documentation of vaccination should be provided to the patient to be shared with his or her medical home and entered into the state or regional immunization information system (ie, registry).

Concerted efforts among the aforementioned groups, plus vaccine manufacturers, distributors, and payers, are necessary to prioritize distribution appropriately to the primary care office setting and patient-centered medical home before other venues, especially when vaccine supplies are delayed or limited. Payers should eliminate remaining patient responsibility cost barriers to the influenza vaccine where they still exist. Similar efforts should be made to eliminate the vaccine supply discrepancy between

privately insured patients and those eligible for vaccination through the Vaccines for Children program. American Indian and Alaskan native children, who are eligible for vaccines through the Vaccines for Children program, are at higher risk for influenza complications and should be prioritized in a vaccine shortage (Table 2).

Population health can benefit from pediatricians' discussions about vaccine safety and effectiveness. Pediatricians and their office staff can influence vaccine acceptance by explaining the importance of annual influenza vaccination for children and emphasizing when a second dose of the vaccine is indicated. The AAP and CDC have created communication resources to convey these important messages and to help the public understand influenza recommendations. Resources will be available on *Red Book Online* (https://redbook.solutions.aap.org/selfserve/ssPage.aspx?SelfServeContentId=influenza-resources).

The AAP supports mandatory influenza vaccination programs for all HCP in all settings, including outpatient settings. Optimal prevention of influenza in the health care setting depends on the vaccination of at least 90% of HCP. Vaccine coverage among HCP was 81.1% during the 2018–2019 season, up from 78.4% the previous year.[86] Influenza vaccination programs for HCP benefit the health of employees, their patients, and members of the community, especially because HCP frequently come into contact with patients at high risk of influenza illness in their clinical settings. Mandatory influenza immunization for all HCP is considered to be ethical, just, and necessary to improve patient safety. For the prevention and control of influenza, HCP must prioritize the health and safety of their patients, honor the requirement of causing no harm, and act as role models for both their patients and colleagues by receiving influenza vaccination annually.

INFLUENZA VACCINE COVERAGE

Although national influenza vaccination coverage among children had remained stable and even increased in the past several seasons before the COVID-19 pandemic, overall vaccination coverage remains suboptimal (Fig 1). The Healthy People 2020 national target of 70% of children and adults vaccinated against influenza was not achieved, with coverage lagging by 6 percentage points for children and almost 20 percentage points for adults. The newly launched Healthy People 2030 has, therefore, set a target for influenza vaccination of people ≥6 months of age at 70%.[87] Additional options for vaccination of children may provide a means to improve coverage, particularly in pharmacies and child care and school-based settings. Achieving high coverage rates of the influenza vaccine in infants and children is a priority to protect them against influenza disease and its complications.

The AAP and CDC recommend vaccine administration at any visit to the medical home during influenza season when it is not contraindicated, at specially arranged vaccine-only sessions, and through cooperation with public health departments, community sites, schools, and Head Start and child care facilities to provide the influenza vaccine. It is important that annual delivery of the influenza vaccine to primary care medical homes be timely to avoid missed opportunities. If alternate venues, including pharmacies and other retail-based clinics, are used for vaccination, a system of patient record transfer is crucial to maintain the accuracy of immunization records. Immunization information systems should be used whenever available and prioritized to document influenza vaccination. Two-dimensional barcodes have been used to facilitate more efficient and accurate documentation of vaccine administration, with limited experience to date. Additional information concerning current vaccines shipped with two-dimensional barcodes can be found at www.cdc.gov/vaccines/programs/iis/2d-vaccine-barcodes/.

Children's likelihood of being immunized according to recommendations appears to be associated with the immunization practices of their parents. The authors of one study found that children were 2.77 times (95% CI, 2.74 to 2.79) more likely to be immunized against seasonal influenza if their parents were immunized.[48] When parents who were previously not immunized had received immunization for seasonal influenza, their children were 5.44 times (95% CI, 5.35 to 5.53) more likely to receive the influenza vaccine.

Pediatric offices may choose to serve as a venue for providing influenza vaccination for parents and other care providers of children, if the practice is acceptable to both pediatricians and the adults who are to be vaccinated, particularly when it can help reduce inequities in vaccination access. Medical liability and payment issues, along with medical record documentation requirements, need to be considered before a pediatrician begins immunizing adults (see risk management guidance associated with adult immunizations in ref 85). Pediatric practices should be aware of payment implications, including nonpayment or having the parent inappropriately attributed by a payer as a patient of the pediatrician's office. The AAP supports efforts to overcome these payment barriers with insurance

payers to maximize influenza immunization rates. To avoid errors in claims processing and payment and in the exchange of immunization data, pediatricians are reminded that parents should have their own basic medical record, in which their influenza vaccination should be documented. Adults should be encouraged to have a medical home and communicate their vaccination status to their primary care provider. Offering adult vaccinations in the pediatric practice setting should not undermine the adult medical home model. Vaccination of close contacts of children at high risk of influenza-related complications (Table 2) is intended to reduce children's risk of exposure to influenza (ie, "cocooning"). The practice of cocooning also may help protect infants younger than 6 months, who are too young to be immunized with the influenza vaccine.

SURVEILLANCE

Information about influenza surveillance is available through the CDC Voice Information System (influenza update at 1-800-232-4636) or at www.cdc.gov/flu/index.htm. Although yearly influenza data on circulating strains do not necessarily predict which and in what proportion strains will circulate in the subsequent season, it is instructive to be aware of the previous season's influenza surveillance data to use as a guide to empirical therapy until current seasonal data are available from the CDC. Information is posted weekly on the CDC Web site (www.cdc.gov/flu/weekly/fluactivitysurv.htm).

INFLUENZA ANTIVIRALS

Antiviral agents available for both influenza treatment and chemoprophylaxis in children of all ages can be found in Table 4 (including doses for preterm infants that have not been evaluated by the FDA) and on the CDC Web site (www.cdc.gov/flu/professionals/antivirals/index.htm). These include the neuraminidase inhibitors (NAIs) (oseltamivir, zanamivir, peramivir) and a selective inhibitor of influenza cap-dependent endonuclease (baloxavir), all of which have activity against influenza A and B viruses.[88]

Oral oseltamivir (Tamiflu) remains the antiviral drug of choice for the management of illness caused by influenza virus infections. Although more difficult to administer, inhaled zanamivir (Relenza) is an equally acceptable alternative for patients who do not have chronic respiratory disease. Options are limited for children who cannot absorb orally or enterally administered oseltamivir or tolerate inhaled zanamivir. Intravenous (IV) peramivir (Rapivab), a third NAI, was approved in September 2017 as a treatment of acute uncomplicated influenza in nonhospitalized children 2 years and older who have been symptomatic for no more than 2 days. The efficacy of peramivir in patients with serious influenza requiring hospitalization has not been established.[88] IV zanamivir is not approved in the United States and has not been available for compassionate use since the 2017–2018 season.[69,70] Baloxavir marboxil (Xofluza) was approved in 2018 for the early treatment of uncomplicated influenza in outpatients 12 years and older who have been ill for no more than 2 days.[89] This antiviral agent for influenza has a different mechanism of action (cap-endonuclease inhibitor) than NAIs and requires only a single oral dose for treatment of uncomplicated influenza. A recently completed phase 3 randomized, double-blind, active controlled study in children 1 to 12 years of age demonstrated that baloxavir treatment was well tolerated and resulted in a similar median time to alleviation of signs and symptoms of influenza as oseltamivir in ambulatory children with acute influenza.[90] Another study suggests that baloxavir is also effective in reducing viral titers and achieving comparable time to alleviation of symptoms as NAIs in high-risk patients ≥12 years of age with uncomplicated influenza.[91] A clinical trial of baloxavir treatment of influenza in hospitalized patients 12 years and older is ongoing (https://clinicaltrials.gov/ct2/show/NCT03684044?cond=baloxavir&rank=6). In November 2020, baloxavir was approved by the FDA for single-dose postexposure prophylaxis in people 12 years of age an older after exposure to someone with influenza.[92,93]

INFLUENZA TREATMENT

Randomized controlled trials (RCTs) conducted to date to evaluate the efficacy of influenza antiviral medications among outpatients with uncomplicated influenza have found that timely treatment can reduce the duration of influenza symptoms and fever in pediatric populations.[94–98] Observational studies in pediatric and adult populations suggest that antiviral agents are safe and could reduce the risk of certain influenza complications, including hospitalization and death.[99–103] The number of published RCTs in children is limited, and interpretation of the results of these studies needs to take into consideration the size of the study (the number of events might not be sufficient to assess specific outcomes in small studies), the variations in the case definition of influenza illness (clinically diagnosed versus laboratory confirmed), the time of treatment administration in relation to the onset of illness, and the child's age and health status as important variables. A Cochrane review of 6

TABLE 4 Recommended Dosage and Schedule of Influenza Antiviral Medications for Treatment and Chemoprophylaxis in Children for the 2021–2022 Influenza Season: United States

Medication	Treatment	Chemoprophylaxis[a]
Oseltamivir[b]		
Adults	75 mg, twice daily for 5 d	75 mg, once daily for 5 d
Children ≥12 mo (based on body wt)	Duration in all groups is 5 d	Duration in all groups is 10 d
≤15 kg (≤33 lb)	30 mg, twice daily	30 mg, once daily
>15–23 kg (>33–51 lb)	45 mg, twice daily	45 mg, once daily
>23–40 kg (>51–88 lb)	60 mg, twice daily	60 mg, once daily
>40 kg (>88 lb)	75 mg, twice daily	75 mg, once daily
Infants 9–11 mo[c]	3.5 mg/kg per dose, twice daily	3.5 mg/kg per dose, once daily
Term infants 0–8 mo[c]	3 mg/kg per dose, twice daily	3 mg/kg per dose, once daily for infants 3–8 mo; not recommended for infants <3 mo old because of limited safety and efficacy data in this age group
Preterm infants[d]		
<38 wk postmenstrual age	1.0 mg/kg per dose, twice daily	—
38–40 wk postmenstrual age	1.5 mg/kg per dose, twice daily	—
>40 wk postmenstrual age	3.0 mg/kg per dose, twice daily	—
Zanamivir[e]		
Adults	10 mg (two 5-mg inhalations), twice daily for 5 d	10 mg (two 5-mg inhalations), once daily for 10 d
Children (≥7 y for treatment, ≥5 y for chemoprophylaxis)	10 mg (two 5-mg inhalations), twice daily for 5 d	10 mg (two 5-mg inhalations), once daily for 10 d
Peramivir		
Adults	One 600-mg IV infusion, given over 15–30 min	Not recommended
Children (2–12 y)	One 12 mg/kg dose, up to 600 mg maximum, via IV infusion for 15–30 min	Not recommended
Children (13–17 y)	One 600 mg dose, via IV infusion for 15–30 min	Not recommended
Baloxavir		
People ≥12 y who weigh >40 kg	40–80 kg: one 40-mg dose, orally ≥80 kg: one 80-mg dose, orally	40–80 kg: one 40-mg dose, orally ≥80 kg: one 80-mg dose, orally

Adapted from Uyeki TM, Bernstein HH, Bradley JS, et al. Clinical practice guidelines by the Infectious Diseases Society of America: 2018 update on diagnosis, treatment, chemoprophylaxis, and institutional outbreak management of seasonal influenza [published correction appears in *Clin Infect Dis*. 2019;68(10):1790]. *Clin Infect Dis*. 2019;68(6):e1–e47; and https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm. —, not applicable.

[a] The CDC recommends routine chemoprophylaxis with oseltamivir or zanamivir for 7 d and for 10 d only if part of an institutional outbreak (https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm).

[b] The duration of treatment with oseltamivir is 5 d. Oseltamivir is administered orally regardless of meals, although administration with meals may improve gastrointestinal tolerability. Oseltamivir is available as Tamiflu in 30-, 45-, and 75-mg capsules and as a powder for oral suspension that is reconstituted to provide a final concentration of 6 mg/mL. For the 6-mg/mL suspension, a 30-mg dose is given with 5 mL of oral suspension, a 45-mg dose is given with 7.5 mL oral suspension, a 60-mg dose is given with 10 mL oral suspension, and a 75-mg dose is given with 12.5 mL oral suspension. If the commercially manufactured oral suspension is not available, a suspension can be compounded by retail pharmacies (final concentration also 6 mg/mL) on the basis of instructions contained in the package label. In patients with renal insufficiency, the dose should be adjusted on the basis of creatinine clearance. For treatment of patients with creatinine clearance 10–30 mL/min: 75 mg once daily for 5 d. For chemoprophylaxis of patients with creatinine clearance 10–30 mL/min: 30 mg once daily for 10 d after exposure or 75 mg, once every other day, for 10 d after exposure (5 doses). See https://www.cdc.gov/flu/professionals/antivirals/summary-clinicians.htm and Infectious Diseases Society of America guidelines.[88]

[c] Approved by the FDA for children as young as 2 wk of age. Given preliminary pharmacokinetic data and limited safety data, oseltamivir can be used to treat influenza in both term and preterm infants from birth because benefits of therapy are likely to outweigh possible risks of treatment. Of note, the CDC recommends 3 mg/kg per dose twice daily for all infants <12 mo old; the Infectious Diseases Society of America guidelines[88] include both AAP and CDC recommendations.

[d] Oseltamivir dosing for preterm infants: the wt-based dosing recommendation for preterm infants is lower than that for term infants. Preterm infants may have lower clearance of oseltamivir because of immature renal function, and doses recommended for term infants may lead to high drug concentrations in this age group. Limited data from the National Institute of Allergy and Infectious Diseases Collaborative Antiviral Study Group provide the basis for dosing preterm infants by using their postmenstrual age (gestational age + chronological age). For extremely preterm infants (<28 wk), please consult a pediatric infectious disease physician.

[e] The duration of treatment with zanamivir is 5 d. Zanamivir is administered by inhalation by using a proprietary "Diskhaler" device distributed together with the medication. Zanamivir is a dry powder, not an aerosol, and should not be administered by using nebulizers, ventilators, or other devices typically used for administering medications in aerosolized solutions. Zanamivir is not recommended for people with chronic respiratory diseases, such as asthma or chronic obstructive pulmonary disease, which increase the risk of bronchospasm.

RCTs involving treatment of 2356 children with clinically diagnosed influenza, of whom 1255 had laboratory-confirmed influenza, showed that in children with laboratory-confirmed influenza, oral oseltamivir and inhaled zanamivir reduced the median duration of illness by 36 hours (26%; $P < .001$) and 1.3 days (24%; $P < .001$), respectively.[98] Among the studies reviewed, one trial of oseltamivir in children with asthma who had laboratory-confirmed influenza showed only a nonsignificant reduction in illness duration (10.4 hours; 8%; $P = .542$). Oseltamivir significantly reduced acute otitis media in children 1 to 5 years of age with laboratory-confirmed influenza (risk difference, −0.14; 95% CI,

−0.24 to −0.04).[98] Another Cochrane review of RCTs in adults and children, which included 20 oseltamivir (9623 participants) and 26 zanamivir trials (14 628 participants),[95] found no effect of oseltamivir in reducing the duration of illness in children with asthma, but in otherwise healthy children, there was a reduction by a mean difference of 29 hours (95% CI, 12 to 47 hours; $P = .001$). No significant effect was observed with zanamivir. Regarding complications, this review did not find a significant effect of NAIs on reducing hospitalizations, pneumonia, bronchitis, otitis media, or sinusitis in children.[95] More recently, a meta-analysis of 5 new RCTs that included 1598 children with laboratory-confirmed influenza showed that treatment with oseltamivir significantly reduced the duration of illness in this population by 17.6 hours (95% CI, −34.7 to −0.62 hours).[96] When children with asthma were excluded, this difference was larger (−29.9 hours; 95% CI, −53.9 to −5.8 hours). The risk of otitis media was 34% lower in this group as well. Similarly, a meta-analysis conducted by Tejada et al[103] showed a statistically significant reduction in the risk of acute otitis media occurrence among treated children over placebo recipients (odds ratio, 0.48; 95% CI, 0.30 to 0.77). Overall, efficacy outcomes are best demonstrated in patients with laboratory-confirmed influenza. All these studies confirmed vomiting as an occasional adverse effect of oseltamivir, occurring in approximately 5% of treated patients. The balance between benefits and harms should be considered when making decisions about the use of NAIs for either treatment or chemoprophylaxis of influenza.

Although prospective comparative studies to determine the efficacy of influenza antiviral medications in hospitalized patients or pediatric patients with comorbidities have not been conducted, and prospectively collected data to determine the role of antiviral agents in treating severe influenza are limited, on the basis of information obtained from retrospective observational studies and meta-analyses conducted to date in both adults and children, most experts support the use of antiviral medications as soon as possible to treat pediatric patients with severe influenza, including hospitalized patients.[97,99–102,104] In an observational epidemiological study conducted in adult patients hospitalized with severe laboratory-confirmed influenza in Spain over 6 influenza seasons (2010–2016), the authors evaluated the effectiveness of NAIs, concluding that when started early after the onset of symptoms (≤48 hours or ≤5 days), NAI treatment was associated with a reduction in influenza-associated deaths (adjusted odds ratio, 0.37 [95% CI, 0.22 to 0.63]; and adjusted odds ratio, 0.50 [95% CI, 0.32 to 0.79], respectively).[99] However, treatment initiation more than 5 days after the onset of influenza symptoms was not associated with reduction in mortality in hospitalized adults.

Importantly, and despite limited evidence from prospectively conducted trials, treatment with oseltamivir for children with serious, complicated, or progressive disease presumptively or definitively caused by influenza, irrespective of influenza vaccination status (the circulating strains may not be well matched with vaccine strains) or whether illness began greater than 48 hours before admission, is recommended by the AAP, CDC, Infectious Diseases Society of America,[88] and Pediatric Infectious Diseases Society. Earlier treatment provides better clinical responses. However, treatment after 48 hours of symptoms in adults and children with moderate to severe disease or with progressive disease has been shown to provide some benefit and should be offered.[105–107] In a retrospective study of 653 PICU admissions from 2009 to 2012, the estimated risk of death was reduced in NAI-treated cases (odds ratio 0.36; 95% CI, 0.16 to 0.83).[105] No additional benefit exists for double-dose NAI therapy on reduction of mortality or virological clearance compared with standard-dose therapy on the basis of a recent systematic review and meta-analysis of 10 published studies[108] (4 RCT and 6 observational studies) involving 20 947 adult and pediatric patients.

Children younger than 2 years are at an increased risk of hospitalization and complications attributable to influenza. The FDA has approved oseltamivir for treatment of children as young as 2 weeks of age. Given preliminary pharmacokinetic data and limited safety data, the CDC and AAP support the use of oseltamivir to treat influenza in both term and preterm infants from birth because benefits of therapy of neonatal influenza are likely to outweigh possible risks of treatment.

Oseltamivir is available in capsule and oral suspension formulations. The available capsule doses are 30, 45, and 75 mg, and the commercially manufactured liquid formulation has a concentration of 6 mg/mL in a 60-mL bottle. If the commercially manufactured oral suspension is not available, the capsule may be opened and the contents mixed with simple syrup or Ora-Sweet SF (sugar free) by retail pharmacies to a final concentration of 6 mg/mL.

In adverse event data collected systematically in prospective trials, vomiting was the only adverse effect

reported more often with oseltamivir compared with a placebo when studied in children 1 to 12 years of age (ie, 15% of treated children versus 9% receiving a placebo). In addition, after reports from Japan of oseltamivir-attributable neuropsychiatric adverse effects, a review of controlled clinical trial data and ongoing surveillance has failed to establish a link between this drug and neurologic or psychiatric events.[109,110]

Clinical judgment (based on underlying conditions, disease severity, time since symptom onset, and local influenza activity) is an important factor in treatment decisions for pediatric patients who present with influenzalike illness. Antiviral treatment should be started as soon as possible after illness onset and should not be delayed while waiting for a definitive influenza test result because early therapy provides the best outcomes.

Influenza diagnostic tests vary by method, availability, processing time, sensitivity, and cost (Table 5), all of which should be considered in making the best clinical decision. Positive and negative predictive values of influenza test results are influenced by the level of influenza activity in the population being tested, the characteristics of a test compared to a gold standard, pretest probability, whether the influenza virus is actively replicating in the person, proper collection and transport of specimens, and proper test procedures. Testing should be performed when timely results will be available to influence clinical management or infection-control measures. Although decisions on treatment and infection control can be made on the basis of positive rapid test results, particularly when influenza is known to be circulating, negative results should not always be used in a similar fashion because of the suboptimal sensitivity and potential for false-negative results. An updated list of rapid influenza diagnostic tests is available at https://www.cdc.gov/flu/professionals/diagnosis/table-ridt.html. Positive results of rapid influenza diagnostic tests are helpful because they may reduce additional testing to identify the cause of the child's influenzalike illness and promote appropriate antimicrobial stewardship. Available FDA-approved rapid molecular assays based on nucleic acid detection are highly sensitive and specific diagnostic tests that can provide rapid results. An updated list of these tests is available at https://www.cdc.gov/flu/professionals/diagnosis/table-nucleic-acid-detection.html. Molecular assays are preferred in hospitalized patients because they are more sensitive compared with antigen detection. Early detection, prompt antiviral treatment, and infection-control interventions can

TABLE 5 Comparison of Types of Influenza Diagnostic Tests[a]

Testing Category	Method	Influenza Viruses Detected	Distinguishes Influenza A Virus Subtypes	Time to Results	Performance
Rapid molecular assay	Nucleic acid amplification	Influenza A or B viral RNA	No	15–30 min	High sensitivity; high specificity
Rapid influenza diagnostic test	Antigen detection	Influenza A or B virus antigens	No	10–15 min	Low to moderate sensitivity (higher with analyzer devise); high specificity
Direct and indirect immunofluorescence assays	Antigen detection	Influenza A or B virus antigens	No	1–4 h	Moderate sensitivity; high specificity
Molecular assays (including RT-PCR)	Nucleic acid amplification	Influenza A or B viral RNA	Yes, if subtype primers are used	1–8 h	High sensitivity; high specificity
Multiplex molecular assays	Nucleic acid amplification	Influenza A or B viral RNA, other viral or bacterial targets (RNA or DNA)	Yes, if subtype primers are used	1–2 h	High sensitivity; high specificity
Rapid cell culture (shell vial and cell mixtures)	Virus isolation	Influenza A or B virus	Yes	1–3 d	High sensitivity; high specificity
Viral culture (tissue cell culture)	Virus isolation	Influenza A or B virus	Yes	3–10 d	High sensitivity; high specificity

Source: Uyeki.[88]

[a] Negative results may not rule out influenza. Respiratory tract specimens should be collected as close to illness onset as possible for testing. Clinicians should consult the manufacturer's package insert for the specific test for the approved respiratory specimen(s). Specificities are generally high (>95%) for all tests compared to reverse transcriptase-polymerase chain reaction (RTP CR). FDA-cleared rapid influenza diagnostic tests are Clinical Laboratory Improvements Act (CLIA)-waived; most FDA-cleared rapid influenza molecular assays are CLIA-waived, depending on the specimen.

lead to improved individual patient outcomes and allow for effective cohorting and disease containment.

People with suspected influenza who are at higher risk of influenza complications should be offered treatment with antiviral medications (Table 2). Efforts should be made to minimize treatment of patients who are not infected with influenza. Otherwise healthy children who have suspected influenza with an uncomplicated presentation at times when influenza viruses are known to be circulating in the community should be considered for antiviral medication, particularly if they are in contact with other children who either are younger than 6 months (because they are not able to receive influenza vaccine) or have high-risk conditions (including age <5 years) that predispose them to complications of influenza. If there is a local shortage of antiviral medications, local public health authorities should be consulted to provide additional guidance about testing and treatment.

INFLUENZA CHEMOPROPHYLAXIS

Randomized placebo-controlled studies showed that oral oseltamivir and inhaled zanamivir were efficacious when administered as chemoprophylaxis to household contacts after a family member had laboratory-confirmed influenza.[88] Baloxavir received FDA approval in November 2020 for influenza chemoprophylaxis.[93,111] When compared with a placebo as a preventive treatment of adults and children, the proportion of household members 12 years and older who developed influenza was 1 in participants treated with a single dose of baloxavir within 48 hours of exposure to a symptomatic household contact with influenza and 13 in the placebo-treated group.[93] Baloxavir was well tolerated in this randomized study conducted in apan during the 2018–2019 influenza season. There are no data on IV peramivir for chemoprophylaxis.

Decisions on whether to administer antiviral chemoprophylaxis should take into account the exposed person's risk of influenza complications, vaccination status, the type and duration of contact, recommendations from local or public health authorities, and clinical judgment. Optimally, postexposure chemoprophylaxis should only be used when antiviral agents can be started within 48 hours of exposure the lower once-daily dosing for chemoprophylaxis with oral oseltamivir or inhaled zanamivir should not be used for treatment of children symptomatic with influenza.[112] Early full treatment doses (rather than chemoprophylaxis doses) should be used in high-risk symptomatic patients without waiting for laboratory confirmation.

Chemoprophylaxis should not be considered a substitute for vaccination. The influenza vaccine should always be offered before and throughout the influenza season when not contraindicated. Antiviral medications are important adjuncts to influenza vaccination for control and prevention of influenza disease. Toxicities may be associated with antiviral agents, and indiscriminate use might limit availability. Pediatricians should inform recipients of antiviral chemoprophylaxis that risk of influenza is lowered but still remains while taking the medication, and susceptibility to influenza returns when medication is discontinued. Although antiviral use is not a contraindication to vaccination with IIVs, it is likely that LAIV effectiveness will be decreased for children receiving oseltamivir or other influenza antiviral agents.[112]

Among some high-risk people, both vaccination with IIV and antiviral chemoprophylaxis may be considered.[112] Updates will be available at www.aapredbook.org/flu and at www.cdc.gov/flu/professionals/antivirals/index.htm.

ANTIVIRAL RESISTANCE

Antiviral resistance to any drug can emerge, necessitating continuous population-based assessment conducted by the CDC. During the 2019–2020 influenza season, >99 of influenza A(H1N1)pdm09 and B/Victoria viruses tested were susceptible to oseltamivir, peramivir, and zanamivir, and all were susceptible to baloxavir. All tested influenza A(H3N2) and B/amagata viruses were susceptible to these antiviral agents. Decreased susceptibility to baloxavir has been reported in apan, where its use has been more common,[113–117] and surveillance for resistance among circulating influenza viruses is ongoing in apan and the United States.[9,118,119] In contrast, high levels of resistance to amantadine and rimantadine persist among the influenza A viruses currently circulating. Adamantane medications are not recommended for use against influenza unless resistance patterns change.[88]

Viral surveillance and resistance data from the CDC and WHO indicate that the majority of currently circulating influenza viruses likely to cause influenza in North America during the 2021–2022 influenza season continue to be susceptible to oseltamivir, zanamivir, peramivir, and baloxavir.[7] If a newly emergent oseltamivir- or peramivir-resistant virus is a concern, recommendations for alternative treatment will be available from the CDC and AAP. Resistance characteristics can change for an individual patient over the duration of a treatment

course, especially in those who are severely immunocompromised. Up-to-date information on current recommendations and therapeutic options can be found on the AAP Web site (www.aap.org or www.aapredbook.org/flu), through state-specific AAP chapter Web sites, or on the CDC Web site (www.cdc.gov/flu/).

FUTURE DIRECTIONS

Safety and effectiveness data for influenza vaccines used during the 2020–2021 influenza season will be analyzed as they become available and reported by the CDC as they are each season. However, new data might not be available given the low levels of circulation of influenza during the COVID-19 pandemic. Continued evaluation of the safety, immunogenicity, and effectiveness of influenza vaccines, especially for at-risk and diverse populations, is important. The duration of protection, the potential role of previous influenza vaccination on overall VE, and VE by vaccine formulation, virus strain, timing of vaccination, and subject age and health status in preventing outpatient medical visits, hospitalizations, and deaths continue to be evaluated. For the 2021–2022 influenza season, it will be particularly important to understand the effect of SARS-CoV-2 and influenza virus cocirculation on the epidemiology and morbidity of influenza in the pediatric population. Understanding how to better educate parents about influenza symptoms and how to recognize when to seek medical attention would be informative. Additionally, with limited data on the use of antiviral agents in hospitalized children and in children with underlying medical conditions, prospective clinical trials to inform optimal timing and efficacy of antiviral treatment in these populations are warranted. This is particularly relevant as new antiviral agents or new indications for existing antiviral agents become available. At this time, the FDA has accepted supplemental new drug applications for baloxavir marboxil for the treatment of acute uncomplicated influenza in pediatric patients from 1 to 12 years of age.[120]

There is also a need for more systematic health services research on influenza vaccine uptake and refusal as well as identification of methods to enhance uptake. Developing influenza vaccination programs in nontraditional settings, including the pediatric emergency department, may also increase distribution.[121,122] Further investigation is needed concerning vaccine acceptance and hesitancy and methods to overcome parental concerns and improve coverage. This might be particularly relevant with the introduction of the COVID-19 vaccine for children and adolescents in 2021. Efforts may include evaluating the strategy of offering to immunize parents and adult child care providers in the pediatric office setting and understanding the level of family contact satisfaction with this approach; how practices handle the logistic, liability, legal, and financial barriers that limit or complicate this service; and most importantly, how this practice may affect disease rates in children and adults. Furthermore, ongoing efforts should include broader implementation and evaluation of mandatory HCP vaccination programs in both inpatient and outpatient settings.

Efforts should be made to create adequate outreach (eg, mobile integrated health care) and infrastructure to facilitate the optimal distribution of the vaccine so that more people are immunized. Given the experience with COVID-19, pediatricians have become more involved in pandemic preparedness and disaster planning efforts. A bidirectional partner dialogue between pediatricians and public health decision-makers assists efforts to address children's issues during the initial state, regional, and local plan development stages. Additional information on this topic can be found at https://pediatrics.aappublications.org/content/pediatrics/early/2017/05/11/peds.2016-3690.full.pdf.

Access-to-care issues, lack of immunization records, and questions regarding who can provide consent may be addressed by linking children (eg, those in foster care or the juvenile justice system or refugee, immigrant, or homeless children) with a medical home, using all health care encounters as vaccination opportunities, and more consistently using immunization registry data.

Development efforts continue for universal influenza vaccines that induce broader protection and eliminate the need for annual vaccination.[123] The success of mRNA and other novel technologies used in the development of COVID-19 vaccines may accelerate the prospects of broad influenza vaccines. Understanding the establishment of immunity against influenza in early life and the development of a safe immunogenic vaccine for infants younger than 6 months are essential. Studies on the effectiveness and safety of influenza vaccines containing adjuvants that enhance immune responses to influenza vaccines or that use novel routes of administration are needed.

Efforts to improve the vaccine development process to allow for a shorter interval between identification of vaccine strains and vaccine production continue. New antiviral drugs are in various development phases given the need to improve options for the treatment and chemoprophylaxis of influenza.

Pediatricians can remain informed of advances and other updates during the influenza season by following the CDC Influenza page (www.cdc.gov/flu) and the AAP *Red Book Online* Influenza Resource Page (www.aapredbook.org/flu).

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Recommended Childhood and Adolescent Immunization Schedule: United States, 2022

COMMITTEE ON INFECTIOUS DISEASES

The 2022 recommended childhood and adolescent immunization schedules have been approved by the Centers for Disease Control and Prevention (CDC), American Academy of Pediatrics, American Academy of Family Physicians, American College of Obstetricians and Gynecologists, American College of Nurse-Midwives, American Academy of Physician Assistants, and National Association of Pediatric Nurse Practitioners. The schedules are revised annually to reflect current recommendations for the use of vaccines licensed by the US Food and Drug Administration.

The 2022 childhood and adolescent immunization schedule has been updated to ensure consistency between the formats of the childhood and adolescent and the adult immunization schedules. Similar to last year, the cover page includes a table with an alphabetical listing of vaccines, approved abbreviations for each vaccine, and vaccine trade names.

Table 1 contains the recommended immunization schedule from birth to 18 years of age.

Table 2 is the catch-up immunization schedule for persons 4 months to 18 years of age who start late or who are more than 1 month behind the recommended age for vaccine administration.

Table 3 lists the vaccines that may be indicated for children and adolescents 18 years of age or younger on the basis of medical conditions.

Similar to the 2021 schedule, the notes are presented in alphabetical order. The following changes to individual footnotes have been made to the 2022 schedule:

DOI: https://doi.org/10.1542/peds.2021-056056

PEDIATRICS (ISSN Numbers: Print, 0031-4005; Online, 1098-4275).

To cite: AAP Committee on Infectious Diseases. Recommended Childhood and Adolescent Immunization Schedule: United States, 2022. *Pediatrics*. 2022;149(3):e2021056056

- In "Additional Information," the text in the section on COVID-19 vaccination recommendations has been updated.
- For dengue vaccination:
  - A new section has been added that contains information regarding routine recommendation for use of dengue vaccine.
- For *Haemophilus influenzae* type b (Hib) vaccination:
  - Text has been edited to include recommendations for use of Vaxelis for routine and catch-up vaccination.
- For hepatitis A vaccination:
  - The note was updated to clarify the age for routine vaccination.
- For human papillomavirus vaccination (HPV):
  - The note has been updated to clarify when an HPV series is complete, and no additional dose of HPV is recommended.
  - The Special Situations section was updated to clarify persons with immunocompromising conditions (including HIV infection) should receive 3 doses of HPV vaccine, regardless of the age at initial vaccination.
- For measles, mumps, and rubella (MMR) vaccination:
  - The section on routine vaccination was updated to include recommendations for the use of the combination measles, mumps, rubella, and varicella vaccine (MMRV).
- For meningococcal serogroup A, C, W, and Y vaccines (MenACWY):
  - Text has been added to clarify MenACWY vaccines can be simultaneously administered with serogroup B meningococcal (MenB) vaccines if indicated but at different anatomic sites, if feasible.
  - In the Special Situations section, the language for the dosing schedule for Menveo in infants was edited for clarity.

Other notable changes in the 2022 child and adolescent immunization schedule include the following:

- Cover page: Dengue vaccine (Dengvaxia) has been added to the table of vaccine abbreviations/trade names.
- Table 1 (Recommended Child and Adolescent Immunization Schedule by Age):
  - Introductory sentences: The text "School entry and adolescent vaccine age groups are shaded in gray" has been removed.
  - The colors of the age columns 4 to 6 years, 11 to 12 years, and 16 years have been changed to make similar to the other columns in the table.
  - HPV row: For the column representing ages 9 to 10 years, the color was changed from blue with an asterisk to yellow with a check mark. The legend now reads "Recommended vaccination can begin in this age group."
  - Tdap (tetanus, diphtheria, acellular pertussis) row: The overlying text "Tdap" in the column representing ages 11 to 12 years has been changed to "1 dose."
  - A new row was added for dengue vaccine.
- Table 2 (Catch-up Immunization Schedule for Persons 4 Months to 18 Years of Age):
  - *H influenzae* type b row: The text for the minimum interval between dose 2 and dose 3 has been edited to include Vaxelis and remove Comvax.
  - A new row was added for dengue vaccine.
- Table 3 (Recommended Child and Adolescent Immunization Schedule by Medical Condition):
  - HIV infection: The descriptive text for the subcolumn was edited and now reads "$<$15% or total CD4 cell count of $<200/mm^3$."
  - Legend: The text that defines the checked yellow box has been edited to include "or vaccine." The text now reads "Vaccination is recommended, and additional doses may be necessary based on medical condition or vaccine. See Notes."
  - A new row was added for dengue vaccine.

The 2022 version of Tables 1 through 3 and the notes are available on the American Academy of Pediatrics Web site (https://redbook.solutions.aap.org/SS/Immunization_Schedules.asp) and the CDC Web site (www.cdc.gov/vaccines/schedules/hcp/child-adolescent.html). A parent-friendly vaccine schedule for children and adolescents is available at www.cdc.gov/vaccines/schedules/index.html. An adult immunization schedule is published in February of each year and is available at www.cdc.gov/vaccines/schedules/hcp/adult.html.

Clinically significant adverse events that follow immunization should be reported to the Vaccine Adverse Event Reporting System. Guidance about how to obtain and complete a Vaccine Adverse Event Reporting System form can be obtained at www.vaers.hhs.gov or by calling 800-822-7967. Additional information can be found in the *Red Book* and at *Red Book Online* (https://publications.aap.org/redbook). Statements from the Advisory Committee on Immunization Practices and CDC that contain detailed recommendations for individual vaccines, including recommendations for children with high-risk conditions, are available at www.cdc.gov/vaccines/hcp/acip-recs/index.html. Information on new vaccine releases, vaccine supplies, and interim recommendations resulting from vaccine shortages and statements on specific vaccines can be found at www.aapredbook.org/news/vaccstatus.shtml.

INTRODUCTION

The National Association of EMS Physicians, along with these coauthoring associations: American Academy of Pediatrics, American College of Surgeons Committee on Trauma, EMS for Children Innovation and Improvement Center, Emergency Nurses Association, and National Association of State EMS Officials and as also endorsed by the National Association of Emergency Medical Technicians, believes that the delivery of high-quality and effective EMS care is dependent on several factors, including but not limited to the presence of the following:

- providers who have been credentialed to ensure they demonstrate appropriate cognitive knowledge, affective ability, psychomotor skills, and critical thinking[1];
- clinical protocols or guidelines that are supported by the best available scientific evidence; and
- equipment and supplies necessary to deliver appropriate care as directed by clinical protocols and/or guidelines for patients of all ages.

Several documents, including previous versions of this joint position statement, the *National Model EMS Clinical Guidelines Version 2.2*, the *2018 National EMS Scope of Practice Model*, the *Clinical Credentialing of EMS Providers*, *Physician Oversight of Pediatric Care in Emergency Medical Services*, *Pediatric Readiness in Emergency Medical Services Systems*, and core performance measures from the US Department of Health and Human Services Health Resources and Services Administration EMS for Children (EMSC) Program have been developed to lay the foundation of several of the concepts noted above.[1–9]

Ensuring that EMS providers are properly equipped to perform their clinical duties is an important function of oversight in EMS systems. In the

To cite: Lyng J, Adelgais K, Alter R, et al. Recommended Essential Equipment for Basic Life Support and Advanced Life Support Ground Ambulances 2020: A Joint Position Statement. *Pediatrics.* 2021;147(6):e2021051508

past, this regulatory oversight has been based on the publication of minimum recommended equipment standards, including previous versions of this document.[2–4] These efforts have attempted to provide a listing of the minimum items recommended for basic life support (BLS) and advanced life support (ALS) ground ambulances.

The field of EMS medicine continues to evolve, and the *EMS Scope of Practice Model* continues to undergo important longitudinal revisions, reflecting ongoing improvements in clinical technology and practice. In effect, these advancements have caused many interventions, once limited to the scope of advanced providers, to begin transitioning into the scope of basic providers. Additionally, interventions that were once considered outside the scope of EMS medicine continue to find appropriate places in the EMS setting of care. These contemporary updates make the delivery of EMS-based interventions safer and easier for EMS providers to perform.

In 201 , our organizations undertook a review and revision of the 2014 version of this joint position statement. Part of this revision process also included review of equipment lists established by individual state and territory rules and statutes for all US states and territories. Our review identified that portions of either the 2014 document and/or state- and territory-level equipment lists required items that:

- are no longer clinically recommended because they have been demonstrated to be either harmful or lacking efficacy or have been replaced by clinically superior options. (eg, military antishock trousers MAST , syrup of ipecac);
- are no longer correctly dichotomized to BLS versus ALS levels of care (eg, continuous positive airway pressure CPAP , nebulized medications);
- fail to include equipment that evidence-based guidelines suggest should be available on ground ambulances (eg, commercial arterial tourniquets are currently lacking on 2 state and territory lists); and
- require arbitrary quantities of items.

Establishing recommended equipment standards has value in helping build consistency across the EMS system of care. Documents such as this can be used to help guide both agency leadership and frontline staff in evaluating whether their agency is properly equipped to provide care that meets recommended community requirements. However, the process of creating and revising rules, statutes, and other legislative mechanisms at the state level of government is often onerous and time consuming and can sometimes have unpredictable results and generate unintended consequences.

Our review of existing state and territory EMS equipment regulations revealed that 3 states and territories had statutory EMS equipment lists that were more than years old. Equipment lists should serve to facilitate advances in the delivery of quality and cost-effective EMS care, not to create a barrier to EMS system improvement and development. In light of this, we offer the following recommendation to governmental entities with jurisdiction involving the practice of EMS medicine–

Ensure that legislative and/or administrative mechanisms that establish equipment standards for ground ambulances:

- avoid requiring arbitrary minimum amounts of equipment list items;
- reflect expert and evidence-based recommendations such as those provided in this position statement;
- undergo review and updates at intervals not to exceed five years;
- do not create unnecessary barriers to implementation of new technology at the local level;
- allow for flexibility and adaptability to make rapid unplanned changes in response to unpredicted equipment or medication shortages affecting local EMS agencies; and
- reinforce that all EMS agencies should carry the age-appropriate equipment, supplies, and medications necessary for their clinical providers to effectively conduct patient care as defined by the clinical protocols and guidelines that are applicable to each agency.

It cannot be overemphasized that the mere presence of certain pieces of equipment on an ambulance does not equate to individual EMS provider competence in the use of that equipment or to an EMS program's practice of high-quality and effective EMS medicine. In addition to establishing minimum equipment standards, we also recommend that states consider establishing standards requiring local EMS agencies to demonstrate that their EMS providers are competent in their use of the equipment and supplies necessary to administer care within their scope of practice as defined or allowed by locally applicable clinical protocols or guidelines. Such assessment of provider competency in use of equipment has been established as a key component of EMS readiness in the joint position statement, "Pediatric Readiness in Emergency Medical Services Systems," and also as a core performance measure by the US Department of Health and Human Services Health Resources and Services Administration through its EMS for Children (EMSC) Program.[8,]

Furthermore, although the implementation of equipment lists at the state level is an important level of system oversight, it remains critically important that EMS agency medical directors evaluate that the equipment available on their agency's

TABLE 1 List of Recommended Essential Equipment for BLS and ALS round Ambulances, 2020

Category	BLS		ALS (All BLS Equipment Plus the Following)	
	Adult	Pediatric	Adult	Pediatric
Airway, ventilation, and oxygenation	• Oxygen supply, portable and on-board • Devices capable of delivering oxygen in a titratable manner through nasal, partial face, or full-face mask routes in sizes to fit neonates through adults • Oropharyngeal airways in sizes to fit neonates to adults • Nasopharyngeal airways in sizes to fit neonates to adults • Manual and or powered suction device(s) with rigid oral and flexible pharyngeal tracheal suction catheters in sizes to fit neonates to adults • A device capable of providing noninvasive positive pressure ventilation • Self-inflating manual ventilation devices and masks to fit neonates to adults[11,12] • Bulb suction		• Direct and or video laryngoscopy equipment appropriate for neonates to adults[a] • Magill forceps • Extraglottic airways in sizes to fit neonates to adults[b]	
Bleeding, hemorrhage control, shock management, and wound care	• Commercial arterial tourniquets • Wound-packing material[c] • auze sponges • Adhesive bandages • Adhesive tape • Fluid for irrigation of wounds • Occlusive dressing (also known as "chest seal")		• Chest decompression needles ≥1 g diameter, minimum length 3.25 in (8.25 cm) or commercial chest decompression device[13–19]	• Chest decompression needles: o 1 g diameter, maximum length 1.5 in (3.8 cm) for patients <5 in (1 cm) long[20] o 23 g diameter, maximum length 0. 5 inches (2 cm) for newborns
Cardiovascular and circulation care	• Automatic external defibrillator with adult and pediatric or combination pads		• A device capable of performing automatic and or manual defibrillation, cardiac rhythm monitoring (in at least 3 leads), 12-lead EC acquisition, and transcutaneous pacing	
Diagnostic Tools	• lucometer • Pulse oximeter with sensors to fit neonates to adults • Stethoscope • Blood pressure cuffs in sizes to fit neonates to adults • Thermometer		• Continuous waveform capnography	
Infection Control	• Items necessary for universal and standard precautions[21]: o Waterless hand cleanser o Sharps container o Supplies for collection or absorption of patient vomit, urine, and or feces o Biohazardous materials collection bags o Products appropriate for cleaning and disinfecting surfaces and equipment • Items necessary for the following transmission-based precautions[22–2]: o Contact precautions: examination gloves, eye protection, gowns o Droplet precautions: surgical masks and eye protection o Airborne precautions: N95 facemasks in provider-appropriate sizes and eye protection or powered air-purifying respirator (PAPR) • eneral trash collection bags		No additional ALS recommendations

	Adult	Pediatric	Adult	Pediatric
Medications	• Medications that are germane to approved agency BLS protocols		• Medications that are germane to approved agency ALS (and/or higher level) protocols	
Medication delivery and vascular access	• Devices and supplies needed to administer medications via routes (oral, inhaled, intramuscular, intranasal) included in locally approved scope of practice and locally applicable protocol(s) and in sizes to fit neonates to adults • Supplies for application of antiseptic to skin	• Tools that provide precalculated wt-based dosing and preclude the need for calculation by EMS providers can reduce dosing errors.[25]	• Devices and supplies needed to administer medications via routes (oral, inhaled, intramuscular, intranasal, intravenous, intraosseous) included in locally approved scope of practice and locally applicable protocol(s) in sizes to fit neonates to adults • Isotonic crystalloid fluids and administration tubing capable of adjustable fluid delivery rate • A device to provide pressure infusion of IV fluids	• A device suitable for administering a fluid bolus to pediatric patients that limits risk for inadvertent overadministration of fluid
Neonatal care		Newborn delivery supplies: • 2 umbilical cord clamps, • Tool for cutting umbilical cord, • Bulb suction, • Infant head cover, • Towels, • Blanket, • Gauze dressings, • Material or device intended to maintain body temperature	No additional ALS recommendations	
Orthopedic injury care	• Splinting material or commercial devices for immobilization of orthopedic extremity injuries including but not limited to: o Femoral splinting materials, which may include either simple nontraction devices or devices that provide femoral traction.[d,26,27] o Pelvic splinting materials, which may include either a commercial pelvic circumferential compression device (PCCD) designed specifically to splint the pelvis or a dedicated bedsheet and towel clips to perform circumferential pelvic antishock sheeting.[28–32] • Cold packs • Elastic bandages		No additional ALS recommendations	
Patient packaging, evacuation, and transport	• Extrication board or device[e,33] • Materials or devices that can be used to provide spinal motion restriction of the cervical, thoracic, and lumbar spine for neonates to adults • Portable stretcher or litter • Collapsible "stair chair" • Wheeled multilevel gurney	• Pediatric-specific restraint system or age/size-appropriate car safety seat[f,34,35]	No additional ALS recommendations	
Safety	• Fire extinguisher (5lb ABC)[36] • ANSI Class 2 or 3 reflective vest or outerwear[37] • Impact-resistant eye protection (ANSI Z87.1)[38] • Nonflammable reflective and/or illuminated roadside warning devices • Portable reusable light source		No additional ALS recommendations	

TABLE 1 Continued

Category	BLS		ALS (All BLS Equipment Plus the Following)	
	Adult	Pediatric	Adult	Pediatric
Temperature management and heat-loss prevention	• Blankets • Towels • Heat packs		No additional ALS recommendations	
Miscellaneous items	• Bandage and trauma shears • A device that allows for two-way communication between the field and EMS communications and dispatch centers, direct medical control, and receiving hospitals • Triage marking system (colored tape, tags, or other system) that is interoperable with other local health care system entities and that follows recommendations from the US Department of Health and Human Services Assistant Secretary for Preparedness and Response[39]		No additional ALS recommendations	
Items that should no longer be carried on BLS or ALS ground ambulances because of evidence of harm or proven lack of clinical efficacy: • Military antishock trousers (MAST), aka pneumatic antishock garment (PASG)[40] • Syrup of ipecac[41]				

ANSI, American National Standards Institute; ECG, electrocardiogram; IV, intravenous.

[a] Laryngoscopy equipment is included to facilitate ALS provider identification and mechanical removal of upper airway foreign bodies by using Magill forceps, regardless of whether the ALS agency includes pediatric or adult endotracheal intubation within their ALS provider scope of practice.

[b] Depending on locally approved scope of practice and locally applicable protocol(s), other invasive airways (endotracheal tubes or needle or surgical cricothyrotomy supplies) may also be carried but are not recommended to be universally required on all ALS ground ambulances.

[c] Wound-packing material may include plain gauze and/or hemostatic dressings.

[d] Traction is not a necessary or required element of prehospital stabilization of suspected femur fracture(s) and is often contraindicated.[26,27]

[e] Devices used for extrication, such as backboards, should not be used for transport. Whenever feasible, patients should be removed from extrication devices before transport. Spinal motion restriction can be maintained by securing the patient to the transport stretcher.[33]

[f] Restraint devices should meet applicable crash-testing standards as they are developed and published and should appropriately meet individual patient wt, length, and developmental status needs.[34,35]

ambulances is appropriate for the delivery of care and transport of both pediatric and adult patients in their service area. Each agency's physician medical director should have direct involvement in the selection, approval, and deployment of the devices each agency chooses to fulfill both the clinical and regulatory equipment requirements that are germane to their agency.

In continued support of establishing and maintaining a foundation for standards of care, our organizations remain committed to periodic review and revision of this position statement. This latest revision was created on the basis of a structured review of the *National Model EMS Clinical Guidelines Version 2.2* to identify the equipment items necessary to deliver the care defined by those guidelines.[6] In addition, to ensure congruity with national definitions of provider scope of practice, the list is differentiated into BLS and ALS levels of service by using the National Scope of Practice–defined levels of emergency medical responder (EMR) and emergency medical technician (EMT) as BLS and advanced emergency medical technician (AEMT) and paramedic as ALS.[5] Equipment items listed within each category were cross-checked against recommended scopes of practice for each level to ensure they were appropriately dichotomized to BLS or ALS levels of care. Some items may be considered optional at the local level, as determined by agency-defined scope of practice and applicable clinical guidelines.

In addition to the items included in this position statement, our organizations agree that, as modeled in the Iowa Administrative Code, "all EMS service programs shall carry equipment and supplies in quantities as determined by the medical director and appropriate to the agency's level of care and available certified EMS personnel and as established in the agency's approved protocols."[10]

Finally, in addition to taking steps to determine that appropriate equipment is routinely available and that EMS providers are competent in using this equipment, our organizations also recommend that all EMS agencies include in their routine quality assurance practices efforts to evaluate that:

- their EMS providers are outfitted with all of the equipment necessary for them to perform clinical care;
- all equipment and supplies undergo appropriate preventive maintenance and routine function checks; and
- malfunctioning or missing equipment issues are rapidly mitigated to preserve readiness to respond and provide patient care continuously.

LIST OF RECOMMENDED ESSENTIAL EQUIPMENT FOR BLS AND ALS GROUND AMBULANCES, 2020

General Principles:

This document is intended to represent minimum essential

equipment recommendations (Table 1) and should not be used to limit the addition of items to a service's repertoire. Carriage of items that supplement those listed herein should be based on local clinical and operational needs, including the needs of specialty transport teams, and should be left to the discretion of the physician medical director and other agency administrative and operational officers.

1. Equipment should always be appropriate for the size and age of patients. Availability and use of appropriate pediatric-sized equipment is necessary, not discretionary.
    a. Adult-sized items should not be substituted or adapted for use on pediatric patients except in cases in which available pediatric-focused equipment has malfunctioned and in which failure to provide further intervention by adapting an adult device for pediatric use would result in serious harm to the pediatric patient.
2. Several items that were included in previous versions of this list, including items previously listed as "optional," are not included in this revision. Their absence from this list demonstrates lack of sufficient evidence to support inclusion of these items universally for all BLS and/or ALS ground ambulances but should not be interpreted to mean that such items should not be carried on *any* BLS and/or ALS ground ambulance. Local clinical protocols and scope of practice may dictate that such items are prudent and proper to carry.
3. Evidence supporting inclusion of specific items in this recommended equipment list is cited where available.
4. Certain items are included in this list on the basis of sound judgment and logic (eg, "portable reusable light source") rather than on the basis of the presence of supporting evidence.
5. Several items were identified on review of existing state and territory equipment lists or in previous versions of this document that should no longer be carried on ground ambulances because of evidence of harm or proven lack of efficacy. These items have been identified in a section that is new in this revision of this joint position statement.
6. Equipment specifications exist for several items contained in this document. The sources for those specifications are cited.
7. Latex-free items should be used whenever possible and practical.
8. Specific medication recommendations have been removed from this minimum recommended equipment list because of the following:
    a. the diversity of clinical protocols across the United States, even across the same echelons of care, precludes development of an appropriately brief but comprehensive recommended medication list;
    b. the frequency and unpredictable nature of medication shortages requiring frequent and rapid revision to local medication supplies preclude the development of a recommended medication list that would remain germane on a daily basis; and
    c. the variability in the availability and use of therapeutic alternatives across EMS agencies precludes development of an appropriately brief but comprehensive recommended medication list.

School-Based Health Centers and Pediatric Practice

- *Policy Statement*

POLICY STATEMENT Organizational Principles to Guide and Define the Child Health Care System and/or Improve the Health of all Children

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

School-Based Health Centers and Pediatric Practice

Chris Kjolhede, MD, MPH, FAAP,[a] April C. Lee, MD, FAAP,[b] COUNCIL ON SCHOOL HEALTH

School-based health centers (SBHCs) are unique health care settings for our nation's school-aged children and adolescents. SBHCs represent the collaboration between the health and school communities to support the health and mental health needs and the academic achievements of children and adolescents, particularly students with health disparities or poor access to health care. SBHCs improve access to health care services for students by decreasing financial, geographic, age, and cultural barriers. This policy statement provides an overview of SBHCs, including the scope of services as well as some of the documented benefits and challenges. This policy statement also reviews the role of SBHCs in working with the pediatric medical home and provides recommendations that support the coordination of SBHCs with pediatric primary care providers and the pediatric medical home.

BACKGROUND

School-based health centers (SBHCs) are unique health care settings for school-aged children and adolescents that have been proven to improve access to care, improve health outcomes, and reduce health disparities.[1,2] Conveniently located in schools or on school grounds, SBHCs provide primary care services that address the physical and mental health needs of students. SBHCs represent a collaborative commitment with the school community to support the health and academic success of children and adolescents.[3]

Significant growth in the number of SBHCs in the United States over the last 2 decades is evident in the most recent data from the National School-Based Health Care Census report conducted by the School-Based Health Alliance (SBHA) in 2016–2017.[4] According to that report, there are 2584 SBHCs that serve students and communities in 48 of 50 states and the District of Columbia and Puerto Rico.[4] The number of SBHCs has more than doubled since 1998.[4] Currently, 46% of SBHCs are in urban communities, 36% are in rural areas, and 18% are in suburban

communities.[4] The growth of SBHCs in rural and suburban areas has outpaced that in urban settings since 2008.[4] According to the 2016–2017 SBHA census report, 17% of SBHCs are located in high schools, 40% are located in elementary schools, 13% are located in middle schools, and 30% are located in schools with unique grade combinations, such as kindergarten through grade 12.[4]

SBHCs were developed as the scope of school health expanded. The Robert Wood Johnson Foundation, instrumental in the promotion of the SBHC model, continues its support today by funding the Center for Health and Health Care in Schools.[5,6] Recognizing that healthier students made better learners, pediatric and nursing health professionals initially pioneered school health services in an effort to address the unmet health care needs of schoolchildren.[7,8] As the scope of school health services expanded, schools began to provide several critical health services, including triage and management of medical emergencies; medication delivery; services for youth with special health care needs; referral for common health problems, such as injury, asthma, and mental and emotional difficulties; and health screenings.[3,9–11] SBHCs provide a "health care 'safety net' for children and adolescents who are uninsured or underinsured or represent special populations who do not regularly access health care."[3]

As SBHCs have evolved over time, the recommendations for best practices for SBHCs have also evolved. Guidelines include community needs assessment, coordination of care with the medical community, and measurement of performance indicators reflecting the effect of SBHC services on students' health and academic outcomes.[12–15]

According to the SBHA, the 7 core competencies of SBHCs are[16] as follows:

- access: the SBHC ensures students' access to health care and support services to help them thrive; SBHCs are located in schools or on school grounds and work within the school to become a part of the school;
- student focus: the SBHC team and services are organized around health issues that affect student well-being and academic success;
- school integration: the SBHC integrates the education and environment to support the school's mission of student success;
- accountability: the SBHC routinely evaluates its performance against accepted standards of quality to achieve optimal outcomes for students;
- school wellness: the SBHC promotes a culture of health across the entire school community;
- systems coordination: the SBHC coordinates across relevant systems of care that share in the well-being of its patients; and
- sustainability: the SBHC employs sound management practices to ensure a sustainable business.

ROLE OF THE S HC IN INCREASIN ACCESS TO HEALTH CARE

SBHCs serve a critical role in increasing access to quality comprehensive and coordinated primary care for children and adolescents, especially underserved, at-risk, and stressed children and adolescents.[1,2] SBHCs are health care centers for students in prekindergarten through 12th grade and are ideally located on-site in the school, thereby decreasing geographic or transportation barriers to health care.[1,2] Recently, the number of SBHCs has increased in rural areas.[4] Demonstrated to be effective in the higher-density urban community, SBHCs in rural areas face challenges because of the low population density.[17] However, for some rural communities with limited or no medical providers, SBHCs can potentially increase access to medical services for students.

SBHCs also increase access to care by addressing financial barriers.[3,17] For uninsured and underinsured students, SBHC services are available at minimal out-of-pocket cost. SBHCs help enroll these eligible students in much needed health insurance, such as Medicaid or the Children's Health Insurance Program.[3] Because SBHCs are generally located in low-income urban areas and in communities with a high proportion of historically disadvantaged populations, this source of student health care and health education may be an effective means of advancing health equity.[1,2]

SBHCs increase adolescent use of health care. Many teenagers, especially male teenagers, are reluctant to seek health care in a traditional medical setting because of cost, confidentiality concerns, and parental involvement.[18–20] By providing convenient and confidential care in a familiar setting with supportive staff, SBHCs reduce barriers to care for adolescents, particularly in the areas of sexual and reproductive health, substance use, and mental health issues.[21–26] In one study by Stone et al[27] in the San Francisco school district, SBHC users reported a caring relationship with program staff. In another study by Allison et al[28] in the Denver Public Schools area, adolescent SBHC users were more likely to have received a health maintenance visit, more likely to have received vaccines, and less likely to have used emergency care than other users. SBHC users were also less

likely than other users to be insured.[28]

SBHCs increase access to care, which is beneficial to all stakeholders. Parents and caregivers benefit with the knowledge that their child can receive health care without leaving school and that this care is covered at no or low cost. School leaders and the school community benefit because the students' health care needs are addressed on-site and there is a reduction in missed class time and absenteeism.[29,30] Employers of parents and caregivers appreciate that there are reduced employee productivity losses because of missed work time to care for sick children or transport them to medical settings.[29] SBHCs help students with special acute and chronic medical and mental health concerns, with the goal to improve their ability to academically succeed in the classroom.[31,32] SBHCs can partner with schools to improve academic outcomes by potentially reducing absenteeism and suspension with the provision of mental health and substance use services. In one urban school district study, the use of SBHCs for medical concerns was associated with an increase in attendance and the use of SBHCs for mental health concerns was associated with an increase in grade point average.[31]

SE ICES O IDED Y S HCS

The range of services provided by SBHCs is dependent on the sponsors' resources as well as the needs of the community. At the minimum, SBHCs provide health care services, which may include health maintenance supervision or well-child care, immunizations, and/or laboratory services. Some SBHCs may provide a wider range of preventive and psychosocial services, including hearing and vision screening, vision services (eg, provision of corrective lenses), reproductive health services, mental health services, social services, health education, and oral health services. Mental health services may include screening, counseling, and substance use disorder services.

Three staffing models exist in SBHCs.[3,29,33] In one model, a single clinician, such as a nurse practitioner or a physician assistant, may provide primary care services. Another staffing model includes staff who provide primary care and mental health services. Finally, a third staffing model provides medical and mental health with expanded services that involve an interdisciplinary team of social workers, health educators, and dental providers. All these SBHC models can provide age-specific and age-sensitive specialized health care for students. Sponsors independent of the school system, such as federally qualified health centers, hospitals, academic medical institutions, medical centers, or departments of health, also provide these services.[29]

Services are usually available during school hours. The majority of SBHCs (75%) are open and provide services during all regular school hours.[4] Enrollment in the SBHC generally requires parental permission.[1,29,32] Additional permission typically would be necessary for the treatment of specific conditions. The child may be able to consent for certain types of health care services, such as reproductive health, as provided by state law. Limited consents for specific types of health care services, such as reproductive health care, may be available to individual students only, again, as regulated by state and local guidelines.[1,32]

Sixty-five percent of all SBHCs provide primary care and mental health services.[4] The percentage of all SBHC sites that report expanded services is 41%.[4] Expanded services may include health education, nutritional counseling, reproductive health, and oral health.[4] Expanded specialized programs may be directed toward prevention or treatment of a specific medical condition, such as asthma or obesity, or a social determinant of health, such as food insecurity or discrimination. Expanded mental health services may include specific areas of need, such as substance use disorder treatment and comanagement with the medical provider for co-occurring medical disorders.

SBHCs serve to increase school connectedness, the concept that students believe the adults and peers in their school care about them as individuals as well as about their learning.[34,35] The staff of the SBHC serves as a resource to the entire school community and often coordinates school health services as well as assists school wellness promotion efforts. By implementing the recommendations of *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents* into clinical practice for health examinations, SBHCs are better able to address the main components of health supervision (disease detection, disease prevention, health promotion, and anticipatory guidance) with the entire school community.[3,36] With this level of involvement, SBHCs also promote the principles of the Whole School, Whole Child, Whole Community model. The Whole School, Whole Child, Whole Community model has 10 components, including health education; physical education and physical activity; nutrition environment services; health services; counseling, psychological, and social services; social and emotional climate; physical environment; employee wellness;

family engagement; and community involvement. It is a coordinated school health program designed to address the health and education needs of the whole child and to promote and support healthy lifestyles for the students, teachers, staff, and community.[37–38]

EFFECTIVENESS OF SBHCS IN IMPROVING OUTCOMES

The effectiveness of SBHCs in improving health outcomes and reducing health disparities has clearly been demonstrated in the literature. Studies have demonstrated improved health outcomes with specific medical conditions and increasing access to mental health services. The literature has shown that SBHCs reduce health disparities by providing services to students from diverse racial and socioeconomic backgrounds, particularly the underinsured or uninsured child.[2,39] The Community Preventive Services Task Force, established by the US Department of Health and Human Services to identify population health interventions scientifically proven to improve the quality of life, recommends the implementation and maintenance of SBHCs in low-income communities on the basis of a systematic review of the impact of SBHCs on educational and health outcomes.[17,40]

Preventive Health Care

Studies have shown that SBHCs increase use of preventive health services. In a study comparing access and quality of health services among students attending an urban high school with an SBHC compared with students attending a high school without an SBHC, students with access to the SBHC were more likely to report having a regular health care provider, awareness of confidential services, support for health services in their school, and willingness to use those services. Users of the SBHC reported higher quality of care compared with nonusers or students in the comparison school. The presence of comprehensive health services via the SBHC led to improved access to health care and improved quality of care.[41] In another study demonstrating improved prevention services, recalling students for SBHC appointments was effective in improving immunization rates for all vaccines recommended for adolescents.[42]

Reproductive Health

The literature supports the concept that SBHCs improve access to reproductive health services and remain an important component in adolescent pregnancy prevention. A study by Minguez et al[43] demonstrated that students with access to comprehensive reproductive health services via an SBHC reported greater exposure to reproductive health education and counseling and greater use of hormonal contraception. In another study, sexually active female students received specific reproductive health care and were more likely to have used a hormonal contraceptive method if their school had an SBHC.[44] In a study comparing an SBHC that dispensed hormonal contraceptive on-site with an SBHC that referred students to an off-campus family planning clinic, the on-site SBHC dispensing hormonal contraception was associated with a lower pregnancy rate than the SBHC referring female students for hormonal contraception.[45] The availability and provision of emergency contraception in an SBHC also improves access to reproductive health services.[43–47] Provision of reproductive health services in SBHCs remains a subject of controversy in some communities. However, in one study of stakeholders, there was strong support for the inclusion of reproductive health services in SBHCs.[48]

Mental Health

Literature shows that schools are ideal settings for mental health intervention. School-based mental health interventions, including the area of substance use services, offer an opportunity to reach the greatest number of affected youth who otherwise may not receive behavioral health care.[49] A study in California comparing the mental health risk profile and health use of SBHC users and nonusers demonstrated that SBHCs play a role in identifying and addressing mental health concerns that might otherwise go unmet, especially among adolescents with public or no insurance.[50] Studies have shown that SBHCs may be important sites to address bullying, violence, and suicide prevention[51–53] and to promote mental health and overall wellness.[54] One study in Oregon schools with SBHCs showed that an increase in mental health services availability was associated with relative reductions in reported depressive episodes and suicidal ideation among adolescent students.[53]

Chronic Conditions Such as Asthma and Obesity

Literature demonstrates that SBHCs are a setting for innovative asthma quality improvement initiatives, demonstrating reduction in activity restriction attributable to asthma and a significant reduction in emergency department visits for asthma.[15] SBHCs are also ideal settings to address obesity and to initiate a weight management intervention because they are on-site and able to address and engage the student community.[55–58]

School Performance

Academic benefits include improved school performance, grade promotion, and high school completion.[2,59,60] In a study by Kerns et al,[31] SBHC use was associated with a reduction in the drop-out rate in a large urban school district, especially by students believed to be at high risk for dropping out of school. By reducing barriers to health care, SBHCs reduce school absenteeism and time missed from school.[30,32] SBHCs help to identify and support any social or emotional sources of stress that interfere with students' academic achievement.[32]

SBHCS AND THE MEDICAL HOME AND THE ROLE OF THE PEDIATRICIAN

SBHCs support the principles of the medical home model, as defined by the American Academy of Pediatrics,[61] which refers to delivery of medical care that should be accessible, continuous, comprehensive, family centered, coordinated, compassionate, and culturally effective.[32,62] In one study conducted in a large low-income urban population, SBHCs met the criteria of the medical home from adolescents' and parents' perspectives.[63] For students who do not have access to a medical home and do not have the involvement of a community pediatrician, SBHCs may indeed become the primary source of health care for youth. In other cases, the SBHC can assist in linking the student and his or her family to a medical home. For students who do have access to a medical home, pediatricians and SBHCs may collaborate and coordinate care to promote linkages so that services are provided when school is not in session and to avoid duplication or fragmentation of care.[3]

In the implementation and planning phase of an SBHC, the SBHC may conduct school community needs assessments and collaborate with a health care sponsor to address the community's documented needs and avoid duplication and fragmentation of care.[3] Sponsors have included community pediatricians who provide care to underserved children in their communities by establishing SBHCs as satellites of their practices with financial support from grants and contracts. Pediatricians, as sponsors, may partner with a school to establish the SBHC as an extension of their pediatric medical home by the provision of direct patient care or by the supervision of health care. This partnership is beneficial to the SBHC because the pediatric practice provides a continuum of access to care, especially after school hours. Using SBHCs as an extension of their pediatric practices, pediatricians can assist as the connection between the SBHC and the community.[29] Sponsors also include local hospitals that can provide prearranged after-hours and school vacation coverage and financial support for SBHCs. This arrangement can be beneficial to local hospitals because services provided in SBHCs can reduce hospital costs by preventing unnecessary emergency or urgent care visits and hospitalizations as well as by enrolling students in public forms of health insurance. As the concept of the medical home matures, the role of SBHCs can also evolve into this model as a collaborating partner or possibly as a medical home.[64] SBHC sponsors may consider engaging in a regional or formal national patient-centered medical home (PCMH) recognition process. From 2017 to 2019, the National Committee for Quality Assurance had offered a PCMH recognition process specifically for SBHCs.[65,66] During this time, SBHC sponsors were able to engage in a national PCMH recognition process. One report noted that of 1212 SBHCs reporting to the 2013–2014 National SBHA Census, 143 (12%) achieved state or regional PCMH accreditation and 203 (17%) received national PCMH accreditation from the National Committee for Quality Assurance, the Accreditation Association of Ambulatory Health Care, or The Joint Commision.[67] In another study, SBHCs were measured for PCMH attributes and were found to be doing well with implementing certain elements of the PCMH model, specifically care management, access, and quality dimensions.[68] Limited financial resources in SBHCs make applying for PCMH status a difficult prospect and may explain why more SBHCs do not apply.[68]

The involvement of community pediatric primary care providers in school health, especially in SBHCs, can be beneficial to both the school community and the medical community. Pediatricians may benefit from the collaboration with school leaders so that they may better understand their patient in the context of a school setting and may better provide health recommendations that can be adopted feasibly in the patient's natural settings, including schools. Pediatricians can provide the guidance and oversight needed in school health services and school wellness promotion efforts. The role of the pediatrician can include serving on state and district school boards, participating in local school health advisory councils, and providing direct clinical services as the school physician or through SBHCs. Pediatricians can collaborate with the advanced practice clinicians who typically staff the SBHCs and can work with SBHCs to improve communication with the primary care medical community. Pediatricians can

also provide the expertise needed to assist SBHCs in care coordination.[3,69]

OPPORTUNITIES

There are numerous opportunities in the field of school health and SBHCs. SBHCs serve as a unique educational training setting for learners such as residents and medical students.[29] It has been shown in the literature that when residents and medical students are exposed to school health during residency, there is an increased likelihood that they will be more aware of and become more involved in school health later in their practice.[70,71]

On the basis of the current SBHA census, the number of SBHCs using electronic health records (EHRs) is growing.[4] Use of an EHR will bring new opportunities (as well as challenges) and could be particularly helpful in implementing the medical home model. The use of an EHR can potentially improve accessibility and coordination of medical records outside of SBHC hours of operation. EHRs have the potential for linking SBHCs and the patients who use them to community pediatricians, to other health systems, to health information exchanges, and to other primary care providers.[33]

The expansion of telehealth technology services can help to address the geographic barriers that have limited the growth of SBHCs in rural communities. One-fifth of all SBHCs have at least one provider available through telehealth services.[4] The percentage of telehealth-exclusive SBHCs, defined as no primary care provider physically on-site, increased from 1% in 2013–2014 to 12% in 2016–2017.[4] SBHCs using telehealth technology are increasing the variety of services they provide, including mental health, nutrition services, and access to pediatric subspecialists.[64] For telehealth technology services to be effective, the telehealth presenter should be someone trained in equipment use and the regulations of the Health Insurance Portability and Accountability Act (HIPAA). The telehealth services should be affiliated with a health system, such as a pediatric office, an academic institution, or a hospital, that can provide standards and guidelines for use and expanded health services for students. The increased use of telehealth technology services remains a great opportunity for SBHCs.[64]

SBHC services complement and extend the work of the school nurses, who are responsible for the entire population of students. SBHCs provide a referral site for students without another medical home. Some SBHCs may provide primary nursing services, and other SBHCs may be integrated with school nursing services.[72] As articulated in the Whole School, Whole Child, Whole Community model, these alliances are crucial to the provision of a wide range of student health services.

CHALLENGES

There are multiple challenges facing SBHCs. One major challenge in any school health program, including SBHCs, involves the concept that health and education systems do not always share the same priorities.[3] There is a logical interface between health and education. Children cannot learn if they are not healthy, not present to receive instruction, and not connected to the school socially and emotionally. SBHC providers and community pediatricians can bring together the health and education sponsors with a common goal of better outcomes for children.[3,23,73,74]

Pediatricians dedicated to initiating a new SBHC may find barriers related to the time commitment involved in engaging appropriate stakeholders, conducting needs assessments, developing the business and/or financial plan, and identifying funding sources. Existing school health advisory councils within the majority of schools or districts can assist in these activities and reduce the burden.[3,13,73,75] Additionally, the SBHA has been a resource to pediatricians and an advocate for the implementation and ongoing operation of SBHCs.[76]

To support the medical home model, communication among the stakeholders (school, SBHCs, and community primary care providers) needs to occur from the planning stages to the operational stages.[3,12,77] Lines of communication between the SBHC and community primary care providers need to be established to discuss shared patients. Communication is equally important when an SBHC closes. To protect the students it serves, an SBHC should have a communication process to ensure continuity of care and transfer of medical records.

There is a wide range of medical and mental health services that can potentially be provided to students in an SBHC. For some SBHCs, the provision of specific health services has been restricted. Some SBHCs are prohibited from dispensing contraception.[3]

There is significant evidence in the literature that SBHCs reduce the cost to the health system by decreasing use of the emergency department and can decrease hospitalizations, reduce absenteeism, and reduce parental productivity losses.[1,2] In an economic evaluation conducted by the Community Preventive Services Task Force of the US Department of Health and Human Services, the

economic benefit of SBHCs exceeded the intervention operating cost. SBHCs have been shown to result in a net savings to Medicaid because of a reduction in emergency department use for services provided to youth with asthma.[2] Despite this economic benefit, the development of a financially sustainable business model remains an ongoing challenge for SBHCs. SBHCs generally require multiple funding sources to remain financially solvent.[4,76] Most SBHCs serve uninsured or underinsured patients, who may additionally require case management or social support that may be inadequately reimbursed by insurance.[4] With potential changes in the Patient Protection and Affordable Care Act, additional start-up and ongoing funding in addition to insurance billing and reimbursement is necessary.[3,13,76]

Confidentiality is another continuous challenge to the provision of services in an SBHC. Privacy concerns can be a barrier to communication and access to health care. Confidentiality for adolescents and health information access and transfer are challenges regulated by HIPAA and the Family Educational Rights and Privacy Act (FERPA). Since 2008, the US Department of Education and the US Department of Health and Human Services have provided guidance in the implementation of HIPAA and FERPA privacy laws.[78] As the use of EHRs and other clinical applications increase in SBHCs, HIPAA and FERPA privacy laws introduce complexity as the need to safeguard protected health information is balanced with the need to increase access to care and increase communication. The SBHA and American School Health Association have developed guidelines and recommendations in the area of confidentiality.[3,16,33,79]

RECOMMENDATIONS

To achieve the best health and educational outcomes for school-aged children and adolescents, pediatricians remain a key role in SBHCs in the following areas:

1. Medical home model: Pediatricians involved with the development and management of SBHCs should recommend care coordination practices that promote patient access to a medical home, with attention to communication between health care providers across settings. Pediatricians should share their expertise to assist not already PCMH-accredited SBHCs to adopt practice changes in support of the medical home model.
2. Coordination of care: SBHCs and community primary care providers should be in communication to facilitate coordination of care and to avoid duplication and fragmentation of care. Use of an EHR-compatible form or a paper form, such as the American Academy of Pediatrics emergency information form for children with special health care needs,[80] should be used, with the goal of strengthening communication. Communication between the community-based pediatric practices and the SBHC is essential in the provision of high-quality, safe, and effective health care, especially in the areas of urgent care and referrals.
3. Clinical services: Pediatricians can support SBHCs and community schools by increased involvement, including providing clinical services, supervising trainees, serving as the SBHC's consultant or medical director, or serving as an SBHC sponsor.
4. School health advisory councils: Pediatricians can advocate for the development of school health advisory councils or participate on established school health advisory councils. These school health advisory councils provide a setting for analyzing and discussing newly emerging trends in health and social behavior and community conditions that might influence student health and academic success and for planning, developing, and monitoring school health services, including SBHCs. Pediatricians remain an essential voice in these school health advisory councils to advocate for best outcomes for the children and adolescents in their community.
5. Funding: With limited financial resources, SBHCs help address the health inequities of underinsured and uninsured children and adolescents. Pediatricians have a unique voice and perspective to advocate for funding for SBHCs from national, state, and local entities so that SBHCs may continue to reduce health inequities and expand services in support of the medical home model.
6. Advocacy: Pediatricians have a responsibility to advocate for programs that reduce health disparities and advance health equities for children and adolescents. Because SBHCs help pediatricians address health inequities attributable to poverty and racial and/or ethnic bias in their local communities, it is important for pediatricians to advocate for legislation that supports SBHCs to maintain them and keep them operational.

There are multiple conditions that can make children prone to having a sudden cardiac arrest (SCA) or sudden cardiac death (SCD). Efforts have been made by multiple organizations to screen children for cardiac conditions, but the emphasis has been on screening before athletic competition. This article is an update of the previous American Academy of Pediatrics policy statement of 2012 that addresses prevention of SCA and SCD. This update includes a comprehensive review of conditions that should prompt more attention and cardiology evaluation. The role of the primary care provider is of paramount importance in the evaluation of children, particularly as they enter middle school or junior high. There is discussion about whether screening should find any cardiac condition or just those that are associated with SCA and SCD. This update reviews the 4 main screening questions that are recommended, not just for athletes, but for all children. There is also discussion about how to handle post-SCA and SCD situations as well as discussion about genetic testing. It is the goal of this policy statement update to provide the primary care provider more assistance in how to screen for life-threatening conditions, regardless of athletic status.

INTRODUCTION

There is a growing movement to identify pediatric and young adult athletes who may be at risk for sudden cardiac arrest (SCA) or sudden cardiac death (SCD) during sports participation.[1–5] The sudden death of a young athlete is always tragic for the family and community. However, the sudden death of a young nonathlete is no less tragic. In today's society, the nonathlete is much less visible because of the great attention paid to athletics in the lay press, which creates the perception that only athletes have an increased risk of sudden cardiac events. SCA and SCD in young people have been addressed in several articles that have focused efforts toward disease recognition as well as

prevention.[6–11] There have been numerous studies addressing preparticipation screening, including whether electrocardiography (ECG) or other noninvasive tests should be added.[2–4,12,13] Currently, several groups are studying the question of the use of preparticipation ECG; to date, none have published conclusive data on its overall effectiveness, practicality of implementation, or cost.[14]

One of the most important people in both primary and secondary prevention models is the primary care provider (PCP), who manages children from infancy into late teenage years or even young adulthood and has a long-standing relationship with the child, family, and community at large. PCPs are involved with school preparticipation screening and are often the first called when a cardiac symptom or cardiac arrest occurs.

The purpose of this article is to provide PCPs with a strategy for screening, evaluation, and management of risk of SCA and SCD in the young with practical and updated information.

As in the 2012 policy statement, "evidence-based recommendations frequently are designated as class I, II, or III, indicating the supporting level of evidence. For pediatric SCA, the level of evidence does not permit a meaningful use of this terminology."[8]

STRATEGY FOR SUDDEN DEATH PREVENTION

This policy statement proposes that the same screening detail that is used for athletes should also be applied to the nonathlete.

Figure 1 demonstrates an encounter of a pediatric patient with the PCP for a routine visit or for new, concerning symptoms.

The PCP encounter should ultimately separate patients into 2 basic groups, those with identifiable or suspicious risk factors for SCA or SCD, to be discussed in a later section, and those without risk factors. For those with risk factors, referral to a pediatric cardiologist or electrophysiologist is the next appropriate step to initiate a comprehensive cardiovascular evaluation appropriate for the presenting risk factors. There are patients who, despite the best screening efforts, could still experience a SCA; therefore, a secondary prevention plan is important.

Multiple studies have led to current resuscitation methods, such as the American Heart Association (AHA)'s Basic Life Support, Pediatric Advanced Life Support, and Advanced Cardiac Life Support, featuring the "chain of survival," with revisions made every few years.[15] Although out-of-hospital cardiac arrest survival statistics remain dismal, there has been improvement in survival, most likely a result of an increase in lay rescuer cardiopulmonary resuscitation (CPR) education, an increase in recognition of cardiac arrest, and an increase in willingness to intervene by lay rescuers who have learned to perform high-quality CPR and automated external defibrillator (AED) use, assisted by an increase in public access to AEDs.[16] The number of lay people with life support training generally remains low.[17] This highlights the important role for the PCP to be a community advocate for more Basic Life Support training.

THE PCP'S ROLE IN PRIMARY PREVENTION

The difficult task of identifying those at risk for cardiac events often begins with the PCP, including physicians, physician assistants, and nurse practitioners, via routine physical examination or when addressing specific symptoms. Although there is no one-size-fits-all screening method to identify those at risk, it is helpful for the PCP to have an understanding of the common conditions that put young patients at risk for SCA and SCD.

Cardiomyopathies

A primary cardiomyopathy is usually associated with an anatomically normal heart with abnormal myocardial cellular structure or function that can affect both systolic and/or diastolic function. The World Health Organization and International Society and Federation of Cardiology Task Force recognize 5 basic forms of cardiomyopathy[18]:

1. Dilated cardiomyopathy: enlarged, dilated left and/or right ventricle with or without decreased systolic function.
2. Hypertrophic cardiomyopathy (HCM): abnormally thickened ventricular myocardium without cause (eg, hypertension, coarctation, aortic stenosis, etc). HCM is reported as the most common cause of SCA and SCD in young athletes.[19]
3. Restrictive cardiomyopathy: normal to thickened ventricular walls and normal ventricular size with impaired diastolic function and often with dilated atria.
4. Arrhythmogenic cardiomyopathy (includes arrhythmogenic right ventricular cardiomyopathy [ACM]): enlarged, dilated right ventricle with orwithout decreased systolic function often associated with frequent arrhythmias (can be seen in the leftventricle as well).
5. Unclassified cardiomyopathies: this includes left ventricular noncompaction (the left ventricular myocardium is abnormal with hypertrabeculation and crypt

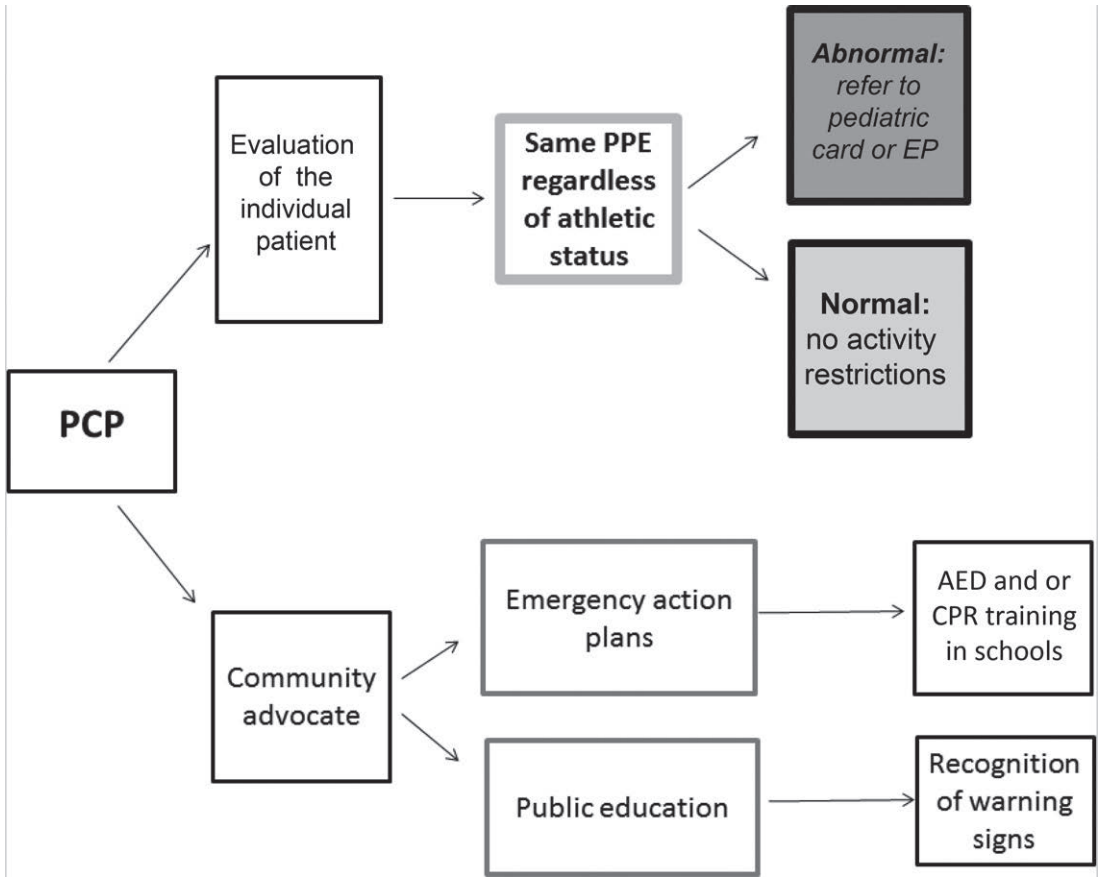

FIGURE 1 Flowchart revealing ideal role of the PCP in prevention of SCD in the young. EP, electrophysiologist.

formation of the left ventricular wall with thickened, normal, or thinned and dilated myocardium with or without impaired systolic function).

The clinical features of each type of cardiomyopathy are displayed in Table 1. Morphologic differences are significant between each type of cardiomyopathy, and, therefore, imaging (echocardiography, MRI, etc) is advised. The potential for life-threatening arrhythmias is a unifying factor for all these cardiomyopathies.

Channelopathies

Channelopathies are generally identified in patients who otherwise have normal cardiac anatomy and function. The defect involves the ion channels in the cardiac cell membrane or in intracellular proteins that interact with ion transport and may result in identifiable abnormalities on the ECG. Imaging is not helpful in diagnosing a channelopathy except to exclude cardiomyopathy as an etiology for a cardiac event. The primary channelopathies include the following:

1. Long QT syndrome (LQTS): prolongation of the corrected QT interval (QTc) with abnormalities in T-wave morphology, some of which are associated with specific genotypes. Sudden infant death syndrome (SIDS) may be attributable to LQTS in approximately 10% of cases.[20]
2. Short QT syndrome: extremely rare condition with abnormal shortening of the QTc with prominent and peaked T waves.
3. Brugada syndrome (BrS): associated with a coved and elevated ST elevation in ECG leads V1 and V2. Specific Brugada T-wave morphologies may indicate an elevated risk of cardiac arrest.
4. Catecholaminergic polymorphic ventricular tachycardia (CPVT): resting ECGs in these patients are almost always normal. CPVT is mostly identified with exercise testing that results in increased ventricular ectopy and even polymorphic ventricular tachycardia (VT).
5. Idiopathic ventricular fibrillation (IVF): patients presenting with ventricular fibrillation (VF) in whom known cardiac, respiratory, metabolic, and toxicological

TABLE 1 Listing of the 5 Classification Groups and Clinical Features of Cardiomyopathies According to the World Health Organization

Cardiomyopathy Class	Age at Presentation	Presentation	Family History	Genetic Inheritance	ECG	Echocardiogram Findings	MRI Findings	Making the Diagnosis	Risk for SCA or SCD
DCM	Any age, including fetal	Can be incidental finding; heart failure; poor cardiac output; failure to thrive; arrhythmias; LMNA mutation-associated DCM can also present with conduction disease.[67]	Inherited DCM can exist in ~50% of those presenting before 18 y of age.[67]	For most familial DCM, inheritance is AD, but X-linked inheritance is also common.[67] LMNA-positive patients have autosomal dominant inheritance. Pediatric patients have a higher incidence of mitochondrial or metabolic-based DCM that are autosomal recessive.	Can be normal; AV block; BBB; atrial or ventricular ectopy; low-voltage QRS.	Dilated LV with mildly to severely reduced function: mitral regurgitation.	Consistent with echocardiogram findings.	Clinical symptoms and/or echocardiogram findings of LV dilation with reduced function; genetic testing is helpful when the family history suggests familial DCM.	Variable depending on genetic mutation (higher with LMNA mutation), degree of myocardial involvement, and presence of arrhythmias; lower incidence of SCD than other cardiomyopathy forms[68]: higher risk with poorer LV function.
HCM	Any age, including fetal	Incidental; heart murmur; anginal chest pain; cardiac arrest.	Often others in family have known HCM or will subsequently be found to have HCM.	For all sarcomeric forms of HCM, inheritance is AD; Danon syndrome (storage disease phenocopy) is X linked.	Can be normal; usually has LVH and/or RVH, sometimes with very large R or S waves; LAD: ventricular arrhythmias.	LV wall thickness >14 mm or 2 SDs for wt; reduced LV cavity size; longer-than-normal anterior mitral valve leaflet; abnormal papillary muscles; resting and/or dynamic LVOT obstruction; MR.	Consistent with echocardiogram findings but can reveal mitral valve morphology more precisely and can be used for detecting late gadolinium enhancement that is associated with ventricular arrhythmias.[69–72]	Echocardiogram and/or MRI findings consistent with HCM; genetics are helpful to identify sarcomeric from other forms including storage disease; can help with prognosis and can help with identification of family members.	In adults, risk is based on established risk factors, including previous SCA, LV thickness ≥30 mm, abnormal BP response to exercise; family history of SCA; LGE >15%; VT on Holter. In children, risk factors include those presenting in infancy or with inborn errors of metabolism[73]; restrictive physiology increases risk of death or transplant; increased LV thickness and LGE correlates with VT.[71]
RCM	Any age	Heart failure; poor cardiac output; fatigue.	Less than half have family history, although there can be some crossover with family members with HCM.	Shares some similar gene mutations as HCM; inheritance is AD.	Can have findings similar to HCM but may be normal as well.	Normal ventricular systolic function with dilated atrial; some hypertrophy may be present.	Evidence of diastolic dysfunction.	Echo criteria indicating abnormal diastolic function along with symptoms of heart failure; some HCM patients have RCM features. Genetic testing can be supportive. Several HCM gene mutations can be seen with RCM.	Significant with generally poor prognosis; two-year survival of <50%.[74]

TABLE 1 Continued

Cardiomyopathy Class	Age at Presentation	Presentation	Family History	Genetic Inheritance	ECG	Echocardiogram Findings	MRI Findings	Making the Diagnosis	Risk for SCA or SCD
ACM	Preadolescence[75]	Incidental; syncope, palpitations, SCA.	Possible to have other family members with the same diagnosis.	Nearly all are AD.	Inverted T waves in the right precordial leads beyond V1; ε waves; LBBB PVCs or VT; Prolonged S waves in V1-V3.	Often normal but may reveal dilated RV, abnormal aneurysmal areas of RV; MRI often reveals more detail.	Fibrofatty replacement of ventricular myocardium; aneurysmal areas of free wall; possible LV involvement.	Needs to meet specific diagnostic criteria per ACM task force[76]; MRI alone will not satisfy task force criteria; genetic testing is helpful when positive.	Significant, even in children; disease is progressive and VT from multiple foci can develop.
LV Noncompaction (LVNC)	Any age including fetal	Incidental; murmur on examination; heart failure; SCA.	Present in 30% of first-degree relatives of index cases.[77]	For identified gene mutations inheritance is autosomal dominant; yield on genetic testing is currently low.	Usually abnormal with LVH, T-wave abnormalities, QT prolongation, or preexcitation[77]; arrhythmias more common with decreased LV function.	Key finding is the spongy appearance of highly trabeculated myocardium with crypts in between trabeculae[78]; LV dimensions and function can be assessed as well as valve function; identification of thrombi in LV; multiple forms described.[78]	Consistent with echo findings, the noncompaction-to-compaction ratio of the LV myocardium should be ≥2.3:1; LV function can be assessed.[79]	Fulfillment of echo and/or MRI criteria; genetic testing when results are positive is helpful but negative-result genetic testing does not diminish diagnosis from task force criteria.	In part dependent on LV function but SD has been reported with normal LV function.[80,81]
Normal variant: Athlete's heart	Teenage and up; has been reported in preadolescent age as well[82]	During screening evaluation or for evaluation of potential cardiac symptoms.	None.	None.	Some benign ECG changes can be seen. Criteria have been modified for use in the athlete. Changes can include sinus brady, first-degree AV block, early repolarization, isolated voltage criteria for LVH, LAE, RAE, LAD, RAD.[83]	LV cavity dilation, normal diastolic properties, wall thickness up to 14 in male individuals (with rare exception in African Americans); female individuals with athlete's heart never have wall thickness >11 mm; rowing and cycling athletes tend to have thicker LV dimensions.[84]	Similar to echo dimensions with LV dilation and limits on LV wall thickness; will not see late gadolinium enhancement.	ECG and echo criteria have been established to help differentiate HCM from athlete's heart. In borderline cases, a period of 3-6 mo of deconditioning may be needed. Those with athlete's heart will have significant return toward normal dimensions, whereas HCM patients will not.[85]	For true athlete's heart that has excluded HCM, no increased risk above the general population.

AD, autosomal dominant; AV, atrioventricular; BBB, bundle branch block; BP, blood pressure; DCM, dilated cardiomyopathy; RCM, restrictive cardiomyopathy; LAD, left axis deviation; LAE, left atrial enlargement; LBBB, left bundle branch block; LGE, late gadolinium enhancement; LMNA, lamin A/C gene; LVOT, left ventricular outflow tract; LV, left ventricle; LVH, left ventricular hypertrophy; MR, mitral regurgitation; MRI, magnetic resonance imaging; PVC, premature ventricular contraction; RAD, right axis deviation; RAE, right atrial enlargement; RV, right ventricle; RVH, right ventricular hypertrophy.

etiologies have been excluded through clinical evaluation. The term IVF is used when the cardiac arrest remains unexplained despite this investigation.

Table 2 demonstrates the features of the most common channelopathies to help discern the characteristics of each. When LQTS or BrS have been diagnosed or suspected, it is important that any new medications, such as antibiotics, antifungal agents, or stimulants for attention-deficit/hyperactivity disorder be checked for potential contraindications in these disorders (for LQTS, use https://Crediblemeds.org, and for BrS, use www.brugadadrugs.org/avoid/). The PCP should be aware that, for patients with BrS, fever can trigger cardiac events.

Congenital Heart Disease

Patients with congenital heart defects, including those that have been surgically repaired or palliated, are at risk for arrhythmias. Risk factors in this population are often a result of scarring from surgery, ongoing hemodynamic abnormalities, residual lesions, or decreased ventricular function.[21,22] The most common association of SCA and congenital heart disease is VT. However, atrial arrhythmias can also cause SCA or SCD if the tachycardia rate is fast enough and rapid atrioventricular conduction occurs.

Wolff-Parkinson-White Syndrome

Wolff-Parkinson-White syndrome (ventricular preexcitation) on the ECG indicates there is at least 1 accessory pathway that conducts antegrade from atrium to ventricle. These pathways are most commonly noted for causing supraventricular tachycardia. Rarely, atrial fibrillation in the presence of Wolff-Parkinson-White syndrome can result in VF as a result of rapid conduction of atrial impulses down the accessory pathway to the ventricles. Criteria based on adult studies define pathways as high risk depending on how rapidly the pathway can conduct.[23–26]

The previous theory that patients with intermittent preexcitation on ECG would be at low risk for SCA or SCD does not seem to hold true for symptomatic pediatric patients.[27] Consultation with a pediatric electrophysiologist should be considered in all cases of Wolff-Parkinson-White pattern on an ECG, regardless of the presence or absence of symptoms, to aid in risk stratification and potentially consider a curative ablation procedure.

Commotio Cordis

Commotio cordis is the term applied to a sudden impact to the chest that causes VF and results in SCA or SCD without evidence of cardiac damage.[28] Commotio cordis is, perhaps, one of the most concerning of all sudden death conditions because it occurs in children with completely normal hearts from both a structural and molecular or ion channel standpoint. The impact is most often from a blunt object such as a ball, fist, elbow, or helmet.

Baseball is the sport with the highest frequency of commotio cordis events. For primary prevention, there is some evidence that some chest protectors may reduce the incidence of commotio cordis.[29] If no cardiac disease is identified in survivors of commotio cordis after a full cardiac evaluation, they can return to sports participation.[30] Prompt recognition of commotio cordis with initiation of CPR and defibrillation is important for survival, although some commotio cordis victims do not survive despite prompt initiation of resuscitation.

Anomalous Coronary Arteries

In multiple studies of the causes of sudden death, an anomalous coronary artery is second only to HCM.[19] Outside the neonatal period, when anomalous left coronary artery from the pulmonary artery is usually identified, detection of an anomalous coronary artery can be difficult because it is rare and often has no symptoms until presenting with SCA, usually in the teenage years. A high index of suspicion is advised for patients with syncope or atypical chest pain (Table 3). Typical pediatric chest pain most commonly represents musculoskeletal pain. Atypical chest pain is pain that raises alarm for an underlying cardiac cause and is not the usual or typical pain.

Echocardiography can often be used to identify the abnormal origins or course of the proximal coronary arteries, but computed tomography scan, MRI, or coronary angiography may be more definitive. ECG in a neonate with anomalous left coronary artery from the pulmonary artery will usually have deep and wide Q waves in leads I and aVL. For other coronary anomalies, the ECG is typically normal at rest. Treatment is surgical unroofing or reimplantation of the anomalous coronary.

Aortopathies

Patients with aortopathies, such as Marfan syndrome, familial thoracic aortic aneurysm and dissection, bicuspid aortic valve with aortic dilation, Loeys-Dietz syndrome, and Ehler-Danlos syndrome are at increased risk of aortic dilation and dissection. Patients frequently have no symptoms, but often there is a family history of aortic dilation or dissection. Aortic rupture or dissection accounts for 2% of sudden deaths in athletes.[13] There is evidence that isometric exercise, exercise that uses Valsalva maneuver, or sudden increases in blood pressure place an extraordinary wall stress on the aorta

TABLE 2 Listing of Common Channelopathic Conditions and Clinical Features

Channelopathy	Age at Presentation	Presentation	Family History	Genetic Inheritance	ECG or Holter	Echocardiogram Findings	Stress Test Findings	Making the Diagnosis	Risk for SCA or SCD
L TS	Any, including fetal.	Incidental detection on ECG; syncope; atypical seizures; cardiac arrest.	Variable penetrance; first-degree relatives tend to have shorter Tcs and possibly less risk of events.[86]	Mostly autosomal dominant; penetrance is variable.	Prolonged Tc >460–470 in male individuals and >470–480 in female individuals with abnormal T waves; T-wave morphology can be dependent on genotype. Tc can be variable on multiple ECGs in the same patient and may have atrial arrhythmias, including atrial fibrillation.	Normal.	Some differences by genotype; long T 1 shows Tc prolongation with exercise that sustains into recovery, whereas L T2 shows an abnormal shortening at peak exercise, followed by abnormally long Tc in recovery.[87] L TS patients may not always achieve the predicted maximum heart rate.	A single ECG cannot always rule in or out L TS. Often, multiple ECGs or stress testing + or − epinephrine challenge are needed. Holter monitoring is not ideal for diagnosis but can be supportive for obvious Tc prolongation and/or the presence of ventricular ectopy. Sinus brady can also be present.	(1) Related to Tc duration, genotype, past history of symptoms, and sex of the individual, with male individuals at greater risk when young and female individuals at greater risk after teenage years.[88,89]; (2) Risk of positive-genotype patients with normal Tc is significantly lower, but higher than genotype-negative family members.[90] Caution is needed in prescribing medicine that could prolong the Tc; (3) SIDS cases attributable to L TS ∼10 .[20]; (4) Previous syncopal event is associated with increased risk.[91]
Short T syndrome	Rare condition; presents at any age including infancy[91]; most common in adolescence to 30s.[92]	Most common presentation is cardiac arrest or syncope.[92] Significant recurrence rate in those already with SCA or syncope.	Present in 44 of familial kindreds.[92]	Autosomal dominant; penetrance favors male individuals.[92]	Short Tc ≤340 ms with tall peaked T waves or <360 ms with pathogenic mutation, family history of S TS, family history of SD in age ≤40, survival of VT or VF[92]; may	Normal anatomy; decreased LV function reported in S TS patients.[93]	Maximum HR may be less than normal. Tc does not shorten and approaches normal at peak exercise.[91]	Gollob S TS Diagnostic Criteria Score: high probability for score ≥4.[94]	Significant for Gollob score >5. Risk is 2.6-fold greater for Tc <300.[95] Reliability of Gollob score in uestion based

TABLE 2 Continued

Channelopathy	Age at Presentation	Presentation	Family History	Genetic Inheritance	ECG or Holter	Echocardiogram Findings	Stress Test Findings	Making the Diagnosis	Risk for SCA or SCD
		Incidental detection on ECG is common.			have atrial arrhythmias including atrial fibrillation.				on report by Mazzanti.[92]
BrS	Predominance in male individuals; prevalence is high in Southeastern Asia; can be at any age but typically in the 4th or 5th decades.[96]	Cardiac arrest at night is common.[96] Syncope; can be asymptomatic with incidental discovery. Nocturnal agonal respiration; chest discomfort; fever can induce Brugada ECG changes and cardiac arrest.[97,98]	History of SCD in 26% of affected patients with BrS. For asymptomatic patients, a type 1 spontaneous ECG pattern was seen in 19%.[99]	Mostly autosomal dominant penetrance favors male individuals. There are 23 susceptibility genes associated with BrS but genetic testing yield remains low.[100]	ST elevation in V1-V2 classified into classes I, II, or III; may have sinus node dysfunction and atrial arrhythmias.[96]	Normal.	Exercise effects in BrS are uncertain. Stress testing of patients with BrS revealed VT, PVCs, and ST elevation in 57% with 5 revealing BrS ECG pattern.[101]	BrS diagnostic criteria based on ECG ST segment morphology. Drug challenge to induce type 1 pattern.	Risk is highest in those with spontaneous type I BrS pattern on ECG and syncope (10% of patients with BrS).[99,102] Fever increases risk of SCA.[98] Antipyretics are indicated and an important treatment in patients with BrS.
CPVT	Mostly children and adolescents but can be any age.	Often can be delayed because of normal ECG[103]; can present with cardiac arrest as the first symptom in 33% to 38% of patients.[104]	Variable penetrance with 50% of family relatives with the CPVT phenotype.[105] Prediction difficult; medical treatment of asymptomatic gene-positive patients may be recommended.	Autosomal dominant for RYR2 and KCNJ2 mutations (60% and 2%, respectively, of CPVT) and autosomal recessive for CASQ2 (2%).[106,107]	Normal baseline ECG; Holter can reveal ventricular arrhythmias, including bidirectional VT; which may have atrial arrhythmias.[104]	Normal.	Induction of ventricular arrhythmias, including PVCs, ventricular couplets, and/or nonsustained VT in 77%.[108]	Stress testing and Holter monitor will frequently reveal increased ventricular ectopy or even VT with increased sinus rate; the presence of bidirectional VT is consistent with CPVT. Sinus bradycardia can also be present.	Significant; initial presentation is cardiac arrest in 33% to 38% of patients.[104]
IVF	Average age reported as 35-40 y[109] but can occur in younger patients[110] and even infants.[111]	Syncope or cardiac arrest; frequently during athletic activity[112]; may be difficult to differentiate from CPVT.	van der Werf revealed 20 relatives of 83 IVF probands (4.9%) of first-degree relatives of IVF patients died, but only 2 were <50 y old.[113]	Limited data but appears genetic related; RYR2 implicated as autosomal dominant.[112]	Normal.	Normal.	Normal.	Difficult but mostly diagnosis of exclusion after documented VF in absence of other channelopathies in the presence of normal cardiac anatomy and function.	Limited in pediatric age; Stefanelli et al[110] reported 1 in 4 surviving IVF patients with appropriate shocks from an ICD.

HR, heart rate; LQT2, long QT 2; LV, left ventricle; PVC, premature ventricular contraction; SQTS, short QT syndrome.

TABLE 3 List of Symptoms Differentiating Between Typical (Benign) Chest Pain and Atypical Chest Pain

Features of "Typical" Chest Pain	Features of "Atypical" Chest Pain
Sharp	Pressure in sternum or left chest
Focal "it hurts right here!"	May radiate to neck or left arm
Brief	Associated diaphoresis
Changes with position	Associated dyspnea
Right sided (could be on left)	Associated nausea
Changes with breathing	Associated syncope
Tenderness can be elicited with palpation or pressure over the area	Onset with exercise, straining, or stress (unless features of typical chest pain are present)

and should be avoided.[31] Collision sports are to be avoided.

WHAT IS THE GOAL OF CARDIAC SCREENING?

The goals of any screening program need to be clarified as to whether they are expected to identify any heart condition, regardless of how significant, or only target those defects associated with SCA and SCD. A thorough personal history, family history, and physical examination are the cornerstone for screening for all children and youth. The AHA recommends a 14-point history and physical screening for athletic participation commonly known as the preparticipation evaluation (PPE) (Table 4).

A positive response to any of the 14 points may prompt the need for cardiovascular evaluation at the discretion of the PCP. This screening has a tendency to detect cardiac problems regardless of their significance. ECG screening has been shown to detect some cardiac lesions that pose a risk for SCA and SCD as well as others that do not pose a risk of SCA and SCD or require restriction from athletic participation.[32,33] There are still limitations because normal resting ECGs would also fail to detect life-threatening cardiac conditions, such as CPVT.

It Is Recommended That the Focus of Screening Should Be on Sudden Death Prevention and Identification of Those at Risk for SCA and SCD

In a 2012 policy statement, the American Academy of Pediatrics (AAP) recommended 4 questions directed toward SCA and SCD detection for which a positive response suggested an increased risk for SCA and SCD.[8] Similar to the AHA screening question tool, the 4 questions in the AAP policy statement are based on expert opinion. In contrast to the AHA tool, the AAP tool is intended to be used in all children regardless of athletic participation. Modifications have been made to these 4 questions with wording that can be directly applied to a family questionnaire. PCPs, at their discretion, may find a positive response to be a significant cue to perform a cardiovascular evaluation. The fifth edition of the AAP publication *Preparticipation Physical Evaluation* noted the AAP recommends an annual comprehensive health supervision visit from ages 6 to 21 years by physicians, nurse practitioners, or physician assistants with the clinical training outlined by state law. The goal of integrating the PPE into the health care home may be more easily achieved if the PPE portion of the examination is addressed every 2 to 3 years, rather than annually, to allow a different focus for evolving child and adolescent risk at each visit.[34] It is recommended that SCA and SCD screening should be performed for all children (athlete or not) at the same time as the PPE examination or at a minimum of every 3 years or on entry into middle or junior high school and into high school. Depending on family and PCP concerns, more frequent screening may be appropriate. The modified 4 questions, also based on expert opinion, are as follows:

1. Have you ever fainted, passed out, or had an unexplained seizure suddenly and without warning, especially during exercise or in response to sudden loud noises, such as doorbells, alarm clocks, and ringing telephones?
2. Have you ever had exercise-related chest pain or shortness of breath?
3. Has anyone in your immediate family (parents, grandparents, siblings) or other, more distant relatives (aunts, uncles, cousins) died of heart problems or had an unexpected sudden death before age 50? This would include unexpected drownings, unexplained auto crashes in which the relative was driving, or SIDS.
4. Are you related to anyone with HCM or hypertrophic obstructive cardiomyopathy, Marfan syndrome, ACM, LQTS, short QT syndrome, BrS, or CPVT or anyone younger than 50 years with a pacemaker or implantable defibrillator?

What Should Be Done With the Child Who Has a Positive Finding on a Screening Examination or Whose Parents Sought ECG Screening and Were Found to Have an ECG Abnormality?

A positive response from the 4 questions above or an abnormal

TABLE 4 Adapted From the AHA's Recommended 14-point Screen for Cardiovascular Disease

AHA's 14-Point PPE
Personal history
1. Chest pain, discomfort, tightness, or pressure related to exertion
2. Unexplained syncope or near-syncope not felt to be vasovagal or neurocardiogenic in origin
3. Excessive and unexplained dyspnea or fatigue or palpitations associated with exercise
4. Previous recognition of a heart murmur
5. Elevated systemic blood pressure
6. Previous restriction from participation in sports
7. Previous testing for the heart, ordered by a physician
8. Family history of premature death (sudden and unexpected or otherwise) before 50 y of age attributable to heart disease in ≥1 relative
9. Disability from heart disease in close relative <50 y of age
10. Hypertrophic or dilated cardiomyopathy, LQTS, or other ion channelopathies, Marfan syndrome, or clinically significant arrhythmias; specific knowledge of genetic cardiac conditions in family members
Physical Examination
11. Heart murmur, not felt to be innocent
12. Femoral pulses to exclude aortic coarctation
13. Physical stigmata of Marfan syndrome
14. Brachial artery blood pressure (sitting position), preferably taken in both arms

Assessment of the 12-lead electrocardiogram as a screening test for detection of cardiovascular disease in healthy general populations of young people (12–25 years of age): a scientific statement from the American Heart Association and the American College of Cardiology. *J Am Coll Cardiol.* 2014;64(14):1479–1514.

ECG should prompt further investigation that may include referral to a pediatric cardiologist or pediatric electrophysiologist. A pediatric electrophysiologist will have better insight for suspected channelopathies or arrhythmia issues and will recommend studies as needed. Ideally, the child with a positive response to these questions should be held out of athletic participation until the cardiovascular evaluation is complete.

THE PRIMARY CARE PHYSICIAN'S ROLE IN SECONDARY PREVENTION

What to Do When a Child Has a Cardiac Arrest

When a child has a cardiac arrest, secondary prevention efforts, including resuscitation, are required. Prompt recognition of cardiac arrest with high-quality CPR and early defibrillation are the major determinants of survival, with survival decreasing by 10% with every minute delay in CPR and AED administration.[35] The AAP and AHA support efforts to improve survival by early symptom recognition, the use of 911 or emergency medical services (EMS), effective bystander CPR, and deployment and use of AEDs in the community. Bystander CPR improves the response time to defibrillation, can more than double the survival to hospital discharge, and leads to improved neurologic outcome.[36] Unfortunately, only 20% to 30% of people who experience a cardiac arrest outside of the hospital receive bystander CPR or defibrillation, and the CPR performed by bystanders may be suboptimal.[37] Annual rates of CPR training in the United States are low, with only 4% of the US population being trained.[17] CPR and AED training is recommended as a high school graduation requirement. To support this effort, there are school-based CPR training programs available from the World Health Organization and the AHA.[38,39]

Evaluation of the Victim or Survivor of Cardiac Arrest

A comprehensive evaluation of the survivor of cardiac arrest should be undertaken at the direction of a cardiologist with expertise in conditions associated with SCA and SCD.

Important elements in the evaluation of SCA include the following:

1. careful review of the medical history and event, including pre-event symptoms;
2. a multigenerational family history;
3. ECG;
4. exercise stress test (some primary arrhythmias are only seen with or immediately after physical exertion);
5. echocardiography to identify structural defects and abnormal cardiac function; and
6. additional testing as needed, including cardiac MRI, computed tomography, electrophysiology testing, and/or provocative drug testing.

If a clinical phenotype is suspected or proven, targeted genetic testing may be indicated. In the survivor of SCA, genetic testing should be guided by the results of medical evaluation. Results may be used for individual diagnosis, treatment, and screening of at-risk family members for subclinical disease.[40] Genetic testing results should be interpreted in consultation with a physician specializing in inherited arrhythmia conditions, a

physician specializing in genetics, and/or a genetic counselor.

What to Do When a Child Cannot Be Resuscitated

SCD occurs in approximately 2000 patients younger than 25 years (excluding SIDS deaths) every year in the United States.[41] Autopsy studies of young individuals who have suffered SCD have shown that a structural cardiac cause (HCM, congenital heart anomalies, and myocarditis) is present in the majority of the patients; however, the cause remains unexplained in a significant proportion (6% to 40%).[42–45] Unexplained SCD is often attributed to cardiac arrhythmia caused by cardiac ion channel dysfunction, which is undetectable in a conventional autopsy. Diagnostic yield in families is 4 times higher when there is a survivor of SCA compared with those in whom there was an SCD.[46] When SCD occurs, assessment of the cardiac anatomy by a skilled medical examiner at the time of autopsy is important. For individuals who do not survive and have no apparent previously identified cause or diagnosis on conventional autopsy, especially if clinical evidence points toward a diagnosis of LQTS or CPVT, a targeted molecular autopsy is recommended[47] (Table 5). Genetic testing results should be interpreted in consultation with a physician specializing in inherited arrhythmia conditions, a physician specializing in genetics, and/or a genetic counselor.

The etiologies of SIDS are varied, with the majority of cases attributable to noncardiac causes. Therefore, victims of SIDS do not necessarily require a rigorous cardiac genetic evaluation unless the circumstances at the time of death or family history are suggestive of an arrhythmic death.

COMMUNICATION AND BEREAVEMENT

After a cardiac arrest, communication between the health care team and the family can have a significant effect on the grief response. The initial reaction is frequently shock, followed by other emotional reactions, including anger, guilt, depression, rage, apathy, and loneliness.[48] Preparing the family for the process that follows death is important (postmortem examination, referral to the medical examiner or coroner, registering the death).[49] Asking questions and receiving information about the cause of death is important to families.[48] Blaming oneself for not saving the life of the family member is common, and therefore, reassurance is key in alleviating the guilt.[48] Survivors of SCA are at risk for posttraumatic stress disorder.[50] Providing information on bereavement support groups can be helpful. The HeartRescue Project's Life After SCA initiative provides resources to help survivors and their loved ones return to living happy, healthy, and fulfilled lives.[51] Parent Heart Watch is a national group of parents whose children have experienced SCA and can provide unique support to bereaved families.

EVALUATION OF REMAINING FAMILY MEMBERS

Many of the cardiovascular diseases that put young individuals at risk for sudden death have a familial inheritance pattern. Screening relatives provides the opportunity to identify at-risk individuals and initiate management.[40] Importantly, in the absence of a diagnosis in the affected individual, cascade screening of first-degree relatives has improved the diagnostic yield of testing. Detailed cardiovascular evaluation of first-degree SCA and SCD relatives has shown that 22% to 30% of these families had evidence of inherited cardiac disease.[52,53] Steinberg et al reported that 18% of surviving relatives of unexplained SCA and SCD victims reported one or more cardiac symptoms in a first-degree relative of the proband.[52] Consistent with these findings, it has been recommended that first-

TABLE 5 Recommendations From the National Association of Medical Examiners for Autopsy Evaluation of Young Sudden Death Victims

Recommendations From Medical Examiner
1. At a minimum, samples should be saved from individuals aged ≤40 y who die suddenly and unexpectedly and whose deaths remain unexplained at the completion of the autopsy.
2. Circumstances that should be considered suspicious for a possible genetic etiology include, but are not limited to, the following:
a. Drowning, particularly in the case of a sober or experienced swimmer;
b. Single motor auto crashes when no mitigating factors are present (eg, toxicology results negative, favorable road conditions);
c. An unexplained seizure;
d. An unexplained death of an individual with a family history of sudden death or inherited heart disease, such as a cardiomyopathy, thoracic aneurysm, or known genetic cardiac diagnosis;
e. All deaths that are sudden and unexplained for which cause of death is not clear at autopsy.
2 For the purpose of potential genetic testing and/or DNA banking, an appropriate sample is 5–10 mL of blood collected at autopsy or as part of an external examination that is preserved with K2 EDTA (usually a purple top tube).[48]

Adapted from Middleton O, Baxter S, Demo E, et al. National Association of Medical Examiners Position Paper: Retaining Postmortem Samples for Genetic Testing. Acad Forensic Pathol. 2013;3(2):191–194.

degree family members of patients with SCA and SCD be informed of the potentially increased risk. An assessment should be offered at a center with experience in the diagnosis and management of inherited cardiac diseases.[40] The initial battery of tests for first-degree relatives usually includes a visit to a pediatric cardiologist or electrophysiologist, an ECG, an exercise stress test (if old enough to exercise), and an echocardiogram. It is reasonable to order molecular genetic testing from the victim after SCA. If a disease-causing variant is identified in the victim, cascade molecular and clinical screening of family members is indicated.[40] Cascade screening means evaluation beginning with first-degree relatives of the SCA victim. Depending on the results of those screening tests, other family members may need testing as well.

UNDERSTANDING IMPLANTABLE CARDIOVASCULAR DEVICES

Cardiovascular implantable electronic devices can store substantial amounts of diagnostic data related to arrhythmia documentation.[54]

- Pacemakers are electronic devices that stimulate the heart with electrical impulses to maintain or restore a normal rhythm in people with slow heart rhythms. Pacemakers can be programmed to record abnormal rhythms but cannot provide a shock to restore sinus rhythm during an arrhythmia.
- Implantable cardioverter-defibrillators (ICDs) have pacemaker functions but are also capable of providing therapy for tachyarrhythmias, including VT and VF. Therapy can involve either overdrive pacing or a shock that restores sinus rhythm. Interrogation of an ICD is important after a delivered shock because the arrhythmia that was treated will be recorded along with the therapy and the post-shock rhythm.
- An implantable loop recorder (ILR) is a small device implanted under the skin that can store ECG recordings of the heart rhythm. An ILR can be programmed to record automatically when the patient's heart rate deviates outside the range that is chosen by the physician. An ILR can also be activated by the patient to record during symptoms. ILRs cannot pace or provide therapy.

AED AND CPR

AEDs can accurately detect VF in children of all ages and differentiate shockable from nonshockable rhythms with a high degree of sensitivity and specificity.[55] For children from birth to 8 years of age, it is reasonable to use an AED pediatric dose-attenuator system and a pediatric pad to reduce delivered energy if one is available; if not, the rescuer should use a standard AED.[55] Current AHA guidelines do not recommend compression-only CPR for young children.[56]

CARDIAC EMERGENCY RESPONSE PLANS AND THE PCP AS ADVOCATE

On any given day, as many as 20% of the combined US adult and child population can be found in schools. Therefore, school nurses, athletic trainers, and teachers are often required to provide emergency care during the school day and for extracurricular activities, including sports.[57] A cardiac emergency response plan (CERP) is needed to facilitate an efficient and structured response to SCA. Essential elements of a CERP include the following:

1. establishing an effective communication system;
2. training of anticipated responders in CPR and AED use;
3. access to an AED for early defibrillation;
4. acquisition of necessary emergency equipment;
5. coordination and integration of on-site responder and AED programs with the local EMS system; and
6. practice and review of the response plan.[58]

This plan should target a collapse-to-EMS call time of $<$1 minute, provision of first aid and CPR when appropriate, and a collapse-to-first shock time of $<$3 minutes for SCA if an AED is on-site. It is recommended that at least 10% of staff and 50% of physical education staff should have current CPR and AED certification.[59] At least 2 successful emergency response drills should be conducted every year.[59]

The PCP and pediatric cardiologist can have a major impact in advocating for schools and school districts not only to have a sufficient number of AEDs but also that the staff is continually well trained, the equipment is maintained, and a CERP is in place. Many states have passed legislation requiring CPR or AED training for students to graduate from high school or as part of the health curriculum.[60] The task force supports efforts through either legislation or local or statewide high school associations to make CPR and/or AED training a requirement for students to graduate from high school.

ROLE OF THE LICENSED ATHLETIC TRAINER

Licensed athletic trainers (LATs) are school-based health care professionals who collaborate with the health care team. The services LATs provide include prevention, emergency care, and therapeutic

intervention.[61] The LAT needs to be able to determine an athlete's readiness to participate and, if necessary, consult with the supervising team physician and/or treating physician. They also play an important role in identifying unsafe facilities or playing environments as well as developing and implementing an emergency action plan in collaboration with supervising team physicians.[61] LATs can be important advocates for CPR and AED use training and for AED placement in public areas, including schools, athletic fields, and arenas.

RETURN TO ACTIVITY AFTER CARDIAC ARREST

The AHA and others have issued recommendations for aerobic and resistance training in children and adolescents.[62] These recommendations are based on findings that regular physical activity reduces the risk of long-term adverse health outcomes. There is evidence that childhood levels of cardiovascular risk factors predict early subclinical atherosclerosis and cardiac pathology and adult morbidity and mortality.[63] Encouraging patients who have suffered cardiac arrest to have a healthy lifestyle including exercise may be beneficial. Exercise restriction needs to be balanced with the potential for lifelong risk of SCA and SCD and the development of other conditions associated with cardiovascular risk. To facilitate a safe return to exercise, these patients may benefit from a medically supervised cardiac rehabilitation program. Any patients, including athletes, who have suffered a cardiac arrest from VT or VF from a cause that cannot be reversed or well-managed with other means (eg, medication) should undergo a thorough evaluation with strong consideration of ICD placement.[64] There are specific recommendations for those desiring athletic participation with ICDs under advisement by the patient's pediatric electrophysiologist. Recommendations include returning to low-level dynamic and static activities (eg, golf, bowling, etc) after 3 months of being free of VT or VF requiring device therapy.[65] Higher-intensity activities can also be considered in discussion with the patient and family in a shared risk arrangement after 3 months without device therapy for VT or VF.[65] The patient should be counseled on the increased risk of ICD shocks as well as device-related trauma when participating in activities that have a risk of affecting the device.[65]

Patients who have suffered a cardiac arrest from a reversible cause, such as myocarditis or electrolyte abnormality, will often not have an ICD implanted. The most recent recommendations suggest refraining from athletic participation until cleared at a 3-month reevaluation and on the advice of the pediatric cardiologist or electrophysiologist. If the condition causing the cardiac arrest has completely resolved, the athlete may then return to competition.[65]

RECOMMENDATIONS AND PRIMARY TAKEAWAY POINTS FROM THIS POLICY STATEMENT

PCPs, as the preeminent providers of health care to children, should be aware of the features of the clinical history, family history, and physical examination suggestive of a risk for SCA and SCD.

1. All children should be evaluated for conditions predisposing to SCA and SCD in the course of routine health care.[14]
2. A thorough and detailed history, family history, and physical examination are necessary to begin assessing SCA and SCD risk.
3. The ECG should be the first test ordered when there is concern for SCA risk. The ECG should be interpreted by a physician trained in recognizing electrical heart disease (ie, a pediatric cardiologist or pediatric electrophysiologist).
   a. To provide optimal care, ECGs should not be performed in isolation without clinical history; referral to a specialist should be considered.
4. Do not trust the computer interpretation of the ECG.

Recognizing that no single screening strategy will be able to detect all the conditions associated with SCA (primary prevention), it is important to advocate for emergency action plans (secondary prevention) and CPR training in the community. CPR and AEDs are effective for secondary SCA prevention.

Survivors of SCA (and family members of SCA or SCD victims) should have a thorough evaluation to assess the potential of a genetic etiology. Some facilities have specialized centers for SCA. A pediatric SCA center is a children's multispecialty medical facility with expertise in pediatric electrophysiology and inherited channelopathies and cardiomyopathies. This evaluation includes not only molecular genetic testing but also genetic counseling for identifying others who may be at risk.[66]

SUMMARY

The strategy put forth in this policy statement emphasizes the importance of sudden death awareness and prevention that is inclusive of all young people regardless of athletic status. The emphasis shifts from focusing on a single group to expanding the primary and secondary

prevention concepts to a broader group who may achieve similar benefits. There have been many efforts made and published on ways to identify those at risk for SCA and SCD, including clinical (history and physical examination), genetic, and ECG screening. Many SCA and SCD victims cannot be identified before their event, even with testing. Therefore, secondary prevention efforts must not be overlooked by those evaluating large numbers of pediatric patients. Although focusing on prevention efforts in all children may seem to create a burden on PCPs by extending the screening program to more patients, simplification to the aforementioned 4 questions can allow this screening to become incorporated into the routine visit at a minimum of every 3 years. This strategy is intended to increase awareness of SCD prevention in young people and will allow for a healthy lifestyle and reduce the risks of SCA and SCD.

SECTION ON TELEHEALTH CARE, COMMITTEE ON PRACTICE AND AMBULATORY MEDICINE, COMMITTEE ON PEDIATRIC WORKFORCE

All children and adolescents deserve access to quality health care regardless of their race/ethnicity, health conditions, financial resources, or geographic location. Despite improvements over the past decades, severe disparities in the availability and access to high-quality health care for children and adolescents continue to exist throughout the United States. Economic and racial factors, geographic maldistribution of primary care pediatricians, and limited availability of pediatric medical subspecialists and pediatric surgical specialists all contribute to inequitable access to pediatric care. Robust, comprehensive telehealth coverage is critical to improving pediatric access and quality of care and services, particularly for under-resourced populations.

INTRODUCTION

The growth and development of telehealth, or the provision of health services remotely, reflects the evolution of health care delivery systems to adapt to new technology and the needs of the population. The exponential growth in the adoption and use of telehealth services during health care disruptions, such as the coronavirus disease 2019 (COVID-19) pandemic, highlights the need to clarify the goals and best practices for using telehealth in child health. This policy statement addresses how telehealth and telehealth policy can increase patient access to primary care and subspecialty pediatric expertise, support care coordinated within the medical home, and enhance communication and collaboration among clinicians and other stakeholders, resulting in cost-efficient, equitable, high-quality care. A forthcoming technical report will provide in-depth discussion of these issues as well as the limitations of telehealth care.

TELEHEALTH IN THE MEDICAL HOME

The pediatric medical home provides a centralized hub for a child's health care to ensure continuity and coordination of care.[1,2]

abstract

Telehealth is a critical infrastructure to efficiently implement the medical home model of care and provide high-value, coordinated, and unfragmented health care. Telehealth coordinated within the medical home will promote continuity of care in a cost-efficient manner and can reduce the risk of potential fraud and abuse from expansion of telehealth coverage.

Pediatric subspecialty care delivered remotely is important for evaluation, preoperative and postoperative surgical care, consultation, and management of complex conditions, especially when in-person care is limited by distance, specialist availability, or travel restrictions.[3,4] Telehealth can involve both the primary care and specialist physicians in care episodes to improve communications and care coordination.[5–7] Physician-to-physician consultation via telehealth can serve as both a consultative and an educational interaction, again increasing the access to specialist input for all caregivers.

These services include a continuum of remote and in-person care options, such as audiovisual, audio only (telephone), store and forward, portal interactions, and remote patient monitoring (particularly for children with complex or chronic illness). Telehealth is particularly important for children and youth with special health care needs who experience significant barriers to receiving necessary care.[8–11] Mental and behavioral health services are especially amenable to remote care and can also be provided as an extension of the medical home. Each of these modalities provides necessary care when the physician and patient cannot meet in person, or they can be used as an adjunct to in-person services.

IMPACT OF THE COVID-19 NATIONAL HEALTH EMERGENCY ON TELEHEALTH

When the health care system is disrupted, as during the COVID-19 pandemic, disparities in access to care can become even more problematic. Disruptions can result in neglect of serious medical conditions, as well as forgoing needed preventive care and immunizations. Missed opportunities for care can have serious immediate and long-term consequences for children's health, development, and welfare that are more severe for populations of children affected by inequities based on race and/or ethnicity, disability, geography, socioeconomic status, and payer policies.[3,12–16] For several years, telehealth has enabled pediatric medical and surgical specialists to offer consultative services to some patients who could not travel to access in-person care, but payment for telehealth services and adoption of these methods have been limited.

In 2020, public health mitigation measures to limit the spread of COVID-19 led to widespread disruptions of services, including pediatric health care. Changes in telehealth policy allowed children with acute and chronic illnesses to connect to their usual and familiar care sources for management of both acute illnesses and chronic diseases and disabilities. In many cases, preventive care was allowed and could be provided via a hybrid model that included a combination of virtual and in-person visits. Telehealth implementation was rapid and widespread. The adoption was made possible by policy changes supporting operations and payment for telehealth care at parity with in-person services, which were promoted by the Centers for Medicare and Medicaid Services, state governments, private payers, and Medicaid (including the Children's Health Insurance Program). The availability of telehealth care enabled greater access to care for many children and adolescents, but gaps in digital infrastructure continue to persist because of poverty, systemic racism, and other inequities, which were a barrier to equitable technology-enabled care.[3,8,10,12,13] The public health emergency led to significant reductions in inpatient, outpatient, and emergency department use, and telehealth played a key role in maintaining care for children and families who chose not to seek in-person care during this time.

PAYMENT FOR TELEHEALTH SERVICES

Recent telehealth payment policies, which were often proposed as temporary enhancements, may not persist in the future because payers who have expressed concerns about the potential for fraud, abuse, and overuse seek to return to previous policies requiring an in-person visit for payment of services. If payment for telehealth is denied because of restrictions on the location of the patient (for example, previous rules did not allow the patient to be located at home) or there is a lack of payment parity, use of these services will decrease over time, reducing access to necessary pediatric health services. The delivery of care determines the value of services provided, whether this delivery occurs by telehealth or in person. Telehealth is foundational to creating efficient, innovative, high-value care models in which patients get the right care at the right place at the right time, as well as investing in preventive care to reduce costly emergency department and hospital visits, all of which benefit all stakeholders in the health care system.

Evaluation and management coding guidelines determine the value of these health care services, and these guidelines apply equally to in-

person and remote care.[17] The time, effort, and medical decision-making required for a patient visit, as well as the associated malpractice risk and documentation requirements, are largely unchanged whether care is delivered virtually or in person. Telehealth visits that require conversion to an in-person evaluation because of the nature of the condition or limitations of the remote evaluation are currently paid as a single visit, which prevents duplicate expense for payers. However, use of telehealth in a traditional practice setting does not reduce the need for office overhead expenses and can increase costs associated with technology.

Remote care coordinated by the medical home can improve access to both primary and specialty care for children when an in-person visit is not possible. In the subspecialty care setting, follow-up care and monitoring of chronic conditions can increase the reach of pediatric medical subspecialists and surgical specialists, especially for children who were not able to access care in the past or who have difficulty visiting a care site because of distance or travel issues. Children with special health care needs have additional challenges receiving primary care, subspecialty care, home health, palliative and/or hospice care, education services, transition to adult care, and developmental and habilitative services, many of which can be improved with the integration of telehealth in the medical home.[18–20] Under-resourced communities can also have improved access to pediatric care, which requires adequate resource support for infrastructure to allow for equitable implementation.

Pediatricians providing remote care will be best able to ensure that these services meet the same standards of care as the services that they provide in person. Telehealth can help reduce inequities and improve children's overall health and well-being by expanding the reach of the medical home, particularly for children with special health care needs and children who have not had access to high-quality care in the past. Adequate payment for these services is necessary to ensure that they will continue to be available to children.

RECOMMENDATIONS

1. Health equity: Inequity in access to health care services for children is discriminatory and unacceptable because it results in unequal care and worse outcomes for children without access. Telehealth can decrease disparities in access to care by extending pediatric expertise and best practices to children no matter where they are located. Addressing barriers, such as language, digital literacy, disability, and access to and payment for technology infrastructure, is required to avoid furthering disparities.
2. Access to pediatric care: Telehealth can expand the footprint and breadth of pediatric medical and surgical specialties by bringing expertise to remote and under-resourced areas and efficiently directing patients to the most appropriate care settings. Appropriate payment for services that enhance the value of pediatric care through timely implementation of best practices and facilitating appropriate dispositions will further the implementation of these services. Including stakeholders across the continuum of care, including families, public health agencies such as the Maternal and Child Health Bureau, state and Title V agencies, and schools in the design of telehealth systems, will ensure that the impact of these systems will benefit all parties.
3. Payment reform:
   a. Payment for telehealth services at parity with the equivalent services provided in person by private insurers, Medicare, and Medicaid and/or Children's Health Insurance Program, including managed care arrangements, will allow the use of the most appropriate place of service for each encounter, as will inclusion of telehealth among the medically necessary services covered under the treatment provisions of Medicaid's Early and Periodic Screening, Diagnostic and Treatment law.
   b. Incentivizing and encouraging private insurance plans, including fully insured plans, Marketplace plans, and those covered by the Employee Retirement Income Security Act, to pay for telehealth services at parity with the equivalent in-person services will support broad use of telehealth care when appropriate, but state mandates may be required to ensure compliance.
   c. Technology can, in many situations, remove perceptions of a difference in value between services provided remotely and those provided in person and can provide greater value with the use of remote patient monitoring by preventing unnecessary emergency department and hospital use, especially in children and youth with special health care needs.
   d. Telehealth policy is a potent tool in reducing inequities in access to health care. Adequate and appropriate payment for remote services based on current and future payment models, including

fee-for-service, capitation, and value-based plans, will affect the potential impact of the use of telehealth services.

e. Children and youth with special health care needs, including those with mental and/or behavioral conditions and medical complexity, will require additional consideration for developing innovative payment structures that promote care integrated across settings that maximize value. Investment in telehealth and remote monitoring infrastructure, including devices and connectivity, for such populations is critical to providing equity in access to pediatric services. Medicaid payment structures (such as waivers and Health Homes), which are used to pay for services for specific populations, can also cover telehealth services in these populations.

4. Care within the medical home: Support for the use of telehealth within the medical home recognizes that the medical home offers continuity and the prudent use of health care resources, avoiding fragmented and episodic care delivered without such coordination.
5. Standards of quality care: All standards of quality apply equally to any patient encounter, whether remote or in person, including high-quality interpretation in the patient and family's preferred language. Adhering to quality standards also includes understanding of the situations when the necessary evaluation is not possible remotely, and an in-person visit is required, so that technical limitations of remote care do not compromise quality of care. National metrics of quality for telehealth, especially in linking to payment, are essential. Pediatricians are key stakeholders in developing these metrics for children.
6. Reduction of barriers: Geographical, economic, and administrative barriers to telehealth care, such as interstate licensure issues, may prevent physicians from providing care to their patients who may be temporarily located in a state in which the physician is not licensed, which may reduce access to and continuity of care.
7. Infrastructure: Lack of high-speed broadband Internet access and limited access to adequate technology impede the delivery of services via telehealth and further inequity in access to care. Every individual, especially those in under-resourced areas of the country, both urban and rural, deserves availability of and support for a reliable technology and telecommunications infrastructure, such as the Lifeline program,[16] to avoid furthering health care disparities.[15,21,22]
8. Federal research funding: Creation of an evidence base to address best practices, workforce needs, patient access to care, quality of care, reduction of health care costs, and patient and/or family and clinician satisfaction will enable future research to improve the function of and access to pediatric care via telehealth, including the impact of alternative payment and care delivery models that use telehealth and remote monitoring for children with special needs to integrate care across settings most effectively.

Topical Nasal Decongestant Oxymetazoline: Safety Considerations for Perioperative Pediatric Use

Richard Cartabuke, MD, FAAP,[a] Joseph D. Tobias, MD, FAAP,[b] Kris R. Jatana, MD, FAAP[c]
SECTION ON ANESTHESIOLOGY AND PAIN MEDICINE, SECTION ON OTOLARYNGOLOGY–HEAD AND NECK SURGERY

The over-the-counter nasal decongestant oxymetazoline (eg, Afrin) is used in the pediatric population for a variety of conditions in the operating room setting. Given its vasoconstrictive properties, it can have cardiovascular adverse effects when systemically absorbed. There have been several reports of cardiac and respiratory complications related to use of oxymetazoline in the pediatric population. Current US Food and Drug Administration approval for oxymetazoline is for patients ≥6 years of age, but medical professionals may elect to use it short-term and off label for younger children in particular clinical scenarios in which the potential benefit may outweigh risks (eg, active bleeding, acute respiratory distress from nasal obstruction, acute complicated sinusitis, improved surgical visualization, nasal decongestion for scope examination, other conditions, etc). To date, there have not been adequate pediatric pharmacokinetic studies of oxymetazoline, so caution should be exercised with both the quantity of dosing and the technique of administration. In the urgent care setting, emergency department, or inpatient setting, to avoid excessive administration of the medication, medical professionals should use the spray bottle in an upright position with the child upright. In addition, in the operating room setting, both monitoring the quantity used and effective communication between the surgeon and anesthesia team are important. Further studies are needed to understand the systemic absorption and effects in children in both nonsurgical and surgical nasal use of oxymetazoline.

STATEMENT OF THE PROBLEM

To date, there are limited objective pediatric data on the safety and specific dosing of topical oxymetazoline (eg, Afrin), and an excessive

unmonitored volume of nasal use could lead to serious adverse effects in children.

BACKGROUND

Oxymetazoline hydrochloride 0.05% is the active ingredient in over-the-counter (OTC) nasal spray decongestants (eg, Afrin; Merck Schering-Plough Pharmaceuticals, North Wales, PA). It was first sold as a prescription medication in 1966 and then became available as an OTC medication in 1975. It is currently approved by the US Food and Drug Administration (FDA) for use in patients ≥6 years of age. Oxymetazoline is an α-adrenergic agonist with greater activity at the α2 versus α1 adrenergic receptor.[1] Its action at the peripheral α2-adrenergic receptor on the smooth muscle of the vasculature results in vasoconstriction, thereby defining its clinical utility as both a decongestant and a topical hemostatic agent. It is used off label in the operating room to prepare the nasal passages during nasal intubation and during ear, nose, and throat (ENT) surgery to improve visualization of the airway and to minimize intraoperative or postoperative bleeding.[2,3]

A superior efficacy and safety profile of oxymetazoline has been demonstrated when compared with other topical agents with vasoconstrictive properties, such as phenylephrine, epinephrine, or cocaine.[2–5] Riegle et al[3] compared the topical nasal mucosal applications of oxymetazoline (0.05%), phenylephrine (0.25%), and cocaine (4%) during functional endoscopic sinus surgery in children. Phenylephrine was associated with an increase in blood pressure (BP), and subjective evaluation of bleeding and surgical visualization was best with oxymetazoline. The authors concluded that oxymetazoline was the preferred vasoconstrictor in children. Higgins et al[4] reviewed the use of topical vasoconstrictors during ENT surgery. They compared the efficacy against the risks associated with the topical use of phenylephrine, cocaine, and oxymetazoline and proposed recommendations to reduce the incidence of systemic complications caused by these agents in the operating room. These authors recommended the use of 0.05% oxymetazoline as the initial vasoconstrictor in patients <12 years of age. Their protocol did not include a recommendation for the maximum volume of oxymetazoline.

Despite a long history of use and its potential advantages over other agents, data seem to be limited regarding the pharmacokinetics of oxymetazoline, including uptake when applied to mucosal membranes or the end-organ effects when used in average concentration and volume during the perioperative period. Although the package insert, anecdotal case reports, and various Web-based programs clearly outline the potential for hypertension and cardiac effects related to the use of this product, the authors of this report believe that there has not been effective emphasis placed on such information in the medical literature. Adverse effects may occur not only with excessive dosing but also when oxymetazoline is used within recommended guidelines. Furthermore, delivery from the commercially available bottle may be variable depending on the position of the bottle and the force with which it is squeezed.

Recently, there have been 2 case reports published regarding significant cardiovascular effects related to the routine perioperative use of this medication in healthy children.[6,7] Latham and Jardine[6] reported adverse effects of topical nasal oxymetazoline in a 14-kg 4-year-old boy during dental restoration. After anesthetic induction and before nasal intubation, both nares were sprayed with oxymetazoline 0.05%. The exact number of sprays was not clarified (merely, both nares were treated with oxymetazoline nasal spray). Approximately 5 minutes after endotracheal intubation, the child's BP, measured by a noninvasive BP cuff, increased from 110/52 to 170/110 mm Hg, with a decrease in heart rate from 118 to 65 beats per minute. The hypertension was treated by increasing the sevoflurane concentration; however, the BP remained elevated for up to 60 minutes, with the diastolic BP above 100 mm Hg for 30 minutes. Ramesh et al[7] reported a similar case that involved postoperative hypertension. The patient was a 14-kg 3-year-old boy who presented with chronic nasal obstruction secondary to inferior turbinate and adenoidal hypertrophy. After the induction of general anesthesia and endotracheal intubation for bilateral inferior turbinate reduction with out-fracturing of the turbinate, oxymetazoline-soaked pledgets were placed in both nares. Adenoidectomy was performed by using electrocautery, and hemostasis was augmented with topical application of oxymetazoline at the termination of the operation. The volume of oxymetazoline was not measured. At the completion of the procedure, the child was then transferred to the postanesthesia care unit (PACU). At the time of arrival to the PACU, bradycardia was noted with a heart rate of 48 beats per minute. The BP was 106/84 mm Hg. Bilateral breath sounds were confirmed by auscultation. Atropine (0.1 mg) was administered intravenously, after which the heart rate increased to 135 beats per minute and the BP increased to 166/129 mm Hg. The

oxymetazoline-soaked nasal pledgets were removed immediately, and 10 mg of propofol was administered. Hypertension persisted, and propofol was administered in incremental doses of 10 mg each. Because no direct-acting vasodilators (hydralazine) were immediately available in the freestanding outpatient surgery center, labetalol was administered intravenously in 1-mg increments to a total of 2 mg. The BP and heart rate remained elevated, but at a lower range. During the next hour, the heart rate and BP gradually normalized to their baseline values. No further hypertension was noted during this patient's PACU stay or after discharge during follow-up with his pediatrician.

These 2 case reports and others from the literature demonstrate the potential toxicity from OTC oxymetazoline, which may be dosed without attention to the volume administered. These concerns are not limited to its perioperative administration because toxicity has been reported with its use for routine indications, including as a nasal decongestant. Although used for its topical effects, vascular absorption of oxymetazoline can have profound systemic effects (most commonly, hypertension related to its action on the α2-adrenergic receptors of the smooth muscle of the vasculature). When used in even larger doses in young children, oxymetazoline can activate central adrenergic receptors and lead to serious adverse effects, including cardiovascular instability, respiratory depression, and sedation, which may be potentially life-threatening.[8–11] In 2012, similar adverse events, secondary to accidental ingestion by children 5 years and younger, were reviewed by the FDA, and the FDA included a list of products like oxymetazoline that should be stored out of the reach and out of sight of children at all times.[12] In these reported cases, children were found to be chewing or sucking on the medication bottle or were found to have an empty bottle next to them.[12]

Imidazole derivatives, such as oxymetazoline, are rapidly absorbed across mucosal membranes in children. Hence, toxicity generally develops within minutes, but resolution may take up to 24 hours.[9,10] Exposure to different imidazoline derivatives was reviewed in 72 children between 2 months and 13 years of age, and most children who had adverse effects were younger than 3 years of age.[13] Giannakopoulos et al[14] studied the cardiovascular effects and pharmacokinetics of an intranasal 3% tetracaine and 0.05% oxymetazoline spray at 2 different dose levels in adult dental patients. The authors administered what they considered to be the maximum recommended dose (MRD) of 18 mg of tetracaine and 0.3 mg of oxymetazoline to 12 volunteers. The medication was sprayed onto the nasal mucosa. One to 3 weeks later, twice the dose (36 mg of tetracaine and 0.6 mg of oxymetazoline) was administered. Physiologic measures remained fairly stable throughout the 2-hour period, with no clinical concerns in the patients and no clinically significant differences between the 2 groups. However, the medications were administered over 8 minutes and 20 minutes in the group that received the MRD and the group that received twice the MRD, respectively, rather than the short-term instillation period typically used for ENT surgery, which may explain the lack of changes in BP and heart rate. Tetracaine plasma levels were undetectable in the majority of the participants, but concentrations of oxymetazoline in the group that received twice the MRD were approximately 50% greater than those in the group that received the MRD. The plasma half-life of oxymetazoline was reported to vary from 1.72 to 2.32 hours. However, there are limited pharmacokinetic data in the pediatric population. In a recent prospective pharmacokinetic study of 27 pediatric patients, researchers measured serum concentrations after administration using soaked cotton pledgets during sinus surgery, adenoidectomy, and turbinate reduction. The authors noted lower systemic absorption than that reported with administration from the bottle (spray technique). No significant hemodynamic changes were noted, and no correlation of hemodynamic changes with serum concentrations was noted. Although preliminary, the authors suggest that the extreme systemic effects that have been reported may be related to variable systemic absorption rates and serum concentrations when oxymetazoline is applied in a more diffuse spray technique compared with soaked cotton pledgets, or it is possible that these responses are idiosyncratic and unrelated to delivery techniques and serum concentrations.[15] Additional research is needed to further delineate these factors.

Various studies have demonstrated alarming information regarding alteration of the delivery of oxymetazoline depending on the position of the bottle. The first of these reports, by Latham and Jardine,[6] demonstrated a fact that had previously received no attention in the literature. There was up to a 75-fold increase in the volume of medication administered when the bottle was held inverted. Given the supine position of patients on the operating room table, it is common practice to hold the bottle inverted and squeeze it. Although squeezing the bottle in the upright position

resulted in a mist with the delivery of 28.9 ± 6.8 μL of fluid, the average volume delivered with the bottle inverted was 1037 ± 527 μL (range 473–2196 μL). With the bottle upright, the amount delivered is effort independent; however, it becomes effort dependent when the bottle is inverted and squeezed. Latham and Jardine[6] also demonstrated that each surgical pledget could hold a significant vol (1511 ± 184 μL), a fact that may further increase delivery during ENT surgery. Two additional sets of investigators have confirmed these findings and have also demonstrated significant interindividual variability in the amount delivered based on effort.[16,17] Oxymetazoline is only intended for short-term use of $<$5 days' duration because the medication can cause rebound nasal congestion and lead to rhinitis medicamentosa with long-term use. In addition, systemic side effects and end-organ injury are unknown with long-term use because only animal studies are available at this time.[18] Given the recent reports in the literature, it seems that the time has come to develop guidelines for the dosing of oxymetazoline in children, especially infants and toddlers.[19–22]

EXISTING GUIDELINES AND JOINT COMMISSION RECOMMENDATIONS

To the authors' knowledge, no published sources of formal practice guidelines or recommendations currently exist for nasal use of topical oxymetazoline. From a Joint Commission general medication standpoint, hospitals, including operating rooms, are required to document the safe administration of medications in the medical record, which includes verification of correct patient, strength, dose, route, labeling, date, and time.[23]

REVIEW OF EVIDENCE

Unfortunately, pediatric pharmacokinetic data on which to base guidelines for use of topical nasal oxymetazoline are limited. The package inserts recommend 2 to 3 sprays into each nostril for patients $\geq$6 years of age. On the basis of data from Latham and Jardine,[6] which demonstrate that each upright spray delivers 30 μL, this would be a total maximum dose of 180 μL, which is far less than the amount held by 1 pledget or the amount delivered by a single spray from an inverted bottle (1 ± 0.5 mL).

Because topical nasal decongestant oxymetazoline is an OTC medication, pediatric complications related to its use may be underappreciated. Given its nasal delivery via a spray mechanism or soaked cotton pledgets, attention to exact dosing or a process to monitor the dose of oxymetazoline given is frequently absent. There are several reports of morbidity, and until additional pediatric data are available, it appears that it is essential to establish a general consensus for responsible use.

CONCLUSIONS

The American Academy of Pediatrics recommends the following for short-term pediatric topical nasal oxymetazoline use:

General Considerations

1. Because limited data exist, remind pediatricians, advanced practice providers, anesthesiologists, and surgeons of the limited available data for use of OTC oxymetazoline in patients $<$6 years of age. Although the current FDA approval is for patients $\geq$6 years of age, medical professionals do elect to use it off label in children $<$6 years of age for specific conditions in which the potential benefit may outweigh risk (eg, active bleeding, acute respiratory distress from nasal obstruction, acute complicated sinusitis, improved surgical visualization, nasal decongestion for scope examination, other conditions, etc). Providers should be aware of potential adverse cardiovascular effects of an unmonitored volume of administration, which may be most relevant in infants or young children and those with comorbid cardiac conditions.
2. Because of the variable dosing risk, be aware that use of oxymetazoline in the supine position with the spray bottle inverted can result in a significantly higher dose (approximately 1 ± 0.5 mL administered per spray), as compared with the spray bottle in an upright position, which results in 30 μL (0.03 mL) per spray. When possible, to avoid excessive nasal dose administration, use the spray bottle in an upright position with child also upright.

Surgeon, Anesthesiologist, and Operating Room Personnel: Surgical Considerations

1. Avoid administration of an unmonitored medication volume. During a surgical procedure, implement a reliable process to keep track of the total volume of medication that is administered.
2. Effective communication between the surgeon and anesthesiologist should occur with intraoperative use of these medications. Routine monitoring of heart rate, BP, and respiration through the intraoperative and postoperative period is essential. If a second medication bottle needs to be opened for use during a case, ensure that the anesthesiologist is aware.
3. Remove excess medication from pharynx. Both during and at the end of the procedure, suction excess medication that has pooled in the nasopharynx and oropharynx to avoid additional potential mucosal absorption.

Future Perspectives

Encourage the initiation of additional pharmacokinetic trials of topical nasal oxymetazoline in the pediatric patient population, including for both surgical and nonsurgical use. In young children, consider evaluation of the hemostatic efficacy of a half-strength concentration of the agent compared with the full-strength concentration.

Rachel Y. Moon, MD, FAAP,[f] COMMITTEE ON FETUS AND NEWBORN, TASK FORCE ON SUDDEN INFANT DEATH SYNDROME

Of the nearly 3.8 million infants born in the United States in 2018, 8.3% had low birth weight (ie, weight <2500 g) and 10% were born preterm (ie, gestational age of <37 weeks). Ten to fifteen percent of infants (approximately 500 000 annually), including low birth weight and preterm infants and others with congenital anomalies, perinatally acquired infections, and other diseases, require admission to a NICU. Every year, approximately 3600 infants in the United States die of sudden unexpected infant death (SUID), including sudden infant death syndrome (SIDS), unknown and undetermined causes, and accidental suffocation and strangulation in an unsafe sleep environment. Preterm and low birth weight infants are 2 to 3 times more likely than healthy term infants to die suddenly and unexpectedly. Thus, it is important that health care professionals prepare families to maintain their infant in a safe home sleep environment as per recommendations of the American Academy of Pediatrics. Medical needs of the NICU infant often require practices such as nonsupine positioning, which should be transitioned as soon as medically possible and well before hospital discharge to sleep practices that are safe and appropriate for the home environment. This clinical report outlines the establishment of appropriate NICU protocols for the timely transition of these infants to a safe home sleep environment. The rationale for these recommendations is discussed in the accompanying technical report "Transition to a Safe Home Sleep Environment for the NICU Patient," included in this issue of *Pediatrics*.

INTRODUCTION

Sudden unexpected infant death (SUID), including sudden infant death syndrome (SIDS), is the leading cause of postneonatal mortality in the United States. In up to 95% of these cases, there are one or more environmental risk factors identified.[1] Preterm and low birth weight infants are 2 to 3 times more likely than healthy term infants to die

suddenly and unexpectedly,[2,3] so it is particularly important to model a safe home sleep environment in the NICU before a neonate is discharged from the hospital. The American Academy of Pediatrics (AAP), through the Committee on Fetus and Newborn, has recommended since 2008 that preterm infants be transitioned to a predominantly supine position by a postmenstrual age of 32 weeks to promote safe sleep, a recommendation supported by the AAP Task Force on Sudden Infant Death Syndrome (henceforth, "task force").[2,4,5] Because the recommendations for infant sleep safety at home also include other postnatal environmental factors (eg, use of a firm, flat sleep surface, avoidance of loose bedding or soft objects, a neutral thermal environment, room sharing without bed sharing, smoke-free environment), safe sleep recommendations for NICU patients should also address these factors. Recognizing that not all infants are ready for such a sleep environment by 32 weeks' postmenstrual age, the task force recommends transitioning the infant to the safe home sleep practices as soon as he or she is medically stable and significantly before the anticipated discharge from the hospital.[4]

Studies have shown that NICU providers do not consistently support infant sleep safety recommendations.[5–7] Researchers in a 2016 study of 96 NICU nurses found that only 53% strongly agreed that safe sleep recommendations make a difference in preventing SIDS, and only 20% strongly agreed that parents would model nurses' behaviors at home.[7] However, research from the well-baby nursery, community settings, and the NICU demonstrate that safe sleep education and modeling in these sites translate into increased knowledge and improved safe sleep practices among new parents.[8–11]

This clinical report reviews the evidence for common NICU sleep practices and provides guidance for transitioning the infant to a sleep environment that is safe and appropriate for the home environment.

SLEEP POSITION

Since 1992, back sleeping has been recommended for the reduction of sleep-related deaths. This recommendation, in conjunction with the Back to Sleep campaign in 1994, resulted in SIDS rates in the United States decreasing by 53% by 1999.[12] Prone and side sleep positions are associated with an increased risk of SIDS, and neither are recommended.[4] The risk of SIDS for preterm and low birth weight infants in the prone position is potentially greater than that of healthy term infants.[4,13] However, there are a number of scenarios in the NICU in which nonsupine positioning is applied for potential therapeutic benefit. Nonsupine positioning in the NICU in all cases can be used as a teachable moment with the family regarding eventual readiness for safe infant sleep positioning and environment.

Respiratory Distress and Chronic Lung Disease

Prone positioning is commonly used in infants with both acute and chronic respiratory distress. Preterm infants in the prone position have improved oxygenation and pulmonary function, including dynamic lung compliance and tidal volume, as well as less intrapulmonary shunting and improved thoraco-abdominal synchrony.[14–16] In the supine position, some lung tissue is dependent to the heart and mediastinal structures, increasing potential for atelectasis. In addition, in the supine position, abdominal contents may limit ventilation through opposition to the excursion of the diaphragm.[14,17] A Cochrane review of positioning for acute respiratory distress in infants and children found small but statistically significant improvements in oxygenation and tachypnea with prone positioning.[18] The benefit of prone positioning during the acute phase of respiratory disease (when infants are closely monitored) may outweigh the importance of modeling safe sleep positioning in the extremely preterm infant.

Data are more limited regarding potential benefits of prone positioning in the preterm infant with evolving chronic lung disease. The studies are small and have shown conflicting results.[19–23] One study found higher oxygen saturations and functional residual capacity in the prone position but no difference in compliance or resistance in oxygen-dependent infants.[19] Another study found prone positioning increased tidal volumes and minute ventilation but also increased work of breathing.[22] Although undefined, at some point the diminishing benefits of prone positioning are outweighed by the concern of reinforcing a sleep position that increases the risk of SUID.

Airway Abnormalities

Although uncommon, there are congenital airway abnormalities that result in respiratory compromise, and some infants with these conditions may benefit from prone positioning. The benefit of prone positioning is particularly relevant in Pierre Robin sequence, in which there is gravity-dependent tongue-based obstruction.[24] Although infants with mild cases of Pierre Robin sequence will be stable sleeping supine and infants with severe cases will have early surgical

intervention, intermediate cases may be more challenging and achieve relief with prone positioning until they outgrow their airway obstruction.

Apnea of Prematurity

Some studies have suggested that the frequency and severity of apnea of prematurity may be decreased through prone positioning, but these studies showed mild benefit and were limited by small sample size.[25,26] More recent studies have disputed this conclusion.[27,28] A 2017 Cochrane review found no statistical differences in apnea, bradycardia, or oxygen saturations and concluded that body position was not relevant to controlling apnea frequency.[29] Nonsupine positioning should not be used as a strategy to decrease apnea of prematurity.

Gastroesophageal Reflux

Positioning has often been touted as a treatment of gastroesophageal reflux disease (GERD), but the risk of sudden unexpected death has decreased enthusiasm for this strategy. The AAP agrees with the recommendation of both the North American Society for Pediatric Gastroenterology, Hepatology and Nutrition and the European Society for Pediatric Gastroenterology, Hepatology and Nutrition "not to use positional therapy (ie, head elevation, elevation of the head of the crib, lateral and prone positioning) to treat symptoms of GERD in sleeping infants."[30] Studies have suggested less reflux when the infant is in the prone position versus the supine position, so it is acceptable to place an awake infant prone after feeding if the infant is continuously monitored.[31,32] Although gastric emptying may be improved by placing the infant in the right lateral position, some studies have demonstrated that when preterm infants are placed in the left lateral position after feeding, there is a decrease in the number of transient relaxations of the lower esophageal sphincter.[32–35] However, infants should not be placed in an inclined or nonsupine position for sleep as treatment of GERD.

Hyperbilirubinemia

Prone positioning is sometimes used in alternation with supine positioning while infants are being treated with phototherapy for hyperbilirubinemia. However, a systematic review found supine positioning was equally effective to periodically turning infants.[36] The National Institute for Health and Clinical Excellence (NICE) in the United Kingdom stated that positioning has no significant influence on the mean change in serum bilirubin concentration or the duration of phototherapy for infants born at term.[37] As such, the NICE recommends infants be placed in the supine position while being treated with phototherapy to ensure consistent advice about SIDS risk.[37] Since the NICE recommendation, a study of infants born at ≥33 weeks' gestation compared supine with alternating positioning and found identical rates of decrease in total serum bilirubin concentration at 12 and 24 hours after initiation of phototherapy.[38] The consistency of the results in both term and preterm infants confirm that barring another medical condition requiring prone position, hyperbilirubinemia should be treated routinely in the supine position.

Neonatal Opioid Withdrawal Syndrome

The infant with neonatal opioid withdrawal syndrome (NOWS) is generally treated with supportive, nonpharmacologic care designed to minimize stimulation and to support the infant's self-regulation.[39,40] In one study, prone positioning was associated with decreased severity of NOWS scores and reduced caloric intake.[41] Although prone positioning may be useful for monitored inpatients during the acute withdrawal phase of NOWS, it should be discontinued when possible and before hospital discharge to decrease SUID risk.

BEDDING AND POSITIONERS

Per AAP recommendations, infants at home should be placed on a flat, firm sleep surface (ie, crib, bassinet, portable crib, or play yard that conforms to the safety standards of the Consumer Product Safety Commission)[2,42,43] covered by a fitted sheet with no other bedding. Because soft bedding and loose objects in the sleep environment can obstruct the infant's airway, increasing the risk of rebreathing, SIDS, and suffocation,[44–52] these items should not be in the sleep environment. Although bedding and positioners are often used for developmentally sensitive care and for treatment of plagiocephaly, these items should be removed from the sleep environment.

Developmentally Sensitive Care

Developmentally sensitive care is an important therapeutic intervention for preterm and other ill infants. However, because such care often may be inconsistent with provisions for a safe infant home sleep environment, staff should use demonstration of these techniques as a teachable moment with the family regarding eventual readiness for safe infant sleep positioning and environment.

Developmentally sensitive care refers to a broad category of

interventions designed to minimize the stress of the extrauterine environment and optimize the physical and neurodevelopmental outcomes for preterm and ill neonates.[53,54] These may include therapeutic positioning, swaddling, or other strategies. Although there is controversy regarding the effectiveness of formalized programs for developmentally sensitive care, components of these approaches may improve short-term outcomes. Integration of developmentally sensitive care has been endorsed by professional organizations, such as the National Association of Neonatal Nurses, with development of guidelines and quality metrics.[54–64]

Therapeutic positioning keeps the infant contained and maintains the fetal midline position of flexion to support comfort and self-regulation.[55–59] This positioning may involve the time-limited use of positioning devices, including blanket rolls and commercially available products. Without support from these devices, the preterm infant will lie flat and asymmetric with hips and joints abducted with abnormal rotation. Over time, this may lead to musculoskeletal and neurodevelopmental abnormalities, including upper extremity hyperabduction and flexion and generalized muscular rigidity.[55] Positioning devices are incompatible with a safe home sleep environment and, although the AAP encourages transitioning to a safe sleep environment at 32 weeks' postmenstrual age, not all infants will have achieved positional stability by this age, resulting in wide interpretation at the bedside.[7,65–67] Through quality improvement research, some centers have developed programs for consistent timing and increased compliance with safe sleep recommendations[8,11,68–73] (see section on A Rational Approach to Transition of the NICU Patient to a Home Sleep Environment).

Positional or Deformational Plagiocephaly

Positional or deformational plagiocephaly (DP) (most commonly unilateral flattening of the parieto-occipital region, with compensatory anterior shift of the ipsilateral ear and anterior displacement of the ipsilateral forehead) results from unevenly distributed external pressure resulting in abnormal head shape.[74] DP is common in the NICU and may occur secondary to limitations on positioning, muscle tone, nursing care practices, and other medical conditions.[75,76] Preterm infants are more susceptible to developing plagiocephaly attributable to decreased mineralization of the skull bones, increased prone positioning, placing the infant repeatedly on the same side and slower motor development. Although pediatric occupational and physical therapists frequently use a variety of positioning devices and supports to correct DP (and the often accompanying torticollis),[77–80] these products should be removed before hospital discharge, because they are contrary to home safe sleep recommendations. Thus, home therapy should be limited to creating a nonrestrictive environment that promotes spontaneous physical movement and symmetrical motor development.[81,82]

As infants who require developmentally sensitive care or treatment of DP mature and approach discharge readiness, an interdisciplinary, collaborative, and thoughtful approach is required to determine how and when positioning devices should be discontinued and removed to achieve a safe home sleep environment. In addition, communication with and education of the infant's family are crucial to promote understanding of safe sleep practices and decrease the inappropriate use of the devices after hospital discharge.

SKIN-TO-SKIN CARE AND THE USE OF A SEPARATE SLEEP SURFACE

The benefits of skin-to-skin care (SSC) are numerous and include improved initiation and maintenance of breastfeeding, thermoregulation and glucose homeostasis, decreased crying, and cardiorespiratory stability.[83–87] In preterm infants, SSC improves autonomic and neurobehavioral maturation and results in better sleep patterns and growth.[58,88] However, there are potential complications, including infant falls and sudden unexpected postnatal collapse, when SSC is not appropriately monitored. When SSC is performed in the NICU, close monitoring is important, and the parent should be educated about the dangers of sharing a sleep surface, whether in the hospital or home. Although parents may unintentionally fall asleep with their infant at home, this is especially dangerous with the preterm or low birth weight infant.[3,13,89] Thus, it is important to reinforce safe sleep education when mothers are rooming-in with their infants and are not under the constant observation of NICU staff. The risk of falls and sudden unexpected postnatal collapse should be mitigated by conducting frequent assessments and monitoring of the mother-infant dyad for maternal fatigue. If the caregiver is becoming drowsy while caring for the infant, then the infant should

be moved to a separate sleep surface.[87]

THERMOREGULATION

In the NICU, thermoregulation issues tend to focus on the prevention of hypothermia, because it is well established that achieving normothermia optimizes outcomes, including reductions in mortality. Preterm infants have more difficulty with thermoregulation than term infants; however, this improves with maturation.[90] Although weight-based criteria for weaning from the incubator to open bassinet varies among NICUs, a Cochrane review found that transfer out of thermoregulatory support at a weight of 1600 g did not adversely affect temperature stability or weight gain.[91–94]

As preterm infants stabilize in an open environment, attention should be redirected from hypothermia to modeling safe sleep with the prevention of overheating and overbundling. Families should be educated on evaluating the infant for signs of overheating, such as sweating or the torso feeling hot to the touch.[2] Parents should also be warned about the potential for head covering, including hats, to contribute to overheating and thermal stress. A recent article found that in a large cohort of preterm infants, the failure rate attributable to hypothermia for transitioning out of supplemental heat without a hat was 2.7%.[95] Given the questionable benefit of hat use and the potential for overheating with head coverings, clinicians should carefully weigh the risks and benefits regarding the discharge of an infant from the NICU with a hat. If the infant is discharged wearing a hat during sleep, the clinician should provide education to the family regarding discontinuation once the infant achieves stable temperatures in the home environment. This should include education about how to determine that the infant's temperature is stable.

SWADDLING

In the NICU, swaddling, or the snug wrapping of an infant in a light blanket, is an important part of developmentally sensitive care. When swaddled, preterm infants should be placed in the supine position, have their hands brought to midline under the chin, and hips and knees should be in the flexed position and able to move freely.[96] Swaddling may be useful in helping preterm infants maintain a normal temperature.

Swaddling is also commonly used in the care of infants with NOWS. Although no studies specifically address swaddling in this population, it has been suggested that it is beneficial in decreasing excessive crying and promotion of sleep.[39,40] This may be related to inhibition of the Moro reflex when swaddling with the arms tucked in the swaddle.

When infants are swaddled, wearable blankets (which often have a swaddle wrap component) are preferred to conventional blankets for providing warmth while preventing head covering. Proper swaddling technique should allow the hips to be flexed and abducted to reduce the risk of exacerbating developmental dysplasia of the hip.[97]

Because there is a much greater risk of sudden unexpected death if infants are swaddled and then placed in a nonsupine position,[97–100] care must be taken to always place swaddled infants supine. In addition, when the infant begins to attempt to roll over, swaddling should be discontinued.

HUMAN MILK AND BREASTFEEDING

There are numerous benefits to breastfeeding, including decreased risk of infection and decreased risk of allergies, asthma, eczema, obesity, inflammatory bowel disease, high cholesterol, type 1 diabetes mellitus, SIDS, and possibly some childhood cancers.[101–104] In the preterm infant, human milk has also been shown to improve feeding tolerance and reduce the risk of necrotizing enterocolitis.[105–108]

Given both the early and long-term benefits for the preterm infant, clinicians should provide family education on the importance of human milk on admission to the NICU or earlier if possible.[109] Multidisciplinary teams should be available to support breastfeeding and expression and provision of mother's milk, not just during the hospitalization but also after discharge for the transition to direct breastfeeding at home.[110,111]

A RATIONAL APPROACH TO TRANSITION OF THE NICU PATIENT TO A HOME SLEEP ENVIRONMENT

Programs to model and teach safe infant sleep in both the newborn nursery and the NICU have been developed.[8,11,68–73,112,113] These programs typically include standardized policies for infant sleep safety consistent with AAP recommendations, education for both staff and families, visible educational prompts, modeling of safe sleep, and audits for quality improvement. One NICU study demonstrated maintenance of improvement at 6-month audits after intervention, with 98% of infants lying supine in open cribs, 93% in a wearable blanket, and 88% of bassinets with a visible safe sleep card.[71] Furthermore, standardized programs have been associated with higher rates of supine sleep and other safe sleep behaviors in the home.[11,72,73]

One of the challenges in transitioning the NICU patient to a safe home

sleep environment relates to resolving therapeutic positioning practices for the infant that are inconsistent with sleep safety at home. Although the AAP through its Committee on Fetus and Newborn recommends that "hospitalized preterm infants should be kept predominantly in the supine position, at least from the postmenstrual age of 32 weeks onward, so that they become acclimated to supine sleeping before discharge,"[5] not all infants will be clinically ready to be maintained in such a sleep environment at that age. To manage clinical variability, algorithms have been developed on the basis of literature review, expert opinion, and unit consensus.[11,114] Quality improvement programs using these algorithms have demonstrated more consistent modeling in the NICU and improved parental adherence with safe sleep practices after hospital discharge.[11,114] In one study, 2 Massachusetts community NICUs improved overall adherence with practices consistent with sleep safety at home from 25.9% to 79.7% ($P < .001$),[114] and this standardized approach to integrating these safe sleep practices into routine NICU care was adopted by all NICUs statewide.[115] In another study, a decision-guiding algorithm led to significant improvement in both NICU staff and parental compliance, with safe sleep practices in the home increasing from 23% to 82% ($P < .001$).[11]

Creating a culture of infant sleep safety in the NICU setting can be challenging. Resistance to change is common, so consensus-building is essential to success. An algorithm such as that published by Gelfer et al[11] can be used as a starting point for the input of a multidisciplinary team including all of those involved with the care of the infant, including but not limited to physicians, advanced practice providers, nursing staff, lactation consultants, respiratory therapists, and developmental therapists (physical therapy, occupational therapy, speech therapy).

Clinicians must address the acute physiologic needs of the NICU infant; incremental transition to a safe home sleep environment can begin as these needs resolve. Because preterm infants are at increased risk of SUID, clinicians should provide regular, repetitive, and consistent safe sleep education with families throughout the hospitalization. Through messaging with not only words but also modeling behaviors, clinicians will enable NICU families to be better prepared for the transition to a safe home sleep environment.

RECOMMENDATIONS

Overall recommendations for transition to safe home sleep for the NICU patient are provided below. Table 1 summarizes transition issues as pertaining to infant sleep safety.

1. The intensive care nursery should develop a safe sleep policy incorporating the points below, with the goal of transitioning the infant to a safe home sleep environment consistent with the recommendations of the AAP Task Force on SIDS.[8,69,72,112,113,116–120]
2. The NICU should use an algorithm for routine and repeated evaluation of each NICU infant for safe home sleep readiness.[11,114,115]
3. Incremental implementation of components of a safe sleep environment can be implemented for NICU infants not ready to completely transition to a safe home sleep environment (eg, the infant may be ready for supine positioning but may still need positioners for plagiocephaly).[11,114,115]
4. All staff involved in the care of NICU infants should receive education on and maintain expertise in infant sleep safety, including the AAP recommendations, hospital policy, and transitional algorithm.*
5. Family education regarding infant sleep safety should be provided early and often throughout the hospital course.† Multiple communication strategies (bedside cards, whiteboards) should be used to increase parental awareness and provide anticipatory guidance for NICU infants who are not clinically ready to transition to a safe home sleep environment. One example is a bedside card denoting that the infant is receiving therapeutic positioning because of prematurity or illness.[11,114,115,121]
6. When the infant is deemed ready for transition to a safe home sleep environment, the therapeutic positioning card should be replaced with messaging that the infant is now being maintained in a safe sleep environment.[11,114,115,121]
7. When the infant transitions to the safe home sleep environment, consideration should be given to using this opportunity to provide formal safe sleep education for the family and celebrate the event on par with a developmental milestone.[11,114,115,121]
8. If an infant has a clinical deterioration after going into a safe home sleep environment, then therapeutic positioning may need to be reinstituted. As soon as the infant is clinically stable again, he or she should be

*Refs 8, 11, 69, 72, 73, 112–115, 118, and 120–123.
†Refs 8, 11, 68–70, 72, 112, 113, 118–120, and 122–125.

TABLE 1 NICU Transition to a Safe Home Sleep Environment

Respiratory distress[11,14,16,17,24,66,112,114]
- a. For the infant with acute respiratory distress, regardless of gestational age, nonsupine positioning may be used as clinically indicated to stabilize/improve respiratory function.
- b. If nonsupine positioning is used, especially as the infant matures, parents should be educated about infant home sleep safety and the reasons for using therapeutic positioning.
- c. Once the acute respiratory distress is resolving, the infant should be placed supine for modeling infant home sleep safety, and the parents should receive additional education before hospital discharge.
- d. For infants who have developed chronic lung disease, periodic assessments should be performed to monitor the infant's progress. Once the infant has weaned to a standardized minimal supplemental respiratory support (determined by the individual institution), then supine positioning can be maintained, and parents should receive additional education before hospital discharge.
- e. The management of the infant with upper airway obstruction needs to be individualized on the basis of the severity of the obstruction. Nonsupine positioning may be necessary to prevent excessive hypercarbia or hypoxemia and consideration should be given to home monitoring of the marginal airway.

Apnea of prematurity[27–29,134]
- a. There is inadequate evidence to justify the use of prone positioning for the treatment of apnea of prematurity.
- b. For more information on apnea of prematurity, please refer to the clinical report on apnea of prematurity from the AAP.[134]

Gastroesophageal reflux and GERD[4,30,33]
- a. Gastroesophageal reflux is extremely common in infants in the NICU.
- b. Because of the increased risk of SUID, infants with gastroesophageal reflux or GERD should not have the head of the bed elevated, nor should they be laid down on their side or prone.
- c. For more information refer to the clinical report on gastroesophageal reflux in the preterm infant by the AAP.

Hyperbilirubinemia and phototherapy[36,38,135,136]
- a. There is no benefit to changing infant position while undergoing phototherapy.
- b. Unless there are other competing medical issues, infants should be kept supine while receiving phototherapy to model and promote infant home sleep safety.

NOWS[2,39–41]
- a. There are some commonly used therapeutic interventions in the treatment of NOWS (ie, prone positioning) that are not consistent with infant home sleep safety.
- b. Early and frequent education is critical to prevent families from thinking that the proper use of therapeutic interventions in the hospital can be replicated in the home environment.
- c. The use of therapeutic interventions that are not consistent with infant home sleep safety should be minimized. When interventions are necessary, it is important to review their use and attempt to transition to a safe home sleep environment as soon as clinically stable.
- d. Clear, consistent, safe home sleep messaging should be emphasized repeatedly with families of infants with NOWS throughout the hospitalization.

Developmentally sensitive care[11,71,112,114,119]
- a. Developmentally sensitive care is an important component to the health and well-being of the preterm infant.
- b. Although many of the tools and therapies used to promote developmentally sensitive care are not consistent with a safe home sleep environment for infants, parental observation of these techniques can serve as a teachable moment for eventual safe sleep readiness.
- c. It is important to transition infants to a safe home sleep environment as early as possible before NICU discharge.
- d. Good communication with the use of a multidisciplinary team is key for consistent transitioning of NICU patients to a safe infant home sleep environment (see A Rational Approach to Transition of the NICU Patient to a Home Sleep Environment for details).

DP and torticollis[2,77–82]
- a. Positioning devices recommended by qualified personnel, such as but not limited to occupational and physical therapists, can be used to prevent, control, and correct DP and torticollis while infants are under continuous monitoring in the NICU.
- b. Parents need to be educated regarding the use of sleep positioning devices: that their use is limited to the inpatient setting under strict monitoring, and that they are not part of a safe home sleep environment.
- c. Education regarding tummy time should emphasize that it be performed during awake, supervised periods only and never when the infant is asleep, even with "close" supervision.

Thermoregulation[2,90,94,99,100,137–140]
- a. Preterm and low birth weight infants are prone to temperature instability and may require additional bundling to avoid hypothermia.
- b. Excessive bundling needs to be avoided because overheating and head covering have been associated with an increased risk of SUID.
- c. If an infant is discharged wearing a hat, families should be counseled to discontinue its use once the infant demonstrates temperature stability in the home environment.
- d. If swaddling is performed, it is important that it is done properly, the infant is always placed supine, and it is discontinued before the infant is able to roll over.

DDH[97–100]
- a. Infants are frequently swaddled in the NICU when approaching hospital discharge; however, improper swaddling can lead to or exacerbate DDH. Proper swaddling technique should allow the hips to be flexed and abducted.
- b. Parents should be well-educated about all safety issues regarding swaddling, in particular the increased risk of SUID with nonsupine positioning.
- c. For more information refer to the clinical report on DDH by the AAP.

Human milk and breastfeeding[2,87,89,101–104,110,111]
- a. The use of human milk is recommended for its numerous health benefits, including a reduced risk for SIDS.
- b. Special care should be taken when mothers are rooming-in and breastfeeding to minimize the risk of falling asleep with the infant in the adult bed.
- c. Provide mothers with appropriate outpatient support to optimize breastfeeding success after hospital discharge.

DDH, developmental dysplasia of the hip.

returned to a safe home sleep environment.[11,114,115,121]

9. Before hospital discharge, all NICU families should receive standardized safe infant sleep education and be queried about a safe home sleep environment followed by applicable counseling.‡
10. If the family does not have the means for a safe home sleep environment, then a referral should be made to social work for assistance and/or referral to resources that can provide cribs or portable play yards at low or no cost.[126–129]
11. Crib audits should be an integral component of a NICU safe sleep program to monitor success or identify areas for improvement. Consider the use of run charts to allow staff to see real-time feedback on whether an intervention is working. This is integral for determining the need for and implementation of plan-do-study-act cycles.§
12. Consideration should be given to incorporating safe sleep education into the electronic medical record. Examples include assessments for a safe sleeping home environment and alerts to perform the assessment and complete the education.[130–133]
13. Include primary and ancillary care providers and neurodevelopmental teams in preparation for a smooth transition to home that includes maintenance and reinforcement of a safe home sleep environment.

Transition to a Safe Home Sleep Environment for the NICU Patient

Michael H. Goodstein, MD, FAAP,[a,b] Dan L. Stewart, MD, FAAP,[c] Erin L. Keels, DNP, APRN-CNP, NNP-BC,[d,e] Rachel Y. Moon, MD, FAAP,[f] COMMITTEE ON FETUS AND NEWBORN, TASK FORCE ON SUDDEN INFANT DEATH SYNDROME

Of the nearly 3.8 million infants born in the United States in 2018, 8.3% had low birth weight (<2500 g [5.5 lb]) and 10% were born preterm (gestational age of <37 completed weeks). Many of these infants and others with congenital anomalies, perinatally acquired infections, and other disease require admission to a NICU. In the past decade, admission rates to NICUs have been increasing; it is estimated that between 10% and 15% of infants will spend time in a NICU, representing approximately 500 000 neonates annually. Approximately 3600 infants die annually in the United States from sleep-related deaths, including sudden infant death syndrome *International Classification of Diseases, 10th Revision* (R95), ill-defined deaths (R99), and accidental suffocation and strangulation in bed (W75). Preterm and low birth weight infants are particularly vulnerable, with an incidence of death 2 to 3 times greater than healthy term infants. Thus, it is important for health care professionals to prepare families to maintain their infant in a safe sleep environment, as per the recommendations of the American Academy of Pediatrics. However, infants in the NICU setting commonly require care that is inconsistent with infant sleep safety recommendations. The conflicting needs of the NICU infant with the necessity to provide a safe sleep environment before hospital discharge can create confusion for providers and distress for families. This technical report is intended to assist in the establishment of appropriate NICU protocols to achieve a consistent approach to transitioning NICU infants to a safe sleep environment as soon as medically possible, well before hospital discharge.

INTRODUCTION

According to the 2016 policy statement from the American Academy of Pediatrics (AAP) Task Force on Sudden Infant Death Syndrome, all infants, including preterm and low birth weight infants, in the NICU should be placed in the supine position for sleep as soon as they are

medically stable and significantly before their anticipated discharge from the hospital. In particular, very preterm infants should be kept predominantly in the supine position by 32 weeks' postmenstrual age (PMA) so that they become acclimated to supine sleeping before discharge from the hospital.[1–3] There are many other factors that define a safe sleep environment to minimize the risk of sudden infant death syndrome (SIDS), accidental suffocation and strangulation, and undetermined sleep deaths (collectively known as sudden unexpected infant death [SUID]), as outlined in the same 2016 policy statement.

During NICU hospitalization, infants are routinely kept in an environment that is not consistent with these recommendations for numerous reasons, on the basis of both treatment of underlying pathophysiology as well as the normal physiology of the preterm infant. Pathologic conditions resulting in short-term respiratory distress (respiratory distress syndrome and transient tachypnea of the newborn) or long-term respiratory compromise (bronchopulmonary dysplasia and pulmonary hypoplasia) result in use of positioning inconsistent with safe sleep messaging. Other conditions that may be pathologic, such as gastroesophageal reflux (GER), lead to the use of therapeutic interventions such as side-lying position and elevation of the head of the bed, maneuvers the literature suggests may be of questionable value.[4] To reduce the need for narcotic and anxiolytic medications, which have been reported to have adverse effects on neurodevelopment,[5–7] infants with neonatal opioid withdrawal syndrome (NOWS) may be positioned prone or swaddled firmly. Developmental care for the optimal growth and maturation of the preterm infant can include the use of nonsupine positioning, soft mattresses, and positioners. Although developmental care has been shown to be beneficial to the long-term neurodevelopmental outcomes of preterm infants, many of the tools involved in the constantly monitored NICU environment are contraindicated after hospital discharge. Transition to a safe sleep environment as soon as medically possible, well before discharge from the hospital, is extremely important because in preterm infants the adjusted odds ratio (aOR) for SIDS is 1.85 to 2.72 and for suffocation is 1.86 to 2.59 compared with term infants, and the sleep environment greatly affects the risk of these sleep-related deaths.[1,8]

Although the AAP through its Committee on Fetus and Newborn recommended the transition to the use of the supine position by 32 weeks' PMA[3] in 2008, and this recommendation was supported by the AAP Task Force on Sudden Infant Death Syndrome in 2011,[1,2] there is long-term and ongoing nonadherence to this recommendation from NICU providers.[3,9,10] Research on resistance to this recommendation has thus far been focused on only NICU nurses. In a 2006 survey of 252 NICU nurses, 65% identified prone positioning as the best general sleep position for preterm infants, followed by 12% who believed either prone or side-lying position was the best sleep position.[9] In addition, the nurses surveyed were inconsistent regarding how they determined when a preterm infant is ready to sleep supine. Answers included close to discharge (13%), when maintaining their body temperature in an open crib (25%), PMA of 34 to 36 weeks (15%), PMA ≥37 weeks (13%), and when the infant's respiratory status was stable (6%). Nursing beliefs and knowledge continue to be a barrier to a culture of consistent safe sleep messaging. A 2016 survey of 96 NICU nurses found that 53% strongly agreed that recommendations make a difference in preventing SIDS, and only 20% strongly agreed that parents would model nurses' behaviors at home.[10]

Various reasons are given to explain why nonsupine positioning and other common practices contrary to a safe sleep environment persist even when infants are approaching discharge from the NICU. However, studies find that when expectant or new parents receive education on infant sleep safety on a consistent basis, their knowledge increases and their safe sleep behaviors improve, regardless of the setting (eg, well-infant nursery, NICU, Special Supplemental Nutrition Program for Women, Infants, and Children office, community health center).[11–14] The purpose of this report is to address the many issues that result in conflict with safe sleep guidelines, looking at the validity of practices based on review of the evidence regarding pathophysiology and normal physiology of the vulnerable infant. The goal of this technical report is not to provide an all-encompassing review of the literature for each issue but rather a summary of data for each issue and provide suggestions to resolve conflicting practices. By creating a consistent approach to transitioning the infant in the NICU to a safe sleep environment as soon as medically possible, well before hospital discharge, families can be exposed to modeling of safe sleep behaviors that could decrease the risk of SUID in this vulnerable population. Areas of concern include developmental care and/or neurodevelopmental issues, positional plagiocephaly and/or torticollis, orthopedic issues

(developmental hip dysplasia), respiratory distress, GER and/or aspiration, thermoregulation, jaundice, and neonatal drug withdrawal. Some of this content and the advice provided may also be applicable to infants in the well newborn and pediatric inpatient units.

DEVELOPMENTALLY SENSITIVE CARE

Infants born preterm have increased risks of poor neurodevelopmental outcomes, with risks increasing as the gestational age decreases.[15,16] Developmentally sensitive care is a broad term given to a number of interventions aimed at modifying the imperfect extrauterine environment to optimize physical and neurodevelopmental outcomes for preterm and ill neonates.[17] This is achieved through a patient-centered approach that protects sleep, manages pain and stress, supports essential activities of daily living (ie, positioning, feeding, and skin care), integrates family and/or caregivers into the plans of care, and modifies the physical environment.[17] Conflicting information exists about the effectiveness of formalized and programmatic approaches to developmentally sensitive care.[18,19] However, there is evidence that components of these approaches, particularly skin-to-skin care (SSC)[20–22] and breastfeeding,[23] promote improved short-term outcomes in response to the suboptimal environment of the NICU. Despite the disagreements in the literature about the effects of programs or packages of developmental care, integration of developmentally sensitive care in the NICU has been endorsed by professional organizations,[24,25] and formal programs, recommendations, guidelines, and quality metrics exist.[26–28] Commonly used techniques of developmental care that may affect the appropriate transition to safe sleep include positioning, use of positioning aids, swaddling, and SSC.

Positioning and Use of Positioning Aids

As the fetus rapidly grows in size during the third trimester of pregnancy, the intrauterine environment becomes more restrictive, and the fetus moves into a midline position of flexion.[29] This position of the head, shoulder, hip, and knee flexion; scapular protraction; and posterior pelvic tilt help the fetus develop appropriate skeletal shapes, flexor muscle tone, stretch reflexes, and self-regulating behaviors.[29] With preterm birth comes, among other things, loss of the physiologic flexion positioning of the intrauterine environment.[29] If not supported, the preterm infant lies flat and asymmetric, with hip and joints abducted with abnormal rotation, unable to bring himself or herself to a flexed and midline position for comfort and self-regulation. Over time, this may lead to musculoskeletal and neurodevelopmental abnormalities, such as upper extremity hyperabduction and flexion and generalized muscular rigidity. To help prevent these morbidities and provide comfort and decrease measures of stress, neonatal nurses, families, and other caregivers therapeutically position the preterm infant in a flexed, midline, and contained position, with the head and neck in a neutral posture, shoulders rounded with hands brought to the midline, trunk in "C" curve, pelvis in posterior tilt, hips and legs in symmetrical and neutral flexion and rotation, and feet supported.[29–31] Therapeutic positioning is achieved through the use of various positioning devices and supports, such as diapers or blanket rolls as well as commercially available products.[30–33] Currently, there is no standardized protocol or device to direct and provide therapeutic positioning, leaving the choice in many cases to the individual nurse or caregiver.[34] The Infant Positioning Assessment Tool was developed to help provide caregiver education, standardization, and evaluation of therapeutic positioning.[35,36] The Infant Positioning Assessment Tool has demonstrated initial validity and reliability but has not been widely implemented.[35,37,38] As the infant matures and approaches readiness for discharge from the hospital, an interdisciplinary, collaborative, and thoughtful approach is required to determine how and when the use of positioning devices is discontinued and removed from the infant's bedding to achieve a safe sleep environment. Additionally, communication and education of the infant's caregivers and family are crucial elements to avoid confusion, conflicting information, and inappropriate use of the devices after discharge from the hospital.[39]

Many developmental care guidelines include the AAP Safe Sleep recommendations and encourage the transition into a safe sleep environment for medically stable infants after the age of 32 weeks' gestation and before discharge from hospital to home.[26–28] However, no specific time frame has been established to meet this goal, leading to wide interpretation at the bedside.[10,40–42] Some centers have developed quality and process improvement programs to establish more concrete timing and increased compliance with the Safe Sleep recommendations.[43,44]

Impact of Light and Noise Reduction on the Safe Sleep Environment

NICUs and special care nurseries can be overstimulating to preterm and sick newborn infants. Lighting, noise, and temperature can be sources of noxious stimuli.[45–47] In an effort to

modify the external environment to decrease stressful stimulation, many nurses and caregivers will place a blanket or other covering over the infant's head of the bed.[48] If not well secured, these coverings could become loose and cover the infant, increasing the risks of smothering. The removal of loose blankets in the crib is an important strategy toward implementing a safe sleep environment.[1,2]

Swaddling

The practice of swaddling infants has been described in many cultures throughout history.[49] Infant swaddling, in which a cloth or device is wrapped around the infant to contain the infant's body and extremities, has been shown to promote sleep[49]; improve self-regulation, particularly in preterm infants[49]; and decrease crying time.[50] Swaddling also has been shown to promote supine sleep position.[51] However, inappropriate use of and/or tight swaddling can increase the risks of developmental hip dysplasia, cause overheating, and restrict breathing. It has been associated with vitamin D deficiency, acute respiratory tract infections, and delayed regain of birth weight and may interfere with early establishment of breastfeeding.[49,52,53] There is a much greater risk of SUID when a swaddled infant is placed in or rolls to the prone position.[54–56] When swaddled, preterm infants should be placed in the supine position, have their hands brought to midline under the chin, and hips and knees should be in the flexed position and able to move freely.[50] Term infants, especially those with NOWS, may benefit from swaddling with arms tucked in the swaddle to reduce startle response and prevent the hazard of loose blankets in escaping from the swaddle. Because of the risk of SUID when swaddled infants are in the side or prone position, swaddling should be discontinued when the infant begins to attempt to roll over.[50,55,56] For a more extensive discussion about the potential risks and benefits of swaddling, refer to the technical report, "SIDS and Other Sleep-Related Infant Deaths: Evidence Base for 2016 Updated Recommendations for a Safe Infant Sleeping Environment" (currently undergoing revision).[1]

Skin-to-Skin Care

SSC, or kangaroo mother care, is the practice of placing the infant's unclothed chest against the mother's unclothed chest for immediate, continuous, and sustained contact and exclusive breastfeeding.[57] SSC was initially adopted as an alternative to incubators in countries with limited resources in the late 1970s and subsequently demonstrated improved survival for preterm and low birth weight infants.[58] Now widely adopted in countries with both limited and abundant resources, the practice of SSC has been shown to promote temperature and blood sugar stability, lower respiratory rate, increase oxygen saturation, decrease symptoms associated with mild to moderate pain, and promote maternal bonding and attachment and breastfeeding. These advantages may all contribute to overall physiologic and neurobehavioral development.[22,59–61] However, safety concerns have arisen with the increased practice of SSC. Dislodgement of life support equipment and dropping small and immature infants, falling out of bed, and airway obstruction have all been reported. When occurring in healthy term or late preterm infants, these events are referred to as sudden unexpected postnatal collapse, which frequently results in death or severe neurologic impairment.[62] These unfortunate but real events remind caregivers and parents to be mindful and vigilant of the position of the infant's airway and the safety of caregiver holding to prevent falls when providing SSC.[22,62] If this is undertaken in the NICU, the infant should be monitored and secured, preferably with a conforming wrap carrier. The parent should be positioned in a recliner or approved kangaroo care chair or hospital bed and the kangaroo care provider should be educated by staff about how this situation differs from the home environment. Because of the concerns noted above and the known dangers of sharing sleep surfaces, such as bed-sharing in the home environment, adults should be thoroughly educated about the dangers of sleeping during SSC.

Conclusions Regarding Developmentally Sensitive Care

1. Developmentally sensitive care is an important component to the health and well-being of the preterm infant.
2. Many of the tools and therapies used to promote developmentally sensitive care are not consistent with a home safe sleep environment.
3. It is important to transition infants to a home safe sleep environment well before discharge from the NICU.
4. Good communication with the use of a multidisciplinary team is key for consistent transitioning of NICU patients to a home safe sleep environment (see A Rational Approach to Transition of the NICU Patient to a Home Sleep Environment for details).

DEFORMATIONAL PLAGIOCEPHALY AND TORTICOLLIS

Variations in head shape are often observed in term and preterm infants in the NICU. These head shape abnormalities can be secondary to nursing care practices, limitations on positioning, muscle

tone, or other medical conditions that can lead to positional or deformational plagiocephaly (DP).[63,64]

Preterm infants are more susceptible to developing plagiocephaly because of decreased mineralization of the skull bones. In addition, they are more likely to have been positioned prone, which may be indicated when the infant is medically unstable to decrease stress, promote sleep, improve feeding tolerance, and enhance oxygenation and ventilation. Although therapeutic positioning to promote medical stability takes precedence during the acute phase of illness, whenever possible, nurses should make efforts to choose positions that promote symmetrical cranial shape.[65–67]

Since the early 1990s, DP has been increasing in prevalence and is being more frequently diagnosed. Most parents and health care professionals attribute this increase to the supine sleep position recommended for infant safety,[68] although this has been challenged in recent studies.[69–72] It was estimated that 46.6% of 7- to 12-week-old infants had nonsynostotic plagiocephaly (NSP) in a Canadian cohort study,[72] and in a Swedish study in 2009, 42% of 2-month-old infants had some degree of NSP.[73] In a prospective New Zealand study, there were significant multivariate risk factors for NSP at 6 weeks, including newborn passive head rotation (aOR: 9.51; 95% confidence interval [CI]: 2.59–34.94), 6-week sleep position (aOR: 5.27; 95% CI: 1.81–15.39), and upright time (aOR: 3.99; 95% CI: 1.42–11.23). At 4 months, risk factors were limited passive head rotation at birth (aOR: 6.51; 95% CI: 1.85–22.98), limited active head rotation at 4 months (aOR: 3.11; 95% CI: 1.21–8.05), tried but unable to vary head position at 6 weeks (aOR: 4.28; 95% CI: 1.58–11.59), low activity level at 4 months (aOR: 3.28; 95% CI: 1.16–9.29), and average to difficult rating on the Pictorial Assessment of Temperament test (aOR: 3.30; 95% CI: 1.17–9.29).[70]

Whether congenital muscular torticollis is the main predisposing factor for DP remains controversial. Although one study found asymmetries of the head and neck to be common in normal newborn infants, and 16 (16%) of 102 were found to have torticollis at birth,[74] other recent studies suggest that cranial shape is more often determined by postnatal factors than prenatal and perinatal factors and that most concomitant cervical imbalance (positional torticollis) develops postnatally along with DP.[75]

DP results from unevenly distributed external pressure, resulting in abnormal head shapes. Most cases involve unilateral occipital flattening, ipsilateral frontal bossing, and anterior shifting of the ipsilateral ear and cheek.[76] A rapidly growing head is malleable and most susceptible to deformation between 2 and 4 months and declines thereafter.[70,72,77] Placing the infant repeatedly on the same side according to infant preferences, as well as slower motor development, are risk factors for the development of DP. In the NICU, occupational and physical therapists often make use of various positioning devices and supports, such as blanket rolls and commercially available products, to prevent progression and to correct DP and torticollis.[30–33] However, these therapies are contraindicated when the infant is getting closer to discharge from the hospital, as they are generally not consistent with home infant sleep safety recommendations.

Many infants with DP undergo additional treatment at home. Such treatments, including physical therapy, need to be in line with safe sleep recommendations. Devices that promote a nonsupine sleep position or have the potential to compromise the airway are not appropriate. The "Congress of Neurological Surgeons Systematic Review and Evidence-Based Guideline on the Management of Patients With Positional Plagiocephaly: The Role of Repositioning" stated that it cannot at this time endorse any sleep positioning device because it would be contrary to the repeated recommendations set forth by the AAP Task Force on Sudden Infant Death Syndrome to avoid placing any soft surface bedding in the infant's crib.[78] Although orthotic helmet therapy can be difficult for the parents and can cause side effects, including sweating, irritation, and pain for the infant, they can provide significant and faster improvement of cranial asymmetry in infants with positional plagiocephaly compared with conservative therapy. The Congress of Neurologic Surgeons recommends a helmet for infants with persistent moderate to severe plagiocephaly after a course of conservative treatment or if the infant presents at an advanced age.[79]

A recent randomized controlled trial in Finland evaluated the causal relationship between DP and cervical imbalance (positional torticollis). The intervention group was given instructions to create a nonrestrictive environment that promotes spontaneous physical movement and symmetrical motor development.[77] The instructions focused on 3 areas: alternating head position laterally (left and right) during feeding and sleep, avoiding excessive awake time in supine position (including prolonged placement in car seats and other devices) in addition to using tummy time daily, and preventing

restriction of movement. Infant neck stretching exercises were performed by the parents if an infant showed signs of muscular imbalance of the neck.[77] Infants in the intervention group were less likely to have DP at follow-up, and if present, the asymmetry was milder. In addition, infants who had DP were more likely to have torticollis. This study concluded that early intervention reduces the prevalence and severity of DP at 3 months.[77]

The Finnish randomized controlled trial was similar to a prevention project among Swedish child health nurses that incorporated a short cranial asymmetry prevention program.[80] In this study, researchers concluded that education of child health nurses, who in turn educate parents about NSP prevention, is successful in increasing parents' awareness of safe interventions to prevent acquired cranial asymmetry.[80]

These studies provide an evidence-based approach that the parents can use to maintain the supine position for infant safety while decreasing the risk of NSP and/or DP and cervical imbalance (positional torticollis). For more information on congenital muscular torticollis, see the 2019 AAP State of the Art report: Congenital Muscular Torticollis: Bridging the Gap Between Research and Clinical Practice.[81] For more information on DP, see the Congress of Neurologic Surgeons Systematic Review and Evidence-Based Guidelines for the Patients With Positional Plagiocephaly.[78,79,82–84]

Conclusions Regarding DP and Torticollis

1. DP and torticollis occur commonly in the NICU environment.
2. The preterm infant is especially at risk for DP because of decreased mineralization of the skull bones, as well as more prone and side positioning.
3. Positioning devices recommended by qualified personnel, such as but not limited to occupational and physical therapists, can be used to prevent, control, and correct DP and torticollis while infants are under continuous monitoring in the NICU.
4. Parents need to be educated regarding the use of sleep positioning devices: that their use is limited to the inpatient setting under strict monitoring and that they are not part of a safe sleep environment.
5. Orthotic helmets may be appropriate for infants with persistent moderate to severe plagiocephaly after a course of conservative treatment or if the infant presents at an advanced age.[79]
6. Parents should be educated to avoid excessive use of car seats and infant positioning devices that can promote DP.
7. Education regarding tummy time should emphasize that it be performed during awake, supervised periods only and never when the infant is asleep, even with close supervision.
8. It is important to transition infants to a safe sleep environment well before discharge from the NICU.

DEVELOPMENTAL DYSPLASIA OF THE HIPS

Clinical hip instability occurs in 1% to 2% of term infants, yet up to 15% of term infants have hip instability or immaturity detectable by imaging studies.[85] Developmental dysplasia of the hip (DDH), which was previously called congenital hip dislocation, is the most common neonatal hip disorder and is no longer considered congenital but developmental in origin. The incidence of DDH is approximately 1 to 2/1000 live births, but this estimate does not encompass the entire spectrum. At birth, an involved hip is rarely dislocated but is dislocatable. The clinical significance depends on whether the hip stabilizes, subluxates, or dislocates and is dependent on many factors, including breech position, female sex, incorrect lower extremity swaddling, and positive family history. Breech presentation may be the single most important risk factor; DDH is reported to occur in 2% to 27% of boys and girls presenting in breech position.[86–88] Other nonsyndromic findings associated with DDH include being the first born, presence of torticollis, foot abnormalities, and oligohydramnios.[89,90]

Many mild forms of DDH resolve without treatment. The clinical hip examination plus or minus abnormalities on ultrasonography will determine the need for an abduction brace (frequently referred to as a Pavlik harness). Potential risks associated with the use of the Pavlik harness include aseptic necrosis of the femoral head, temporary femoral nerve palsy, and obturator (inferior) hip dislocation.[88,91,92] Stopping treatment after 3 weeks if the hip does not reduce and proper strap placement with weekly monitoring are important to minimize the risks associated with brace treatment.[93,94] Some clinicians use double or even triple diapering to manage DDH; although innocuous, it is probably ineffective.[95]

Transitioning the NICU patient to a safe home sleep environment often involves swaddling, which reduces crying and facilitates better sleep. In utero, the infants' legs are in the fetal position with the knees bent up and across each other. Sudden straightening can loosen the joints and damage the soft cartilage of the socket. Improper swaddling may lead to hip dysplasia and should be avoided in infants with this diagnosis. Infants should never be placed in prone or side positions while swaddled. Proper hip swaddling techniques can be found

at https://hipdysplasia.org/wp-content/uploads/2020/05/HipHealthySwaddlingBrochure.pdf.

A leading proponent of swaddling states that contemporary swaddling techniques permit infants to be snugly wrapped with their hips being safely flexed and abducted.[96] This position should be encouraged. An alternative method is to swaddle only the upper extremities and allow the lower limbs to move freely.[97] For a more extensive discussion of the diagnosis and management of DDH, refer to the AAP clinical report "Evaluation and Referral for Developmental Dysplasia of the Hip in Infants."[85]

Conclusions Regarding DDH

1. Infants are frequently swaddled in the NICU when approaching hospital discharge.
2. Improper swaddling can lead to or exacerbate DDH.
3. Proper swaddling technique should allow the hips to be flexed and abducted.
4. Parents should be well-educated about all safety issues regarding swaddling, in particular the increased risk of SUID with nonsupine positioning.
5. For more information, refer to the AAP clinical report on DDH.[85]

RESPIRATORY DISTRESS (ACUTE AND CHRONIC)

One of the most common reasons for admission to the NICU is respiratory distress. Some infants will have acute respiratory distress with rapid resolution, such as transient tachypnea of the newborn, and others will develop chronic respiratory conditions, such as bronchopulmonary dysplasia. Some infants will have respiratory distress from airway compromise or other systemic problems affecting respiration.

It may seem counterintuitive to place infants with respiratory distress in the prone position, because it has been shown to increase the risk of rebreathing exhaled gases, which can result in hypoxia or hypercarbia.[98–101] The prone position decreases the rate of heat loss and increases body temperature, putting the infant at risk for overheating.[102,103] Prone positioning has been shown to alter autonomic regulation of the cardiovascular system, especially in preterm infants, potentially decreasing cerebral oxygenation.[104–106] Prone positioning also encourages longer and deeper sleep periods with fewer awakenings and behaviors associated with stress.[107,108] The SIDS triple risk hypothesis suggests that some infants who die because of SIDS had an intrinsic abnormality in the brainstem that prevented appropriate arousal to an environmental threat. All of these elements (rebreathing, overheating, and impaired sleep arousal) have been implicated in increased SIDS risk. However, there is some evidence of potential respiratory benefit with prone positioning.

Acute Respiratory Distress

Once umbilical catheters are removed, one of the commonly used interventions to decrease respiratory symptoms in the newborn infant is prone positioning. Numerous studies have been performed to understand what components of ventilation and oxygenation are affected by prone positioning, as well as the effects of PMA and degree of illness (acute versus chronic lung disease). Wagaman et al[109] found that prone positioning of preterm infants with acute respiratory disease resulted in significantly improved arterial oxygen tension, dynamic lung compliance, and tidal volume. Improved diaphragmatic excursion may contribute to increased tidal volume seen with prone positioning. In the supine position, the abdominal contents can oppose excursion of the diaphragm, limiting ventilation. Improvement in oxygenation may be related to improved ventilation-perfusion matching. In the supine position, some lung tissue is dependent to the heart and mediastinal structures, increasing the risk of atelectasis in the unstable newborn lung.[109,110] In addition to improved lung volume, there is evidence of less intrapulmonary shunting and improved thoracoabdominal synchrony in the prone position.[111,112]

In a Cochrane review[113] from 2012, researchers evaluated positioning for acute respiratory distress in hospitalized infants and children using data from 24 studies with a total of 581 participants. Although the data combined studies of infants and children, 60% were preterm infants. Seventy percent of the study participants were evaluated while on mechanical ventilation. Results were limited because of lack of data for many parameters, small participant numbers, and short study times. There was a small but statistically significant improvement in oxygenation (2% higher oxygen saturations) when positioned prone. Prone positioning also provided a small improvement in tachypnea, with a decrease of 4 breaths per minute.

Although these results are statistically significant, they may be of marginal clinical relevance. However, because the extremely preterm infant will have a prolonged hospital course in the NICU, the benefit of prone positioning during the acute phase of respiratory illness may outweigh the importance of modeling safe sleep positioning at that time. Nonsupine positioning can still be viewed as a teachable

moment between clinician and family. Early safe sleep education can be incorporated into explanations as to why the infant is positioned nonsupine during acute respiratory distress.

Chronic Respiratory Distress

Fewer data are available for determining any benefits of prone positioning in the convalescent preterm infant with resolving pulmonary disease. A small study of 20 preterm infants (median gestational age of 30 weeks; range, 27–32 weeks) recovering from respiratory distress syndrome evaluated pulmonary mechanics at a median postconceptional age of 35 weeks.[114] In oxygen-dependent infants, oxygen saturations and functional residual capacity were higher in the prone position, but there were no differences in compliance or resistance of the respiratory system. In addition, there were no differences in any of the measurements for non–oxygen-dependent infants.

In another study of healthy preterm infants approaching discharge with no history of respiratory distress, there was no effect of prone versus supine positioning regarding respiratory rate; tidal volume; minute ventilation; lung compliance; pleural pressure; or inspiratory, elastic, and resistive work of breathing.[115] Other studies have shown conflicting results; Hutchinson et al found increased tidal and minute volumes but also increased work of breathing in late preterm infants in the prone position.[116] Elder et al found no impact of position on oxygen saturations in preterm infants approaching hospital discharge.[117] Leipala et al[118] found an increase in tidal volume but lower respiratory muscle strength in the prone compared with the supine position in preterm infants studied immediately before discharge from the hospital.

The contradiction of improved respiratory function for some preterm infants with the decreased risk of SIDS or sleep-related deaths must be resolved or, as Poets and von Bodman[119] noted, we are left with a "cognitive dissonance otherwise resulting from parents seeing their infant being nursed in the prone position for several weeks while being told that they must place their infant supine once at home."[119] At some point, the diminishing benefits of prone positioning are outweighed by the risk of SUID, a leading cause of postneonatal mortality. Clearly, this needs to be addressed well before discharge from the NICU.

Upper Airway Obstruction

Numerous congenital abnormalities of the airway can result in respiratory compromise. Pierre Robin sequence can be particularly challenging in regard to infant sleep safety because of the gravity-dependent tongue-based obstruction.[120] For infants on the mildest end of the spectrum who do not experience significant airway obstruction while in the supine position and have normal arterial saturations and adequate gas exchange, there is no need to deviate from standard safe sleep recommendations. In the 40% of cases that are severe,[120] infants will require an inpatient surgical intervention, such as mandibular distraction osteogenesis, tongue-lip adhesion, or tracheostomy, resulting in a stable airway in supine position at discharge. However, the intermediate cases are more problematic because they are not severe enough for early surgical intervention but require the side or prone position for a stable airway. In these cases, it may be appropriate for an infant to sleep on the side or in prone position with consideration of using a home monitor with or without pulse oximetry. Although home monitoring does not prevent or reduce the risk of SUID and is not recommended for that purpose, in this situation monitoring including consideration of pulse oximetry is appropriate for limiting airway obstruction, which could lead to hypoxic injury or death. Regardless, these infants should be managed by a specialized team proficient in the care of such disorders.

Conclusions Regarding Respiratory Distress

1. For the infant with acute respiratory distress, regardless of gestational age, nonsupine positioning may be used as clinically indicated to stabilize and/or improve respiratory function.
2. If nonsupine positioning is used, especially as the infant matures, parents should be educated about infant sleep safety and the reasons for deviating from home safe sleep recommendations.
3. Once the acute respiratory distress is resolving, the infant should be placed supine for modeling home safe sleep, and the parents should receive additional education before hospital discharge.
4. For infants who have developed chronic lung disease, periodic assessments can be performed to monitor the infant's progress. Once the infant has weaned to a standardized minimal supplemental respiratory support (determined by the individual institution), then supine positioning can be maintained, and parents should receive additional education before hospital discharge.
5. Management of the infant with upper airway obstruction needs to be individualized on the basis of the severity of the obstruction. Nonsupine positioning may be necessary to prevent excessive hypercarbia or hypoxemia.

Consideration should be given to home monitoring of the marginal airway.

APNEA OF PREMATURITY

Infant apnea is defined by the AAP as "an unexplained episode of cessation of breathing for 20 seconds or longer, or a shorter respiratory pause associated with bradycardia, cyanosis, pallor, and/or marked hypotonia."[121] Apnea can be classified as central, obstructive, or mixed, on the basis of airflow and respiratory effort. The incidence of apnea is inversely proportional to gestational age. Although all infants born at less than 28 weeks' gestation will have recurrent apnea, the incidence decreases to 20% by 34 weeks' gestation, and these events resolve in 98% of infants by 40 weeks' PMA.[122] It is unclear as to what degree of apnea is considered acceptable, and there is concern about the long-term neurodevelopmental effects of recurrent apnea and periodic breathing on the preterm infant. Measurements of cerebral oxygenation using near-infrared spectrophotometry have demonstrated decreases in tissue oxygenation during apneic events in preterm infants both late in hospitalization and up to 6 months' postterm corrected age.[105] It has been suggested that intermittent hypoxia resulting from continuing apnea and periodic breathing can cause hypoxic cerebral injury[123] and worsening of neurodevelopmental outcomes.[124,125]

Some research has suggested that use of the prone position may reduce apnea frequency and/or severity. In a small study of 35 preterm infants that used a crossover design placing each infant supine and prone, there were significantly more central and mixed apneas in the supine position.[126] In addition, during mixed apneas, there were greater decreases in heart rate ($P = .02$), longer duration of bradycardia ($P = .0003$), and longer accompanying desaturations ($P = .03$) when infants were in the supine position. In another small crossover design study of 14 stable preterm infants, there was no positional difference in the incidence of bradycardia, but there was an increase in apnea density, defined as the number of episodes lasting >6 seconds during quiet sleep (4.5 vs 2.5; $P = .01$), and periodic breathing (percentage of quiet sleep, 13.6% vs 7.7%; $P = .015$) when infants were in the supine position.[127]

In more recent studies, researchers have found either no positional differences in the incidence of apnea or bradycardia or a reduction in alarms with supine positioning.[128,129] Bhat et al found preterm infants in prone position to have more central apneas (median: 5.6 vs 2.2; $P = .04$) but fewer obstructive apneas (0.5 vs 0.9; $P = .007$). While supine, the infants had more awakenings (9.7 vs 3.5; $P = .003$) and arousals per hour (13.6 vs 9.0; $P = .001$).[129] These studies were also limited by small sample size. A 2017 Cochrane review identified 5 eligible trials totaling 114 infants in which no statistical differences were identified between supine and prone positioning with regard to the frequency of apnea, bradycardia, or oxygen desaturations.[130] The overall quality of evidence was low, and the reviewers concluded that they "cannot recommend use of one body position over another for spontaneously breathing preterm infants with apnea." For additional information on apnea of prematurity, refer to the AAP clinical report: Apnea of Prematurity.[131]

Home Monitors

Home monitors are frequently used in the NICU setting to allow for earlier discharge of infants with mild, persistent apnea of prematurity. However, they have not been found to be protective against SUID and are not recommended for this purpose. In addition, the use of non–medical-grade monitors has increased in popularity. As per task force recommendations,[1] parents should be educated that no monitor takes the place of following the safe sleep recommendations.

Conclusions Regarding Apnea and Prone Positioning

1. There is inadequate evidence to justify the use of prone positioning for the treatment of apnea of prematurity.
2. For more information on apnea of prematurity, refer to the AAP clinical report on apnea of prematurity.[131]

GASTROESOPHAGEAL REFLUX DISEASE

GER is a normal developmental process that involves the involuntary passage of gastric contents into the esophagus. GER episodes are usually brief, with little or no symptoms. Many healthy, term infants have 30 or more episodes per day of GER and are known as "happy spitters." Generally, these episodes dissipate over the first year of life as the smooth muscle of the lower end of the esophagus increases in tone with maturation. These episodes of GER are classified as transient lower esophageal sphincter relaxations,[132,133] whereas pathologic GER, or gastroesophageal reflux disease (GERD), involves signs and symptoms of esophagitis with reflux into the esophagus, oral cavity, and/or airways. Putative morbidities of GERD in preterm infants include frequent vomiting, aspiration pneumonia, irritability, failure to thrive, and exacerbations of respiratory symptoms.[134] GER and GERD probably represent 2 ends of a spectrum of the same

condition, varying with the severity of the gastric reflux.[134,135]

As feeding volume increases and/or abdominal straining occurs, the likelihood of acid reflux episodes increases.[132] The presence of a nasogastric or orogastric tube may also contribute to GER because its presence impairs the ability of the lower esophageal sphincter to completely close, especially in the first postprandial hour.[136,137] Esophageal motility, transit time, and gastric emptying are known to be slower in the preterm infant. Full maturation of the intestinal motor function does not occur for several months. Contractions of the gastrointestinal tract with feedings are neurally regulated but modulated by gastrointestinal tract hormones.[138]

Small enteral feedings (20–24 mL/kg per feeding) produce a more mature motor pattern validated by improved feeding tolerance and faster gastric emptying and intestinal transit time.[139] Approximately 80% of infants with uncomplicated GER will improve with conservative measures alone, including small frequent feeds and holding the infant upright for 20 to 30 minutes after feeding. If present, removal of a nasogastric or orogastric tube may also improve symptoms of GER.[137,140]

In term infants, GER symptoms can be abated by avoidance of overfeeding and exposure to tobacco smoke, change of formula, and the use of thickened feeds.[141] Thickening of human milk with starch is problematic because the viscosity decreases over time because of amylase in the milk, which degrades the starch in the thickener.[142] Care should be taken with thickening feeds for preterm infants because a xanthan gum product has been linked to late-onset necrotizing enterocolitis.[143] In addition, commercially available formulas that thicken on acidification in the stomach are not nutritionally optimal for the preterm infant. Although there is no reason to suspect that thickening of feeds would work differently in preterm as compared with term infants, there are few data showing the efficacy of thickened feeds in this population.[4]

According to Salvatore and Vandenplas in 2002, as many as 15% to 40% of infants with GER or GERD have a cow milk protein intolerance or dietary protein–induced gastroenteropathy. After the neonatal period, a trial of an elemental formula may be indicated in infants younger than 1 year if a cow milk protein intolerance is suspected.[144] For infants receiving human milk, similar improvement can be obtained by restricting all dairy, including casein and whey, in the mother's diet.[141] Cow milk protein intolerance is most often diagnosed in infants on the basis of their symptoms and how they respond to dietary changes. There is evidence to support a trial of an extensively hydrolyzed protein formula for 2 to 4 weeks in term infants, but if no improvement occurs with this dietary change, the infant's normal diet can be resumed.

In the preterm infant, the persistence of symptoms, despite holding the infant upright for 20 to 30 minutes, small frequent feeds, and removal of the nasogastric or orogastric tube if feasible, often leads to the use of therapeutic interventions, such as side-lying and elevation of the head of the bed. There is no benefit to elevating the head of the bed, and it should be avoided, especially after discharge, because it may actually increase the risks of SUID.[145] Often, a combination of pH and electrical impedance monitoring is used to evaluate the effect of body positioning on GER and GERD.[145–148] Placing the preterm infant in the left lateral position after feeding versus right lateral position and placing the infant prone versus supine may decrease GER episodes.[147,149,150] Although placement of the infant in the right lateral position may increase GER episodes, it may promote gastric emptying.[150] Prone and lateral positioning of infants from birth to 12 months is associated with an increased risk of SUID and should be avoided. The risks associated with prone and/or lateral positioning outweigh any benefit gained. Multiple studies in different countries have not shown an increase in the incidence of aspiration since the change to supine sleeping.[151–153]

Despite the evidence against aspiration in the supine position, many parents and caregivers remain unconvinced.[154–162] Coughing or gagging is misconstrued as aspiration, although it represents the normal protective gag reflex. The AAP concurs with the North American Society for Pediatric Gastroenterology, Hepatology and Nutrition that the risk of SUID outweighs the benefit of prone or lateral sleep position on GER. Therefore, most infants from birth to 12 months of age should be positioned supine during sleep. Elevating the head of the infant's crib while the infant is supine is not effective in reducing GER.[163,164] If the head of the bed is elevated, the infant may slide into positions that may compromise the airway and result in the death of the infant.

In the 1980s, the US Food and Drug Administration had approved several devices to reduce GER or positional plagiocephaly. However, after reports to the Consumer Product Safety Commission (CPSC) of a number of deaths, the Food and

Drug Administration required manufacturers to demonstrate that the product benefit outweighed the risk of suffocation.[165] Many manufacturers dropped their claims of medical benefit, but devices continued to be sold by retailers directly to the public as non–medical-grade devices.

In 2019, inclined sleepers (which are frequently advertised as being beneficial for infants with GER) came under additional scrutiny after a series of deaths were reported to the CPSC and additional deaths were uncovered in a *Consumer Reports* article.[166] Major manufacturers voluntarily recalled their products. The CPSC issued a statement for a supplemental proposed rule (Supplemental NPR), proposing to adopt the current ASTM International standard for inclined sleep products, with modifications that would make the mandatory standard more stringent than the voluntary standard. The proposed changes include limiting the seat back angle for sleep to 10 degrees or less.[167]

Often, health care providers are pressured to elevate the head of the bed and/or provide pharmacologic interventions despite the lack of evidence supporting these practices. A recent study demonstrated that infants could more easily roll from supine to prone in an inclined sleeper, and once in the prone position, they would fatigue faster than they would on a stable, flat surface because of the high musculoskeletal demands necessary to maintain safe posture to prevent suffocation.[168] The study also found that prone positioning on an inclined sleep surface places the infant at higher risk of airway obstruction or suffocation, as evidenced by oxygen saturation results. These results may provide a mechanism to some of the suffocation deaths related to car seats and other sitting and carrying devices.[169]

Safe sleep is paramount during maturation of the lower esophageal sphincter, which will abate the symptoms of GER with time. Therefore, supine positioning is the preferred safe sleep position for infants with GER or GERD. For a more extensive discussion of GER and GERD in the preterm and young infant, see the AAP clinical report "Diagnosis and Management of Gastroesophageal Reflux in Preterm Infants"[4] or the "Pediatric Gastroesophageal Reflux Clinical Practice Guidelines: Joint Recommendations of the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition and the European Society for Pediatric Gastroenterology, Hepatology, and Nutrition."[141]

CONCLUSIONS REGARDING GER AND GERD

1. GER is extremely common in infants in the NICU.
2. Because of the increased risk of SUID, infants should not have the head of the bed elevated, nor should they be laid down on their side or prone.
3. Term infants can be treated with small, frequent feeds; holding the infant upright after feeding; thickened feeds; elemental formula; and removal of the nasogastric or orogastric tube, when appropriate. If the mother is providing human milk, elimination of all cow milk protein from her diet may be beneficial.
4. Preterm infants can be treated as above, but care should be taken to avoid commercial thickeners because of the association with necrotizing enterocolitis.
5. For more information, refer to the AAP clinical report on GER in the preterm infant ("Diagnosis and Management of Gastroesophageal Reflux in Preterm Infants"[4]).

THERMOREGULATION

Temperature regulation in the newborn infant is frequently referred to as being immature at birth secondary to the lack of completely developed thermoregulatory mechanisms, including large surface area-to-volume ratios and the relatively small insulating body shell.[170] As a result of this immaturity, neonates do show greater fluctuations of body temperature and difficulty in achieving acceptable thermoregulation.

It is well-established that prevention of hypothermia and achieving normothermia in newborn infants decreases mortality and optimizes outcomes. Achieving a neutral thermal environment is the goal for every patient in the NICU. Achieving a neutral thermal environment requires that thermoregulatory control be a balance between heat production and heat loss. Measures to achieve this goal include drying the infant at birth; providing warmth and insulated surfaces, as needed; providing radiant heat; and avoiding cool air currents. In addition, humidity is routinely used in incubators in the NICU. Certain clinical scenarios require chemical mattresses and polyethylene wraps or bags to prevent heat loss.[171,172] Hats are also routinely used in the delivery room to reduce heat loss. Estimates of heat loss from the head and face of the newborn infant vary but have been reported at up to 85%.[173] Some estimates, based on study of clothed adults, may be significantly inflated. An infant simulation study using a heated mannequin model found wearing a hat decreased the local heat loss by an average of 18.9% in all clothed and thermal conditions.[174] The type of hat used to reduce heat loss is

important. A simple stocking net hat has been shown to provide minimal improvement in temperature.[175] Although data are inconsistent, a polyethylene hat has been shown to be more effective in preventing heat loss in the delivery room for preterm infants.[176] In a small study, researchers found a cotton-wool (Gamgee) material reduced heat loss in term infants.[177]

Although preterm infants cannot regulate their body temperature as well as term infants, their thermoregulatory ability improves with maturation.[178] Weight-based criteria for weaning out of the incubator to a cot or bassinet varies from center to center.[179–181] A Cochrane review in 2011 concluded that transfer to a cot when the infant attained a weight of 1600 g did not have adverse effects on temperature stability or weight gain, and earlier weaning from the incubator did not necessarily lead to earlier discharge.[182]

Discharge readiness is usually determined by demonstration of functional maturation, including the physiologic competencies of thermoregulation.[178] Often, the ability to increase metabolism and generate heat reaches that of the term infant before 40 weeks' PMA, which is reassuring at the time of discharge planning from the NICU. Prone sleeping infants have a reduced ability to lose heat, which can lead to overheating.[102] Evidence points toward probable differences in autonomic control of metabolism and cardiorespiratory function in the prone versus supine position.[170] Nonetheless, overheating, as well as prone positioning, is an independent risk factor for SUID and must be avoided.[1] Although studies have shown an increased risk of SUID with overheating, the definition of overheating has varied, making it difficult to recommend a specific room temperature guideline to avoid overheating.[183,184]

Infants should be dressed appropriately for the environment.[175–177] In term infants, this is usually 1 layer more than an adult. However, there is significant variation in how preterm infants are transitioned from the incubator to the open crib, including weight criteria, PMA, number of layers of clothing provided, and use of wearable blankets and hats.[179,180] In one study, infants were placed in the bassinet with 2 layers of blankets or a sleep sack and a hat.[180] Although the focus during transition to the open bassinet is on prevention of hypothermia, once the infant demonstrates temperature stability, providers should turn their attention to modeling safe sleep and the dangers of overheating and overbundling. Infants are safest when they do not sleep with blankets.[173,185] If there is concern that the infant will become cold, an infant sleeping bag, sleeping sack, or wearable blanket is recommended as an alternative to blankets. When using a sleeping bag, special care should be taken with the preterm infant to ensure they cannot slip inside and that the head cannot become covered.[186] Some wearable blankets come with a swaddle feature. There is no evidence to recommend swaddling (wrapping the infant in a light blanket or wearable blanket with a wrap) as a strategy to reduce the risk of SUID.[1] Refer to the section on developmentally sensitive care for a discussion of the risks and benefits of swaddling.

Parents and/or caregivers should be educated on evaluating the infant for signs of overheating, including sweating or the chest feeling hot to the touch.[1] Overbundling and covering of the face and head should be avoided.[173] Head covering is associated with an increased risk of SUID. This increased risk with head coverings generally refers to covering with bedding or bed clothes. Only one study refers specifically to hats, finding that although the majority did not wear hats, there were significantly more hat-wearing infants among the SIDS infants compared with the control infants.[187] A systematic review of 10 population-based, age-matched controlled studies found the pooled prevalence of head covering in SIDS victims was 24.6% compared with 3.2% of controls. The causal mechanism of this increased risk remains unclear, but hypoxia, rebreathing, and thermal stress have been hypothesized as mechanisms.[173] Although it may be unlikely that dislodgement of a hat could lead to obstruction of an infant's airway, there may be legitimate concern regarding their contribution to overheating and/or thermal stress. A recent article questioned the necessity of hats for preterm infants after initial stabilization.[188] A chart review of 729 infants transitioned out of supplemental heat without the use of hats found a failure rate attributable to hypothermia of 2.7%. Given the questionable benefit of hat use and the potential for harm, clinicians should weigh the risk/benefit ratio in regard to discharging an infant from the NICU with a hat. If the infant is discharged wearing a hat, the clinician should provide instruction for families to discontinue use once the infant demonstrates stable temperatures in the home environment. This should include education about how to determine that the infant's temperature is stable.

CONCLUSIONS REGARDING THERMOREGULATION

1. Preterm and low birth weight infants are prone to temperature instability and may require

additional bundling to avoid hypothermia.
2. Excessive bundling should be avoided because overheating and head covering have been associated with an increased risk of SUID.
3. If an infant is discharged wearing a hat, families should be counseled to discontinue its use once the infant demonstrates temperature stability in the home environment.
4. If swaddling is performed, it is important that it is done properly, the infant is always placed supine, and it is discontinued when the infant begins to attempt to roll.

HYPERBILIRUBINEMIA AND PHOTOTHERAPY

Hyperbilirubinemia is an extremely common problem in both the term and preterm infant. During the first week of life, up to 60% of term newborn infants and 80% of preterm infants will develop jaundice because of the immaturity of the liver, leading to elevated concentrations of circulating unconjugated bilirubin.[189] Beyond the common physiologic jaundice of the newborn infant, there are many hemolytic conditions and other abnormalities that can lead to excessive jaundice. Nomograms are available to help the clinician detect which term and late preterm infants are at higher risk of going on to develop excessive jaundice that untreated could lead to kernicterus and permanent bilirubin encephalopathy.[190]

The mainstay of therapy for neonatal unconjugated hyperbilirubinemia is phototherapy. The factors that affect the dose of phototherapy are the irradiance of the light used, the distance from the light source, and the amount of skin exposed.[189] The infant should be naked except for diaper and eye protection. The phototherapy dose increases as the distance from the light to the infant decreases. Spectral power increases as the amount of skin exposed to phototherapy increases and can be maximized by using a phototherapy blanket under the infant while using phototherapy lamps over the infant.

When using standard phototherapy units, many providers choose to rotate the infant between supine and prone positioning. Several small studies have been undertaken to evaluate the utility of changing the position of the neonate during phototherapy, and no benefit in relation to decrease in bilirubin concentrations was found.[191–193] All recent studies have been evaluated in a systematic review that also concluded that supine positioning is as effective as turning infants periodically.[192] Two more recent and larger trials provide additional evidence suggesting that positional change is unnecessary for successful use of phototherapy. Donneborg included infants as young as 33 weeks' gestation and used higher light irradiance compared with older studies.[193] The study demonstrated identical rates of decrease in total serum bilirubin at 12 and 24 hours after initiation of phototherapy, regardless of supine or alternating positioning. Most recently, Bhethanabhotla et al[194] studied 100 infants of greater than 34 weeks' gestational age and found no difference with or without positioning in the duration of phototherapy or the rate of decrease in total serum bilirubin concentration.

Although the AAP guideline "Management of Hyperbilirubinemia in the Newborn Infant 35 or More Weeks of Gestation" did not comment on positioning of the infant during phototherapy, there is an analysis and statement from the United Kingdom's National Institute for Health and Clinical Excellence (NICE) on this issue.[195] The NICE Guideline Development Group accepted that, in term infants, the position of the infant during phototherapy has no significant influence on duration of phototherapy or mean change in serum bilirubin concentration. It concluded that to ensure consistent advice regarding the risk of SIDS, infants should be placed in a supine position.[195]

The NICE recommendation did not include preterm infants, because it was released before the most recent studies that included infants as early as 33 weeks' gestation. However, the consistency of the results in both term and middle-to-late preterm infants should provide clinicians with confidence in maintaining these infants in a strictly supine position if there is no other contraindicating medical condition. Modeling the supine position is a powerful tool in the education of families regarding infant sleep safety and SUID risk reduction. These more mature preterm and term infants are likely to have short stays in the NICU, so early modeling of safe sleep is more pressing, and the use of phototherapy should not interfere with supine sleep positioning.[196]

CONCLUSIONS REGARDING PHOTOTHERAPY

1. Hyperbilirubinemia and the use of phototherapy is common in term and preterm infants in the NICU.
2. There is no benefit to changing an infant's position while under phototherapy. However, the provider may choose to place the infant on a bilirubin blanket, in addition to an overhead phototherapy unit, if the absolute total serum bilirubin concentration is increasing rapidly, in effect,

performing double-sided phototherapy.
3. Unless there are other competing medical issues, infants should be kept supine while receiving phototherapy to model and promote infant sleep safety.

NEONATAL OPIOID WITHDRAWAL SYNDROME

NOWS is a clinical condition observed in neonates experiencing withdrawal from in utero opiate exposure.[197] Symptoms caused by central nervous system irritability, autonomic nervous system dysfunction, and gastrointestinal and respiratory tract distress typically appear 2 to 3 days after birth and can last for weeks or months.[197] Although opiate replacement therapy may be indicated on the basis of the severity of clinical presentation, the foundation of treatment and support of the infant with NOWS is directed at supportive, nonpharmacologic care aimed at minimizing the stimulation that is being experienced and/or supporting the infant to self-regulate.[198,199] These measures include promoting SSC,[200] rooming-in and breastfeeding,[201–203] decreasing light and noise,[200] swaddling and positioning,[200] use of pacifiers and/or rockers,[200] and massage.[200] Many of these interventions, commonly associated with developmentally sensitive care, previously described in this report, have variably been shown to help support preterm infants' neuroregulation, decrease length of medical treatment, and decrease hospital length of stay.[198,200,203] Despite a paucity of evidence, these interventions are being used to help support infants struggling with NOWS.[198,200,203]

SSC has been recommended as a strategy to help support infants with NOWS for many of the same reasons as previously mentioned in this article, such as improved neurologic regulation, establishment of breastfeeding, and maternal bonding.[200] One of the benefits of SSC is to enhance breastfeeding,[204] which in turn has been shown to decrease the severity of NOWS symptoms, days of pharmacologic treatment, and hospital stay.[198,205] Current recommendations support breastfeeding when the mother is compliant with maintenance therapy.[197]

The importance of not falling asleep with the infant during SSC, especially after hospital discharge, should be stressed with opioid-dependent parents. The opioid-dependent parent falling asleep with the infant would be analogous to bed-sharing with someone who is impaired in his or her alertness or ability to arouse because of sedating medications, which greatly increases the risk of SIDS.[1] Falling asleep with the infant during SSC is of particular concern for the mother of an infant with NOWS, because during pregnancy, women often require increases in methadone dosing because of factors such as increased intravascular volume and increased tissue reservoir and hepatic metabolism of the drug.[206] The optimal approach to methadone dose management in the postpartum period, however, is not well defined, and there is the theoretical concern that methadone concentrations may increase as plasma volume and hepatic clearance return to the prepregnant state. Yet in a study of 101 methadone-maintained pregnant women, researchers found no significant increase in oversedation events: after adjusting for benzodiazepine prescriptions, the incident relative rate of an event among postpartum women compared with pregnant women was 1.74 (95% CI: 0.56–5.30).[206] Nevertheless, opioid exposure is still of concern because a retrospective study has implicated opiates in sudden infant death, with maternal methadone use identified in 31% of 32 neonatal deaths evaluated by autopsy.[207] It is unclear whether the deaths were directly related to the methadone or other environmental factors. In addition, the frequent occurrence of polysubstance use (eg, tobacco and alcohol) among those who use opioids further increases the risk of sudden infant death, particularly associated with bed-sharing.[208–210] Thus, presence of maternal substance use disorder warrants extensive safe sleep education before discharge from the hospital.

Swaddling is frequently used in the care of infants with NOWS and seems to be an effective therapeutic intervention for this population. Although no studies specifically address swaddling and infants with NOWS, it is believed the intervention may be useful to decrease excessive crying and promote sleep.[198,199,211] Refer to the section on developmentally sensitive care for additional information on benefits and risks of swaddling.

Swings and motion devices are commonly used in NICUs, well newborn units, and pediatric inpatient units to calm fussy infants, particularly those suffering from NOWS. Rocking devices have been used through the ages for their calming effect on crying infants. Although not extensively studied, there are reports demonstrating the consoling effect of rocking.[212,213] The data are inconsistent regarding direction of the movement, and one study showed more benefit by rocking at 60 cycles per minute versus 45 cycles per minute.[213] A recent study showed benefit of rocking by either a parent or mechanical device, although rocking by the parent appeared to be more effective.[214] It is important that staff use motion devices appropriately,

while infants are awake and properly monitored. In addition, infants should be moved to a safe sleep environment if they fall asleep in a swing or motion device, because these are not considered safe sleep surfaces. Although infants are under constant monitoring in the NICU environment, leaving a sleeping infant in a swing or motion device is poor modeling for families and undermines safe sleep messaging.

There is some evidence that placing infants who are experiencing narcotic withdrawal in the prone position decreases the severity of NOWS scores as well as caloric intake.[215] As described previously in this article, prone positioning may increase the risks of musculoskeletal abnormalities[108] as well as SUID, is not consistent with AAP safe sleep recommendations, and is not recommended as a strategy to console infants with NOWS outside of a monitored unit. Prone positioning may be useful for monitored inpatients during the acute withdrawal phase of NOWS but should be discontinued, and the patient should be placed in supine position as soon as possible and before discharge from the hospital.

The time that the infant may need these interventions focused on neurodevelopmentally sensitive care will depend on the length and severity of NOWS symptoms. Particularly in infants whose NOWS symptoms seem to worsen without these interventions, transition to safe sleep practices before discharge from the hospital often presents challenges to NICU clinicians and families. Each center caring for infants with NOWS should develop and implement a standardized process to identify when the infant has reached medical stability and transition to safe sleep recommendations before discharge from the hospital.

CONCLUSIONS REGARDING NOWS

1. There are some commonly used interventions in the treatment of NOWS (ie, prone positioning) that are not consistent with home infant sleep safety.
2. Early and frequent education is critical to prevent families from thinking that therapeutic interventions in the hospital that are not consistent with home infant safe sleep guidelines can be replicated in the home environment.
3. The use of therapeutic interventions that are not consistent with home infant sleep safety should be minimized. When they are necessary, it is important to review their use and transition to a safe sleep environment as early as possible.
4. Clear, consistent, safe sleep messaging should be emphasized with families of infants with NOWS well in advance of discharge from the hospital.

HUMAN MILK AND BREASTFEEDING

Although not directly related to the transition to safe sleep, a discussion about infant sleep safety is not complete without mentioning breastfeeding and human milk feeding. The benefits of breastfeeding are numerous, including decreased risk of infection; decreased risk of allergies, asthma, and eczema; decreased risk of obesity, inflammatory bowel disease, high cholesterol, and type I diabetes mellitus; and possibly decreased risk of some childhood cancers.[216] In addition, in preterm infants, human milk has been shown to improve feeding tolerance and reduce the risk of necrotizing enterocolitis.[217–220] Multiple studies have shown that breastfeeding is associated with a decreased risk of SUID.[221–223] A recent meta-analysis found that providing term infants with any human milk for at least the first 2 months of life decreased the risk of SUID by 40% (relative risk 0.60 [0.44–0.82]).[224]

The reduction in risk of SUID from human milk may be multifactorial. Human milk has biologically active components that are immunoprotective through their antimicrobial and immunomodulatory activity. Among the many components are white blood cells, stem cells, immunoglobulins (especially secretory immunoglobulin A), lactoferrin, lysozyme, and human milk oligosaccharides.[225,226] The decrease in viral infections (which have been associated with an increased risk of SUID[1]) may partially explain this protective effect of human milk. In addition, polyunsaturated fatty acids in human milk, in particular docosahexaenoic acid, are important in the overall maturation of the central nervous system, especially the cardiorespiratory center, and myelination of the brain.[227–230] In one study, infants who died of SIDS had delayed myelination of the brain compared with control infants.[231]

Given the increased risk of SUID in the preterm infant, breastfeeding and the use of human milk after discharge may be even more important in this population. However, successful maternal milk production is dependent on early initiation, and in the case of the preterm or term infant with respiratory distress, it requires the mother to provide expressed milk through pumping or hand expression. As a result, clinicians need to provide education regarding the benefits of breastfeeding on admission to the NICU, or earlier if possible,[232] and work in multidisciplinary teams to enhance support for breastfeeding, milk expression, and provision of mother's milk throughout the NICU stay.[233] Furthermore, preterm infants and their mothers require

significant support when they are discharged from the hospital and transition to direct breastfeeding in the home setting.[234]

Finally, as noted in the previous discussion on SSC, it is critical that parents be aware of the dangers of falling asleep with their infant. This is especially important when mothers are rooming-in with their infant and not under constant observation by NICU staff. Although it is often stated that breastfeeding naturally results in maternal drowsiness from the release of prolactin and oxytocin, there are few data to support this concept.[235,236] Breastfeeding mothers are often exhausted in the early days and weeks from sleep deprivation and disruptions in their normal circadian rhythms. In a 2019 study, researchers found that after delivery, new mothers averaged 3.7 hours of sleep, and the longest interval of sleep observed was between 2 and 3 hours throughout the postpartum hospital course.[237] Of the 101 participants, 50 required at least 1 intervention or corrective action to address unsafe sleep.[237]

Mothers may also be emotionally or physically exhausted from the stress and other demands of a NICU hospitalization.[238] The risks for infant falls or smothering are analogous to those seen with rooming-in on the well newborn unit with healthy mother-infant dyads. Studies have observed associations between postpartum sleepiness and fatigue and decline in cognitive neurobehavioral functioning.[239,240] Education of staff and families is crucial, and staff should also take care to evaluate the mother's level of sleepiness.[238,241] The risk of falls and sudden unexpected postnatal collapse should be minimized by conducting frequent assessments and monitoring of the mother-infant dyad and evaluating the level of maternal fatigue. If the mother or caregiver is tired or sleepy while holding the infant, the infant should be moved to a separate sleep surface.[62]

This can be an opportunity for open, nonjudgmental discussion regarding the family's infant sleep safety plan for home. The AAP 2016 policy statement on SIDS recommends room-sharing with the infant on a separate sleep surface.[2] The policy also states numerous conditions under which bed-sharing is particularly dangerous. And even in situations in which there are no other risk factors, there is some evidence of increased risk with bed-sharing, especially in the youngest age groups and among those who were born preterm or with low birth weight. Sample size limitations prevent a determination of how large that risk is, but clearly the data do not support a definitive conclusion that bed-sharing in the youngest group is safe, even under less hazardous circumstances. For additional information, refer to both the AAP clinical report "Safe Sleep and Skin-to-Skin Care in the Neonatal Period for Healthy Term Newborns"[62] and AAP technical report "SIDS and Other Sleep-Related Infant Deaths: Evidence Base for 2016 Updated Recommendations for a Safe Infant Sleeping Environment."[1]

CONCLUSIONS REGARDING HUMAN MILK AND BREASTFEEDING

1. The use of human milk is recommended for its numerous health benefits, including reducing the risk of SUID.
2. Special care should be taken when mothers are rooming-in and breastfeeding to minimize the risk of falling asleep with the infant in the adult bed.
3. Provide mothers with appropriate outpatient support to optimize breastfeeding success after discharge from the hospital.

A RATIONAL APPROACH TO TRANSITION OF THE NICU PATIENT TO A HOME SLEEP ENVIRONMENT

Consistent messaging and modeling in the newborn nursery have been shown to improve parental intent to keep infants supine and not share sleep surfaces.[11,242–244] In the NICU environment, McMullin et al found that a bundled intervention for nursing can lead to consistent modeling of safe sleep before hospital discharge. The intervention included nursing education, crib cards, written instructions reviewed with parents, and sleep sacks for modeling to parents. Audits 6 months after the intervention found 98% of infants supine in open cribs, 93% of infants in sleep sacks, and 88% of bassinets with safe sleep crib cards visible.[245]

Standardized programs have also demonstrated higher rates of supine sleep and other safe sleep behaviors in the home.[246,247] Given that 20% of SUID cases involve preterm infants and preterm infants are at a twofold to threefold increased risk of SUID,[248–250] it is critical that families of infants in the NICU be exposed to safe sleep environmental modeling and education for a successful transition to a safe sleep environment in the home. The AAP through its Committee on Fetus and Newborn recommends that "preterm infants should be placed supine for sleeping, just as term infants should, and the parents of preterm infants should be counseled about the importance of supine sleeping in preventing SUID. Hospitalized preterm infants should be kept predominantly in the supine position, at least from the postmenstrual age of 32 weeks onward, so that they become acclimated to supine sleeping before discharge."[3]

However, as outlined in this document, not all infants will be clinically ready to be maintained in a safe sleep environment by 32 weeks' PMA. Algorithms that account for some of the variables discussed in this report have been developed on the basis of literature review, expert opinions, and unit consensus.[14,251] Quality improvement programs using these algorithms can result in both more consistent modeling in the NICU and improved parental compliance with safe sleep practices. Hwang et al[251] showed a pre- to postintervention improvement with overall safe sleep environmental compliance in 2 community NICUs from 25.9% to 79.7% ($P < .001$). In another study, NICU compliance with supine positioning increased from 39% to 83% ($P < .001$), provision of a firm sleeping surface increased from 5% to 96% ($P = .001$), and the removal of soft objects from the bed improved from 45% to 75% ($P = .001$). Furthermore, parental compliance with safe sleep practices in the days after discharge from the NICU improved from 23% to 82% ($P < .001$). The largest improvements involved placing infants supine for sleep (93% vs 73%), dressing infants appropriately (93% vs 66%), and removing extra soft blankets from the crib (97% vs 61%).[14]

Although many of the studies showing improvement in modeling safe sleep have been single-center studies, a recent evaluation by Hwang et al[252] of a statewide quality improvement project, including 10 level III NICUs in Massachusetts, not only confirmed the utility of an integrated approach to safe sleep in the NICU but also demonstrated that it can be amplified across institutions at the state level via perinatal quality collaboratives. Over a 2-year period, 7261 cribs were audited for compliance with safe sleep, which was defined by 4 parameters: supine positioning; a flat crib with no incline; no positioning devices; and no toys, comforters, or fluffy blankets. Compliance increased from 48% at the start of the project to 76% at 1 year and 81% by 2 years. Three of the individual components had compliance greater than 90% at the end of the study.

Many states have been focusing efforts on hospital-based interventions to promote safe sleep behaviors, anticipating that the downstream effect will be a decrease in SUID and infant sleep-related deaths. Some studies and epidemiological data support this tactic. In Tennessee, Heitmann et al analyzed a Department of Health program to implement a safe sleep policy at all 71 birthing hospitals in the state. Audits revealed a 45.6% decrease in infants found with any risk factors for unsafe sleep. There were significant decreases in infants found asleep nonsupine, with a toy or object in the crib, and not sleeping in a crib.[253]

Creating a culture of infant sleep safety in the NICU setting can be challenging. At the institutional level, diffusion of innovation theory can help guide culture change. Successful quality improvement efforts require a team of key players, including (1) opinion leaders, the respected leaders who have influence over others; (2) change agents, the key people who support change, stabilize adoption, and solve problems; and (3) change aides, trustworthy people on the front lines who help maintain change.

In addition, people respond differently to change, so it is important to seek out the innovators or risk takers who like new things and the early adopters who accept change readily. It is equally important that change agents and aides work closely with the late majority or skeptics and the traditionalists who prefer the status quo. Resistance to change is common, so consensus building is essential to success. Ideally, the components of change should be developed by a multidisciplinary team to reflect input from physicians, nursing, lactation consultants, respiratory therapists, and development therapists (physical therapists, occupational therapists, and speech therapists). Having access to local, state, and national statistics regarding SUID can facilitate breakdown of barriers to promoting consistent safe sleep education and modeling. Statistics can be obtained through multiple sources, including state departments of health; the Centers for Disease Control and Prevention, through CDC Wonder linked birth and infant death records (https://wonder.cdc.gov/lbd.html); and yearly state child death review reports. In addition, hospitals can work together with local coroners, medical examiners, and child death review teams to provide feedback on the effectiveness of safety efforts. One study demonstrated the efficacy of a sustained quality improvement effort that linked outcome data from local child fatality review teams. The average death rate decreased from 1.08 infants per 1000 births preintervention to 0.48 infants per 1000 births after complete intervention with feedback from child fatality review teams and performance improvement methodology.[254] The authors concluded that repeated messaging and education by the entire nursery staff has the potential to play a role in reducing sleep-related deaths in infants born at a hospital.

CONCLUSIONS

As clinicians, we must find equipoise between the acute physiologic needs of the infant and the inevitable necessity to provide a home safe sleep environment before discharge from the hospital. There are many

competing and conflicting needs for the NICU patient and family. Preterm infants are at increased risk of SUID, so as providers, we should focus on sharing regular, repetitive, and consistent education with families throughout the hospitalization. Through our messaging with not only our words but also our modeling behaviors, we will enable NICU families to be properly prepared for the transition home to a safe sleep environment.

Trauma-Informed Care

- *Clinical Report*

CLINICAL REPORT Guidance for the Clinician in Rendering Pediatric Care

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Trauma-Informed Care

Heather Forkey, MD, FAAP,[a] Moira Szilagyi, MD, PhD, FAAP,[b] Erin T. Kelly, MD, FAAP, FACP,[c] James Duffee, MD, MPH, FAAP,[d]
THE COUNCIL ON FOSTER CARE, ADOPTION, AND KINSHIP CARE, COUNCIL ON COMMUNITY PEDIATRICS, COUNCIL ON CHILD ABUSE AND NEGLECT, COMMITTEE ON PSYCHOSOCIAL ASPECTS OF CHILD AND FAMILY HEALTH

Most children will experience some type of trauma during childhood, and many children suffer from significant adversities. Research in genetics, neuroscience, and epidemiology all provide evidence that these experiences have effects at the molecular, cellular, and organ level, with consequences on physical, emotional, developmental, and behavioral health across the life span. Trauma-informed care translates that science to inform and improve pediatric care and outcomes. To practically address trauma and promote resilience, pediatric clinicians need tools to assess childhood trauma and adversity experiences as well as practical guidance, resources, and interventions. In this clinical report, we summarize current, practical advice for rendering trauma-informed care across varied medical settings.

INTRODUCTION

Experiences in childhood, both positive and negative, have a significant effect on subsequent health, mental health, and developmental trajectories. For many children and adolescents, traumatic experiences are all too common. Almost one-half of American children, or 34 million younger than 18 years, have faced at least 1 potentially traumatic early childhood experience.[1–7] Such traumas may include those originating outside the home, such as community violence, natural disasters, unintentional injuries, terrorism, immigrant or refugee traumas (including detention, discrimination,[6,8,9] or racism), and/or those involving the caregiving relationship, such as intimate partner violence, parental substance use, parental mental illness, caregiver death, separation from a caregiver, neglect, or abuse, originally defined as adverse childhood experiences (ACEs).[10] For many children, medical events, such as injury, medical procedures, and/or invasive medical treatments, can be traumatic. Given the robust science explaining the physiologic consequences of accumulated trauma experiences on the brain and body,[11–14] there have been calls for pediatric clinicians to address childhood trauma and child traumatic stress.[10,14–16] However,

practical guidance about how to consider, address, and operationalize this care, although necessary, has been insufficient.

Pediatric clinicians are on the front lines of caring for children and adolescents and, thus, have the greatest potential for early identification of and response to childhood trauma. Data indicate that, although pediatric providers intuitively understand the negative effects of trauma, they report a lack of knowledge, time, and resources as major barriers to providing trauma-informed care (TIC).[5,6] Yet, experts believe that the complete assessment of child and adolescent behavioral, developmental, emotional, and physical health requires consideration of trauma as part of the differential diagnosis to improve diagnostic accuracy and appropriateness of care.[17,18]

TIC is defined by the National Child Traumatic Stress Network as medical care in which all parties involved assess, recognize, and respond to the effects of traumatic stress on children, caregivers, and health care providers. This includes attention to secondary traumatic stress (STS), the emotional strain that results when an individual hears about the first-hand trauma experiences of another. In the clinical setting, TIC includes the prevention, identification, and assessment of trauma, response to trauma, and recovery from trauma as a focus of all services. TIC can be conceptualized in a public health stratification, as summarized in Table 1:

- primary prevention of trauma and promotion of resilience;
- secondary prevention and intervention for those exposed to potentially traumatic experiences, including caregivers, siblings, guardians, and health care workers; and
- tertiary care for children who display symptoms related to traumatic experiences.

This clinical report and the accompanying policy statement[19] address secondary prevention and intervention: practical strategies for identifying children at risk for trauma and/or experiencing trauma symptoms. "Children," unless otherwise specified, refers to youth from birth to 21 years of age. These clinical strategies and skills include the following[16,20]:

- knowledge about trauma and its potential lifelong effects;
- support for the caregiver-child relationship to build resilience and prevent traumatic stress reactions;
- screening for trauma history and symptoms;
- recognition of cultural context of trauma experiences, response, and recovery;
- anticipatory guidance for families and health care workers;
- avoidance of retraumatization;
- processes for referral to counseling with evidence-based therapies when indicated; and
- attention to the prevention and treatment of STS and associated sequelae.

Pediatricians have a powerful voice and reach that could promote the policies and procedures necessary to transform pediatric health care into a TIC system. This guidance for pediatric clinicians is organized around 5 strategies for implementation to become trauma informed: awareness, readiness, detection and assessment, management, and integration. The companion policy statement[19] outlines broad recommendations for implementing TIC in child health systems.

AWARENESS

Pediatric clinicians can promote resilience, identify adversity and trauma, and ameliorate the effects of adversity in their work with children and families. Although the epidemiology and physiology of trauma have been explored in the literature,[9,12,13,21,22] few concepts have been translated into the provision of practical TIC in pediatric settings.[6,16,23] Awareness of the science and epidemiology of trauma provides the scientific grounding for the practices of TIC.

TABLE 1 Range of Trauma Experiences, Symptoms, and Response

Potentially Traumatic Experiences	Trauma Symptoms (Table 5)	Office Response
None	None to some	Primary prevention: anticipatory guidance; resilience promotion
Single-incident or minor trauma	None or latent or mild	Secondary prevention: anticipatory guidance; resilience promotion; trauma-informed guidance; close monitoring: screen for trauma history and symptoms
Major event or cumulative	Mild to moderate	Secondary and tertiary prevention: anticipatory guidance; resilience promotion; psychoeducation; trauma-informed guidance, close monitoring, and follow-up; possible referrals to community services, mental health
Major event or cumulative	Moderate to severe	Tertiary prevention and treatment: anticipatory guidance; resilience promotion; psychoeducation; trauma-informed guidance, close monitoring, and follow-up; avoidance of retraumatization; referrals to community services; referral to evidence-based and evidence-informed trauma mental health services

Adapted from Forkey H, Griffin J, Szilagyi M. *Childhood Trauma and Resilience: A Practical Guide.* Itasca, IL: American Academy of Pediatrics; 2021.

Safe, Stable, and Nurturing Relationships

The most fundamental adaptational mechanism for any child is a secure relationship with a safe, stable, nurturing adult who is continuous over time in the child's life.[24] This is usually the child's parent or caregiver but can involve extended family and biological or fictive kin. It is in the protective context of this secure relationship that the child develops the varied resilience skills that will prevent or ameliorate the effects of cumulative adversities. The nurturing caregiver protects the child from harm, mediates the world for the child, and helps the child to develop the adaptive skills to manage stressful experiences. Physiology, in addition to psychology, is affected by protective relationships.[14,25–27]

Toxic Stress and Trauma

All children experience some stress and adversity at some point in life, but when it is managed within the context of these nurturing relationships, such events can be weathered and even used for growth. Adverse events that lead to the frequent or prolonged activation of the stress response (see Fig 1) in the relative absence of protective relationships has been termed "toxic stress" in the pediatric literature.[14] Toxic stress responses result from events that may be long lasting, severe in intensity, or frequent in occurrence. The available caregiver support is insufficient to turn off the body's stress response. It is critical to note that the toxic stress response has 2 components: the significant stressors and the relative insufficiency of protective relationships. In sum, there is a marked imbalance between stressors and protective factors.[28]

Toxic stress responses can result in potentially long-lasting or lifelong impairments in physical and mental health through biological processes that embed developmental, neurologic, epigenetic, and immunologic

Stress Responses

Freeze	• Originates in central nucleus of the amygdala and mediated by hypothalamus and superior colliculus[222] • Typically brief response, forces the organism to alert to danger • Can be followed by the fight-or-flight responses • Parasympathetic and vagal response can lead to dissociation or faint
Fight or flight	• Results from adrenal release of epinephrine and cortisol that allow the threat to be addressed • Short term: physiological changes, including increased heart rate and blood pressure • Excess or frequent activation in childhood can result in long-term changes in HPA axis function, which leads to dysregulation of the neuroendocrine stress response and consequent physiologic changes (see Table 2)[12,223]
Affiliate (gather social support, "tend and befriend")	• Higher brain response mediated by oxytocin,[224,225] appears to mediate stress within the social context by promoting the ability to look to others in the environment for support in managing a threat (social salience)[70,226] • With the provision of support, stress response declines[70,227] • Having no support or a hostile environment leads to negative perceptions of others, induces less adaptive responses and antisocial behaviors, and leads to increased perception of stress and increased cortisol[70,228-230] • Emerging science underlying the affiliative response elucidates how safe, stable, nurturing relationships can buffer adversity and promote resilience 
FIGURE 1 Stress responses. HPA, hypothalamic-pituitary-adrenal.

TABLE 2 Physiologic Effects of Trauma in Children

Area	Impact	Specifics	Implications and Associations
Brain connectivity[93]	Cortisol acts on rapidly developing brain structures	Amygdala overactive; hippocampus underactive; prefrontal cortex not accessible	Preliminary association with more severe clinical course in major depressive disorder
Epigenetic changes[21]	Methylation patterns impacted by threat, mediated by cortisol	Methyl groups attach to promoter region or come off promotor regions of genes, leading to the transcription or lack of transcription of genes	Adult stress and reactivity behavior[231,232]
Immune function[80]	Alteration of immune system in response to constant threat	Inflammatory system up-regulated; humoral immunity diminished; cytokine-induced "sickness behavior"[81] (feeling sick)	Symptoms including the following: decreased appetite, fatigue, mood changes including depression and irritability, poor cognitive function

changes.[12,14] The lifelong effects of toxic stress are statistically related to many adult illnesses, particularly those related to chronic inflammation, and causes for early mortality.[29] The robust literature on the physiologic effects of toxic stress is beyond the scope of this clinical report yet briefly summarized in Table 2.

Trauma is a broader term used to describe both a precipitant and a human response. The Substance Abuse and Mental Health Services Administration defines trauma as an event, series of events, or circumstances experienced by a person as physically or emotionally harmful that have long-lasting adverse effects on the person's functioning and well-being (emotional, physical, or spiritual).[16] This definition accounts for the fact that people may respond differently to potentially traumatic events and informs TIC with appreciation that the traumas people experience can result in behavioral changes that may allow them to manage the trauma in the short-term but can have lasting negative effects on conduct. These difficulties should not be viewed as malicious actions or even intentional but as consequences of adversity.[30]

Because these epidemiological and physiologic studies provide the background and impetus for TIC, understanding the terminology derived from this literature is important in appreciating the scope, variety, and nuances of TIC and how to actualize them. These are summarized in Table 3.

High-risk Populations

It is important to be aware that the exposures of some child populations and their families put them at particular risk of experiencing trauma but also that the components of TIC can benefit these children and families.[31–34] More than 7.4 million children, or nearly 1 in 10 children, are reported as potential victims of child abuse and neglect annually.[35] In 2019, more than 670 000 children spent time in foster care.[36] Children who remain at home after child protective services investigation or are moved to kinship care resemble their peers in foster care in having an extremely high prevalence of significant childhood trauma.[37–39] Immigrant and refugee children may have left poverty, war, and violence, may have encountered abuse or separation from family members, and can be at risk for deportation, detention, and separation and discrimination.[6,40,41] Poverty, or near poverty, affects approximately 43% of US children, and both urban and rural poverty have been linked with multiple stressors and increased risk of trauma.[42–44] Children of underrepresented racial, ethnic, and religious groups are more likely to be exposed to discrimination.[45,46] The psychological, interpersonal, and perhaps physiologic effects of trauma inflicted on a community (particularly because of race, identity, or ethnicity) may be passed to succeeding generations and is referred to as historical trauma.[47,48] Community violence and bullying, along with cyberbullying, are experienced by many children and recognized as traumatic exposures included in expanded definitions of ACEs.[49–51] Lesbian, gay, bisexual, transgender, and queer children and adolescents, children of color, American Indian and Alaskan native children, immigrant children, neurodiverse children and adolescents, and children and adolescents with overweight and obesity are all more likely to experience discrimination, both overt and as a series of microaggressions (small slights, insults, or indignities either intentional or unintentional) that accumulate over time.[52–54] Additionally, children of military families have a higher prevalence of trauma, abuse, grief, and loss.[55] Populations at higher risk for pediatric medical traumatic stress include preterm infants, children with complex and/or chronic medical conditions, and those suffering from serious injury or illness.[56] Up to 80% of children and family members experience trauma

TABLE 3 Definitions of Terminology in TIC

Terminology of Traumas	Definitions
Acute stress disorder and Post-traumatic stress disorder (PTSD)	Psychiatric diagnoses that include having experienced or witnessed a traumatic event and then having persistent symptoms that include the following: reexperiencing (intrusive thoughts, nightmares, or flashbacks); avoidance (feeling numb, refusing to talk about the event); hyperarousal (irritability, exaggerated startle response, always expecting danger); acute stress disorder: symptoms occur 3 d to 1 mo after traumatic exposure[81]; PTSD: symptoms must occur ≥3 mo after the trauma[233]
ACEs	Stressful or traumatic events, including child abuse and neglect, that occur within the primary caregiving relationship; often breach the parent-child relationship, which is fundamental to nurturing healthy development; linked in population studies to physiologic and behavioral changes impacting the health and well-being of patients over their life course with a wide array of health problems, including associations with substance misuse.[10,21,24,80] The original ACEs (from initial study published in 1998) are the following: physical abuse, sexual abuse, emotional abuse, physical neglect, emotional neglect, intimate partner violence, mother treated violently, substance misuse within household, household mental illness, parental separation or divorce, and incarcerated household member. Subsequent studies have expanded the original ACE panel to include other adversities,[9,234] including the following: experiencing racism, experiencing bullying, separation from caregiver (resulting from immigration, foster care, incarceration, death, or any other reason), witnessing violence, community violence,[49] adverse neighborhood experience,[235] and financial insecurity[236]
Complex childhood trauma (as defined by the National Child Traumatic Stress Network)	Encompasses both a child's exposure to multiple interpersonal traumatic events, including maltreatment and household dysfunction, and the broad, pervasive, and predictable impact this exposure has on the individual child[83,237]; can disrupt a child's attachment with caregivers, development, and sense of self
Developmental trauma disorder (DTD)	A proposed diagnosis based on evidence that children exposed to complex trauma are at risk for severe pervasive disruptions in their development in the domains of emotional health, physical health, attention, cognition, learning, behavior, interpersonal relationships, and sense of self; sometimes used interchangeably with complex childhood trauma; describes problems in affect dysregulation, negative self-concept, and difficulty with relationships that occur as a result of trauma-related developmental impairments; symptoms overlap or co-occur with several PTSD symptoms, but DTD includes a fuller spectrum of dysregulation resulting from the insults to multiple pathways in the developing brain when nurturing and is seen as a result of complex childhood trauma; more accurately describes the outcomes of such trauma in children than does the diagnosis PTSD[158,238]
Pediatric medical traumatic stress (PMTS)	The distress that children and family members experience during hospitalization for a perceived life-threatening diagnosis or while living with or caring for someone with life-altering chronic conditions[239–241]; often related to the person's subjective experience of the medical event rather than its objective severity and is mitigated by SSNRs that promote resilience
Secondary traumatic stress (STS)	A response that may occur in parents, other family members, and health care workers such as physicians, nurses, other hospital staff (including nonclinical staff), first responders, and therapists who are exposed to the suffering of others, particularly children[242]; may have many of the same long-term effects on health that affect children exposed to trauma; individual trauma histories can contribute to the reaction
Social determinants of health (SDoHs)	Conditions of the greater ecology or environment, occurring where people live, learn, work and play, which affect the neuroendocrine stress response and affect a wide range of health risks and outcomes[8,22]; can be mitigated by an SSNR and other protective factors and exacerbated by ACEs and intrafamilial and interpersonal traumas; examples include: poverty, food insecurity, homelessness, and lack of access to health care; examples that also overlap with the expanded ACEs include racism, discrimination, and community violence
Trauma	An event, series of events, or set of circumstances an individual experiences as physically or emotionally harmful that can have lasting adverse effects on the person's functioning and mental, physical, emotional, or spiritual well-being[14]; can occur outside caregiving relationships (eg, dog bites, natural disasters), within the context of the caregiving relationship (eg, exposure to domestic violence, various forms of abuse or disordered caregiving because of parental mental illness or substance use disorder), or in the context of relationships outside the family (racism, bias, discrimination, bullying)

symptoms after a life-threatening illness, injury, or painful medical procedure.[57]

READINESS

TIC transforms the fundamental questions in medical care from "What is wrong with you?" to "What happened to you?" and, finally, to "What's strong with you?" A trauma-informed approach acknowledges the biological effects of adversity without suggesting that childhood adversity is destiny. It requires a compassionate approach that does not suggest blame. It requires pediatric health care workers at every level to understand the context of a child's relationships, especially within the family, and ask, "What are the caregiver's strengths and challenges?" "What are the child's strengths and challenges?" and "Who supports you?" This changes the pediatric role from "I must fix you" to "I must understand you (and the relationships that created you and can help you heal)."[25,58] Thus, readiness includes an understanding of what provides resilience and how to promote it.

Relational Health Care

TIC is fundamentally relational health care, the ability to form and maintain safe, stable, and nurturing relationships (SSNRs). Pediatricians are able to support the caregiver-child relationship, the context in which there can be recovery from trauma and the restoration of resilience. Fundamental to these concepts is an understanding of attachment.

Attachment

Attachment describes the emotionally attuned give-and-take between caregiver and child and the trust, safety, and security provided to the child[59] that promotes healthy brain growth, development of accurate mental maps of self and others, development of resilience, and protection from trauma.[60] Fundamentally, the predictable compassionate availability of the caregiver promotes the secure attachment of the child.[61,62] Recent studies show attachment remains malleable beyond infancy, even into adolescence and adulthood, to some extent.[63,64]

Effective Parenting

Effective parenting encompasses the skills that caregivers bring to the task of parenting and is the context in which secure attachment develops and is relied on during and after traumatic experiences. Although caregivers approach parenting with a range of skills, attitudes, and beliefs rooted in their cultural and family contexts, studies have shown that effective or positive parenting has some universal features.[65–67]

It is through secure attachment with a predictably empathic caregiver that children learn to regulate their emotions. Children start by turning to a caregiver when upset. The caregiver comforts the child by touch, words, and compassion, which shuts down the stress response and restores emotional regulation. Secure attachment happens as a child predictably receives this sympathetic support from the caregiver when the child is distressed and the child comes to confidently anticipate that support. This relationship becomes a reliable source of safety, and the caregiver is a secure base from which the child can explore their environment.[62] Multiple studies have shown that a secure attachment relationship is the best means for building or rebuilding resilience in children; it is also the context for promoting healthy brain growth and development.[62,65,68,69] With these positive affiliative experiences, modulation of the stress response begins and includes the release of oxytocin, a potent hormone regulator of the sense of safety and well-being.[68,70]

Thus, the first step of TIC is to assess this aspect of the relationship, observing the child-caregiver interaction, including the caregiver's attention to the child, the caregiver's ability to read and respond to the child in developmentally appropriate ways, and the child's ease, comfort, and response to the caregiver. Discussion can begin by focusing on the caregiver's and child's strengths and noting the constructive aspects of the relationship while providing the caregiver with empathy. When attachment is strained, caregivers have often lost empathy for the child. The positive regard and attuned attentive listening provided before and while raising concerns supports the caregiver. The empathy provided to the caregiver thus allows the opportunity for them to reattune to the child.[62]

Resilience

Resilience is defined as a dynamic process of positive adaptation to or despite significant adversities.[71] This is not a static or innate quality but includes skills children can learn over time with reliable support from attachment figures. The development of resilience includes aptitudes that are attained through play, exploration, and exposure to a variety of normal activities and resources. Studies have shown that development can be robust, even in the face of severe adversity, if certain basic adaptational mechanisms of human development (resilience factors) are protected and in good working order. These mechanisms include attachment to a competent caregiver, cognitive development with opportunity for continued growth, mastery of age-salient developmental tasks, self-control or self-regulation, belief that life has meaning, hope for the future, a sense of self-efficacy, and a network of supportive relationships.[71] On the other hand, if those basic adaptational mechanisms or protective factors are absent or impaired before, during, or after the adversity, then the outcomes for children tend to be poorer[71] (see Table 4).

TABLE 4 Adaptational Mechanisms of Resilience

T	Thinking and learning brain, with opportunity for continued growth; cognitive development
H	Hope, optimism, faith, belief in a future for oneself
R	Regulation (self-regulation, self-control of emotions, behaviors, attention, and impulses)
E	Efficacy (self-efficacy) or sense that one can impact their environment or outcomes
A	Attachment, secure attachment relationship with safe, stable, and nurturing caregiver or competent caregiver
D	Development, mastery of age-salient developmental tasks
S	Social context, or the larger network of healthy relationships in which one lives and learns

Adapted from Masten AS. Ordinary magic. Resilience processes in development. *Am Psychol.* 2001;56(3)227–238; Forkey H, Griffin J, Szilagyi M. *Childhood Trauma and Resilience: A Practical Guide.* Itasca, IL: American Academy of Pediatrics; 2021.

Robust implementation of TIC is strength-based, building on family protective factors rather than emphasizing deficits. At almost every encounter, from early childhood through adolescence, pediatric care can include resilience promotion, building on identified strengths. Because resilience is a dynamic process of positive adaptation, routine anticipatory guidance about development or safety can be used to promote relational health and positive childhood experiences, including achievements at home, at school, and in neighborhoods, which enhance resilience.[72] When addressing adversities or concerns about development, surmounting the challenges can be framed with resilience and positive experiences as the goal.[73] For example, when speaking with a caregiver about a child learning to fall asleep on their own, sleep skills can be framed as building resilience by supporting self-regulation and self-efficacy. Alternatively, when a caregiver expresses concern about a child or teenager who had been sleeping until experiencing a traumatic event, the discussion can be framed around what resilience factors are being challenged (developmental skill mastery, self-efficacy, self-regulation) and which ones can be used to support the child's recovery (attachment and thinking).

DETECTION AND ASSESSMENT

Detection involves both surveillance and formal screening to identify children and families with the history of exposure to potentially traumatic experiences as well as those who exhibit signs and symptoms of trauma. Although TIC is common in social services and other mental health settings, in a health care environment, TIC can be conceptualized by using a medical model. Similar to other medical conditions, TIC includes purposeful triage, engagement, history-taking, surveillance and screening, examination, differential diagnosis, sharing of the diagnosis, and management, which may include office-based anticipatory guidance, referral, psychopharmacology, and/or follow-up or recommendations.

Surveillance for maladaptation after experiencing trauma includes consideration of all those who may be affected by exposure to the direct suffering of the child. Health care workers, such as first responders, nurses, social workers, trainees, physicians, and nonclinical hospital or clinic employees, may be deeply affected by witnessing or hearing about the traumatic experiences of children. Parents (biological, foster, kinship, or adoptive) are particularly at risk for prolonged trauma reactions that may impair their ability to care for and comfort their children. Siblings may also be affected, particularly when there is complex trauma or exposure to suffering, such as having a sibling with cancer or another life-altering disease that involves chronic pain.

Peri-trauma

Peri-trauma refers to situations in which medical providers are caring for children as the traumatic events are unfolding. One example is pediatric medical traumatic stress. Pediatric medical traumatic stress is a situation in which children experience medical procedures or other aspects of medical care as traumatic events. The effects of such trauma can be mitigated by attending to the child's and family's experience of medical care and reducing (as much as possible) frightening or painful aspects of necessary care and procedures. This mitigation can include asking children (and caregivers) about their fears and worries, optimizing pain management and comfort measures, and working with caregivers to increase their ability to provide effective support for their child. The Healthcare Toolbox includes a number of specific suggestions, including assessing distress (D), providing emotional support (E), and addressing the family needs (F)—a D, E, F protocol to follow the A, B, Cs of resuscitation.[74]

Another comprehensive strategy used by schools and community agencies when a mass trauma or disaster occurs is Psychological First Aid (PFA).[75] Developed by the National Child Traumatic Stress Network, PFA is an evidence-informed program that is designed to help children, families, adults, and other witnesses in the immediate aftermath of a disaster or terror event. Core skills for implementation of PFA are identical to TIC: establish an emotionally safe environment, connect with primary support persons (relational health), link to community resources, and provide psychoeducational materials to help understand the potential responses of children to the exposure.

Triage

The first step in medical care is to identify an emergency versus nonemergency situation. When dealing with trauma, its causes, or its consequences, consideration of whether a child may be emergently at risk requires assessment and response as a top priority. In practicing TIC, protocols and practices to identify and address child or family safety issues, both physical and psychological, are integral to care.

Trauma may result from children being in unsafe settings because of abuse, neglect, or impaired caregiving. When the practitioner suspects maltreatment or failure of the caregiver to protect a child at any point in a health encounter, referral to child protective services

is necessary and mandated. These issues need to be considered even before screening and addressed with standard protocols to respond to identified risks.[76–78]

Other immediate safety issues may arise when a consequence of trauma is self-harm or intent to injure others. Screening for suicidality, self-injury, or intent to harm others is included in TIC along with clear protocols for how to address positive endorsement of these issues.

Engagement

TIC creates a respectful and emotionally safe space in which to engage children, adolescents, and families around the discussion and management of these issues and to prevent retraumatization. Discussion of trauma may raise stress levels, and appropriate engagement reassures the child and family that the setting is safe. Culture can also affect how trauma is experienced and understood by families, and cultural awareness can ease the conversation. Engaging children and families begins with greeting the patient and family and being fully present in the moment while maintaining a balance between professionalism and friendliness. It involves initially asking open-ended questions, followed by more specific and probing questions as needed and that are elicited by caregiver and child or adolescent responses. It involves listening in an active, nonjudgmental, attuned way, reflecting back to the family what is heard for clarification and confirmation, seeking clarification when necessary, paraphrasing, attending to and reflecting on the emotions that accompany the information, and summarizing what is discussed. Implicit bias can affect the provider's ability to be nonjudgmental in these conversations.[46,79] Acceptance, curiosity, and empathy are conveyed to the patient or caregiver in the process of attentive listening.[61] Engagement also involves mutual regard between the provider and family. Adolescents and capable children bring their own perspective. Each brings expertise to the TIC of the child or adolescent. The provider has expertise in medicine, whereas the patient and family have expertise about the child, what happened, and their situation, beliefs, strengths, and culture.

When working with families and patients who have experienced trauma, the provider's body language, affect, and tone of voice can promote or inhibit care. Affect describes the facial and body expressions that reflect our emotional state. Individuals who have experienced trauma are more sensitive to body language, facial expressions, and tone of voice.[70] Approaching children slowly and calmly or letting them sit with a caregiver and using higher pitched, more musical speech may ease a child's tension because these sounds are associated with the release of oxytocin in the amygdala, resulting in calming of this threat-sensitive brain area. A shift to low tones during a discussion may alert a child or caregiver to potential danger and stimulate defensive responses.[61]

History

Much of the information needed to integrate TIC into practice may be obtained as part of the routine health evaluation. Social, developmental, and medical history are all opportunities to identify risks, stressors, and strengths. The health history provides an opportunity to assess child and family resilience factors, social connectedness, parenting attitudes, and skills. The review of systems allows the medical provider to collect symptoms of trauma that may not have been identified in the chief complaint but that can offer valuable insight into the current impact of trauma on the patient.[80,81] Symptoms may be functional, neurodevelopmental, or related to immune function.

1. Functional symptoms: Manifestation of the symptoms of trauma may evolve over time. Functional complaints can result after single-incident traumas (eg, automobile crash, hurricane) or may be early manifestations of complex trauma.[82–84] Sleep difficulty, changes in appetite, toileting concerns (eg, constipation, abdominal pain or enuresis), and challenges with school functioning (eg, poor attention or attendance) may be the early presentation of ongoing trauma.[84,85] Diagnostic criteria for attention-deficit/hyperactivity disorder and adjustment disorder overlap with some of these functional symptoms. When these signs and symptoms are noted, it can be useful to include trauma in the differential diagnosis.[17,86,87]
2. Neurodevelopmental symptoms: Some of the most recognizable manifestations of early trauma result from the effect on areas of the rapidly developing brain of young children. Developmental skill acquisition (higher brain) can be hindered as recognition of and response to threat is prioritized (lower brain).[88,89] Specific areas of the brain affected are the limbic system, hippocampus, and prefrontal cortex.[12,13,90–92] The prefrontal cortex is involved in cognition, emotional regulation, attention, impulse control, and executive function. Consequently, children may have developmental delay and behave as if they are younger than their actual age[89,93] (see Table 5 for an easy way to remember these effects). Other

TABLE 5 Most Common Symptoms of Trauma Exposure

F	Frets (anxiety and worry) and fears
R	Regulation difficulties (disorders of behaviors or emotions; hyperactive, impulsive, easily becomes aggressive or emotional; inattentive)
A	Attachment challenges (insecure attachment relationships with caregivers); poor peer relationships
Y	Yawning (sleep problems) and yelling (aggression, impulsivity)
E	Educational and developmental delays (especially cognitive, social-emotional, and communication)
D	Defeated (hopeless), depressed, or dissociated (separated from reality of moment, lives in own head)

Adapted from Forkey H, Griffin J, Szilagyi M. *Childhood Trauma and Resilience: A Practical Guide.* Itasca, IL: American Academy of Pediatrics; 2021.

observed symptoms may include the following:

- rapid, reflexive response to stimuli, reminders, or triggers[93,94];
- inattention, poor focus, hyperactivity, and difficulty completing tasks[86,95];
- difficulty tolerating negative mood so the child seeks ways to defuse the tension through hyperactivity, impulsive behaviors, aggression, self-harm, such as cutting and suicidality, or engagement in health risk behaviors (substance use, sexual activity)[89,95,96];
- reactions to stimuli, triggers, or reminders can be transient and flip suddenly back to "normal"; this appears to the observer as emotional lability[88,92]; and
- negative world view and self-narrative; flat affect; difficulty engaging socially or viewing themselves as worthless.[88,92,97]

3. Immune function symptoms: When a child is exposed to early, severe, or prolonged trauma, the immune system is chronically pressed into action, and, over time, changes can occur in the inflammatory system and humoral immunity.[80,89] A persistent inflammatory response can leave children vulnerable to diseases, such as asthma and metabolic syndrome.[80,98,99] Humoral immunity may be impaired so that children are more susceptible to infection. Additionally, immune system stimulation may result in the "sick syndrome," which is a perception of feeling unwell that can include headaches, stomachaches, and lethargy.[80,81]

Surveillance

Surveillance or monitoring is the process of recognizing children who might be at risk for being affected by trauma and is modeled after developmental surveillance. Surveillance is less formal than screening and can be conducted at every visit. Asking about caregivers' concerns, obtaining a trauma history, observing the child, and identifying risk and protective factors provides information about resilience supports and trauma exposure.[100] Surveillance requires attention to relationships and engagement. Questions such as "Has anything scary or concerning happened to you or your child since the last visit?" are a way to more specifically explore the possibility of adverse experiences.[85] Recognizing that certain symptoms may indicate exposure to childhood adversities, we can ask, "What has happened to you (or your family)?" For adolescents, these questions can be asked as part of the HEADSSS (questions about Home environment, Education and employment, Eating, peer-related Activities, Drugs, Sexuality, Suicide/depression, and Safety) psychosocial interview.[101,102] Questions that are considered less threatening are asked first and followed with questions that may be perceived as more intrusive.[101] Providers may be concerned that asking questions about a family's needs, a child's trauma history, or a child's symptoms may distress the child or caregiver, but studies in which this topic has been explored indicate that, when the topic is raised, families respond well to having the issues acknowledged and addressed in a supportive setting.[85,103,104]

Children only heal from trauma in the context of SSNRs, so it is also necessary to ask about the strengths that are already present in the family. Starting these conversations with questions about child, adolescent, or family strengths frames the conversation in a positive and resilience-focused way.[105,106] For instance, a clinician may ask how the child, adolescent, or family copes with stress, what a teenager does well, whether they have frequent family meetings to talk about solving problems, and whether each member of the family has someone to turn to for safety and comfort when they are upset. Trauma that occurs because of problems in the primary attachment relationship represents the greatest threat to the child or adolescent and may be the most challenging for providers to explore. Caregivers may have their own trauma histories or mental health struggles, substance use issues, and/or multiple stressors related to social determinants of health (SDoHs), including poverty, housing instability, and violence exposure that affect their parenting. Exploring parenting stressors, strengths, and attitudes in conversation can help the provider to pinpoint specific leverage points to help children but may also create an opportunity for the caregiver to reflect about the effects of their parenting or stressors on the child. TIC is compassionate and assumes that all caregivers love their children and are doing the best they can. It also assumes that children

are doing the best they can.[107,108] Adolescents should be included in these conversations and have a role in identifying strengths and challenges. Pediatricians who have cared for a family over time may already have considerable insight into the family's dynamics and be able to engage the caregivers in an empathic yet open conversation. Furthermore, compassionate surveillance can be combined with use of screeners or questionnaires to elicit more information.

Screening

Validated screeners used at preventive health care visits can provide valuable information about child development, mental health, and behavior.[109] They can be reassuring when normal or alert the pediatric provider to symptoms or risks when borderline or abnormal. Commonly used tools, such as the Ages and Stages Questionnaire,[110] the Pediatric Symptom Checklist,[111] the Strengths and Difficulties Questionnaire,[112] and the Patient Health Questionnaire-9[113] may elicit symptoms that are the possible result of trauma (developmental delays, social-emotional problems, anxiety, etc). Perinatal depression screening may not only identify symptoms of this illness but provide opportunities to explore maternal stressors and strengths.[114] Those exposed to known traumas can be evaluated by using standardized posttraumatic stress disorder (PTSD) screening tools such as the PTSD Reaction Index Brief Form,[115] and those exposed to medical traumas can be evaluated by using a tool such as the Psychosocial Assessment Tool.[116,117] The Pediatric Traumatic Stress Screening Tool in the Intermountain Care Process Model has been recently developed to screen for pediatric traumatic stress in the primary care setting, either as a universal screen or with targeted screening when traumas are known.[118] These tools effectively help identify the diagnostic criteria for PTSD, although they are not designed to identify the full spectrum of symptoms of complex trauma (developmental trauma disorder [DTD]).

Screening, per American Academy of Pediatrics (AAP) guidelines, suggests using instruments that are standardized and validated and have defined psychometric properties (sensitivity, specificity, positive predictive value). By that definition, there are currently no screening tools for ACEs and only a few validated screening tools for SDoHs. However, standardized (but not validated) tools are being used in some pediatric settings to assess ACEs and SDoHs and are using aggregate risk scoring to target providing increased support.[119–121] Many of the available screening tools expanded on the domains included in the original Centers for Disease Control and Prevention/Kaiser ACE study to include additional items applicable to urban and minority populations, including witnessing neighborhood violence and experiencing bullying or discrimination.[9] Parental ACE screening may offer the opportunity to align with caregivers and build a partnership to explore issues that may be affecting their parenting. Indeed, several recent studies suggest that parental ACEs can be linked with concerning outcomes for children.[122–125] Concurrent resilience screening offers the opportunity to identify protective factors that can buffer identified stressors, thus providing more nuanced understanding of a child's risk. Screening also offers the opportunity to then frame the discussion around promoting strengths in the caregiver-child relationship to protect a child from toxic stress and build adaptive skills.[107] Similar to ACE screening, there are few available standardized validated resilience screening tools, although the Connor-Davidson Resilience Scale[126] and Brief Resilience Scale[127] assess caregiver resilience.[128] (Readers are referred to the AAP Screening Technical Assistance Web site at https://www.aap.org/en-us/advocacy-and-policy/aap-health-initiatives/Screening/Pages/About-Us.aspx for developmental and SDoH screening tools.)

A limitation of ACE and SDoH screening tools is their lack of nuance: they identify risk factors that have been derived from epidemiological studies, not outcomes at the individual level.[129,130] Those outcomes are the result of the physiologic response to adversities. Although currently only available in the research setting, biomarkers of this physiologic response have the potential to be more accurate measures of the effects of adversity at the individual level.[131–133] Eventually, clinic-friendly, noninvasive biomarkers could also be used to identify patient-specific response to both stressors and therapeutic interventions.[134,135]

Screening health care workers for the effects of hearing about and addressing the trauma experiences of others is most commonly achieved with informal self-assessment strategies to identify symptoms or experiences that may be associated with burnout or STS.[136] Substance use disorder, depression, and suicidality may be associated with exposure to secondary trauma, and there appears to be overlap between burnout and STS.[137–144] An example of a screening tool for health care workers is the Professional Quality of Life Scale,[145] which includes subscales for compassion satisfaction, burnout, and STS.

Cultural considerations affect all aspects of TIC, including screening. Instruments that are not normed for the population or translated and validated in the language of the patient and family can result in misleading results. Thus, it is important to consider screening results cautiously with consideration of the family's culture and ethnicity in relation to the screening tool being used.[146]

Examination

Blood pressure measurement at preventive health visits or when stress is a potential etiologic factor for concerns is indicated.[147] Elevated blood pressure may be the first symptom of childhood traumatic stress, especially as youth age.[148,149] Abnormalities in hearing, vision, and growth parameters can be clues to adversities.[150,151] Overweight and obesity have been associated with ACEs.[152–154] Physical examination may reveal signs of neglect or abuse. The immunologic effect of trauma may result in inflammatory or infectious consequences identifiable on examination.[1,80,99,155,156] Children who have sustained cumulative ACEs and traumas may exhibit certain common behaviors the provider may witness during physical and mental health evaluation (refer to history and symptoms described earlier).

Differential Diagnosis Considerations and Comorbidities

The provider is encouraged to consider trauma as a possible etiology in the assessment of developmental, mental health, behavioral, and physical symptoms in all pediatric encounters because of the following: (1) the experience of adversity is so common; (2) the symptoms of trauma overlap with the symptoms of other common pediatric conditions[87,95]; and (3) failure to do so might lead to an incorrect or incomplete diagnosis and treatment, enabling the effects of trauma to further embed.[17,157,158] Trauma may be mistaken for other conditions, such as attention-deficit/hyperactivity disorder, and includes symptoms that overlap with other diagnostic categories, such as anxiety and depression.[86,87,159] It has been proposed that trauma may result in a different "ecophenotype" of common conditions that have a different trajectory and different response to common treatments.[93] Children may also have comorbid conditions, such as ADHD, anxiety, depression, or developmental and learning issues, because they frequently accompany childhood trauma. A more detailed description of diagnoses that are commonly confused with trauma or comorbid with it are covered in the AAP clinical report "Children Exposed to Maltreatment: Assessment and the Role of Psychotropic Medication."[87]

Diagnostic Continuum

Pediatric providers may encounter children with a wide range of symptoms resulting from trauma. As noted, trauma can result in short-term changes in behavior or have a more lasting impact depending on the child, the trauma itself, and the supports or emotional buffers in a child's life. When traumatic events are more severe, prolonged, or less buffered by a caregiver, effects on various aspects of functioning can be more severe.[1,160–163] Children exposed to chaotic households, abuse, or neglect, especially in the early years of life, may have more severe symptoms and symptoms that evolve over time.[94,159,164,165] Diagnostically, this may result in children who have functional symptoms (short-term problems with sleeping, eating, toileting), adjustment disorder, PTSD, or complex trauma symptoms.[163,166,167]

MANAGEMENT

Sharing the Diagnosis With Children and Caregivers

Some parents and caregivers may come to understand the role of adversities in their child's symptoms through discussion of the trauma history and symptoms, and others will require the provider to explain this connection before they can appreciate the provider's advice and recommendations. Psychoeducation is the first step in management of childhood trauma and includes empathic, nonjudgmental sharing of diagnostic information and provider concerns about the etiology of a child's symptoms The provider's role is to integrate the child or adolescent and caregiver's concerns, the child or adolescent's symptoms, and elements of a thorough history and examination into an explanation of why this raises a concern about trauma exposure or why trauma may be the underlying cause or one of the causes of a child's symptoms, much as is done for any diagnosis. A simple explanation of the pathophysiology of trauma may help the caregiver to move from frustration with the child or adolescent's behaviors or symptoms to empathy. In some situations, the explanation may also provide the caregiver with insight into their own history of trauma and its impact on their parenting behaviors or responses to their child's behaviors, or how an event that affected their child may have traumatized the caregiver as well.

Psychoeducation includes acknowledging that a trauma history can affect behavior and thoughts, with some discussion of how that happens. Table 6 has information on specific psychoeducation. The variable responses of children to trauma can be frustrating or confusing. Discussion of the emerging data on the biological sensitivity to context may be useful

TABLE 6 Responses to Trauma to Explain to Caregivers: Psychoeducation

Impacts of Trauma on Function and Behavior	Clinical Presentation
Changes in auditory processing	Children may lose the ability to hear sounds of safety (musical high-pitched voice) and be preferentially attuned to low-pitched sounds that warn of caregiver depression and anger.[247]
Changes in how children interpret facial expressions	Children may misinterpret the affects and emotions of others, particularly confusing anger and fear.[93]
Limited vocabulary for emotions	Children may also not accurately recognize or express their own emotions, leading them to act out or respond in ways that seem "off." What a child (or caregiver) identifies as "anger" may be disappointment, frustration, fear, grief, or anxiety.[88]
Negativity	Trauma results in children having overactive limbic systems with a focus on safety and a presumption of danger. This can result in strong negative reactions as the first response to a stimulus that might be benign or ambiguous.[61]
Triggers	Triggers can be physical (smells or sounds that recall details of the trauma) or emotional (feeling embarrassed or shamed, recalling how child felt during abuse). Prevention of exposures to reminders or triggers is the best approach. Triggers may be subtle, so educating and assisting caregivers with their identification is key. This helps caregivers understand a child's response.[167]
Learned Behavior	Behaviors that were adaptive for a child in a previous environment may be maladaptive in their current environment. These behaviors can evoke some of the same reactions from caregivers that the child experienced with other adults, reinforcing a familiar pattern of interactions that may not be productive in the new setting.[61]

to caregivers.[168,169] Genetic variations in how a person responds to stress may contribute to a child's sensitivity to adversity.[170] Yet, those with high reactivity who are supported and learn to channel that reactivity to positive activities and passions may have the greatest potential.[168] This information, along with specific suggestions about how to support children, can address some of the consternation of caregivers regarding children's heterogeneous responses to both adversity and interventions.

Office-Based Anticipatory Guidance and Management

Trauma-informed anticipatory guidance provided by pediatricians can help families promote resilience and begin to address the effects of trauma. If screening for SDoHs is being conducted and/or social needs are identified, referral to applicable community-based services is indicated (eg, food bank, pro bono legal aid, etc). Having a list of community providers, such as Early Head Start, Head Start, evidence-based maternal, infant, and early childhood home visiting programs, state Maternal Child Health Title V programs, and Family to Family Health Information Centers ready for distribution, directly contacting the referral provider with the patient present, or providing formal care coordination all facilitate family engagement and help families connect to needed community resources. For older children and adolescents, trauma-informed schools and teenager crisis centers may be available in the community. In trauma-informed schools, personnel at all levels have a basic realization about trauma and an understanding of how trauma affects student learning and behavior in the school environment.[171,172]

Every encounter in an office setting, from those with young children to those with adolescents, is an opportunity to strengthen the attachment between a child and caregiver.[173] Through techniques such as reinforcing positive back-and-forth interactions between a parent and a child (serve and return), helping the caregiver to understand the child's experience (keeping the child's mind in mind), helping the children to learn words to describe a variety of emotions, and promoting self-reflection concerning the caregiver's own trauma history, the pediatric clinician can render primary prevention against the development of anxious and maladaptive attachment patterns and promote regulation.[82,174] Examples of relevant anticipatory guidance include advice, resources, or referrals to community programs, including Reach Out and Read[175–177]; developmentally appropriate play with others[178–180]; promoting positive, authoritative (in contrast to punitive or authoritarian) parenting styles[181–183]; and mindfulness.[184–186] Table 7 includes specific advice to promote regulation after trauma.

Referral for Treatment

The presence of complex symptoms, mental health diagnoses, substance abuse, and/or a significant trauma history are indications for referral to evidence-based trauma-informed mental health services.

TABLE 7 Anticipatory Guidance

	Office-Based Guidance to Promote Regulation After Trauma
Restoring safety	To reduce the stress response after trauma, caregivers can: repeatedly assure a child or teenager that they are safe now; allow the youth to express how they feel and listen attentively; provide extra physical contact (if appropriate) with hugs, touch, and rocking for younger children.
Routines	Routines or rituals also help reduce the stress response after the unpredictability and chaos of trauma by restoring a sense of order. Caregivers can use visual (pictorial schedule or charts) and verbal cues for well-defined mealtimes, sleep times, and rituals ("Before bed, we are going to brush teeth, read a story, sing a song, and then turn lights out"). Preparing children for changes in routines, or, for the child in foster care or the child of separated or divorced parents, for visitation, can reduce stress responses.
Relaxation techniques	Provide information verbally, with printed instructions or on phone apps that guide relaxation, meditation, and mindfulness. Refer to community programs that provide training in belly breathing, guided imagery, meditation, mindfulness, yoga, stretching, and massage, which can help to reduce the fight-or-flight responses and symptoms.[247]
Time-in or special time	Dedicated, child-chosen or child-directed play with a caregiver. Caregiver chooses a time that works for them and plans to spend 10 to 30 min with the child in fun activity of child's choosing. For infant or toddler, reading time is a good example of "time-in." Recommended for children from early childhood through adolescence.
Small successes	Children who experience trauma may have delays in skill development. Expectations may need to be tailored to the child's developmental level rather than actual age. It may take lots of repetition and practice before a skill or behavior is learned, so it is useful to celebrate and reward small steps toward desired behaviors.
Emotional container	Child may have strong emotions if reminded of trauma, and the emotions may be directed at the caregiver, although they are usually not about the caregiver. Caregiver needs to remain calm to model self-regulation and avoid retraumatizing the child.
Cognitive triangle	Thoughts impact feelings, which then impact behavior, which then reimpacts thoughts. For example, if children worry they cannot fall asleep, they will then feel nervous and stressed, and then not be able to fall asleep, reinforcing their cognitive belief that they cannot fall asleep. Similarly, if children think no one likes them, they will feel rejected and may lash out at another child, leading to rejection by that child and reinforcing their belief that they are not liked. It can help to identify this triangle and break the link between thoughts and emotions (through new experiences that link thought with different emotions) and/or the link between the emotions and the behavior ("It is ok to feel ___, but it is better to do ___ than to do ____." This technique involves labeling the emotions and teaching an alternative behavior.)
Distraction	Children who are dysregulating may benefit from distraction from the traumatic thoughts by suggesting a game, music, calling a friend, or deep breathing in a calm environment.
Positive parenting techniques	Positive parenting techniques have to be adapted to the age and developmental stage of the child, but they are principles that are known to work: (1) helping children identify and name their emotions; the next step for the child is to understand the emotion and then to learn healthy ways to express the emotion and build regulation skills; (2) reassuring safety and keeping the child safe both emotionally and physically; (3) attuned, attentive listening, which starts in infancy with "serve and return" but evolves into conversational exchanges over time; (4) setting appropriate boundaries and providing guidance through connecting and listening with children; it is best to teach rather than tell or command; for example, "We draw on paper, not on walls, because it is hard to wash markers off the walls"; (5) catching the child being good and offering the child positive, specific praise for good behaviors; (6) implementing rewards and privileges to create opportunities to develop skills; start small so the child can earn a reward quickly and then build up; (7) using positive language instead of "no" commands: for example, "We color on paper, not on the table," is a better way to approach a child who is drawing on the table than, "Stop that," Or, "we use gentle hands—we don't hit others"; (8) being a good role model as child mimics what they see rather than what they are told; (9) having some fun together as a family (time-in): read, talk, sing, play; (10) reinforcing positive skills as they develop: cooperation, politeness, appropriate assertiveness, kindness, etc; and (11) the law of natural consequences: sometimes the best lesson is letting the consequences play out (not cleaning your room means it will be a mess when your friends come over).

The most effective therapies are evidence-based treatments (EBTs) with demonstrated efficacy for children who have experienced trauma.[85,187,188] Treatments that are designated as evidence based have had the most rigorous evaluation, whereas evidence-informed treatments range from newly emerging practices that are building evidence support to less rigorously studied tools. Sege et al[189] published an overview of evidence-based individual and family-based psychotherapeutic interventions. Gleason et al[190] specifically outlined services for the treatment of young children. Having these services available on-site or through direct communication with colleagues in mental health (a "warm handoff") has been revealed to be the most effective approach.[191] It is important for caregivers who have their own history of trauma to seek individual therapy, and the pediatric provider may find it useful to have a list of adult mental health providers who address trauma. As research continues to elucidate the neurocognitive basis of trauma symptoms and methods to address those effects, new treatment modalities are being developed and may offer increased therapeutic resources for both adults and children.[192–194]

Even if therapies are not available on-site, it is useful to familiarize self and staff with evidence-based trauma therapies, how they work, how to refer locally and how to incorporate principals of treatment into pediatric anticipatory guidance. A quick reference for EBTs that includes a brief description of each and the level of evidence can be found on the California Evidence-Based Clearinghouse for Child Welfare (http://www.cebc4cw.org/). Some EBTs have been successfully adapted for telehealth,[195,196] and, in the wake of the coronavirus disease 2019 pandemic, opportunities for EBT via telehealth have expanded.[197] Telehealth is a mechanism to provide EBT in rural and other underresourced communities.[196]

Psychopharmacology

No medication, to date, is approved by the US Food and Drug Administration for trauma-specific symptoms or PTSD in children and adolescents. Medications may be judiciously considered for specific symptoms that are interfering with a child's ability to function normatively in specific ways.[72] Readers are referred to the AAP clinical report "Children Exposed to Maltreatment: Assessment and the Role of Psychotropic Medication" for discussion of medication use in identified comorbid mental health conditions.[87]

Role of Close Follow-up and Support

A commitment to working with the family over time may prevent or reduce feelings of abandonment or rejection, especially when community and mental health resources are in short supply. The pediatric provider who is continuous over time can continue to listen attentively and offer practical trauma-informed advice that reinforces resilience building and healing. Obtaining consent to share information with a mental health provider may also be reassuring to the caregiver or patient even after a referral and linkage to mental health care is established.

Integration

Once these aspects of care are part of a provider's repertoire of care, integrating knowledge about trauma into policies and procedures and daily practice are the next steps in creating a trauma-informed medical setting.[198,199]

Train All Staff in TIC

All staff, from schedulers to billers to nurses and care coordinators, can benefit from training in TIC that is thorough and discipline specific and includes information about physiology, presentation, recognition, and response.[15,200,201] This training would ideally promote patient empowerment and include caregiver and patient perspectives.

Implementing TIC in any setting is effective when there is consideration of clinic workflow to maintain efficiency. Specific strategies can include a warm and welcoming waiting room, clear communication of expectations and procedures, and providing choices when possible (eg, do you want blood pressure taken on right arm or left?).[201] As noted earlier, the care of a child who has experienced trauma requires an approach that is similar to addressing other health concerns. TIC can include members of the staff, all aware of and empowered to emphasize safety, patient self-efficacy, and a trauma-informed approach.[15,201] Use of formalized training in TIC for all staff has been found to be effective in changing staff-reported beliefs and behaviors for caregivers of children in residential care[202,203,204] and in improving child functioning and behavioral regulation.[204] In pediatrics, training of pediatrics residents caring for substance-exposed infants in TIC was effective at changing attitudes and improving therapeutic relationships.[205]

Office personnel may engage with caregivers and patients in ways that trigger strong emotions, especially if they themselves have experienced adversity or trauma. Financial considerations, scheduling, and conflict in the small spaces of an office can also be explored from a TIC perspective. Personnel would ideally engage in some planning

about how to handle a crisis or difficult situations that occasionally arise, such as the following: patients or caregivers who are indifferent or shut down, demanding, provocative, rejecting or hostile, or inattentive and distracted; or a child who is out of control and threatening to elope from the office. It is helpful to monitor one's own response when difficult situations arise and resist the urge to be angry or retaliate. It is less provocative to focus or comment on the emotion than the behavior: "I can see that you are angry, worried, sad, upset, etc," or "You probably don't want to be here right now." These responses are more affiliative and can help to shut down the stress response of the patient or caregiver whose fight-or-flight response may have been triggered by the health care setting, the interaction, or the medical stressor.

Integrated Health Care

Many providers find that the most efficient TIC can be provided by integrating physical and mental health services and social supports. Integrated care has been found to increase social-emotional screening rates[206] through colocation of services with clear strategies for medical provider introduction of the patient to the behavioral health consultant in real-time (warm handoff), by reducing the stigma of a mental health referral, or through facilitated or prearranged referral protocols.[191,207] Financial and staffing resource issues vary significantly by region, but investigating opportunities for primary care and mental health integration, social work, and/or formal engagement of referral sources and partnering organizations may increase the efficiencies of TIC. Providing case management to address the social modifiers of health (eg, referral to food bank, legal aid) can help to increase family resilience and prevent the consequences of trauma. Referring to resources has been revealed to be associated with increased employment, use of child care, and a decrease in the use of homeless shelters.[208]

Two-Generation Approach

Growing evidence has linked increasing parental ACE scores and negative effects on child health and development,[122,123,125,209] providing compelling evidence that taking a 2-generation approach is important. Families may customarily live in multigenerational family units, and this is a cultural norm for some. The opioid crisis has produced many kinship and grand-families, emphasizing the need for multigenerational care because both children and caregivers have suffered traumatic losses and may be influenced by their own trauma histories.[210] Addressing how adversity experienced by a caregiver in childhood may affect their parenting and resilience can have profound effects on a child's health and outcomes. This approach can include asking these questions in engagement, surveillance, and screening; careful consideration of how the provider or practice can and will respond to elicited issues is important before integrating this into practice flow.

Community Partnerships

Pediatric offices can develop methods to coordinate trauma-related care with schools, child care, early educators, courts, legal supports, child welfare services, and other community partners (see policy statement[19]).

Staff and Provider Support

Addressing the trauma experiences of others can have significant consequences for health providers and staff. Per the National Child Traumatic Stress Network, STS is the emotional distress that results when an individual hears about the first-hand trauma experiences of another.[136] The essential act of listening to trauma stories may take an emotional toll that compromises professional functioning and diminishes quality of life. Burnout is a syndrome characterized by a high degree of emotional exhaustion and depersonalization (ie, cynicism) and a low sense of personal accomplishment from work. Burnout refers more to general occupational stress and is not used to describe the effects of indirect trauma exposure specifically.[136] At least one meta-analysis concluded that job burnout contributes to, or at least increases the risk of, STS.[142] Recent surveys of medical students and residents reveal a high rate of depression (Patient Health Questionnaire-9 score >10) of 25% to 30%.[139,211] Some data indicate that more than 50% of the physician workforce in the United States suffers from burnout related to their profession.[212–214] For the individual physician, burnout can result in increased rates of apathy, depression, substance abuse, and suicide and can affect personal relationships.[139,212] STS similarly affects providers, although it is more often discussed in the mental health and child welfare literature rather than the medical literature.[144]

Detailed discussion of the response to burnout and STS is beyond the scope of this clinical report. However, effective TIC includes recognition of the effect of indirect trauma exposure on the workforce and safeguards to protect those caring for children and caregivers.[136,143] Acknowledgment that these are issues and providing resources to address them, with attention to leadership and supervision, have been cited as the most important first steps.[143,212,215] For both burnout and STS, support from the immediate supervisor and

organizational leadership have been demonstrated to be effective ways to combat the effects of trauma.[143,209] Team-based care, efficiencies in practice, and opportunities to share successes and frustrations with peers can all be helpful.[216–218] Promoting self-care remains an important part of TIC, with adequate time for rest, distance from the office or hospital, exercise, healthy diet, and prayer, meditation, or mindfulness shown to reduce symptoms of burnout and STS.[143,219,220] Such interventions are integral to developing and sustaining a trauma-informed practice and include all members of the health care team.

SUMMARY

TIC recognizes that exposure to adversities is common to many, if not most, children and that the developmental, behavioral, and health consequences can be profound and long lasting. Pediatric clinicians with an understanding of the physiology of both resilience and trauma are in a position to promote resilience, recognize and respond to traumas, and promote recovery.

Key Points

1. TIC is fundamentally relational health care, the ability to form and maintain SSNRs. Pediatric clinicians are well positioned to use a 2-generation approach, evaluate attachment relationships, and harness these attachments to encourage the caregiver's role in promoting regulation and resilience.
2. Providing TIC is achieved through common pediatric practices, starting with engagement and providing a safe setting for patients and families. Obtaining history, using surveillance or screening tools appropriate to the pediatric setting and clinical need, and effecting a response involving the pediatric provider and other community resources is consistent with addressing most health-related issues.
3. Trauma symptoms can vary, from changes in eating and sleeping to severe physical and mental health effects requiring extensive treatment. Individual differences in trauma symptoms relate to the interplay of exposures and buffering from SSNRs as well as genetic variations impacted by the early environment (biological differential sensitivity to context).
4. Treatment can begin in the office setting with psychoeducation and brief guidance for caregivers. Facilitating linkages to community resources for families to programs that promote positive parenting skills, regulation, and self-efficacy; address the SDoHs (poverty, housing, food insecurity, etc); or provide EBT further supports those at risk and can effectively treat those who are symptomatic.
5. Integrating this relational model of care to prevent and mitigate the impact of trauma so that all members of the care team feel supported and valued is integral to TIC. Addressing safety and supporting relationships that promote affiliative responses, decrease stress responses, and promote building resilience are principles of TIC for children, caregivers, and health care personnel.

Trauma-Informed Care in Child Health Systems

James Duffee, MD, MPH, FAAP,[a] Moira Szilagyi, MD, PhD, FAAP,[b] Heather Forkey, MD, FAAP,[c] Erin T. Kelly, MD, FAAP, FACP,[d]
COUNCIL ON COMMUNITY PEDIATRICS, COUNCIL ON FOSTER CARE, ADOPTION, AND KINSHIP CARE, COUNCIL ON CHILD ABUSE AND NEGLECT, COMMITTEE ON PSYCHOSOCIAL ASPECTS OF CHILD AND FAMILY HEALTH

Recent progress in understanding the lifelong effects of early childhood adversities has clarified the need for an organized strategy to identify and intervene with children, adolescents, and families who may be at risk for maladaptive responses. Trauma-informed care (TIC) in child health care operationalizes the biological evidence of toxic stress with the insights of attachment and resilience to enhance health care delivery to mitigate the effects of trauma. The resulting pediatric health care delivery strategy promotes and restores resilience in children and adolescents, partners with families to support relational health, and reduces secondary trauma among pediatric health care clinicians. This policy statement summarizes what policy makers, legislators, and health care organizations need to consider in terms of infrastructure, resources, and financial support to facilitate the integration of TIC principles into all pediatric points of care. The accompanying clinical report describes the elements of TIC in the direct care of children, adolescents, and families and covers the spectrum from prevention to treatment. The recommendations in this statement and the clinical report build on other American Academy of Pediatrics policies that address the needs of special populations (such as children and adolescents in foster or kinship care, in immigrant and refugee families, or in poor or homeless families) and are congruent with American Academy of Pediatrics policies and technical reports concerning the role of pediatric clinicians in the promotion of lifelong health.

INTRODUCTION

Over the past 2 decades, basic science has explained how cumulative adverse childhood experiences in the relative absence of safe, stable, nurturing relationships (SSNRs)[1] alter neurohormonal stress responses, gene expression, telomere length, brain development, and immunity, enabling researchers to elucidate how the body biologically embeds

childhood trauma. Recent studies of toxic stress support assertions that the origins of lifelong health are in early childhood and that chronic stress in childhood strongly predicts adult health status.[2,3] In the context of expanding evidence, pediatricians and others involved in community-based early childhood systems need strategies to mitigate the damaging effects of early childhood trauma and to promote resilience in children and families. Trauma-informed care (TIC) offers an organizing principle for pediatric practice that improves awareness of the spectrum of trauma-related symptoms, promotes an emotionally safe environment of care, and provides specific interventions to mitigate the effects of trauma exposure.[4,5] This policy statement presents recommendations for policy makers, legislators, and health care organizations for implementation of TIC into pediatric health systems. The accompanying clinical report[6] presents best-practice guidance for TIC in the direct care of children and adolescents.

BACKGROUND

TIC is defined by the National Child Traumatic Stress Network as medical care in which all parties involved assess, recognize, and respond to the effects of traumatic stress on children, caregivers, and health care providers. TIC also includes attention to secondary traumatic stress (STS), the emotional strain that results when an individual, whether a health care worker or parent, hears about or witnesses the traumatic experiences, past or present, of children.

TIC Promotes Relational Health and Resilience

Every pediatric encounter presents opportunities to promote family resilience and relational health.[7] Informed by research in infant mental health and neurodevelopment, early relational health refers to the establishment of foundational relationships during the first 3 years of life that are central to successful physiologic, emotional, and moral development of the young child.[8] Relational health, in a more general sense, is applicable to all age groups, is dyadic, and includes the capacity of both the child and caregiver to enter into a safe, secure, nurturing relationship allowing both to thrive.[1,9,10] Strong foundational relationships support resilience and buffer stress in children, so they can be considered primary prevention of stress-related disturbance. Trauma-informed practices also support relational health and family resilience as important protective factors for those who have been exposed to persistent adversity or potentially traumatic events (see Fig 1).

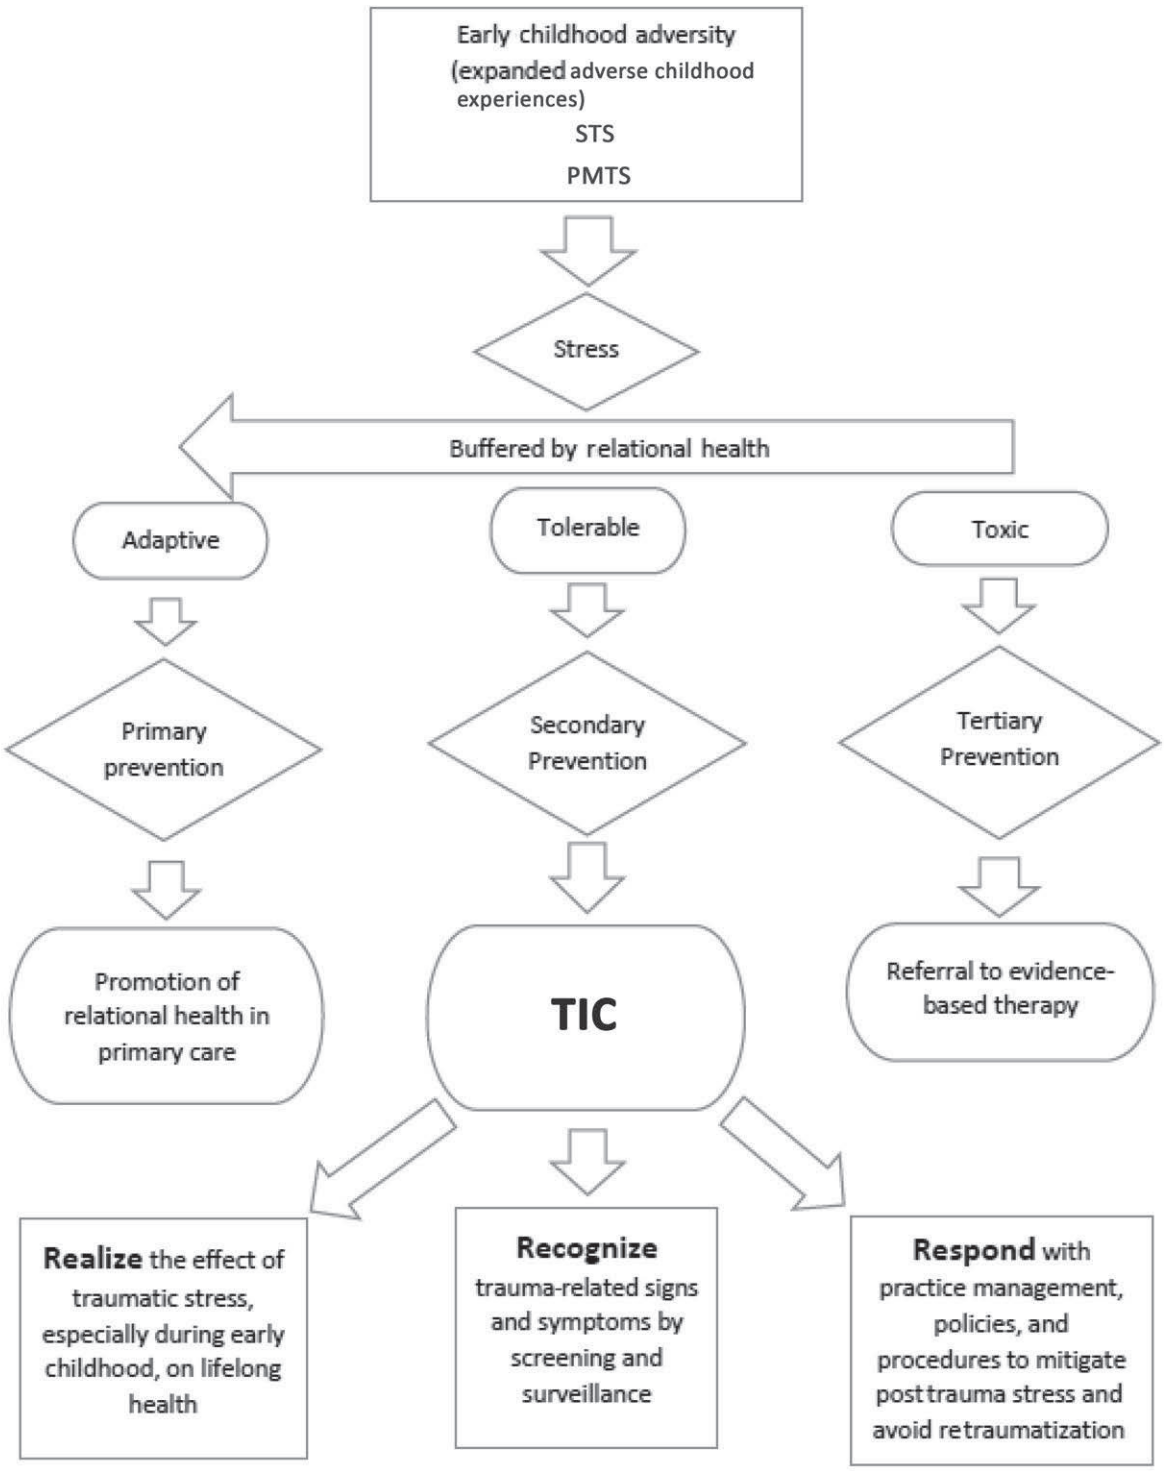
Human neuroendocrine–immune networks respond to internal and external sensors that identify danger and safety by activating in dangerous circumstances and deactivating when danger has subsided.[11] Toxic stress responses occur with prolonged activation of the neuroendocrine–immune system and dysregulation of homeostasis (or allostasis if multiple systems are involved)[12] in the absence of buffering by SSNRs. Toxic stress responses can result in lifelong impairments in physical, mental, and relational health.[13]

The concept of toxic stress adds an important physiologic basis to the study of attachment and our understanding of trauma. Trauma is defined as an event, series of events, or circumstances experienced by a person as physically or emotionally harmful that can have long-lasting adverse effects on the person's functioning and well-being (emotional, physical, or spiritual).[14] Attachment theory describes the deep and enduring relationship between a child and adult caregiver that ideally provides a secure base from which the child can develop and explore the world.[15]

Resilience is the dynamic process of adaptation to or despite significant adversity by using protective factors and learned skills to manage stressful circumstances.[16] Resilience may allow a person to experience tolerable rather than toxic stress in response to adversity. Some characteristics of resilient children include strong executive functions (self-control of attention and impulses) and a strong personal identity, often related to a cultural or faith tradition.[17] However, most important to both resilience and relational health is the capacity for young children to form at least one stable, caring, and supportive relationship.[9,18]

Exposure to Trauma Is Common

Almost half of American children, or 34 million younger than 18 years, have faced at least one potentially traumatic early childhood experience.[19] More than 1 in 7 adults report exposure during childhood to 4 or more adverse childhood experiences such as abuse, neglect, or other household adversity,[20] including intimate partner violence or parental incarceration. Certain populations are at higher risk for trauma exposure, both physical and emotional. In surveys, poverty or financial stress is the most commonly reported childhood adversity, second only to loss of a parent.[21,22] Exposure to divorce, child maltreatment, sexual abuse, intimate partner violence, bullying, parental mental illness, parental substance use problems, and community violence are also common.[21] Specific populations at high risk for trauma include children and adolescents who



397

FIGURE 1 Pediatric approach to TIC.

identify as LGBTQ, have developmental or behavioral problems,[23–25] are in foster or kinship care, are incarcerated, are living in deep poverty, or are immigrants. Potentially traumatic environmental and community-level conditions include economic stress, school or community violence,

adverse experiences during and after immigration, natural disasters, pandemics, and mass-casualty events such as shootings or bombings.

Racism is a common cross-cutting risk factor. Racial, ethnic, or religious bigotry magnifies the risk inherent to other special populations.[26] Experiences ranging from hate crimes, police profiling, bullying, or microaggressions to covert discrimination are traumatic events and may be internalized as trauma by those who are victims, indirectly or directly, of the events.[27,28] Historical trauma refers to the collective, transgenerational emotional and psychological injury of specific ethnic, racial, or cultural groups and their descendants who have experienced major events of oppression such as genocide, forced displacement, or slavery.[29,30] Originally applied to children of the Holocaust, the concept is now applied to American Indian and Alaskan native people, African American people, Mexican American people, Japanese American people, and other groups of people who have experienced mass trauma.[30] Investigators link historical "soul wounding" to current health and behavioral disorders including substance use disorder, domestic violence, and suicide, particularly in Indigenous communities.[29,31] Children separated from families during immigration and/or detained in group facilities overseen by the Office of Refugee Resettlement are a recent special population at severe risk for long-term sequelae resulting from forced family separation.[32,33]

The Effects of Early Life Trauma Are Felt Over the Life Course

In November 2019, the Centers for Disease Control and Prevention reviewed the emerging literature linking early childhood adversity with adult illnesses[20,34] and analyzed survey data from 25 states over 2 years.[3,35] Researchers concluded that reducing exposure to early childhood trauma and mitigating posttrauma effects would generally and significantly reduce adult morbidity and mortality. Using logistic regression modeling, they estimated potential reductions in incidence from low for obesity (1.7%) to high for heavy drinking, chronic obstructive pulmonary disease, and depression (23.9%, 27.0%, and 44.1%, respectively). Recommendations included creating healthy communities, supporting SSNRs, and developing programs that apply primary (reducing exposure to childhood adversity) and secondary prevention (mitigating the effects of exposure) on the basis of principles of TIC.

There Is Need for a Child-Specific Trauma Nosology

The *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (DSM-5) presents a list of trauma-related disorders ranging from mild (adjustment disorder) to severe (posttraumatic stress disorder [PTSD]).[36] Two additional categories, reactive attachment disorder and disinhibited social engagement disorder, are specific to young children (please see the DSM-5 for complete diagnostic criteria). This nosology can be expanded to describe other presentations common in pediatric health care settings: developmental trauma disorder (DTD), pediatric medical traumatic stress (PMTS), and STS, the last being most relevant for health care workers, family members, and caregivers.

DTD

The diagnosis of PTSD, as outlined in the current DSM-5, does not adequately describe the variable presentations of trauma manifestations in children across developmental stages.[37] Children with complex trauma histories often exhibit heterogeneous developmental symptoms as well as difficulties with intimate relationships and with regulation of attention and impulse control.[38] DTD is a proposed new diagnostic category that incorporates these differences and attempts to better describe the disturbances that occur in multiple developmental domains.[39] The omission of DTD in the DSM-5 has been controversial,[40] and the search for a better nosology of trauma, including DTD, is ongoing.[41]

PMTS

PMTS refers to the distress that patients and family members experience during hospitalization for a perceived life-threatening diagnosis or while living with or caring for individuals with life-altering chronic conditions.[42] PMTS is underrecognized and rarely addressed despite its high prevalence.[43,44] Up to 80% of ill or injured children and their families may have traumatic stress reactions after a life-threatening illness, injury, or procedure.[45] In some surveys, up to 20% of parents of children admitted to a PICU develop PTSD within a few months.[45] The suffering of family members and caregivers is often not addressed because of existing structural and reimbursement obstacles for multigenerational care.

Although research on PMTS (and on pediatric postintensive care syndrome)[46,47] is ongoing, researchers in 1 study found that approximately 10% of children developed PTSD 3 to 5 months after major surgery, and 28% developed posttraumatic stress symptoms (PTSS) resulting in functional disability by parent report.[48] PTSS can also occur after a severe injury or diagnosis of an illness such as cancer. In another family study,

more than 10% of children had persistent functional impairment from PTSS at 6 weeks and 1 year after a potentially life-threatening injury or diagnosis, and 15% of mothers and 8% of fathers met criteria for PTSD at 1 year.[49]

STS

As described earlier, STS may occur in parents, other family members, and health care workers such as physicians, nurses, other hospital staff, first responders, and therapists. STS may have many of the same long-term effects on health that affect children exposed to trauma.[50] Some health care workers may also develop disabling posttrauma symptoms that can interfere with quality of life both at work and home. Health care workers may have their own trauma histories that contribute to their reactions when exposed to the suffering of others. Nonclinical staff may also experience STS triggered by their own trauma histories, especially if the health care facility is located in an area with high adversity and nonclinical staff live in the vicinity.

Burnout and STS

Preliminary evidence exists of a synergistic effect among STS, depression, and burnout in affected health care workers.[51] STS in combination with burnout has been associated with a significant increase in the frequency of medical errors.[52,53] Depression, anxiety, and suicide are greater risks for physicians than for the general population. In the United States, the rate of suicide among female physicians is 130% higher than among women who are not physicians; the rate for male physicians is 40% higher than for men who are not physicians.[51] Burnout includes a spectrum of pathologic conditions that develop in the context of occupational stress and is almost twice as prevalent among physicians. The risk among nurses for burnout, depression, and STS is even higher. More than half of nurses reported suboptimal mental or physical health,[54] approximately 35% reported a high degree of emotional exhaustion,[55] and 18% reported depression in national surveys. Reports of posttraumatic stress among health care workers related to the coronavirus disease 2019 pandemic prompted worldwide concern for increased awareness and trauma-informed support for the mental health of all involved.[56]

CORE ELEMENTS OF TRAUMA-INFORMED SYSTEMS

Core principles that can be helpful for policy development, outlined by the National Council on Behavioral Health (2019)[57] are outlined in the following sections. Implementation of TIC at a practice level is described in detail in the accompanying clinical report.[6]

Safe Physical and Emotional Environment

The health care organization, workspace, and every encounter should be characterized by compassion, cultural humility, equity, collaboration, and safety for families and employees. An emotionally safe workplace includes acknowledgment of and particular attention to racial and gender discrimination, including implicit bias both in rendering care and workplace human relations. A review of health care settings from the viewpoints of patients, families, and staff can uncover practices, processes, or details in the environment that are potentially traumatizing.

Leadership Commitment to TIC

Hospital and health system leadership can annually review policies and procedures to ensure a safe work environment and setting to provide TIC, to reduce STS and burnout, and to promote sensitivity to the needs of trauma survivors.[58] The alignment of financial and human capital resources to support an optimal health environment in all levels and locations of care is extremely important. Surveys designed to assess system readiness for implementation are available and can be adapted for pediatric health care settings.

Surveillance and standardized screening to assess staff and patients for trauma exposure, symptoms, and strengths are important components of trauma-informed pediatric care. Universal screening, when implemented within the larger context of trauma-informed approaches and endorsed and supported by administrative leadership, reduces stigma and allows standardized responses such as time off or referral to an employee assistance program. Families and youth may be queried at the point of care, such as at the time of hospital admission. Formal screening should always be for the benefit of children and adolescents, avoid retraumatization, and identify protective as well as risk factors.[59] More specific information about screening is included in the accompanying clinical report.[6]

Patient and Family Empowerment

Involvement of families and youth in the development of TIC policies and practices, particularly regarding cultural, historical, and gender issues, is essential to building an environment of support and mutuality.[14] Both formal and informal structures, such as Family Advisory Councils and family-centered rounds,[60] create a cultural expectation of collaboration and enable the health care team to understand the strengths and vulnerabilities of individual families

and of the populations served. When appropriate, tribal elders, traditional healers, and other faith community leaders can be included in developing individual care plans or institutional quality-improvement efforts. A whole-person, whole-family, whole-community perspective promotes improved awareness of how cultural backgrounds affect the perception of trauma, safety, and privacy.[61,62]

TIC Continuous Through the Health Care System

TIC, from a public health perspective, includes primary, secondary, and tertiary prevention strategies. Primary prevention is a comprehensive approach that addresses social determinants of health (such as structural racism, poverty, and violence) that are often root causes of community trauma.[63] Promotion of relational health and other resilience factors (such as strong executive function and self-efficacy) may be considered primary prevention.[64] Following the fourth edition of *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents*, promotion of early childhood relational health is a core purpose of both pediatric primary care and early childhood education.[65]

The National Child Traumatic Stress Network includes the promotion of child and family resilience, enhancement of protective factors, awareness of parent or caregiver trauma, and involvement of families in program development and evaluation as secondary prevention.[66] Trauma-informed therapies (eg, trauma-focused cognitive behavioral therapy) for symptomatic children and youth are considered tertiary prevention. These therapies are especially important for high-risk populations as identified earlier.[67–70]

Attachment-based dyadic therapies, such as parent–child interaction therapy, may serve to prevent development of persistent traumatic stress symptoms in high-risk families[71] and may be considered both secondary and tertiary prevention.

Recruitment and Training of a Trauma-Informed and Compassionate Workforce

Recruitment and pre-employment practices may help discern the capacity for empathy among prospective employees.[72] Training and education of all administrators, clinicians, and staff, both clinical and nonclinical, can promote the appreciation of the lifelong effects of trauma on child and adolescent development and family resilience and the implementation of trauma-aware practices. Continuous quality-improvement programs translate new knowledge and skills about childhood trauma into supervision, training, and patient care.

Prevention of STS requires specific training of all staff to raise awareness, promote resilience, and explore the interaction among STS, burnout, depression, substance use, and professional quality of life. Supportive supervision and peer mentoring offer opportunities for all employees to reflect on their own trauma histories and to promote compassion, nonjudgmental attitudes and collaboration.[73]

Coordination of Care Across Family-Serving Systems in the Community

Trauma-informed health care systems establish and support collaborative, interdisciplinary relationships among community and public health agencies that serve children and adolescents to coordinate care for children, adolescents, and families exposed to trauma. Schools,[74] juvenile justice programs,[75] mental health professionals,[76] home visiting services, child welfare systems,[76] and foster care agencies[77] are natural partners for pediatric health organizations in promoting community resilience. Many have established TIC programs. Community early intervention programs can help prevent and mitigate adversity and often have the advantage of caring for young children in their natural environment as home visitors.[78–80]

RECOMMENDATIONS FOR SYSTEM-LEVEL IMPLEMENTATION

Federal and State Funding

Federal agencies such as the Centers for Disease Control and Prevention can continue and expand research to improve understanding of the developmental effects of trauma and the efficacy of specific interventions for historically resilient populations. Urgently needed are successful strategies to interrupt the intergenerational transfer of family violence. Strategies are also crucial to blunt the impact of historical trauma in communities of color and in American Indian and Alaskan native populations in the United States.[30] It is particularly important to identify the origins of and successfully mitigate community violence, including racism, misogyny, and religious, ethnic, and cultural bias.

State-level resources can be directed to implementation, dissemination, and evaluation of trauma-informed community programs, such as interagency and multigenerational strategies for opioid dependency. One example of a state interagency, multigenerational treatment program is Ohio START (Sobriety, Treatment and Reducing Trauma).[81] States could develop a communication infrastructure to

facilitate data sharing, improve interdisciplinary/interagency cooperation, and engage community partners including foundations and academic institutions.

Federal guidelines can require that state Medicaid programs ensure comprehensive coverage for all children and adolescents and pregnant mothers without regard for legal or immigration status and mandate that coverage include mental health and substance use disorder services. Financing that increases access to high-quality, comprehensive, coordinated, culturally competent health care for high-risk populations is a high priority. Federal and state regulations can require all insurers, including Medicaid and private health insurers, to include coverage for TIC elements, including surveillance, screening, diagnosis, counseling, case management, follow-up, community collaboration, mental health care, and home visiting.

Large Health Systems, Insurers, and Managed Care Organizations

In large health systems, leadership can align its mission and financing with the core elements of trauma-informed systems.[82] Supporting TIC includes payment for trauma-informed, integrated mental health services, care coordination, rigorous case management, and seamless referral networks for intensive treatment. Prevention of secondary trauma, including care of affected health care workers, should be built into the mission of the health system.

Academic Centers and Children's Hospitals

Academic health centers train and educate the next generation of physicians, nurses, and ancillary health personnel and can promote the transformation to TIC in all health settings through education, research, and advocacy. Children's hospitals and health systems can model mental health integration[83] and trauma-informed practices throughout all service lines.[84] Because children's hospitals embrace population health management and community advocacy, they may serve as the anchor institution collaborating with community agencies to address social adversity at the neighborhood level while promoting TIC services.[85] Together with community pediatric care systems, academic health centers and children's hospitals can integrate core elements of education into workforce training for health care workers and community partners such as first responders, child welfare workers, teachers, and juvenile justice personnel.[86,87]

SUMMARY OF RECOMMENDATIONS

Federal and State Government

- Continue and expand research funding for the National Institutes of Health, Centers for Disease Control and Prevention, Substance Abuse and Mental Health Services Administration, and other federal agencies to improve the understanding of the root causes and developmental effects of trauma and effective interventions.
- Support epidemiological research of at-risk populations emphasizing prevention, early identification, and mitigation of the effects of community trauma.
- Facilitate interdisciplinary and interagency cooperation and data sharing to promote seamless care, research data collection, and amplification of promising practices in TIC.
- Engage national partners, foundations, and academic institutions in cross-systems planning to support early relational health.
- Support curriculum development and implementation through mechanisms such as the Agency for Healthcare Research and Quality.
- Expand health care coverage and payment for enhanced services such as integrated mental and social care.
- Mandate coverage for TIC services by government and private payers, including screening, diagnosis, office-based management, counseling, case management, community collaboration, and home visiting.

Large Health Systems and Managed Care Organizations

- Commit to becoming a trauma-informed system of care and integrate clinical practice of TIC into all services.
- Recruit, retain, and train a trauma-informed workforce.
- Expand and improve system-wide strategies for identification and treatment of all children and adolescents affected by traumatizing experiences.
- Build seamless referral networks for intensive treatment when indicated.
- Develop care models and fair payment mechanisms to promote implementation of TIC, including practice-level case management.
- Promote system-wide trauma-informed quality-improvement programs.
- Support engagement by including family advisors and employees in service planning and quality improvement, with particular emphasis on cultural, ethnic, gender, and racial concerns.

- Develop, implement, and evaluate policies and procedures to reduce retraumatization and STS and to identify, support, and refer for treatment health care workers who are symptomatic from traumatic stress.

American Academy of Pediatrics, American Academy of Pediatrics Chapters, and Academic Institutions

- Develop curricula on trauma and resilience for trainees, practicing pediatricians, and their teams.
- Support community collaboration with agencies that serve children and adolescents to create a seamless trauma-informed system of care.
- Develop and share quality improvement and maintenance of certification modules at state, chapter, and national levels.
- Develop a comprehensive research agenda for TIC in pediatric health systems.
- Partner with organizations such as the National Child Traumatic Stress Network to investigate new models of integrated care including pediatric and psychiatric telenetworks.
- Include questions about TIC in periodic surveys of pediatricians.
- Evaluate intervention and treatment strategies in collaboration with federal and state initiatives and mental health partners.
- Provide workshops, seminars, or online modules to train cross-system professionals about childhood trauma and resilience.

Tuberculosis Infection in Children and Adolescents: Testing and Treatment

Dawn Nolt, MD, MPH, FAAP,[a] Jeffrey R. Starke, MD, FAAP,[b] COMMITTEE ON INFECTIOUS DISEASES

Tuberculosis (TB) remains an important problem among children in the United States and throughout the world. There is no diagnostic reference standard for latent tuberculosis infection (also referred to as tuberculosis infection [TBI]). The tuberculin skin test (TST) has many limitations, including difficulty in administration and interpretation, the need for a return visit by the patient, and false-positive results caused by cross-reaction with Mycobacterium bovis–bacille Calmette-Guerin vaccines and many nontuberculous mycobacteria. Interferon-gamma release assays (IGRAs) are blood tests that use antigens specific for M tuberculosis; as a result, IGRAs yield fewer false-positive results than the TST. Both IGRAs and the TST have reduced sensitivity in immunocompromised children, including children with severe TB disease. Both methods have high positive predictive value when applied to children with risk factors for TBI, especially recent contact with a person who has TB disease. The advantages of using IGRAs and diminished experience with the placement and interpretation of the TST favor expanded use of IGRAs in children in the United States. There are now several effective and safe regimens for the treatment of TBI in children. For improved adherence to therapy, the 3 rifamycin-based regimens are preferred because of their short duration. Daily isoniazid can be used if there is intolerance or drug interactions with rifamycins. A TB specialist should be involved when there are questions regarding testing interpretation, selection of an appropriate treatment regimen, or management of adverse effects.

INTRODUCTION

Tuberculosis (TB) remains an important disease in the United States and throughout the world. Approximately 9000 new cases occur each year in the United States.[1] Of the 5175 children and adolescents younger than 18 years with TB disease reported in the United States from 2010 to 2017, 32% were born in other countries.[2] Infants and young children (younger

than 4 years) have the highest rate for tuberculosis infection (TBI) progressing to TB disease rapidly after exposure, within a few weeks to several months. Children who move to the United States from countries with high TB burden (eg, Asia, Middle East, Africa, Latin America, countries of the former Soviet Union) often received no testing for TBI, expanding the pool of infected children in the United States. Some of these children developed TB disease or are evaluated and treated for TBI after emigrating, but many have untreated TBI and are at risk for developing TB disease later in life. In addition, many US-born children who have been infected with *Mycobacterium tuberculosis* within the United States or abroad have gone undetected.

In most children and adolescents, initial infection with *M tuberculosis* is eliminated or contained by host defenses, and the person remains asymptomatic. However, residual bacilli may remain viable and become active again to cause TB disease. Treatment of TBI substantially reduces the risk of developing TB disease in children who adhere to therapy by 90% in both the immediate and distant future.[3] Therefore, the goal of testing for TBI is to identify individuals who are at risk for developing TB disease and will benefit from treatment.[4–6]

In the pediatric population, infants and children (younger than 4 years) and adolescents are at higher risk of progressing from TBI to TB disease than are primary school-aged children. The risk of progression in infants younger than 12 months with untreated TBI is 40% to 50%, decreases to 25% in children 1 to 2 years of age, drops to 5% to 10% in school-aged children, and is 10% to 15% in adolescents (Table 1). Epidemiological factors also define risk of infection: children who were born and lived in or have traveled to an area of the world with a high prevalence of TB and those who have had a household or family member with TB disease or TBI are at higher risk for TBI than the general population. As a result, selective testing for TBI of children on the basis of their risk factors has been adopted as the main strategy in the United States.[7,8]

Although the diagnosis of TB disease is confirmed by the detection of *M tuberculosis* in a clinical sample, there is no diagnostic gold standard for diagnosis of TBI.[3,9,10] Two available but imperfect methods for identification of TBI are the tuberculin skin test (TST) and the interferon-γ release assay (IGRA). Both methods depend on cell-mediated immunity and provide immunologic evidence of host sensitization to antigens of *M tuberculosis*. Neither method can distinguish between TBI and TB disease, and both methods display suboptimal performance in immunocompromised patients, who are at greatest risk for progression of TBI to TB disease.

GENERAL TESTING CONSIDERATIONS

Both the TST and IGRA depend on the host immune response to specific antigens found in *M tuberculosis*. Determining the sensitivity and specificity of both test types for children is difficult. They were studied and compared initially in children with culture-confirmed TB disease because microbiologic confirmation is the only real proof of TB disease. However, children with culture-proven TB disease tend to have more severe manifestations and clinical illness. Increased severity of disease may result in immunosuppression and diminish the sensitivity of tests that rely on the immune response, such as both the IGRA and TST. As a result, the sensitivity of both test types can be low for TB disease.[11,12] Children with less severe TB disease often do not have microbiologic confirmation, lacking the absolute proof of infection that is needed to accurately assess test sensitivity and specificity, and many studies have used less reliable methods of clinical diagnosis of TB disease instead. The major difficulty for interpreting studies of the relative performance of the TST and IGRA is that there is no gold standard test, so it is difficult to determine for discordant test results whether the negative test result is more specific or the positive test result is more sensitive.

TABLE 1 Age-Associated Risk of Progression From TBI to TB Disease

Age	Risk of Progression from TBI to Disease if Untreated, %
<12 mo	40–50
1–2 y	25
School-aged	5–10
Adolescents	10–15
Adults	5–10

Risk of progression is also increased in immunocompromised individual and those recently infected with *M tuberculosis*.

The TST

The TST is the intradermal injection of 5 TU of purified protein derivative (PPD) or 2 tuberculin units (TU) of PPD-RT23, the latter used predominantly in Europe. PPD tuberculin solution contains dozens of TB antigens, with the exact composition varying among batches and preparations. Many of these antigens also are present in environmental nontuberculous mycobacteria (NTM) prevalent throughout the United States and in the bacille Calmette-Guérin (BCG) vaccines. A patient who mounts a cell-mediated response to tuberculin antigens has a delayed-type hypersensitivity response usually within 48 to 72 hours, causing measurable induration at the injection site.

TST results can be difficult to interpret. The test depends on accurate intradermal injection, which should be performed by an experienced individual. Interpretation requires that the patient returns in 48 to 72 hours. Correct interpretation of the reaction involves careful measurement of induration that should be determined by a provider with experience in this measurement. The measurement should be recorded to the nearest millimeter of the transverse diameter of the induration (Fig 1). Reaction size can vary (on average) within the same individual by 15%, which has been described when the test is placed simultaneously on both arms.[13] The variability in measuring induration among experienced observers also varies by about 15% and is much greater among inexperienced personnel and untrained people, especially family members.[13] Therefore, family members should not be allowed to interpret a TST result. False-negative TST results can be caused by improper handling of the tuberculin solution, improper placement of the test, and incorrect interpretation of the results.[13]

FIGURE 1 Measurement of TST reaction. The technician is marking the widest edges of the patient's induration (a hard, dense, raised formation) with a pen for accurate measurement of the TST reaction. To locate the skin test site, the arm should be inspected in good light and on a firm surface. A light, gentle motion is used to sweep the fingertips over the surface of the forearm to locate the margins or edges of induration. As in this image, the widest edges of the induration are marked with a pen, using the fingertips as a guide. A millimeter ruler is then used to measure the diameter of the induration between the 2 marks. Image courtesy of CDC/Gabrielle Benenson.

Induration at the site of the TST is caused by migration of mostly mononuclear cells to the area and the inflammatory process secondary to these cells' response. This response can be attributable to infection with *M tuberculosis*, exposure to NTM, or receipt of BCG vaccine. The patient's history and the size of the induration help to determine which of these 3 potential causes may be likely associated with TST reaction. People with exposure to environmental NTM often have indurations $<$10 mm, but larger reactions are not uncommon. Among populations with a low prevalence of TB but a high prevalence of exposure to environmental NTM, such as in the United States, the distribution of reactions between individuals with TBI and those with NTM exposure overlap to a considerable degree.[7] The most effective way to minimize false-positive results is to avoid testing individuals who lack a risk factor for TBI (Table 2).

To improve TST performance, the practice has been to vary the cutoff for the size of the TST reaction considered positive to optimize the sensitivity and specificity of the result. The cutoff is set at $\geq$15 mm to optimize specificity for people lacking TBI risk factors but who are tested for administrative reasons, $\geq$10 mm for people with a risk factor for TBI, and $\geq$5 mm to optimize sensitivity for people at high risk of having or developing TB disease if they have TBI (clinical evidence of TB disease, recent TB exposure, or significant immune compromise).[14]

BCG vaccines are administered in countries with high TB burden because they reduce the risk of disseminated (miliary) and central nervous system TB in children.[15] Interpretation of TST results in BCG recipients who are known contacts of a person with TB disease or at high risk for TB disease is the same as for people who have not received BCG vaccine. For a foreign-born child, history of BCG vaccination should be determined by examination of the vaccination record and the finding of a typical BCG scar, usually located on the deltoid region of either arm. Many of the antigens in PPD also are found in *M bovis*-BCG, the organism in the BCG vaccines. Some individuals who are not infected with *M tuberculosis* may express induration in response to the TST that reflects previous receipt of a BCG vaccination. The size of the TST reaction varies with the strain and dose of vaccine,[16] the route of administration,[17] age at vaccination,[18] the time interval since vaccination,[19] and the number of BCG doses. Approximately half of infants who received a BCG vaccination will respond with significant induration to a TST. Although most, perhaps as many as 90%, of children 5 years or older who received a BCG vaccine as an infant will not have a positive response to a TST (unless also infected with *M tuberculosis*, which may not be prevented by BCG vaccination), some will retain this response, causing a false-positive result. The induration often measures $<$10 mm but can be $>$15 mm.[7,20] Children born in countries with a high TB burden (Table 2) are candidates for selective testing for TBI, but a large number of false-positive results occur when the TST is used on children who have received a BCG vaccine. Children who have received a BCG vaccination also may be subject to "boosting" from the TST, the immunologic recall of

TABLE 2 Risk Factors for Increased Risk of Acquiring TBI and/or Progressing to TB Disease

Contacts of people with confirmed or suspected contagious TB (contact investigation)
Children with radiographic or clinical findings suggesting TB disease
Children immigrating from countries with endemic infection (eg Asia, Middle East, Africa, Latin America, countries of the former Soviet Union), including international adoptees
Children with history of significant travel[a] to countries with endemic infection who have substantial contact with the resident population
Children with HIV infection
Children with other medical conditions, including diabetes mellitus, chronic renal failure, malnutrition, or congenital or acquired immunodeficiencies and children receiving TNF-α antagonists, which may enhance the possibility for progression to severe disease

[a] Determination of significant travel should account for the frequency of travel and the duration of time. Testing should be conducted 8–10 wk after completion of travel, to allow for the known incubation period of *M tuberculosis*.

hypersensitivity to antigens in the PPD that are also present in *M bovis*-BCG, which creates a false-positive TST result.[21,22]

False-negative TST results can occur because of limited ability of certain children with TBI or TB disease to mount an appropriate delayed-type sensitivity response, especially those who are immunosuppressed either by disease (such as advanced HIV infection, advanced TB, cancer, or malnutrition) or who receive immunosuppressive treatments (such as corticosteroids, cancer chemotherapy, and immunomodulating biological agents, especially the tumor necrosis factor-α [TNF-α] inhibitors or live-virus vaccines). Unfortunately, children for whom the TST has diminished sensitivity are those individuals most likely to progress to TB disease if infected.[3]

In summary, there are limitations to both the sensitivity and the specificity of the TST. The positive predictive value of the TST is much greater when it is applied to individuals who have a recognized risk factor for TBI. When the TST is used for individuals lacking risk factors, the vast majority of the positive results may be falsely positive, and this problem is accentuated in children who received a BCG vaccine.[7] One large study using latent class analysis (a method of analysis that creates a statistical gold standard when no such test is available) demonstrated that the positive predictive value of the TST for TBI among foreign-born children younger than 5 years, most of whom had received a BCG vaccine, was 10%, meaning that 90% of the positive results were presumably falsely positive.[23] In addition, the test has poor sensitivity in immunocompromised children, who have the greatest risk of progression to TB disease. Because of these limitations, some experts have called for the "retirement" of the TST in favor of the IGRA.[24]

The IGRA

IGRAs are ex vivo blood tests that detect interferon-γ (IFN-γ) release from a patient's $CD4^+$ and $CD8^+$ T lymphocytes after stimulation by antigens found on *M tuberculosis* complex (which includes *M tuberculosis*, *M bovis*, *M africanum*, *M microti*, and *M canetti*). Two IGRAs are available commercially: the QuantiFERON-TB Gold Plus assay (QFT; Qiagen, Hilden, Germany), which has largely replaced the previously used and studied QuantiFERON-TB Gold In-Tube assay, and the T-SPOT.TB assay (T-SPOT; Oxford Immunotec, Abingdon, United Kingdom). However, the studies of QFT published before 2017 used the QuantiFERON-TB Gold In-Tube assay. Both the QFT and T-SPOT use early secreted antigenic target 6 (ESAT-6) and culture filter protein 10 (CFP-10) encoded by genes located within the region of difference 1 (RD1) locus of the *M tuberculosis* genome. The RD1 antigens used in the 2 IGRAs are not encoded in the genomes of *M bovis*-BCG strains, although they are present on wild-type *M bovis*, or most species of NTM, specifically not on the *M avium* complex organisms that are the most ubiquitous pathogenic environmental NTMs. The RD1 antigens may be found on other NTM strains that are rare causes of human disease (*M marinum*, *M kansasii*, *M szulgai*, and *M flavescens*). As a result, because the antigens in IGRAs are not found on most clinically relevant NTM and *M bovis*-BCG strains, one would expect that IGRAs will be more specific than the TST, yielding fewer false-positive results. Like the TST, IGRAs do not distinguish between TBI and TB disease.[25]

Test Characteristics

Both IGRAs are performed with positive and negative controls. The QFT assay is an enzyme-linked immunosorbent assay (ELISA) whole blood test. The QFT has 2 TB antigen tubes: tuberculosis antigen tube 1 (TB1) and tuberculosis antigen tube 2 (TB2). TB1 contains peptides from ESAT-6 and CFP-10, which are designed to elicit an immune response from $CD4^+$ T-helper lymphocytes. TB2 contains an additional set of peptides targeted for a cell-mediated immune response from $CD8^+$ cytotoxic T lymphocytes, included to bolster overall test sensitivity. The test result is considered positive when the IFN-γ response to the TB antigens (contained in TB1 and

TB2) is above the test cutoff of 0.35 IU/mL (after subtracting the negative control value from the test antigen value). If the test result is negative but the positive control also shows a poor response (a positive control failure from immunosuppression), or the background response in the negative control is too high (a negative control failure, perhaps from high baseline IFN-γ production attributable to systemic inflammation[26]), the result is considered indeterminate (neither negative nor positive). In this situation, testing on a different specimen is recommended.[27]

The T-SPOT assay is an enzyme-linked immunosorbent spot (ELISPOT) assay performed on peripheral blood mononuclear cells that have been incubated with peptides from ESAT-6 and CFP-10. The result is reported as the number of IFN-γ producing T-cells (spot-forming cells). The test result is considered positive when the number of spots in the test sample, after subtracting the number of spots in the negative control, exceeds a specific threshold of $\geq$8 spots; the test result is negative if there are 4 or fewer spots. Results with a corrected spot count of 5, 6, or 7 are considered borderline (equivocal), and retesting on a different specimen is recommended by the manufacturer. If the positive control shows a poor response ($<$20 spots), or if the background response in the negative control is too high ($\geq$10 spots), the result is termed invalid or indeterminate (neither negative nor positive).[9] In this situation, testing on a different specimen is recommended.[27]

Although there are standard manufacturer instructions for performing IGRAs, concerns have been raised about the reproducibility of the results on serial performance. Serial testing of health care workers at low risk of TBI have revealed cases of unexplained cases of low-level positive IGRA results reverting to negative on repeat testing.[28] Nkurunungi et al[29] performed T-SPOT tests on 405 Ugandan children at age 5 years and then repeated the test 3 weeks later. Of 79 children who had an initial positive T-SPOT result, only 30 (38%) had a positive result 3 weeks later, whereas 96% of the children with an initial negative result had a negative result on repeat testing. The test agreement was better among children who were household contacts of a person with TB (κ = 0.77) than among noncontacts (κ = 0.29). The majority of the reversions and conversions occur among low-level results, usually between 0.35 and 1.0 IU/mL for QFT, although they can occur at higher levels.[30,31] The exact cause(s) of low-level false-positive results are unknown, but there appear to be seasonal variations that might explain increased nonspecific reactivity in the assay.[32]

A further explanation of low-level positive IGRA results is the concept of test-retest variability.[33] For example, a test with 80% sensitivity and 70% specificity and a 5% test-retest variability would be associated with a conversion rate of 3.7% in the absence of TBI and a reversion rate of 7.7%. However, a test with 80% sensitivity and 95% specificity but 10% test-retest variability would be associated with a conversion rate of 5.5% and a reversion rate of 57%. T-lymphocyte assays are susceptible to test-retest variability by numerous factors, including manufacturing issues; sample collection issues, such as inconsistencies in specimen collection, inadequate blood volume, delays in isolation and incubation of cells, and inadequate shaking (mixing) of the IGRA collection tubes; and laboratory issues caused by systematic or random error.[34] Efforts to reduce test variability through better specimen collection and handling and laboratory standardization will minimize low-level false-positive results.[3,33]

Published studies have shown a variety of differences in outcomes between the 2 basic IGRA techniques, ELISA (QFT) and ELISPOT (T-SPOT). However, these differences have been small and inconsistent among studies, and the preponderance of evidence supports the conclusion that, in terms of accuracy, neither IGRA is strongly preferred over the other.

General Aspects of Studies in Children

The major difficulty for interpreting studies of TBI is determining, for discordant test results between the TST and IGRAs, whether the negative test result is attributable to enhanced test specificity or whether the positive test result is attributable to enhanced test sensitivity. Four systematic reviews and meta-analyses of the available studies of the use of IGRAs in children were published in 2011 and 2012[35–38]; analysis of the studies was hampered by the heterogeneous methodologies used, including varying definitions of a clinical case of TB disease. Some of the early published studies used ELISA and ELISPOT techniques that were different from those that currently are commercially available. More recent rigorous studies using commercially available assays have clarified some issues. Studies have been performed in countries with both low and high TB burden, which often differ greatly in the severity of TB disease, rates of malnutrition in children, availability of TB diagnostic tools, structures of households where transmission often occurs, and the use of various

BCG strains and vaccination techniques.

Test Specificity in Children

Although there are variable results among individual published studies, the strongest and most consistent result is that IGRAs have a higher specificity for TBI, especially in settings of low TB burden and for BCG-vaccinated children.[39–43] This conclusion is based on comparison of test results across exposure gradients of contact investigations in schools and the community in otherwise low-burden settings.[44,45] In their meta-analysis, Sun et al[37] included 7 studies that assessed IGRA specificity in populations with rates of BCG vaccination ranging from 0% to 100%. The specificity of ELISPOT was 89% for BCG-vaccinated and 95% for BCG-unvaccinated children, compared with a TST specificity of 49% for BCG-vaccinated and 93% for BCG-unvaccinated children: agreement (measured by κ scores) between the TST and IGRA in BCG-unvaccinated children was higher than in vaccinated children, probably because of false-positive TST results caused by previous BCG vaccination. Lighter et al[44] found that among 207 children in New York, only 23% of the children with a positive TST result had a positive QFT, and, unlike the TST results, positive QFT results correlated with increased risk of TB exposure. Chun et al[46] also found among 227 BCG-vaccinated children in South Korea that QFT results were more closely associated with exposure to a TB case than were TST results.

The most convincing evidence of increased specificity of IGRAs would be to determine rates of progression to TB disease among untreated children who have positive TST results and negative IGRA results. Ling et al[47] evaluated how clinicians in Montreal used IGRA results to determine management of children. Among 55 children with positive TST results and negative QFT results who were part of TB contact investigations, the negative QFT result changed management in only 3 children; 52 children received isoniazid. However, of 201 children with positive TST results and negative QFT results who were tested in school and immigration screenings, 145 did not receive treatment, and none developed TB disease in 1 year of follow-up. Researchers in a prospective multicenter trial in the United Kingdom studied 431 children who were recently exposed in their household to an infectious case of TB; 18 children with a positive TST but negative IGRA result went untreated, and none developed TB disease.[48] A large multicenter trial in the United States performed a TST and IGRA on 3593 children at risk for TBI and/or progression to TB disease (mostly because of birth in a country with high burden of disease). Of 533 children with positive TST and negative IGRA results who were not treated for TBI, including 54 children younger than 2 years, none progressed to disease over a 2-year period.[10] Lowenthal et al[49] reviewed the results from California of testing for TBI among children moving to the United States from 2002 to 2013. Among 4035 children who had a positive TST result before entry, only 23% had a positive IGRA result after entry, and as expected, the proportion with a positive IGRA increased with age, reflecting higher risk of true infection over time. Finally, among 762 healthy children with a preimmigration positive TST result arriving to Sweden, only 33% with a BCG scar had a positive QFT result, compared with 76% without a BCG scar.[50]

However, low-level (<1.00 IU/mL for QFT, <8 spots for T-SPOT) false-positive IGRA results do occur, not because of cross-reaction with BCG vaccination or NTM but caused by nonspecific reactivity or technical factors in testing. Low-level IGRA test conversions (negative to positive) and reversions (positive to negative) occur frequently among low-risk health care workers in serial testing programs and do not represent TBI. Although there are no specific data for children, it is recommended that if a patient has an unexpected low-level positive IGRA result, either the same test should be repeated or a different test should be performed, and action should be taken on the second result. The best way to minimize false-positive results with any test of TBI is to test only children with legitimate risk factors for TBI.

The sum of all published studies supports the concept that IGRAs are more specific than TST in children of all ages.[51] Despite the greater apparent specificity of IGRAs, the decision to treat or not in a patient with a positive TST result and a negative IGRA result should be based on clinical judgment that takes into consideration the risk of progression to disease and the degree of exposure. For example, children who were recently exposed to a case of contagious TB disease should be considered to have TBI if either the TST or IGRA result is positive, because they have a high risk of progressing rapidly to TB disease.

Test Sensitivity in Children

The analysis of studies in children of the sensitivity of IGRAs compared with TST is far more difficult, and the results have been highly variable. The earliest information came from the meta-analyses of studies of children with TB disease, diagnosed by either culture or clinical diagnosis.[35–38] Sun et al[37] found a sensitivity for all TB disease

in children of 70% for ELISA (mostly QFT [range, 57% to 96%]), 62% for ELISPOT (mostly T-SPOT [range, 40% to 100%]), and 71% for TST (range, 43% to 100%). When the analysis was divided into cases of culture-confirmed TB and clinically diagnosed TB, the sensitivities were 85% and 64% for ELISA (mostly QFT), 76% and 58% for ELISPOT (mostly T-SPOT), and 85% and 66% for the TST, respectively. All 3 tests had lower sensitivity in clinically diagnosed cases; there are many possible explanations, including misdiagnosis of TB in the clinically diagnosed group.[52] Another study conducted in a setting with high TB burden also found low sensitivity of IGRAs and the TST for TB disease, which did not add value to the clinical data and conventional tests for diagnosis of TB disease in these children.[53] A systematic review and meta-analysis (15 studies included) of the performance of TST and IGRAs in immunocompetent children with microbiologically confirmed TB disease calculated the sensitivities of the TST, QFT, and T-SPOT to be 88.2%, 89.6%, and 88.5%, respectively.[54] Kay et al[55] analyzed California TB registry data for 778 patients 18 years or younger with laboratory-confirmed TB. Among children ages 5 to 18 years, the sensitivity of the IGRA was 96% vs 83% for the TST; IGRA sensitivity compared with TST in children ages 2 to 4 years was 91% vs 91% (so equivalent), and the sensitivity compared with TST in children younger than 2 years was 80% vs 87%. A smaller study in Italy of children with TB disease demonstrated the sensitivity of QFT to be 93.3% vs 86.5% for the TST.[56] The sum of all published studies suggests that the sensitivity of IGRAs in settings of low TB burden is comparable to the TST, with both being less sensitive in settings of high TB burden and for extrapulmonary TB disease.[11,39]

There is some evidence that the sensitivity is increased when both a TST and IGRA are performed and the child is considered infected if either test result is positive. Hill et al[57] investigated child household contacts of adult TB cases in the Gambia. Overall agreement between the TST and ELISPOT was 83%, with each test result being positive in 32% of the children, and neither test was affected by BCG vaccination. An additional Gambian study demonstrated a 10% sensitivity benefit for using both a TST and IGRA in children at high risk.[58]

Indeterminate/Invalid Results in Children

Indeterminate (preferably called invalid in relation to the T-SPOT test) results occur most commonly when the test sample is negative but the positive control has insufficient activity but also occur when the background activity in the negative control is too high. Indeterminate/invalid results often occur because of technical factors, most frequently inadequate shaking of the IGRA tubes after the patient's sample has been added.[3] Rates of indeterminate/invalid results among children varied in early studies between 0% and 35%,[36,59–61] but the reported rates have been lower (0% to 8%) with the more recent versions of the commercially available tests.[32,34,62–64] Rego et al[65] reviewed 645 947 T-SPOT assays, finding 0.6% invalid and 1.8% borderline results. When 5044 borderline tests were repeated, 59.2% were negative, 20.0% were positive, and 20.2% remained borderline; the subject's age did not affect the results. Indeterminate/invalid rates generally are higher among individuals with compromised immune systems whose T lymphocytes cannot mount an adequate response to the positive control, especially people living with HIV infection[62,66]; these rates also have been noted to be higher in children with poorly controlled inflammatory bowel disease, hepatitis, malaria, and helminthic infection.[67,68] Some researchers have found that otherwise healthy children younger than 3 years are more likely to have indeterminate/invalid test results than older children and adolescents.[69–72] However, authors of a recent systematic review and meta-analysis of 133 studies using IGRAs to diagnose TB found a 4% rate of invalid results and no difference between children 0 to 7 years of age and those 8 years or older.[73]

Test Performance in Immune-Compromised Children

Data are scarce for determining the sensitivity and specificity of IGRAs for immune-compromised children, who are at increased risk of developing TB disease if they are infected with *M tuberculosis*. There are scant data for children living with HIV infection, because IGRAs are generally not available in areas with high TB burden where there is also a high burden of HIV infection. Systematic reviews of the performance of IGRAs in people living with HIV infection, mostly adults, have concluded that the T-SPOT test may be slightly more sensitive than the QFT (72% vs 61%), but neither was more sensitive than the TST.[66,74,75] Several small studies have included children living with HIV infection with varied results; in general, the IGRAs have less concordance with the TST in children with advanced HIV infection, especially if they have concomitant malnutrition.[76–78] The risk of TB disease among people with HIV infection remains higher than that of the general population, and the cadence of TB testing in

HIV-infected patients is discussed elsewhere.[79]

Researchers in 2 small studies have examined the performance of IGRAs and the TST in children with cancer. Stefan et al found that among 37 children with untreated cancer in Cape Town, South Africa, a region with extremely high rates of TB, 7 had positive results with at least 1 test; there was a higher rate of positive results with the T-SPOT, poor concordance among the TST and IGRAs, and a high rate of test failure because of low lymphocyte counts in patients.[80] During a contact investigation of 18 children in a pediatric hematology-oncology hospital unit after a patient was found to have pulmonary TB, only 2 patients had a positive T-SPOT result, and this test had more invalid/indeterminate results than the QFT.[81]

Screening for TB risk factors should be performed before any immunosuppressing therapy is given, but it is especially important before therapy with immunomodulating biological agents, such as monoclonal antibodies against TNF-α.[3] This topic has been the subject of many small adult studies.[82,83] Most of the adult patients in these studies also had been treated with a variety of other immunosuppressing agents, which may have affected the results of the TST or IGRAs. Rates of indeterminate/invalid results were higher than usual in the adult patients because of immune suppression by both disease and drugs. Within one small study of 79 children in Greece receiving antirheumatic treatment (only 18 were tested before treatment with an anti–TNF-α drug), patients with a risk factor for TBI were 27.6 times more likely to have a positive QFT result, and no child had a positive TST result.[84] For these children, test sensitivity is more important than specificity because of the increased risk of progression of TBI to TB disease. The current evidence does not consistently suggest that IGRAs are better than the TST in identifying immunosuppressed individuals who will benefit from treatment of TBI. It is commonly recommended that all patients who will be receiving an immunomodulating biological agent, regardless of specific TB risk factors, should be tested for TBI before starting the therapy. Many experts have suggested that to increase sensitivity, both the TST and an IGRA should be performed initially for patients who also have a risk factor for TBI, and appropriate treatment of TBI should be started if either test result is positive once TB disease has been ruled out.[82–88] Patients whose initial test results for TBI are negative should be screened annually for new TBI risk factors, but annual testing is not generally recommended in the absence of a new risk factor while on continued immunosuppression.

Effect of Age on Test Results

There has been a hesitancy to use IGRAs in children younger than 5 years because of a lack of data for this age group and concerns about inadequate sensitivity of the IGRAs. Because infants and young children (younger than 4 years) are more likely than older children to have progression from untreated TBI to TB disease and young children are more prone to develop serious forms of TB, failure to accurately diagnose TBI in this age group can have dire consequences.[14] Resolution of this issue has been hampered by the lack of a reference standard for TBI. The earliest studies suggested that IGRA sensitivity is diminished in young children, but the results were inconsistent.[36] However, subsequent studies have demonstrated better performance of newer versions of the commercially available IGRAs in young children than previously reported. Debord et al[89] found that among 19 children with TB disease, 6 of 10 children younger than 2 years and 9 of 9 children who were 2 to 5 years of age had a positive QFT result. Moyo et al[90] studied 397 children in South Africa who were younger than 3 years and were suspected of having TB disease. Agreement between the QFT and TST was 94%, but both tests had lower sensitivity for TB disease (38% for QFT and 35% for the TST) than has been reported in older age groups.

Although the IGRAs have low sensitivity for detecting TB disease in young children whose immune responses may be blunted by malnutrition and TB itself, it is not clear whether they have a higher sensitivity for detecting TBI in otherwise healthy young children. Pavic et al[91] studied 142 healthy BCG-vaccinated children in Croatia who recently had been exposed to infectious TB disease. Both the QFT and TST had proportions of positive results that were associated with degree of exposure, and there was no evidence that age affected QFT performance. Critselis et al[72] performed a TST and QFT in 761 healthy Greek children in 4 age groups who were referred for several indications. Among the 198 children younger than 5 years (74 children were younger than 2 years), infants with positive QFT results produced a greater mean titer of IFN-γ than older children and adolescents. Agreement between the TST and QFT results was not significantly different between younger and older children. Velasco-Arnaiz et al[92] found that among 39 children younger than 5 years with confirmed TB disease (15 children were younger than 2 years), the sensitivity of QFT was 93%, and in 79 children with either

TBI or TB disease, there was no correlation between age and antigen-stimulated IFN-γ responses. From 2005 to 2008, the San Francisco TB program followed 146 untreated TST-positive/QFT-negative children, including 44 children younger than 2 years, and none developed TB disease.[93]

It is clear that the use of the TST in infants and young children who received a BCG vaccine will lead to many false-positive results caused by cross-reaction with the BCG. Although some experts currently support the use of IGRAs to test for TBI in infants and toddlers, especially those at low risk of TBI who have received a BCG vaccine, others do not recommend their routine use in children younger than 2 years until additional supportive data are available. In summary, if an IGRA is performed in an infant or young child, a positive result likely indicates infection with *M tuberculosis*, but a negative result does not rule it out. A negative result for either a TST or an IGRA should be considered as especially unreliable in infants younger than 3 months. The rates of indeterminate/invalid results appear to be higher in infants and toddlers than in older children.

TABLE 3 Comparison of the TST and IGRAs

Characteristic	TST	IGRA
Antigens used	Many: PPD	3 (QFT) or 2 (T-SPOT)
Sample	Intradermal injection	Blood draw
Patient visits required	2	1
Distinguish between TBI and disease	No	No
Cross-reactivity with BCG	Yes	No
Cross-reactivity with NTM	Yes	Only rare species[a]
Differing threshold for positive values by level of risk for TBI	Yes	No
Causes boosting	Yes	No
Subject to boosting by previous TST	Yes	Unknown but possible
Durability over time (stays positive with or without treatment)	Yes	Unknown but likely
Difficulties with test reproducibility	Yes	Yes
Location of need for trained staff	"Bedside"	Laboratory
Age <2 y[b]	Recommended	Acceptable
Estimated specificity in BCG-unvaccinated children, %	95–100	90–95
Estimated specificity in BCG-vaccinated children, %	49–65	89–100
Estimated sensitivity (confirmed TB disease), %	75–85	80–85
Estimated sensitivity (clinical TB disease), %	50–70	60–80

[a] *Mycobacterium marinum*, *Mycobacterium kansasii*, *Mycobacterium szulgai*, and *Mycobacterium flavescens*.
[b] Negative result of either the TST or an IGRA should be considered especially unreliable in a child younger than 3 mo.

STRATEGIES FOR THE USE OF IGRAs IN CHILDREN

Some of the major differences between the TST and IGRAs are summarized in Table 3. The basis for deciding which diagnostic test to use is fundamentally different for a child than for an adult, and it differs between the diagnosis of TBI and TB disease. When testing otherwise healthy individuals, the purpose of the TST or an IGRA is to determine if the person is infected with *M tuberculosis* and will benefit from treatment. The positive predictive value of both tests for the development of TB disease is low in adults and children 5 years or older, because only 5% to 10% of those who test positive and go untreated will develop TB disease in their lifetime. In these groups, test specificity is important to avoid massive overtreatment of individuals with false-positive results. However, children younger than 2 years with untreated TBI have a 25% to 50% risk of developing TB disease within 1 year, so optimizing test sensitivity is important for this age group. In addition, children tend to tolerate the treatment of TBI much better than adults, so their risk of adverse events caused by treatment is less. However, test specificity is also an issue for the youngest children, especially if they have received a BCG vaccine or have a likelihood of exposure to NTM in their environment; testing them with only the TST will lead to an appreciable proportion of false-positive results when the prevalence of TBI is low, as in the United States.

Both the TST and IGRAs are imperfect methods. As a result, only children who have a risk factor for TBI or TB disease, have a disease or condition that may require significant therapeutic immunosuppression, or are suspected of having TB disease should be tested. However, a negative result from either type of test is not reliable for excluding the presence of TB disease. Deciding which test to use involves a consideration of sensitivity and specificity. When high specificity is desired (for example, otherwise low-risk BCG-vaccinated children), the IGRAs are the clearly superior tests. Neither method has a clear advantage in sensitivity; when sensitivity is the main concern, such as recent contact with a contagious case of TB disease, a positive result with either the TST or IGRA should be considered indicative of infection with *M tuberculosis*. When sensitivity is paramount, such as high suspicion of TB disease or testing a child who has a TB risk factor and who will soon receive an immunomodulating biological agent, performing both an IGRA and a TST should be strongly considered, with a positive result for either test leading to the child being diagnosed with TBI. Performing both tests will lower the overall specificity and lead to some false-positive results, but in children with a high risk of

progression to TB disease, this is an acceptable trade-off.

Summary of Recommendations Regarding Testing

Table 4 shows potential strategies for testing. Some specific points are as follows:

- Only children who have a risk factor for TBI or are at risk for progressing to disease, are suspected of having TB disease, or who have an immunosuppressive disease or about to start immunosuppressive therapy should be tested with a TST or an IGRA.
- There is no compelling evidence to support the use of one IGRA (QFT, T-SPOT) over the other.
- If the child of any age has been exposed to an infectious case of TB disease, he or she should be evaluated and, if determined not to have TB disease, given a full course of treatment of TBI if either a TST or IGRA result is interpreted to be positive.
- Even with a negative initial test result, contacts of a person with known TB disease should be retested in 8 to 10 weeks, usually with the same test, regardless of whether the initial test used was a TST or IGRA.
- ^ For exposed contacts with impaired immunity (eg, HIV infection) and all contacts younger than 5 years, treatment of possible TBI should be initiated, even if the initial TST or IGRA result is negative, once TB disease is excluded (often referred to as "window prophylaxis"). If the TST or IGRA result still is negative with repeat testing in 8 to 10 weeks, treatment can be discontinued. If a TST or IGRA result of a contact becomes positive, the regimen for TBI should be completed.
- For children who have received a BCG vaccine and have no known exposure to a contagious TB case and no other TB risk factor other than birth in a foreign country, 2 strategies can be used[9]:
  (1) an IGRA can be used and the result acted on; or
- (2) a TST can be performed, and if the result is negative, no further testing is necessary; if the result is positive, an IGRA should be performed and its result acted on.
- When evaluating a child of any age for TB disease, both a TST and one or both IGRAs can be performed to maximize sensitivity. However, neither method can be used to rule out TB disease, and a negative result of either the TST or an IGRA should be considered especially unreliable in a child younger than 3 months.
- Indeterminate/invalid IGRA results are more common in very young children (younger than 2 years) and immunosuppressed patients. When an IGRA result is indeterminate/invalid, either a repeat IGRA test using the same or the other IGRA can be performed, ensuring proper technique of specimen collection and processing, or a TST can be performed.
- For children without TB risk factors other than foreign birth who have an unexpected low-level positive IGRA result (QFT <1.00 IU/mL, T-SPOT with 5–7 spots), a second diagnostic test, either an IGRA or a TST, should be performed; the child is considered infected only if results of both tests are positive.[9]
- Although IGRAs are more expensive than the TST, their use may be more cost-effective than the TST because of time savings for the family and the elimination of many false-positive results.[94]
- A TB specialist should be involved when there is a question about testing interpretation.
- Early communication with public health authorities during evaluation for a positive test result in children is strongly encouraged.

TABLE 4 Suggested Uses of TST and IGRA in Children

TST preferred, IGRA acceptable[a]
Children younger than 2 y[b]
IGRA preferred[a]
Children 2 y or older, especially those who have received BCG vaccine
Children of any age who are unlikely to return for the TST reading
Both[c] the TST and an IGRA should be considered when:
The initial and repeat IGRA results are indeterminate or invalid
The initial test (TST or IGRA) result is negative and:
There is clinical suspicion of TB disease[c] (to maximize sensitivity)
The child has a risk factor and is at high risk of progression and poor outcome (especially therapy with an immunomodulating biological agent, such as a TNF-α antagonist)[c,d]
An initial TST is positive and:
The child has a history of BCG vaccination
Additional evidence is needed to increase adherence with therapy

[a] In situations of testing obligated by law or credentialing bodies in person unlikely to be uninfected with TB, IGRA is preferred.[9]

[b] Many experts will use an IGRA in children of any age, especially if the child has received a BCG vaccine but have no other significant risk factors other than foreign birth. However, data from children in this age group are few.

[c] A positive result of either test is considered significant in these groups.

[d] The clinician should obtain the complementary test (eg, if a TST was initially performed, then IGRA should be obtained for a complete set).

TREATMENT OF TBI

Rationale

The goal of treatment is to prevent TBI from progressing to TB disease and to diminish the reservoir for future TB cases. All children who have TBI should receive a course of therapy. The risk of developing TB disease is highest during the 6 months after infection and remains high for 2 years.[95] Not all people with TBI have the same level of risk of progression to disease. Three

high-risk groups bear special attention for disease progression:

1. Infants and young children (particularly those younger than 2 years) may progress rapidly to disease (40% to 50% of infected children younger than 1 year; 25% of infected children 1–2 years of age) including meningitis or miliary disease (15% of infected children younger than 1 year; 5% to 7% of infected children 1–2 years of age).
2. Postpubertal adolescents (older than 12 years) who also have the risk of progression to adult-type disease.
3. Children and adolescents with immunocompromising conditions or receiving certain immunosuppressing treatments, including patients with diabetes mellitus, chronic renal failure, malnutrition, congenital or acquired immunodeficiencies; patients with malignancy; patients receiving TNF-α antagonists or blocking agents; and patients preparing for or experiencing organ or hematologic transplant.

There are several barriers to completion of treatment of TBI. Children with infection are asymptomatic, and families do not readily observe a response to treatment[96] and often do not appreciate a clear need to continue medications. Pediatric formulations of anti-TB medications are not generally available in the United States, requiring compounding or adaptation of adult formulations such as crushing pills or opening capsules (see "Administration of Antituberculosis Medication to Children"). Medical providers for children and adolescents should be familiar with all the regimens available to treat TBI to select the best regimen for the individual child and family. The regimen ultimately prescribed for children should be safe, effective, and relatively inexpensive, allow easy administration to young children, and result in a high completion rate. The one characteristic that consistently inversely correlates with completion of treatment is the length of treatment: the shorter the duration, the higher the completion rate.

General Principles

The practitioner should be cognizant of the following principles and assumptions when caring for pediatric patients with TBI:

- Infants and children with TBI who have been recently infected have an increased risk of rapid disease development, and young age at infection predicts more years at risk for disease progression into adulthood.
- Assume that the causative *M tuberculosis* is susceptible to multiple drugs unless specific knowledge of drug resistance is available. The incidence of isoniazid resistance among TB isolates from US patients is approximately 9%,[97] and the incidence of rifampin resistance is $<1\%$.[98] The assumption is negated if the source case is known to have a drug-resistant isolate.
- A thorough physical examination and high-quality chest radiographs (posterior-anterior and lateral views) should be performed before starting treatment. It is crucial to ensure that TB disease is not inadvertently treated with an inadequate drug regimen; otherwise, the risk of developing drug-resistant TB while on therapy is high (particularly with monotherapy with isoniazid or rifampin). Chest radiographs rule out lung parenchymal disease and any enlarged thoracic adenopathy,[95] and the physical examination helps to exclude extrapulmonary TB (including adenopathy and hepatosplenomegaly). If evidence of TB disease is found, additional diagnostic procedures should be performed, and the treatment regimens will be different from those for TBI.
- Anti-TB treatment regimens that are efficacious in adults will be effective in children. Performing efficacy trials exclusively in children to mirror those previously conducted in study populations of both adults and children (which enrolled $>100\,000$ patients on isoniazid) would be difficult and expensive. Extensive experience has shown that treatment regimens for both TBI and TB disease that are effective in adults also will be effective in children. Rather than focusing on efficacy, studies regarding TB regimens in children are designed to assess and improve medication safety, tolerability, pharmacokinetics, and adherence.
- Laboratory testing before or during treatment is not necessary in otherwise healthy pediatric patients. The use of isoniazid monotherapy for pediatric TBI causes low rates of hepatotoxicity ($<1\%$). Alternate regimens, which may include 2 drugs but for a shorter duration, are even less hepatotoxic than the 9 months of isoniazid monotherapy. This reduced toxicity stems, in part, from the overall decreased time of drug exposure.[99,100] However, increased risk of hepatotoxicity can be experienced by children who are obese and have nonalcoholic steatohepatitis, are taking other potentially hepatotoxic medications (especially anticonvulsants), are pregnant in the first 12 weeks of gestation, or have underlying liver disease. These children should have baseline hepatic function tests (alanine transaminase, aspartate

transaminase) and periodic laboratory monitoring (eg, monthly) during therapy.

- Completion of regimens for TBI in high-risk groups (including children and adolescents) is imperative. Historically, medication regimens for TBI have been through self-administered therapy (SAT). Although completion of isoniazid by SAT was >80% within the context of a research study, completion rates decrease to approximately 60% in the real world because of patient fatigue or drug intolerance.[101] Adherence may be improved by directly observed therapy (DOT), when medications are administered directly to the patient by a health care professional or trained third party (not a relative or friend) who observes and documents that the patient ingests each dose of medication. There has been success in administering DOT through school-based health centers.[102] DOT should be considered for treatment of children and adolescents with TBI who are at high risk of rapid progression to disease. When well conducted, DOT is a package of services, including enablers and reinforcements, designed to help the patient and family complete therapy.
  - DOT provides the highest rates of medication completion (approximately 80% to 95%).[96] It requires both financial and staff resources, usually from the local health department, and can be time consuming for the staff and families. The time and resources required often make DOT unacceptable to patients and providers.
  - SAT-hybrid models may be alternate methods for improving patient compliance. One example is self-administration, with text reminders from providers.[99,103] A successful program in Houston, Texas, has been SAT-based, but the health department delivers the medications to the patient's home on a monthly basis and contacts the family weekly to support the treatment.[100]
  - Video DOT may be used in lieu of the traditional in-person DOT strategy, provided the patient has a personal device and that privacy restrictions of the Health Insurance Portability and Accountability Act are applied.[104,105] Video DOT may be synchronous (in real time) or asynchronous (video clips are recorded and then uploaded for later review).
- Children with adequate anti-TB treatment need not be retested. The test of infection (either TST or IGRA) remains positive after adequate treatment and should not be used as a test of cure or as surveillance for emergence of TB disease.

Treatment Selection

Anti-TB drugs kill or inhibit multiplication of *M tuberculosis*, thereby arresting progression of infection and preventing most complications. Historically, the dominant regimen was 6 to 9 months of isoniazid monotherapy by SAT. Other alternatives to treatment of TBI have emerged, with similar rates of efficacy to protect against development of disease. Factors to consider in regimen selection include the child's age and requirement for liquid formulations, need for speedy treatment (such as a pending stem cell or solid organ transplant), use of concomitant hepatotoxic medications, concurrent HIV infection, and suspected infection with drug-resistant *M tuberculosis*. If therapy is completed successfully, there is no need to perform additional tests or chest radiographs unless a new exposure is documented or the child develops a clinical illness consistent with TB, the latter being extremely rare in North America. A TB specialist should be involved if questions arise regarding selection of an appropriate treatment regimen or management of adverse effects.

Specific Drugs

Isoniazid

Pediatric experience with isoniazid is extensive and well published. Isoniazid can inhibit pyridoxine metabolism; however, otherwise healthy children and adolescents in the United States given recommended doses rarely develop associated peripheral neuritis or seizures and do not need pyridoxine supplements as a preventive measure. However, isoniazid overdose, as in a suicide attempt, can lead to generalized seizures that are difficult to control unless large doses of pyridoxine are administered. Routine pyridoxine supplementation is recommended for exclusively breastfed infants and for children and adolescents on meat- and milk-deficient diets; children with nutritional deficiencies, including all symptomatic children living with HIV infection; and pregnant adolescents and women. Bioavailability of isoniazid is improved with administration on an empty stomach, although dyspepsia may be alleviated with small amounts of food.

Hepatotoxicity caused by isoniazid is rare in otherwise healthy children, and routine laboratory testing is not necessary (Table 5). There can be transiently mild elevations of transaminases, with no clinical consequence given that these resolve spontaneously. When testing is indicated because of development of clinical signs or symptoms (eg, abdominal pain, vomiting, jaundice) that could be caused by hepatitis, hepatotoxicity may be defined as

transaminase elevations of 2 to 3 times the upper limit of normal if the patient is symptomatic, or >5 times the upper limit of normal if the patient is asymptomatic.[106]

Rifampin

Rifampin is a rifamycin that, because of its short half-life, must be administered daily. Rifampin is readily available by prescription, including a standard compounded liquid formulation for young children. Bioavailability of rifampin is improved with administration on an empty stomach, although dyspepsia may be alleviated with small amounts of food (Table 5).

A major concern with using any rifamycin-containing regimen is drug–drug interactions. These interactions should be appreciated as the number of pediatric immunocompromised patients (such as those undergoing treatment of HIV infection, with oncologic diseases, or who are transplant recipients) increases. The rifamycins are potent inducers of the hepatic CYP 450 enzyme. This increased enzymatic activity will heighten metabolism of classes of antiretroviral drugs such as the protease inhibitors. Conversely, the rifamycins may increase the exposure to specific immunosuppressive drugs, necessitating a dose reduction of agents such as tacrolimus and cyclosporine.

An additional drug interaction concern with rifampin is that it can lower the effectiveness of oral contraceptives. Female adolescents taking rifampin must be counseled that they should rely on other forms of birth control while taking this medication. Also, patients should be warned that rifampin will cause urine, sweat, saliva, and tears to turn a red-brown color and can cause staining of contact lenses.

Rifapentine

Rifapentine is a rifamycin with a long half-life allowing for weekly administration, versus the daily dosing of rifampin. The bioavailability of rifapentine is enhanced by food (particularly products containing fat, such as milk or egg), and this medication should be given as possible with fatty food. The dosing of the 2 components (isoniazid, rifapentine) varies by weight and age of the patient (Table 6). The drug-drug interactions with rifapentine appear less when compared with those of rifampin.

Treatment Regimens for TBI

Once-Weekly Dosing of Isoniazid and Rifapentine (3HP) (12 Doses)

This regimen includes the use of isoniazid and rifapentine, given once weekly, for 12 doses. The regimen is commonly referred to as once-weekly dosing of isoniazid and rifapentine (3HP): the H is the international symbol for isoniazid, the P is the symbol for rifapentine, and the 3 refers to a treatment length of 3 months. The 3HP regimen is considered complete if at least 11 doses have been taken over 16 weeks. This regimen has similar efficacy to 9 months of isoniazid (see below) but is associated with higher completion rates in adults,[99] children, and adolescents.[100,107]

When first introduced, 3HP was prescribed under DOT, and rifapentine was available only through local health departments. However, an open-label, phase 4 clinical trial of adult patients (18 years or older) demonstrated noninferiority for completion rates and safety of 3HP given by SAT compared with DOT.[103] As a result, the Centers for Disease Control and Prevention (CDC) has recommended that 3HP may be given via SAT when DOT is not available or feasible.[108,109] Because the study did not include children or adolescents, it is not known whether the similarity of completion rates observed in adults given 3HP by SAT or DOT would be seen in children and adolescents. Use of DOT may be preferred for patients at increased risk of rapid progression to TB disease (recent contacts of infectious cases, immune-compromised patients, age younger than 5 years, some adolescents).

The 3HP regimen, despite the use of 2 agents, appears to be equally or less hepatotoxic than 9 months of isoniazid monotherapy.[100] Providers should be cognizant that the pill burden of this regimen may be high; a child weighing 25 kg would need to take 6 tablets (4 of rifapentine, 2 of isoniazid) simultaneously.

This regimen is recommended for children 2 years or older (there is a paucity of data on rifapentine pharmacokinetics in very young children). 3HP can be used in HIV-infected individuals barring drug-drug interactions with antiretroviral medications.

4 Months of Daily Rifampin (4R) (120 Doses)

The 4-month regimen of daily rifampin (4R) is usually taken by SAT (15–20 mg/kg per dose, maximum 600 mg per dose). Rifampin is bactericidal against *M tuberculosis*. Therapy is deemed completed if 120 doses have been administered within 6 months. Efficacy is similar to 9 months of isoniazid, but the shorter period allows for a significantly higher rate of completion.[110–112]

Drug–drug interactions preclude it as a regimen for HIV-infected individuals. Because HIV-infected individuals with low $CD4^+$ T-lymphocyte counts may have subclinical TB disease, using

TABLE 5 Characteristics of Medications Used in Pediatric Patients With TBI

Drug	Common Adverse Effects	Bioavailability	Drug-Safety Monitoring for All Agents
Isoniazid	Hepatotoxicity Peripheral neuropathy Gastrointestinal upset (common, particularly if isoniazid is taken on empty stomach) Diarrhea Rash	Best if on empty stomach, although small amounts of food may alleviate dyspepsia	• Otherwise healthy patient: no baseline LFTs needed. If symptomatic on treatment, obtain LFTs • Patient with existing liver disease or with concomitant hepatotoxic drugs: baseline and periodic (often monthly) LFTs recommended
Rifampin	Gastrointestinal upset (common, particularly if these are taken on empty stomach) Hepatotoxicity Rash Thrombocytopenia Hypersensitivity response (rare in children) Orange discoloration of body fluids (urine, sweat, tears)	Best if on empty stomach, although small amounts of food may alleviate dyspepsia	
Rifapentine		Should be given with fatty food to enhance absorption	

Adapted from Cruz AT, Ahmed A, Mandalakas AM, Starke JR. Treatment of latent tuberculosis infection in children. *J Pediatr Infect Dis.* 2013;2(3):248–258. LFT, liver function test.

rifampin monotherapy may inadvertently increase TB resistance in those people.

There is no age restriction for the use of 4R. The adverse effect profile of 4R is excellent, with similar transaminase elevations as with 9 months of isoniazid (see below).[110–112] Hence, 4R is preferred in children without HIV infection of all ages who are not able to undergo DOT, or if there is a concern of an isoniazid-resistant isolate as judged from the exposure history.

3 Months of Daily Therapy With Isoniazid and Rifampin (3HR) (90 Doses)

This regimen consists of 3 months of daily isoniazid and rifampin (3HR), using the same doses as when each drug is used alone. There is no age restriction for the use of 3HR. In combining isoniazid and rifampin, this regimen is similar in principle to 3HP; however, the medications are given daily because of the relatively short half-life of rifampin compared with rifapentine. Efficacy and rates of completion of 3HR are comparable or better when compared with isoniazid monotherapy.[113]

6 or 9 Months of Isoniazid (6H) (9H)

Isoniazid monotherapy has been the most widely recommended and used treatment of pediatric TBI. Isoniazid is bactericidal against *M tuberculosis*. Isoniazid may be given daily by SAT (10–15 mg/kg per dose, maximum 300 mg per dose) or twice weekly via DOT (20–30 mg/kg per dose, maximum 900 mg per dose).[96] Therapy with 6 months of isoniazid (6H) is complete if the child has received 180 doses (if given daily via SAT) or 52 doses (if given twice weekly under DOT) within 9 months. If using a 9-month regimen, therapy is complete if the child has received 270 doses (if given daily via SAT) or

TABLE 6 Regimens Used in Pediatric Patients With TBI

Regimen	Agent(s)	Dose and Age Group	Administration	Duration, mo	No. Doses Needed for Completion	Rates of Completion, %	Age Restriction	Comments
3HP	Isoniazid + Rifapentine	Age ≥12 y Isoniazid: 15 mg/kg rounded up: nearest 50 or 100 mg (max 900 mg) Rifapentine (by wt): 10–14 kg: 300 mg 14.1–25 kg: 450 mg 25.1–32 kg: 600 mg 32.1–49.9 kg: 750 mg ≥50.0 kg: 900 mg Age 2–11 y Isoniazid: 25 mg/kg rounded up: nearest 50 or 100 mg (max 900 mg) Rifapentine: see above	Weekly (SAT or DOT)	3	12	63–97	Not for children <2 y	Take with food, containing fat if possible; pyridoxine for selected patients[a]
4R	Rifampin	Adult: 10 mg/kg (max 600 mg) Child: 15–20 mg/kg (max 600 mg)	Daily (SAT)	4	120	72–96	None	Drug–drug interactions
3HR	Isoniazid + rifampin	Same doses as when drugs are used individually	Daily (SAT)	3	90	82	None	Not considered unless 3HP or 4R are not feasible
6H	Isoniazid	Adult: 5 mg/kg (max dose 300 mg) Child: 10–15 mg/kg (max 300 mg)	Daily (SAT)	6	180	20–93	None	Seizures with overdose; pyridoxine for selected patients[a]
		Adult: 15 mg/kg (max dose 900 mg) Child: 20–30 mg/kg (max 900 mg)	Twice weekly (DOT)		52			
9H	Isoniazid	Adult: 5 mg/kg (max dose 300 mg) Child: 10–15 mg/kg (max 300 mg)	Daily (SAT)	9[a]	270	20–93	None	Seizures with overdose; pyridoxine for selected patients[a]
		Adult: 15 mg/kg (max dose 900 mg) Child: 20–30 mg/kg (max 900 mg)	Twice weekly (DOT)		76			

Table adapted from Cruz AT, Ahmed A, Mandalakas AM, Starke JR. Treatment of latent tuberculosis infection in children. *J Pediatr Infect Dis*. 2013;2(3):248–258. 6H, 6 months of isoniazid; 9H, 9 months of isoniazid; —, not applicable.

[a] Exclusively breastfed infants and for children and adolescents on meat- and milk-deficient diets; children with nutritional deficiencies, including all symptomatic children living with HIV; pregnant adolescents and women.

76 doses (if given twice weekly under DOT) within 12 months.

The efficacy of isoniazid monotherapy reaches 98% against development of TB disease.[106] The World Health Organization recommends a treatment duration of 6 months[114] to provide high coverage of the population in countries with a high disease burden. A 9-month regimen gives an additional 20% to 30% increase in efficacy.[97] The CDC and National TB Controllers Association recommends 6-month or 9-month durations of isoniazid monotherapy, if shorter-course rifamycin-based regimens cannot be used.[108]

Although isoniazid is readily available, the long duration of isoniazid monotherapy results in poor adherence and low completion rates. This option may be unattractive to patients and families. Many TB care providers and clinics use this regimen only when a rifamycin-containing regimen cannot be used because of drug interactions.

Administration of Antituberculosis Medication to Children

Given the common inability of young children to swallow pills and to mitigate the common adverse effect of gastrointestinal tract upset right after taking the medication, guidance for administering medication (particularly isoniazid) is warranted. Commercially available isoniazid suspension contains large amounts of sorbitol and often causes nausea and diarrhea if the volume exceeds 5 mL and/or if it is taken when the child has fasted. If the child is unable to swallow pills, the pills can be crushed and mixed into syrup or other palatable liquid to appeal to the young child, and in the smallest volume possible to ensure the entire dose is taken (ie, not in a full bottle of milk). Rifampin should be given on an empty stomach or with a small amount of food. Rifapentine should be administered with food, particularly with a high fat content, to enhance absorption.

For mothers receiving treatment for TBI or TB disease who are also breastfeeding, their infants may be indirectly receiving TB medications. The amount being received is miniscule and is the basis for recommendations for mothers to continue breastfeeding even while receiving TB treatment with first-line agents.[115]

Evaluation and Management of Adverse Reactions

Regardless of the treatment regimen selected, all children should be clinically monitored on a regular basis. This allows the medical provider to assess for medication adverse effects, determine if there is advancement of the TBI to disease, and continue to educate patients and families on the importance of treatment and adherence. Monthly clinical evaluation (at a minimum) to observe for signs or symptoms of hepatitis and other adverse effects of drug therapy is appropriate and can be done without routine laboratory monitoring of serum transaminase concentrations. Children receiving other known potentially hepatotoxic medications or who have known or suspected liver dysfunction (including obese children at risk for nonalcoholic steatohepatitis) should have baseline transaminase levels determined and followed closely for clinical signs or symptoms of hepatitis. The increasing use of telehealth visits in ambulatory care settings may allow increased access for monitoring but has the disadvantage of not allowing a thorough physical examination in a child who is taking hepatotoxic drugs.

End-of-Therapy Assessment

Families should be advised that either test of infection (TST or IGRA) will remain positive after treatment completion because of immunologic memory and is not a sign of treatment failure. Patients and their parents also should be aware that the child should not receive a TST in the future, because there may be an accelerated reaction that can result in a blister or even a scar at the site of the injection. Repeat chest radiography after treatment completion is not necessary. If there is a clinical change or a new risk factor has emerged, then a complete physical examination and chest radiography should be performed for assessment of TB disease.

Common Drug-Related Adverse Reactions

Hepatotoxicity

I f any patient, while on treatment, exhibits clinical signs and symptoms concerning for a significant adverse reaction from the medication (including but not limited to abdominal pain, anorexia, jaundice, dark-colored urine, pale stools), the medication should be stopped immediately while the clinician is contacted and directs evaluation. Many patients who eventually suffer severe hepatotoxicity had continued to take the medications even after clinical signs or symptoms became apparent. Transaminases should be assessed and, if elevated, measured weekly until either resolution or concern prompting gastroenterology consultation. Resolution of clinical symptoms and/or laboratory abnormalities may allow rechallenge with the same regimen. In situations in which resolution does not occur after medication discontinuation, or previously resolved abnormalities resurface at the time of rechallenge, a different regimen not containing the suspected offending drug should be started. This decision to use drugs other than isoniazid or a

rifamycin should be made in consultation with an expert in treatment of pediatric TB.

Respiratory Issues

It is exceedingly rare to develop pulmonary TB disease while on therapy for TBI, unless adherence is poor. The anti-TB medications have a low rate of adverse respiratory effects, and respiratory illnesses occurring while on therapy are usually intercurrent infections or asthma exacerbations. Evaluation and management usually should target acute community-acquired viral or bacterial pathogens, rather than emergent TB disease, and transmission-based precautions should be followed (ie, droplet and/or contact precautions with eye protection) when examining patients with respiratory symptoms.

Gastrointestinal Tract Upset

Gastrointestinal tract upset (nausea, vomiting, anorexia, abdominal pain) may occur, particularly in the first few weeks of therapy. Symptoms occurring shortly after administration of the drugs are rarely a sign of hepatitis but, more often, are attributable to irritation of the stomach mucosa. Having a small amount of food or milk in the stomach may alleviate these symptoms. However, isoniazid and rifampin should not be taken with large amounts of food, because this will affect absorption. If treatment is by SAT, dyspepsia may be minimized by taking medications at bedtime. If medications are not able to be taken at night, taking antacids concurrently may alleviate symptoms without compromising absorption,[116] although pharmacokinetic studies regarding this issue did not include children. By contrast, rifapentine always should be taken with food, preferably with an appreciable fat content, to enhance absorption. It is incumbent on the clinician to ensure that gastrointestinal tract upset, if not easily relieved with above measures, is not secondary to medication-induced hepatotoxicity.

Interruptions in Therapy

Questions may arise regarding how to manage patients who experience interruptions in therapy because of poor adherence, assessment of possible drug-related toxicity, or temporary lack of available medications. No formal trials of interrupted treatment courses and efficacy have been conducted. Published guidance and medical expert opinion have put forth acceptable options for completion of certain regimens (see specifics in drug regimens above).

Interruptions in treatment regimens with already short duration of the rifamycin-based regimens likely have more detrimental impact on effectiveness. The clinician needs to determine if to restart the regimen or extend the date of completion. If the interruption occurred early or over an extended time (over a month), it may be prudent to restart courses of rifamycin-based regimens.

Special Considerations

Treatment of Multidrug-Resistant TBI

Multidrug-resistant TB is defined as infection or disease caused by a strain of *M tuberculosis* that is resistant to at least isoniazid and rifampin, the 2 first-line drugs with greatest efficacy. Optimal therapy for multidrug-resistant TBI has not been established and needs to be individualized on the basis of the exact drug resistance pattern of the isolate. Although there have been no randomized controlled trials, many experts recommend that a fluoroquinolone antibiotic, either levofloxacin or moxifloxacin, alone or in combination with a second drug to which the isolate is susceptible, is the best currently available regimen.[117] The optimal length of therapy is unknown, with most experts recommending treatment duration between 6 and 12 months. These cases should be managed in consultation with a specialist with expertise in managing pediatric TB.

Children Living With HIV Infection

The CDC and National TB Controllers Association prefer short-course rifamycin-based regimens for TBI if there are no prohibitive drug-drug interactions with antiretroviral medications.[108] Specifically, 3HP is recommended for children 2 years and older in this situation, followed by 3HR in children of all ages. The combination of isoniazid and rifapentine has been given successfully to adults living with HIV infection,[118,119] and some data are available for children.[107,109] Treatment of coinfected individuals should be guided by clinicians experienced in the management of both conditions.

SUMMARY OF RECOMMENDATIONS REGARDING TREATMENT REGIMENS

- The risk of a child progressing from having TBI to TB disease depends on the child's age and immune status. Young children (younger than 4 years), adolescents, and immunocompromised individuals are at higher relative risk to progress from infection to disease.
- Short-course rifamycin-based regimens are preferred for treatment of TBI. On the basis of safety, adherence and completion, and effectiveness, many experts prefer 3HP, by DOT, in patients 2 years or older. When DOT is not available or the child cannot handle the pill burden of 3HP, 4R or 3HR may be the best regimen.
- Patient monitoring for adherence (DOT or SAT-hybrid) should be

strongly considered for patients at high risk for progression to TB disease.
- Routine laboratory monitoring is not needed for healthy patients but should be considered for patients with immune compromise, those with existing liver disease, or those who are taking other potentially hepatotoxic medications.
- Respiratory illnesses are rarely a harbinger of progression to disease but likely represent intercurrent community-acquired infections.

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN®

Use of Probiotics in Preterm Infants

Brenda Poindexter, MD, MS, FAAP, COMMITTEE ON FETUS AND NEWBORN

Probiotic products in the United States are available for use in the general category of dietary supplements, bypassing the rigor of the US Food and Drug Administration (FDA) approval process in safety, efficacy, and manufacturing standards. As a result, currently available probiotics lack FDA-approved drug labeling and cannot be marketed to treat or prevent disease in preterm infants, including necrotizing enterocolitis and late-onset sepsis. Despite lack of availability of a pharmaceutical-grade product, the number of preterm infants receiving probiotics in the United States and Canada is steadily increasing. According to recent reports from large collaborative databases in the United States, approximately 10% of extremely low gestational age neonates receive a probiotic preparation during their stay in the NICU, with wide variation in practice among units. In sum, more than 10 000 preterm infants have been enrolled in randomized clinical trials of probiotic supplementation worldwide. Methodologic differences among study protocols included different strains and combinations of therapy, masking of trials, and a priori definitions of the primary outcome measure. Large meta-analyses of these trials have demonstrated the efficacy of multiple-strain probiotics in reducing necrotizing enterocolitis and all-cause mortality, whereas the efficacy of single-strain probiotic preparations is less certain. In the absence of an appropriate medical-grade product in the United States, dietary supplement–grade probiotics, some of which have been the subject of recent recalls for contamination, are being prescribed. Given the lack of FDA-regulated pharmaceutical-grade products in the United States, conflicting data on safety and efficacy, and potential for harm in a highly vulnerable population, current evidence does not support the routine, universal administration of probiotics to preterm infants, particularly those with a birth weight of <1000 g.

INTRODUCTION

There is a rapidly growing body of literature related to the developing intestinal microbiome and the use of probiotics and prebiotics in the maintenance of health and in the prevention and treatment of a number of disease states. In preterm infants, probiotics have been evaluated in

abstract

a number of randomized clinical trials for the prevention of severe necrotizing enterocolitis (NEC), late-onset sepsis, and all-cause mortality.[1] Despite significant differences in the combination of probiotic preparations used in these trials and the lack of availability of a pharmaceutical-grade probiotic product in the United States, the number of preterm infants receiving probiotics is steadily increasing. According to recent reports from large collaborative databases in the United States, approximately 10% of extremely low gestational age neonates receive some type of probiotic during their stay in the NICU, with wide variation in practice among units.[2] Although some infant formulas for term infants available in the United States now contain probiotics, formulas for preterm infants do not.

The purpose of this clinical report is to (1) highlight differences among commercially available probiotic preparations and the current (lack of) regulatory standards in the United States; (2) outline potential risks associated with the use of probiotics, supporting a cautionary approach with their routine use in preterm infants; (3) review the current evidence evaluating the use of probiotics in both prevention and treatment of NEC, late-onset sepsis, and mortality; and (4) highlight the need for pharmaceutical-grade probiotics that have been rigorously evaluated for safety and efficacy.

INTESTINAL MICROBIOME OF THE PRETERM INFANT

Over the past decade, the role of the intestinal microbiome as a marker of health and disease in preterm infants has been increasingly recognized. Differences in the intestinal microbiota among infants born at term and those born preterm have been demonstrated, with fewer bacterial species, less diversity, and increased proportions of potentially pathogenic strains in preterm infants. In addition, a number of factors are known to alter the microbiota in preterm infants, including mode of delivery, exposure to antibiotics, use of histamine antagonists, and diet (especially human milk, promoting prevalence of *Bifidobacterium* species).[3,4] Numerous studies have described intestinal dysbiosis preceding the onset of NEC in preterm infants, most commonly characterized by increased *Proteobacteria* and decreased relative abundancies of *Firmicutes* and *Bacteroidetes* species.[5] Proposed benefits of probiotics include preventing intestinal dysbiosis and assisting in metabolism of dietary nutrients, leading to byproducts essential for intestinal health. For example, *Bifidobacterium longum* subspecies *infantis* consumes human milk oligosaccharides, promoting a healthy intestinal microbiota.[6]

PROBIOTIC PREPARATIONS

An expert panel convened by the International Scientific Association for Probiotics and Prebiotics defined probiotics as "live microorganisms that, when administered in adequate amounts, confer a health benefit to the host."[7] In contrast, a prebiotic is a nutrient (oligosaccharides, for example) that can modify the gut microbiota. Importantly, this consensus panel proposed benchmark standards, recognizing differences in regulatory approaches for probiotics in different countries. Such differences have significant implications for interpretation of studies of probiotic supplementation and for recommendations for clinical use of probiotics in the NICU, including but not limited to the number of colony-forming units (CFUs) in the product, claims of benefit that are not strain specific, and the intent to support a healthy gut microbiota versus to prevent disease. Unlike products used as dietary supplements, probiotics labeled with the intent to treat are required to meet higher regulatory standards. Indeed, the International Scientific Association for Probiotics and Prebiotics expert panel noted distinctive criteria for a "probiotic drug" with a specific indication for treatment or prevention of disease to require a defined strain(s) of live microbe, proof of delivery of viable probiotic at efficacious dose at end of shelf-life, and a risk/benefit assessment to justify use based on appropriate trials to meet regulatory standards for drugs.[8] It is important to note that none of the probiotic trials published to date in preterm infants for the prevention of NEC meet these criteria or level of evidence. In the United States, probiotic products are typically manufactured as a dietary supplement. If a probiotic is going to be marketed as a drug for treatment of a disease or disorder, it has to meet stricter requirements, including proof of safety and efficacy for its intended use through clinical trials and approval by the US Food and Drug Administration before it can be sold.[9,10]

Probiotic preparations may include a single bacterial strain or a combination of multiple strains. In addition to the particular bacterial species on the probiotic product label, the preparations are highly variable in terms of the number of viable microorganisms both at the time of manufacturing and after shelf storage.

Studies evaluating the efficacy of oral probiotics for the prevention of NEC have included single bacterial strains and mixtures of probiotics, often including *Lactobacillus*, *Bifidobacterium*, and/or *Saccharomyces* species. Despite the observation that infants receiving human milk are colonized with *Bifidobacterium breve* and *Bifidobacterium infantis*,[6] not all probiotic preparations contain these bacteria. It is also important to note that the duration of colonization of the gastrointestinal tract after

administration of products containing *Bifidobacterium* organisms is discontinued may only persist for a few months.[11] In a recent study, 16 different commercially available probiotic products were evaluated to determine if the bacteria species listed on the label matched that obtained by culture and polymerase chain reaction in the laboratory. Disturbingly, only 1 of the 16 products containing *Bifidobacterium* organisms matched the label exactly, and there was substantial variability in the composition of probiotics by lot and pill. One of the products tested did not contain any of the species listed.[12]

SAFETY

The potential infectious risk associated with probiotic supplementation may be related to the risk of sepsis associated with the bacterial strain in the probiotic product that colonizes the infant or from contamination of the product with a pathogen during the manufacturing process.

Although there have been a few cases of probiotic-associated sepsis reported in neonates receiving *Lactobacillus rhamnosus GG*,[13] a meta-analysis including more than 5000 infants in randomized trials reported no systemic infection with the supplemental probiotic organism.[14] Although the risk appears to be low, the potential of bacterial cross-colonization among infants within a unit is also a potential risk.[15] In the Probiotics in Very Preterm Infants (PiPS) trial, *B breve* was identified as a cross contaminant in 37% of infants randomly assigned to the placebo control group.[16] However, it may be difficult to distinguish the change in the infant from the change in the resident flora of the NICU.

There have been several recent recalls of dietary supplement–grade probiotics for contamination, including with *Salmonella, Rhizopus,* and *Penicillium* species. Gastrointestinal mucormycosis has been reported in a preterm infant receiving contaminated ABC Dophilus Powder.[17]

The Agency for Healthcare Research and Quality recently issued a report on the safety of probiotics to reduce risk and prevent or treat disease including 622 studies. Unfortunately, one-third of the studies reported only nonspecific safety statements (such as "well-tolerated"), and the authors noted that adverse events were not well documented in the majority of studies. The conclusions of this report were as follows: "There is a lack of assessment and systematic reporting of adverse events in probiotic intervention studies, and interventions are poorly documented. The available evidence in [randomized controlled trials] does not indicate an increased risk; however, rare adverse events are difficult to assess, and despite the substantial number of publications, the current literature is not well equipped to answer questions on the safety of probiotic interventions with confidence."[18] Other systematic reviews have similarly reported inadequate reporting of adverse and serious adverse events in studies evaluating probiotics in high-risk patients.[19,20]

CURRENT EVIDENCE

Probiotics for the Prevention of NEC

Several recent meta-analyses have evaluated the effects of probiotics to prevent NEC (Bell stage 2 or 3), late-onset sepsis, and death in preterm infants (typically very low birth weight infants). In the past 5 years, there have been numerous published systematic reviews.[21,22] Despite great heterogeneity among studies, the cumulative pooled risk ratio (RR) for NEC (including more than 10 000 infants) is strongly in favor of treatment with probiotics for the prevention of NEC.[22]

Three of the earliest randomized trials of probiotics in preterm infants suggesting benefit were conducted outside the United States. Bin-Nun et al[23] (Israel) evaluated the mixture of *B infantis*, *Streptococcus thermophilus*, and *Bifidobacteria bifidus*; Dani et al[24] (Italy) evaluated *L rhamnosus* GG; and Lin et al[25] (Taiwan) evaluated *Lactobacillus acidophilus* and *B infantis*. In each of these early studies, researchers found a reduction in the incidence of NEC in infants who were randomly assigned to receive probiotics when compared with those in the control group. These 3 studies and those that have followed have had wide heterogeneity of subjects and interventions and are also limited by the small number of infants with a birth weight less than 1000 g, the population at highest risk for NEC.

The studies are hindered by methodologic differences among study protocols, including different strains and combinations of therapy, masking of trials, and having an a priori definition of the primary outcome measure. It is not clear whether it is appropriate to pool data from trials by using different strains of probiotics, leading many investigators to urge caution in interpretation of meta-analyses of probiotics for the prevention of morbidity in preterm infants.[26]

The PiPS trial, conducted in the United Kingdom, was a large, multicenter, randomized controlled trial of *B breve* supplementation in 1315 very preterm infants. In contrast to some of the earlier trials conducted in low-resource settings, in the PiPS trial, researchers found no difference in the primary outcomes of NEC (RR, 0.93; 95% confidence interval [CI], 0.68–1.27), sepsis (RR, 0.97; 95% CI, 0.73–1.29), or death (RR, 0.93; 95% CI, 0.67–1.30) before hospital discharge.[16]

The ProPrems trial, conducted in 10 perinatal centers in Australia and New Zealand, evaluated the effect of

a probiotic combination (*B infantis*, *Streptococcus thermophiles*, and *Bifidobacterium lactis*) in 1099 very low birth weight (<1500 g) infants with high exposure to human milk. Although no difference in the primary outcome of late-onset sepsis was found in this trial, the incidence of NEC (Bell stage 2 or greater) was reduced (2.0% vs 4.4%) in infants randomly assigned to receive the probiotic combination (RR, 0.46; 95% CI, 0.23–0.93). However, in a prespecified subgroup analysis of infants born at <28 weeks' gestational age and with a birth weight of <1000 g, there was no difference in the rate of NEC.[27]

Not All Probiotics Are Equal: Single Versus Multiple Strain

Multiple-strain probiotics were associated with a significant reduction in NEC (pooled odds ratio, 0.36; 95% CI, 0.24–0.53) and mortality (pooled odds ratio, 0.58; 95% CI, 0.43–0.79), whereas interventions using single-strain probiotic (usually *Lactobacillus*) had only a borderline effect in reducing NEC and no effect on mortality.[28] The European Society for Paediatric Gastroenterology, Hepatology and Nutrition (ESPGHAN) recently published a strain-specific systematic review of the efficacy of probiotics for prevention of NEC, highlighting important differences among various bacterial strains.[29]

Probiotics for the Prevention of Culture-Proven Sepsis in Preterm Infants

In a 2014 Cochrane review that included 19 randomized or quasi-randomized trials of probiotic supplementation in 5338 preterm infants, there was no evidence of significant reduction of nosocomial sepsis (RR, 0.91; 95% CI, 0.80–1.03).[14]

CURRENT PRACTICE GUIDELINES

The American Academy of Pediatrics, Canadian Pediatric Society, and ESPGHAN have all issued statements advocating for caution with regard to routine use of probiotics in preterm infants. In 2010, an American Academy of Pediatrics clinical report cautioned that "the combinations of probiotics most convincing for NEC prevention are not available in the United States… not all probiotics have been studied; therefore, all probiotics cannot be generally recommended."[30] In 2019, the Canadian Pediatric Society reaffirmed the lack of safety and efficacy data for infants with a birth weight of <1000 g as follows: "Probiotics may help to prevent NEC. Administering live microorganisms to preterm newborns should be approached with caution. Along with breastfeeding promotion, probiotics can be considered for the prevention of NEC in preterm infants >1 kg who are at risk for NEC. There is currently no data for infants weighing <1000 g."[31] The ESPGHAN recently published consensus-based guidance for the potential use of probiotics in preterm infants.[32] With regard to the safety of administration of probiotics to preterm infants, the panel stipulated that local laboratories should have the ability to detect probiotic bacteremia, that only products manufactured according to current good manufacturing practices should be used, and that the potential risks and benefits are provided to parents of preterm infants. The panel conditionally recommended use of *L rhamnosus GG* (dose from 1×10^9 CFUs to 6×10^9 CFUs) or a combination of *B infantis*, *B lactis*, and *S thermophilus* (dose of 3.0 to 3.5 $\times$ 10^8 CFUs of each strain) for the reduction of stage 2 or 3 NEC but noted low certainty of evidence. In addition, the panel recommended against the use of certain probiotic preparations on the basis of safety concerns and uncertainty of evidence. Finally, the panel noted the lack of evidence related to the optimal start and length of treatment. Most recently, the American Gastroenterological Association published recommendations using the Grading of Recommendations Assessment, Development and Evaluation approach.[33] Similar to the ESPGHAN, the American Gastroenterological Association made a conditional recommendation for use of a certain probiotic strain or strain combination for the prevention of NEC in preterm infants but did not address the lack of a pharmaceutical-grade product for this population.

PROS AND CONS OF ADMINISTRATION OF CURRENTLY AVAILABLE PROBIOTIC PRODUCTS

NEC remains a devastating disease in preterm infants, with high mortality and morbidity.[34] Given the number of publications in favor of using probiotics for the prevention of NEC, it is not at all surprising that the use of probiotics is increasing, even with the inherent limitations of dietary supplement–grade products that are currently available in the United States. A recent series of articles has eloquently outlined the pros and cons of routine usage of currently available probiotic products,[35,36] and other groups have also urged caution before implementation of routine use of probiotics.[37]

Some of the products currently available in the United States include Culturelle (*L rhamnosus GG*), Similac Probiotic Tri-Blend (*B infantis*, *S thermophilus*, and *B lactis*), and Evivo (*B infantis*). Each of these preparations are categorized as dietary supplements and are not labeled with the number of CFUs for the probiotic strain(s).

LONG-TERM CONSIDERATIONS

The long-term implications of giving probiotics to preterm infants and how administration of microorganisms may permanently alter the microbiome is currently unknown. Jacobs et al[38] found comparable rates of survival without major neurodevelopmental impairment among subjects enrolled in the ProPrems trial. Although reassuring that administration of the probiotic preparation was not associated with adverse neurodevelopmental

outcomes, future studies are needed to more rigorously assess the effects of probiotics on longer-term outcomes.

ONGOING CLINICAL TRIALS

Although many trials involving probiotics use of a dietary supplement–grade product, a phase Ib study evaluating the safety and tolerability of 2 doses of a pharmaceutical-grade probiotic (STP206; NCT01954017) in preterm infants was recently completed. In addition, a phase III randomized clinical trial to evaluate the safety and efficacy of *Lactobacillus reuteri* (IBP-9414; NCT03978000) to prevent NEC in preterm infants is currently ongoing. Proponents for routine administration of probiotics for NEC prevention agree that future research should compare high-quality probiotic products (both purity and viability of microbes) and doses.[36]

SUMMARY

- In studies supporting the use of probiotics to decrease the risk of NEC and late-onset infection, researchers have used multiple different products in diverse settings and in diverse preterm target populations. The most recent modern trials have not demonstrated a reduction in NEC in infants at the highest risk for this morbidity. A pharmaceutical-grade probiotic product is not currently available in the United States. Long-term safety remains unknown. For these reasons, current evidence does not support the routine, universal administration of probiotics to preterm infants, particularly those with a birth weight of <1000 g.
- Centers making the decision to administer probiotics to select preterm infants should discuss the potential risks and benefits of this therapy with parents and should strongly consider a formalized informed consent process. Such centers should develop local guidelines addressing probiotic use and conduct surveillance to assess local impacts because the introduction of probiotics has been shown to alter the center's flora and potentially affect all infants cared for in the center.
- Clinicians must be aware of the lack of regulatory standards for commercially available probiotic preparations manufactured as dietary supplements and the potential for contamination with pathogenic species.
- Centers choosing to administer probiotics should carefully document outcomes, adverse events, and safety.

Web Services and Cloud Computing in Pediatric Care

- *Technical Report*

TECHNICAL REPORT

American Academy of Pediatrics
DEDICATED TO THE HEALTH OF ALL CHILDREN™

Web Services and Cloud Computing in Pediatric Care

Michael G. Leu, MD, MS, MHS, FAAP, FAMIA,[a] Stuart T. Weinberg, MD, FAAP, FAMIA,[b] Craig Monsen, MD, MS,[c] Christoph U. Lehmann, MD, FAAP, FACMI, FIAHSI,[d] COUNCIL ON CLINICAL INFORMATION TECHNOLOGY

Electronic health record (EHR) systems do not uniformly implement pediatric-supportive functionalities. One method of adding these capabilities across EHR platforms is to integrate Web services and Web applications that may perform decision support and store data in the cloud when the EHR platform is able to integrate Web services. Specific examples of these services are described, such as immunization clinical decision support services, consumer health resources, and bilirubin nomograms. Health care providers, EHR vendors, and developers share responsibilities in the appropriate development, integration, and use of Web services and Web applications as they relate to best practices in the areas of data security and confidentiality, technical availability, audit trails, terminology and messaging standards, compliance with the Health Insurance Portability and Accountability Act, testing, usability, and other considerations. It is desirable for health care providers to have knowledge of Web services and Web applications that can improve pediatric capabilities in their own EHRs because this will naturally inform discussions concerning EHR features and facilitate implementation and subsequent use of these capabilities by clinicians caring for children.

INTRODUCTION

The Health Information Technology for Economic and Clinical Health Act, part of the 2009 American Recovery and Reinvestment Act, helped to drive adoption of electronic health records (EHRs). This act paid incentives to eligible health care providers meeting meaningful use requirements.[1] Per the Office of the National Coordinator for Health Information Technology, 96% of hospitals and 78% of physician offices use certified EHR technology.[2,3]

Unfortunately, some EHRs used by pediatricians are still not supportive of pediatric functionalities, such as plotting growth charts or computing anthropometric percentiles, tracking adherence to well-child visits and

immunizations, supporting weight-based dosing, or determining catch-up immunizations.[4,5] Safe pediatric medication prescribing, in particular, has been noted as an area where meaningful use has fallen short.[6,7] In addition to these fundamental pediatric EHR capabilities, additional pediatric EHR requirements that have been previously described for outpatient[8] and inpatient[9] systems have not routinely been available in the systems adopted.[10]

Web services and applications often require local customization, either by the practice or by the EHR vendor (with corresponding time lag). This report explores the technical and legal foundations when creating and integrating clinical Web services and applications for use in pediatric health care.

WEB SERVICES AND CLOUD COMPUTING: DEFINITIONS

A software service is code that can be executed within the context of another process or application.[11] The earliest software services were based on technologies such as remote procedure calls, whereby an application could communicate with another application on the same computer to process information using the other application's processing or memory space.[12]

The ability to encapsulate computer logic to be run between computer processes and applications gains a lot of power when expanded to the Internet. Web services are software services in which the calling application uses Internet protocols to access services on a different machine (or cloud of machines). Logic encapsulated in a service can be called from applications anywhere on the World Wide Web and processed by the service using the Web service's processor or memory, with results returned to the calling applications. Web services typically use standard communications protocols for information transport and structure. Some services, such as Simple Object Access Protocol (SOAP), use data exchange with Hypertext Transport Protocol, unsecured or secured (HTTP versus HTTPS), with information these days often encoded in extensible markup language (XML).[11,13,14,15]

Some Web services support the sharing of resources within the Web services using representational state transfer (REST), in which resources are accessed via uniform resource identifiers (URIs). These resources are accessed by using standard interfaces and protocols such, as GET, PUT, POST, and DELETE. When representational state transfer is used, interactions with resources require that the resources be passed explicitly through the interfaces.[16]

It is fairly common for applications to use Web services provided by a vendor (eg, Amazon Web Services, Microsoft Azure, Salesforce Customer Relationship Management) to allow the application writer to focus on the more novel parts of their application, letting the Web service platform handle the minutiae of straightforward operations (eg, data storage, databases), authentication, networking, messaging and/or e-mail, cross-platform functionality, and updating, or to encapsulate the complex processing of "big" clinical data. The concept of Web service requests that can be processed by multiple different processors and by different vendors is known more broadly as "cloud computing." Cloud computing places the maintenance and expertise related to maintaining hardware and software in the hands of the Web service vendor, reducing the customer's needs to supply the computing power.[17]

More recently, SMART (Substitutable Medical Applications, Reusable Technologies) application programming interface (API) has been defined to allow applications built atop EHRs to access EHR data in a way that is more independent of EHRs.[18] The SMART API is used to access information in the EHR, such as medications, and the resulting data, such as a decision support solution, come back in a SMART data format. EHR vendors implement the SMART API on their EHRs by mapping their internal data structures to the normalized clinical data structures that SMART is expecting. SMART applications also support an authentication standard and selected terminology standards, such as RxNorm, Logical Observation Identifiers Names and Codes (LOINC), and Systematized Nomenclature of Medicine–Clinical Terms (SNOMED CT) . SMART applications are HTML5 applications that can run within Web browsers and frames. The SMART standards include open-source libraries, a "sandbox" for application testing, and an app gallery for users.[18]

More recently, Health Level Seven defined standards for Fast Healthcare Interoperability Resources (FHIR), with implementers using this standard to support laboratory result exchanges.[19] FHIR represents clinical resource profiles as intuitive interoperable concepts, such as MedicationPrescription, which may refer to a prescriber, patient, and drug prescribed. The SMART group took these FHIR specifications (which included FHIR descriptions of about 50 clinical resource profiles with APIs for data access) and added the SMART concepts of authorization, authentication, additional SMART resource profiles, and user interface

integration, which they call SMART on FHIR.[20]

SMART resource definitions require EHR vendors to normalize their data, and early developer experiences with SMART on FHIR suggest that vendors are reluctant to adopt this technology.[20] Although FHIR does not require the data normalization, the combination of SMART on FHIR typically requires some adjustments to run on each individual vendor platform.

WHY DEVELOP WEB SERVICES AND APPLICATIONS?

Web-based services and applications are desirable because they allow for clinical logic to be developed and programmed once and then shared across many different applications and/or EHRs. The ability of developing a shareable resource only once is the major benefit of "modular programming," in which logic is encapsulated in a module instead of being repeatedly redeveloped with the potential for errors. Established technical protocols like SMART on FHIR allow for Web services to be accessed from multiple platforms.

Encapsulate Expertise

Web-based services and applications hold the promise that they may speed the implementation of computable pediatric clinical functions in EHRs. Instead of focusing resources on understanding and correctly interpreting clinical algorithms or logic, the vendors need to focus only on how to call the Web service and correctly integrate and display its results. For the vendor, the underlying logic and operation of the Web service may remain a black box. For simple Web services, such as some that provide content for discharge instructions, vendors simply call the Web service to retrieve the discharge instruction information then customize format and display for printing.[21] The encapsulation of expertise may allow medical specialty societies and organizations to serve as the clinical experts if they can provide Web services and applications that permit integration with EHRs.[22]

Ease of Maintenance

In addition to encapsulating expertise, Web services and applications simplify the maintenance of clinical logic. Web services can, for example, provide immunization forecasting based on the immunizations already given to the patient.[23] When EHR vendors integrate such a service, any Web service logic update that reflects updatd immunization recommendations from the American Academy of Pediatrics or from the Centers for Disease Control and Prevention Advisory Committee on Immunization Practices would immediately be available to users of different EHRs without any required changes to the EHR software, assuming that the interface remains preserved.

Testing Can Be Shared and Automated

Another advantage of creating Web services and applications relates to testing. Because the logic is encapsulated in one place, the Web service can be called by a small test application to ensure that it is working correctly before integrating the service with the more complex environment of EHRs. Calls to the Web service can be automated so that regression testing scenarios (eg, in the immunization example, ensuring that immunization logic for parts of the immunization schedule that were not updated still works correctly). And because the Web service is ubiquitously available on the Internet, testing efforts can be shared among multiple stakeholders in different locations instead of reliance on vendor internal testing and discovery of errors by end-user clinicians.[24]

EXAMPLES OF WEB SERVICES AND APPLICATIONS

There are abundant examples of nonmedical Web services that are used by Web sites people visit every day. Maps that are integrated into hotel or restaurant Web sites are usually externally generated and then incorporated into the site through a Web service. Calculations of latitude and longitude are externally determined to measure distances between addresses when searching for the shortest route. Centralized data from real estate listings are accessed and integrated into individual realtor Web sites. There are also Web services that support data storage and cloud computing, although these services may or may not always be secure enough in managing protected health information to comply with the Health Insurance Portability and Accountability Act (HIPAA).[25]

Clinical Web services and applications are more limited at this time. Initial experiments with encapsulated logic included independently developed solutions to improve EHR safety.[26] For example, a calculator for continuously infused medication was integrated with a vendor EHR. Web services and applications offer opportunities to catalyze the integration of pediatric-specific functionalities into EHRs. Immunization decision support could be accomplished by sending immunization data and relevant demographic and clinical data to a resource that performs an assessment and returns forecasted results. A multitude of pediatric-specific calculations, such as percentiles for pediatric hypertension assessment, could also be readily available through Web services.[27]

WHAT KINDS OF WEB SERVICES AND APPLICATIONS EXIST TODAY?

Infobuttons: Hypertext Markup Language and XML Handout Generators

One of the simplest types of Web services takes a term and uses a Web service to find out more information about that term. This type of functionality is called "Infobutton" technology because it is based on the user interface concept of being able to highlight a term then click on an "info button" or menu selection to learn more about what has been highlighted.[28]

One example of this technology is when users can send the Web service a diagnosis code in SNOMED, *International Classification of Diseases, Ninth Revision*, or *International Classification of Diseases, 10th Revision*, and an XML (or JavaScript Object Notation [JSON] or JSON with Padding [JSONP]) construct will be returned that contains patient education information for that medical condition. Services are also provided to support pharmacy and/or medication lookup by RXCUI (RxNorm concept unique identifer for the clinical drug or substance)/ NDC and laboratory test lookup by LOINC. In addition to being accessible by EHR programs.[29]

Clinical Calculators

Clinical calculators take selected patient information and use it to provide a customized report or calculation. Calculation Web services are best if they not only provide good calculations and can handle erroneous or missing inputs gracefully but also provide references and explanations for their calculation results.[30] Some examples amenable to being provided as Web services to support pediatrics may include the following:

- Fahrenheit (English) to Celsius (metric) conversion;
- length or height, weight, weight for height, and BMI percentiles, including condition-specific growth charts, such as for cerebral palsy[31] or Down syndrome[32];
- blood pressure percentiles;
- neonatal morbidity and mortality calculations for preterm infants;
- medical translation services; and
- services that take input and use natural language processing to spell check, grammar check, or correct text.

One published example of a simple pediatric Web service that can be easily integrated into an EHR relates to plotting values on a bilirubin nomogram. Such a Web service can take 3 arguments (hour of life, bilirubin level, and units) as part of a URL and return a Web page that describes the infant's risk for developing severe hyperbilirubinemia based the American Academy of Pediatrics bilirubin nomogram.[33–35]

Clinical Decision Support for Immunizations

Several Web services exist to provide clinical decision support for immunizations.[36–38] These services can be integrated into EHRs, allowing for both the forecasting of future vaccine doses and the validation of existing documented doses. The different services may have different business models and methods of integration.

SMART Applications

The SMART App Gallery lists applications for bilirubin level charting, blood pressure percentiles, rheumatology summaries (including joint homunculi), and growth charts.[39] Although these apps are likely in use at the institutions that developed them, it is unclear whether these apps are in use at other institutions.

Considerations for Web Services and Applications

The factors that both vendors and users need to consider when Web services and applications are used are similar to those to assess when practices are considering purchasing an EHR: application availability, downtime procedures, data ownership, interoperability and vocabularies, and workflow analysis and simulation. In addition, there are 2 new underappreciated areas to consider: transparency of the logic of the Web service and concerns about the ability to identify individuals from their data.[40,41]

Service and Application Availability and Downtime Procedures

Performance and uptime characteristics are critical. Delays in results from the Web service will often be perceived by end users as failures in the EHR itself. If the EHR fails or generates cryptic error messages because of a Web service failure, health care providers may become disgruntled, and it may be difficult for the practice and for the vendor to address the problem in real time because the Web service is controlled by a third party. Health care providers have the expectation that their EHRs will be available when they are needed, and some health care providers may require that these systems be available 24/7 (eg, for emergency and/or inpatient care).

Acceptable downtime for Web services is driven by the agreements between the end users (physicians or EHR vendors) and by the type of services. If the Web service provides a low risk service which can easily be done manually (eg, plotting a point on a growth chart), downtime may be more tolerable than if it performs a more mission critical operation (eg, dose range checking). It will be up to the health care

provider and his or her EHR vendor to negotiate response time to unforeseen problems with Web service providers.

Data and Storage

Clinical calculators may take a fixed set of inputs and return a fixed output. For example, a Web service can convert from English to metric units (eg, Fahrenheit to Celsius, pounds to kilograms, inches to centimeters). Although such a Web service would, in theory, not need to store any data, it could (eg, it could store what it was called with and/or administrative data included in the Web request, such as the IP address of where the request originated). Web service developers have used information passed to them to try to improve their services and to attempt to generate revenue (eg, targeted advertising through Google AdSense).

Web services and applications may save data so that in the event of interruption, they can continue from where they left off. The information may be stored in the client (EHR) application or in the application's storage. To keep track of stored information, apps may use identifiers. If identifiers use protected health information, either individually or in aggregate (eg, Social Security numbers), HIPAA may apply. Web services and applications need to validate sent data in a way that does not compromise the security of the calling application or computing environment. Hackers may attempt to exploit Web services to gain control over the process and/or memory to which Web services have access (as seen with recent events related to ransomware) or to access health information, which is of increasing value on the black market.[42] Ideally, Web services will execute within a protected address space where any failures cannot compromise the processor or memory running the Web service.

Just as a Web service must maintain integrity with inputs, EHR applications that call Web services must process returns from the Web service in a safe manner. EHR data sent to a Web service that would contain protected health information should be (1) securely transmitted between the application and the Web service; (2) managed per HIPAA rules by the Web service (as described in business associate agreements between EHR vendors, Web service or application vendors, and the clinical practice); and (3) controlled by an agreement that describes any storing of information sent to the Web service and its ownership and use.[43]

A potential additional risk of Web services using the Internet and storing data are that these separate data repositories can become compromised. If the application vendor stores data using Web services, and authentication is insufficient (as reported with the initial version of Apple iCloud, which allowed celebrity passwords to be guessed by brute force without lockouts after a certain number of failed password attempts), the data stores may be hacked, allowing access to data backed up from phones.[44]

Interoperability and Vocabularies

It is desirable to use existing data and vocabulary standards when developing Web services. Using existing standards, such as RxNorm, LOINC, SNOMED, and *International Classification of Diseases*, will allow data to be exchanged with other clinical systems, will capitalize on vendor support for these standards, and will reduce the effort required to connect to and integrate Web services.[40]

Workflow Analysis and Simulation

Consumers of different Web services and applications may vary significantly. Ideally, Web services for clinicians will be integrated in the regular workflow; for example, the Web service is available through the clinician's EHR, which autopopulates data sent to the service with the appropriate patient information. Some Web services or applications can be accessed via links to Web pages.

Transparency: "Show Your Work"

From a technical standpoint, Web services and applications constitute software code that can be used ubiquitously. End users may, by default, assume that applications have been tested and are safe. They may not have a clear understanding of how results, such as recommendations or calculated values, are achieved. All clinical software should be transparent as to the evidence applied and calculations made. Making the work transparent allows stakeholders (such as informaticians and clinician end users) to be informed when determining whether the software supports organizational goals when deciding whether to integrate the software.

Web services and applications, especially those that perform calculations, should cite references and provide transparency to algorithms used so that any recommendation can be validated and verified. Transparency will aid both users and developers. Users who disagree with the Web service's recommendation can review the underlying assumptions and rules and may be able to contact the developer and suggest changes and corrections. If improvements or corrections are needed in a Web service or application, the Web service should be reconfigured rapidly, with the anticipated time

frame communicated, to maintain clinician cooperation and engagement.[30]

Identifiability of Individuals

Health care identities are considered more valuable than simple credit card numbers and achieve higher prices on the black market. Health care identities may be used to apply for credit, to file fraudulent tax returns, or to commit Medicare and/or Medicaid fraud. Measures to protect identities are only as good as the most insecure step. Data passed to Web services should be limited to the minimum needed for execution, especially if protected health information is requested. Use of heuristics to allow patient record deduplication is recommended when possible.[45]

A simple way to determine the correct amount of information to pass to a Web service involves simulation in which the developer team examines the data being requested or sent to the Web service and reviews them in aggregate and in the context of the mission and functionality of the Web service. A Web service designed to perform Fahrenheit to Celsius conversion that is requesting patient identifiers would raise concerns and be flagged as requesting more data than required. Such analysis is critically important, especially in the case of identified data, because data in transit or stored outside of the system may potentially be more vulnerable to compromise.

Aggregating data from one source with other sources allows previously anonymous data to be identified. Even if identifying information has not been provided, an unintended consequence of sharing data with Web services and applications is the discerning of identities, especially if the data are combined with the increasing amount of public data on individuals. For example, when AOL released a list of searches that were grouped by anonymous search identifiers, the identity of one searcher was revealed just from queries.[46] When similar events occur in a health context, patients could be vulnerable not only to a lack of privacy but also to blackmail, discrimination, or other threats.

APPROPRIATE USE OF WEB SERVICES AND APPLICATIONS

To support successful implementation, the Web service interface and outputs should be clearly specified. The application must respect the data requirements of the Web service (eg, if a Web service is passing a length or height of a patient and the Web service requires that the length or height be specified in centimeters, then the calling application needs to provide the length or height in the appropriate units). The application is responsible for converting data into the format required by the Web service.

Secure Connections

The EHR application calling the Web service should transmit information via a secure, encrypted channel, especially if protected health information is involved. The EHR vendor must ensure that the Web service will handle data securely. This can be achieved by either an agreement, such as a business associates agreement, or, in exceptional cases, by reviewing source code to ensure that (1) the Web service does not store data or (2) the Web service stores data in a secure manner and in a secure location not vulnerable to compromise. Ideally, the business associates agreement will also describe what data the Web service is collecting, the ownership of data, and the permissible data uses.

Protected Environment

Currently, many EHR systems authenticate users using a username, password, and location-based authentication. EHR vendors are to determine when a Web service is accessing user data, how the Web service will be authenticated, and what access and permissions are allowed. Ideally, when Web services are authenticated, they would not authenticate through an existing user profile with potentially broad permissions, but instead, in a way that the service would have limited or no access to protected health information. This would force the Web service to work with information explicitly supplied to the service.

Web services may represent a security risk in the event that (1) the EHR application is redirected to a different Web service with ill intent or (2) the Web service itself is not robust and/or mishandles data. Therefore, the calling application must be able to manage situations in which (1) the Web service tries to perform actions within the calling application that it should not, (2) the Web service corrupts data sent to it, or (3) the Web service returns results that are not valid. EHR applications should provide a limited and protected environment in which they execute Web service code (eg, a sandbox) and the service cannot cause harm resulting in data breaches, impermissible access, or data corruption.

Performance

Applications may manage performance of Web services by multitasking when Web services are in use (running them in separate threads or processes), allowing the user to continue with his or her work while awaiting results. Alternately, the Web service could

be timed and stopped if it is taking too long.

Needs for Authentication and Auditing

Health care applications such as EHRs are held to a higher standard than consumer applications. EHRs ensure that the chain of data from entry to storage and retrieval is secure, auditable, and restricted to individuals with appropriate authorization.[43] These requirements of ensuring adequate privacy and security protections for protected health information are reinforced by meaningful use criteria.[1]

Access to and editing of patient information are often restricted by role. Inappropriate chart access may be a terminable offense. Records are to be accessed only by individuals who are authorized by policy, and access to patient charts should be audited. Web services and applications need to preserve these safeguards, including user authentication and authorization, and are not allowed to take shortcuts, such as permitting Web services or applications to use a higher level of privileges than the user.

Audits of who accessed data to determine if access was proper and legal are important. When Web services that access and/or store data are implemented, this access must be recognizably recorded for auditing purposes so that practices can determine if data compromise is a result of data stored by Web services or a breach of security at the practice.

Testing

Web services will generate clinical recommendations to clinicians. It is imperative that a Web service delivers what is advertised and expected by the user. Preferable testing approaches would include automatic testing and logging of returned results compared with the expected results for all possible inputs to the Web service. For example, if a Web service input is three-dimensional (age, sex, laboratory value), testing scripts should cover every possible combination of each input parameter or, at a minimum, the most common use cases. Direct usability testing with users, ideally before roll out to inform training efforts, is desirable before any software releases.

Versions and Maintenance

As clinical knowledge grows, Web services will require updates and modifications. Other reasons to update a Web service include functionality enhancements, bug fixes, and safety and security enhancements.

Versioning (keeping track of modifications and their implementation) that includes the output created by the Web service is critical. Health care providers are required to practice the standard of care, which develops and changes over time. For medical-legal reasons, it is critical to be able to have a discovery process recreate the output of a Web service at a previous date to demonstrate the adherence to the standards of care at that time. Web services and applications should provide version information, and client software, such as EHRs, should capture this information so that practices can audit and reconstruct which data and rules were being used at different points in time.

With any Web service update, developers are required to provide documentation to prepare users for functionality or output modifications. Web service and application vendors will supply predocumentation of upcoming releases to allow end users to learn about future anticipated behavior of the Web service or application. Ideally, practices and EHR vendors will be allowed to accept or decline the updates. Release dates (and, if applicable, anticipated expiration dates) are obtained to support communication to users.

If an owner of a Web service or application is not willing or able to maintain and update his or her software in response to new knowledge or technology or security issues, the Web service should be explicit about this or should be retired for use.

FUTURE WEB SERVICES

More sophisticated Web services may return XML outputs that the invoking application can then interpret and/or display. For example, a Google Web service takes a text string representing a location and returns XML that represents that location on a map. A Web service that takes information such as sex, age, and weight could plot those weights and return a personalized growth chart[43,47] that would include likely interpretations for the growth chart (eg, consistent with failure to thrive versus consistent with hypothyroidism). A Web service could take a collection of addresses in a neighborhood of patients exposed to a toxin or infectious disease and return a geographical map with the specified locations highlighted.[48]

CONCLUSIONS

Web services and cloud computing in health care are near the “peak of inflated expectations” on the hype cycle,[49] in which many small prototype applications exist that have not been broadly adopted because of underlying infrastructure issues, lack of integration with clinical workflows, and/or lack of perceived impact for cost to integrate. Given the rapid speed at which this field is developing, more Web-based services than are referenced in this document will be

developed and marketed to clinicians in practice; thus, this report constitutes some illustrative examples only. It will be important to identify and prioritize needed Web services for the support of pediatrics to facilitate the development of these Web services, to help disseminate these services through either endorsement or integration with implementation tool kits, and to keep these concepts in mind when pediatricians and pediatric practices decide whether to put new Web services into practice.

2021 RECOMMENDATIONS FOR PREVENTIVE PEDIATRIC HEALTH CARE

Committee on Practice and Ambulatory Medicine and Bright Futures Periodicity Schedule Workgroup

ABSTRACT. The 2021 Recommendations for Preventive Pediatric Health Care (Periodicity Schedule) has been approved by the American Academy of Pediatrics (AAP) and represents a consensus of the AAP and the Bright Futures Periodicity Schedule Workgroup. Each child and family is unique; therefore, these recommendations are designed for the care of children who are receiving competent parenting, have no manifestations of any important health problems, and are growing and developing in a satisfactory fashion. Developmental, psychosocial, and chronic disease issues for children and adolescents may require frequent counseling and treatment visits separate from preventive care visits. Additional visits also may become necessary if circumstances suggest variations from normal. (2/21)

AAP DIVERSITY AND INCLUSION STATEMENT

American Academy of Pediatrics

ABSTRACT. The vision of the American Academy of Pediatrics (AAP) is that all children have optimal health and well-being and are valued by society and that AAP members practice the highest quality health care and experience professional satisfaction and personal well-being. From the founding of the AAP, pursuing this vision has included treasuring the uniqueness of each child and fostering a profession, health care system, and communities that celebrate all aspects of the diversity of each child and family. (3/18)

ABUSIVE HEAD TRAUMA IN INFANTS AND CHILDREN

Sandeep K. Narang, MD, JD, FAAP; Amanda Fingarson, DO, FAAP; James Lukefahr, MD, FAAP; and Council on Child Abuse and Neglect

ABSTRACT. Abusive head trauma (AHT) remains a significant cause of morbidity and mortality in the pediatric population, especially in young infants. In the past decade, advancements in research have refined medical understanding of the epidemiological, clinical, biomechanical, and pathologic factors comprising the diagnosis, thereby enhancing clinical detection of a challenging diagnostic entity. Failure to recognize AHT and respond appropriately at any step in the process, from medical diagnosis to child protection and legal decision-making, can place children at risk. The American Academy of Pediatrics revises the 2009 policy statement on AHT to incorporate the growing body of knowledge on the topic. Although this statement incorporates some of that growing body of knowledge, it is not a comprehensive exposition of the science. This statement aims to provide pediatric practitioners with general guidance on a complex subject. The Academy recommends that pediatric practitioners remain vigilant for the signs and symptoms of AHT, conduct thorough medical evaluations, consult with pediatric medical subspecialists when necessary, and embrace the challenges and need for strong advocacy on the subject. ACCESS TO OPTIMAL EMERGENCY CARE FOR CHILDREN

Kathleen M. Brown, MD, FAAP, FACEP; Alice D. Ackerman, MD, MBA, FAAP; Timothy K. Ruttan, MD, FACEP, FAAP; Sally K. Snow, RN, BSN, CPEN, FAEN; Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee, 2018–2019)

ABSTRACT. Every year, millions of pediatric patients seek emergency care. Significant barriers limit access to optimal emergency services for large numbers of children. The American Academy of Pediatrics, American College of Emergency Physicians, and Emergency Nurses Association have a strong commitment to identifying these barriers, working to overcome them, and encouraging, through education and system changes, improved access to emergency care for all children. ACHIEVING QUALITY HEALTH SERVICES FOR ADOLESCENTS

Committee on Adolescence

ABSTRACT. This update of the 2008 statement from the American Academy of Pediatrics redirects the discussion of quality health care from the theoretical to the practical within the medical home. This statement reviews the evolution of the medical home concept and challenges the provision of quality adolescent health care within the patient-centered medical home. Areas of attention for quality adolescent health care are reviewed, including developmentally appropriate care, confidentiality, location of adolescent care, providers who offer such care, the role of research in advancing care, and the transition to adult care. (7/16)

ACHIEVING THE PEDIATRIC MENTAL HEALTH COMPETENCIES (TECHNICAL REPORT)

Cori M. Green, MD, MS, FAAP; Jane Meschan Foy, MD, FAAP; Marian F. Earls, MD, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Mental Health Leadership Work Group

ABSTRACT. Mental health disorders affect 1 in 5 children; however, the majority of affected children do not receive appropriate services, leading to adverse adult outcomes. To meet the needs of children, pediatricians need to take on a larger role in addressing mental health problems. The accompanying policy statement, "Mental Health Competencies for Pediatric Practice," articulates mental health competencies pediatricians could achieve to improve the mental health care of children; yet, the majority of pediatricians do not feel prepared to do so. In this technical report, we summarize current initiatives and resources that exist for trainees and practicing pediatricians across the training continuum. We also identify gaps in mental

health clinical experience and training and suggest areas in which education can be strengthened. With this report, we aim to stimulate efforts to address gaps by summarizing educational strategies that have been applied and could be applied to undergraduate medical education, residency and fellowship training, continuing medical education, maintenance of certification, and practice quality improvement activities to achieve the pediatric mental health competencies. In this report, we also articulate the research questions important to the future of pediatric mental health training and practice. (10/19)

ADDRESSING EARLY CHILDHOOD EMOTIONAL AND BEHAVIORAL PROBLEMS

Council on Early Childhood, Committee on Psychosocial Aspects of Child and Family Health, and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Emotional, behavioral, and relationship problems can develop in very young children, especially those living in high-risk families or communities. These early problems interfere with the normative activities of young children and their families and predict long-lasting problems across multiple domains. A growing evidence base demonstrates the efficacy of specific family-focused therapies in reducing the symptoms of emotional, behavioral, and relationship symptoms, with effects lasting years after the therapy has ended. Pediatricians are usually the primary health care providers for children with emotional or behavioral difficulties, and awareness of emerging research about evidence-based treatments will enhance this care. In most communities, access to these interventions is insufficient. Pediatricians can improve the care of young children with emotional, behavioral, and relationship problems by calling for the following: increased access to care; increased research identifying alternative approaches, including primary care delivery of treatments; adequate payment for pediatric providers who serve these young children; and improved education for pediatric providers about the principles of evidence-based interventions. (11/16)
https://doi.org/10.1542/peds.2016-3023

ADDRESSING EARLY CHILDHOOD EMOTIONAL AND BEHAVIORAL PROBLEMS (TECHNICAL REPORT)

Mary Margaret Gleason, MD, FAAP; Edward Goldson, MD, FAAP; Michael W. Yogman, MD, FAAP; Council on Early Childhood; Committee on Psychosocial Aspects of Child and Family Health; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. More than 10% of young children experience clinically significant mental health problems, with rates of impairment and persistence comparable to those seen in older children. For many of these clinical disorders, effective treatments supported by rigorous data are available. On the other hand, rigorous support for psychopharmacologic interventions is limited to 2 large randomized controlled trials. Access to psychotherapeutic interventions is limited. The pediatrician has a critical role as the leader of the medical home to promote well-being that includes emotional, behavioral, and relationship health. To be effective in this role, pediatricians promote the use of safe and effective treatments and recognize the limitations of psychopharmacologic interventions. This technical report reviews the data supporting treatments for young children with emotional, behavioral, and relationship problems and supports the policy statement of the same name. (11/16)
https://doi.org/10.1542/peds.2016-3025

ADMISSION AND DISCHARGE GUIDELINES FOR THE PEDIATRIC PATIENT REQUIRING INTERMEDIATE CARE (CLINICAL REPORT)

Committee on Hospital Care and Section on Critical Care (joint with Society of Critical Care Medicine)

ABSTRACT. During the past 3 decades, the specialty of pediatric critical care medicine has grown rapidly, leading to a number of pediatric intensive care units opening across the country. Many patients who are admitted to the hospital require a higher level of care than routine inpatient general pediatric care, yet not to the degree of intensity of pediatric critical care; therefore, an intermediate care level has been developed in institutions providing multidisciplinary subspecialty pediatric care. These patients may require frequent monitoring of vital signs and nursing interventions, but usually they do not require invasive monitoring. The admission of the pediatric intermediate care patient is guided by physiologic parameters depending on the respective organ system involved relative to an institution's resources and capacity to care for a patient in a general care environment. This report provides admission and discharge guidelines for intermediate pediatric care. Intermediate care promotes greater flexibility in patient triage and provides a cost-effective alternative to admission to a pediatric intensive care unit. This level of care may enhance the efficiency of care and make health care more affordable for patients receiving intermediate care. (5/04, reaffirmed 2/08, 5/17, 2/20)

ADOLESCENT AND YOUNG ADULT TATTOOING, PIERCING, AND SCARIFICATION (CLINICAL REPORT)

Cora C. Breuner, MD, MPH; David A. Levine, MD; and Committee on Adolescence

ABSTRACT. Tattoos, piercing, and scarification are now commonplace among adolescents and young adults. This first clinical report from the American Academy of Pediatrics on voluntary body modification will review the methods used to perform the modifications. Complications resulting from body modification methods, although not common, are discussed to provide the pediatrician with management information. Body modification will be contrasted with nonsuicidal self-injury. When available, information also is presented on societal perceptions of body modification. (9/17)

ADOLESCENT DRUG TESTING POLICIES IN SCHOOLS

Sharon Levy, MD, MPH, FAAP; Miriam Schizer, MD, MPH, FAAP; and Committee on Substance Abuse

ABSTRACT. School-based drug testing is a controversial approach to preventing substance use by students. Although school drug testing has hypothetical benefits, and studies have noted modest reductions in self-reported student drug use, the American Academy of Pediatrics opposes widespread implementation of these programs because of the lack of solid evidence for their effectiveness. (3/15)
https://doi.org/10.1542/peds.2015-0054

ADOLESCENT DRUG TESTING POLICIES IN SCHOOLS (TECHNICAL REPORT)

Sharon Levy, MD, MPH, FAAP; Miriam Schizer, MD, MPH, FAAP; and Committee on Substance Abuse

ABSTRACT. More than a decade after the US Supreme Court established the legality of school-based drug testing, these programs remain controversial, and the evidence evaluating efficacy and risks is inconclusive. The objective of this technical report is to review the relevant literature that explores the benefits, risks, and costs of these programs. (3/15)
https://doi.org/10.1542/peds.2015-0055

ADOLESCENT PREGNANCY: CURRENT TRENDS AND ISSUES (CLINICAL REPORT)

Jonathan D. Klein, MD, MPH, and Committee on Adolescence

ABSTRACT. The prevention of unintended adolescent pregnancy is an important goal of the American Academy of Pediatrics and our society. Although adolescent pregnancy and birth rates have been steadily decreasing, many adolescents still become pregnant. Since the last statement on adolescent pregnancy was issued by the Academy in 1998, efforts to prevent adolescent pregnancy have increased, and new observations, technologies, and prevention effectiveness data have emerged. The purpose of this clinical report is to review current trends and issues related to adolescent pregnancy, update practitioners on this topic, and review legal and policy implications of concern to pediatricians. (7/05)

https://doi.org/10.1542/peds.2005-0999

ADOLESCENT PREGNANCY: CURRENT TRENDS AND ISSUES—ADDENDUM

Committee on Adolescence

INTRODUCTION. The purpose of this addendum is to update pediatricians and other professionals on recent research and data regarding adolescent sexuality, contraceptive use, and childbearing since publication of the original 2005 clinical report, "Adolescent Pregnancy: Current Trends and Issues." There has been a trend of decreasing sexual activity and teen births and pregnancies since 1991, except between the years of 2005 and 2007, when there was a 5% increase in birth rates. Currently, teen birth rates in the United States are at a record low secondary to increased use of contraception at first intercourse and use of dual methods of condoms and hormonal contraception among sexually active teenagers. Despite these data, the United States continues to lead other industrialized countries in having unacceptably high rates of adolescent pregnancy, with over 700 000 pregnancies per year, the direct health consequence of unprotected intercourse. Importantly, the 2006–2010 National Survey of Family Growth (NSFG) revealed that less than one-third of 15- to 19-year-old female subjects consistently used contraceptive methods at last intercourse. (4/14)

ADOLESCENTS AND HIV INFECTION: THE PEDIATRICIAN'S ROLE IN PROMOTING ROUTINE TESTING

Committee on Pediatric AIDS

ABSTRACT. Pediatricians can play a key role in preventing and controlling HIV infection by promoting risk-reduction counseling and offering routine HIV testing to adolescent and young adult patients. Most sexually active youth do not feel that they are at risk of contracting HIV and have never been tested. Obtaining a sexual history and creating an atmosphere that promotes nonjudgmental risk counseling is a key component of the adolescent visit. In light of increasing numbers of people with HIV/AIDS and missed opportunities for HIV testing, the Centers for Disease Control and Prevention recommends universal and routine HIV testing for all patients seen in health care settings who are 13 to 64 years of age. There are advances in diagnostics and treatment that help support this recommendation. This policy statement reviews the epidemiologic data and recommends that routine screening be offered to all adolescents at least once by 16 to 18 years of age in health care settings when the prevalence of HIV in the patient population is more than 0.1%. In areas of lower community HIV prevalence, routine HIV testing is encouraged for all sexually active adolescents and those with other risk factors for HIV. This statement addresses many of the real and perceived barriers that pediatricians face in promoting routine HIV testing for their patients. (10/11, reaffirmed 9/15)

https://doi.org/10.1542/peds.2011-1761

THE ADOLESCENT'S RIGHT TO CONFIDENTIAL CARE WHEN CONSIDERING ABORTION

Committee on Adolescence

ABSTRACT. In this statement, the American Academy of Pediatrics reaffirms its position that the rights of adolescents to confidential care when considering abortion should be protected. Adolescents should be encouraged to involve their parents and other trusted adults in decisions regarding pregnancy termination, and most do so voluntarily. The majority of states require that minors have parental consent for an abortion. However, legislation mandating parental involvement does not achieve the intended benefit of promoting family communication, and it increases the risk of harm to the adolescent by delaying access to appropriate medical care. This statement presents a summary of pertinent current information related to the benefits and risks of legislation requiring mandatory parental involvement in an adolescent's decision to obtain an abortion. https://doi.org/10.1542/peds.2016-3861

ADVANCED PRACTICE IN NEONATAL NURSING

Committee on Fetus and Newborn

ABSTRACT. The participation of advanced practice registered nurses in neonatal care continues to be accepted and supported by the American Academy of Pediatrics. Recognized categories of advanced practice neonatal nursing are the neonatal clinical nurse specialist and the neonatal nurse practitioner. (5/09, reaffirmed 1/14)

ADVOCACY AND COLLABORATIVE HEALTH CARE FOR JUSTICE-INVOLVED YOUTH

Mikah C. Owen, MD, MPH, FAAP; Stephenie B. Wallace, MD, MSPH, FAAP; and Committee on Adolescence

ABSTRACT. Children and adolescents who become involved with the justice system often do so with complex medical, mental health, developmental, social, and legal needs. Most have been exposed to childhood trauma or adversity, which both contribute to their involvement with the justice system and negatively impact their health and well-being. Whether youth are held in confinement or in their home communities, pediatricians play a critical role in promoting the health and well-being of justice-involved youth. Having a working knowledge of the juvenile justice system and common issues facing justice-involved youth may help pediatricians enhance their clinical care and advocacy efforts. This policy statement is a revision of the 2011 policy "Health Care for Youth in the Juvenile Justice System." It provides an overview of the juvenile justice system, describes racial bias and overrepresentation of youth of color in the justice system, reviews the health and mental health status of justice-involved youth, and identifies advocacy opportunities for juvenile justice reform. (6/20)

ADVOCACY FOR IMPROVING NUTRITION IN THE FIRST 1000 DAYS TO SUPPORT CHILDHOOD DEVELOPMENT AND ADULT HEALTH

Sarah Jane Schwarzenberg, MD, FAAP; Michael K. Georgieff, MD, FAAP; and Committee on Nutrition

ABSTRACT. Maternal prenatal nutrition and the child's nutrition in the first 2 years of life (1000 days) are crucial factors in a child's neurodevelopment and lifelong mental health. Child and adult health risks, including obesity, hypertension, and diabetes, may be programmed by nutritional status during this period. Calories are essential for growth of both fetus and child but are not sufficient for normal brain development. Although all nutrients are necessary for brain growth, key nutrients that support neurodevelopment include protein; zinc; iron; choline; folate; iodine; vitamins A, D, B_6, and B_{12}; and long-chain poly-

unsaturated fatty acids. Failure to provide key nutrients during this critical period of brain development may result in lifelong deficits in brain function despite subsequent nutrient repletion. Understanding the complex interplay of micro- and macronutrients and neurodevelopment is key to moving beyond simply recommending a "good diet" to optimizing nutrient delivery for the developing child. Leaders in pediatric health and policy makers must be aware of this research given its implications for public policy at the federal and state level. Pediatricians should refer to existing services for nutrition support for pregnant and breastfeeding women, infants, and toddlers. Finally, all providers caring for children can advocate for healthy diets for mothers, infants, and young children in the first 1000 days. Prioritizing public policies that ensure the provision of adequate nutrients and healthy eating during this crucial time would ensure that all children have an early foundation for optimal neurodevelopment, a key factor in long-term health. (1/18)

ADVOCATING FOR LIFE SUPPORT TRAINING OF CHILDREN, PARENTS, CAREGIVERS, SCHOOL PERSONNEL, AND THE PUBLIC

James M. Callahan, MD, FAAP; Susan M. Fuchs, MD, FAAP; and Committee on Pediatric Emergency Medicine

ABSTRACT. Out-of-hospital cardiac arrest occurs frequently among people of all ages, including more than 6000 children annually. Pediatric cardiac arrest in the out-of-hospital setting is a stressful event for family, friends, caregivers, classmates, school personnel, and witnesses. Immediate bystander cardiopulmonary resuscitation and the use of automated external defibrillators are associated with improved survival in adults. There is some evidence in which improved survival in children who receive immediate bystander cardiopulmonary resuscitation is shown. Pediatricians, in their role as advocates to improve the health of all children, are uniquely positioned to strongly encourage the training of children, parents, caregivers, school personnel, and the lay public in the provision of basic life support, including pediatric basic life support, as well as the appropriate use of automated external defibrillators. (5/18)
https://doi.org/10.1542/peds.2018-0704

ADVOCATING FOR LIFE SUPPORT TRAINING OF CHILDREN, PARENTS, CAREGIVERS, SCHOOL PERSONNEL, AND THE PUBLIC (TECHNICAL REPORT)

Susan M. Fuchs, MD, FAAP, and Committee on Pediatric Emergency Medicine

ABSTRACT. Pediatric cardiac arrest in the out-of-hospital setting is a traumatic event for family, friends, caregivers, classmates, and school personnel. Immediate bystander cardiopulmonary resuscitation and the use of automatic external defibrillators have been shown to improve survival in adults. There is some evidence to show improved survival in children who receive immediate bystander cardiopulmonary resuscitation. AGE LIMIT OF PEDIATRICS

Amy Peykoff Hardin, MD, FAAP; Jesse M. Hackell, MD, FAAP; and Committee on Practice and Ambulatory Medicine

ABSTRACT. Pediatrics is a multifaceted specialty that encompasses children's physical, psychosocial, developmental, and mental health. Pediatric care may begin periconceptionally and continues through gestation, infancy, childhood, adolescence, and young adulthood. Although adolescence and young adulthood are recognizable phases of life, an upper age limit is not easily demarcated and varies depending on the individual patient. The establishment of arbitrary age limits on pediatric care by health care providers should be discouraged. The decision to continue care with a pediatrician or pediatric medical or surgical subspecialist should be made solely by the patient (and family, when appropriate) and the physician and must take into account the physical and psychosocial needs of the patient and the abilities of the pediatric provider to meet these needs. (8/17)
https://doi.org/10.1542/peds.2017-2151

AGE TERMINOLOGY DURING THE PERINATAL PERIOD

Committee on Fetus and Newborn

ABSTRACT. Consistent definitions to describe the length of gestation and age in neonates are needed to compare neurodevelopmental, medical, and growth outcomes. The purposes of this policy statement are to review conventional definitions of age during the perinatal period and to recommend use of standard terminology including gestational age, postmenstrual age, chronological age, corrected age, adjusted age, and estimated date of delivery. (11/04, reaffirmed 10/07, 11/08, 7/14)
https://doi.org/10.1542/peds.2004-1915

ALCOHOL USE BY YOUTH

Joanna Quigley, MD, FAAP, and Committee on Substance Use and Prevention

ABSTRACT. Alcohol use continues to be problematic for youth and young adults in the United States. Understanding of neurobiology and neuroplasticity continues to highlight the potential adverse impact of underage drinking on the developing brain. This policy statement provides the position of the American Academy of Pediatrics on the issue of alcohol and is supported by an accompanying technical report. (6/19)
https://doi.org/10.1542/peds.2019-1356

ALCOHOL USE BY YOUTH (TECHNICAL REPORT)

Sheryl A. Ryan, MD, FAAP; Patricia Kokotailo, MD, MPH, FAAP; and Committee on Substance Use and Prevention

ABSTRACT. Alcohol use continues to be a major concern from preadolescence through young adulthood in the United States. Results of recent neuroscience research have helped to elucidate neurobiological models of addiction, substantiated the deleterious effects of alcohol on adolescent brain development, and added additional evidence to support the call to prevent and reduce underage drinking. This technical report reviews the relevant literature and supports the accompanying policy statement in this issue of *Pediatrics.* (6/19)
https://doi.org/10.1542/peds.2019-1357

ALLERGY TESTING IN CHILDHOOD: USING ALLERGEN-SPECIFIC IGE TESTS (CLINICAL REPORT)

Scott H. Sicherer, MD; Robert A. Wood, MD; and Section on Allergy and Immunology

ABSTRACT. A variety of triggers can induce common pediatric allergic diseases which include asthma, allergic rhinitis, atopic dermatitis, food allergy, and anaphylaxis. Allergy testing serves to confirm an allergic trigger suspected on the basis of history. Tests for allergen-specific immunoglobulin E (IgE) are performed by in vitro assays or skin tests. The tests are excellent for identifying a sensitized state in which allergen-specific IgE is present, and may identify triggers to be eliminated and help guide immunotherapy treatment. However, a positive test result does not always equate with clinical allergy. Newer enzymatic assays based on anti-IgE antibodies have supplanted the radioallergosorbent test (RAST). This clinical report focuses on allergen-specific IgE testing, emphasizing that the medical history and

knowledge of disease characteristics are crucial for rational test selection and interpretation. (12/11)
https://doi.org/10.1542/peds.2011-2382

ALL-TERRAIN VEHICLE INJURY PREVENTION: TWO-, THREE-, AND FOUR-WHEELED UNLICENSED MOTOR VEHICLES

Committee on Injury and Poison Prevention

ABSTRACT. Since 1987, the American Academy of Pediatrics (AAP) has had a policy about the use of motorized cycles and all-terrain vehicles (ATVs) by children. The purpose of this policy statement is to update and strengthen previous policy. This statement describes the various kinds of motorized cycles and ATVs and outlines the epidemiologic characteristics of deaths and injuries related to their use by children in light of the 1987 consent decrees entered into by the US Consumer Product Safety Commission and the manufacturers of ATVs. Recommendations are made for public, patient, and parent education by pediatricians; equipment modifications; the use of safety equipment; and the development and improvement of safer off-road trails and responsive emergency medical systems. In addition, the AAP strengthens its recommendation for passage of legislation in all states prohibiting the use of 2- and 4-wheeled off-road vehicles by children younger than 16 years, as well as a ban on the sale of new and used 3-wheeled ATVs, with a recall of all used 3-wheeled ATVs. (6/00, reaffirmed 5/04, 1/07, 5/13, 11/19)
https://doi.org/10.1542/peds.105.6.1352

ALUMINUM EFFECTS IN INFANTS AND CHILDREN (TECHNICAL REPORT)

Mark R. Corkins, MD, FAAP, and Committee on Nutrition

ABSTRACT. Aluminum has no known biological function; however, it is a contaminant present in most foods and medications. Aluminum is excreted by the renal system, and patients with renal diseases should avoid aluminum-containing medications. Studies demonstrating long-term toxicity from the aluminum content in parenteral nutrition components led the US Food and Drug Administration to implement rules for these solutions. Large-volume ingredients were required to reduce the aluminum concentration, and small-volume components were required to be labeled with the aluminum concentration. Despite these rules, the total aluminum concentration from some components continues to be above the recommended final concentration. The concerns about toxicity from the aluminum present in infant formulas and antiperspirants have not been substantiated but require more research. Aluminum is one of the most effective adjuvants used in vaccines, and a large number of studies have documented minimal adverse effects from this use. Long-term, high-concentration exposure to aluminum has been linked in meta-analyses with the development of Alzheimer disease. (11/19)
https://doi.org/10.1542/peds.2019-3148

AMBIENT AIR POLLUTION: HEALTH HAZARDS TO CHILDREN

Heather L. Brumberg, MD, MPH, FAAP; Catherine J. Karr, MD, PhD, FAAP; and Council on Environmental Health

ABSTRACT. Ambient air pollution is produced by sources including vehicular traffic, coal-fired power plants, hydraulic fracturing, agricultural production, and forest fires. It consists of primary pollutants generated by combustion and secondary pollutants formed in the atmosphere from precursor gases. Air pollution causes and exacerbates climate change, and climate change worsens health effects of air pollution. Infants and children are uniquely sensitive to air pollution, because their organs are developing and they have higher air per body weight intake. Health effects linked to air pollution include not only exacerbations of respiratory diseases but also reduced lung function development and increased asthma incidence. Additional outcomes of concern include preterm birth, low birth weight, neurodevelopmental disorders, IQ loss, pediatric cancers, and increased risks for adult chronic diseases. These effects are mediated by oxidative stress, chronic inflammation, endocrine disruption, and genetic and epigenetic mechanisms across the life span. Natural experiments demonstrate that with initiatives such as increased use of public transportation, both air quality and community health improve. Similarly, the Clean Air Act has improved air quality, although exposure inequities persist. Other effective strategies for reducing air pollution include ending reliance on coal, oil, and gas; regulating industrial emissions; reducing exposure with attention to proximity of residences, schools, and child care facilities to traffic; and a greater awareness of the Air Quality Index. This policy reviews both short- and long-term health consequences of ambient air pollution, especially in relation to developmental exposures. It examines individual, community, and legislative strategies to mitigate air pollution. (5/21)

ANTENATAL COUNSELING REGARDING RESUSCITATION AND INTENSIVE CARE BEFORE 25 WEEKS OF GESTATION (CLINICAL REPORT)

James Cummings, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. The anticipated birth of an extremely low gestational age (<25 weeks) infant presents many difficult questions, and variations in practice continue to exist. Decisions regarding care of periviable infants should ideally be well informed, ethically sound, consistent within medical teams, and consonant with the parents' wishes. Each health care institution should consider having policies and procedures for antenatal counseling in these situations. Family counseling may be aided by the use of visual materials, which should take into consideration the intellectual, cultural, and other characteristics of the family members. Although general recommendations can guide practice, each situation is unique; thus, decision-making should be individualized. In most cases, the approach should be shared decision-making with the family, guided by considering both the likelihood of death or morbidity and the parents' desires for their unborn child. If a decision is made not to resuscitate, providing comfort care, encouraging family bonding, and palliative care support are appropriate. (8/15)

ANTERIOR CRUCIATE LIGAMENT INJURIES: DIAGNOSIS, TREATMENT, AND PREVENTION (CLINICAL REPORT)

Cynthia R. LaBella, MD, FAAP; William Hennrikus, MD, FAAP; Timothy E. Hewett, PhD, FACSM; Council on Sports Medicine and Fitness; and Section on Orthopaedics

ABSTRACT. The number of anterior cruciate ligament (ACL) injuries reported in athletes younger than 18 years has increased over the past 2 decades. Reasons for the increasing ACL injury rate include the growing number of children and adolescents participating in organized sports, intensive sports training at an earlier age, and greater rate of diagnosis because of increased awareness and greater use of advanced medical imaging. ACL injury rates are low in young children and increase sharply during puberty, especially for girls, who have higher rates of noncontact ACL injuries than boys do in similar sports. Intrinsic risk factors for ACL injury include higher BMI, subtalar joint overpronation, generalized ligamentous laxity, and decreased neuromuscular control of knee motion. ACL injuries often require surgery and/or many months of rehabilitation and substantial time lost from school and sports participation. Unfortunately, regardless of treatment, athletes with ACL injuries are up to 10 times more likely to develop degenerative arthritis of the knee. Safe and effective surgical techniques for children and adoles-

cents continue to evolve. Neuromuscular training can reduce risk of ACL injury in adolescent girls. This report outlines the current state of knowledge on epidemiology, diagnosis, treatment, and prevention of ACL injuries in children and adolescents. (4/14, reaffirmed 7/18)

ANTIBIOTIC STEWARDSHIP IN PEDIATRICS

Jeffrey S. Gerber, MD, PhD, FAAP; Mary Anne Jackson, MD, FAAP; Pranita D. Tamma, MD, MHS; Theoklis E. Zaoutis, MD, FAAP; Committee on Infectious Diseases (joint with Pediatric Infectious Diseases Society)

ABSTRACT. Antibiotic overuse contributes to antibiotic resistance, which is a threat to public health. Antibiotic stewardship is a practice dedicated to prescribing antibiotics only when necessary and, when antibiotics are considered necessary, promoting use of the appropriate agent(s), dose, duration, and route of therapy to optimize clinical outcomes while minimizing the unintended consequences of antibiotic use. Because there are differences in common infectious conditions, drug-specific considerations, and the evidence surrounding treatment recommendations (eg, first-line therapy, duration of therapy) between children and adults, this statement provides specific guidance for the pediatric population. This policy statement discusses the rationale for inpatient and outpatient antibiotic stewardship programs; essential personnel, infrastructure, and activities required; approaches to evaluating their effectiveness; and gaps in knowledge that require further investigation. Key guidance for both inpatient and outpatient antibiotic stewardship programs are provided. (12/20)

THE APGAR SCORE

Committee on Fetus and Newborn (joint with American College of Obstetricians and Gynecologists Committee on Obstetric Practice)

ABSTRACT. The Apgar score provides an accepted and convenient method for reporting the status of the newborn infant immediately after birth and the response to resuscitation if needed. The Apgar score alone cannot be considered as evidence of, or a consequence of, asphyxia; does not predict individual neonatal mortality or neurologic outcome; and should not be used for that purpose. An Apgar score assigned during resuscitation is not equivalent to a score assigned to a spontaneously breathing infant. The American Academy of Pediatrics and the American College of Obstetricians and Gynecologists encourage use of an expanded Apgar score reporting form that accounts for concurrent resuscitative interventions. (9/15)
https://doi.org/10.1542/peds.2015-2651

APNEA OF PREMATURITY (CLINICAL REPORT)

Eric C. Eichenwald, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Apnea of prematurity is one of the most common diagnoses in the NICU. Despite the frequency of apnea of prematurity, it is unknown whether recurrent apnea, bradycardia, and hypoxemia in preterm infants are harmful. Research into the development of respiratory control in immature animals and preterm infants has facilitated our understanding of the pathogenesis and treatment of apnea of prematurity. However, the lack of consistent definitions, monitoring practices, and consensus about clinical significance leads to significant variation in practice. The purpose of this clinical report is to review the evidence basis for the definition, epidemiology, and treatment of apnea of prematurity as well as discharge recommendations for preterm infants diagnosed with recurrent apneic events. (12/15)
https://doi.org/10.1542/peds.2015-3757

ASSESSMENT AND MANAGEMENT OF INGUINAL HERNIA IN INFANTS (CLINICAL REPORT)

Kasper S. Wang, MD; Committee on Fetus and Newborn; and Section on Surgery

ABSTRACT. Inguinal hernia repair in infants is a routine surgical procedure. However, numerous issues, including timing of the repair, the need to explore the contralateral groin, use of laparoscopy, and anesthetic approach, remain unsettled. Given the lack of compelling data, consideration should be given to large, prospective, randomized controlled trials to determine best practices for the management of inguinal hernias in infants. (9/12, reaffirmed 5/21)
https://doi.org/10.1542/peds.2012-2008

ATOPIC DERMATITIS: SKIN-DIRECTED MANAGEMENT (CLINICAL REPORT)

Megha M. Tollefson, MD; Anna L. Bruckner, MD, FAAP; and Section on Dermatology

ABSTRACT. Atopic dermatitis is a common inflammatory skin condition characterized by relapsing eczematous lesions in a typical distribution. It can be frustrating for pediatric patients, parents, and health care providers alike. The pediatrician will treat the majority of children with atopic dermatitis as many patients will not have access to a pediatric medical subspecialist, such as a pediatric dermatologist or pediatric allergist. This report provides up-to-date information regarding the disease and its impact, pathogenesis, treatment options, and potential complications. The goal of this report is to assist pediatricians with accurate and useful information that will improve the care of patients with atopic dermatitis. (11/14)
https://doi.org/10.1542/peds.2014-2812

ATTENTION-DEFICIT/HYPERACTIVITY DISORDER AND SUBSTANCE ABUSE (CLINICAL REPORT)

Elizabeth Harstad, MD, MPH, FAAP; Sharon Levy, MD, MPH, FAAP; and Committee on Substance Abuse

ABSTRACT. Attention-deficit/hyperactivity disorder (ADHD) and substance use disorders are inextricably intertwined. Children with ADHD are more likely than peers to develop substance use disorders. Treatment with stimulants may reduce the risk of substance use disorders, but stimulants are a class of medication with significant abuse and diversion potential. The objectives of this clinical report were to present practical strategies for reducing the risk of substance use disorders in patients with ADHD and suggestions for safe stimulant prescribing. (6/14, reaffirmed 10/20)

BARRIER PROTECTION USE BY ADOLESCENTS DURING SEXUAL ACTIVITY

Laura K. Grubb, MD, MPH, FAAP, and Committee on Adolescence

ABSTRACT. Rates of sexual activity, pregnancies, and births among adolescents have continued to decline during the past decade to historic lows. Despite these positive trends, many adolescents remain at risk for unintended pregnancy and sexually transmitted infections (STIs). When used consistently and correctly, latex and synthetic barrier methods reduce the risk of many STIs, including HIV, and pregnancy. This update of the 2013 policy statement is intended to assist pediatricians in understanding and supporting the use of barrier methods by their patients to prevent unintended pregnancies and STIs and address obstacles to their use. (7/20)
https://doi.org/10.1542/peds.2020-007237

BARRIER PROTECTION USE BY ADOLESCENTS DURING SEXUAL ACTIVITY (TECHNICAL REPORT)

Laura K. Grubb, MD, MPH, FAAP, and Committee on Adolescence

ABSTRACT. Rates of sexual activity, pregnancies, and births among adolescents have continued to decline during the past decade to historic lows. Despite these positive trends, many adolescents remain at risk for unintended pregnancy and sexually transmitted infections (STIs). This technical report discusses the new data and trends in adolescent sexual behavior and barrier protection use. Since 2017, STI rates have increased and use of barrier methods, specifically external condom use, has declined among adolescents and young adults. Interventions that increase availability of or accessibility to barrier methods are most efficacious when combined with additional individual, small-group, or community-level activities that include messages about safer sex. Continued research informs public health interventions for adolescents that increase the consistent and correct use of barrier methods and promote dual protection of barrier methods for STI prevention together with other effective methods of contraception. BEST PRACTICES FOR IMPROVING FLOW AND CARE OF PEDIATRIC PATIENTS IN THE EMERGENCY DEPARTMENT (TECHNICAL REPORT)

Isabel A. Barata, MD, FACEP; Kathleen M. Brown, MD, FACEP; Laura Fitzmaurice, MD, FACEP, FAAP; Elizabeth Stone Griffin, RN; Sally K. Snow, BSN, RN; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. This report provides a summary of best practices for improving flow, reducing waiting times, and improving the quality of care of pediatric patients in the emergency department. (12/14, reaffirmed 7/20)

https://doi.org/10.1542/peds.2014-3425

BICYCLE HELMETS

Committee on Injury and Poison Prevention

ABSTRACT. Bicycling remains one of the most popular recreational sports among children in America and is the leading cause of recreational sports injuries treated in emergency departments. An estimated 23 000 children younger than 21 years sustained head injuries (excluding the face) while bicycling in 1998. The bicycle helmet is a very effective device that can prevent the occurrence of up to 88% of serious brain injuries. Despite this, most children do not wear a helmet each time they ride a bicycle, and adolescents are particularly resistant to helmet use. Recently, a group of national experts and government agencies renewed the call for all bicyclists to wear helmets. This policy statement describes the role of the pediatrician in helping attain universal helmet use among children and teens for each bicycle ride. (10/01, reaffirmed 1/05, 2/08, 11/11)

https://doi.org/10.1542/peds.108.4.1030

BINGE DRINKING (CLINICAL REPORT)

Lorena Siqueira, MD, MSPH, FAAP; Vincent C. Smith, MD, MPH, FAAP; and Committee on Substance Abuse

ABSTRACT. Alcohol is the substance most frequently abused by children and adolescents in the United States, and its use is associated with the leading causes of death and serious injury at this age (ie, motor vehicle accidents, homicides, and suicides). Among youth who drink, the proportion who drink heavily is higher than among adult drinkers, increasing from approximately 50% in those 12 to 14 years of age to 72% among those 18 to 20 years of age. In this clinical report, the definition, epidemiology, and risk factors for binge drinking; the neurobiology of intoxication, blackouts, and hangovers; genetic considerations; and adverse outcomes are discussed. The report offers guidance for the pediatrician. As with any high-risk behavior, prevention plays a more important role than later intervention and has been shown to be more effective. In the pediatric office setting, it is important to ask every adolescent about alcohol use. (8/15)

https://doi.org/10.1542/peds.2015-2337

BIOLOGICS FOR ASTHMA AND ALLERGIC SKIN DISEASES IN CHILDREN (CLINICAL REPORT)

Heather Hoch De Keyser, MD, MSCS, FAAP; Bradley Chipps, MD, FAAP; Chitra Dinakar, MD, FAAP; Section on Allergy and Immunology; and Section on Pediatric Pulmonology and Sleep Medicine

ABSTRACT. An estimated 7 million children in the United States have asthma, which causes a significant health care burden and affects quality of life. The minority of these children have asthma that does not respond to Global Initiative for Asthma steps 4 and 5 care, and biological medications are recommended at this level in the 2019 Global Initiative for Asthma recommendations. In addition, biologics have been introduced into the care of children with allergic skin diseases. Omalizumab and mepolizumab are approved for children as young as 6 years, and benralizumab and dupilumab are approved for people aged ≥12 years. Reslizumab is approved only for people aged ≥18 years. These monoclonal antibodies may be added for appropriate patients when asthma or allergic skin diseases are not well controlled. Pediatricians and pediatric subspecialists should work together and be aware of the benefits and risks of these medications for their patients, as well as the practical implications of providing these options for their patients. This clinical report serves as an evaluation of the current literature on these types of medications in the treatment of children with asthma and allergic skin disease. (10/21)

BONE DENSITOMETRY IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Laura K. Bachrach, MD; Catherine M. Gordon, MD, MS; and Section on Endocrinology

ABSTRACT. Concerns about bone health and potential fragility in children and adolescents have led to a high interest in bone densitometry. Pediatric patients with genetic and acquired chronic diseases, immobility, and inadequate nutrition may fail to achieve expected gains in bone size, mass, and strength, leaving them vulnerable to fracture. In older adults, bone densitometry has been shown to predict fracture risk and reflect response to therapy. The role of densitometry in the management of children at risk of bone fragility is less clear. This clinical report summarizes current knowledge about bone densitometry in the pediatric population, including indications for its use, interpretation of results, and risks and costs. The report emphasizes updated consensus statements generated at the 2013 Pediatric Position Development Conference of the International Society of Clinical Densitometry by an international panel of bone experts. Some of these recommendations are evidence-based, whereas others reflect expert opinion, because data are sparse on many topics. The statements from this and other expert panels provide general guidance to the pediatrician, but decisions about ordering and interpreting bone densitometry still require clinical judgment. The interpretation of bone densitometry results in children differs from that in older adults. The terms "osteopenia" and "osteoporosis" based on bone densitometry findings alone should not be used in younger patients; instead, bone mineral content or density that falls >2 SDs below expected is labeled "low for age." Pediatric osteoporosis is defined by the Pediatric Position Development Conference by using 1 of the following

criteria: ≥1 vertebral fractures occurring in the absence of local disease or high-energy trauma (without or with densitometry measurements) or low bone density for age and a significant fracture history (defined as ≥2 long bone fractures before 10 years of age or ≥3 long bone fractures before 19 years of age). Ongoing research will help define the indications and best methods for assessing bone strength in children and the clinical factors that contribute to fracture risk. The Pediatric Endocrine Society affirms the educational value of this publication. (9/16)

BOXING PARTICIPATION BY CHILDREN AND ADOLESCENTS

Council on Sports Medicine and Fitness (joint with Canadian Paediatric Society Healthy Active Living and Sports Medicine Committee)

ABSTRACT. Thousands of boys and girls younger than 19 years participate in boxing in North America. Although boxing provides benefits for participants, including exercise, self-discipline, and self-confidence, the sport of boxing encourages and rewards deliberate blows to the head and face. Participants in boxing are at risk of head, face, and neck injuries, including chronic and even fatal neurologic injuries. Concussions are one of the most common injuries that occur with boxing. Because of the risk of head and facial injuries, the American Academy of Pediatrics and the Canadian Paediatric Society oppose boxing as a sport for children and adolescents. These organizations recommend that physicians vigorously oppose boxing in youth and encourage patients to participate in alternative sports in which intentional head blows are not central to the sport. (8/11, reaffirmed 2/15, 3/20)

BREASTFEEDING AND THE USE OF HUMAN MILK

Section on Breastfeeding

ABSTRACT. Breastfeeding and human milk are the normative standards for infant feeding and nutrition. Given the documented short- and long-term medical and neurodevelopmental advantages of breastfeeding, infant nutrition should be considered a public health issue and not only a lifestyle choice. The American Academy of Pediatrics reaffirms its recommendation of exclusive breastfeeding for about 6 months, followed by continued breastfeeding as complementary foods are introduced, with continuation of breastfeeding for 1 year or longer as mutually desired by mother and infant. Medical contraindications to breastfeeding are rare. Infant growth should be monitored with the World Health Organization (WHO) Growth Curve Standards to avoid mislabeling infants as underweight or failing to thrive. Hospital routines to encourage and support the initiation and sustaining of exclusive breastfeeding should be based on the American Academy of Pediatrics-endorsed WHO/UNICEF "Ten Steps to Successful Breastfeeding." National strategies supported by the US Surgeon General's Call to Action, the Centers for Disease Control and Prevention, and The Joint Commission are involved to facilitate breastfeeding practices in US hospitals and communities. Pediatricians play a critical role in their practices and communities as advocates of breastfeeding and thus should be knowledgeable about the health risks of not breastfeeding, the economic benefits to society of breastfeeding, and the techniques for managing and supporting the breastfeeding dyad. The "Business Case for Breastfeeding" details how mothers can maintain lactation in the workplace and the benefits to employers who facilitate this practice. (2/12)
https://doi.org/10.1542/peds.2011-3552

THE BREASTFEEDING-FRIENDLY PEDIATRIC OFFICE PRACTICE (CLINICAL REPORT)

Joan Younger Meek, MD, MS, RD, FAAP, IBCLC; Amy J. Hatcher, MD, FAAP; and Section on Breastfeeding

ABSTRACT. The landscape of breastfeeding has changed over the past several decades as more women initiate breastfeeding in the postpartum period and more hospitals are designated as Baby-Friendly Hospitals by following the evidence-based Ten Steps to Successful Breastfeeding. The number of births in such facilities has increased more than sixfold over the past decade. With more women breastfeeding and stays in the maternity facilities lasting only a few days, the vast majority of continued breastfeeding support occurs in the community. Pediatric care providers evaluate breastfeeding infants and their mothers in the office setting frequently during the first year of life. The office setting should be conducive to providing ongoing breastfeeding support. Likewise, the office practice should avoid creating barriers for breastfeeding mothers and families or unduly promoting infant formula. This clinical report aims to review practices shown to support breastfeeding that can be implemented in the outpatient setting, with the ultimate goal of increasing the duration of exclusive breastfeeding and the continuation of any breastfeeding. (4/17)

THE BUILT ENVIRONMENT: DESIGNING COMMUNITIES TO PROMOTE PHYSICAL ACTIVITY IN CHILDREN

Committee on Environmental Health

ABSTRACT. An estimated 32% of American children are overweight, and physical inactivity contributes to this high prevalence of overweight. This policy statement highlights how the built environment of a community affects children's opportunities for physical activity. Neighborhoods and communities can provide opportunities for recreational physical activity with parks and open spaces, and policies must support this capacity. Children can engage in physical activity as a part of their daily lives, such as on their travel to school. Factors such as school location have played a significant role in the decreased rates of walking to school, and changes in policy may help to increase the number of children who are able to walk to school. Environment modification that addresses risks associated with automobile traffic is likely to be conducive to more walking and biking among children. Actions that reduce parental perception and fear of crime may promote outdoor physical activity. Policies that promote more active lifestyles among children and adolescents will enable them to achieve the recommended 60 minutes of daily physical activity. By working with community partners, pediatricians can participate in establishing communities designed for activity and health. (5/09, reaffirmed 1/13)

CALCIUM AND VITAMIN D REQUIREMENTS OF ENTERALLY FED PRETERM INFANTS (CLINICAL REPORT)

Steven A. Abrams, MD, and Committee on Nutrition

ABSTRACT. Bone health is a critical concern in managing preterm infants. Key nutrients of importance are calcium, vitamin D, and phosphorus. Although human milk is critical for the health of preterm infants, it is low in these nutrients relative to the needs of the infants during growth. Strategies should be in place to fortify human milk for preterm infants with birth weight <1800 to 2000 g and to ensure adequate mineral intake during hospitalization and after hospital discharge. Biochemical monitoring of very low birth weight infants should be performed during their hospitalization. Vitamin D should be provided at 200 to 400 IU/day both during hospitalization and after discharge from the hospital. Infants with radiologic evidence of rickets should have efforts made to maximize calcium and phosphorus intake

by using available commercial products and, if needed, direct supplementation with these minerals. (4/13)
https://doi.org/10.1542/peds.2013-0420

CARDIOVASCULAR MONITORING AND STIMULANT DRUGS FOR ATTENTION-DEFICIT/HYPERACTIVITY DISORDER

James M. Perrin, MD; Richard A. Friedman, MD; Timothy K. Knilans, MD; Black Box Working Group; and Section on Cardiology and Cardiac Surgery

ABSTRACT. A recent American Heart Association (AHA) statement recommended electrocardiograms (ECGs) routinely for children before they start medications to treat attention-deficit/hyperactivity disorder (ADHD). The AHA statement reflected the thoughtful work of a group committed to improving the health of children with heart disease. However, the recommendation to obtain an ECG before starting medications for treating ADHD contradicts the carefully considered and evidence-based recommendations of the American Academy of Child and Adolescent Psychiatry and the American Academy of Pediatrics (AAP). These organizations have concluded that sudden cardiac death (SCD) in persons taking medications for ADHD is a very rare event, occurring at rates no higher than those in the general population of children and adolescents. Both of these groups also noted the lack of any evidence that the routine use of ECG screening before beginning medication for ADHD treatment would prevent sudden death. The AHA statement pointed out the importance of detecting silent but clinically important cardiac conditions in children and adolescents, which is a goal that the AAP shares. The primary purpose of the AHA statement is to prevent cases of SCD that may be related to stimulant medications. The recommendations of the AAP and the rationale for these recommendations are the subject of this statement. (8/08)

CARE OF ADOLESCENT PARENTS AND THEIR CHILDREN (CLINICAL REPORT)

Makia E. Powers, MD, MPH, FAAP; Jennifer Takagishi, MD, FAAP; Committee on Adolescence; and Council on Early Childhood

ABSTRACT. Teen pregnancy and parenting remain important public health issues in the United States and around the world. A significant proportion of teen parents reside with their families of origin, which may positively or negatively affect the family structure. Teen parents, defined as those 15 to 19 years of age, are at high risk for repeat births. Pediatricians can play an important role in the care of adolescent parents and their children. This clinical report updates a previous report on the care of adolescent parents and their children and addresses clinical management specific to this population, including updates on breastfeeding, prenatal management, and adjustments to parenthood. Challenges unique to teen parents and their children are reviewed, along with suggestions for the pediatrician on models for intervention and care. (4/21)

THE CARE OF CHILDREN WITH CONGENITAL HEART DISEASE IN THEIR PRIMARY MEDICAL HOME

M. Regina Lantin-Hermoso, MD, FAAP, FACC; Stuart Berger, MD, FAAP; Ami B. Bhatt, MD, FACC; Julia E. Richerson, MD, FAAP; Robert Morrow, MD, FAAP; Michael D. Freed, MD, FAAP, FACC; Robert H. Beekman III, MD, FAAP, FACC; and Section on Cardiology and Cardiac Surgery

ABSTRACT. Congenital heart disease (CHD) is the most common birth anomaly. With advances in repair and palliation of these complex lesions, more and more patients are surviving and are discharged from the hospital to return to their families. Patients with CHD have complex health care needs that often must be provided for or coordinated for by the primary care provider (PCP) and medical home. This policy statement aims to provide the PCP with general guidelines for the care of the child with congenital heart defects and outlines anticipated problems, serving as a repository of current knowledge in a practical, readily accessible format. A timeline approach is used, emphasizing the role of the PCP and medical home in the management of patients with CHD in their various life stages. (10/17)

CARE OF THE ADOLESCENT AFTER AN ACUTE SEXUAL ASSAULT (CLINICAL REPORT)

James E. Crawford-Jakubiak, MD, FAAP; Elizabeth M. Alderman, MD, FAAP, SAHM; John M. Leventhal, MD, FAAP; Committee on Child Abuse and Neglect; and Committee on Adolescence

ABSTRACT. Sexual violence is a broad term that encompasses a wide range of sexual victimizations. Since the American Academy of Pediatrics published its last policy statement on sexual assault in 2008, additional information and data have emerged about sexual violence affecting adolescents and the treatment and management of the adolescent who has been a victim of sexual assault. This report provides new information to update physicians and focuses on the acute assessment and care of adolescent victims who have experienced a recent sexual assault. Follow-up of the acute assault, as well as prevention of sexual assault, are also discussed. (2/17)
https://doi.org/10.1542/peds.2016-4243

CAREGIVER-FABRICATED ILLNESS IN A CHILD: A MANIFESTATION OF CHILD MALTREATMENT (CLINICAL REPORT)

Emalee G. Flaherty, MD, FAAP; Harriet L. MacMillan, MD; and Committee on Child Abuse and Neglect

ABSTRACT. Caregiver-fabricated illness in a child is a form of child maltreatment caused by a caregiver who falsifies and/or induces a child's illness, leading to unnecessary and potentially harmful medical investigations and/or treatment. This condition can result in significant morbidity and mortality. Although caregiver-fabricated illness in a child has been widely known as Munchausen syndrome by proxy, there is ongoing discussion about alternative names, including pediatric condition falsification, factitious disorder (illness) by proxy, child abuse in the medical setting, and medical child abuse. Because it is a relatively uncommon form of maltreatment, pediatricians need to have a high index of suspicion when faced with a persistent or recurrent illness that cannot be explained and that results in multiple medical procedures or when there are discrepancies between the history, physical examination, and health of a child. This report updates the previous clinical report "Beyond Munchausen Syndrome by Proxy: Identification and Treatment of Child Abuse in the Medical Setting." The authors discuss the need to agree on appropriate terminology, provide an update on published reports of new manifestations of fabricated medical conditions, and discuss approaches to assessment, diagnosis, and management, including how best to protect the child from further harm. (8/13, reaffirmed 8/18)

CARING FOR AMERICAN INDIAN AND ALASKA NATIVE CHILDREN AND ADOLESCENTS

Shaquita Bell, MD, FAAP; Jason F. Deen, MD, FAAP; Molly Fuentes, MD, MS; Kelly Moore, MD, FAAP; and Committee on Native American Child Health

ABSTRACT. American Indian and Alaska Native (AI/AN) populations have substantial health inequities, and most of their disease entities begin in childhood. In addition, AI/AN

children and adolescents have excessive disease rates compared with the general pediatric population. Because of this, providers of pediatric care are in a unique position not only to attenuate disease incidence during childhood but also to improve the health status of this special population as a whole. This policy statement examines the inequitable disease burden observed in AI/AN youth, with a focus on toxic stress, mental health, and issues related to suicide and substance use disorder, risk of and exposure to injury and violence in childhood, obesity and obesity-related cardiovascular risk factors and disease, foster care, and the intersection of lesbian, gay, bisexual, transgender, queer, and Two-Spirit and AI/AN youth. Opportunities for advocacy in policy making also are presented. (3/21)

CHEERLEADING INJURIES: EPIDEMIOLOGY AND RECOMMENDATIONS FOR PREVENTION

Council on Sports Medicine and Fitness

ABSTRACT. Over the last 30 years, cheerleading has increased dramatically in popularity and has evolved from leading the crowd in cheers at sporting events into a competitive, year-round sport involving complex acrobatic stunts and tumbling. Consequently, cheerleading injuries have steadily increased over the years in both number and severity. Sprains and strains to the lower extremities are the most common injuries. Although the overall injury rate remains relatively low, cheerleading has accounted for approximately 66% of all catastrophic injuries in high school girl athletes over the past 25 years. Risk factors for injuries in cheerleading include higher BMI, previous injury, cheering on harder surfaces, performing stunts, and supervision by a coach with low level of training and experience. This policy statement describes the epidemiology of cheerleading injuries and provides recommendations for injury prevention. (10/12, reaffirmed 7/15, 3/21)

https://doi.org/10.1542/peds.2012-2480

CHEMICAL-BIOLOGICAL TERRORISM AND ITS IMPACT ON CHILDREN

Sarita Chung, MD, FAAP; Carl R. Baum, MD, FACMT, FAAP; Ann-Christine Nyquist, MD, MSPH, FAAP; Disaster Preparedness Advisory Council; Council on Environmental Health; and Committee on Infectious Diseases

ABSTRACT. Chemical and biological events (including infectious disease outbreaks) may affect children disproportionately, and the threat of a chemical or biological attack remains in the United States and worldwide. Although federal programs and funding support a broad range of federal initiatives for public health preparedness and response, funding at the state and local levels has been flat or is decreasing, potentially leaving communities vulnerable. Consequently, pediatricians need to prepare and be ready to care for children in their communities before, during, and after a chemical or biological event, including during long-term recovery. Some medical countermeasures for particular chemical and biological agents have not been adequately studied or approved for children. The American Academy of Pediatrics provides resources and education on disaster preparedness and response, including information on the pediatrician's role in disasters, pediatric medical countermeasures, and mental health after an event as well as individual and family preparedness. This policy statement addresses the steps that clinicians and policy makers can take to protect children and mitigate the effects of a chemical or biological attack. (1/20)

https://doi.org/10.1542/peds.2019-3749

CHEMICAL-BIOLOGICAL TERRORISM AND ITS IMPACT ON CHILDREN (TECHNICAL REPORT)

Sarita Chung, MD, FAAP; Carl R. Baum, MD, FACMT, FAAP; Ann-Christine Nyquist, MD, MSPH, FAAP; Disaster Preparedness Advisory Council; Council on Environmental Health; and Committee on Infectious Diseases

ABSTRACT. Children are potential victims of chemical or biological terrorism. In recent years, children have been victims of terrorist acts such as the chemical attacks (2017–2018) in Syria. Consequently, it is necessary to prepare for and respond to the needs of children after a chemical or biological attack. A broad range of public health initiatives have occurred since the terrorist attacks of September 11, 2001. However, in many cases, these initiatives have not ensured the protection of children. Since 2001, public health preparedness has broadened to an all-hazards approach, in which response plans for terrorism are blended with those for unintentional disasters or outbreaks (eg, natural events such as earthquakes or pandemic influenza or man-made catastrophes such as a hazardous-materials spill). In response to new principles and programs that have evolved over the last decade, this technical report supports the accompanying update of the American Academy of Pediatrics 2006 policy statement "Chemical-Biological Terrorism and its Impact on Children." The roles of the pediatrician and public health agencies continue to evolve, and only their coordinated readiness and response efforts will ensure that the medical and mental health needs of children will be met successfully. In this document, we will address chemical and biological incidents. Radiation disasters are addressed separately. (1/20)

https://doi.org/10.1542/peds.2019-3750

CHEMICAL-MANAGEMENT POLICY: PRIORITIZING CHILDREN'S HEALTH

Council on Environmental Health

ABSTRACT. The American Academy of Pediatrics recommends that chemical-management policy in the United States be revised to protect children and pregnant women and to better protect other populations. The Toxic Substance Control Act (TSCA) was passed in 1976. It is widely recognized to have been ineffective in protecting children, pregnant women, and the general population from hazardous chemicals in the marketplace. It does not take into account the special vulnerabilities of children in attempting to protect the population from chemical hazards. Its processes are so cumbersome that in its more than 30 years of existence, the TSCA has been used to regulate only 5 chemicals or chemical classes of the tens of thousands of chemicals that are in commerce. Under the TSCA, chemical companies have no responsibility to perform premarket testing or postmarket follow-up of the products that they produce; in fact, the TSCA contains disincentives for the companies to produce such data. Voluntary programs have been inadequate in resolving problems. Therefore, chemical-management policy needs to be rewritten in the United States. Manufacturers must be responsible for developing information about chemicals before marketing. The US Environmental Protection Agency must have the authority to demand additional safety data about a chemical and to limit or stop the marketing of a chemical when there is a high degree of suspicion that the chemical might be harmful to children, pregnant women, or other populations. (4/11, reaffirmed 9/16)

https://doi.org/10.1542/peds.2011-0523

CHILD ABUSE, CONFIDENTIALITY, AND THE HEALTH INSURANCE PORTABILITY AND ACCOUNTABILITY ACT

Committee on Child Abuse and Neglect

ABSTRACT. The federal Health Insurance Portability and Accountability Act (HIPAA) of 1996 has significantly affected clinical practice, particularly with regard to how patient infor-

mation is shared. HIPAA addresses the security and privacy of patient health data, ensuring that information is released appropriately with patient or guardian consent and knowledge. However, when child abuse or neglect is suspected in a clinical setting, the physician may determine that release of information without consent is necessary to ensure the health and safety of the child. This policy statement provides an overview of HIPAA regulations with regard to the role of the pediatrician in releasing or reviewing patient health information when the patient is a child who is a suspected victim of abuse or neglect. This statement is based on the most current regulations provided by the US Department of Health and Human Services and is subject to future changes and clarifications as updates are provided. (12/09, reaffirmed 1/14)

CHILD FATALITY REVIEW

Cindy W. Christian, MD; Robert D. Sege, MD, PhD; Committee on Child Abuse and Neglect; Committee on Injury, Violence, and Poison Prevention; and Council on Community Pediatrics

ABSTRACT. Injury remains the leading cause of pediatric mortality and requires public health approaches to reduce preventable deaths. Child fatality review teams, first established to review suspicious child deaths involving abuse or neglect, have expanded toward a public health model of prevention of child fatality through systematic review of child deaths from birth through adolescence. Approximately half of all states report reviewing child deaths from all causes, and the process of fatality review has identified effective local and state prevention strategies for reducing child deaths. This expanded approach can be a powerful tool in understanding the epidemiology and preventability of child death locally, regionally, and nationally; improving accuracy of vital statistics data; and identifying public health and legislative strategies for reducing preventable child fatalities. The American Academy of Pediatrics supports the development of federal and state legislation to enhance the child fatality review process and recommends that pediatricians become involved in local and state child death reviews. CHILD LIFE SERVICES

Barbara Romito, MA, CCLS; Jennifer Jewell, MD, FAAP; Meredith Jackson, MD, FAAP; Committee on Adolescence; and Association of Child Life Professionals

ABSTRACT. Child life programs are an important component of pediatric hospital-based care; they address the psychosocial concerns that accompany hospitalization and other health care experiences. Child life specialists focus on the optimal development and well-being of infants, children, adolescents, and young adults while promoting coping skills and minimizing the adverse effects of hospitalization, health care encounters, and/or other potentially stressful experiences. In collaboration with the entire health care team and family, child life specialists provide interventions that include therapeutic play, expressive modalities, and psychological preparation to facilitate coping and normalization at times and under circumstances that might otherwise prove overwhelming for the child. Play and developmentally appropriate communication are used to (1) promote optimal development, (2) educate children and families about health conditions, (3) prepare children and partner with families for medical events or procedures, (4) plan and rehearse useful coping and pain-management strategies with patients and families, (5) help children work through feelings about past or impending experiences, and (6) partner with families to establish therapeutic relationships between patients, siblings, and caregivers. Child life specialists collaborate with the entire interdisciplinary team to promote coping and enhance the overall health care experience for patients and families. (12/20)

CHILD PASSENGER SAFETY

Dennis R. Durbin, MD, MSCE, FAAP; Benjamin D. Hoffman, MD, FAAP; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. Child passenger safety has dramatically evolved over the past decade; however, motor vehicle crashes continue to be the leading cause of death for children 4 years and older. This policy statement provides 4 evidence-based recommendations for best practices in the choice of a child restraint system to optimize safety in passenger vehicles for children from birth through adolescence: (1) rear-facing car safety seats as long as possible; (2) forward-facing car safety seats from the time they outgrow rear-facing seats for most children through at least 4 years of age; (3) belt-positioning booster seats from the time they outgrow forward-facing seats for most children through at least 8 years of age; and (4) lap and shoulder seat belts for all who have outgrown booster seats. In addition, a fifth evidence-based recommendation is for all children younger than 13 years to ride in the rear seats of vehicles. It is important to note that every transition is associated with some decrease in protection; therefore, parents should be encouraged to delay these transitions for as long as possible. These recommendations are presented in the form of an algorithm that is intended to facilitate implementation of the recommendations by pediatricians to their patients and families and should cover most situations that pediatricians will encounter in practice. The American Academy of Pediatrics urges all pediatricians to know and promote these recommendations as part of child passenger safety anticipatory guidance at every health supervision visit. (10/18)
https://doi.org/10.1542/peds.2018-2460

CHILD PASSENGER SAFETY (TECHNICAL REPORT)

Dennis R. Durbin, MD, MSCE, FAAP; Benjamin D. Hoffman, MD, FAAP; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. Despite significant reductions in the number of children killed in motor vehicle crashes over the past decade, crashes continue to be the leading cause of death to children 4 years and older. Therefore, the American Academy of Pediatrics continues to recommend the inclusion of child passenger safety anticipatory guidance at every health supervision visit. This technical report provides a summary of the evidence in support of 5 recommendations for best practices to optimize safety in passenger vehicles for children from birth through adolescence that all pediatricians should know and promote in their routine practice. These recommendations are presented in the revised policy statement on child passenger safety in the form of an algorithm that is intended to facilitate their implementation by pediatricians with their patients and families. The algorithm is designed to cover the majority of situations that pediatricians will encounter in practice. In addition, a summary of evidence on a number of additional issues affecting the safety of children in motor vehicles, including the proper use and installation of child restraints, exposure to air bags, travel in pickup trucks, children left in or around vehicles, and the importance of restraint laws, is provided. Finally, this technical report provides pediatricians with a number of resources for additional information to use when providing anticipatory guidance to families. (10/18)

CHILD SEX TRAFFICKING AND COMMERCIAL SEXUAL EXPLOITATION: HEALTH CARE NEEDS OF VICTIMS (CLINICAL REPORT)

Jordan Greenbaum, MD; James E. Crawford-Jakubiak, MD, FAAP; and Committee on Child Abuse and Neglect

ABSTRACT. Child sex trafficking and commercial sexual exploitation of children (CSEC) are major public health problems in the United States and throughout the world. Despite large numbers of American and foreign youth affected and a plethora of serious physical and mental health problems associated with CSEC, there is limited information available to pediatricians regarding the nature and scope of human trafficking and how pediatricians and other health care providers may help protect children. Knowledge of risk factors, recruitment practices, possible indicators of CSEC, and common medical and behavioral health problems experienced by victims will help pediatricians recognize potential victims and respond appropriately. As health care providers, educators, and leaders in child advocacy, pediatricians play an essential role in addressing the public health issues faced by child victims of CSEC. Their roles can include working to increase recognition of CSEC, providing direct care and anticipatory guidance related to CSEC, engaging in collaborative efforts with medical and nonmedical colleagues to provide for the complex needs of youth, and educating child-serving professionals and the public. THE CHILD WITNESS IN THE COURTROOM

Robert H. Pantell, MD, FAAP, and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Beginning in the 1980s, children have increasingly served as witnesses in the criminal, civil, and family courts; currently, >100 000 children appear in court each year. This statement updates the 1992 American Academy of Pediatrics (AAP) policy statement "The Child as a Witness" and the subsequent 1999 "The Child in Court: A Subject Review." It also builds on existing AAP policy on adverse life events affecting children and resources developed to understand and address childhood trauma. The purpose of this policy statement is to provide background information on some of the legal issues involving children testifying in court, including the accuracy and psychological impact of child testimony; to provide suggestions for how pediatricians can support patients who will testify in court; and to make recommendations for policy improvements to minimize the adverse psychological consequences for child witnesses. These recommendations are, for the most part, based on studies on the psychological and physiologic consequences of children witnessing and experiencing violence, as well as appearing in court, that have emerged since the previous AAP publications on the subject. The goal is to reduce the secondary traumatization of and long-term consequences for children providing testimony about violence they have experienced or witnessed. This statement primarily addresses children appearing in court as victims of physical or sexual abuse or as witnesses of violent acts; most of the scientific literature addresses these specific situations. It may apply, in certain situations, to children required to provide testimony in custody disputes, child welfare proceedings, or immigration court. It does not address children appearing in court as offenders or as part of juvenile justice proceedings. (2/17)

CHILDREN, ADOLESCENTS, AND THE MEDIA

Council on Communications and Media

ABSTRACT. Media, from television to the "new media" (including cell phones, iPads, and social media), are a dominant force in children's lives. Although television is still the predominant medium for children and adolescents, new technologies are increasingly popular. The American Academy of Pediatrics continues to be concerned by evidence about the potential harmful effects of media messages and images; however, important positive and prosocial effects of media use should also be recognized. Pediatricians are encouraged to take a media history and ask 2 media questions at every well-child visit: How much recreational screen time does your child or teenager consume daily? Is there a television set or Internet-connected device in the child's bedroom? Parents are encouraged to establish a family home use plan for all media. Media influences on children and teenagers should be recognized by schools, policymakers, product advertisers, and entertainment producers. (10/13)

https://doi.org/10.1542/peds.2013-2656

CHILDREN AND ADOLESCENTS AND DIGITAL MEDIA (TECHNICAL REPORT)

Yolanda (Linda) Reid Chassiakos, MD, FAAP; Jenny Radesky, MD, FAAP; Dimitri Christakis, MD, FAAP; Megan A. Moreno, MD, MSEd, MPH, FAAP; Corinn Cross, MD, FAAP; and Council on Communications and Media

ABSTRACT. Today's children and adolescents are immersed in both traditional and new forms of digital media. Research on traditional media, such as television, has identified health concerns and negative outcomes that correlate with the duration and content of viewing. Over the past decade, the use of digital media, including interactive and social media, has grown, and research evidence suggests that these newer media offer both benefits and risks to the health of children and teenagers. Evidence-based benefits identified from the use of digital and social media include early learning, exposure to new ideas and knowledge, increased opportunities for social contact and support, and new opportunities to access health promotion messages and information. Risks of such media include negative health effects on sleep, attention, and learning; a higher incidence of obesity and depression; exposure to inaccurate, inappropriate, or unsafe content and contacts; and compromised privacy and confidentiality. This technical report reviews the literature regarding these opportunities and risks, framed around clinical questions, for children from birth to adulthood. To promote health and wellness in children and adolescents, it is important to maintain adequate physical activity, healthy nutrition, good sleep hygiene, and a nurturing social environment. A healthy Family Media Use Plan (www.healthychildren.org/MediaUsePlan) that is individualized for a specific child, teenager, or family can identify an appropriate balance between screen time/online time and other activities, set boundaries for accessing content, guide displays of personal information, encourage age-appropriate critical thinking and digital literacy, and support open family communication and implementation of consistent rules about media use. (10/16)

CHILDREN EXPOSED TO MALTREATMENT: ASSESSMENT AND THE ROLE OF PSYCHOTROPIC MEDICATION (CLINICAL REPORT)

Brooks Keeshin, MD, FAAP; Heather C. Forkey, MD, FAAP; George Fouras, MD, DFAACAP; Harriet L. MacMillan, CM, MD, MSc, FRCPC; Council on Child Abuse and Neglect; and Council on Foster Care, Adoption, and Kinship Care (joint with American Academy of Child and Adolescent Psychiatry Committee on Child Maltreatment and Violence and Committee on Adoption and Foster Care)

ABSTRACT. Pediatricians regularly care for children who have experienced child maltreatment. Child maltreatment is a risk factor for a broad range of mental health problems. Issues specific to child maltreatment make addressing emotional and behavioral challenges among maltreated children difficult. This clinical report focuses on 2 key issues necessary for the care of maltreated children and adolescents in pediatric settings: trauma-informed

assessments and the role of pharmacotherapy in maltreated children and adolescents. Specific to assessment, current or past involvement of the child in the child welfare system can hinder obtaining necessary information or access to appropriate treatments. Furthermore, trauma-informed assessments can help identify the need for specific interventions. Finally, it is important to take both child welfare system and trauma-informed assessment approaches into account when considering the use of psychotropic agents because there are critical diagnostic and systemic issues that affect the prescribing and discontinuing of psychiatric medications among children with a history of child maltreatment. CHILDREN WITH INTELLECTUAL AND DEVELOPMENTAL DISABILITIES AS ORGAN TRANSPLANTATION RECIPIENTS

Mindy B. Statter, MD, MBE; Garey Noritz, MD; Committee on Bioethics; and Council on Children With Disabilities

ABSTRACT. The demand for transplantable solid organs far exceeds the supply of deceased donor organs. Patient selection criteria are determined by individual transplant programs; given the scarcity of solid organs for transplant, allocation to those most likely to benefit takes into consideration both medical and psychosocial factors. Children with intellectual and developmental disabilities have historically been excluded as potential recipients of organ transplants. When a transplant is likely to provide significant health benefits, denying a transplant to otherwise eligible children with disabilities may constitute illegal and unjustified discrimination. Children with intellectual and developmental disabilities should not be excluded from the potential pool of recipients and should be referred for evaluation as recipients of solid organ transplants. (4/20)

CHILDREN'S HEALTH INSURANCE PROGRAM (CHIP): ACCOMPLISHMENTS, CHALLENGES, AND POLICY RECOMMENDATIONS

Committee on Child Health Financing

ABSTRACT. Sixteen years ago, the 105th Congress, responding to the needs of 10 million children in the United States who lacked health insurance, created the State Children's Health Insurance Program (SCHIP) as part of the Balanced Budget Act of 1997. Enacted as Title XXI of the Social Security Act, the Children's Health Insurance Program (CHIP; or SCHIP as it has been known at some points) provided states with federal assistance to create programs specifically designed for children from families with incomes that exceeded Medicaid thresholds but that were insufficient to enable them to afford private health insurance. Congress provided $40 billion in block grants over 10 years for states to expand their existing Medicaid programs to cover the intended populations, to erect new stand-alone SCHIP programs for these children, or to effect some combination of both options. Congress reauthorized CHIP once in 2009 under the Children's Health Insurance Program Reauthorization Act and extended its life further within provisions of the Patient Protection and Affordable Care Act of 2010. The purpose of this statement is to review the features of CHIP as it has evolved over the 16 years of its existence; to summarize what is known about the effects that the program has had on coverage, access, health status, and disparities among participants; to identify challenges that remain with respect to insuring this group of vulnerable children, including the impact that provisions of the new Affordable Care Act will have on the issue of health insurance coverage for near-poor children after 2015; and to offer recommendations on how to expand and strengthen the national commitment to provide health insurance to all children regardless of means. (2/14, reaffirmed 8/20)

CIRCUMCISION POLICY STATEMENT

Task Force on Circumcision

ABSTRACT. Male circumcision is a common procedure, generally performed during the newborn period in the United States. In 2007, the American Academy of Pediatrics (AAP) formed a multidisciplinary task force of AAP members and other stakeholders to evaluate the recent evidence on male circumcision and update the Academy's 1999 recommendations in this area. Evaluation of current evidence indicates that the health benefits of newborn male circumcision outweigh the risks and that the procedure's benefits justify access to this procedure for families who choose it. Specific benefits identified included prevention of urinary tract infections, penile cancer, and transmission of some sexually transmitted infections, including HIV. The American College of Obstetricians and Gynecologists has endorsed this statement. (8/12)

CLIMATIC HEAT STRESS AND EXERCISING CHILDREN AND ADOLESCENTS

Council on Sports Medicine and Fitness and Council on School Health

ABSTRACT. Results of new research indicate that, contrary to previous thinking, youth do not have less effective thermoregulatory ability, insufficient cardiovascular capacity, or lower physical exertion tolerance compared with adults during exercise in the heat when adequate hydration is maintained. Accordingly, besides poor hydration status, the primary determinants of reduced performance and exertional heat-illness risk in youth during sports and other physical activities in a hot environment include undue physical exertion, insufficient recovery between repeated exercise bouts or closely scheduled same-day training sessions or rounds of sports competition, and inappropriately wearing clothing, uniforms, and protective equipment that play a role in excessive heat retention. Because these known contributing risk factors are modifiable, exertional heat illness is usually preventable. With appropriate preparation, modifications, and monitoring, most healthy children and adolescents can safely participate in outdoor sports and other physical activities through a wide range of challenging warm to hot climatic conditions. (8/11, reaffirmed 2/15, 11/19)

CLINICAL CONSIDERATIONS RELATED TO THE BEHAVIORAL MANIFESTATIONS OF CHILD MALTREATMENT (CLINICAL REPORT)

Robert D. Sege, MD, PhD, FAAP; Lisa Amaya-Jackson, MD, MPH, FAACAP; Committee on Child Abuse and Neglect; and Council on Foster Care, Adoption, and Kinship Care (joint with American Academy of Child and Adolescent Psychiatry Committee on Child Maltreatment and Violence and National Center for Child Traumatic Stress)

ABSTRACT. Children who have suffered early abuse or neglect may later present with significant health and behavior problems that may persist long after the abusive or neglectful environment has been remediated. Neurobiological research suggests that early maltreatment may result in an altered psychological and physiologic response to stressful stimuli, a response that deleteriously affects the child's subsequent development. Pediatricians can assist caregivers by helping them recognize the abused or neglected child's emotional and behavioral responses associated with child maltreatment and guide them in the use of positive parenting strategies, referring the children and families to evidence-based therapeutic treatment and mobilizing available community resources. (3/17)

CLINICAL GENETIC EVALUATION OF THE CHILD WITH MENTAL RETARDATION OR DEVELOPMENTAL DELAYS (CLINICAL REPORT)

John B. Moeschler, MD; Michael Shevell, MD; and Committee on Genetics

ABSTRACT. This clinical report describes the clinical genetic evaluation of the child with developmental delays or mental retardation. The purpose of this report is to describe the optimal clinical genetics diagnostic evaluation to assist pediatricians in providing a medical home for children with developmental delays or mental retardation and their families. The literature supports the benefit of expert clinical judgment by a consulting clinical geneticist in the diagnostic evaluation. However, it is recognized that local factors may preclude this particular option. No single approach to the diagnostic process is supported by the literature. This report addresses the diagnostic importance of clinical history, 3-generation family history, dysmorphologic examination, neurologic examination, chromosome analysis (≥650 bands), fragile X molecular genetic testing, fluorescence in situ hybridization studies for subtelomere chromosome rearrangements, molecular genetic testing for typical and atypical presentations of known syndromes, computed tomography and/or magnetic resonance brain imaging, and targeted studies for metabolic disorders. (6/06, reaffirmed 5/12)

https://doi.org/10.1542/peds.2006-1006

CLINICAL PRACTICE POLICY TO PROTECT CHILDREN FROM TOBACCO, NICOTINE, AND TOBACCO SMOKE

Section on Tobacco Control

ABSTRACT. Tobacco dependence starts in childhood. Tobacco exposure of children is common and causes illness and premature death in children and adults, with adverse effects starting in the womb. There is no safe level of tobacco smoke exposure. Pediatricians should screen for use of tobacco and other nicotine delivery devices and provide anticipatory guidance to prevent smoking initiation and reduce tobacco smoke exposure. Pediatricians need to be aware of the different nicotine delivery systems marketed and available.

Parents and caregivers are important sources of children's tobacco smoke exposure. Because tobacco dependence is a severe addiction, to protect children's health, caregiver tobacco dependence treatment should be offered or referral for treatment should be provided (such as referral to the national smoker's quitline at 1-800-QUIT-NOW). If the source of tobacco exposure cannot be eliminated, counseling about reducing exposure to children should be provided.

Health care delivery systems should facilitate the effective prevention, identification, and treatment of tobacco dependence in children and adolescents, their parents, and other caregivers. Health care facilities should protect children from tobacco smoke exposure and tobacco promotion. Tobacco dependence prevention and treatment should be part of medical education, with knowledge assessed as part of board certification examinations. (10/15, reaffirmed 6/20)

CLINICAL TOOLS TO ASSESS ASTHMA CONTROL IN CHILDREN (CLINICAL REPORT)

Chitra Dinakar, MD, FAAP; Bradley E. Chipps, MD, FAAP; Section on Allergy and Immunology; and Section on Pediatric Pulmonology and Sleep Medicine

ABSTRACT. Asthma affects an estimated 7 million children and causes significant health care and disease burden. The most recent iteration of the National Heart, Lung and Blood Institute asthma guidelines, the Expert Panel Report 3, emphasizes the assessment and monitoring of asthma control in the management of asthma. Asthma control refers to the degree to which the manifestations of asthma are minimized by therapeutic interventions and the goals of therapy are met. Although assessment of asthma severity is used to guide initiation of therapy, monitoring of asthma control helps determine whether therapy should be maintained or adjusted. The nuances of estimation of asthma control include understanding concepts of current impairment and future risk and incorporating their measurement into clinical practice. Impairment is assessed on the basis of frequency and intensity of symptoms, variations in lung function, and limitations of daily activities. "Risk" refers to the likelihood of exacerbations, progressive loss of lung function, or adverse effects from medications. Currently available ambulatory tools to measure asthma control range are subjective measures, such as patient-reported composite asthma control score instruments or objective measures of lung function, airway hyperreactivity, and biomarkers. Because asthma control exhibits short- and long-term variability, health care providers need to be vigilant regarding the fluctuations in the factors that can create discordance between subjective and objective assessment of asthma control. Familiarity with the properties, application, and relative value of these measures will enable health care providers to choose the optimal set of measures that will adhere to national standards of care and ensure delivery of high-quality care customized to their patients. COCHLEAR IMPLANTS IN CHILDREN: SURGICAL SITE INFECTIONS AND PREVENTION AND TREATMENT OF ACUTE OTITIS MEDIA AND MENINGITIS

Lorry G. Rubin, MD; Blake Papsin, MD; Committee on Infectious Diseases; and Section on Otolaryngology—Head and Neck Surgery

ABSTRACT. The use of cochlear implants is increasingly common, particularly in children younger than 3 years. Bacterial meningitis, often with associated acute otitis media, is more common in children with cochlear implants than in groups of control children. Children with profound deafness who are candidates for cochlear implants should receive all age-appropriate doses of pneumococcal conjugate and Haemophilus influenzae type b conjugate vaccines and appropriate annual immunization against influenza. In addition, starting at 24 months of age, a single dose of 23-valent pneumococcal polysaccharide vaccine should be administered. Before implant surgery, primary care providers and cochlear implant teams should ensure that immunizations are up-to-date, preferably with completion of indicated vaccines at least 2 weeks before implant surgery. Imaging of the temporal bone/inner ear should be performed before cochlear implantation in all children with congenital deafness and all patients with profound hearing impairment and a history of bacterial meningitis to identify those with inner-ear malformations/cerebrospinal fluid fistulas or ossification of the cochlea. During the initial months after cochlear implantation, the risk of complications of acute otitis media may be higher than during subsequent time periods. Therefore, it is recommended that acute otitis media diagnosed during the first 2 months after implantation be initially treated with a parenteral antibiotic (eg, ceftriaxone or cefotaxime). Episodes occurring 2 months or longer after implantation can be treated with a trial of an oral antimicrobial agent (eg, amoxicillin or amoxicillin/clavulanate at a dose of approximately 90 mg/kg per day of amoxicillin component), provided the child does not appear toxic and the implant does not have a spacer/positioner, a wedge that rests in the cochlea next to the electrodes present in certain implant models available between 1999 and 2002. "Watchful waiting" without antimicrobial therapy is inappropriate for children with implants with acute otitis media. If feasible, tympanocentesis should be performed for acute otitis media, and the material

should be sent for culture, but performance of this procedure should not result in an undue delay in initiating antimicrobial therapy. For patients with suspected meningitis, cerebrospinal fluid as well as middle-ear fluid, if present, should be sent for culture. Empiric antimicrobial therapy for meningitis occurring within 2 months of implantation should include an agent with broad activity against Gram-negative bacilli (eg, meropenem) plus vancomycin. For meningitis occurring 2 months or longer after implantation, standard empiric antimicrobial therapy for meningitis (eg, ceftriaxone plus vancomycin) is indicated. For patients with meningitis, urgent evaluation by an otolaryngologist is indicated for consideration of imaging and surgical exploration. (7/10, reaffirmed 1/18)
https://doi.org/10.1542/peds.2010-1427

CODEINE: TIME TO SAY "NO" (CLINICAL REPORT)

Joseph D. Tobias, MD, FAAP; Thomas P. Green, MD, FAAP; Charles J. Coté, MD, FAAP; Section on Anesthesiology and Pain Medicine; and Committee on Drugs

ABSTRACT. Codeine has been prescribed to pediatric patients for many decades as both an analgesic and an antitussive agent. Codeine is a prodrug with little inherent pharmacologic activity and must be metabolized in the liver into morphine, which is responsible for codeine's analgesic effects. However, there is substantial genetic variability in the activity of the responsible hepatic enzyme, *CYP2D6,* and, as a consequence, individual patient response to codeine varies from no effect to high sensitivity. Drug surveillance has documented the occurrence of unanticipated respiratory depression and death after receiving codeine in children, many of whom have been shown to be ultrarapid metabolizers. Patients with documented or suspected obstructive sleep apnea appear to be at particular risk because of opioid sensitivity, compounding the danger among rapid metabolizers in this group. Recently, various organizations and regulatory bodies, including the World Health Organization, the US Food and Drug Administration, and the European Medicines Agency, have promulgated stern warnings regarding the occurrence of adverse effects of codeine in children. These and other groups have or are considering a declaration of a contraindication for the use of codeine for children as either an analgesic or an antitussive. Additional clinical research must extend the understanding of the risks and benefits of both opioid and nonopioid alternatives for orally administered, effective agents for acute and chronic pain. (9/16)

COLLABORATIVE CARE IN THE IDENTIFICATION AND MANAGEMENT OF PSYCHOSIS IN ADOLESCENTS AND YOUNG ADULTS (CLINICAL REPORT)

Liwei L. Hua, MD, PhD, and Committee on Adolescence

ABSTRACT. Pediatricians are often the first physicians to encounter adolescents and young adults presenting with psychotic symptoms. Although pediatricians would ideally be able to refer these patients immediately into psychiatric care, the shortage of child and adolescent psychiatry services may sometimes require pediatricians to make an initial assessment or continue care after recommendations are made by a specialist. Knowing how to identify and further evaluate these symptoms in pediatric patients and how to collaborate with and refer to specialty care is critical in helping to minimize the duration of untreated psychosis and to optimize outcomes. Because not all patients presenting with psychotic-like symptoms will convert to a psychotic disorder, pediatricians should avoid prematurely assigning a diagnosis when possible. Other contributing factors, such as co-occurring substance abuse or trauma, should also be considered. This clinical report describes psychotic and psychotic-like symptoms in the pediatric age group as well as etiology, risk factors, and recommendations for pediatricians, who may be among the first health care providers to identify youth at risk. (5/21)

COLLABORATIVE ROLE OF THE PEDIATRICIAN IN THE DIAGNOSIS AND MANAGEMENT OF BIPOLAR DISORDER IN ADOLESCENTS (CLINICAL REPORT)

Benjamin N. Shain, MD, PhD, and Committee on Adolescence

ABSTRACT. Despite the complexity of diagnosis and management, pediatricians have an important collaborative role in referring and partnering in the management of adolescents with bipolar disorder. This report presents the classification of bipolar disorder as well as interviewing and diagnostic guidelines. Treatment options are described, particularly focusing on medication management and rationale for the common practice of multiple, simultaneous medications. Medication adverse effects may be problematic and better managed with collaboration between mental health professionals and pediatricians. Case examples illustrate a number of common diagnostic and management issues. (11/12)
https://doi.org/10.1542/peds.2012-2756

COMMUNICATING WITH CHILDREN AND FAMILIES: FROM EVERYDAY INTERACTIONS TO SKILL IN CONVEYING DISTRESSING INFORMATION (TECHNICAL REPORT)

Marcia Levetown, MD, and Committee on Bioethics

ABSTRACT. Health care communication is a skill that is critical to safe and effective medical practice; it can and must be taught. Communication skill influences patient disclosure, treatment adherence and outcome, adaptation to illness, and bereavement. This article provides a review of the evidence regarding clinical communication in the pediatric setting, covering the spectrum from outpatient primary care consultation to death notification, and provides practical suggestions to improve communication with patients and families, enabling more effective, efficient, and empathic pediatric health care. (5/08, reaffirmed 12/16)
https://doi.org/10.1542/peds.2008-0565

COMMUNITY PEDIATRICS: NAVIGATING THE INTERSECTION OF MEDICINE, PUBLIC HEALTH, AND SOCIAL DETERMINANTS OF CHILDREN'S HEALTH

Council on Community Pediatrics

ABSTRACT. This policy statement provides a framework for the pediatrician's role in promoting the health and well-being of all children in the context of their families and communities. It offers pediatricians a definition of community pediatrics, emphasizes the importance of recognizing social determinants of health, and delineates the need to partner with public health to address population-based child health issues. It also recognizes the importance of pediatric involvement in child advocacy at local, state, and federal levels to ensure all children have access to a high-quality medical home and to eliminate child health disparities. This statement provides a set of specific recommendations that underscore the critical nature of this dimension of pediatric practice, teaching, and research. (2/13, reaffirmed 10/16)
https://doi.org/10.1542/peds.2012-3933

COMPREHENSIVE EVALUATION OF THE CHILD WITH INTELLECTUAL DISABILITY OR GLOBAL DEVELOPMENTAL DELAYS (CLINICAL REPORT)

John B. Moeschler, MD, MS, FAAP, FACMG; Michael Shevell, MDCM, FRCP; and Committee on Genetics

ABSTRACT. Global developmental delay and intellectual disability are relatively common pediatric conditions. This report describes the recommended clinical genetics diagnostic approach. The report is based on a review of published reports, most consisting of medium to large case series of diagnostic tests

used, and the proportion of those that led to a diagnosis in such patients. Chromosome microarray is designated as a first-line test and replaces the standard karyotype and fluorescent in situ hybridization subtelomere tests for the child with intellectual disability of unknown etiology. Fragile X testing remains an important first-line test. The importance of considering testing for inborn errors of metabolism in this population is supported by a recent systematic review of the literature and several case series recently published. The role of brain MRI remains important in certain patients. There is also a discussion of the emerging literature on the use of whole-exome sequencing as a diagnostic test in this population. Finally, the importance of intentional comanagement among families, the medical home, and the clinical genetics specialty clinic is discussed. (8/14, reaffirmed 10/19)
https://doi.org/10.1542/peds.2014-1839

COMPREHENSIVE HEALTH EVALUATION OF THE NEWLY ADOPTED CHILD (CLINICAL REPORT)

Veronnie Faye Jones, MD, PhD, MSPH, FAAP; Elaine E. Schulte, MD, MPH, FAAP; and Council on Foster Care, Adoption, and Kinship Care

ABSTRACT. Children who join families through the process of adoption, whether through a domestic or international route, often have multiple health care needs. Pediatricians and other health care personnel are in a unique position to guide families in achieving optimal health for the adopted children as families establish a medical home. Shortly after placement in an adoptive home, it is recommended that children have a timely comprehensive health evaluation to provide care for known medical needs and identify health issues that are unknown. It is important to begin this evaluation with a review of all available medical records and pertinent verbal history. A complete physical examination then follows. The evaluation should also include diagnostic testing based on findings from the history and physical examination as well as the risks presented by the child's previous living conditions. Age-appropriate screenings may include, but are not limited to, newborn screening panels and hearing, vision, dental, and formal behavioral and/or developmental screenings. The comprehensive assessment may occur at the time of the initial visit to the physician after adoptive placement or can take place over several visits. Adopted children can be referred to other medical specialists as deemed appropriate. The Council on Adoption, Foster Care, and Kinship Care is a resource within the American Academy of Pediatrics for physicians providing care for children who are being adopted. (4/19)
https://doi.org/10.1542/peds.2019-0657

CONFLICTS BETWEEN RELIGIOUS OR SPIRITUAL BELIEFS AND PEDIATRIC CARE: INFORMED REFUSAL, EXEMPTIONS, AND PUBLIC FUNDING

Committee on Bioethics

ABSTRACT. Although respect for parents' decision-making authority is an important principle, pediatricians should report suspected cases of medical neglect, and the state should, at times, intervene to require medical treatment of children. Some parents' reasons for refusing medical treatment are based on their religious or spiritual beliefs. In cases in which treatment is likely to prevent death or serious disability or relieve severe pain, children's health and future autonomy should be protected. Because religious exemptions to child abuse and neglect laws do not equally protect all children and may harm some children by causing confusion about the duty to provide medical treatment, these exemptions should be repealed. Furthermore, public health care funds should not cover alternative unproven religious or spiritual healing practices. Such payments may inappropriately legitimize these practices as appropriate medical treatment. (10/13, reaffirmed 12/16, 11/17)
https://doi.org/10.1542/peds.2013-2716

CONGENITAL BRAIN AND SPINAL CORD MALFORMATIONS AND THEIR ASSOCIATED CUTANEOUS MARKERS (CLINICAL REPORT)

Mark Dias, MD, FAANS, FAAP; Michael Partington, MD, FAANS, FAAP; and Section on Neurologic Surgery

ABSTRACT. The brain, spinal cord, and skin are all derived from the embryonic ectoderm; this common derivation leads to a high association between central nervous system dysraphic malformations and abnormalities of the overlying skin. A myelomeningocele is an obvious open malformation, the identification of which is not usually difficult. However, the relationship between congenital spinal cord malformations and other cutaneous malformations, such as dimples, vascular anomalies (including infantile hemangiomata and other vascular malformations), congenital pigmented nevi or other hamartomata, or midline hairy patches may be less obvious but no less important. Pediatricians should be aware of these associations, recognize the cutaneous markers associated with congenital central nervous system malformations, and refer children with such markers to the appropriate specialist in a timely fashion for further evaluation and treatment. (9/15)
https://doi.org/10.1542/peds.2015-2854

CONSENT BY PROXY FOR NONURGENT PEDIATRIC CARE (CLINICAL REPORT)

Jonathan M. Fanaroff, MD, JD, FAAP, FCLM, and Committee on Medical Liability and Risk Management

ABSTRACT. Minor-aged patients are often brought to the pediatrician for nonurgent acute medical care, physical examinations, or health supervision visits by someone other than their legally authorized representative, which, in most situations, is a parent. These surrogates or proxies can be members of the child's extended family, such as a grandparent, adult sibling, or aunt/uncle; a noncustodial parent or stepparent in cases of divorce and remarriage; an adult who lives in the home but is not biologically or legally related to the child; or even a child care provider (eg, au pair, nanny, private-duty nurse/nurse's aide, group home supervisor). This report identifies common situations in which pediatricians may encounter "consent by proxy" for nonurgent medical care for minors, including physical examinations, and explains the potential for liability exposure associated with these circumstances. The report suggests practical steps that balance the need to minimize the physician's liability exposure with the patient's access to health care. Key issues to be considered when creating or updating office policies for obtaining and documenting consent by proxy are offered. (1/17)
https://doi.org/10.1542/peds.2016-3911

CONSENT FOR EMERGENCY MEDICAL SERVICES FOR CHILDREN AND ADOLESCENTS

Committee on Pediatric Emergency Medicine and Committee on Bioethics

ABSTRACT. Parental consent generally is required for the medical evaluation and treatment of minor children. However, children and adolescents might require evaluation of and treatment for emergency medical conditions in situations in which a parent or legal guardian is not available to provide consent or conditions under which an adolescent patient might possess the legal authority to provide consent. In general, a medical screening examination and any medical care necessary and likely to prevent imminent and significant harm to the pediatric patient with an emergency medical condition should not be withheld or delayed because of problems obtaining consent. The purpose of this policy statement is to provide guidance in those situations in which parental consent is not readily available, in which parental consent is not necessary, or in which parental refusal of consent

places a child at risk of significant harm. (7/11, reaffirmed 9/15, 4/20)

CONSUMPTION OF RAW OR UNPASTEURIZED MILK AND MILK PRODUCTS BY PREGNANT WOMEN AND CHILDREN

Committee on Infectious Diseases and Committee on Nutrition

ABSTRACT. Sales of raw or unpasteurized milk and milk products are still legal in at least 30 states in the United States. Raw milk and milk products from cows, goats, and sheep continue to be a source of bacterial infections attributable to a number of virulent pathogens, including *Listeria monocytogenes, Campylobacter jejuni, Salmonella* species, *Brucella* species, and *Escherichia coli* O157. These infections can occur in both healthy and immunocompromised individuals, including older adults, infants, young children, and pregnant women and their unborn fetuses, in whom life-threatening infections and fetal miscarriage can occur. Efforts to limit the sale of raw milk products have met with opposition from those who are proponents of the purported health benefits of consuming raw milk products, which contain natural or unprocessed factors not inactivated by pasteurization. However, the benefits of these natural factors have not been clearly demonstrated in evidence-based studies and, therefore, do not outweigh the risks of raw milk consumption. Substantial data suggest that pasteurized milk confers equivalent health benefits compared with raw milk, without the additional risk of bacterial infections. The purpose of this policy statement was to review the risks of raw milk consumption in the United States and to provide evidence of the risks of infectious complications associated with consumption of unpasteurized milk and milk products, especially among pregnant women, infants, and children. (12/13, reaffirmed 11/19)

CONTRACEPTION FOR ADOLESCENTS

Committee on Adolescence

ABSTRACT. Contraception is a pillar in reducing adolescent pregnancy rates. The American Academy of Pediatrics recommends that pediatricians develop a working knowledge of contraception to help adolescents reduce risks of and negative health consequences related to unintended pregnancy. Over the past 10 years, a number of new contraceptive methods have become available to adolescents, newer guidance has been issued on existing contraceptive methods, and the evidence base for contraception for special populations (adolescents who have disabilities, are obese, are recipients of solid organ transplants, or are HIV infected) has expanded. The Academy has addressed contraception since 1980, and this policy statement updates the 2007 statement on contraception and adolescents. It provides the pediatrician with a description and rationale for best practices in counseling and prescribing contraception for adolescents. It is supported by an accompanying technical report. (9/14, reaffirmed 3/21)
https://doi.org/10.1542/peds.2014-2299

CONTRACEPTION FOR ADOLESCENTS (TECHNICAL REPORT)

Mary A. Ott, MD, MA, FAAP; Gina S. Sucato, MD, MPH, FAAP; and Committee on Adolescence

ABSTRACT. A working knowledge of contraception will assist the pediatrician in both sexual health promotion as well as treatment of common adolescent gynecologic problems. Best practices in adolescent anticipatory guidance and screening include a sexual health history, screening for pregnancy and sexually transmitted infections, counseling, and if indicated, providing access to contraceptives. Pediatricians' long-term relationships with adolescents and families allow them to help promote healthy sexual decision-making, including abstinence and contraceptive use. Additionally, medical indications for contraception, such as acne, dysmenorrhea, and heavy menstrual bleeding, are frequently uncovered during adolescent visits. This technical report provides an evidence base for the accompanying policy statement and addresses key aspects of adolescent contraceptive use, including the following: (1) sexual history taking, confidentiality, and counseling; (2) adolescent data on the use and side effects of newer contraceptive methods; (3) new data on older contraceptive methods; and (4) evidence supporting the use of contraceptives in adolescent patients with complex medical conditions. (9/14, reaffirmed 3/21)

CONTRACEPTION FOR HIV-INFECTED ADOLESCENTS (CLINICAL REPORT)

Athena P. Kourtis, MD, PhD, MPH, FAAP; Ayesha Mirza, MD, FAAP; and Committee on Pediatric AIDS

ABSTRACT. Access to high-quality reproductive health care is important for adolescents and young adults with HIV infection to prevent unintended pregnancies, sexually transmitted infections, and secondary transmission of HIV to partners and children. As perinatally HIV-infected children mature into adolescence and adulthood and new HIV infections among adolescents and young adults continue to occur in the United States, medical providers taking care of such individuals often face issues related to sexual and reproductive health. Challenges including drug interactions between several hormonal methods and antiretroviral agents make decisions regarding contraceptive options more complex for these adolescents. Dual protection, defined as the use of an effective contraceptive along with condoms, should be central to ongoing discussions with HIV-infected young women and couples wishing to avoid pregnancy. Last, reproductive health discussions need to be integrated with discussions on HIV care, because a reduction in plasma HIV viral load below the level of detection (an "undetectable viral load") is essential for the individual's health as well as for a reduction in HIV transmission to partners and children. https://doi.org/10.1542/peds.2016-1892

CONTROVERSIES CONCERNING VITAMIN K AND THE NEWBORN

Committee on Fetus and Newborn

ABSTRACT. Prevention of early vitamin K deficiency bleeding (VKDB) of the newborn, with onset at birth to 2 weeks of age (formerly known as classic hemorrhagic disease of the newborn), by oral or parenteral administration of vitamin K is accepted practice. In contrast, late VKDB, with onset from 2 to 12 weeks of age, is most effectively prevented by parenteral administration of vitamin K. Earlier concern regarding a possible causal association between parenteral vitamin K and childhood cancer has not been substantiated. This revised statement presents updated recommendations for the use of vitamin K in the prevention of early and late VKDB. (7/03, reaffirmed 5/06, 5/09, 9/14, 2/20)

CORD BLOOD BANKING FOR POTENTIAL FUTURE TRANSPLANTATION

William T. Shearer, MD, PhD, FAAP; Bertram H. Lubin, MD, FAAP; Mitchell S. Cairo, MD, FAAP; Luigi D. Notarangelo, MD; Section on Hematology/Oncology; and Section on Allergy and Immunology

ABSTRACT. This policy statement is intended to provide information to guide pediatricians, obstetricians, and other medical specialists and health care providers in responding to parents' questions about cord blood donation and banking as well as the types (public versus private) and quality of cord blood

banks. Cord blood is an excellent source of stem cells for hematopoietic stem cell transplantation in children with some fatal diseases. Cord blood transplantation offers another method of definitive therapy for infants, children, and adults with certain hematologic malignancies, hemoglobinopathies, severe forms of T-lymphocyte and other immunodeficiencies, and metabolic diseases. The development of universal screening for severe immunodeficiency assay in a growing number of states is likely to increase the number of cord blood transplants. Both public and private cord blood banks worldwide hold hundreds of thousands of cord blood units designated for the treatment of fatal or debilitating illnesses. The procurement, characterization, and cryopreservation of cord blood is free for families who choose public banking. However, the family cost for private banking is significant and not covered by insurance, and the unit may never be used. Quality-assessment reviews by several national and international accrediting bodies show private cord blood banks to be underused for treatment, less regulated for quality control, and more expensive for the family than public cord blood banks. There is an unquestionable need to study the use of cord blood banking to make new and important alternative means of reconstituting the hematopoietic blood system in patients with malignancies and blood disorders and possibly regenerating tissue systems in the future. Recommendations regarding appropriate ethical and operational standards (including informed consent policies, financial disclosures, and conflict-of-interest policies) are provided for physicians, institutions, and organizations that operate or have a relationship with cord blood banking programs. The information on all aspects of cord blood banking gathered in this policy statement will facilitate parental choice for public or private cord blood banking. (10/17)

CORPORAL PUNISHMENT IN SCHOOLS

Committee on School Health

ABSTRACT. The American Academy of Pediatrics recommends that corporal punishment in schools be abolished in all states by law and that alternative forms of student behavior management be used. (8/00, reaffirmed 6/03, 5/06, 2/12, 12/18)
https://doi.org/10.1542/peds.106.2.343

COUNSELING IN PEDIATRIC POPULATIONS AT RISK FOR INFERTILITY AND/OR SEXUAL FUNCTION CONCERNS (CLINICAL REPORT)

Leena Nahata, MD, FAAP; Gwendolyn P. Quinn, PhD; Amy C. Tishelman, PhD; and Section on Endocrinology

ABSTRACT. Reproductive health is an important yet often overlooked topic in pediatric health care; when addressed, the focus is generally on prevention of sexually transmitted infections and unwanted pregnancy. Two aspects of reproductive health counseling that have received minimal attention in pediatrics are fertility and sexual function for at-risk pediatric populations, and youth across many disciplines are affected. Although professional organizations, such as the American Academy of Pediatrics and the American Society of Clinical Oncology, have published recommendations about fertility preservation discussions, none of these guidelines address how to have ongoing conversations with at-risk youth and their families about the potential for future infertility and sexual dysfunction in developmentally appropriate ways. Researchers suggest many pediatric patients at risk for reproductive problems remain uncertain and confused about their fertility or sexual function status well into young adulthood. Potential infertility may cause distress and anxiety, has been shown to affect formation of romantic relationships, and may lead to unplanned pregnancy in those who incorrectly assumed they were infertile. Sexual dysfunction is also common and may lead to problems with intimacy and self-esteem; survivors of pediatric conditions consistently report inadequate guidance from clinicians in this area. Health care providers and parents report challenges in knowing how and when to discuss these issues. In this context, the goal of this clinical report is to review evidence and considerations for providers related to information sharing about impaired fertility and sexual function in pediatric patients attributable to congenital and acquired conditions or treatments. COUNSELING PARENTS AND TEENS ABOUT MARIJUANA USE IN THE ERA OF LEGALIZATION OF MARIJUANA (CLINICAL REPORT)

Sheryl A. Ryan, MD, FAAP; Seth D. Ammerman, MD, FAAP; and Committee on Substance Use and Prevention

ABSTRACT. Many states have recently made significant changes to their legislation making recreational and/or medical marijuana use by adults legal. Although these laws, for the most part, have not targeted the adolescent population, they have created an environment in which marijuana increasingly is seen as acceptable, safe, and therapeutic. This clinical report offers guidance to the practicing pediatrician based on existing evidence and expert opinion/consensus of the American Academy of Pediatrics regarding anticipatory guidance and counseling to teenagers and their parents about marijuana and its use. The recently published technical report provides the detailed evidence and references regarding the research on which the information in this clinical report is based. (2/17)

COUNTERING VACCINE HESITANCY (CLINICAL REPORT)

Kathryn M. Edwards, MD, FAAP; Jesse M. Hackell, MD, FAAP; Committee on Infectious Diseases; and Committee on Practice and Ambulatory Medicine

ABSTRACT. Immunizations have led to a significant decrease in rates of vaccine-preventable diseases and have made a significant impact on the health of children. However, some parents express concerns about vaccine safety and the necessity of vaccines. The concerns of parents range from hesitancy about some immunizations to refusal of all vaccines. This clinical report provides information about addressing parental concerns about vaccination. (8/16)

COVID-19 VACCINES IN CHILDREN AND ADOLESCENTS

Committee on Infectious Diseases

ABSTRACT. Vaccines are safe and effective in protecting individuals and populations against infectious diseases. New vaccines are evaluated by a long-standing, rigorous, and transparent process through the US Food and Drug Administration (FDA) and the Centers for Disease Control and Prevention (CDC) by which safety and efficacy data are reviewed prior to authorization and recommendation. CRITICAL ELEMENTS FOR THE PEDIATRIC PERIOPERATIVE ANESTHESIA ENVIRONMENT

Section on Anesthesiology and Pain Medicine

ABSTRACT. The American Academy of Pediatrics proposes guidance for the pediatric perioperative anesthesia environment. Essential components are identified to optimize the perioperative environment for the anesthetic care of infants and children. Such an environment promotes the safety and well-being of infants and children by reducing the risk of adverse events. (11/15)

THE CRUCIAL ROLE OF RECESS IN SCHOOL

Council on School Health

ABSTRACT. Recess is at the heart of a vigorous debate over the role of schools in promoting the optimal development of the whole child. A growing trend toward reallocating time in school to accentuate the more academic subjects has put this important facet of a child's school day at risk. Recess serves as a necessary break from the rigors of concentrated, academic challenges in the classroom. But equally important is the fact that safe and well-supervised recess offers cognitive, social, emotional, and physical benefits that may not be fully appreciated when a decision is made to diminish it. Recess is unique from, and a complement to, physical education—not a substitute for it. The American Academy of Pediatrics believes that recess is a crucial and necessary component of a child's development and, as such, it should not be withheld for punitive or academic reasons. DEALING WITH THE CARETAKER WHOSE JUDGMENT IS IMPAIRED BY ALCOHOL OR DRUGS: LEGAL AND ETHICAL CONSIDERATIONS (CLINICAL REPORT)

Steven A. Bondi, JD, MD, FAAP; James Scibilia, MD, FAAP; and Committee on Medical Liability and Risk Management

ABSTRACT. An estimated 8.7 million children live in a household with a substance-using parent or guardian. Substance-using caretakers may have impaired judgment that can negatively affect their child's well-being, including his or her ability to receive appropriate medical care. Although the physician-patient relationship exists between the pediatrician and the child, obligations related to safety and confidentiality should be considered as well. In managing encounters with impaired caretakers who may become disruptive or dangerous, pediatricians should be aware of their responsibilities before acting. In addition to fulfilling the duty involved with an established physician-patient relationship, the pediatrician should take reasonable care to safeguard patient confidentiality; protect the safety of their patient, other patients in the facility, visitors, and employees; and comply with reporting mandates. This clinical report identifies and discusses the legal and ethical concepts related to these circumstances. The report offers implementation suggestions when establishing anticipatory procedures and training programs for staff in such situations to maximize the patient's well-being and safety and minimize the liability of the pediatrician. DEATH OF A CHILD IN THE EMERGENCY DEPARTMENT

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. The American Academy of Pediatrics, American College of Emergency Physicians, and Emergency Nurses Association have collaborated to identify practices and principles to guide the care of children, families, and staff in the challenging and uncommon event of the death of a child in the emergency department in this policy statement and in an accompanying technical report. (6/14, reaffirmed 9/19)

https://doi.org/10.1542/peds.2014-1245

DEATH OF A CHILD IN THE EMERGENCY DEPARTMENT (TECHNICAL REPORT)

Patricia J. O'Malley, MD, FAAP; Isabel A. Barata, MD, FACEP, FAAP; Sally K. Snow, RN, BSN, CPEN, FAEN; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. The death of a child in the emergency department (ED) is one of the most challenging problems facing ED clinicians. This revised technical report and accompanying policy statement reaffirm principles of patient- and family-centered care. Recent literature is examined regarding family presence, termination of resuscitation, bereavement responsibilities of ED clinicians, support of child fatality review efforts, and other issues inherent in caring for the patient, family, and staff when a child dies in the ED. Appendices are provided that offer an approach to bereavement activities in the ED, carrying out forensic responsibilities while providing compassionate care, communicating the news of the death of a child in the acute setting, providing a closing ritual at the time of terminating resuscitation efforts, and managing the child with a terminal condition who presents near death in the ED. (6/14, reaffirmed 9/19)

DEFINITION OF A PEDIATRICIAN

Committee on Pediatric Workforce

POLICY. The American Academy of Pediatrics (AAP) has developed the following definition of pediatrics and a pediatrician:

Pediatrics is the specialty of medical science concerned with the physical, mental, and social health of children from birth to young adulthood. Pediatric care encompasses a broad spectrum of health services ranging from preventive health care to the diagnosis and treatment of acute and chronic diseases.

Pediatrics is a discipline that deals with biological, social, and environmental influences on the developing child and with the impact of disease and dysfunction on development. Children differ from adults anatomically, physiologically, immunologically, psychologically, developmentally, and metabolically.

The pediatrician, a term that includes primary care pediatricians, pediatric medical subspecialists, and pediatric surgical specialists, understands this constantly changing functional status of his or her patients' incident to growth and development and the consequent changing standards of "normal" for age. A pediatrician is a physician who is concerned primarily with the health, welfare, and development of children and is uniquely qualified for these endeavors by virtue of interest and initial training. This training includes 4 years of medical school education, plus an additional year or years (usually at least 3) of intensive training devoted solely to all aspects of medical care for children, adolescents, and young adults. Maintenance of these competencies is achieved by experience, training, continuous education, self-assessment, and practice improvement.

A pediatrician is able to define accurately the child's health status and to serve as a consultant and make use of other specialists as consultants as needed, ideally in the context of, or in conjunction with, the physician-led medical home. Because the child's welfare is heavily dependent on the home and family, the pediatrician supports efforts to create a nurturing environment. Such support includes education about healthful living and anticipatory guidance for both patients and parents.

A pediatrician participates at the community level in preventing or solving problems in child health care and publicly advocates the causes of children. (3/15, reaffirmed 12/19)

https://doi.org/10.1542/peds.2015-0056

DETENTION OF IMMIGRANT CHILDREN

Julie M. Linton, MD, FAAP; Marsha Griffin, MD, FAAP; Alan J. Shapiro, MD, FAAP; and Council on Community Pediatrics

ABSTRACT. Immigrant children seeking safe haven in the United States, whether arriving unaccompanied or in family units, face a complicated evaluation and legal process from the point of arrival through permanent resettlement in communities. The conditions in which children are detained and the support services that are available to them are of great concern

to pediatricians and other advocates for children. In accordance with internationally accepted rights of the child, immigrant and refugee children should be treated with dignity and respect and should not be exposed to conditions that may harm or traumatize them. The Department of Homeland Security facilities do not meet the basic standards for the care of children in residential settings. The recommendations in this statement call for limited exposure of any child to current Department of Homeland Security facilities (ie, Customs and Border Protection and Immigration and Customs Enforcement facilities) and for longitudinal evaluation of the health consequences of detention of immigrant children in the United States. From the moment children are in the custody of the United States, they deserve health care that meets guideline-based standards, treatment that mitigates harm or traumatization, and services that support their health and well-being. This policy statement also provides specific recommendations regarding postrelease services once a child is released into communities across the country, including a coordinated system that facilitates access to a medical home and consistent access to education, child care, interpretation services, and legal services. (4/17)

https://doi.org/10.1542/peds.2017-0483

DEVELOPMENTAL DYSPLASIA OF THE HIP PRACTICE GUIDELINE (TECHNICAL REPORT)

Harold P. Lehmann, MD, PhD; Richard Hinton, MD, MPH; Paola Morello, MD; Jeanne Santoli, MD; in conjunction with Steering Committee on Quality Improvement and Subcommittee on Developmental Dysplasia of the Hip

ABSTRACT. *Objective.* To create a recommendation for pediatricians and other primary care providers about their role as screeners for detecting developmental dysplasia of the hip (DDH) in children.

Patients. Theoretical cohorts of newborns.

Method. Model-based approach using decision analysis as the foundation. Components of the approach include the following:

Perspective: Primary care provider.

Outcomes: DDH, avascular necrosis of the hip (AVN).

Options: Newborn screening by pediatric examination; orthopaedic examination; ultrasonographic examination; orthopaedic or ultrasonographic examination by risk factors. Intercurrent health supervision-based screening.

Preferences: 0 for bad outcomes, 1 for best outcomes.

Model: Influence diagram assessed by the Subcommittee and by the methodology team, with critical feedback from the Subcommittee.

Evidence Sources: Medline and EMBASE search of the research literature through June 1996. Hand search of sentinel journals from June 1996 through March 1997. Ancestor search of accepted articles.

Evidence Quality: Assessed on a custom subjective scale, based primarily on the fit of the evidence to the decision model.

Results. After discussion, explicit modeling, and critique, an influence diagram of 31 nodes was created. The computer-based and the hand literature searches found 534 articles, 101 of which were reviewed by 2 or more readers. Ancestor searches of these yielded a further 17 articles for evidence abstraction. Articles came from around the globe, although primarily Europe, British Isles, Scandinavia, and their descendants. There were 5 controlled trials, each with a sample size less than 40. The remainder were case series. Evidence was available for 17 of the desired 30 probabilities. Evidence quality ranged primarily between one third and two thirds of the maximum attainable score (median: 10–21; interquartile range: 8–14).

Based on the raw evidence and Bayesian hierarchical meta-analyses, our estimate for the incidence of DDH revealed by physical examination performed by pediatricians is 8.6 per 1000; for orthopaedic screening, 11.5; for ultrasonography, 25. The odds ratio for DDH, given breech delivery, is 5.5; for female sex, 4.1; for positive family history, 1.7, although this last factor is not statistically significant. Postneonatal cases of DDH were divided into mid-term (younger than 6 months of age) and late-term (older than 6 months of age). Our estimates for the mid-term rate for screening by pediatricians is 0.34/1000 children screened; for orthopaedists, 0.1; and for ultrasonography, 0.28. Our estimates for late-term DDH rates are 0.21/1000 newborns screened by pediatricians; 0.08, by orthopaedists; and 0.2 for ultrasonography. The rates of AVN for children referred before 6 months of age is estimated at 2.5/1000 infants referred. For those referred after 6 months of age, our estimate is 109/1000 referred infants.

The decision model (reduced, based on available evidence) suggests that orthopaedic screening is optimal, but because orthopaedists in the published studies and in practice would differ, the supply of orthopaedists is relatively limited, and the difference between orthopaedists and pediatricians is statistically insignificant, we conclude that pediatric screening is to be recommended. The place of ultrasonography in the screening process remains to be defined because there are too few data about postneonatal diagnosis by ultrasonographic screening to permit definitive recommendations. These data could be used by others to refine the conclusions based on costs, parental preferences, or physician style. Areas for research are well defined by our model-based approach. (4/00)

DIAGNOSIS, EVALUATION, AND MANAGEMENT OF HIGH BLOOD PRESSURE IN CHILDREN AND ADOLESCENTS (TECHNICAL REPORT)

Carissa M. Baker-Smith, MD, MS, MPH, FAAP, FAHA; Susan K. Flinn, MA; Joseph T. Flynn, MD, MS, FAAP; David C. Kaelber, MD, PhD, MPH, FAAP, FACP, FACMI; Douglas Blowey, MD; Aaron E. Carroll, MD, MS, FAAP; Stephen R. Daniels, MD, PhD, FAAP; Sarah D. de Ferranti, MD, MPH, FAAP; Janis M. Dionne, MD, FRCPC; Bonita Falkner, MD; Samuel S. Gidding, MD; Celeste Goodwin; Michael G. Leu, MD, MS, MHS, FAAP; Makia E. Powers, MD, MPH, FAAP; Corinna Rea, MD, MPH, FAAP; Joshua Samuels, MD, MPH, FAAP; Madeline Simasek, MD, MSCP, FAAP; Vidhu V. Thaker, MD, FAAP; Elaine M. Urbina, MD, MS, FAAP; and Subcommittee on Screening and Management of High Blood Pressure in Children

ABSTRACT. Systemic hypertension is a major cause of morbidity and mortality in adulthood. High blood pressure (HBP) and repeated measures of HBP, hypertension (HTN), begin in youth. Knowledge of how best to diagnose, manage, and treat systemic HTN in children and adolescents is important for primary and subspecialty care providers.

Objectives: To provide a technical summary of the methodology used to generate the 2017 "Clinical Practice Guideline for Screening and Management of High Blood Pressure in Children and Adolescents," an update to the 2004 "Fourth Report on the Diagnosis, Evaluation, and Treatment of High Blood Pressure in Children and Adolescents."

Data Sources: Medline, Cochrane Central Register of Controlled Trials, and Excerpta Medica Database references published between January 2003 and July 2015 followed by an additional search between August 2015 and July 2016.

Study Selection: English-language observational studies and randomized trials.

Methods: Key action statements (KASs) and additional recommendations regarding the diagnosis, management, and treatment of HBP in youth were the product of a detailed systematic review of the literature. A content outline establishing the

breadth and depth was followed by the generation of 4 patient, intervention, comparison, outcome, time questions. Key questions addressed: (1) diagnosis of systemic HTN, (2) recommended work-up of systemic HTN, (3) optimal blood pressure (BP) goals, and (4) impact of high BP on indirect markers of cardiovascular disease in youth. Once selected, references were subjected to a 2-person review of the abstract and title followed by a separate 2-person full-text review. Full citation information, population data, findings, benefits and harms of the findings, as well as other key reference information were archived. Selected primary references were then used for KAS generation. Level of evidence (LOE) scoring was assigned for each reference and then in aggregate. Appropriate language was used to generate each KAS based on the LOE and the balance of benefit versus harm of the findings. Topics that could not be researched via the stated approach were (1) definition of HTN in youth, and (2) definition of left ventricular hypertrophy. KASs related to these stated topics were generated via expert opinion.

Results: Nearly 15 000 references were identified during an initial literature search. After a deduplication process, 14 382 references were available for title and abstract review, and 1379 underwent full text review. One hundred twenty-four experimental and observational studies published between 2003 and 2016 were selected as primary references for KAS generation, followed by an additional 269 primary references selected between August 2015 and July 2016. The LOE for the majority of references was C. In total, 30 KASs and 27 additional recommendations were generated; 12 were related to the diagnosis of HTN, 13 were related to management and additional diagnostic testing, 3 to treatment goals, and 2 to treatment options. Finally, special additions to the clinical practice guideline included creation of new BP tables based on BP values obtained solely from children with normal weight, creation of a simplified table to enhance screening and recognition of abnormal BP, and a revision of the criteria for diagnosing left ventricular hypertrophy.

Conclusions: An extensive and detailed systematic approach was used to generate evidence-based guidelines for the diagnosis, management, and treatment of youth with systemic HTN. (8/18)

DIAGNOSIS, MANAGEMENT, AND TREATMENT OF FEMALE GENITAL MUTILATION OR CUTTING IN GIRLS (CLINICAL REPORT)

Janine Young, MD, FAAP; Nawal M. Nour, MD, MPH, FACOG; Robert C. Macauley, MD, FAAP; Sandeep K. Narang, MD, JD, FAAP; Crista Johnson-Agbakwu, MD, MSc, FACOG; Section on Global Health; Committee on Medical Liability and Risk Management; and Committee on Bioethics

ABSTRACT. Female genital mutilation or cutting (FGM/C) involves medically unnecessary cutting of parts or all of the external female genitalia. It is outlawed in the United States and much of the world but is still known to occur in more than 30 countries. FGM/C most often is performed on children, from infancy to adolescence, and has significant morbidity and mortality. In 2018, an estimated 200 million girls and women alive at that time had undergone FGM/C worldwide. Some estimate that more than 500 000 girls and women in the United States have had or are at risk for having FGM/C. However, pediatric prevalence of FGM/C is only estimated given that most pediatric cases remain undiagnosed both in countries of origin and in the Western world, including in the United States. It is a cultural practice not directly tied to any specific religion, ethnicity, or race and has occurred in the United States. Although it is mostly a pediatric practice, currently there is no standard FGM/C teaching required for health care providers who care for children, including pediatricians, family physicians, child abuse pediatricians, pediatric urologists, and pediatric urogynecologists. This clinical report is the first comprehensive summary of FGM/C in children and includes education regarding a standard-of-care approach for examination of external female genitalia at all health supervision examinations, diagnosis, complications, management, treatment, culturally sensitive discussion and counseling approaches, and legal and ethical considerations. (7/20)

DIAGNOSIS, TREATMENT, AND PREVENTION OF CONGENITAL TOXOPLASMOSIS IN THE UNITED STATES (TECHNICAL REPORT)

Yvonne A. Maldonado, MD, FAAP; Jennifer S. Read, MD, MS, MPH, DTM&H, FAAP; and Committee on Infectious Diseases

ABSTRACT. Congenital toxoplasmosis (CT) is a parasitic disease that can cause significant fetal and neonatal harm. Coordinated efforts by pregnant women, researchers, physicians, and health policy makers regarding potential primary and secondary preventive measures for CT and their implementation may lead to a lower incidence of CT as well as lower morbidity and mortality rates associated with CT. The purpose of this technical report is to summarize available information regarding the diagnosis, treatment, and prevention of CT. (1/17)

https://doi.org/10.1542/peds.2016-3860

DIAGNOSIS AND MANAGEMENT OF CHILDHOOD OBSTRUCTIVE SLEEP APNEA SYNDROME (TECHNICAL REPORT)

Carole L. Marcus, MBBCh; Lee J. Brooks, MD; Sally Davidson Ward, MD; Kari A. Draper, MD; David Gozal, MD; Ann C. Halbower, MD; Jacqueline Jones, MD; Christopher Lehmann, MD; Michael S. Schechter, MD, MPH; Stephen Sheldon, MD; Richard N. Shiffman, MD, MCIS; Karen Spruyt, PhD; Steering Committee on Quality Improvement and Management; and Subcommittee on Obstructive Sleep Apnea Syndrome

ABSTRACT. *Objective.* This technical report describes the procedures involved in developing recommendations on the management of childhood obstructive sleep apnea syndrome (OSAS).

Methods. The literature from 1999 through 2011 was evaluated.

Results and Conclusions. A total of 3166 titles were reviewed, of which 350 provided relevant data. Most articles were level II through IV. The prevalence of OSAS ranged from 0% to 5.7%, with obesity being an independent risk factor. OSAS was associated with cardiovascular, growth, and neurobehavioral abnormalities and possibly inflammation. Most diagnostic screening tests had low sensitivity and specificity. Treatment of OSAS resulted in improvements in behavior and attention and likely improvement in cognitive abilities. Primary treatment is adenotonsillectomy (AT). Data were insufficient to recommend specific surgical techniques; however, children undergoing partial tonsillectomy should be monitored for possible recurrence of OSAS. Although OSAS improved postoperatively, the proportion of patients who had residual OSAS ranged from 13% to 29% in low-risk populations to 73% when obese children were included and stricter polysomnographic criteria were used. Nevertheless, OSAS may improve after AT even in obese children, thus supporting surgery as a reasonable initial treatment. A significant number of obese patients required intubation or continuous positive airway pressure (CPAP) postoperatively, which reinforces the need for inpatient observation. CPAP was effective in the treatment of OSAS, but adherence is a major barrier. For this reason, CPAP is not recommended as first-line therapy for OSAS when AT is an option. Intranasal steroids may ameliorate mild OSAS, but follow-up is needed. Data were insufficient to recommend rapid maxillary expansion. (8/12)

DIAGNOSIS AND MANAGEMENT OF GASTROESOPHAGEAL REFLUX IN PRETERM INFANTS (CLINICAL REPORT)

Eric C. Eichenwald, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Gastroesophageal reflux (GER), generally defined as the passage of gastric contents into the esophagus, is an almost universal phenomenon in preterm infants. It is a common diagnosis in the NICU; however, there is large variation in its treatment across NICU sites. In this clinical report, the physiology, diagnosis, and symptomatology in preterm infants as well as currently used treatment strategies in the NICU are examined. Conservative measures to control reflux, such as left lateral body position, head elevation, and feeding regimen manipulation, have not been shown to reduce clinically assessed signs of GER in the preterm infant. In addition, preterm infants with clinically diagnosed GER are often treated with pharmacologic agents; however, a lack of evidence of efficacy together with emerging evidence of significant harm (particularly with gastric acid blockade) strongly suggest that these agents should be used sparingly, if at all, in preterm infants. (6/18)

DIAGNOSIS AND MANAGEMENT OF INFANTILE HEMANGIOMA (CLINICAL REPORT)

David H. Darrow, MD, DDS; Arin K. Greene, MD; Anthony J. Mancini, MD; Amy J. Nopper, MD; Section on Dermatology; Section on Otolaryngology—Head & Neck Surgery; and Section on Plastic Surgery

ABSTRACT. Infantile hemangiomas (IHs) are the most common tumors of childhood. Unlike other tumors, they have the unique ability to involute after proliferation, often leading primary care providers to assume they will resolve without intervention or consequence. Unfortunately, a subset of IHs rapidly develop complications, resulting in pain, functional impairment, or permanent disfigurement. As a result, the primary clinician has the task of determining which lesions require early consultation with a specialist. Although several recent reviews have been published, this clinical report is the first based on input from individuals representing the many specialties involved in the treatment of IH. Its purpose is to update the pediatric community regarding recent discoveries in IH pathogenesis, treatment, and clinical associations and to provide a basis for clinical decision-making in the management of IH. (9/15)

https://doi.org/10.1542/peds.2015-2485

DIAGNOSIS AND MANAGEMENT OF INFANTILE HEMANGIOMA: EXECUTIVE SUMMARY

David H. Darrow, MD, DDS, FAAP; Arin K. Greene, MD, FAAP; Anthony J. Mancini, MD, FAAP; Amy J. Nopper, MD, FAAP; Section on Dermatology; Section on Otolaryngology—Head & Neck Surgery; and Section on Plastic Surgery

ABSTRACT. Infantile hemangiomas (IHs) are the most common tumors of childhood. Unlike other tumors, they have the capacity to involute after proliferation, often leading primary care providers to assume they will resolve without intervention or consequence. However, a subset of IHs may be associated with complications, resulting in pain, functional impairment, or permanent disfigurement. As a result, the primary care provider is often called on to decide which lesions should be referred for early consultation with a specialist.

This document provides a summary of the guidance contained in the clinical report "Diagnosis and Management of Infantile Hemangioma," published concurrently in the online version of *Pediatrics* (*Pediatrics.* 2015;136[4]:e1060–e1104, available at: www.pediatrics.org/content/136/4/e1060). The report is uniquely based on input from the many specialties involved in the treatment of IH. Its purpose is to update the pediatric community about recent discoveries in IH pathogenesis, clinical associations, and treatment and to provide a knowledge base and framework for clinical decision-making in the management of IH. https://doi.org/10.1542/peds.2015-2482

DIAGNOSIS AND PREVENTION OF IRON DEFICIENCY AND IRON-DEFICIENCY ANEMIA IN INFANTS AND YOUNG CHILDREN (0–3 YEARS OF AGE) (CLINICAL REPORT)

Robert D. Baker, MD, PhD; Frank R. Greer, MD; and Committee on Nutrition

ABSTRACT. This clinical report covers diagnosis and prevention of iron deficiency and iron-deficiency anemia in infants (both breastfed and formula fed) and toddlers from birth through 3 years of age. Results of recent basic research support the concerns that iron-deficiency anemia and iron deficiency without anemia during infancy and childhood can have long-lasting detrimental effects on neurodevelopment. Therefore, pediatricians and other health care providers should strive to eliminate iron deficiency and iron-deficiency anemia. Appropriate iron intakes for infants and toddlers as well as methods for screening for iron deficiency and iron-deficiency anemia are presented. (10/10)

DIAGNOSIS OF HIV-1 INFECTION IN CHILDREN YOUNGER THAN 18 MONTHS IN THE UNITED STATES (TECHNICAL REPORT)

Jennifer S. Read, MD, MS, MPH, DTM&H, and Committee on Pediatric AIDS

ABSTRACT. The objectives of this technical report are to describe methods of diagnosis of HIV-1 infection in children younger than 18 months in the United States and to review important issues that must be considered by clinicians who care for infants and young children born to HIV-1–infected women. Appropriate HIV-1 diagnostic testing for infants and children younger than 18 months differs from that for older children, adolescents, and adults because of passively transferred maternal HIV-1 antibodies, which may be detectable in the child's bloodstream until 18 months of age. Therefore, routine serologic testing of these infants and young children is generally only informative before the age of 18 months if the test result is negative. Virologic assays, including HIV-1 DNA or RNA assays, represent the gold standard for diagnostic testing of infants and children younger than 18 months. With such testing, the diagnosis of HIV-1 infection (as well as the presumptive exclusion of HIV-1 infection) can be established within the first several weeks of life among nonbreastfed infants. Important factors that must be considered when selecting HIV-1 diagnostic assays for pediatric patients and when choosing the timing of such assays include the age of the child, potential timing of infection of the child, whether the infection status of the child's mother is known or unknown, the antiretroviral exposure history of the mother and of the child, and characteristics of the virus. If the mother's HIV-1 serostatus is unknown, rapid HIV-1 antibody testing of the newborn infant to identify HIV-1 exposure is essential so that antiretroviral prophylaxis can be initiated within the first 12 hours of life if test results are positive. For HIV-1–exposed infants (identified by positive maternal test results or positive antibody results for the infant shortly after birth), it has been recommended that diagnostic testing with HIV-1 DNA or RNA assays be performed within the first 14 days of life, at 1 to 2 months of age, and at 3 to 6 months of age. If any of these test results are positive, repeat testing is recommended to confirm the diagnosis of HIV-1 infection. A diagnosis of HIV-1 infection can be made on the basis of 2 positive HIV-1 DNA or RNA assay results. In nonbreastfeeding children younger than 18 months with no positive HIV-1 virologic test results, presumptive exclusion of HIV-1 infection can be based on 2 negative virologic test results (1 obtained at ≥2 weeks and 1 obtained at ≥4 weeks of age); 1 negative virologic test result obtained at ≥8 weeks of age; or 1 negative HIV-1 anti-

body test result obtained at ≥6 months of age. Alternatively, presumptive exclusion of HIV-1 infection can be based on 1 positive HIV-1 virologic test with at least 2 subsequent negative virologic test results (at least 1 of which is performed at ≥8 weeks of age) or negative HIV-1 antibody test results (at least 1 of which is performed at ≥6 months of age). Definitive exclusion of HIV-1 infection is based on 2 negative virologic test results, 1 obtained at ≥1 month of age and 1 obtained at ≥4 months of age, or 2 negative HIV-1 antibody test results from separate specimens obtained at ≥6 months of age. For both presumptive and definitive exclusion of infection, the child should have no other laboratory (eg, no positive virologic test results) or clinical (eg, no AIDS-defining conditions) evidence of HIV-1 infection. Many clinicians confirm the absence of HIV-1 infection with a negative HIV-1 antibody assay result at 12 to 18 months of age. For breastfeeding infants, a similar testing algorithm can be followed, with timing of testing starting from the date of complete cessation of breastfeeding instead of the date of birth. (12/07, reaffirmed 4/10, 2/15)

DIAGNOSIS OF PREGNANCY AND PROVIDING OPTIONS COUNSELING FOR THE ADOLESCENT PATIENT (CLINICAL REPORT)

Laurie L. Hornberger, MD, MPH, FAAP, and Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics policy statement "Options Counseling for the Pregnant Adolescent Patient" recommends the basic content of the pediatrician's counseling for an adolescent facing a new diagnosis of pregnancy. However, options counseling is just one aspect of what may be one of the more challenging scenarios in the pediatric office. Pediatricians must remain alert to the possibility of pregnancy among their adolescent female patients. When discovering symptoms suggestive of pregnancy, pediatricians must obtain a relevant history, perform diagnostic testing and properly interpret the results, and understand the significance of the results from the patient perspective and reveal them to the patient in a sensitive manner. If the patient is indeed pregnant, the pediatrician, in addition to providing comprehensive options counseling, may need to help recruit adult support for the patient and should offer continued assistance to the adolescent and her family after the office visit. All pediatricians should be aware of the legal aspects of adolescent reproductive care and the resources for pregnant adolescents in their communities. This clinical report presents a more comprehensive view of the evaluation and management of pregnancy in the adolescent patient and a context for options counseling. (8/17)

DIAGNOSTIC IMAGING OF CHILD ABUSE

Section on Radiology

ABSTRACT. The role of imaging in cases of child abuse is to identify the extent of physical injury when abuse is present and to elucidate all imaging findings that point to alternative diagnoses. Effective diagnostic imaging of child abuse rests on high-quality technology as well as a full appreciation of the clinical and pathologic alterations occurring in abused children. This statement is a revision of the previous policy published in 2000. (4/09)
https://doi.org/10.1542/peds.2009-0558

DIGITAL ADVERTISING TO CHILDREN

Jenny Radesky, MD, FAAP; Yolanda (Linda) Reid Chassiakos, MD, FAAP, FACP; Nusheen Ameenuddin, MD, MPH, MPA, FAAP; Dipesh Navsaria, MPH, MSLIS, MD, FAAP; and Council on Communication and Media

ABSTRACT. Advertising to children and teenagers is a multibillion-dollar industry. This policy statement reviews the forms of advertising that children and teenagers encounter, including newer forms of digital marketing, such as sponsored content, influencers, data collection, persuasive design, and personalized behavioral marketing driven by machine learning. Parents and pediatric health care providers need to be aware of the ways different marketing messages reach children and teenagers, including Internet sites, social media, and mobile apps. Evidence suggests that exposure to advertising is associated with unhealthy behaviors, such as intake of high-calorie, low-nutrient food and beverages; use of tobacco products and electronic cigarettes; use of alcohol and marijuana; and indoor tanning. Children are uniquely vulnerable to the persuasive effects of advertising because of immature critical thinking skills and impulse inhibition. School-aged children and teenagers may be able to recognize advertising but often are not able to resist it when it is embedded within trusted social networks, encouraged by celebrity influencers, or delivered next to personalized content. This policy statement expresses concern about the practice of tracking and using children's digital behavior to inform targeted marketing campaigns, which may contribute to health disparities among vulnerable children or populations. Pediatricians should guide parents and children to develop digital literacy skills to prevent or mitigate negative outcomes, but it is equally important that policy makers and technology companies embrace digital design, data collection, and marketing practices within today's broad digital environment that support healthier decision-making and outcomes. DISASTER PREPAREDNESS IN NEONATAL INTENSIVE CARE UNITS (CLINICAL REPORT)

Wanda D. Barfield, MD, MPH, FAAP, RADM USPHS; Steven E. Krug, MD, FAAP; Committee on Fetus and Newborn; and Disaster Preparedness Council

ABSTRACT. Disasters disproportionally affect vulnerable, technology-dependent people, including preterm and critically ill newborn infants. It is important for health care providers to be aware of and prepared for the potential consequences of disasters for the NICU. Neonatal intensive care personnel can provide specialized expertise for their hospital, community, and regional emergency preparedness plans and can help develop institutional surge capacity for mass critical care, including equipment, medications, personnel, and facility resources. (4/17)

DISCLOSURE OF ADVERSE EVENTS IN PEDIATRICS

Committee on Medical Liability and Risk Management and Council on Quality Improvement and Patient Safety

ABSTRACT. Despite increasing attention to issues of patient safety, preventable adverse events (AEs) continue to occur, causing direct and consequential injuries to patients, families, and health care providers. Pediatricians generally agree that there is an ethical obligation to inform patients and families about preventable AEs and medical errors. Nonetheless, barriers, such as fear of liability, interfere with disclosure regarding preventable AEs. Changes to the legal system, improved communications skills, and carefully developed disclosure policies and programs can improve the quality and frequency of appropriate AE disclosure communications. DISPENSING MEDICATIONS AT THE HOSPITAL UPON DISCHARGE FROM AN EMERGENCY DEPARTMENT (TECHNICAL REPORT)

Loren G. Yamamoto, MD, MPH, MBA; Shannon Manzi, PharmD; and Committee on Pediatric Emergency Medicine

ABSTRACT. Although most health care services can and should be provided by their medical home, children will be referred or

require visits to the emergency department (ED) for emergent clinical conditions or injuries. Continuation of medical care after discharge from an ED is dependent on parents or caregivers' understanding of and compliance with follow-up instructions and on adherence to medication recommendations. ED visits often occur at times when the majority of pharmacies are not open and caregivers are concerned with getting their ill or injured child directly home. Approximately one-third of patients fail to obtain priority medications from a pharmacy after discharge from an ED. The option of judiciously dispensing ED discharge medications from the ED's outpatient pharmacy within the facility is a major convenience that overcomes this obstacle, improving the likelihood of medication adherence. Emergency care encounters should be routinely followed up with primary care provider medical homes to ensure complete and comprehensive care. (1/12, reaffirmed 9/15, 7/19)

DISTINGUISHING SUDDEN INFANT DEATH SYNDROME FROM CHILD ABUSE FATALITIES (CLINICAL REPORT)

Kent P. Hymel, MD, and Committee on Child Abuse and Neglect (joint with National Association of Medical Examiners)

ABSTRACT. Fatal child abuse has been mistaken for sudden infant death syndrome. When a healthy infant younger than 1 year dies suddenly and unexpectedly, the cause of death may be certified as sudden infant death syndrome. Sudden infant death syndrome is more common than infanticide. Parents of sudden infant death syndrome victims typically are anxious to provide unlimited information to professionals involved in death investigation or research. They also want and deserve to be approached in a nonaccusatory manner. This clinical report provides professionals with information and suggestions for procedures to help avoid stigmatizing families of sudden infant death syndrome victims while allowing accumulation of appropriate evidence in potential cases of infanticide. This clinical report addresses deficiencies and updates recommendations in the 2001 American Academy of Pediatrics policy statement of the same name. (7/06, reaffirmed 4/09, 3/13, 7/17)

DONOR HUMAN MILK FOR THE HIGH-RISK INFANT: PREPARATION, SAFETY, AND USAGE OPTIONS IN THE UNITED STATES

Committee on Nutrition, Section on Breastfeeding, and Committee on Fetus and Newborn

ABSTRACT. The use of donor human milk is increasing for high-risk infants, primarily for infants born weighing <1500 g or those who have severe intestinal disorders. Pasteurized donor milk may be considered in situations in which the supply of maternal milk is insufficient. The use of pasteurized donor milk is safe when appropriate measures are used to screen donors and collect, store, and pasteurize the milk and then distribute it through established human milk banks. The use of nonpasteurized donor milk and other forms of direct, Internet-based, or informal human milk sharing does not involve this level of safety and is not recommended. It is important that health care providers counsel families considering milk sharing about the risks of bacterial or viral contamination of nonpasteurized human milk and about the possibilities of exposure to medications, drugs, or herbs in human milk. Currently, the use of pasteurized donor milk is limited by its availability and affordability. The development of public policy to improve and expand access to pasteurized donor milk, including policies that support improved governmental and private financial support for donor milk banks and the use of donor milk, is important. DRINKING WATER FROM PRIVATE WELLS AND RISKS TO CHILDREN

Committee on Environmental Health and Committee on Infectious Diseases

ABSTRACT. Drinking water for approximately one sixth of US households is obtained from private wells. These wells can become contaminated by pollutant chemicals or pathogenic organisms and cause illness. Although the US Environmental Protection Agency and all states offer guidance for construction, maintenance, and testing of private wells, there is little regulation. With few exceptions, well owners are responsible for their own wells. Children may also drink well water at child care or when traveling. Illness resulting from children's ingestion of contaminated water can be severe. This policy statement provides recommendations for inspection, testing, and remediation for wells providing drinking water for children. (5/09, reaffirmed 1/13, 9/19)
https://doi.org/10.1542/peds.2009-0751

DRINKING WATER FROM PRIVATE WELLS AND RISKS TO CHILDREN (TECHNICAL REPORT)

Walter J. Rogan, MD; Michael T. Brady, MD; Committee on Environmental Health; and Committee on Infectious Diseases

ABSTRACT. Drinking water for approximately one sixth of US households is obtained from private wells. These wells can become contaminated by pollutant chemicals or pathogenic organisms, leading to significant illness. Although the US Environmental Protection Agency and all states offer guidance for construction, maintenance, and testing of private wells, there is little regulation, and with few exceptions, well owners are responsible for their own wells. Children may also drink well water at child care or when traveling. Illness resulting from children's ingestion of contaminated water can be severe. This report reviews relevant aspects of groundwater and wells; describes the common chemical and microbiologic contaminants; gives an algorithm with recommendations for inspection, testing, and remediation for wells providing drinking water for children; reviews the definitions and uses of various bottled waters; provides current estimates of costs for well testing; and provides federal, national, state, and, where appropriate, tribal contacts for more information. (5/09, reaffirmed 1/13, 9/19)

DRUGS USED TO TREAT PEDIATRIC EMERGENCIES (CLINICAL REPORT)

Rohit P. Shenoi, MD, FAAP; Nathan Timm, MD, FAAP; Committee on Drugs; and Committee on Pediatric Emergency Medicine

ABSTRACT. This clinical report is a revision of "Preparing for Pediatric Emergencies: Drugs to Consider." It updates the list, indications, and dosages of medications used to treat pediatric emergencies in the prehospital, pediatric clinic, and emergency department settings. Although it is not an all-inclusive list of medications that may be used in all emergencies, this resource will be helpful when treating a vast majority of pediatric medical emergencies. Dosage recommendations are consistent with current emergency references such as the Advanced Pediatric Life Support and Pediatric Advanced Life Support textbooks and American Heart Association resuscitation guidelines. (12/19)
https://doi.org/10.1542/peds.2019-3450

E-CIGARETTES AND SIMILAR DEVICES

Brian P. Jenssen, MD, MSHP, FAAP; Susan C. Walley, MD, FAAP; and Section on Tobacco Control

ABSTRACT. Electronic cigarettes (e-cigarettes) are the most commonly used tobacco product among youth. The 2016 US Surgeon General's Report on e-cigarette use among youth and young adults concluded that e-cigarettes are unsafe for children and adolescents. Furthermore, strong and consistent evidence

finds that children and adolescents who use e-cigarettes are significantly more likely to go on to use traditional cigarettes—a product that kills half its long-term users. E-cigarette manufacturers target children with enticing candy and fruit flavors and use marketing strategies that have been previously successful with traditional cigarettes to attract youth to these products. Numerous toxicants and carcinogens have been found in e-cigarette solutions. Nonusers are involuntarily exposed to the emissions of these devices with secondhand and thirdhand aerosol. To prevent children, adolescents, and young adults from transitioning from e-cigarettes to traditional cigarettes and minimize the potential public health harm from e-cigarette use, there is a critical need for e-cigarette regulation, legislative action, and counterpromotion to protect youth. (1/19)

EARLY CHILDHOOD ADVERSITY, TOXIC STRESS, AND THE ROLE OF THE PEDIATRICIAN: TRANSLATING DEVELOPMENTAL SCIENCE INTO LIFELONG HEALTH

Committee on Psychosocial Aspects of Child and Family Health; Committee on Early Childhood, Adoption, and Dependent Care; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Advances in a wide range of biological, behavioral, and social sciences are expanding our understanding of how early environmental influences (the ecology) and genetic predispositions (the biologic program) affect learning capacities, adaptive behaviors, lifelong physical and mental health, and adult productivity. A supporting technical report from the American Academy of Pediatrics (AAP) presents an integrated ecobiodevelopmental framework to assist in translating these dramatic advances in developmental science into improved health across the life span. Pediatricians are now armed with new information about the adverse effects of toxic stress on brain development, as well as a deeper understanding of the early life origins of many adult diseases. As trusted authorities in child health and development, pediatric providers must now complement the early identification of developmental concerns with a greater focus on those interventions and community investments that reduce external threats to healthy brain growth. To this end, AAP endorses a developing leadership role for the entire pediatric community—one that mobilizes the scientific expertise of both basic and clinical researchers, the family-centered care of the pediatric medical home, and the public influence of AAP and its state chapters—to catalyze fundamental change in early childhood policy and services. AAP is committed to leveraging science to inform the development of innovative strategies to reduce the precipitants of toxic stress in young children and to mitigate their negative effects on the course of development and health across the life span. (12/11, reaffirmed 7/16)

EARLY CHILDHOOD CARIES IN INDIGENOUS COMMUNITIES

Steve Holve, MD; Patricia Braun, MD, MPH; James D. Irvine, MD; Kristen Nadeau, MD, MS; Robert J. Schroth, DMD, MSc, PhD; Committee on Native American Child Health; and Section on Oral Health (joint with Canadian Paediatric Society First Nations Inuit and Métis Health Committee)

ABSTRACT. The oral health of Indigenous children of Canada (First Nations, Inuit, and Métis) and the United States (American Indian and Alaska native) is a major child health disparity when compared with the general population of both countries. Early childhood caries (ECC) occurs in Indigenous children at an earlier age, with a higher prevalence, and at much greater severity than in the general population. ECC results in adverse oral health, affecting childhood health and well-being, and may result in high rates of costly surgical treatment under general anesthesia. ECC is an infectious disease that is influenced by multiple factors, but the social determinants of health are particularly important. This policy statement includes recommendations for preventive and clinical oral health care for infants, toddlers, preschool-aged children, and pregnant women by primary health care providers. It also addresses community-based health-promotion initiatives and access to dental care for Indigenous children. This policy statement encourages oral health interventions at early ages in Indigenous children, including referral to dental care for the use of sealants, interim therapeutic restorations, and silver diamine fluoride. Further community-based research on the microbiology, epidemiology, prevention, and management of ECC in Indigenous communities is also needed to reduce the dismally high rate of caries in this population. (5/21)

EARLY CHILDHOOD HOME VISITING

James H. Duffee, MD, MPH, FAAP; Alan L. Mendelsohn, MD, FAAP; Alice A. Kuo, MD, PhD, FAAP; Lori A. Legano, MD, FAAP; Marian F. Earls, MD, MTS, FAAP; Council on Community Pediatrics; Council on Early Childhood; and Committee on Child Abuse and Neglect

ABSTRACT. High-quality home-visiting services for infants and young children can improve family relationships, advance school readiness, reduce child maltreatment, improve maternal-infant health outcomes, and increase family economic self-sufficiency. The American Academy of Pediatrics supports unwavering federal funding of state home-visiting initiatives, the expansion of evidence-based programs, and a robust, coordinated national evaluation designed to confirm best practices and cost-efficiency. Community home visiting is most effective as a component of a comprehensive early childhood system that actively includes and enhances a family-centered medical home. (8/17)
https://doi.org/10.1542/peds.2017-2150

EARLY INTERVENTION, IDEA PART C SERVICES, AND THE MEDICAL HOME: COLLABORATION FOR BEST PRACTICE AND BEST OUTCOMES (CLINICAL REPORT)

Richard C. Adams, MD; Carl Tapia, MD; and Council on Children With Disabilities

ABSTRACT. The medical home and the Individuals With Disabilities Education Act Part C Early Intervention Program share many common purposes for infants and children ages 0 to 3 years, not the least of which is a family-centered focus. Professionals in pediatric medical home practices see substantial numbers of infants and toddlers with developmental delays and/or complex chronic conditions. Economic, health, and family-focused data each underscore the critical role of timely referral for relationship-based, individualized, accessible early intervention services and the need for collaborative partnerships in care. The medical home process and Individuals With Disabilities Education Act Part C policy both support nurturing relationships and family-centered care; both offer clear value in terms of economic and health outcomes. Best practice models for early intervention services incorporate learning in the natural environment and coaching models. Proactive medical homes provide strategies for effective developmental surveillance, family-centered resources, and tools to support high-risk groups, and comanagement of infants with special health care needs, including the monitoring of services provided and outcomes achieved. (9/13, reaffirmed 5/17)

ECHOCARDIOGRAPHY IN INFANTS AND CHILDREN

Section on Cardiology

ABSTRACT. It is the intent of this statement to inform pediatric providers on the appropriate use of echocardiography. Although

on-site consultation may be impossible, methods should be established to ensure timely review of echocardiograms by a pediatric cardiologist. With advances in data transmission, echocardiography information can be exchanged, in some cases eliminating the need for a costly patient transfer. By cooperating through training, education, and referral, complete and cost-effective echocardiographic services can be provided to all children. (6/97, reaffirmed 3/03, 3/07)
https://doi.org/10.1542/peds.99.6.921

EFFECTIVE DISCIPLINE TO RAISE HEALTHY CHILDREN

Robert D. Sege, MD, PhD, FAAP; Benjamin S. Siegel, MD, FAAP; Council on Child Abuse and Neglect; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Pediatricians are a source of advice for parents and guardians concerning the management of child behavior, including discipline strategies that are used to teach appropriate behavior and protect their children and others from the adverse effects of challenging behavior. Aversive disciplinary strategies, including all forms of corporal punishment and yelling at or shaming children, are minimally effective in the short-term and not effective in the long-term. With new evidence, researchers link corporal punishment to an increased risk of negative behavioral, cognitive, psychosocial, and emotional outcomes for children. In this Policy Statement, the American Academy of Pediatrics provides guidance for pediatricians and other child health care providers on educating parents about positive and effective parenting strategies of discipline for children at each stage of development as well as references to educational materials. This statement supports the need for adults to avoid physical punishment and verbal abuse of children. (11/18)
https://doi.org/10.1542/peds.2018-3112

THE EFFECTS OF ARMED CONFLICT ON CHILDREN

Sherry Shenoda, MD, FAAP; Ayesha Kadir, MD, MSc, FAAP; Shelly Pitterman, PhD; Jeffrey Goldhagen, MD, MPH, FAAP; and Section on International Child Health

ABSTRACT. Children are increasingly exposed to armed conflict and targeted by governmental and nongovernmental combatants. Armed conflict directly and indirectly affects children's physical, mental, and behavioral health. It can affect every organ system, and its impact can persist throughout the life course. In addition, children are disproportionately impacted by morbidity and mortality associated with armed conflict. A children's rights–based approach provides a framework for collaboration by the American Academy of Pediatrics, child health professionals, and national and international partners to respond in the domains of clinical care, systems development, and policy formulation. The American Academy of Pediatrics and child health professionals have critical and synergistic roles to play in the global response to the impact of armed conflict on children. (11/18)
https://doi.org/10.1542/peds.2018-2585

THE EFFECTS OF ARMED CONFLICT ON CHILDREN (TECHNICAL REPORT)

Ayesha Kadir, MD, MSc, FAAP; Sherry Shenoda, MD, FAAP; Jeffrey Goldhagen, MD, MPH, FAAP; Shelly Pitterman, PhD; and Section on International Child Health

ABSTRACT. More than 1 in 10 children worldwide are affected by armed conflict. The effects are both direct and indirect and are associated with immediate and long-term harm. The direct effects of conflict include death, physical and psychological trauma, and displacement. Indirect effects are related to a large number of factors, including inadequate and unsafe living conditions, environmental hazards, caregiver mental health, separation from family, displacement-related health risks, and the destruction of health, public health, education, and economic infrastructure. Children and health workers are targeted by combatants during attacks, and children are recruited or forced to take part in combat in a variety of ways. Armed conflict is both a toxic stress and a significant social determinant of child health. In this Technical Report, we review the available knowledge on the effects of armed conflict on children and support the recommendations in the accompanying Policy Statement on children and armed conflict. (11/18)

THE EFFECTS OF EARLY NUTRITIONAL INTERVENTIONS ON THE DEVELOPMENT OF ATOPIC DISEASE IN INFANTS AND CHILDREN: THE ROLE OF MATERNAL DIETARY RESTRICTION, BREASTFEEDING, HYDROLYZED FORMULAS, AND TIMING OF INTRODUCTION OF ALLERGENIC COMPLEMENTARY FOODS (CLINICAL REPORT)

Frank R. Greer, MD, FAAP; Scott H. Sicherer, MD, FAAP; A. Wesley Burks, MD, FAAP; Committee on Nutrition; and Section on Allergy and Immunology

ABSTRACT. This clinical report updates and replaces a 2008 clinical report from the American Academy of Pediatrics, which addressed the roles of maternal and early infant diet on the prevention of atopic disease, including atopic dermatitis, asthma, and food allergy. As with the previous report, the available data still limit the ability to draw firm conclusions about various aspects of atopy prevention through early dietary interventions. Current evidence does not support a role for maternal dietary restrictions during pregnancy or lactation. Although there is evidence that exclusive breastfeeding for 3 to 4 months decreases the incidence of eczema in the first 2 years of life, there are no short- or long-term advantages for exclusive breastfeeding beyond 3 to 4 months for prevention of atopic disease. The evidence now suggests that any duration of breastfeeding ≥3 to 4 months is protective against wheezing in the first 2 years of life, and some evidence suggests that longer duration of any breastfeeding protects against asthma even after 5 years of age. No conclusions can be made about the role of breastfeeding in either preventing or delaying the onset of specific food allergies. There is a lack of evidence that partially or extensively hydrolyzed formula prevents atopic disease. There is no evidence that delaying the introduction of allergenic foods, including peanuts, eggs, and fish, beyond 4 to 6 months prevents atopic disease. There is now evidence that early introduction of peanuts may prevent peanut allergy. (3/19)

ELECTRONIC COMMUNICATION OF THE HEALTH RECORD AND INFORMATION WITH PEDIATRIC PATIENTS AND THEIR GUARDIANS

Emily C. Webber, MD, FAAP, FAMIA; David Brick, MD, FAAP; James P. Scibilia, MD, FAAP; Peter Dehnel, MD, FAAP; Council on Clinical Information Technology; Committee on Medical Liability and Risk Management; and Section on Telehealth Care

ABSTRACT. Communication of health data has evolved rapidly with the widespread adoption of electronic health records (EHRs) and communication technology. What used to be sent to patients via paper mail, fax, or e-mail may now be accessed by patients via their EHRs, and patients may also communicate securely with their medical team via certified technology. Although EHR technologies have great potential, their most effective applications and uses for communication between pediatric and adolescent patients, guardians, and medical teams has not been realized. There are wide variations in available technologies, guiding policies, and practices; some physicians and patients are successful in using certified tools but others are forced to limit their patients' access to e-health data and associated communication altogether. In general, pediatric and adolescent patients are less likely than adult patients to have

electronic access and the ability to exchange health data. There are several reasons for these limitations, including inconsistent standards and recommendations regarding the recommended age for independent access, lack of routine EHR support for the ability to filter or proxy such access, and conflicting laws about patients' and physicians' rights to access EHRs and ability to communicate electronically. Effective, safe electronic exchange of health data requires active collaboration between physicians, patients, policy makers, and health information technology vendors. This policy statement addresses current best practices for these stakeholders and delineates the continued gaps and how to address them. (6/19)

ELECTRONIC DOCUMENTATION IN PEDIATRICS: THE RATIONALE AND FUNCTIONALITY REQUIREMENTS

Heather C. O'Donnell, MD, MSc, FAAP; Srinivasan Suresh, MD, MBA, FAAP; and Council on Clinical Information Technology

ABSTRACT. Clinical documentation is a fundamental component of the practice of medicine. It has significantly evolved over the past decade, largely because of the growth of health information technology and electronic health records. Although government agencies and other professional organizations have published position statements on the structure and use of electronic documentation, few have specifically addressed the documentation needs for the care of children. A policy statement on electronic documentation of clinical care by general pediatric and subspecialist providers by the American Academy of Pediatrics is needed. This statement provides insight on the unmet needs of key stakeholders to direct future research and development of the electronic media necessary to enhance the wellness of children and improve health care delivery. It also addresses the challenges and opportunities for efficient and effective clinical documentation in pediatrics. (6/20)
https://doi.org/10.1542/peds.2020-1682

ELECTRONIC DOCUMENTATION IN PEDIATRICS: THE RATIONALE AND FUNCTIONALITY REQUIREMENTS (TECHNICAL REPORT)

Heather C. O'Donnell, MD, MSc, FAAP; Srinivasan Suresh, MD, MBA, FAAP; and Council on Clinical Information Technology

ABSTRACT. Clinical documentation has dramatically changed since the implementation and use of electronic health records and electronic provider documentation. The purpose of this report is to review these changes and promote the development of standards and best practices for electronic documentation for pediatric patients. In this report, we evaluate the unique aspects of clinical documentation for pediatric care, including specialized information needs and stakeholders specific to the care of children. Additionally, we explore new models of documentation, such as shared documentation, in which patients may be both authors and consumers, and among care teams while still maintaining the ability to clearly define care and services provided to patients in a given day or encounter. Finally, we describe alternative documentation techniques and newer technologies that could improve provider efficiency and the reuse of clinical data. (6/20)

ELECTRONIC PRESCRIBING IN PEDIATRICS: TOWARD SAFER AND MORE EFFECTIVE MEDICATION MANAGEMENT

Council on Clinical Information Technology

ABSTRACT. This policy statement identifies the potential value of electronic prescribing (e-prescribing) systems in improving quality and reducing harm in pediatric health care. On the basis of limited but positive pediatric data and on the basis of federal statutes that provide incentives for the use of e-prescribing systems, the American Academy of Pediatrics recommends the adoption of e-prescribing systems with pediatric functionality. The American Academy of Pediatrics also recommends a set of functions that technology vendors should provide when e-prescribing systems are used in environments in which children receive care. (3/13, reaffirmed 12/18)
https://doi.org/10.1542/peds.2013-0192

ELECTRONIC PRESCRIBING IN PEDIATRICS: TOWARD SAFER AND MORE EFFECTIVE MEDICATION MANAGEMENT (TECHNICAL REPORT)

Kevin B. Johnson, MD, MS; Christoph U. Lehmann, MD; and Council on Clinical Information Technology

ABSRACT. This technical report discusses recent advances in electronic prescribing (e-prescribing) systems, including the evidence base supporting their limitations and potential benefits. Specifically, this report acknowledges that there are limited but positive pediatric data supporting the role of e-prescribing in mitigating medication errors, improving communication with dispensing pharmacists, and improving medication adherence. On the basis of these data and on the basis of federal statutes that provide incentives for the use of e-prescribing systems, the American Academy of Pediatrics recommends the adoption of e-prescribing systems with pediatric functionality. This report supports the accompanying policy statement from the American Academy of Pediatrics recommending the adoption of e-prescribing by pediatric health care providers. (3/13, reaffirmed 12/18)
https://doi.org/10.1542/peds.2013-0193

ELIMINATION OF PERINATAL HEPATITIS B: PROVIDING THE FIRST VACCINE DOSE WITHIN 24 HOURS OF BIRTH

Committee on Infectious Diseases and Committee on Fetus and Newborn

ABSTRACT. After the introduction of the hepatitis B vaccine in the United States in 1982, a greater than 90% reduction in new infections was achieved. However, approximately 1000 new cases of perinatal hepatitis B infection are still identified annually in the United States. Prevention of perinatal hepatitis B relies on the proper and timely identification of infants born to mothers who are hepatitis B surface antigen positive and to mothers with unknown status to ensure administration of appropriate postexposure immunoprophylaxis with hepatitis B vaccine and immune globulin. To reduce the incidence of perinatal hepatitis B transmission further, the American Academy of Pediatrics endorses the recommendation of the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention that all newborn infants with a birth weight of greater than or equal to 2000 g receive hepatitis B vaccine by 24 hours of age. EMERGENCY CONTRACEPTION

Krishna K. Upadhya, MD, MPH, FAAP, and Committee on Adolescence

ABSTRACT. Despite significant declines over the past 2 decades, the United States continues to experience birth rates among teenagers that are significantly higher than other high-income nations. Use of emergency contraception (EC) within 120 hours after unprotected or underprotected intercourse can reduce the risk of pregnancy. Emergency contraceptive methods include oral medications labeled and dedicated for use as EC by the US Food and Drug Administration (ulipristal and levonorgestrel), the "off-label" use of combined oral contraceptives, and insertion of a copper intrauterine device. Indications for the use of EC include intercourse without use of contraception; condom breakage or slippage; missed or late doses of contraceptives, including the oral contraceptive pill, contraceptive patch, contraceptive

ring, and injectable contraception; vomiting after use of oral contraceptives; and sexual assault. Our aim in this updated policy statement is to (1) educate pediatricians and other physicians on available emergency contraceptive methods; (2) provide current data on the safety, efficacy, and use of EC in teenagers; and (3) encourage routine counseling and advance EC prescription as 1 public health strategy to reduce teenaged pregnancy. EMERGENCY INFORMATION FORMS AND EMERGENCY PREPAREDNESS FOR CHILDREN WITH SPECIAL HEALTH CARE NEEDS

Committee on Pediatric Emergency Medicine and Council on Clinical Information Technology (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

ABSTRACT. Children with chronic medical conditions rely on complex management plans for problems that cause them to be at increased risk for suboptimal outcomes in emergency situations. The emergency information form (EIF) is a medical summary that describes medical condition(s), medications, and special health care needs to inform health care providers of a child's special health conditions and needs so that optimal emergency medical care can be provided. This statement describes updates to EIFs, including computerization of the EIF, expanding the potential benefits of the EIF, quality-improvement programs using the EIF, the EIF as a central repository, and facilitating emergency preparedness in disaster management and drills by using the EIF. (3/10, reaffirmed 7/14, 10/14)

EMERGING ISSUES IN MALE ADOLESCENT SEXUAL AND REPRODUCTIVE HEALTH CARE (CLINICAL REPORT)

Laura K. Grubb, MD, MPH, FAAP; Makia Powers, MD, MPH, MSc, FAAP; and Committee on Adolescence

ABSTRACT. Pediatricians are encouraged to address male adolescent sexual and reproductive health on a regular basis, including taking a sexual history, discussing healthy sexuality, performing an appropriate physical examination, providing patient-centered and age-appropriate anticipatory guidance, and administering appropriate vaccinations. These services can be provided to male adolescent patients in a confidential and culturally appropriate manner, can promote healthy sexual relationships and responsibility, can and involve parents in age-appropriate discussions about sexual health. (4/20)

ENDORSEMENT OF HEALTH AND HUMAN SERVICES RECOMMENDATION FOR PULSE OXIMETRY SCREENING FOR CRITICAL CONGENITAL HEART DISEASE

Section on Cardiology and Cardiac Surgery Executive Committee

ABSTRACT. Incorporation of pulse oximetry to the assessment of the newborn infant can enhance detection of critical congenital heart disease (CCHD). Recently, the Secretary of Health and Human Services (HHS) recommended that screening for CCHD be added to the uniform screening panel. The American Academy of Pediatrics (AAP) has been a strong advocate of early detection of CCHD and fully supports the decision of the Secretary of HHS.

The AAP has published strategies for the implementation of pulse oximetry screening, which addressed critical issues such as necessary equipment, personnel, and training, and also provided specific recommendations for assessment of saturation by using pulse oximetry as well as appropriate management of a positive screening result. The AAP is committed to the safe and effective implementation of pulse oximetry screening and is working with other advocacy groups and governmental agencies to promote pulse oximetry and to support widespread surveillance for CCHD.

Going forward, AAP chapters will partner with state health departments to implement the new screening strategy for CCHD and will work to ensure that there is an adequate system for referral for echocardiographic/pediatric cardiac evaluation after a positive screening result. It is imperative that AAP members engage their respective policy makers in adopting and funding the recommendations made by the Secretary of HHS. (12/11)

ENHANCING PEDIATRIC WORKFORCE DIVERSITY AND PROVIDING CULTURALLY EFFECTIVE PEDIATRIC CARE: IMPLICATIONS FOR PRACTICE, EDUCATION, AND POLICY MAKING

Committee on Pediatric Workforce

ABSTRACT. This policy statement serves to combine and update 2 previously independent but overlapping statements from the American Academy of Pediatrics (AAP) on culturally effective health care (CEHC) and workforce diversity. The AAP has long recognized that with the ever-increasing diversity of the pediatric population in the United States, the health of all children depends on the ability of all pediatricians to practice culturally effective care. CEHC can be defined as the delivery of care within the context of appropriate physician knowledge, understanding, and appreciation of all cultural distinctions, leading to optimal health outcomes. The AAP believes that CEHC is a critical social value and that the knowledge and skills necessary for providing CEHC can be taught and acquired through focused curricula across the spectrum of lifelong learning.

This statement also addresses workforce diversity, health disparities, and affirmative action. The discussion of diversity is broadened to include not only race, ethnicity, and language but also cultural attributes such as gender, religious beliefs, sexual orientation, and disability, which may affect the quality of health care. The AAP believes that efforts must be supported through health policy and advocacy initiatives to promote the delivery of CEHC and to overcome educational, organizational, and other barriers to improving workforce diversity. ENSURING COMPREHENSIVE CARE AND SUPPORT FOR TRANSGENDER AND GENDER-DIVERSE CHILDREN AND ADOLESCENTS

Jason Rafferty, MD, MPH, EdM, FAAP; Committee on Psychosocial Aspects of Child and Family Health; Committee on Adolescence; and Section on Lesbian, Gay, Bisexual, and Transgender Health and Wellness

ABSTRACT. As a traditionally underserved population that faces numerous health disparities, youth who identify as transgender and gender diverse (TGD) and their families are increasingly presenting to pediatric providers for education, care, and referrals. The need for more formal training, standardized treatment, and research on safety and medical outcomes often leaves providers feeling ill equipped to support and care for patients that identify as TGD and families. In this policy statement, we review relevant concepts and challenges and provide suggestions for pediatric providers that are focused on promoting the health and positive development of youth that identify as TGD while eliminating discrimination and stigma. (9/18)

ENSURING THE HEALTH OF CHILDREN IN DISASTERS

Disaster Preparedness Advisory Council and Committee on Pediatric Emergency Medicine

ABSTRACT. Infants, children, adolescents, and young adults have unique physical, mental, behavioral, developmental, communication, therapeutic, and social needs that must be addressed and met in all aspects of disaster preparedness, response, and

recovery. Pediatricians, including primary care pediatricians, pediatric medical subspecialists, and pediatric surgical specialists, have key roles to play in preparing and treating families in cases of disasters. Pediatricians should attend to the continuity of practice operations to provide services in time of need and stay abreast of disaster and public health developments to be active participants in community planning efforts. Federal, state, tribal, local, and regional institutions and agencies that serve children should collaborate with pediatricians to ensure the health and well-being of children in disasters. (10/15, reaffirmed 4/21)
https://doi.org/10.1542/peds.2015-3112

EPIDEMIOLOGY AND DIAGNOSIS OF HEALTH CARE–ASSOCIATED INFECTIONS IN THE NICU (TECHNICAL REPORT)

Committee on Fetus and Newborn and Committee on Infectious Diseases

ABSTRACT. Health care–associated infections in the NICU are a major clinical problem resulting in increased morbidity and mortality, prolonged length of hospital stays, and increased medical costs. Neonates are at high risk for health care–associated infections because of impaired host defense mechanisms, limited amounts of protective endogenous flora on skin and mucosal surfaces at time of birth, reduced barrier function of neonatal skin, the use of invasive procedures and devices, and frequent exposure to broad-spectrum antibiotics. This statement will review the epidemiology and diagnosis of health care–associated infections in newborn infants. (3/12, reaffirmed 2/16)
https://doi.org/10.1542/peds.2012-0147

EPINEPHRINE FOR FIRST-AID MANAGEMENT OF ANAPHYLAXIS (CLINICAL REPORT)

Scott H. Sicherer, MD, FAAP; F. Estelle R. Simons, MD, FAAP; and Section on Allergy and Immunology

ABSTRACT. Anaphylaxis is a severe, generalized allergic or hypersensitivity reaction that is rapid in onset and may cause death. Epinephrine (adrenaline) can be life-saving when administered as rapidly as possible once anaphylaxis is recognized. This clinical report from the American Academy of Pediatrics is an update of the 2007 clinical report on this topic. It provides information to help clinicians identify patients at risk of anaphylaxis and new information about epinephrine and epinephrine autoinjectors (EAs). The report also highlights the importance of patient and family education about the recognition and management of anaphylaxis in the community. Key points emphasized include the following: (1) validated clinical criteria are available to facilitate prompt diagnosis of anaphylaxis; (2) prompt intramuscular epinephrine injection in the mid-outer thigh reduces hospitalizations, morbidity, and mortality; (3) prescribing EAs facilitates timely epinephrine injection in community settings for patients with a history of anaphylaxis and, if specific circumstances warrant, for some high-risk patients who have not previously experienced anaphylaxis; (4) prescribing epinephrine for infants and young children weighing <15 kg, especially those who weigh 7.5 kg and under, currently presents a dilemma, because the lowest dose available in EAs, 0.15 mg, is a high dose for many infants and some young children; (5) effective management of anaphylaxis in the community requires a comprehensive approach involving children, families, preschools, schools, camps, and sports organizations; and (6) prevention of anaphylaxis recurrences involves confirmation of the trigger, discussion of specific allergen avoidance, allergen immunotherapy (eg, with stinging insect venom, if relevant), and a written, personalized anaphylaxis emergency action plan; and (7) the management of anaphylaxis also involves education of children and supervising adults about anaphylaxis recognition and first-aid treatment. EQUIPMENT FOR GROUND AMBULANCES

American Academy of Pediatrics (joint with American College of Emergency Physicians, American College of Surgeons Committee on Trauma, Emergency Medical Services for Children, Emergency Nurses Association, National Association of EMS Physicians, and National Association of State EMS Officials)

On January 1, 2014, the American Academy of Pediatrics, American College of Emergency Physicians, American College of Surgeons Committee on Trauma, Emergency Medical Services for Children, Emergency Nurses Association, National Association of EMS Physicians, and National Association of State EMS Officials coauthored a joint policy statement, "Equipment for Ground Ambulances" (*Prehosp Emerg Care.* 2014;19[1]:92–97). The full text of the joint policy statement is available at: http://informahealthcare.com/doi/full/10.3109/10903127.2013.851312. (8/14, reaffirmed 1/20)
https://doi.org/10.1542/peds.2014-1698

ERADICATING POLIO: HOW THE WORLD'S PEDIATRICIANS CAN HELP STOP THIS CRIPPLING ILLNESS FOREVER (CLINICAL REPORT)

Walter A. Orenstein, MD, FAAP, and Committee on Infectious Diseases

ABSTRACT. The American Academy of Pediatrics strongly supports the Polio Eradication and Endgame Strategic Plan of the Global Polio Eradication Initiative. This plan was endorsed in November 2012 by the Strategic Advisory Group of Experts on Immunization of the World Health Organization and published by the World Health Organization in April 2013. As a key component of the plan, it will be necessary to stop oral polio vaccine (OPV) use globally to achieve eradication, because the attenuated viruses in the vaccine rarely can cause polio. The plan includes procedures for elimination of vaccine-associated paralytic polio and circulating vaccine-derived polioviruses (cVDPVs). cVDPVs can proliferate when vaccine viruses are transmitted among susceptible people, resulting in mutations conferring both the neurovirulence and transmissibility characteristics of wild polioviruses. Although there are 3 different types of wild poliovirus strains, the polio eradication effort has already resulted in the global elimination of type 2 poliovirus for more than a decade. Type 3 poliovirus may be eliminated because the wild type 3 poliovirus was last detected in 2012. Thus, of the 3 wild types, only wild type 1 poliovirus is still known to be circulating and causing disease. OPV remains the key vaccine for eradicating wild polioviruses in polio-infected countries because it induces high levels of systemic immunity to prevent paralysis and intestinal immunity to reduce transmission. However, OPV is a rare cause of paralysis and the substantial decrease in wild-type disease has resulted in estimates that the vaccine is causing more polio-related paralysis annually in recent years than the wild virus. The new endgame strategic plan calls for stepwise removal of the type 2 poliovirus component from trivalent oral vaccines, because type 2 wild poliovirus appears to have been eradicated (since 1999) and yet is the main cause of cVDPV outbreaks and approximately 40% of vaccine-associated paralytic polio cases. The Endgame and Strategic Plan will be accomplished by shifting from trivalent OPV to bivalent OPV (containing types 1 and 3 poliovirus only). It will be necessary to introduce trivalent inactivated poliovirus vaccine (IPV) into routine immunization programs in all countries using OPV to provide population immunity to type 2 before the switch from trivalent OPV to bivalent OPV. The Global Polio Eradication Initiative hopes to achieve global eradication of polio by 2018 with this strategy, after which all OPV use will be stopped. Challenges expected for adding IPV into routine immunization schedules include higher cost of IPV compared with OPV, cold-chain capacity limits, more complex administration of vaccine because IPV requires injections as opposed to oral administra-

tion, and inferior intestinal immunity conferred by IPV. The goal of this report is to help pediatricians understand the change in strategy and outline ways that pediatricians can help global polio eradication efforts, including advocating for the resources needed to accomplish polio eradication and for incorporation of IPV into routine immunization programs in all countries. (12/14, reaffirmed 5/19)

ESSENTIAL CONTRACTUAL LANGUAGE FOR MEDICAL NECESSITY IN CHILDREN

Committee on Child Health Financing

ABSTRACT. The previous policy statement from the American Academy of Pediatrics, "Model Language for Medical Necessity in Children," was published in July 2005. Since that time, there have been new and emerging delivery and payment models. The relationship established between health care providers and health plans should promote arrangements that are beneficial to all who are affected by these contractual arrangements. Pediatricians play an important role in ensuring that the needs of children are addressed in these emerging systems. It is important to recognize that health care plans designed for adults may not meet the needs of children. Language in health care contracts should reflect the health care needs of children and families. Informed pediatricians can make a difference in the care of children and influence the role of primary care physicians in the new paradigms. This policy highlights many of the important elements pediatricians should assess as providers develop a role in emerging care models. (7/13, reaffirmed 9/17)

ESTABLISHING A STANDARD PROTOCOL FOR THE VOIDING CYSTOURETHROGRAPHY (CLINICAL REPORT)

Dominic Frimberger, MD; Maria-Gisela Mercado-Deane, MD, FAAP; Section on Urology; and Section on Radiology

ABSTRACT. The voiding cystourethrogram (VCUG) is a frequently performed test to diagnose a variety of urologic conditions, such as vesicoureteral reflux. The test results determine whether continued observation or an interventional procedure is indicated. VCUGs are ordered by many specialists and primary care providers, including pediatricians, family practitioners, nephrologists, hospitalists, emergency department physicians, and urologists. Current protocols for performing and interpreting a VCUG are based on the International Reflux Study in 1985. However, more recent information provided by many national and international institutions suggests a need to refine those recommendations. The lead author of the 1985 study, R.L. Lebowitz, agreed to and participated in the current protocol. In addition, a recent survey directed to the chairpersons of pediatric radiology of 65 children's hospitals throughout the United States and Canada showed that VCUG protocols vary substantially. Recent guidelines from the American Academy of Pediatrics (AAP) recommend a VCUG for children between 2 and 24 months of age with urinary tract infections but did not specify how this test should be performed. To improve patient safety and to standardize the data obtained when a VCUG is performed, the AAP Section on Radiology and the AAP Section on Urology initiated the current VCUG protocol to create a consensus on how to perform this test. (10/16)
https://doi.org/10.1542/peds.2016-2590

ETHICAL AND POLICY ISSUES IN GENETIC TESTING AND SCREENING OF CHILDREN

Committee on Bioethics and Committee on Genetics (joint with American College of Medical Genetics and Genomics)

ABSTRACT. The genetic testing and genetic screening of children are commonplace. Decisions about whether to offer genetic testing and screening should be driven by the best interest of the child. The growing literature on the psychosocial and clinical effects of such testing and screening can help inform best practices. This policy statement represents recommendations developed collaboratively by the American Academy of Pediatrics and the American College of Medical Genetics and Genomics with respect to many of the scenarios in which genetic testing and screening can occur. (2/13, reaffirmed 6/18)
https://doi.org/10.1542/peds.2012-3680

ETHICAL CONSIDERATIONS IN PEDIATRICIANS' USE OF SOCIAL MEDIA (CLINICAL REPORT)

Robert Macauley, MD, FAAP; Nanette Elster, JD, MPH; Jonathan M. Fanaroff, MD, JD, FAAP; Committee on Bioethics; and Committee on Medical Liability and Risk Management

ABSTRACT. Increasing use of social media by patients and clinicians creates opportunities as well as dilemmas for pediatricians, who must recognize the inherent ethical and legal complexity of these communication platforms and maintain professionalism in all contexts. Social media can be a useful tool in the practice of medicine by educating both physicians and patients, expanding access to health care, identifying high-risk behaviors, contributing to research, promoting networking and online support, enhancing advocacy, and nurturing professional compassion. At the same time, there are confidentiality, privacy, professionalism, and boundary issues that need to be considered whenever potential interactions occur between physicians and patients via social media. This clinical report is designed to assist pediatricians in identifying and navigating ethical issues to harness the opportunities and avoid the pitfalls of social media. (2/21)

ETHICAL CONSIDERATIONS IN RESEARCH WITH SOCIALLY IDENTIFIABLE POPULATIONS

Committee on Native American Child Health and Committee on Community Health Services

ABSTRACT. Community-based research raises ethical issues not normally encountered in research conducted in academic settings. In particular, conventional risk-benefits assessments frequently fail to recognize harms that can occur in socially identifiable populations as a result of research participation. Furthermore, many such communities require more stringent measures of beneficence that must be applied directly to the participating communities. In this statement, the American Academy of Pediatrics sets forth recommendations for minimizing harms that may result from community-based research by emphasizing community involvement in the research process. (1/04, reaffirmed 10/07, 1/13)
https://doi.org/10.1542/peds.113.1.148

ETHICAL CONTROVERSIES IN ORGAN DONATION AFTER CIRCULATORY DEATH

Committee on Bioethics

ABSTRACT. The persistent mismatch between the supply of and need for transplantable organs has led to efforts to increase the supply, including controlled donation after circulatory death (DCD). Controlled DCD involves organ recovery after the planned withdrawal of life-sustaining treatment and the declaration of death according to the cardiorespiratory criteria. Two central ethical issues in DCD are when organ recovery can begin and how to manage conflicts of interests. The "dead donor rule" should be maintained, and donors in cases of DCD should only be declared dead after the permanent cessation of circulatory function. Permanence is generally established by a 2- to 5-minute waiting period. Given ongoing controversy over whether the cessation must also be irreversible, physicians should not be required to participate in DCD. Because the preparation for organ recovery in DCD begins before the declaration

of death, there are potential conflicts between the donor's and recipient's interests. These conflicts can be managed in a variety of ways, including informed consent and separating the various participants' roles. For example, informed consent should be sought for premortem interventions to improve organ viability, and organ procurement organization personnel and members of the transplant team should not be involved in the discontinuation of life-sustaining treatment or the declaration of death. It is also important to emphasize that potential donors in cases of DCD should receive integrated interdisciplinary palliative care, including sedation and analgesia. (4/13, reaffirmed 12/16)
https://doi.org/10.1542/peds.2013-0672

EVALUATING CHILDREN WITH FRACTURES FOR CHILD PHYSICAL ABUSE (CLINICAL REPORT)

Emalee G. Flaherty, MD, FAAP; Jeannette M. Perez-Rossello, MD; Michael A. Levine, MD; William L. Hennrikus, MD; Committee on Child Abuse and Neglect; Section on Radiology; Section on Endocrinology; and Section on Orthopaedics (joint with Society for Pediatric Radiology)

ABSTRACT. Fractures are common injuries caused by child abuse. Although the consequences of failing to diagnose an abusive injury in a child can be grave, incorrectly diagnosing child abuse in a child whose fractures have another etiology can be distressing for a family. The aim of this report is to review recent advances in the understanding of fracture specificity, the mechanism of fractures, and other medical diseases that predispose to fractures in infants and children. This clinical report will aid physicians in developing an evidence-based differential diagnosis and performing the appropriate evaluation when assessing a child with fractures. (1/14)
https://doi.org/10.1542/peds.2013-3793

EVALUATING FOR SUSPECTED CHILD ABUSE: CONDITIONS THAT PREDISPOSE TO BLEEDING (TECHNICAL REPORT)

Shannon L. Carpenter, MD, MS; Thomas C. Abshire, MD; James D. Anderst, MD, MS; Section on Hematology/Oncology; and Committee on Child Abuse and Neglect

ABSTRACT. Child abuse might be suspected when children present with cutaneous bruising, intracranial hemorrhage, or other manifestations of bleeding. In these cases, it is necessary to consider medical conditions that predispose to easy bleeding/bruising. When evaluating for the possibility of bleeding disorders and other conditions that predispose to hemorrhage, the pediatrician must consider the child's presenting history, medical history, and physical examination findings before initiating a laboratory investigation. Many medical conditions can predispose to easy bleeding. Before ordering laboratory tests for a disease, it is useful to understand the biochemical basis and clinical presentation of the disorder, condition prevalence, and test characteristics. This technical report reviews the major medical conditions that predispose to bruising/bleeding and should be considered when evaluating for abusive injury. (3/13, reaffirmed 7/16)

EVALUATION AND MANAGEMENT OF CHILDREN AND ADOLESCENTS WITH ACUTE MENTAL HEALTH OR BEHAVIORAL PROBLEMS. PART I: COMMON CLINICAL CHALLENGES OF PATIENTS WITH MENTAL HEALTH AND/OR BEHAVIORAL EMERGENCIES (CLINICAL REPORT)

Thomas H. Chun, MD, MPH, FAAP; Sharon E. Mace, MD, FAAP, FACEP; Emily R. Katz, MD, FAAP; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

INTRODUCTION. Mental health problems are among the leading contributors to the global burden of disease. Unfortunately, pediatric populations are not spared of mental health problems. In the United States, 21% to 23% of children and adolescents have a diagnosable mental health or substance use disorder. Among patients of emergency departments (EDs), 70% screen positive for at least 1 mental health disorder, 23% meet criteria for 2 or more mental health concerns, 45% have a mental health problem resulting in impaired psychosocial functioning, and 10% of adolescents endorse significant levels of psychiatric distress at the time of their ED visit. In pediatric primary care settings, the reported prevalence of mental health and behavioral disorders is between 12% to 22% of children and adolescents.

Although the American Academy of Pediatrics (AAP) has published a policy statement on mental health competencies and a Mental Health Toolkit for pediatric primary care providers, no such guidelines or resources exist for clinicians who care for pediatric mental health emergencies. This clinical report supports the 2006 joint policy statement of the AAP and American College of Emergency Physicians (ACEP) on pediatric mental health emergencies, with the goal of addressing the knowledge gaps in this area. The report is written primarily from the perspective of ED clinicians, but it is intended for all clinicians who care for children and adolescents with acute mental health and behavioral problems.

Recent epidemiologic studies of mental health visits have revealed a rapid burgeoning of both ED and primary care visits. An especially problematic trend is the increase in "boarding" of psychiatric patients in the ED and inpatient pediatric beds (ie, extended stays lasting days or even weeks). Although investigation of boarding practices is still in its infancy, the ACEP and the American Medical Association have both expressed concern about it, because it significantly taxes the functioning and efficiency of both the ED and hospital, and mental health services may not be available in the ED.

In addition, compared with other pediatric care settings, ED patients are known to be at higher risk of mental health disorders, including depression, anxiety, posttraumatic stress disorder, and substance abuse. These mental health conditions may be unrecognized not only by treating clinicians but also by the child/adolescent and his or her parents. A similar phenomenon has been described with suicidal patients. Individuals who have committed suicide frequently visited a health care provider in the months preceding their death. Although a minority of suicidal patients present with some form of self-harm, many have vague somatic complaints (eg, headache, gastrointestinal tract distress, back pain, concern for a sexually transmitted infection) masking their underlying mental health condition.

Despite studies demonstrating moderate agreement between emergency physicians and psychiatrists in the assessment and management of patients with mental health problems, ED clinicians frequently cite lack of training and confidence in their abilities as barriers to caring for patients with mental health emergencies. Another study of emergency medicine and pediatric emergency medicine training programs found that formal training in psychiatric problems is not required nor offered by most programs. Pediatric primary care providers report similar barriers to caring for their patients with mental health problems.

Part I of this clinical report focuses on the issues relevant to patients presenting to the ED with a mental health chief complaint and covers the following topics:

- Medical clearance of pediatric psychiatric patients
- Suicidal ideation and suicide attempts
- Involuntary hospitalization
- Restraint of the agitated patient
  - — Verbal restraint
  - — Chemical restraint
  - — Physical restraint
- Coordination with the medical home

Part II discusses challenging patients with primarily medical or indeterminate presentations, in which the contribution of an underlying mental health condition may be unclear or a complicating factor, including:

- Somatic symptom and related disorders
- Adverse effects to psychiatric medications
  — Antipsychotic adverse effects
  — Neuroleptic malignant syndrome
  — Serotonin syndrome
- Children with special needs in the ED (autism spectrum and developmental disorders)
- Mental health screening in the ED

An executive summary of this clinical report can be found at www.pediatrics.org/cgi/doi/10.1542/peds.2016-1571. (8/16)
https://doi.org/10.1542/peds.2016-1570

EVALUATION AND MANAGEMENT OF CHILDREN AND ADOLESCENTS WITH ACUTE MENTAL HEALTH OR BEHAVIORAL PROBLEMS. PART I: COMMON CLINICAL CHALLENGES OF PATIENTS WITH MENTAL HEALTH AND/OR BEHAVIORAL EMERGENCIES—EXECUTIVE SUMMARY (CLINICAL REPORT)

Thomas H. Chun, MD, MPH, FAAP; Sharon E. Mace, MD, FAAP, FACEP; Emily R. Katz, MD, FAAP; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

ABSTRACT. The number of children and adolescents seen in emergency departments (EDs) and primary care settings for mental health problems has skyrocketed in recent years, with up to 23% of patients in both settings having diagnosable mental health conditions. Even when a mental health problem is not the focus of an ED or primary care visit, mental health conditions, both known and occult, may challenge the treating clinician and complicate the patient's care.

Although the American Academy of Pediatrics has published a policy statement on mental health competencies and a Mental Health Toolkit for pediatric primary care providers, no such guidelines or resources exist for clinicians who care for pediatric mental health emergencies. Many ED and primary care physicians report a paucity of training and lack of confidence in caring for pediatric psychiatry patients. The 2 clinical reports (www.pediatrics.org/cgi/doi/10.1542/peds.2016-1570 and www.pediatrics.org/cgi/doi/10.1542/peds.2016-1573) support the 2006 joint policy statement of the American Academy of Pediatrics and the American College of Emergency Physicians on pediatric mental health emergencies, with the goal of addressing the knowledge gaps in this area. Although written primarily from the perspective of ED clinicians, they are intended for all clinicians who care for children and adolescents with acute mental health and behavioral problems.

The clinical reports are organized around the common clinical challenges pediatric caregivers face, both when a child or adolescent presents with a psychiatric chief complaint or emergency (part I) and also when a mental health condition may be an unclear or complicating factor in a non–mental health clinical presentation (part II). Part II of the clinical reports (www.pediatrics.org/cgi/doi/10.1542/peds.2016-1573) includes discussions of somatic symptom and related disorders, adverse effects of psychiatric medications including neuroleptic malignant syndrome and serotonin syndrome, caring for children with special needs such as autism and developmental disorders, and mental health screening. This executive summary is an overview of part I of the clinical reports. The full text of the below topics can be accessed online at (www.pediatrics.org/cgi/doi/10.1542/peds.2016-1570). (8/16)
https://doi.org/10.1542/peds.2016-1571

EVALUATION AND MANAGEMENT OF CHILDREN WITH ACUTE MENTAL HEALTH OR BEHAVIORAL PROBLEMS. PART II: RECOGNITION OF CLINICALLY CHALLENGING MENTAL HEALTH RELATED CONDITIONS PRESENTING WITH MEDICAL OR UNCERTAIN SYMPTOMS (CLINICAL REPORT)

Thomas H. Chun, MD, MPH, FAAP; Sharon E. Mace, MD, FAAP, FACEP; Emily R. Katz, MD, FAAP; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

INTRODUCTION. Part I of this clinical report (http://www.pediatrics.org/cgi/doi/10.1542/peds.2016-1570) discusses the common clinical issues that may be encountered in caring for children and adolescents presenting to the emergency department (ED) or primary care setting with a mental health condition or emergency and includes the following:

- Medical clearance of pediatric psychiatric patients
- Suicidal ideation and suicide attempts
- Involuntary hospitalization
- Restraint of the agitated patient
  — Verbal restraint
  — Chemical restraint
  — Physical restraint
- Coordination with the medical home

Part II discusses the challenges a pediatric clinician may face when evaluating patients with a mental health condition, which may be contributing to or a complicating factor for a medical or indeterminate clinical presentation. Topics covered include the following:

- Somatic symptom and related disorders
- Adverse effects of psychiatric medications
  — Antipsychotic adverse effects
  — Neuroleptic malignant syndrome
  — Serotonin syndrome
- Children with special needs (autism spectrum disorders [ASDs] and developmental disorders [DDs])
- Mental health screening

The report is written primarily from the perspective of ED clinicians, but it is intended for all clinicians who care for children and adolescents with acute mental health and behavioral problems. An executive summary of this clinical report can be found at http://www.pediatrics.org/cgi/doi/10.1542/peds.2016-1574. (8/16)
https://doi.org/10.1542/peds.2016-1573

EVALUATION AND MANAGEMENT OF CHILDREN WITH ACUTE MENTAL HEALTH OR BEHAVIORAL PROBLEMS. PART II: RECOGNITION OF CLINICALLY CHALLENGING MENTAL HEALTH RELATED CONDITIONS PRESENTING WITH MEDICAL OR UNCERTAIN SYMPTOMS—EXECUTIVE SUMMARY (CLINICAL REPORT)

Thomas H. Chun, MD, MPH, FAAP; Sharon E. Mace, MD, FAAP, FACEP; Emily R. Katz, MD, FAAP; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee)

ABSTRACT. The number of children and adolescents seen in emergency departments (EDs) and primary care settings for mental health problems has skyrocketed in recent years, with up to 23% of patients in both settings having diagnosable mental health conditions. Even when a mental health problem is not the focus of an ED or primary care visit, mental health conditions, both known and occult, may challenge the treating clinician and complicate the patient's care.

Although the American Academy of Pediatrics (AAP) has published a policy statement on mental health competencies and a Mental Health Toolkit for pediatric primary care providers,

no such guidelines or resources exist for clinicians who care for pediatric mental health emergencies. Many ED and primary care physicians report paucity of training and lack of confidence in caring for pediatric psychiatry patients. The 2 clinical reports support the 2006 joint policy statement of the AAP and the American College of Emergency Physicians on pediatric mental health emergencies, with the goal of addressing the knowledge gaps in this area. Although written primarily from the perspective of ED clinicians, it is intended for all clinicians who care for children and adolescents with acute mental health and behavioral problems. They are organized around the common clinical challenges pediatric caregivers face, both when a child or adolescent presents with a psychiatric chief complaint or emergency (part I) and when a mental health condition may be an unclear or complicating factor in a non-mental health ED presentation (part II). Part I of the clinical reports includes discussions of Medical Clearance of Pediatric Psychiatric Patients; Suicide and Suicidal Ideation; Restraint of the Agitated Patient Including Verbal, Chemical, and Physical Restraint; and Coordination of Care With the Medical Home, and it can be accessed online at www.pediatrics.org/cgi/doi/10.1542/peds.2016-1570. This executive summary is an overview of part II of the clinical reports. Full text of the following topics can be accessed online at www.pediatrics.org/cgi/doi/10.1542/peds.2016-1573. (8/16)

https://doi.org/10.1542/peds.2016-1574

EVALUATION AND MANAGEMENT OF THE INFANT EXPOSED TO HIV IN THE UNITED STATES (CLINICAL REPORT)

Ellen Gould Chadwick, MD, FAAP; Echezona Edozie Ezeanolue, MD, MPH, FAAP; and Committee on Pediatric AIDS

ABSTRACT. Pediatricians play a crucial role in optimizing the prevention of perinatal transmission of HIV infection. Pediatricians provide antiretroviral prophylaxis to infants born to women with HIV type 1 (HIV) infection during pregnancy and to those whose mother's status was first identified during labor or delivery. Infants whose mothers have an undetermined HIV status should be tested for HIV infection within the boundaries of state laws and receive presumptive HIV therapy if the results are positive. Pediatricians promote avoidance of postnatal HIV transmission by advising mothers with HIV not to breastfeed. Pediatricians test the infant exposed to HIV for determination of HIV infection and monitor possible short- and long-term toxicity from antiretroviral exposure. Finally, pediatricians support families living with HIV by providing counseling to parents or caregivers as an important component of care. (10/20)

https://doi.org/10.1542/peds.2020-029058

EVALUATION AND MANAGEMENT OF WELL-APPEARING FEBRILE INFANTS 8 TO 60 DAYS OLD

Robert H. Pantell, MD, FAAP; Kenneth B. Roberts, MD, FAAP; William G. Adams, MD, FAAP; Benard P. Dreyer, MD, FAAP; Nathan Kuppermann, MD, MPH, FAAP, FACEP; Sean T. O'Leary, MD, MPH, FAAP; Kymika Okechukwu, MPA; Charles R. Woods Jr, MD, MS, FAAP; and Subcommittee on Febrile Infants

ABSTRACT. This guideline addresses the evaluation and management of well-appearing, term infants, 8 to 60 days of age, with fever ≥38.0°C. Exclusions are noted. After a commissioned evidence-based review by the Agency for Healthcare Research and Quality, an additional extensive and ongoing review of the literature, and supplemental data from published, peer-reviewed studies provided by active investigators, 21 key action statements were derived. For each key action statement, the quality of evidence and benefit-harm relationship were assessed and graded to determine the strength of recommendations. When appropriate, parents' values and preferences should be incorporated as part of shared decision-making. For diagnostic testing, the committee has attempted to develop numbers needed to test, and for antimicrobial administration, the committee provided numbers needed to treat. Three algorithms summarize the recommendations for infants 8 to 21 days of age, 22 to 28 days of age, and 29 to 60 days of age. The recommendations in this guideline do not indicate an exclusive course of treatment or serve as a standard of medical care. Variations, taking into account individual circumstances, may be appropriate. (7/21)

https://doi.org/10.1542/peds.2021-052228

EVALUATION AND REFERRAL FOR DEVELOPMENTAL DYSPLASIA OF THE HIP IN INFANTS (CLINICAL REPORT)

Brian A. Shaw, MD, FAAOS, FAAP; Lee S. Segal, MD, FAAOS, FAAP; and Section on Orthopaedics

ABSTRACT. Developmental dysplasia of the hip (DDH) encompasses a wide spectrum of clinical severity, from mild developmental abnormalities to frank dislocation. Clinical hip instability occurs in 1% to 2% of full-term infants, and up to 15% have hip instability or hip immaturity detectable by imaging studies. Hip dysplasia is the most common cause of hip arthritis in women younger than 40 years and accounts for 5% to 10% of all total hip replacements in the United States. Newborn and periodic screening have been practiced for decades, because DDH is clinically silent during the first year of life, can be treated more effectively if detected early, and can have severe consequences if left untreated. However, screening programs and techniques are not uniform, and there is little evidence-based literature to support current practice, leading to controversy. Recent literature shows that many mild forms of DDH resolve without treatment, and there is a lack of agreement on ultrasonographic diagnostic criteria for DDH as a disease versus developmental variations. The American Academy of Pediatrics has not published any policy statements on DDH since its 2000 clinical practice guideline and accompanying technical report. Developments since then include a controversial US Preventive Services Task Force "inconclusive" determination regarding usefulness of DDH screening, several prospective studies supporting observation over treatment of minor ultrasonographic hip variations, and a recent evidence-based clinical practice guideline from the American Academy of Orthopaedic Surgeons on the detection and management of DDH in infants 0 to 6 months of age. The purpose of this clinical report was to provide literature-based updated direction for the clinician in screening and referral for DDH, with the primary goal of preventing and/or detecting a dislocated hip by 6 to 12 months of age in an otherwise healthy child, understanding that no screening program has eliminated late development or presentation of a dislocated hip and that the diagnosis and treatment of milder forms of hip dysplasia remain controversial. (11/16, reaffirmed 6/21)

EVALUATION AND REFERRAL OF CHILDREN WITH SIGNS OF EARLY PUBERTY (CLINICAL REPORT)

Paul Kaplowitz, MD, PhD, FAAP; Clifford Bloch, MD, FAAP; and Section on Endocrinology

ABSTRACT. Concerns about possible early pubertal development are a common cause for referral to pediatric medical subspecialists. Several recent studies have suggested that onset of breast and/or pubic hair development may be occurring earlier than in the past. Although there is a chance of finding pathology in girls with signs of puberty before 8 years of age and in boys before 9 years of age, the vast majority of these children with signs of apparent puberty have variations of normal growth and physical development and do not require laboratory testing, bone age radiographs, or intervention. The most common of these signs of early puberty are premature adrenarche (early onset of pubic hair and/or body odor), premature thelarche (nonprogressive breast development, usually occurring before 2

years of age), and lipomastia, in which girls have apparent breast development which, on careful palpation, is determined to be adipose tissue. Indicators that the signs of sexual maturation may represent true, central precocious puberty include progressive breast development over a 4- to 6-month period of observation or progressive penis and testicular enlargement, especially if accompanied by rapid linear growth. Children exhibiting these true indicators of early puberty need prompt evaluation by the appropriate pediatric medical subspecialist. Therapy with a gonadotropin-releasing hormone agonist may be indicated, as discussed in this report. (12/15)

EVALUATION FOR BLEEDING DISORDERS IN SUSPECTED CHILD ABUSE (CLINICAL REPORT)

James D. Anderst, MD, MS; Shannon L. Carpenter, MD, MS; Thomas C. Abshire, MD; Section on Hematology/Oncology; and Committee on Child Abuse and Neglect

ABSTRACT. Bruising or bleeding in a child can raise the concern for child abuse. Assessing whether the findings are the result of trauma and/or whether the child has a bleeding disorder is critical. Many bleeding disorders are rare, and not every child with bruising/bleeding concerning for abuse requires an evaluation for bleeding disorders. In some instances, however, bleeding disorders can present in a manner similar to child abuse. The history and clinical evaluation can be used to determine the necessity of an evaluation for a possible bleeding disorder, and prevalence and known clinical presentations of individual bleeding disorders can be used to guide the extent of the laboratory testing. This clinical report provides guidance to pediatricians and other clinicians regarding the evaluation for bleeding disorders when child abuse is suspected. (3/13, reaffirmed 7/16)

THE EVALUATION OF CHILDREN IN THE PRIMARY CARE SETTING WHEN SEXUAL ABUSE IS SUSPECTED (CLINICAL REPORT)

Carole Jenny, MD, MBA, FAAP; James E. Crawford-Jakubiak, MD, FAAP; and Committee on Child Abuse and Neglect

ABSTRACT. This clinical report updates a 2005 report from the American Academy of Pediatrics on the evaluation of sexual abuse in children. The medical assessment of suspected child sexual abuse should include obtaining a history, performing a physical examination, and obtaining appropriate laboratory tests. The role of the physician includes determining the need to report suspected sexual abuse; assessing the physical, emotional, and behavioral consequences of sexual abuse; providing information to parents about how to support their child; and coordinating with other professionals to provide comprehensive treatment and follow-up of children exposed to child sexual abuse. (7/13, reaffirmed 8/18)
https://doi.org/10.1542/peds.2013-1741

THE EVALUATION OF SEXUAL BEHAVIORS IN CHILDREN (CLINICAL REPORT)

Nancy D. Kellogg, MD, and Committee on Child Abuse and Neglect

ABSTRACT. Most children will engage in sexual behaviors at some time during childhood. These behaviors may be normal but can be confusing and concerning to parents or disruptive or intrusive to others. Knowledge of age-appropriate sexual behaviors that vary with situational and environmental factors can assist the clinician in differentiating normal sexual behaviors from sexual behavior problems. Most situations that involve sexual behaviors in young children do not require child protective services intervention; for behaviors that are age-appropriate and transient, the pediatrician may provide guidance in supervision and monitoring of the behavior. If the behavior is intrusive, hurtful, and/or age-inappropriate, a more comprehensive assessment is warranted. Some children with sexual behavior problems may reside or have resided in homes characterized by inconsistent parenting, violence, abuse, or neglect and may require more immediate intervention and referrals. (8/09, reaffirmed 3/13, 10/18)

THE EVALUATION OF SUSPECTED CHILD PHYSICAL ABUSE (CLINICAL REPORT)

Cindy W. Christian, MD, FAAP, and Committee on Child Abuse and Neglect

ABSTRACT. Child physical abuse is an important cause of pediatric morbidity and mortality and is associated with major physical and mental health problems that can extend into adulthood. Pediatricians are in a unique position to identify and prevent child abuse, and this clinical report provides guidance to the practitioner regarding indicators and evaluation of suspected physical abuse of children. The role of the physician may include identifying abused children with suspicious injuries who present for care, reporting suspected abuse to the child protection agency for investigation, supporting families who are affected by child abuse, coordinating with other professionals and community agencies to provide immediate and long-term treatment to victimized children, providing court testimony when necessary, providing preventive care and anticipatory guidance in the office, and advocating for policies and programs that support families and protect vulnerable children. (4/15)

EVIDENCE FOR THE DIAGNOSIS AND TREATMENT OF ACUTE UNCOMPLICATED SINUSITIS IN CHILDREN: A SYSTEMATIC REVIEW (TECHNICAL REPORT)

Michael J. Smith, MD, MSCE

ABSTRACT. In 2001, the American Academy of Pediatrics published clinical practice guidelines for the management of acute bacterial sinusitis (ABS) in children. The technical report accompanying those guidelines included 21 studies that assessed the diagnosis and management of ABS in children. This update to that report incorporates studies of pediatric ABS that have been performed since 2001. Overall, 17 randomized controlled trials of the treatment of sinusitis in children were identified and analyzed. Four randomized, double-blind, placebo-controlled trials of antimicrobial therapy have been published. The results of these studies varied, likely due to differences in inclusion and exclusion criteria. Because of this heterogeneity, formal meta-analyses were not performed. However, qualitative analysis of these studies suggests that children with greater severity of illness at presentation are more likely to benefit from antimicrobial therapy. An additional 5 trials compared different antimicrobial therapies but did not include placebo groups. Six trials assessed a variety of ancillary treatments for ABS in children, and 3 focused on subacute sinusitis. Although the number of pediatric trials has increased since 2001, there are still limited data to guide the diagnosis and management of ABS in children. Diagnostic and treatment guidelines focusing on severity of illness at the time of presentation have the potential to identify those children most likely to benefit from antimicrobial therapy and at the same time minimize unnecessary use of antibiotics. EXECUTIVE SUMMARY: CRITERIA FOR CRITICAL CARE OF INFANTS AND CHILDREN: PICU ADMISSION, DISCHARGE, AND TRIAGE PRACTICE STATEMENT AND LEVELS OF CARE GUIDANCE

Benson S. Hsu, MD, MBA, FAAP; Vanessa Hill, MD, FAAP; Lorry R. Frankel, MD, FCCM; Timothy S. Yeh, MD, MCCM; Shari Simone, CRNP, DNP, FCCM, FAANP, FAAN; Marjorie J. Arca, MD, FACS, FAAP; Jorge A. Coss-Bu, MD; Mary E. Fallat, MD, FACS, FAAP; Jason Foland, MD; Samir Gadepalli, MD, MBA; Michael O. Gayle, BS, MD, FCCM; Lori A. Harmon, RRT, MBA, CPHQ; Christa A. Joseph, RN, MSN; Aaron D. Kessel, BS, MD; Niranjan Kissoon, MD, MCCM; Michele Moss, MD, FCCM; Mohan R. Mysore, MD, FAAP, FCCM; Michele C. Papo, MD, MPH, FCCM; Kari L. Rajzer-Wakeham, CCRN, MSN, PCCNP, RN; Tom B. Rice, MD; David L. Rosenberg, MD, FAAP, FCCM; Martin K. Wakeham, MD; Edward E. Conway, Jr, MD, FCCM, MS; Michael S.D. Agus, MD, FAAP, FCCM

ABSTRACT. This is an executive summary of the 2019 update of the 2004 guidelines and levels of care for PICU. Since previous guidelines, there has been a tremendous transformation of Pediatric Critical Care Medicine with advancements in pediatric cardiovascular medicine, transplant, neurology, trauma, and oncology as well as improvements of care in general PICUs. This has led to the evolution of resources and training in the provision of care through the PICU. Outcome and quality research related to admission, transfer, and discharge criteria as well as literature regarding PICU levels of care to include volume, staffing, and structure were reviewed and included in this statement as appropriate. Consequently, the purposes of this significant update are to address the transformation of the field and codify a revised set of guidelines that will enable hospitals, institutions, and individuals in developing the appropriate PICU for their community needs. The target audiences of the practice statement and guidance are broad and include critical care professionals; pediatricians; pediatric subspecialists; pediatric surgeons; pediatric surgical subspecialists; pediatric imaging physicians; and other members of the patient care team such as nurses, therapists, dieticians, pharmacists, social workers, care coordinators, and hospital administrators who make daily administrative and clinical decisions in all PICU levels of care. EXECUTIVE SUMMARY: IDENTIFICATION, EVALUATION, AND MANAGEMENT OF CHILDREN WITH AUTISM SPECTRUM DISORDER (CLINICAL REPORT)

Susan L. Hyman, MD, FAAP; Susan E. Levy, MD, MPH, FAAP; Scott M. Myers, MD, FAAP; Council on Children With Disabilities; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Autism spectrum disorder (ASD) is a common neurodevelopmental disorder with reported prevalence in the United States of 1 in 59 children (approximately 1.7%). ASD significantly influences the lives of affected children and families because they may need extensive behavioral, educational, health, and other services. Primary care providers play a critical role in identifying, diagnosing, and managing ASD in children and providing support for their families. This document provides a summary of the clinical report "Identification, Evaluation, and Management of Children with Autism Spectrum Disorder," published concurrently in the online version of *Pediatrics*. In the years since 2007, when the American Academy of Pediatrics published the clinical reports "Identification and Diagnosis of Children with Autism Spectrum Disorders" and "Management of Children with Autism Spectrum Disorders," reported prevalence rates of children with ASD have increased, understanding of potential risk factors has expanded, awareness of co-occurring medical and behavioral conditions and genetic contribution to etiology has improved, and the body of research supporting evidence-based interventions has grown substantially. The updated document discusses evaluation and treatment as a continuum in 1 publication with a table of contents to help the reader identify topic areas within the report. ASD is more commonly diagnosed than in the past, and the significant health, educational, and social needs of individuals with ASD and their families constitute an area of critical need for resources, research, and professional education. (12/19)

EXPERT WITNESS PARTICIPATION IN CIVIL AND CRIMINAL PROCEEDINGS

Stephan R. Paul, MD, JD, FAAP; Sandeep K. Narang, MD, JD, FAAP; and Committee on Medical Liability and Risk Management

ABSTRACT. The interests of the public and both the medical and legal professions are best served when scientifically sound and unbiased expert witness testimony is readily available in civil and criminal proceedings. As members of the medical community, patient advocates, and private citizens, pediatricians have ethical and professional obligations to assist in the civil and criminal judicial processes. This policy statement offers recommendations on advocacy, education, research, qualifications, standards, and ethical business practices all aimed at improving expert testimony. (2/17)
https://doi.org/10.1542/peds.2016-3862

EXPERT WITNESS PARTICIPATION IN CIVIL AND CRIMINAL PROCEEDINGS (TECHNICAL REPORT)

Sandeep K. Narang, MD, JD, FAAP; Stephan R. Paul, MD, JD, FAAP; and Committee on Medical Liability and Risk Management

ABSTRACT. The interests of the public and both the medical and legal professions are best served when scientifically sound and unbiased expert witness testimony is readily available in civil and criminal proceedings. As members of the medical community, patient advocates, and private citizens, pediatricians have ethical and professional obligations to assist in the civil and criminal judicial processes. This technical report explains how the role of the expert witness differs in civil and criminal proceedings, legal and ethical standards for expert witnesses, and strategies that have been employed to deter unscientific and irresponsible testimony. A companion policy statement offers recommendations on advocacy, education, research, qualifications, standards, and ethical business practices all aimed at improving expert testimony. (2/17)
https://doi.org/10.1542/peds.2016-4122

EXPOSURE TO NONTRADITIONAL PETS AT HOME AND TO ANIMALS IN PUBLIC SETTINGS: RISKS TO CHILDREN (CLINICAL REPORT)

Larry K. Pickering, MD; Nina Marano, DVM, MPH; Joseph A. Bocchini, MD; Frederick J. Angulo, DVM, PhD; and Committee on Infectious Diseases

ABSTRACT. Exposure to animals can provide many benefits during the growth and development of children. However, there are potential risks associated with animal exposures, including exposure to nontraditional pets in the home and animals in public settings. Educational materials, regulations, and guidelines have been developed to minimize these risks. Pediatricians, veterinarians, and other health care professionals can provide advice on selection of appropriate pets as well as prevention of disease transmission from nontraditional pets and when children contact animals in public settings. (10/08, reaffirmed 12/11, 1/15, 6/15, 5/19)
https://doi.org/10.1542/peds.2008-1942

THE EYE EXAMINATION IN THE EVALUATION OF CHILD ABUSE (CLINICAL REPORT)

Cindy W. Christian, MD, FAAP; Alex V. Levin, MD, MHSc, FAAO, FRCSC, FAAP; Council on Child Abuse and Neglect; and Section on Ophthalmology (joint with American Association of Certified Orthoptists, American Association for Pediatric Ophthalmology and Strabismus, and American Academy of Ophthalmology)

ABSTRACT. Child abuse can cause injury to any part of the eye. The most common manifestations are retinal hemorrhages (RHs) in infants and young children with abusive head trauma (AHT). Although RHs are an important indicator of possible AHT, they are also found in other conditions. Distinguishing the number, type, location, and pattern of RHs is important in evaluating a differential diagnosis. Eye trauma can be seen in cases of physical abuse or AHT and may prompt referral for ophthalmologic assessment. Physicians have a responsibility to consider abuse in the differential diagnosis of pediatric eye trauma. Identification and documentation of inflicted ocular trauma requires a thorough examination by an ophthalmologist, including indirect ophthalmoscopy, most optimally through a dilated pupil, especially for the evaluation of possible RHs. An eye examination is helpful in detecting abnormalities that can help identify a medical or traumatic etiology for previously well young children who experience unexpected and unexplained mental status changes with no obvious cause, children with head trauma that results in significant intracranial hemorrhage and brain injury, and children with unexplained death. FACILITIES AND EQUIPMENT FOR THE CARE OF PEDIATRIC PATIENTS IN A COMMUNITY HOSPITAL (CLINICAL REPORT)

Committee on Hospital Care

ABSTRACT. Many children who require hospitalization are admitted to community hospitals that are more accessible for families and their primary care physicians but vary substantially in their pediatric resources. The intent of this clinical report is to provide basic guidelines for furnishing and equipping a pediatric area in a community hospital. (5/03, reaffirmed 5/07, 8/13, 1/17)

https://doi.org/10.1542/peds.111.5.1120

FALLS FROM HEIGHTS: WINDOWS, ROOFS, AND BALCONIES

Committee on Injury and Poison Prevention

ABSTRACT. Falls of all kinds represent an important cause of child injury and death. In the United States, approximately 140 deaths from falls occur annually in children younger than 15 years. Three million children require emergency department care for fall-related injuries. This policy statement examines the epidemiology of falls from heights and recommends preventive strategies for pediatricians and other child health care professionals. Such strategies involve parent counseling, community programs, building code changes, legislation, and environmental modification, such as the installation of window guards and balcony railings. https://doi.org/10.1542/peds.107.5.1188

FAMILIES AFFECTED BY PARENTAL SUBSTANCE USE (CLINICAL REPORT)

Vincent C. Smith, MD, MPH, FAAP; Celeste R. Wilson, MD, FAAP; and Committee on Substance Use and Prevention

ABSTRACT. Children whose parents or caregivers use drugs or alcohol are at increased risk of short- and long-term sequelae ranging from medical problems to psychosocial and behavioral challenges. In the course of providing health care services to children, pediatricians are likely to encounter families affected by parental substance use and are in a unique position to intervene. Therefore, pediatricians need to know how to assess a child's risk in the context of a parent's substance use. The purposes of this clinical report are to review some of the short-term effects of maternal substance use during pregnancy and long-term implications of fetal exposure; describe typical medical, psychiatric, and behavioral symptoms of children and adolescents in families affected by substance use; and suggest proficiencies for pediatricians involved in the care of children and adolescents of families affected by substance use, including screening families, mandated reporting requirements, and directing families to community, regional, and state resources that can address needs and problems. (7/16)

https://doi.org/10.1542/peds.2016-1575

FATHERS' ROLES IN THE CARE AND DEVELOPMENT OF THEIR CHILDREN: THE ROLE OF PEDIATRICIANS (CLINICAL REPORT)

Michael Yogman, MD, FAAP; Craig F. Garfield, MD, FAAP; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Fathers' involvement in and influence on the health and development of their children have increased in a myriad of ways in the past 10 years and have been widely studied. The role of pediatricians in working with fathers has correspondingly increased in importance. This report reviews new studies of the epidemiology of father involvement, including nonresidential as well as residential fathers. The effects of father involvement on child outcomes are discussed within each phase of a child's development. Particular emphasis is placed on (1) fathers' involvement across childhood ages and (2) the influence of fathers' physical and mental health on their children. Implications and advice for all child health providers to encourage and support father involvement are outlined. (6/16)

https://doi.org/10.1542/peds.2016-1128

THE FEMALE ATHLETE TRIAD (CLINICAL REPORT)

Amanda K. Weiss Kelly, MD, FAAP; Suzanne Hecht, MD, FACSM; and Council on Sports Medicine and Fitness

ABSTRACT. The number of girls participating in sports has increased significantly since the introduction of Title XI in 1972. As a result, more girls have been able to experience the social, educational, and health-related benefits of sports participation. However, there are risks associated with sports participation, including the female athlete triad. The triad was originally recognized as the interrelationship of amenorrhea, osteoporosis, and disordered eating, but our understanding has evolved to recognize that each of the components of the triad exists on a spectrum from optimal health to disease. The triad occurs when energy intake does not adequately compensate for exercise-related energy expenditure, leading to adverse effects on reproductive, bone, and cardiovascular health. Athletes can present with a single component or any combination of the components. The triad can have a more significant effect on the health of adolescent athletes than on adults because adolescence is a critical time for bone mass accumulation. This report outlines the current state of knowledge on the epidemiology, diagnosis, and treatment of the triad conditions. (7/16)

FERTILITY PRESERVATION FOR PEDIATRIC AND ADOLESCENT PATIENTS WITH CANCER: MEDICAL AND ETHICAL CONSIDERATIONS (CLINICAL REPORT)

Sigal Klipstein, MD, FACOG; Mary E. Fallat, MD, FAAP; Stephanie Savelli, MD, FAAP; Committee on Bioethics; Section on Hematology/Oncology; and Section on Surgery

ABSTRACT. Many cancers presenting in children and adolescents are curable with surgery, chemotherapy, and/or radiotherapy. Potential adverse consequences of treatment include

sterility, infertility, or subfertility as a result of gonad removal, damage to germ cells as a result of adjuvant therapy, or damage to the pituitary and hypothalamus or uterus as a result of irradiation. In recent years, treatment of solid tumors and hematologic malignancies has been modified in an attempt to reduce damage to the gonadal axis. Simultaneously, advances in assisted reproductive technology have led to new possibilities for the prevention and treatment of infertility. This clinical report reviews the medical aspects and ethical considerations that arise when considering fertility preservation in pediatric and adolescent patients with cancer. (2/20)
https://doi.org/10.1542/peds.2019-3994

FETAL ALCOHOL SPECTRUM DISORDERS (CLINICAL REPORT)

Janet F. Williams, MD, FAAP; Vincent C. Smith, MD, MPH, FAAP; and Committee on Substance Abuse

ABSTRACT. Prenatal exposure to alcohol can damage the developing fetus and is the leading preventable cause of birth defects and intellectual and neurodevelopmental disabilities. In 1973, fetal alcohol syndrome was first described as a specific cluster of birth defects resulting from alcohol exposure in utero. Subsequently, research unequivocally revealed that prenatal alcohol exposure causes a broad range of adverse developmental effects. Fetal alcohol spectrum disorder (FASD) is the general term that encompasses the range of adverse effects associated with prenatal alcohol exposure. The diagnostic criteria for fetal alcohol syndrome are specific, and comprehensive efforts are ongoing to establish definitive criteria for diagnosing the other FASDs. A large and growing body of research has led to evidence-based FASD education of professionals and the public, broader prevention initiatives, and recommended treatment approaches based on the following premises:

- Alcohol-related birth defects and developmental disabilities are completely preventable when pregnant women abstain from alcohol use.
- Neurocognitive and behavioral problems resulting from prenatal alcohol exposure are lifelong.
- Early recognition, diagnosis, and therapy for any condition along the FASD continuum can result in improved outcomes.
- During pregnancy:
  - — no amount of alcohol intake should be considered safe;
  - — there is no safe trimester to drink alcohol;
  - — all forms of alcohol, such as beer, wine, and liquor, pose similar risk; and
  - — binge drinking poses dose-related risk to the developing fetus. (10/15, reaffirmed 1/21)

FEVER AND ANTIPYRETIC USE IN CHILDREN (CLINICAL REPORT)

Janice E. Sullivan, MD; Henry C. Farrar, MD; Section on Clinical Pharmacology and Therapeutics; and Committee on Drugs

ABSTRACT. Fever in a child is one of the most common clinical symptoms managed by pediatricians and other health care providers and a frequent cause of parental concern. Many parents administer antipyretics even when there is minimal or no fever, because they are concerned that the child must maintain a "normal" temperature. Fever, however, is not the primary illness but is a physiologic mechanism that has beneficial effects in fighting infection. There is no evidence that fever itself worsens the course of an illness or that it causes long-term neurologic complications. Thus, the primary goal of treating the febrile child should be to improve the child's overall comfort rather than focus on the normalization of body temperature. When counseling the parents or caregivers of a febrile child, the general well-being of the child, the importance of monitoring activity, observing for signs of serious illness, encouraging appropriate fluid intake, and the safe storage of antipyretics should be emphasized. Current evidence suggests that there is no substantial difference in the safety and effectiveness of acetaminophen and ibuprofen in the care of a generally healthy child with fever. There is evidence that combining these 2 products is more effective than the use of a single agent alone; however, there are concerns that combined treatment may be more complicated and contribute to the unsafe use of these drugs. Pediatricians should also promote patient safety by advocating for simplified formulations, dosing instructions, and dosing devices. (2/11, reaffirmed 7/16)

FINANCING GRADUATE MEDICAL EDUCATION TO MEET THE NEEDS OF CHILDREN AND THE FUTURE PEDIATRICIAN WORKFORCE

Committee on Pediatric Workforce

ABSTRACT. The American Academy of Pediatrics (AAP) believes that an appropriately financed graduate medical education (GME) system is critical to ensuring that sufficient numbers of trained pediatricians are available to provide optimal health care to all children. A shortage of pediatric medical subspecialists and pediatric surgical specialists currently exists in the United States, and this shortage is likely to intensify because of the growing numbers of children with chronic health problems and special health care needs. It is equally important to maintain the supply of primary care pediatricians. The AAP, therefore, recommends that children's hospital GME positions funded by the Health Resources and Services Administration be increased to address this escalating demand for pediatric health services. The AAP also recommends that GME funding for pediatric physician training provide full financial support for all years of training necessary to meet program requirements. In addition, all other entities that gain from GME training should participate in its funding in a manner that does not influence curriculum, requirements, or outcomes. Furthermore, the AAP supports funding for training innovations that improve the health of children. Finally, the AAP recommends that all institutional recipients of GME funding allocate these funds directly to the settings where training occurs in a transparent manner. (3/16)

FINANCING OF PEDIATRIC HOME HEALTH CARE

Edwin Simpser, MD, FAAP; Mark L. Hudak, MD, FAAP; Section on Home Care; and Committee on Child Health Financing

ABSTRACT. Pediatric home health care is an effective and holistic venue of treatment of children with medical complexity or developmental disabilities who otherwise may experience frequent and/or prolonged hospitalizations or who may enter chronic institutional care. Demand for pediatric home health care is increasing while the provider base is eroding, primarily because of inadequate payment or restrictions on benefits. As a result, home care responsibilities assumed by family caregivers have increased and imposed financial, physical, and psychological burdens on the family. The Patient Protection and Affordable Care Act set forth 10 mandated essential health benefits. Home care should be considered as an integral component of the habilitative and rehabilitative services and devices benefit, even though it is not explicitly recognized as a specific category of service. Pediatric-specific home health care services should be defined clearly as components of pediatric services, the 10th essential benefit, and recognized by all payers. Payments for home health care services should be sufficient to maintain an adequate provider work force with the pediatric-specific expertise and skills to care for children with medical complexity or developmental disability. Furthermore, coordination of care among various providers and the necessary direct patient care

from which these care coordination plans are developed should be required and enabled by adequate payment. The American Academy of Pediatrics advocates for high-quality care by calling for development of pediatric-specific home health regulations and the licensure and certification of pediatric home health providers. (2/17)

FIREARM-RELATED INJURIES AFFECTING THE PEDIATRIC POPULATION

Council on Injury, Violence, and Poison Prevention Executive Committee

ABSTRACT. The absence of guns from children's homes and communities is the most reliable and effective measure to prevent firearm-related injuries in children and adolescents. Adolescent suicide risk is strongly associated with firearm availability. Safe gun storage (guns unloaded and locked, ammunition locked separately) reduces children's risk of injury. Physician counseling of parents about firearm safety appears to be effective, but firearm safety education programs directed at children are ineffective. The American Academy of Pediatrics continues to support a number of specific measures to reduce the destructive effects of guns in the lives of children and adolescents, including the regulation of the manufacture, sale, purchase, ownership, and use of firearms; a ban on semiautomatic assault weapons; and the strongest possible regulations of handguns for civilian use. (10/12, reaffirmed 12/16, 1/21)
https://doi.org/10.1542/peds.2012-2481

FIREWORKS-RELATED INJURIES TO CHILDREN

Committee on Injury and Poison Prevention

ABSTRACT. An estimated 8500 individuals, approximately 45% of them children younger than 15 years, were treated in US hospital emergency departments during 1999 for fireworks-related injuries. The hands (40%), eyes (20%), and head and face (20%) are the body areas most often involved. Approximately one third of eye injuries from fireworks result in permanent blindness. During 1999, 16 people died as a result of injuries associated with fireworks. Every type of legally available consumer (so-called "safe and sane") firework has been associated with serious injury or death. In 1997, 20,100 fires were caused by fireworks, resulting in $22.7 million in direct property damage. Fireworks typically cause more fires in the United States on the Fourth of July than all other causes of fire combined on that day. Pediatricians should educate parents, children, community leaders, and others about the dangers of fireworks. Fireworks for individual private use should be banned. Children and their families should be encouraged to enjoy fireworks at public fireworks displays conducted by professionals rather than purchase fireworks for home or private use. FISH, SHELLFISH, AND CHILDREN'S HEALTH: AN ASSESSMENT OF BENEFITS, RISKS, AND SUSTAINABILITY (TECHNICAL REPORT)

Aaron S. Bernstein, MD, MPH, FAAP; Emily Oken, MD, MPH; Sarah de Ferranti, MD, MPH, FAAP; Council on Environmental Health; and Committee on Nutrition

ABSTRACT. American children eat relatively little fish and shellfish in comparison with other sources of animal protein, despite the health benefits that eating fish and shellfish may confer. At the same time, fish and shellfish may be sources of toxicants. This report serves to inform pediatricians about available research that elucidates health risks and benefits associated with fish and shellfish consumption in childhood as well as the sustainability of fish and shellfish harvests. (5/19)

FLUORIDE USE IN CARIES PREVENTION IN THE PRIMARY CARE SETTING (CLINICAL REPORT)

Melinda B. Clark, MD, FAAP; Martha Ann Keels, DDS, PhD; Rebecca L. Slayton, DDS, PhD; and Section on Oral Health

ABSTRACT. Dental caries remains the most common chronic disease of childhood in the United States. Caries is a largely preventable condition, and fluoride has proven effectiveness in caries prevention. This clinical report aims to clarify the use of available fluoride modalities for caries prevention in the primary care setting and to assist pediatricians in using fluoride to achieve maximum protection against dental caries, while minimizing the likelihood of enamel fluorosis. Fluoride varnish application is now considered the standard of care in pediatric primary care. This report highlights administration, billing, and payment information regarding the fluoride varnish procedure. (11/20)
https://doi.org/10.1542/peds.2020-034637

FOLIC ACID FOR THE PREVENTION OF NEURAL TUBE DEFECTS

Committee on Genetics

ABSTRACT. The American Academy of Pediatrics endorses the US Public Health Service (USPHS) recommendation that all women capable of becoming pregnant consume 400 µg of folic acid daily to prevent neural tube defects (NTDs). Studies have demonstrated that periconceptional folic acid supplementation can prevent 50% or more of NTDs such as spina bifida and anencephaly. For women who have previously had an NTD-affected pregnancy, the Centers for Disease Control and Prevention (CDC) recommends increasing the intake of folic acid to 4000 µg per day beginning at least 1 month before conception and continuing through the first trimester. Implementation of these recommendations is essential for the primary prevention of these serious and disabling birth defects. Because fewer than 1 in 3 women consume the amount of folic acid recommended by the USPHS, the Academy notes that the prevention of NTDs depends on an urgent and effective campaign to close this prevention gap. (8/99, reaffirmed 9/16)

FOLLOW-UP MANAGEMENT OF CHILDREN WITH TYMPANOSTOMY TUBES

Section on Otolaryngology and Bronchoesophagology

ABSTRACT. The follow-up care of children in whom tympanostomy tubes have been placed is shared by the pediatrician and the otolaryngologist. Guidelines are provided for routine follow-up evaluation, perioperative hearing assessment, and the identification of specific conditions and complications that warrant urgent otolaryngologic consultation. These guidelines have been developed by a consensus of expert opinions. (2/02)

FOOD ADDITIVES AND CHILD HEALTH

Leonardo Trasande, MD, MPP, FAAP; Rachel M. Shaffer, MPH; Sheela Sathyanarayana, MD, MPH; and Council on Environmental Health

ABSTRACT. Our purposes with this policy statement and its accompanying technical report are to review and highlight emerging child health concerns related to the use of colorings, flavorings, and chemicals deliberately added to food during processing (direct food additives) as well as substances in food contact materials, including adhesives, dyes, coatings, paper, paperboard, plastic, and other polymers, which may contaminate food as part of packaging or manufacturing equipment (indirect food additives); to make reasonable recommendations that the pediatrician might be able to adopt into the guidance

provided during pediatric visits; and to propose urgently needed reforms to the current regulatory process at the US Food and Drug Administration (FDA) for food additives. Concern regarding food additives has increased in the past 2 decades, in part because of studies in which authors document endocrine disruption and other adverse health effects. In some cases, exposure to these chemicals is disproportionate among minority and low-income populations. Regulation and oversight of many food additives is inadequate because of several key problems in the Federal Food, Drug, and Cosmetic Act. Current requirements for a "generally recognized as safe" (GRAS) designation are insufficient to ensure the safety of food additives and do not contain sufficient protections against conflict of interest. Additionally, the FDA does not have adequate authority to acquire data on chemicals on the market or reassess their safety for human health. These are critical weaknesses in the current regulatory system for food additives. Data about health effects of food additives on infants and children are limited or missing; however, in general, infants and children are more vulnerable to chemical exposures. Substantial improvements to the food additives regulatory system are urgently needed, including greatly strengthening or replacing the "generally recognized as safe" (GRAS) determination process, updating the scientific foundation of the FDA's safety assessment program, retesting all previously approved chemicals, and labeling direct additives with limited or no toxicity data. (7/18)

FOOD ADDITIVES AND CHILD HEALTH (TECHNICAL REPORT)

Leonardo Trasande, MD, MPP, FAAP; Rachel M. Shaffer, MPH; Sheela Sathyanarayana, MD, MPH; and Council on Environmental Health

ABSTRACT. Increasing scientific evidence suggests potential adverse effects on children's health from synthetic chemicals used as food additives, both those deliberately added to food during processing (direct) and those used in materials that may contaminate food as part of packaging or manufacturing (indirect). Concern regarding food additives has increased in the past 2 decades in part because of studies that increasingly document endocrine disruption and other adverse health effects. In some cases, exposure to these chemicals is disproportionate among minority and low-income populations. This report focuses on those food additives with the strongest scientific evidence for concern. Further research is needed to study effects of exposure over various points in the life course, and toxicity testing must be advanced to be able to better identify health concerns prior to widespread population exposure. The accompanying policy statement describes approaches policy makers and pediatricians can take to prevent the disease and disability that are increasingly being identified in relation to chemicals used as food additives, among other uses. (7/18)

FORGOING MEDICALLY PROVIDED NUTRITION AND HYDRATION IN CHILDREN (CLINICAL REPORT)

Douglas S. Diekema, MD, MPH; Jeffrey R. Botkin, MD, MPH; and Committee on Bioethics

ABSTRACT. There is broad consensus that withholding or withdrawing medical interventions is morally permissible when requested by competent patients or, in the case of patients without decision-making capacity, when the interventions no longer confer a benefit to the patient or when the burdens associated with the interventions outweigh the benefits received. The withdrawal or withholding of measures such as attempted resuscitation, ventilators, and critical care medications is common in the terminal care of adults and children. In the case of adults, a consensus has emerged in law and ethics that the medical administration of fluid and nutrition is not fundamentally different from other medical interventions such as use of ventilators; therefore, it can be forgone or withdrawn when a competent adult or legally authorized surrogate requests withdrawal or when the intervention no longer provides a net benefit to the patient. In pediatrics, forgoing or withdrawing medically administered fluids and nutrition has been more controversial because of the inability of children to make autonomous decisions and the emotional power of feeding as a basic element of the care of children. This statement reviews the medical, ethical, and legal issues relevant to the withholding or withdrawing of medically provided fluids and nutrition in children. The American Academy of Pediatrics concludes that the withdrawal of medically administered fluids and nutrition for pediatric patients is ethically acceptable in limited circumstances. Ethics consultation is strongly recommended when particularly difficult or controversial decisions are being considered. (7/09, reaffirmed 1/14)

FRUIT JUICE IN INFANTS, CHILDREN, AND ADOLESCENTS: CURRENT RECOMMENDATIONS

Melvin B. Heyman, MD, FAAP; Steven A. Abrams, MD, FAAP; Section on Gastroenterology, Hepatology, and Nutrition; and Committee on Nutrition

ABSTRACT. Historically, fruit juice was recommended by pediatricians as a source of vitamin C and as an extra source of water for healthy infants and young children as their diets expanded to include solid foods with higher renal solute load. It was also sometimes recommended for children with constipation. Fruit juice is marketed as a healthy, natural source of vitamins and, in some instances, calcium. Because juice tastes good, children readily accept it. Although juice consumption has some benefits, it also has potential detrimental effects. High sugar content in juice contributes to increased calorie consumption and the risk of dental caries. In addition, the lack of protein and fiber in juice can predispose to inappropriate weight gain (too much or too little). Pediatricians need to be knowledgeable about juice to inform parents and patients on its appropriate uses. (5/17)
https://doi.org/10.1542/peds.2017-0967

GASTROESOPHAGEAL REFLUX: MANAGEMENT GUIDANCE FOR THE PEDIATRICIAN (CLINICAL REPORT)

Jenifer R. Lightdale, MD, MPH; David A. Gremse, MD; and Section on Gastroenterology, Hepatology, and Nutrition

ABSTRACT. Recent comprehensive guidelines developed by the North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition define the common entities of gastroesophageal reflux (GER) as the physiologic passage of gastric contents into the esophagus and gastroesophageal reflux disease (GERD) as reflux associated with troublesome symptoms or complications. The ability to distinguish between GER and GERD is increasingly important to implement best practices in the management of acid reflux in patients across all pediatric age groups, as children with GERD may benefit from further evaluation and treatment, whereas conservative recommendations are the only indicated therapy in those with uncomplicated physiologic reflux. This clinical report endorses the rigorously developed, well-referenced North American Society for Pediatric Gastroenterology, Hepatology, and Nutrition guidelines and likewise emphasizes important concepts for the general pediatrician. A key issue is distinguishing between clinical manifestations of GER and GERD in term infants, children, and adolescents to identify patients who can be managed with conservative treatment by the pediatrician and to refer patients who require consultation with the gastroenterologist. Accordingly, the evidence basis presented by the guidelines for diagnostic approaches as well as treatments is discussed. Lifestyle changes are emphasized as first-line therapy in both GER and GERD,

whereas medications are explicitly indicated only for patients with GERD. Surgical therapies are reserved for children with intractable symptoms or who are at risk for life-threatening complications of GERD. Recent black box warnings from the US Food and Drug Administration are discussed, and caution is underlined when using promoters of gastric emptying and motility. Finally, attention is paid to increasing evidence of inappropriate prescriptions for proton pump inhibitors in the pediatric population. (4/13)

GLOBAL CLIMATE CHANGE AND CHILDREN'S HEALTH

Council on Environmental Health
ABSTRACT. Rising global temperatures are causing major physical, chemical, and ecological changes in the planet. There is wide consensus among scientific organizations and climatologists that these broad effects, known as "climate change," are the result of contemporary human activity. Climate change poses threats to human health, safety, and security, and children are uniquely vulnerable to these threats. The effects of climate change on child health include: physical and psychological sequelae of weather disasters; increased heat stress; decreased air quality; altered disease patterns of some climate-sensitive infections; and food, water, and nutrient insecurity in vulnerable regions. The social foundations of children's mental and physical health are threatened by the specter of far-reaching effects of unchecked climate change, including community and global instability, mass migrations, and increased conflict. Given this knowledge, failure to take prompt, substantive action would be an act of injustice to all children. A paradigm shift in production and consumption of energy is both a necessity and an opportunity for major innovation, job creation, and significant, immediate associated health benefits. Pediatricians have a uniquely valuable role to play in the societal response to this global challenge. (10/15, reaffirmed 5/21)
https://doi.org/10.1542/peds.2015-3232

GLOBAL CLIMATE CHANGE AND CHILDREN'S HEALTH (TECHNICAL REPORT)

Samantha Ahdoot, MD, FAAP; Susan E. Pacheco, MD, FAAP; and Council on Environmental Health
ABSTRACT. Rising global temperature is causing major physical, chemical, and ecological changes across the planet. There is wide consensus among scientific organizations and climatologists that these broad effects, known as climate change, are the result of contemporary human activity. Climate change poses threats to human health, safety, and security. Children are uniquely vulnerable to these threats. The effects of climate change on child health include physical and psychological sequelae of weather disasters, increased heat stress, decreased air quality, altered disease patterns of some climate-sensitive infections, and food, water, and nutrient insecurity in vulnerable regions. Prompt implementation of mitigation and adaptation strategies will protect children against worsening of the problem and its associated health effects. This technical report reviews the nature of climate change and its associated child health effects and supports the recommendations in the accompanying policy statement on climate change and children's health. GLOBAL HUMAN TRAFFICKING AND CHILD VICTIMIZATION

Jordan Greenbaum, MD; Nia Bodrick, MD, MPH, FAAP; Committee on Child Abuse and Neglect; and Section on International Child Health
ABSTRACT. Trafficking of children for labor and sexual exploitation violates basic human rights and constitutes a major global public health problem. Pediatricians and other health care professionals may encounter victims who present with infections, injuries, posttraumatic stress disorder, suicidality, or a variety of other physical or behavioral health conditions. Preventing child trafficking, recognizing victimization, and intervening appropriately require a public health approach that incorporates rigorous research on the risk factors, health impact, and effective treatment options for child exploitation as well as implementation and evaluation of primary prevention programs. Health care professionals need training to recognize possible signs of exploitation and to intervene appropriately. They need to adopt a multidisciplinary, outward-focused approach to service provision, working with nonmedical professionals in the community to assist victims. Pediatricians also need to advocate for legislation and policies that promote child rights and victim services as well as those that address the social determinants of health, which influence the vulnerability to human trafficking. This policy statement outlines major issues regarding public policy, medical education, research, and collaboration in the area of child labor and sex trafficking and provides recommendations for future work. (11/17)
https://doi.org/10.1542/peds.2017-3138

GUIDANCE FOR THE ADMINISTRATION OF MEDICATION IN SCHOOL

Council on School Health
ABSTRACT. Many children who take medications require them during the school day. This policy statement is designed to guide prescribing health care professionals, school physicians, and school health councils on the administration of medications to children at school. All districts and schools need to have policies and plans in place for safe, effective, and efficient administration of medications at school. Having full-time licensed registered nurses administering all routine and emergency medications in schools is the best situation. When a licensed registered nurse is not available, a licensed practical nurse may administer medications. When a nurse cannot administer medication in school, the American Academy of Pediatrics supports appropriate delegation of nursing services in the school setting. Delegation is a tool that may be used by the licensed registered school nurse to allow unlicensed assistive personnel to provide standardized, routine health services under the supervision of the nurse and on the basis of physician guidance and school nursing assessment of the unique needs of the individual child and the suitability of delegation of specific nursing tasks. Any delegation of nursing duties must be consistent with the requirements of state nurse practice acts, state regulations, and guidelines provided by professional nursing organizations. Long-term, emergency, and short-term medications; over-the-counter medications; alternative medications; and experimental drugs that are administered as part of a clinical trial are discussed in this statement. This statement has been endorsed by the American School Health Association. (9/09, reaffirmed 2/13)

GUIDANCE ON COMPLETING A WRITTEN ALLERGY AND ANAPHYLAXIS EMERGENCY PLAN (CLINICAL REPORT)

Julie Wang, MD, FAAP; Scott H. Sicherer, MD, FAAP; and Section on Allergy and Immunology
ABSTRACT. Anaphylaxis is a potentially life-threatening, severe allergic reaction. The immediate assessment of patients having an allergic reaction and prompt administration of epinephrine,

if criteria for anaphylaxis are met, promote optimal outcomes. National and international guidelines for the management of anaphylaxis, including those for management of allergic reactions at school, as well as several clinical reports from the American Academy of Pediatrics, recommend the provision of written emergency action plans to those at risk of anaphylaxis, in addition to the prescription of epinephrine autoinjectors. This clinical report provides information to help health care providers understand the role of a written, personalized allergy and anaphylaxis emergency plan to enhance the care of children at risk of allergic reactions, including anaphylaxis. This report offers a comprehensive written plan, with advice on individualizing instructions to suit specific patient circumstances. (2/17)
https://doi.org/10.1542/peds.2016-4005

GUIDANCE ON FORGOING LIFE-SUSTAINING MEDICAL TREATMENT

Kathryn L. Weise, MD, MA, FAAP; Alexander L. Okun, MD, FAAP; Brian S. Carter, MD, FAAP; Cindy W. Christian, MD, FAAP; Committee on Bioethics; Section on Hospice and Palliative Medicine; and Committee on Child Abuse and Neglect

ABSTRACT. Pediatric health care is practiced with the goal of promoting the best interests of the child. Treatment generally is rendered under a presumption in favor of sustaining life. However, in some circumstances, the balance of benefits and burdens to the child leads to an assessment that forgoing life-sustaining medical treatment (LSMT) is ethically supportable or advisable. Parents are given wide latitude in decision-making concerning end-of-life care for their children in most situations. Collaborative decision-making around LSMT is improved by thorough communication among all stakeholders, including medical staff, the family, and the patient, when possible, throughout the evolving course of the patient's illness. Clear communication of overall goals of care is advised to promote agreed-on plans, including resuscitation status. Perceived disagreement among the team of professionals may be stressful to families. At the same time, understanding the range of professional opinions behind treatment recommendations is critical to informing family decision-making. Input from specialists in palliative care, ethics, pastoral care, and other disciplines enhances support for families and medical staff when decisions to forgo LSMT are being considered. Understanding specific applicability of institutional, regional, state, and national regulations related to forgoing LSMT is important to practice ethically within existing legal frameworks. This guidance represents an update of the 1994 statement from the American Academy of Pediatrics on forgoing LSMT. (8/17)

GUIDANCE ON MANAGEMENT OF ASYMPTOMATIC NEONATES BORN TO WOMEN WITH ACTIVE GENITAL HERPES LESIONS (CLINICAL REPORT)

Committee on Infectious Diseases and Committee on Fetus and Newborn

ABSTRACT. Herpes simplex virus (HSV) infection of the neonate is uncommon, but genital herpes infections in adults are very common. Thus, although treating an infant with neonatal herpes is a relatively rare occurrence, managing infants potentially exposed to HSV at the time of delivery occurs more frequently. The risk of transmitting HSV to an infant during delivery is determined in part by the mother's previous immunity to HSV. Women with primary genital HSV infections who are shedding HSV at delivery are 10 to 30 times more likely to transmit the virus to their newborn infants than are women with recurrent HSV infection who are shedding virus at delivery. With the availability of commercial serological tests that reliably can distinguish type-specific HSV antibodies, it is now possible to determine the type of maternal infection and, thus, further refine management of infants delivered to women who have active genital HSV lesions. The management algorithm presented herein uses both serological and virological studies to determine the risk of HSV transmission to the neonate who is delivered to a mother with active herpetic genital lesions and tailors management accordingly. The algorithm does not address the approach to asymptomatic neonates delivered to women with a history of genital herpes but no active lesions at delivery. (1/13, reaffirmed 9/16)

GUIDELINES FOR DEVELOPING ADMISSION AND DISCHARGE POLICIES FOR THE PEDIATRIC INTENSIVE CARE UNIT (CLINICAL REPORT)

Committee on Hospital Care and Section on Critical Care (joint with Society of Critical Care Medicine Pediatric Section Admission Criteria Task Force)

ABSTRACT. These guidelines were developed to provide a reference for preparing policies on admission to and discharge from pediatric intensive care units. They represent a consensus opinion of physicians, nurses, and allied health care professionals. By using this document as a framework for developing multidisciplinary admission and discharge policies, use of pediatric intensive care units can be optimized and patients can receive the level of care appropriate for their condition. (4/99, reaffirmed 5/17)
https://doi.org/10.1542/peds.103.4.840

GUIDELINES FOR MONITORING AND MANAGEMENT OF PEDIATRIC PATIENTS BEFORE, DURING, AND AFTER SEDATION FOR DIAGNOSTIC AND THERAPEUTIC PROCEDURES

Charles J. Coté, MD, FAAP; Stephen Wilson, DMD, MA, PhD; and American Academy of Pediatrics (joint with American Academy of Pediatric Dentistry)

ABSTRACT. The safe sedation of children for procedures requires a systematic approach that includes the following: no administration of sedating medication without the safety net of medical/dental supervision, careful presedation evaluation for underlying medical or surgical conditions that would place the child at increased risk from sedating medications, appropriate fasting for elective procedures and a balance between the depth of sedation and risk for those who are unable to fast because of the urgent nature of the procedure, a focused airway examination for large (kissing) tonsils or anatomic airway abnormalities that might increase the potential for airway obstruction, a clear understanding of the medication's pharmacokinetic and pharmacodynamic effects and drug interactions, appropriate training and skills in airway management to allow rescue of the patient, age- and size-appropriate equipment for airway management and venous access, appropriate medications and reversal agents, sufficient numbers of appropriately trained staff to both carry out the procedure and monitor the patient, appropriate physiologic monitoring during and after the procedure, a properly equipped and staffed recovery area, recovery to the presedation level of consciousness before discharge from medical/dental supervision, and appropriate discharge instructions. This report was developed through a collaborative effort of the American Academy of Pediatrics and the American Academy of Pediatric Dentistry to offer pediatric providers updated information and guidance in delivering safe sedation to children. GUIDELINES FOR PEDIATRIC CANCER CENTERS

Section on Hematology/Oncology

ABSTRACT. Since the American Academy of Pediatrics published guidelines for pediatric cancer centers in 1986 and 1997, significant changes in the delivery of health care have prompted a review of the role of tertiary medical centers in the

care of pediatric patients. The potential effect of these changes on the treatment and survival rates of children with cancer led to this revision. The intent of this statement is to delineate personnel and facilities that are essential to provide state-of-the-art care for children and adolescents with cancer. This statement emphasizes the importance of board-certified pediatric hematologists/oncologists, pediatric subspecialty consultants, and appropriately qualified pediatric medical subspecialists and pediatric surgical specialists overseeing the care of all pediatric and adolescent cancer patients and the need for facilities available only at a tertiary center as essential for the initial management and much of the follow-up for pediatric and adolescent cancer patients. (6/04, reaffirmed 10/08, 10/18)

GUIDELINES FOR THE DETERMINATION OF BRAIN DEATH IN INFANTS AND CHILDREN: AN UPDATE OF THE 1987 TASK FORCE RECOMMENDATIONS (CLINICAL REPORT)

Thomas A. Nakagawa, MD; Stephen Ashwal, MD; Mudit Mathur, MD; Mohan Mysore, MD; Section on Critical Care; and Section on Neurology (joint with Society of Critical Care Medicine and Child Neurology Society)

ABSTRACT. *Objective.* To review and revise the 1987 pediatric brain death guidelines.

Methods. Relevant literature was reviewed. Recommendations were developed using the GRADE system.

Conclusions and Recommendations.

1. Determination of brain death in term newborns, infants and children is a clinical diagnosis based on the absence of neurologic function with a known irreversible cause of coma. Because of insufficient data in the literature, recommendations for preterm infants less than 37 weeks' gestational age are not included in this guideline.
2. Hypotension, hypothermia, and metabolic disturbances should be treated and corrected and medications that can interfere with the neurologic examination and apnea testing should be discontinued allowing for adequate clearance before proceeding with these evaluations.
3. Two examinations including apnea testing with each examination separated by an observation period are required. Examinations should be performed by different attending physicians. Apnea testing may be performed by the same physician. An observation period of 24 hours for term newborns (37 weeks' gestational age) to 30 days of age, and 12 hours for infants and children (> 30 days to 18 years) is recommended. The first examination determines the child has met the accepted neurologic examination criteria for brain death. The second examination confirms brain death based on an unchanged and irreversible condition. Assessment of neurologic function following cardiopulmonary resuscitation or other severe acute brain injuries should be deferred for 24 hours or longer if there are concerns or inconsistencies in the examination.
4. Apnea testing to support the diagnosis of brain death must be performed safely and requires documentation of an arterial $Paco_2$ 20 mm Hg above the baseline and ≥60 mm Hg with no respiratory effort during the testing period. If the apnea test cannot be safely completed, an ancillary study should be performed.
5. Ancillary studies (electroencephalogram and radionuclide cerebral blood flow) are not required to establish brain death and are not a substitute for the neurologic examination. Ancillary studies may be used to assist the clinician in making the diagnosis of brain death (1) when components of the examination or apnea testing cannot be completed safely due to the underlying medical condition of the patient; (2) if there is uncertainty about the results of the neurologic examination; (3) if a medication effect may be present; or (4) to reduce the inter-examination observation period. When ancillary studies are used, a second clinical examination and apnea test should be performed and components that can be completed must remain consistent with brain death. In this instance the observation interval may be shortened and the second neurologic examination and apnea test (or all components that are able to be completed safely) can be performed at any time thereafter.
6. Death is declared when the above criteria are fulfilled. (8/11, reaffirmed 1/15, 5/19)

GUIDELINES FOR THE ETHICAL CONDUCT OF STUDIES TO EVALUATE DRUGS IN PEDIATRIC POPULATIONS (CLINICAL REPORT)

Robert E. Shaddy, MD; Scott C. Denne, MD; Committee on Drugs; and Committee on Pediatric Research

ABSTRACT. The proper ethical conduct of studies to evaluate drugs in children is of paramount importance to all those involved in these types of studies. This report is an updated revision to the previously published guidelines from the American Academy of Pediatrics in 1995. Since the previous publication, there have been great strides made in the science and ethics of studying drugs in children. There have also been numerous legislative and regulatory advancements that have promoted the study of drugs in children while simultaneously allowing for the protection of this particularly vulnerable group. This report summarizes these changes and advances and provides a framework from which to guide and monitor the ethical conduct of studies to evaluate drugs in children. (3/10, reaffirmed 1/14, 2/18)

GUIDING PRINCIPLES FOR MANAGED CARE ARRANGEMENTS FOR THE HEALTH CARE OF NEWBORNS, INFANTS, CHILDREN, ADOLESCENTS, AND YOUNG ADULTS

Committee on Child Health Financing

ABSTRACT. By including the precepts of primary care and the medical home in the delivery of services, managed care can be effective in increasing access to a full range of health care services and clinicians. A carefully designed and administered managed care plan can minimize patient under- and overutilization of services, as well as enhance quality of care. Therefore, the American Academy of Pediatrics urges the use of the key principles outlined in this statement in designing and implementing managed care programs for newborns, infants, children, adolescents, and young adults to maximize the positive potential of managed care for pediatrics. (10/13)
https://doi.org/10.1542/peds.2013-2655

GUIDING PRINCIPLES FOR TEAM-BASED PEDIATRIC CARE

Julie P. Katkin, MD, FAAP; Susan J. Kressly, MD, FAAP; Anne R. Edwards, MD, FAAP; James M. Perrin, MD, FAAP; Colleen A. Kraft, MD, FAAP; Julia E. Richerson, MD, FAAP; Joel S. Tieder, MD, MPH, FAAP; Liz Wall; and Task Force on Pediatric Practice Change

ABSTRACT. The American Academy of Pediatrics (AAP) recognizes that children's unique and ever-changing needs depend on a variety of support systems. Key components of effective support systems address the needs of the child and family in the context of their home and community and are dynamic so that they reflect, monitor, and respond to changes as the needs of the child and family change. The AAP believes that team-based care involving medical providers and community partners (eg, teachers and state agencies) is a crucial and necessary component of providing high-quality care to children and their families.

Team-based care builds on the foundation of the medical home by reaching out to a potentially broad array of participants in the life of a child and incorporating them into the care provided. Importantly, the AAP believes that a high-functioning team includes children and their families as essential partners. The overall goal of team-based care is to enhance communication and cooperation among the varied medical, social, and educational partners in a child's life to better meet the global needs of children and their families, helping them to achieve their best potential. In support of the team-based approach, the AAP urges stakeholders to invest in infrastructure, education, and privacy-secured technology to meet the needs of children. This statement includes limited specific examples of potential team members, including health care providers and community partners, that are meant to be illustrative and in no way represent a complete or comprehensive listing of all team members who may be of importance for a specific child and family. (7/17)

GYNECOLOGIC EXAMINATION FOR ADOLESCENTS IN THE PEDIATRIC OFFICE SETTING (CLINICAL REPORT)

Paula K. Braverman, MD; Lesley Breech, MD; and Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics promotes the inclusion of the gynecologic examination in the primary care setting within the medical home. Gynecologic issues are commonly seen by clinicians who provide primary care to adolescents. Some of the most common concerns include questions related to pubertal development; menstrual disorders such as dysmenorrhea, amenorrhea, oligomenorrhea, and abnormal uterine bleeding; contraception; and sexually transmitted and non–sexually transmitted infections. The gynecologic examination is a key element in assessing pubertal status and documenting physical findings. Most adolescents do not need an internal examination involving a speculum or bimanual examination. However, for cases in which more extensive examination is needed, the primary care office with the primary care clinician who has established rapport and trust with the patient is often the best setting for pelvic examination. This report reviews the gynecologic examination, including indications for the pelvic examination in adolescents and the approach to this examination in the office setting. Indications for referral to a gynecologist are included. The pelvic examination may be successfully completed when conducted without pressure and approached as a normal part of routine young women's health care. (8/10, reaffirmed 5/13)

HALF CENTURY SINCE SIDS: A REAPPRAISAL OF TERMINOLOGY (CLINICAL REPORT)

Carrie K. Shapiro-Mendoza, PhD, MPH; Vincent J. Palusci, MD, MS, FAAP; Benjamin Hoffman, MD, FAAP; Erich Batra, MD, FAAP; Marc Yester, MD, FAAP; Tracey S. Corey, MD; Mary Ann Sens, MD, PhD; Task Force on Sudden Infant Death Syndrome; Council on Child Abuse and Neglect; Council on Injury, Violence, and Poison Prevention; and Section on Child Death Review and Prevention (joint with National Association of Medical Examiners)

ABSTRACT. After a sudden infant death, parents and caregivers need accurate and open communication about why their infant died. Communicating tragic news about a child's death to families and caregivers is difficult. Shared and consistent terminology is essential for pediatricians, other physicians, and nonphysician clinicians to improve communication with families and among themselves. When families do not have complete information about why their child died, pediatricians will not be able to support them through the process and make appropriate referrals for pediatric specialty and mental health care. Families can only speculate about the cause and may blame themselves or others for the infant's death. The terminology used to describe infant deaths that occur suddenly and unexpectedly includes an assortment of terms that vary across and among pediatrician, other physician, or nonphysician clinician disciplines. Having consistent terminology is critical to improve the understanding of the etiology, pathophysiology, and epidemiology of these deaths and communicate with families. A lack of consistent terminology also makes it difficult to reliably monitor trends in mortality and hampers the ability to develop effective interventions. This report describes the history of sudden infant death terminology and summarizes the debate over the terminology and the resulting diagnostic shift of these deaths. This information is to assist pediatricians, other physicians, and nonphysician clinicians in caring for families during this difficult time. The importance of consistent terminology is outlined, followed by a summary of progress toward consensus. Recommendations for pediatricians, other physicians, and nonphysician clinicians are proposed. (9/21)

HANDOFFS: TRANSITIONS OF CARE FOR CHILDREN IN THE EMERGENCY DEPARTMENT

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. Transitions of care (ToCs), also referred to as handoffs or sign-outs, occur when the responsibility for a patient's care transfers from 1 health care provider to another. Transitions are common in the acute care setting and have been noted to be vulnerable events with opportunities for error. Health care is taking ideas from other high-risk industries, such as aerospace and nuclear power, to create models of structured transition processes. Although little literature currently exists to establish 1 model as superior, multiorganizational consensus groups agree that standardization is warranted and that additional work is needed to establish characteristics of ToCs that are associated with clinical or practice outcomes. The rationale for structuring ToCs, specifically those related to the care of children in the emergency setting, and a description of identified strategies are presented, along with resources for educating health care providers on ToCs. Recommendations for development, education, and implementation of transition models are included. (10/16, reaffirmed 12/20)

HEAD LICE (CLINICAL REPORT)

Cynthia D. Devore, MD, FAAP; Gordon E. Schutze, MD, FAAP; Council on School Health; and Committee on Infectious Diseases

ABSTRACT. Head lice infestation is associated with limited morbidity but causes a high level of anxiety among parents of school-aged children. Since the 2010 clinical report on head lice was published by the American Academy of Pediatrics, newer medications have been approved for the treatment of head lice. This revised clinical report clarifies current diagnosis and treatment protocols and provides guidance for the management of children with head lice in the school setting. (4/15, reaffirmed 6/20)
https://doi.org/10.1542/peds.2015-0746

HEALTH AND MENTAL HEALTH NEEDS OF CHILDREN IN US MILITARY FAMILIES (CLINICAL REPORT)

CDR Chadley R. Huebner, MD, MPH, FAAP; Section on Uniformed Services; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Children in US military families share common experiences and unique challenges, including parental

deployment and frequent relocation. Although some of the stressors of military life have been associated with higher rates of mental health disorders and increased health care use among family members, there are various factors and interventions that have been found to promote resilience. Military children often live on or near military installations, where they may attend Department of Defense–sponsored child care programs and schools and receive medical care through military treatment facilities. However, many families live in remote communities without access to these services. Because of this wide geographic distribution, military children are cared for in both military and civilian medical practices. This clinical report provides a background to military culture and offers practical guidance to assist civilian and military pediatricians caring for military children. (12/18)

HEALTH CARE ISSUES FOR CHILDREN AND ADOLESCENTS IN FOSTER CARE AND KINSHIP CARE

Council on Foster Care, Adoption, and Kinship Care; Committee on Adolescence; and Council on Early Childhood

ABSTRACT. Children and adolescents who enter foster care often do so with complicated and serious medical, mental health, developmental, oral health, and psychosocial problems rooted in their history of childhood trauma. Ideally, health care for this population is provided in a pediatric medical home by physicians who are familiar with the sequelae of childhood trauma and adversity. As youth with special health care needs, children and adolescents in foster care require more frequent monitoring of their health status, and pediatricians have a critical role in ensuring the well-being of children in out-of-home care through the provision of high-quality pediatric health services, health care coordination, and advocacy on their behalves. (9/15)
https://doi.org/10.1542/peds.2015-2655

HEALTH CARE ISSUES FOR CHILDREN AND ADOLESCENTS IN FOSTER CARE AND KINSHIP CARE (TECHNICAL REPORT)

Moira A. Szilagyi, MD, PhD; David S. Rosen, MD, MPH; David Rubin, MD, MSCE; Sarah Zlotnik, MSW, MSPH; Council on Foster Care, Adoption, and Kinship Care; Committee on Adolescence; and Council on Early Childhood

ABSTRACT. Children and adolescents involved with child welfare, especially those who are removed from their family of origin and placed in out-of-home care, often present with complex and serious physical, mental health, developmental, and psychosocial problems rooted in childhood adversity and trauma. As such, they are designated as children with special health care needs. There are many barriers to providing high-quality comprehensive health care services to children and adolescents whose lives are characterized by transience and uncertainty. Pediatricians have a critical role in ensuring the well-being of children in out-of-home care through the provision of high-quality pediatric health services in the context of a medical home, and health care coordination and advocacy on their behalf. This technical report supports the policy statement of the same title. (9/15)
https://doi.org/10.1542/peds.2015-2656

HEALTH CARE OF YOUTH AGING OUT OF FOSTER CARE

Council on Foster Care, Adoption, and Kinship Care and Committee on Early Childhood

ABSTRACT. Youth transitioning out of foster care face significant medical and mental health care needs. Unfortunately, these youth rarely receive the services they need because of lack of health insurance. Through many policies and programs, the federal government has taken steps to support older youth in foster care and those aging out. The Fostering Connections to Success and Increasing Adoptions Act of 2008 (Pub L No. 110-354) requires states to work with youth to develop a transition plan that addresses issues such as health insurance. In addition, beginning in 2014, the Patient Protection and Affordable Care Act of 2010 (Pub L No. 111-148) makes youth aging out of foster care eligible for Medicaid coverage until age 26 years, regardless of income. Pediatricians can support youth aging out of foster care by working collaboratively with the child welfare agency in their state to ensure that the ongoing health needs of transitioning youth are met. HEALTH CARE SUPERVISION FOR CHILDREN WITH WILLIAMS SYNDROME (CLINICAL REPORT)

Colleen A. Morris, MD; Stephen R. Braddock, MD; and Council on Genetics

ABSTRACT. This set of recommendations is designed to assist the pediatrician in caring for children with Williams syndrome (WS) who were diagnosed by using clinical features and with chromosome 7 microdeletion confirmed by fluorescence in situ hybridization, chromosome microarray, or multiplex ligation-dependent probe amplification. The recommendations in this report reflect review of the current literature, including previously peer-reviewed and published management suggestions for WS, as well as the consensus of physicians and psychologists with expertise in the care of individuals with WS. These general recommendations for the syndrome do not replace individualized medical assessment and treatment. (1/20)

HEALTH DISPARITIES IN TOBACCO USE AND EXPOSURE: A STRUCTURAL COMPETENCY APPROACH

Jyothi Marbin, MD, FAAP; Sophie J. Balk, MD, FAAP; Valerie Gribben, MD, FAAP; Judith Groner, MD, FAAP; and Section on Tobacco Control

ABSTRACT. Fourteen percent of US adults use tobacco products. Because many of those who use tobacco are parents and/or caregivers, children are disproportionately exposed to tobacco smoke. People who use tobacco products often become addicted to nicotine, resulting in tobacco dependence, a chronic, relapsing disease. Tobacco use and exposure are more likely to occur in vulnerable and marginalized groups, including those living in poverty. Although some view tobacco use as a personal choice, evidence suggests that structural forces play an important role in tobacco uptake, subsequent nicotine addiction, and perpetuation of use. Viewing tobacco use and tobacco dependence through a structural competency lens promotes recognition of the larger systemic forces perpetuating tobacco use, including deliberate targeting of groups by the tobacco industry, lack of enforcement of age-for-sale laws, inferior access to health insurance and health care, poor access to cessation resources, and economic stress. Each of these forces perpetuates tobacco initiation and use; in turn, tobacco use perpetuates the user's adverse health and economic conditions. Pediatricians are urged to view family tobacco use as a social determinant of health. In addition to screening adolescents for tobacco use and providing resources and treatment of tobacco dependence, pediatricians are encouraged to systematically screen children for secondhand smoke exposure and support family members who smoke with tobacco cessation. Additionally, pediatricians can address the structural issues perpetuating tobacco use by becoming involved in policy and advocacy initiatives. (12/20)

HEALTH INFORMATION TECHNOLOGY AND THE MEDICAL HOME

Council on Clinical Information Technology

ABSTRACT. The American Academy of Pediatrics (AAP) supports development and universal implementation of a comprehensive electronic infrastructure to support pediatric information functions of the medical home. These functions include (1) timely and continuous management and tracking of health data and services over a patient's lifetime for all providers, patients, families, and guardians, (2) comprehensive organization and secure transfer of health data during patient-care transitions between providers, institutions, and practices, (3) establishment and maintenance of central coordination of a patient's health information among multiple repositories (including personal health records and information exchanges), (4) translation of evidence into actionable clinical decision support, and (5) reuse of archived clinical data for continuous quality improvement. The AAP supports universal, secure, and vendor-neutral portability of health information for all patients contained within the medical home across all care settings (ambulatory practices, inpatient settings, emergency departments, pharmacies, consultants, support service providers, and therapists) for multiple purposes including direct care, personal health records, public health, and registries. The AAP also supports financial incentives that promote the development of information tools that meet the needs of pediatric workflows and that appropriately recognize the added value of medical homes to pediatric care. (4/11, reaffirmed 7/15)

https://doi.org/10.1542/peds.2011-0454

HEALTH SUPERVISION FOR CHILDREN WITH DOWN SYNDROME (CLINICAL REPORT)

Marilyn J. Bull, MD, and Committee on Genetics

ABSTRACT. These guidelines are designed to assist the pediatrician in caring for the child in whom a diagnosis of Down syndrome has been confirmed by chromosome analysis. Although a pediatrician's initial contact with the child is usually during infancy, occasionally the pregnant woman who has been given a prenatal diagnosis of Down syndrome will be referred for review of the condition and the genetic counseling provided. Therefore, this report offers guidance for this situation as well. (7/11, reaffirmed 9/16, 1/18)

https://doi.org/10.1542/peds.2011-1605

HEALTH SUPERVISION FOR CHILDREN WITH FRAGILE X SYNDROME (CLINICAL REPORT)

Joseph H. Hersh, MD; Robert A. Saul, MD; and Committee on Genetics

ABSTRACT. Fragile X syndrome (an *FMR1*–related disorder) is the most commonly inherited form of mental retardation. Early physical recognition is difficult, so boys with developmental delay should be strongly considered for molecular testing. The characteristic adult phenotype usually does not develop until the second decade of life. Girls can also be affected with developmental delay. Because multiple family members can be affected with mental retardation and other conditions (premature ovarian failure and tremor/ataxia), family history information is of critical importance for the diagnosis and management of affected patients and their families. This report summarizes issues for fragile X syndrome regarding clinical diagnosis, laboratory diagnosis, genetic counseling, related health problems, behavior management, and age-related health supervision guidelines. The diagnosis of fragile X syndrome not only involves the affected children but also potentially has significant health consequences for multiple generations in each family. (4/11)

https://doi.org/10.1542/peds.2010-3500

HEALTH SUPERVISION FOR CHILDREN WITH MARFAN SYNDROME (CLINICAL REPORT)

Brad T. Tinkle, MD, PhD; Howard M. Saal, MD; and Committee on Genetics

ABSTRACT. Marfan syndrome is a systemic, heritable connective tissue disorder that affects many different organ systems and is best managed by using a multidisciplinary approach. The guidance in this report is designed to assist the pediatrician in recognizing the features of Marfan syndrome as well as caring for the individual with this disorder. (9/13, reaffirmed 10/19)

https://doi.org/10.1542/peds.2013-2063

HEALTH SUPERVISION FOR CHILDREN WITH NEUROFIBROMATOSIS TYPE 1 (CLINICAL REPORT)

David T. Miller, MD, PhD, FAAP; Debra Freedenberg, MD, PhD, FAAP; Elizabeth Schorry, MD; Nicole J. Ullrich, MD, PhD; David Viskochil, MD, PhD; Bruce R. Korf, MD, PhD, FAAP; and Council on Genetics (joint with American College of Medical Genetics and Genomics)

ABSTRACT. Neurofibromatosis type 1 (NF1) is a multisystem disorder that primarily involves the skin and peripheral nervous system. Its population prevalence is approximately 1 in 3000. The condition is usually recognized in early childhood, when pigmentary manifestations emerge. Although NF1 is associated with marked clinical variability, most children affected follow patterns of growth and development within the normal range. Some features of NF1 can be present at birth, but most manifestations emerge with age, necessitating periodic monitoring to address ongoing health and developmental needs and minimize the risk of serious medical complications. In this report, we provide a review of the clinical criteria needed to establish a diagnosis, the inheritance pattern of NF1, its major clinical and developmental manifestations, and guidelines for monitoring and providing intervention to maximize the health and quality of life of a child affected. (4/19)

https://doi.org/10.1542/peds.2019-0660

HEALTH SUPERVISION FOR CHILDREN WITH PRADER-WILLI SYNDROME (CLINICAL REPORT)

Shawn E. McCandless, MD, and Committee on Genetics

ABSTRACT. This set of guidelines was designed to assist the pediatrician in caring for children with Prader-Willi syndrome diagnosed by clinical features and confirmed by molecular testing. Prader-Willi syndrome provides an excellent example of how early diagnosis and management can improve the long-term outcome for some genetic disorders. (12/10)

https://doi.org/10.1542/peds.2010-2820

HEALTH SUPERVISION FOR CHILDREN WITH SICKLE CELL DISEASE

Section on Hematology/Oncology and Committee on Genetics

ABSTRACT. Sickle cell disease (SCD) is a group of complex genetic disorders with multisystem manifestations. This statement provides pediatricians in primary care and subspecialty practice with an overview of the genetics, diagnosis, clinical manifestations, and treatment of SCD. Specialized comprehensive medical care decreases morbidity and mortality during childhood. The provision of comprehensive care is a time-intensive endeavor that includes ongoing patient and family education, periodic comprehensive evaluations and other disease-specific health maintenance services, psychosocial care, and genetic counseling. Timely and appropriate treatment of acute illness is critical, because life-threatening complications develop rapidly. It is essential that every child with SCD receive comprehensive care that is coordinated through a medical home with appropriate expertise. (3/02, reaffirmed 1/06, 1/11, 2/16, 9/20)

https://doi.org/10.1542/peds.109.3.526

HEALTH SUPERVISION FOR PEOPLE WITH ACHONDROPLASIA (CLINICAL REPORT)

Julie Hoover-Fong, MD, PhD, FACMG; Charles I. Scott, MD, FAAP; Marilyn C. Jones, MD, FAAP; and Committee on Genetics

ABSTRACT. Achondroplasia is the most common short-stature skeletal dysplasia, additionally marked by rhizomelia, macrocephaly, midface hypoplasia, and normal cognition. Potential medical complications associated with achondroplasia include lower extremity long bone bowing, middle-ear dysfunction, obstructive sleep apnea, and, more rarely, cervicomedullary compression, hydrocephalus, thoracolumbar kyphosis, and central sleep apnea. This is the second revision to the original 1995 health supervision guidance from the American Academy of Pediatrics for caring for patients with achondroplasia. Although many of the previously published recommendations remain appropriate for contemporary medical care, this document highlights interval advancements in the clinical methods available to monitor for complications associated with achondroplasia. This document is intended to provide guidance for health care providers to help identify individual patients at high risk of developing serious sequelae and to enable intervention before complications develop. (5/20)

https://doi.org/10.1542/peds.2020-1010

HELPING CHILDREN AND FAMILIES DEAL WITH DIVORCE AND SEPARATION (CLINICAL REPORT)

George J. Cohen, MD, FAAP; Carol C. Weitzman, MD, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. For the past several years in the United States, there have been more than 800 000 divorces and parent separations annually, with over 1 million children affected. Children and their parents can experience emotional trauma before, during, and after a separation or divorce. Pediatricians can be aware of their patients' behavior and parental attitudes and behaviors that may indicate family dysfunction and that can indicate need for intervention. Age-appropriate explanation and counseling for the child and advice and guidance for the parents, as well as recommendation of reading material, may help reduce the potential negative effects of divorce. Often, referral to professionals with expertise in the social, emotional, and legal aspects of the separation and its aftermath may be helpful for these families. (11/16)

https://doi.org/10.1542/peds.2016-3020

HIGH-DEDUCTIBLE HEALTH PLANS

Committee on Child Health Financing

ABSTRACT. High-deductible health plans (HDHPs) are insurance policies with higher deductibles than conventional plans. The Medicare Prescription Drug Improvement and Modernization Act of 2003 linked many HDHPs with tax-advantaged spending accounts. The 2010 Patient Protection and Affordable Care Act continues to provide for HDHPs in its lower-level plans on the health insurance marketplace and provides for them in employer-offered plans. HDHPs decrease the premium cost of insurance policies for purchasers and shift the risk of further payments to the individual subscriber. HDHPs reduce utilization and total medical costs, at least in the short term. Because HDHPs require out-of-pocket payment in the initial stages of care, primary care and other outpatient services as well as elective procedures are the services most affected, whereas higher-cost services in the health care system, incurred after the deductible is met, are unaffected. HDHPs promote adverse selection because healthier and wealthier patients tend to opt out of conventional plans in favor of HDHPs. Because the ill pay more than the healthy under HDHPs, families with children with special health care needs bear an increased cost burden in this model. HDHPs discourage use of nonpreventive primary care and thus are at odds with most recommendations for improving the organization of health care, which focus on strengthening primary care.

This policy statement provides background information on HDHPs, discusses the implications for families and pediatric care providers, and suggests courses of action. (4/14, reaffirmed 10/18)

https://doi.org/10.1542/peds.2014-0555

HIV TESTING AND PROPHYLAXIS TO PREVENT MOTHER-TO-CHILD TRANSMISSION IN THE UNITED STATES

Committee on Pediatric AIDS

ABSTRACT. Universal HIV testing of pregnant women in the United States is the key to prevention of mother-to-child transmission of HIV. Repeat testing in the third trimester and rapid HIV testing at labor and delivery are additional strategies to further reduce the rate of perinatal HIV transmission. Prevention of mother-to-child transmission of HIV is most effective when antiretroviral drugs are received by the mother during her pregnancy and continued through delivery and then administered to the infant after birth. Antiretroviral drugs are effective in reducing the risk of mother-to-child transmission of HIV even when prophylaxis is started for the infant soon after birth. New rapid testing methods allow identification of HIV-infected women or HIV-exposed infants in 20 to 60 minutes. The American Academy of Pediatrics recommends documented, routine HIV testing for all pregnant women in the United States after notifying the patient that testing will be performed, unless the patient declines HIV testing ("opt-out" consent or "right of refusal"). For women in labor with undocumented HIV-infection status during the current pregnancy, immediate maternal HIV testing with opt-out consent, using a rapid HIV antibody test, is recommended. Positive HIV antibody screening test results should be confirmed with immunofluorescent antibody or Western blot assay. For women with a positive rapid HIV antibody test result, antiretroviral prophylaxis should be administered promptly to the mother and newborn infant on the basis of the positive result of the rapid antibody test without waiting for results of confirmatory HIV testing. If the confirmatory test result is negative, then prophylaxis should be discontinued. For a newborn infant whose mother's HIV serostatus is unknown, the health care professional should perform rapid HIV antibody testing on the mother or on the newborn infant, with results reported to the health care professional no later than 12 hours after the infant's birth. If the rapid HIV antibody test result is positive, antiretroviral prophylaxis should be instituted as soon as possible after birth but certainly by 12 hours after delivery, pending completion of confirmatory HIV testing. The mother should be counseled not to breastfeed the infant. Assistance with immediate initiation of hand and pump expression to stimulate milk production should be offered to the mother, given the possibility that the confirmatory test result may be negative. If the confirmatory test result is negative, then prophylaxis should be stopped and breastfeeding may be initiated. If the confirmatory test result is positive, infants should receive antiretroviral prophylaxis for 6 weeks after birth, and the mother should not breastfeed the infant. (11/08, reaffirmed 6/11, 11/14, 10/20)

HOME CARE OF CHILDREN AND YOUTH WITH COMPLEX HEALTH CARE NEEDS AND TECHNOLOGY DEPENDENCIES (CLINICAL REPORT)

Ellen Roy Elias, MD; Nancy A. Murphy, MD; and Council on Children With Disabilities

ABSTRACT. Children and youth with complex medical issues, especially those with technology dependencies, experience frequent and often lengthy hospitalizations. Hospital discharges for these children can be a complicated process that requires a delib-

erate, multistep approach. In addition to successful discharges to home, it is essential that pediatric providers develop and implement an interdisciplinary and coordinated plan of care that addresses the child's ongoing health care needs. The goal is to ensure that each child remains healthy, thrives, and obtains optimal medical home and developmental supports that promote ongoing care at home and minimize recurrent hospitalizations. This clinical report presents an approach to discharging the child with complex medical needs with technology dependencies from hospital to home and then continually addressing the needs of the child and family in the home environment. (4/12, reaffirmed 5/17)

HONORING DO-NOT-ATTEMPT-RESUSCITATION REQUESTS IN SCHOOLS

Council on School Health and Committee on Bioethics

ABSTRACT. Increasingly, children and adolescents with complex chronic conditions are living in the community. Federal legislation and regulations facilitate their participation in school. Some of these children and adolescents and their families may wish to forego life-sustaining medical treatment, including cardiopulmonary resuscitation, because they would be ineffective or because the risks outweigh the benefits. Honoring these requests in the school environment is complex because of the limited availability of school nurses and the frequent lack of supporting state legislation and regulations. Understanding and collaboration on the part of all parties is essential. Pediatricians have an important role in helping school nurses incorporate a specific action plan into the student's individualized health care plan. The action plan should include both communication and comfort-care plans. Pediatricians who work directly with schools can also help implement policies, and professional organizations can advocate for regulations and legislation that enable students and their families to effectuate their preferences. HOSPITAL DISCHARGE OF THE HIGH-RISK NEONATE

Committee on Fetus and Newborn

ABSTRACT. This policy statement updates the guidelines on discharge of the high-risk neonate first published by the American Academy of Pediatrics in 1998. As with the earlier document, this statement is based, insofar as possible, on published, scientifically derived information. This updated statement incorporates new knowledge about risks and medical care of the high-risk neonate, the timing of discharge, and planning for care after discharge. It also refers to other American Academy of Pediatrics publications that are relevant to these issues. This statement draws on the previous classification of high-risk infants into 4 categories: (1) the preterm infant; (2) the infant with special health care needs or dependence on technology; (3) the infant at risk because of family issues; and (4) the infant with anticipated early death. The issues of deciding when discharge is appropriate, defining the specific needs for follow-up care, and the process of detailed discharge planning are addressed as they apply in general to all 4 categories; in addition, special attention is directed to the particular issues presented by the 4 individual categories. Recommendations are given to aid in deciding when discharge is appropriate and to ensure that all necessary care will be available and well coordinated after discharge. The need for individualized planning and physician judgment is emphasized. (11/08, reaffirmed 5/11, 11/18)

THE HOSPITAL RECORD OF THE INJURED CHILD AND THE NEED FOR EXTERNAL CAUSE-OF-INJURY CODES

Committee on Injury and Poison Prevention

ABSTRACT. Proper record-keeping of emergency department visits and hospitalizations of injured children is vital for appropriate patient management. Determination and documentation of the circumstances surrounding the injury event are essential. This information not only is the basis for preventive counseling, but also provides clues about how similar injuries in other youth can be avoided. The hospital records have an important secondary purpose; namely, if sufficient information about the cause and mechanism of injury is documented, it can be subsequently coded, electronically compiled, and retrieved later to provide an epidemiologic profile of the injury, the first step in prevention at the population level. To be of greatest use, hospital records should indicate the "who, what, when, where, why, and how" of the injury occurrence and whether protective equipment (eg, a seat belt) was used. The pediatrician has two important roles in this area: to document fully the injury event and to advocate the use of standardized external cause-of-injury codes, which allow such data to be compiled and analyzed. HOSPITAL STAY FOR HEALTHY TERM NEWBORN INFANTS

William E. Benitz, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. The hospital stay of the mother and her healthy term newborn infant should be long enough to allow identification of problems and to ensure that the mother is sufficiently recovered and prepared to care for herself and her newborn at home. The length of stay should be based on the unique characteristics of each mother-infant dyad, including the health of the mother, the health and stability of the newborn, the ability and confidence of the mother to care for herself and her newborn, the adequacy of support systems at home, and access to appropriate follow-up care in a medical home. Input from the mother and her obstetrical care provider should be considered before a decision to discharge a newborn is made, and all efforts should be made to keep a mother and her newborn together to ensure simultaneous discharge. HUMAN EMBRYONIC STEM CELL (HESC) AND HUMAN EMBRYO RESEARCH

Committee on Pediatric Research and Committee on Bioethics

ABSTRACT. Human embryonic stem cell research has emerged as an important platform for the understanding and treatment of pediatric diseases. From its inception, however, it has raised ethical concerns based not on the use of stem cells themselves but on objections to the source of the cells—specifically, the destruction of preimplantation human embryos. Despite differences in public opinion on this issue, a large majority of the public supports continued research using embryonic stem cells. Given the possible substantial benefit of stem cell research on child health and development, the American Academy of Pediatrics believes that funding and oversight for human embryo and embryonic stem cell research should continue. HYPOTHERMIA AND NEONATAL ENCEPHALOPATHY (CLINICAL REPORT)

Committee on Fetus and Newborn

ABSTRACT. Data from large randomized clinical trials indicate that therapeutic hypothermia, using either selective head cooling or systemic cooling, is an effective therapy for neonatal encephalopathy. Infants selected for cooling must meet the criteria outlined in published clinical trials. The implementation of cooling

needs to be performed at centers that have the capability to manage medically complex infants. Because the majority of infants who have neonatal encephalopathy are born at community hospitals, centers that perform cooling should work with their referring hospitals to implement education programs focused on increasing the awareness and identification of infants at risk for encephalopathy, and the initial clinical management of affected infants. IDENTIFICATION, EVALUATION, AND MANAGEMENT OF CHILDREN WITH AUTISM SPECTRUM DISORDER (CLINICAL REPORT)

Susan L. Hyman, MD, FAAP; Susan E. Levy, MD, MPH, FAAP; Scott M. Myers, MD, FAAP; Council on Children With Disabilities; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Autism spectrum disorder (ASD) is a common neurodevelopmental disorder with reported prevalence in the United States of 1 in 59 children (approximately 1.7%). Core deficits are identified in 2 domains: social communication/interaction and restrictive, repetitive patterns of behavior. Children and youth with ASD have service needs in behavioral, educational, health, leisure, family support, and other areas. Standardized screening for ASD at 18 and 24 months of age with ongoing developmental surveillance continues to be recommended in primary care (although it may be performed in other settings), because ASD is common, can be diagnosed as young as 18 months of age, and has evidenced-based interventions that may improve function. More accurate and culturally sensitive screening approaches are needed. Primary care providers should be familiar with the diagnostic criteria for ASD, appropriate etiologic evaluation, and co-occurring medical and behavioral conditions (such as disorders of sleep and feeding, gastrointestinal tract symptoms, obesity, seizures, attention-deficit/hyperactivity disorder, anxiety, and wandering) that affect the child's function and quality of life. There is an increasing evidence base to support behavioral and other interventions to address specific skills and symptoms. Shared decision making calls for collaboration with families in evaluation and choice of interventions. This single clinical report updates the 2007 American Academy of Pediatrics clinical reports on the evaluation and treatment of ASD in one publication with an online table of contents and section view available through the American Academy of Pediatrics Gateway to help the reader identify topic areas within the report. IDENTIFICATION AND CARE OF HIV-EXPOSED AND HIV-INFECTED INFANTS, CHILDREN, AND ADOLESCENTS IN FOSTER CARE

Committee on Pediatric AIDS

ABSTRACT. As a consequence of the expanding human immunodeficiency virus (HIV) epidemic and major advances in medical management of HIV-exposed and HIV-infected persons, revised recommendations are provided for HIV testing of infants, children, and adolescents in foster care. Updated recommendations also are provided for the care of HIV-exposed and HIV-infected persons who are in foster care. (7/00, reaffirmed 12/16)
https://doi.org/10.1542/peds.106.1.149

IDENTIFICATION AND MANAGEMENT OF EATING DISORDERS IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Laurie L. Hornberger, MD, MPH, FAAP; Margo A. Lane, MD, FRCPC, FAAP; and Committee on Adolescence

ABSTRACT. Eating disorders are serious, potentially life-threatening illnesses afflicting individuals through the life span, with a particular impact on both the physical and psychological development of children and adolescents. Because care for children and adolescents with eating disorders can be complex and resources for the treatment of eating disorders are often limited, pediatricians may be called on to not only provide medical supervision for their patients with diagnosed eating disorders but also coordinate care and advocate for appropriate services. This clinical report includes a review of common eating disorders diagnosed in children and adolescents, outlines the medical evaluation of patients suspected of having an eating disorder, presents an overview of treatment strategies, and highlights opportunities for advocacy. IDENTIFYING CHILD ABUSE FATALITIES DURING INFANCY (CLINICAL REPORT)

Vincent J. Palusci, MD, MS, FAAP; Amanda J. Kay, MD, MPH, FAAP; Erich Batra, MD, FAAP; Rachel Y. Moon, MD, FAAP; Council on Child Abuse and Neglect; Section on Child Death Review and Prevention; and Task Force on Sudden Infant Death Syndrome (joint with Tracey S. Corey, MD; Thomas Andrew, MD; Michael Graham, MD; and National Association of Medical Examiners)

ABSTRACT. When a healthy infant dies suddenly and unexpectedly, it is critical to correctly determine if the death was caused by child abuse or neglect. Sudden unexpected infant deaths should be comprehensively investigated, ancillary tests and forensic procedures should be used to more-accurately identify the cause of death, and parents deserve to be approached in a nonaccusatory manner during the investigation. Missing a child abuse death can place other children at risk, and inappropriately approaching a sleep-related death as maltreatment can result in inappropriate criminal and protective services investigations. Communities can learn from these deaths by using multidisciplinary child death reviews. Pediatricians can support families during investigation, advocate for and support state policies that require autopsies and scene investigation, and advocate for establishing comprehensive and fully funded child death investigation and reviews at the local and state levels. Additional funding is also needed for research to advance our ability to prevent these deaths. (8/19)

IDENTIFYING INFANTS AND YOUNG CHILDREN WITH DEVELOPMENTAL DISORDERS IN THE MEDICAL HOME: AN ALGORITHM FOR DEVELOPMENTAL SURVEILLANCE AND SCREENING

Council on Children With Disabilities, Section on Developmental and Behavioral Pediatrics, Bright Futures Steering Committee, and Medical Home Initiatives for Children With Special Needs Project Advisory Committee

ABSTRACT. Early identification of developmental disorders is critical to the well-being of children and their families. It is an integral function of the primary care medical home and an appropriate responsibility of all pediatric health care professionals. This statement provides an algorithm as a strategy to support health care professionals in developing a pattern and practice for addressing developmental concerns in children from birth through 3 years of age. The authors recommend that developmental surveillance be incorporated at every well-child preventive care visit. Any concerns raised during surveillance should be promptly addressed with standardized developmental screening tests. In addition, screening tests should be administered regularly at the 9-, 18-, and 30-month visits. (Because the 30-month visit is not yet a part of the preventive care system and is often not reimbursable by third-party payers at this time, developmental screening can be performed at 24 months of age.

In addition, because the frequency of regular pediatric visits decreases after 24 months of age, a pediatrician who expects that his or her patients will have difficulty attending a 30-month visit should conduct screening during the 24-month visit.) The early identification of developmental problems should lead to further developmental and medical evaluation, diagnosis, and treatment, including early developmental intervention. Children diagnosed with developmental disorders should be identified as children with special health care needs, and chronic-condition management should be initiated. Identification of a developmental disorder and its underlying etiology may also drive a range of treatment planning, from medical treatment of the child to family planning for his or her parents. (7/06, reaffirmed 12/09, 8/14)

IDENTIFYING THE MISSHAPEN HEAD: CRANIOSYNOSTOSIS AND RELATED DISORDERS (CLINICAL REPORT)

Mark S. Dias, MD, FAAP, FAANS; Thomas Samson, MD, FAAP; Elias B. Rizk, MD, FAAP, FAANS; Lance S. Governale, MD, FAAP, FAANS; Joan T. Richtsmeier, PhD; Section on Neurologic Surgery; and Section on Plastic and Reconstructive Surgery

ABSTRACT. Pediatric care providers, pediatricians, pediatric subspecialty physicians, and other health care providers should be able to recognize children with abnormal head shapes that occur as a result of both synostotic and deformational processes. The purpose of this clinical report is to review the characteristic head shape changes, as well as secondary craniofacial characteristics, that occur in the setting of the various primary craniosynostoses and deformations. As an introduction, the physiology and genetics of skull growth as well as the pathophysiology underlying craniosynostosis are reviewed. This is followed by a description of each type of primary craniosynostosis (metopic, unicoronal, bicoronal, sagittal, lambdoid, and frontosphenoidal) and their resultant head shape changes, with an emphasis on differentiating conditions that require surgical correction from those (bathrocephaly, deformational plagiocephaly/brachycephaly, and neonatal intensive care unit-associated skill deformation, known as NICUcephaly) that do not. The report ends with a brief discussion of microcephaly as it relates to craniosynostosis as well as fontanelle closure. The intent is to improve pediatric care providers' recognition and timely referral for craniosynostosis and their differentiation of synostotic from deformational and other nonoperative head shape changes. IMMERSION IN WATER DURING LABOR AND DELIVERY (CLINICAL REPORT)

Committee on Fetus and Newborn (joint with American College of Obstetricians and Gynecologists Committee on Obstetric Practice)

ABSTRACT. Immersion in water has been suggested as a beneficial alternative for labor, delivery, or both and over the past decades has gained popularity in many parts of the world. Immersion in water during the first stage of labor may be associated with decreased pain or use of anesthesia and decreased duration of labor. However, there is no evidence that immersion in water during the first stage of labor otherwise improves perinatal outcomes, and it should not prevent or inhibit other elements of care. The safety and efficacy of immersion in water during the second stage of labor have not been established, and immersion in water during the second stage of labor has not been associated with maternal or fetal benefit. Given these facts and case reports of rare but serious adverse effects in the newborn, the practice of immersion in the second stage of labor (underwater delivery) should be considered an experimental procedure that only should be performed within the context of an appropriately designed clinical trial with informed consent. Facilities that plan to offer immersion in the first stage of labor need to establish rigorous protocols for candidate selection, maintenance and cleaning of tubs and immersion pools, infection control procedures, monitoring of mothers and fetuses at appropriate intervals while immersed, and immediately and safely moving women out of the tubs if maternal or fetal concerns develop. IMMUNIZATION INFORMATION SYSTEMS

Committee on Practice and Ambulatory Medicine

ABSTRACT. The American Academy of Pediatrics continues to support the development and implementation of immunization information systems, previously referred to as immunization registries, and other systems for the benefit of children, pediatricians, and their communities. Pediatricians and others must be aware of the value that immunization information systems have for society, the potential fiscal influences on their practice, the costs and benefits, and areas for future improvement. IMMUNIZING AGAINST HATE: OVERCOMING ASIAN AMERICAN AND PACIFIC ISLANDER RACISM

Lee Savio Beers, MD, FAAP; Moira Szilagyi, MD, PhD, FAAP; Warren M. Seigel, MD, MBA, FAAP; Wendy S. Davis, MD, FAAP; Yasuko Fukuda, MD, FAAP; Madeline Joseph, MD, FAAP; Joseph L. Wright, MD, MPH, FAAP; Sara H. Goza, MD, FAAP; Board of Directors Executive Committee; and Board Committee on Equity

ABSTRACT. It has been more than a year since Immediate Past President of the American Academy of Pediatrics (AAP), Sally Goza, MD, FAAP, warned against the threat severe acute respiratory syndrome-coronavirus 2 (SARS-CoV-2) posed to children and families, including the harm coronavirus disease 2019 (COVID-19)–fueled racism and xenophobia could cause the Asian American community. Sadly, as the COVID-19 pandemic spread, racism and violent attacks on Asian Americans spread along with it. (6/21)

IMMUNIZING PARENTS AND OTHER CLOSE FAMILY CONTACTS IN THE PEDIATRIC OFFICE SETTING (TECHNICAL REPORT)

Herschel R. Lessin, MD; Kathryn M. Edwards, MD; Committee on Practice and Ambulatory Medicine; and Committee on Infectious Diseases

ABSTRACT. Additional strategies are needed to protect children from vaccine-preventable diseases. In particular, very young infants, as well as children who are immunocompromised, are at especially high risk for developing the serious consequences of vaccine-preventable diseases and cannot be immunized completely. There is some evidence that children who become infected with these diseases are exposed to pathogens through household contacts, particularly from parents or other close family contacts. Such infections likely are attributable to adults who are not fully protected from these diseases, either because their immunity to vaccine-preventable diseases has waned over time or because they have not received a vaccine. There are many challenges that have added to low adult immunization rates in the United States. One option to increase immunization coverage for parents and close family contacts of infants and vulnerable children is to provide alternative locations for these adults to be immunized, such as the pediatric office setting. Ideally, adults should receive immunizations in their medical homes; however, to provide greater protection to these adults and reduce the exposure of children to pathogens, immunizing parents or other adult family contacts in the pediatric office setting could increase immunization coverage for this population to protect themselves

as well as children to whom they provide care. (12/11, reaffirmed 8/16)

THE IMPACT OF MARIJUANA POLICIES ON YOUTH: CLINICAL, RESEARCH, AND LEGAL UPDATE

Committee on Substance Abuse and Committee on Adolescence

ABSTRACT. This policy statement is an update of the American Academy of Pediatrics policy statement "Legalization of Marijuana: Potential Impact on Youth," published in 2004. Pediatricians have special expertise in the care of children and adolescents and may be called on to advise legislators about the potential impact of changes in the legal status of marijuana on adolescents. Parents also may look to pediatricians for advice as they consider whether to support state-level initiatives that propose to legalize the use of marijuana for medical and nonmedical purposes or to decriminalize the possession of small amounts of marijuana. This policy statement provides the position of the American Academy of Pediatrics on the issue of marijuana legalization. The accompanying technical report reviews what is currently known about the relationships of marijuana use with health and the developing brain and the legal status of marijuana and adolescents' use of marijuana to better understand how change in legal status might influence the degree of marijuana use by adolescents in the future. (2/15)
https://doi.org/10.1542/peds.2014-4146

THE IMPACT OF MARIJUANA POLICIES ON YOUTH: CLINICAL, RESEARCH, AND LEGAL UPDATE (TECHNICAL REPORT)

Seth Ammerman, MD, FAAP; Sheryl Ryan, MD, FAAP; William P. Adelman, MD, FAAP; Committee on Substance Abuse; and Committee on Adolescence

ABSTRACT. This technical report updates the 2004 American Academy of Pediatrics technical report on the legalization of marijuana. Current epidemiology of marijuana use is presented, as are definitions and biology of marijuana compounds, side effects of marijuana use, and effects of use on adolescent brain development. Issues concerning medical marijuana specifically are also addressed. Concerning legalization of marijuana, 4 different approaches in the United States are discussed: legalization of marijuana solely for medical purposes, decriminalization of recreational use of marijuana, legalization of recreational use of marijuana, and criminal prosecution of recreational (and medical) use of marijuana. These approaches are compared, and the latest available data are presented to aid in forming public policy. The effects on youth of criminal penalties for marijuana use and possession are also addressed, as are the effects or potential effects of the other 3 policy approaches on adolescent marijuana use. Recommendations are included in the accompanying policy statement. (2/15)
https://doi.org/10.1542/peds.2014-4147

THE IMPACT OF RACISM ON CHILD AND ADOLESCENT HEALTH

Maria Trent, MD, MPH, FAAP, FSAHM; Danielle G. Dooley, MD, MPhil, FAAP; Jacqueline Dougé, MD, MPH, FAAP; Section on Adolescent Health; Council on Community Pediatrics; and Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics is committed to addressing the factors that affect child and adolescent health with a focus on issues that may leave some children more vulnerable than others. Racism is a social determinant of health that has a profound impact on the health status of children, adolescents, emerging adults, and their families. Although progress has been made toward racial equality and equity, the evidence to support the continued negative impact of racism on health and well-being through implicit and explicit biases, institutional structures, and interpersonal relationships is clear. The objective of this policy statement is to provide an evidence-based document focused on the role of racism in child and adolescent development and health outcomes. By acknowledging the role of racism in child and adolescent health, pediatricians and other pediatric health professionals will be able to proactively engage in strategies to optimize clinical care, workforce development, professional education, systems engagement, and research in a manner designed to reduce the health effects of structural, personally mediated, and internalized racism and improve the health and well-being of all children, adolescents, emerging adults, and their families. (7/19)
https://doi.org/10.1542/peds.2019-1765

THE IMPACT OF SOCIAL MEDIA ON CHILDREN, ADOLESCENTS, AND FAMILIES (CLINICAL REPORT)

Gwenn Schurgin O'Keeffe, MD; Kathleen Clarke-Pearson, MD; and Council on Communications and Media

ABSTRACT. Using social media Web sites is among the most common activity of today's children and adolescents. Any Web site that allows social interaction is considered a social media site, including social networking sites such as Facebook, MySpace, and Twitter; gaming sites and virtual worlds such as Club Penguin, Second Life, and the Sims; video sites such as YouTube; and blogs. Such sites offer today's youth a portal for entertainment and communication and have grown exponentially in recent years. For this reason, it is important that parents become aware of the nature of social media sites, given that not all of them are healthy environments for children and adolescents. Pediatricians are in a unique position to help families understand these sites and to encourage healthy use and urge parents to monitor for potential problems with cyberbullying, "Facebook depression," sexting, and exposure to inappropriate content. (3/11)
https://doi.org/10.1542/peds.2011-0054

IMPROVING HEALTH AND SAFETY AT CAMP

Michael J. Ambrose, MD, FAAP; Edward A. Walton, MD, FAAP; and Council on School Health

ABSTRACT. The American Academy of Pediatrics has created recommendations for health appraisal and preparation of young people before participation in day, resident, or family camps and to guide health and safety practices at camp. These recommendations are intended for parents and families, primary health care providers, and camp administration and health center staff. Although camps have diverse environments, there are general guidelines that apply to all situations and specific recommendations that are appropriate under special conditions. This policy statement has been reviewed and is supported by the American Camp Association and Association of Camp Nursing. (6/19)
https://doi.org/10.1542/peds.2019-1355

INCIDENTAL FINDINGS ON BRAIN AND SPINE IMAGING IN CHILDREN (CLINICAL REPORT)

Cormac O. Maher, MD, FAAP; Joseph H. Piatt Jr, MD, FAAP; and Section on Neurologic Surgery

ABSTRACT. In recent years, the utilization of diagnostic imaging of the brain and spine in children has increased dramatically, leading to a corresponding increase in the detection of incidental findings of the central nervous system. Patients with unexpected findings on imaging are often referred for subspecialty evaluation. Even with rational use of diagnostic imaging and subspecialty consultation, the diagnostic process will always generate unexpected findings that must be explained and managed. Familiarity with the most common findings that are discovered incidentally on diagnostic imaging of the brain and spine will assist the pediatrician in providing counseling to families and in making recommendations in conjunction with a

neurosurgeon, when needed, regarding additional treatments and prognosis. (3/15)
https://doi.org/10.1542/peds.2015-0071

INCORPORATING RECOGNITION AND MANAGEMENT OF PERINATAL DEPRESSION INTO PEDIATRIC PRACTICE

Marian F. Earls, MD, MTS, FAAP; Michael W. Yogman, MD, FAAP; Gerri Mattson, MD, MSPH, FAAP; Jason Rafferty, MD, MPH, EdM, FAAP; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Perinatal depression (PND) is the most common obstetric complication in the United States. Even when screening results are positive, mothers often do not receive further evaluation, and even when PND is diagnosed, mothers do not receive evidence-based treatments. Studies reveal that postpartum depression (PPD), a subset of PND, leads to increased costs of medical care, inappropriate medical treatment of the infant, discontinuation of breastfeeding, family dysfunction, and an increased risk of abuse and neglect. PPD, specifically, adversely affects this critical early period of infant brain development. PND is an example of an adverse childhood experience that has potential long-term adverse health complications for the mother, her partner, the infant, and the mother-infant dyad. However, PND can be treated effectively, and the stress on the infant can be buffered. Pediatric medical homes should coordinate care more effectively with prenatal providers for women with prenatally diagnosed maternal depression; establish a system to implement PPD screening at the 1-, 2-, 4-, and 6-month well-child visits; use community resources for the treatment and referral of the mother with depression; and provide support for the maternal-child (dyad) relationship, including breastfeeding support. State chapters of the American Academy of Pediatrics, working with state departments of public health, public and private payers, and maternal and child health programs, should advocate for payment and for increased training for PND screening and treatment. American Academy of Pediatrics recommends advocacy for workforce development for mental health professionals who care for young children and mother-infant dyads, and for promotion of evidence-based interventions focused on healthy attachment and parent-child relationships. (12/18)
https://doi.org/10.1542/peds.2018-3259

INCORPORATING RECOGNITION AND MANAGEMENT OF PERINATAL DEPRESSION INTO PEDIATRIC PRACTICE (TECHNICAL REPORT)

Jason Rafferty, MD, MPH, EdM, FAAP; Gerri Mattson, MD, MSPH, FAAP; Marian F. Earls, MD, MTS, FAAP; Michael W. Yogman, MD, FAAP; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Perinatal depression is the most common obstetric complication in the United States, with prevalence rates of 15% to 20% among new mothers. Untreated, it can adversly affect the well-being of children and families through increasing the risk for costly complications during birth and lead to deterioration of core supports, including partner relationships and social networks. Perinatal depression contributes to long-lasting, and even permanent, consequences for the physical and mental health of parents and children, including poor family functioning, increased risk of child abuse and neglect, delayed infant development, perinatal obstetric complications, challenges with breastfeeding, and costly increases in health care use. Perinatal depression can interfere with early parent-infant interaction and attachment, leading to potentially long-term disturbances in the child's physical, emotional, cognitive, and social development. Fortunately, perinatal depression is identifiable and treatable. The US Preventive Services Task Force, Centers for Medicare and Medicaid Services, and many professional organizations recommend routine universal screening for perinatal depression in women to facilitate early evidence-based treatment and referrals, if necessary. Despite significant gains in screening rates from 2004 to 2013, a minority of pediatricians routinely screen for postpartum depression, and many mothers are still not identified or treated. Pediatric primary care clinicians, with a core mission of promoting child and family health, are in an ideal position to implement routine postpartum depression screens at several well-child visits throughout infancy and to provide mental health support through referrals and/or the interdisciplinary services of a pediatric patient-centered medical home model. (12/18)

INCREASING ANTIRETROVIRAL DRUG ACCESS FOR CHILDREN WITH HIV INFECTION

Committee on Pediatric AIDS and Section on International Child Health

ABSTRACT. Although there have been great gains in the prevention of pediatric HIV infection and provision of antiretroviral therapy for children with HIV infection in resource-rich countries, many barriers remain to scaling up HIV prevention and treatment for children in resource-limited areas of the world. Appropriate testing technologies need to be made more widely available to identify HIV infection in infants. Training of practitioners in the skills required to care for children with HIV infection is required to increase the number of children receiving antiretroviral therapy. Lack of availability of appropriate antiretroviral drug formulations that are easily usable and inexpensive is a major impediment to optimal care for children with HIV. The time and energy spent trying to develop liquid antiretroviral formulations might be better used in the manufacture of smaller pill sizes or crushable tablets, which are easier to dispense, transport, store, and administer to children. (4/07, reaffirmed 4/10, 4/16)
https://doi.org/10.1542/peds.2007-0273

INCREASING IMMUNIZATION COVERAGE

Committee on Practice and Ambulatory Medicine and Council on Community Pediatrics

ABSTRACT. In 1977, the American Academy of Pediatrics issued a statement calling for universal immunization of all children for whom vaccines are not contraindicated. In 1995, the policy statement "Implementation of the Immunization Policy" was published by the American Academy of Pediatrics, followed in 2003 with publication of the first version of this statement, "Increasing Immunization Coverage." Since 2003, there have continued to be improvements in immunization coverage, with progress toward meeting the goals set forth in *Healthy People 2010.* Data from the 2007 National Immunization Survey showed that 90% of children 19 to 35 months of age have received recommended doses of each of the following vaccines: inactivated poliovirus (IPV), measles-mumps-rubella (MMR), varicella-zoster virus (VZB), hepatitis B virus (HBV), and *Haemophilus influenzae* type b (Hib). For diphtheria and tetanus and acellular pertussis (DTaP) vaccine, 84.5% have received the recommended 4 doses by 35 months of age. Nevertheless, the *Healthy People 2010* goal of at least 80% coverage for the full series (at least 4 doses of DTaP, 3 doses of IPV, 1 dose of MMR, 3 doses of Hib, 3 doses of HBV, and 1 dose of varicella-zoster virus vaccine) has not yet been met, and immunization coverage of adolescents continues to lag behind the goals set forth in *Healthy People 2010.* Despite these encouraging data, a vast number of new challenges that threaten continued success toward the goal of universal immunization coverage have emerged. These challenges include an increase in new vaccines and new vaccine combinations as well as a significant number of vaccines currently under development; a dramatic increase in the acquisition cost of vaccines, coupled with a lack

of adequate payment to practitioners to buy and administer vaccines; unanticipated manufacturing and delivery problems that have caused significant shortages of various vaccine products; and the rise of a public antivaccination movement that uses the Internet as well as standard media outlets to advance a position, wholly unsupported by any scientific evidence, linking vaccines with various childhood conditions, particularly autism. Much remains to be accomplished by physician organizations; vaccine manufacturers; third-party payers; the media; and local, state, and federal governments to ensure dependable vaccine supply and payments that are sufficient to continue to provide immunizations in public and private settings and to promote effective strategies to combat unjustified misstatements by the antivaccination movement.

Pediatricians should work individually and collectively at the local, state, and national levels to ensure that all children without a valid contraindication receive all childhood immunizations on time. Pediatricians and pediatric organizations, in conjunction with government agencies such as the Centers for Disease Control and Prevention, must communicate effectively with parents to maximize their understanding of the overall safety and efficacy of vaccines. Most parents and children have not experienced many of the vaccine-preventable diseases, and the general public is not well informed about the risks and sequelae of these conditions. A number of recommendations are included for pediatricians, individually and collectively, to support further progress toward the goal of universal immunization coverage of all children for whom vaccines are not contraindicated. THE INDIVIDUALS WITH DISABILITIES EDUCATION ACT (IDEA) FOR CHILDREN WITH SPECIAL EDUCATIONAL NEEDS (CLINICAL REPORT)

Paul H. Lipkin, MD, FAAP; Jeffrey Okamoto, MD, FAAP; Council on Children With Disabilities; and Council on School Health

ABSTRACT. The pediatric health care provider has a critical role in supporting the health and well-being of children and adolescents in all settings, including early intervention (EI), preschool, and school environments. It is estimated that 15% of children in the United States have a disability. The Individuals with Disabilities Education Act entitles every affected child in the United States from infancy to young adulthood to a free appropriate public education through EI and special education services. These services bolster development and learning of children with various disabilities. This clinical report provides the pediatric health care provider with a summary of key components of the most recent version of this law. Guidance is also provided to ensure that every child in need receives the EI and special education services to which he or she is entitled. (11/15, reaffirmed 10/19)

INDOOR ENVIRONMENTAL CONTROL PRACTICES AND ASTHMA MANAGEMENT (CLINICAL REPORT)

Elizabeth C. Matsui, MD, MHS, FAAP; Stuart L. Abramson, MD, PhD, AE-C, FAAP; Megan T. Sandel, MD, MPH, FAAP; Section on Allergy and Immunology; and Council on Environmental Health

ABSTRACT. Indoor environmental exposures, particularly allergens and pollutants, are major contributors to asthma morbidity in children; environmental control practices aimed at reducing these exposures are an integral component of asthma management. Some individually tailored environmental control practices that have been shown to reduce asthma symptoms and exacerbations are similar in efficacy and cost to controller medications. As a part of developing tailored strategies regarding environmental control measures, an environmental history can be obtained to evaluate the key indoor environmental exposures that are known to trigger asthma symptoms and exacerbations, including both indoor pollutants and allergens. An environmental history includes questions regarding the presence of pets or pests or evidence of pests in the home, as well as knowledge regarding whether the climatic characteristics in the community favor dust mites. In addition, the history focuses on sources of indoor air pollution, including the presence of smokers who live in the home or care for children and the use of gas stoves and appliances in the home. Serum allergen-specific immunoglobulin E antibody tests can be performed or the patient can be referred for allergy skin testing to identify indoor allergens that are most likely to be clinically relevant. Environmental control strategies are tailored to each potentially relevant indoor exposure and are based on knowledge of the sources and underlying characteristics of the exposure. Strategies include source removal, source control, and mitigation strategies, such as high-efficiency particulate air purifiers and allergen-proof mattress and pillow encasements, as well as education, which can be delivered by primary care pediatricians, allergists, pediatric pulmonologists, other health care workers, or community health workers trained in asthma environmental control and asthma education. INFANT FEEDING AND TRANSMISSION OF HUMAN IMMUNODEFICIENCY VIRUS IN THE UNITED STATES

Committee on Pediatric AIDS

ABSTRACT. Physicians caring for infants born to women infected with HIV are likely to be involved in providing guidance to HIV-infected mothers on appropriate infant feeding practices. It is critical that physicians are aware of the HIV transmission risk from human milk and the current recommendations for feeding HIV-exposed infants in the United States. Because the only intervention to completely prevent HIV transmission via human milk is not to breastfeed, in the United States, where clean water and affordable replacement feeding are available, the American Academy of Pediatrics recommends that HIV-infected mothers not breastfeed their infants, regardless of maternal viral load and antiretroviral therapy. (1/13, reaffirmed 4/16)

INFANT METHEMOGLOBINEMIA: THE ROLE OF DIETARY NITRATE IN FOOD AND WATER (CLINICAL REPORT)

Frank R. Greer, MD; Michael Shannon, MD; Committee on Nutrition; and Committee on Environmental Health

ABSTRACT. Infants for whom formula may be prepared with well water remain a high-risk group for nitrate poisoning. This clinical report reinforces the need for testing of well water for nitrate content. There seems to be little or no risk of nitrate poisoning from commercially prepared infant foods in the United States. However, reports of nitrate poisoning from home-prepared vegetable foods for infants continue to occur. Breastfeeding infants are not at risk of methemoglobinemia even when mothers ingest water with very high concentrations of nitrate nitrogen (100 ppm). (9/05, reaffirmed 4/09)

INFECTION PREVENTION AND CONTROL IN PEDIATRIC AMBULATORY SETTINGS

Mobeen H. Rathore, MD, FAAP; Mary Anne Jackson, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. Since the American Academy of Pediatrics published its statement titled "Infection Prevention and Control in Pediatric Ambulatory Settings" in 2007, there have been significant changes that prompted this updated statement. Infection prevention and control is an integral part of pediatric practice in ambulatory medical settings as well as in hospitals.

Infection prevention and control practices should begin at the time the ambulatory visit is scheduled. All health care personnel should be educated regarding the routes of transmission and techniques used to prevent the transmission of infectious agents. Policies for infection prevention and control should be written, readily available, updated every 2 years, and enforced. Many of the recommendations for infection control and prevention from the Centers for Disease Control and Prevention for hospitalized patients are also applicable in the ambulatory setting. These recommendations include requirements for pediatricians to take precautions to identify and protect employees likely to be exposed to blood or other potentially infectious materials while on the job. In addition to emphasizing the key principles of infection prevention and control in this policy, we update those that are relevant to the ambulatory care patient. These guidelines emphasize the role of hand hygiene and the implementation of diagnosis- and syndrome-specific isolation precautions, with the exemption of the use of gloves for routine diaper changes and wiping a well child's nose or tears for most patient encounters. Additional topics include respiratory hygiene and cough etiquette strategies for patients with a respiratory tract infection, including those relevant for special populations like patients with cystic fibrosis or those in short-term residential facilities; separation of infected, contagious children from uninfected children when feasible; safe handling and disposal of needles and other sharp medical devices; appropriate use of personal protective equipment, such as gloves, gowns, masks, and eye protection; and appropriate use of sterilization, disinfection, and antisepsis. Lastly, in this policy, we emphasize the importance of public health interventions, including vaccination for patients and health care personnel, and outline the responsibilities of the health care provider related to prompt public health notification for specific reportable diseases and communication with colleagues who may be providing subsequent care of an infected patient to optimize the use of isolation precautions and limit the spread of contagions. (10/17)

INFECTIOUS COMPLICATIONS WITH THE USE OF BIOLOGIC RESPONSE MODIFIERS IN INFANTS AND CHILDREN (CLINICAL REPORT)

H. Dele Davies, MD, FAAP, and Committee on Infectious Diseases

ABSTRACT. Biologic response modifiers (BRMs) are substances that interact with and modify the host immune system. BRMs that dampen the immune system are used to treat conditions such as juvenile idiopathic arthritis, psoriatic arthritis, or inflammatory bowel disease and often in combination with other immunosuppressive agents, such as methotrexate and corticosteroids. Cytokines that are targeted include tumor necrosis factor α; interleukins (ILs) 6, 12, and 23; and the receptors for IL-1α (IL-1A) and IL-1β (IL-1B) as well as other molecules. Although the risk varies with the class of BRM, patients receiving immune-dampening BRMs generally are at increased risk of infection or reactivation with mycobacterial infections (*Mycobacterium tuberculosis* and nontuberculous mycobacteria), some viral (herpes simplex virus, varicella-zoster virus, Epstein-Barr virus, hepatitis B) and fungal (histoplasmosis, coccidioidomycosis) infections, as well as other opportunistic infections. The use of BRMs warrants careful determination of infectious risk on the basis of history (including exposure, residence, and travel and immunization history) and selected baseline screening test results. Routine immunizations should be given at least 2 weeks (inactivated or subunit vaccines) or 4 weeks (live vaccines) before initiation of BRMs whenever feasible, and inactivated influenza vaccine should be given annually. Inactivated and subunit vaccines should be given when needed while taking BRMs, but live vaccines should be avoided unless under special circumstances in consultation with an infectious diseases specialist. If the patient develops a febrile or serious respiratory illness during BRM therapy, consideration should be given to stopping the BRM while actively searching for and treating possible infectious causes. (7/16, reaffirmed 3/21)

INFECTIOUS DISEASES ASSOCIATED WITH ORGANIZED SPORTS AND OUTBREAK CONTROL (CLINICAL REPORT)

H. Dele Davies, MD, MS, MHCM, FAAP; Mary Anne Jackson, MD, FAAP; Stephen G. Rice, MD, PhD, MPH, FAAP; Committee on Infectious Diseases; and Council on Sports Medicine and Fitness

ABSTRACT. Participation in organized sports has a variety of health benefits but also has the potential to expose the athlete to a variety of infectious diseases, some of which may produce outbreaks. Major risk factors for infection include skin-to-skin contact with athletes who have active skin infections, environmental exposures and physical trauma, and sharing of equipment and contact with contaminated fomites. Close contact that is intrinsic to team sports and psychosocial factors associated with adolescence are additional risks. Minimizing risk requires leadership by the organized sports community (including the athlete's primary care provider) and depends on outlining key hygiene behaviors, recognition, diagnosis, and treatment of common sports-related infections, and the implementation of preventive interventions. (9/17)

INFLUENZA IMMUNIZATION FOR ALL HEALTH CARE PERSONNEL: KEEP IT MANDATORY

Committee on Infectious Diseases

ABSTRACT. The purpose of this statement is to reaffirm the American Academy of Pediatrics' support for a mandatory influenza immunization policy for all health care personnel. With an increasing number of organizations requiring influenza vaccination, coverage among health care personnel has risen to 75% in the 2013 to 2014 influenza season but still remains below the Healthy People 2020 objective of 90%. Mandatory influenza immunization for all health care personnel is ethical, just, and necessary to improve patient safety. It is a crucial step in efforts to reduce health care–associated influenza infections. (9/15, reaffirmed 3/20)

INFORMED CONSENT IN DECISION-MAKING IN PEDIATRIC PRACTICE

Committee on Bioethics

ABSTRACT. Informed consent should be seen as an essential part of health care practice; parental permission and childhood assent is an active process that engages patients, both adults and children, in health care. Pediatric practice is unique in that developmental maturation allows, over time, for increasing inclusion of the child's and adolescent's opinion in medical decision-making in clinical practice and research. (7/16)
https://doi.org/10.1542/peds.2016-1484

INFORMED CONSENT IN DECISION-MAKING IN PEDIATRIC PRACTICE (TECHNICAL REPORT)

Aviva L. Katz, MD, FAAP; Sally A. Webb, MD, FAAP; and Committee on Bioethics

ABSTRACT. Informed consent should be seen as an essential part of health care practice; parental permission and childhood assent is an active process that engages patients, both adults and children, in their health care. Pediatric practice is unique in that developmental maturation allows, over time, for increasing inclusion of the child's and adolescent's opinion in medical decision-making in clinical practice and research. This technical

report, which accompanies the policy statement "Informed Consent in Decision-Making in Pediatric Practice," was written to provide a broader background on the nature of informed consent, surrogate decision-making in pediatric practice, information on child and adolescent decision-making, and special issues in adolescent informed consent, assent, and refusal. It is anticipated that this information will help provide support for the recommendations included in the policy statement. (7/16)

INJURIES ASSOCIATED WITH INFANT WALKERS

Committee on Injury and Poison Prevention

ABSTRACT. In 1999, an estimated 8800 children younger than 15 months were treated in hospital emergency departments in the United States for injuries associated with infant walkers. Thirty-four infant walker-related deaths were reported from 1973 through 1998. The vast majority of injuries occur from falls down stairs, and head injuries are common. Walkers do not help a child learn to walk; indeed, they can delay normal motor and mental development. The use of warning labels, public education, adult supervision during walker use, and stair gates have all been demonstrated to be insufficient strategies to prevent injuries associated with infant walkers. To comply with the revised voluntary standard (ASTM F977-96), walkers manufactured after June 30, 1997, must be wider than a 36-in doorway or must have a braking mechanism designed to stop the walker if 1 or more wheels drop off the riding surface, such as at the top of a stairway. Because data indicate a considerable risk of major and minor injury and even death from the use of infant walkers, and because there is no clear benefit from their use, the American Academy of Pediatrics recommends a ban on the manufacture and sale of mobile infant walkers. If a parent insists on using a mobile infant walker, it is vital that they choose a walker that meets the performance standards of ASTM F977-96 to prevent falls down stairs. Stationary activity centers should be promoted as a safer alternative to mobile infant walkers. (9/01, reaffirmed 1/05, 2/08, 10/11, 11/14)
https://doi.org/10.1542/peds.108.3.790

INJURY RISK OF NONPOWDER GUNS (TECHNICAL REPORT)

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Nonpowder guns (ball-bearing [BB] guns, pellet guns, air rifles, paintball guns) continue to cause serious injuries to children and adolescents. The muzzle velocity of these guns can range from approximately 150 ft/second to 1200 ft/second (the muzzle velocities of traditional firearm pistols are 750 ft/second to 1450 ft/second). Both low- and high-velocity nonpowder guns are associated with serious injuries, and fatalities can result from high-velocity guns. A persisting problem is the lack of medical recognition of the severity of injuries that can result from these guns, including penetration of the eye, skin, internal organs, and bone. Nationally, in 2000, there were an estimated 21840 (coefficient of variation: 0.0821) injuries related to nonpowder guns, with approximately 4% resulting in hospitalization. Between 1990 and 2000, the US Consumer Product Safety Commission reported 39 nonpowder gun–related deaths, of which 32 were children younger than 15 years. The introduction of high-powered air rifles in the 1970s has been associated with approximately 4 deaths per year. The advent of war games and the use of paintball guns have resulted in a number of reports of injuries, especially to the eye. Injuries associated with nonpowder guns should receive prompt medical management similar to the management of firearm-related injuries, and nonpowder guns should never be characterized as toys. (11/04, reaffirmed 2/08, 10/11)

IN-LINE SKATING INJURIES IN CHILDREN AND ADOLESCENTS

Committee on Injury and Poison Prevention and Committee on Sports Medicine and Fitness

ABSTRACT. In-line skating has become one of the fastest-growing recreational sports in the United States. Recent studies emphasize the value of protective gear in reducing the incidence of injuries. Recommendations are provided for parents and pediatricians, with special emphasis on the novice or inexperienced skater. (4/98, reaffirmed 1/02, 1/06, 1/09, 11/11)
https://doi.org/10.1542/peds.101.4.720

INSTITUTIONAL ETHICS COMMITTEES

Margaret Moon, MD, MPH, FAAP, and Committee on Bioethics

ABSTRACT. In hospitals throughout the United States, institutional ethics committees (IECs) have become a standard vehicle for the education of health professionals about biomedical ethics, for the drafting and review of hospital policy, and for clinical ethics case consultation. In addition, there is increasing interest in a role for the IEC in organizational ethics. Recommendations are made about the membership and structure of an IEC, and guidance is provided for those serving on an IEC. (4/19)

INSUFFICIENT SLEEP IN ADOLESCENTS AND YOUNG ADULTS: AN UPDATE ON CAUSES AND CONSEQUENCES (TECHNICAL REPORT)

Judith Owens, MD, MPH, FAAP; Adolescent Sleep Working Group; and Committee on Adolescence

ABSTRACT. Chronic sleep loss and associated sleepiness and daytime impairments in adolescence are a serious threat to the academic success, health, and safety of our nation's youth and an important public health issue. Understanding the extent and potential short- and long-term repercussions of sleep restriction, as well as the unhealthy sleep practices and environmental factors that contribute to sleep loss in adolescents, is key in setting public policies to mitigate these effects and in counseling patients and families in the clinical setting. This report reviews the current literature on sleep patterns in adolescents, factors contributing to chronic sleep loss (ie, electronic media use, caffeine consumption), and health-related consequences, such as depression, increased obesity risk, and higher rates of drowsy driving accidents. The report also discusses the potential role of later school start times as a means of reducing adolescent sleepiness. (8/14)
https://doi.org/10.1542/peds.2014-1696

INTEGRATING WEB SERVICES/APPLICATIONS TO IMPROVE PEDIATRIC FUNCTIONALITIES IN ELECTRONIC HEALTH RECORDS

Stuart T. Weinberg, MD, FAAP, FAMIA; Craig Monsen, MD, MS; Christoph U. Lehmann, MD, FAAP, FACMI, FIAHSI; Michael G. Leu, MD, MS, MHS, FAAP, FAMIA; and Council on Clinical Information Technology

ABSTRACT. The past decade has seen a substantial increase in the use of electronic health records (EHRs) by health care providers caring for children. However, gaps in pediatric-specific functionalities continue to exist in some EHR systems, including population-specific growth curves, immunization clinical decision support, weight-based medication dosing with rounding, calculation of pediatric hypertension percentiles, age-specific developmental assessment, newborn bilirubin nomograms, anticipatory guidance reminders, and other functionalities described elsewhere. Implementing pediatric functionalities into EHRs is critical to the provision of safe pediatric care. As an alternative to direct implementation in EHRs, EHR vendor agnostic Web applications, Web services, and application programming interfaces offer an opportunity to provide pediatric

functionalities and eliminate the need for each vendor to develop these functionalities. Successful implementation of Web services and related technologies requires responsible attention from both EHR vendors and developers of Web services, Web applications, and application programming interfaces to the use of data terminology standards, adherence to privacy and security requirements, rigorous testing, change management processes, and robust system support and maintenance. Education of health care providers about opportunities to improve pediatric functionalities in EHRs by using these services can facilitate discussions in EHR user groups in which vendors can be lobbied to implement them. This policy statement emphasizes the need to address pediatric-specific functionalities in EHRs by providing insight and recommendations into the development, maintenance, integration, and support of these novel solutions. INTERFERON-γ RELEASE ASSAYS FOR DIAGNOSIS OF TUBERCULOSIS INFECTION AND DISEASE IN CHILDREN (TECHNICAL REPORT)

Jeffrey R. Starke, MD, FAAP, and Committee on Infectious Diseases

ABSTRACT. Tuberculosis (TB) remains an important problem among children in the United States and throughout the world. Although diagnosis and treatment of infection with *Mycobacterium tuberculosis* (also referred to as latent tuberculosis infection [LTBI] or TB infection) remain the lynchpins of TB prevention, there is no diagnostic reference standard for LTBI. The tuberculin skin test (TST) has many limitations, including difficulty in administration and interpretation, the need for a return visit by the patient, and false-positive results caused by significant cross-reaction with *Mycobacterium bovis*–bacille Calmette-Guérin (BCG) vaccines and many nontuberculous mycobacteria. Interferon-γ release assays (IGRAs) are blood tests that measure ex vivo T-lymphocyte release of interferon-γ after stimulation by antigens specific for *M tuberculosis.* Because these antigens are not found on *M bovis*–BCG or most nontuberculous mycobacteria, IGRAs are more specific tests than the TST, yielding fewer false-positive results. However, IGRAs have little advantage over the TST in sensitivity, and both methods have reduced sensitivity in immunocompromised children, including children with severe TB disease. Both methods have a higher positive predictive value when applied to children with risk factors for LTBI. Unfortunately, neither method distinguishes between TB infection and TB disease. The objective of this technical report is to review what IGRAs are most useful for: (1) increasing test specificity in children who have received a BCG vaccine and may have a false-positive TST result; (2) using with the TST to increase sensitivity for finding LTBI in patients at high risk of developing progression from LTBI to disease; and (3) helping to diagnose TB disease. (11/14, reaffirmed 7/18)

https://doi.org/10.1542/peds.2014-2983

INTERPRETATION OF DO NOT ATTEMPT RESUSCITATION ORDERS FOR CHILDREN REQUIRING ANESTHESIA AND SURGERY (CLINICAL REPORT)

Mary E. Fallat, MD, FAAP; Courtney Hardy, MD, MBA, FAAP; Section on Surgery; Section on Anesthesiology and Pain Medicine; and Committee on Bioethics

ABSTRACT. This clinical report addresses the topic of preexisting do not attempt resuscitation or limited resuscitation orders for children and adolescents undergoing anesthesia and surgery. Pertinent considerations for the clinician include the rights of children, decision-making by parents or legally approved representatives, the process of informed consent, and the roles of surgeon and anesthesiologist. A process of re-evaluation of the do not attempt resuscitation orders, called "required reconsideration," should be incorporated into the process of informed consent for surgery and anesthesia, distinguishing between goal-directed and procedure-directed approaches. The child's individual needs are best served by allowing the parent or legally approved representative and involved clinicians to consider whether full resuscitation, limitations based on procedures, or limitations based on goals is most appropriate. (4/18)

https://doi.org/10.1542/peds.2018-0598

INTIMATE PARTNER VIOLENCE: THE ROLE OF THE PEDIATRICIAN (CLINICAL REPORT)

Jonathan D. Thackeray, MD; Roberta Hibbard, MD; M. Denise Dowd, MD, MPH; Committee on Child Abuse and Neglect; and Committee on Injury, Violence, and Poison Prevention

ABSTRACT. The American Academy of Pediatrics and its members recognize the importance of improving the physician's ability to recognize intimate partner violence (IPV) and understand its effects on child health and development and its role in the continuum of family violence. Pediatricians are in a unique position to identify abused caregivers in pediatric settings and to evaluate and treat children raised in homes in which IPV may occur. Children exposed to IPV are at increased risk of being abused and neglected and are more likely to develop adverse health, behavioral, psychological, and social disorders later in life. Identifying IPV, therefore, may be one of the most effective means of preventing child abuse and identifying caregivers and children who may be in need of treatment and/or therapy. Pediatricians should be aware of the profound effects of exposure to IPV on children. (4/10, reaffirmed 1/14, 3/19)

IODINE DEFICIENCY, POLLUTANT CHEMICALS, AND THE THYROID: NEW INFORMATION ON AN OLD PROBLEM

Council on Environmental Health

ABSTRACT. Many women of reproductive age in the United States are marginally iodine deficient, perhaps because the salt in processed foods is not iodized. Iodine deficiency, per se, can interfere with normal brain development in their offspring; in addition, it increases vulnerability to the effects of certain environmental pollutants, such as nitrate, thiocyanate, and perchlorate. Although pregnant and lactating women should take a supplement containing adequate iodide, only about 15% do so. Such supplements, however, may not contain enough iodide and may not be labeled accurately. The American Thyroid Association recommends that pregnant and lactating women take a supplement with adequate iodide. The American Academy of Pediatrics recommends that pregnant and lactating women also avoid exposure to excess nitrate, which would usually occur from contaminated well water, and thiocyanate, which is in cigarette smoke. Perchlorate is currently a candidate for regulation as a water pollutant. The Environmental Protection Agency should proceed with appropriate regulation, and the Food and Drug Administration should address the mislabeling of the iodine content of prenatal/lactation supplements. (5/14)

https://doi.org/10.1542/peds.2014-0900

LACTOSE INTOLERANCE IN INFANTS, CHILDREN, AND ADOLESCENTS (CLINICAL REPORT)

Melvin B. Heyman, MD, MPH, and Committee on Nutrition

ABSTRACT. The American Academy of Pediatrics Committee on Nutrition presents an updated review of lactose intolerance in infants, children, and adolescents. Differences between primary, secondary, congenital, and developmental lactase deficiency that may result in lactose intolerance are discussed. Children with suspected lactose intolerance can be assessed clinically by dietary lactose elimination or by tests including noninvasive hydrogen breath testing or invasive intestinal biopsy determination of lactase (and other disaccharidase) concentrations. Treatment consists of use of lactase-treated dairy products or oral

lactase supplementation, limitation of lactose-containing foods, or dairy elimination. The American Academy of Pediatrics supports use of dairy foods as an important source of calcium for bone mineral health and of other nutrients that facilitate growth in children and adolescents. If dairy products are eliminated, other dietary sources of calcium or calcium supplements need to be provided. (9/06, reaffirmed 8/12)
https://doi.org/10.1542/peds.2006-1721

"LATE-PRETERM" INFANTS: A POPULATION AT RISK (CLINICAL REPORT)

William A. Engle, MD; Kay M. Tomashek, MD; Carol Wallman, MSN; and Committee on Fetus and Newborn

ABSTRACT. Late-preterm infants, defined by birth at 34$^{6}/_{7}$ through 36$^{6}/_{7}$ weeks' gestation, are less physiologically and metabolically mature than term infants. Thus, they are at higher risk of morbidity and mortality than term infants. The purpose of this report is to define "late preterm," recommend a change in terminology from "near term" to "late preterm," present the characteristics of late-preterm infants that predispose them to a higher risk of morbidity and mortality than term infants, and propose guidelines for the evaluation and management of these infants after birth. (12/07, reaffirmed 5/10, 6/18)

LAWN MOWER-RELATED INJURIES TO CHILDREN

Committee on Injury and Poison Prevention

ABSTRACT. Lawn mower-related injuries to children are relatively common and can result in severe injury or death. Many amputations during childhood are caused by power mowers. Pediatricians have an important role as advocates and educators to promote the prevention of these injuries. (6/01, reaffirmed 10/04, 5/07, 6/10)
https://doi.org/10.1542/peds.107.6.1480

LAWN MOWER-RELATED INJURIES TO CHILDREN (TECHNICAL REPORT)

Committee on Injury and Poison Prevention

ABSTRACT. In the United States, approximately 9400 children younger than 18 years receive emergency treatment annually for lawn mower-related injuries. More than 7% of these children require hospitalization, and power mowers cause a large proportion of the amputations during childhood. Prevention of lawn mower-related injuries can be achieved by design changes of lawn mowers, guidelines for mower operation, and education of parents, child caregivers, and children. Pediatricians have an important role as advocates and educators to promote the prevention of these injuries. (6/01, reaffirmed 10/04, 5/07, 6/10)
https://doi.org/10.1542/peds.107.6.e106

LEARNING DISABILITIES, DYSLEXIA, AND VISION

Section on Ophthalmology and Council on Children With Disabilities (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists)

ABSTRACT. Learning disabilities, including reading disabilities, are commonly diagnosed in children. Their etiologies are multifactorial, reflecting genetic influences and dysfunction of brain systems. Learning disabilities are complex problems that require complex solutions. Early recognition and referral to qualified educational professionals for evidence-based evaluations and treatments seem necessary to achieve the best possible outcome. Most experts believe that dyslexia is a language-based disorder. Vision problems can interfere with the process of learning; however, vision problems are not the cause of primary dyslexia or learning disabilities. Scientific evidence does not support the efficacy of eye exercises, behavioral vision therapy, or special tinted filters or lenses for improving the long-term educational performance in these complex pediatric neurocognitive conditions. Diagnostic and treatment approaches that lack scientific evidence of efficacy, including eye exercises, behavioral vision therapy, or special tinted filters or lenses, are not endorsed and should not be recommended. (7/09, reaffirmed 7/14)
https://doi.org/10.1542/peds.2009-1445

LEARNING DISABILITIES, DYSLEXIA, AND VISION (TECHNICAL REPORT)

Sheryl M. Handler, MD; Walter M. Fierson, MD; Section on Ophthalmology; and Council on Children With Disabilities (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists)

ABSTRACT. Learning disabilities constitute a diverse group of disorders in which children who generally possess at least average intelligence have problems processing information or generating output. Their etiologies are multifactorial and reflect genetic influences and dysfunction of brain systems. Reading disability, or dyslexia, is the most common learning disability. It is a receptive language-based learning disability that is characterized by difficulties with decoding, fluent word recognition, rapid automatic naming, and/or reading-comprehension skills. These difficulties typically result from a deficit in the phonologic component of language that makes it difficult to use the alphabetic code to decode the written word. Early recognition and referral to qualified professionals for evidence-based evaluations and treatments are necessary to achieve the best possible outcome. Because dyslexia is a language-based disorder, treatment should be directed at this etiology. Remedial programs should include specific instruction in decoding, fluency training, vocabulary, and comprehension. Most programs include daily intensive individualized instruction that explicitly teaches phonemic awareness and the application of phonics. Vision problems can interfere with the process of reading, but children with dyslexia or related learning disabilities have the same visual function and ocular health as children without such conditions. Currently, there is inadequate scientific evidence to support the view that subtle eye or visual problems cause or increase the severity of learning disabilities. Because they are difficult for the public to understand and for educators to treat, learning disabilities have spawned a wide variety of scientifically unsupported vision-based diagnostic and treatment procedures. Scientific evidence does not support the claims that visual training, muscle exercises, ocular pursuit-and-tracking exercises, behavioral/perceptual vision therapy, "training" glasses, prisms, and colored lenses and filters are effective direct or indirect treatments for learning disabilities. There is no valid evidence that children who participate in vision therapy are more responsive to educational instruction than children who do not participate. (3/11)

LEUKODYSTROPHIES IN CHILDREN: DIAGNOSIS, CARE, AND TREATMENT (CLINICAL REPORT)

Joshua L. Bonkowsky, MD, PhD, FAAP; Stephanie Keller, MD, FAAP; Section on Neurology; and Council on Genetics

ABSTRACT. Leukodystrophies are a group of genetically determined disorders that affect development or maintenance of central nervous system myelin. Leukodystrophies have an incidence of at least 1 in 4700 live births and significant morbidity and elevated risk of early death. This report includes a discussion of the types of leukodystrophies; their prevalence, clinical presentation, symptoms, and diagnosis; and current and future treatments. Leukodystrophies can present at any age from infancy to adulthood, with variability in disease progression and clinical presentation, ranging from developmental delay to seizures to

spasticity. Diagnosis is based on a combination of history, examination, and radiologic and laboratory findings, including genetic testing. Although there are few cures, there are significant opportunities for care and improvements in patient well-being. Rapid advances in imaging and diagnosis, the emergence of and requirement for timely treatments, and the addition of leukodystrophy screening to newborn screening, make an understanding of the leukodystrophies necessary for pediatricians and other care providers for children. LEVELS OF NEONATAL CARE

Committee on Fetus and Newborn

ABSTRACT. Provision of risk-appropriate care for newborn infants and mothers was first proposed in 1976. This updated policy statement provides a review of data supporting evidence for a tiered provision of care and reaffirms the need for uniform, nationally applicable definitions and consistent standards of service for public health to improve neonatal outcomes. Facilities that provide hospital care for newborn infants should be classified on the basis of functional capabilities, and these facilities should be organized within a regionalized system of perinatal care. (8/12, reaffirmed 9/15)

THE LIFELONG EFFECTS OF EARLY CHILDHOOD ADVERSITY AND TOXIC STRESS (TECHNICAL REPORT)

Jack P. Shonkoff, MD; Andrew S. Garner, MD, PhD; Committee on Psychosocial Aspects of Child and Family Health; Committee on Early Childhood, Adoption, and Dependent Care; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Advances in fields of inquiry as diverse as neuroscience, molecular biology, genomics, developmental psychology, epidemiology, sociology, and economics are catalyzing an important paradigm shift in our understanding of health and disease across the lifespan. This converging, multidisciplinary science of human development has profound implications for our ability to enhance the life prospects of children and to strengthen the social and economic fabric of society. Drawing on these multiple streams of investigation, this report presents an ecobiodevelopmental framework that illustrates how early experiences and environmental influences can leave a lasting signature on the genetic predispositions that affect emerging brain architecture and long-term health. The report also examines extensive evidence of the disruptive impacts of toxic stress, offering intriguing insights into causal mechanisms that link early adversity to later impairments in learning, behavior, and both physical and mental well-being. The implications of this framework for the practice of medicine, in general, and pediatrics, specifically, are potentially transformational. They suggest that many adult diseases should be viewed as developmental disorders that begin early in life and that persistent health disparities associated with poverty, discrimination, or maltreatment could be reduced by the alleviation of toxic stress in childhood. An ecobiodevelopmental framework also underscores the need for new thinking about the focus and boundaries of pediatric practice. It calls for pediatricians to serve as both front-line guardians of healthy child development and strategically positioned, community leaders to inform new science-based strategies that build strong foundations for educational achievement, economic productivity, responsible citizenship, and lifelong health. (12/11, reaffirmed 7/16)

THE LINK BETWEEN SCHOOL ATTENDANCE AND GOOD HEALTH

Mandy A. Allison, MD, MSPH, FAAP; Elliott Attisha, DO, FAAP; and Council on School Health

ABSTRACT. More than 6.5 million children in the United States, approximately 13% of all students, miss 15 or more days of school each year. The rates of chronic absenteeism vary between states, communities, and schools, with significant disparities based on income, race, and ethnicity. Chronic school absenteeism, starting as early as preschool and kindergarten, puts students at risk for poor school performance and school dropout, which in turn, put them at risk for unhealthy behaviors as adolescents and young adults as well as poor long-term health outcomes. Pediatricians and their colleagues caring for children in the medical setting have opportunities at the individual patient and/or family, practice, and population levels to promote school attendance and reduce chronic absenteeism and resulting health disparities. Although this policy statement is primarily focused on absenteeism related to students' physical and mental health, pediatricians may play a role in addressing absenteeism attributable to a wide range of factors through individual interactions with patients and their parents and through community-, state-, and federal-level advocacy. (1/19)

LITERACY PROMOTION: AN ESSENTIAL COMPONENT OF PRIMARY CARE PEDIATRIC PRACTICE

Council on Early Childhood

ABSTRACT. Reading regularly with young children stimulates optimal patterns of brain development and strengthens parent-child relationships at a critical time in child development, which, in turn, builds language, literacy, and social-emotional skills that last a lifetime. Pediatric providers have a unique opportunity to encourage parents to engage in this important and enjoyable activity with their children beginning in infancy. Research has revealed that parents listen and children learn as a result of literacy promotion by pediatricians, which provides a practical and evidence-based opportunity to support early brain development in primary care practice. The American Academy of Pediatrics (AAP) recommends that pediatric providers promote early literacy development for children beginning in infancy and continuing at least until the age of kindergarten entry by (1) advising all parents that reading aloud with young children can enhance parent-child relationships and prepare young minds to learn language and early literacy skills; (2) counseling all parents about developmentally appropriate shared-reading activities that are enjoyable for children and their parents and offer language-rich exposure to books, pictures, and the written word; (3) providing developmentally appropriate books given at health supervision visits for all high-risk, low-income young children; (4) using a robust spectrum of options to support and promote these efforts; and (5) partnering with other child advocates to influence national messaging and policies that support and promote these key early shared-reading experiences. The AAP supports federal and state funding for children's books to be provided at pediatric health supervision visits to children at high risk living at or near the poverty threshold and the integration of literacy promotion, an essential component of pediatric primary care, into pediatric resident education. This policy statement is supported by the AAP technical report "School Readiness" and supports the AAP policy statement "Early Childhood Adversity, Toxic Stress, and the Role of the Pediatrician: Translating Developmental Science Into Lifelong Health." LONG-ACTING REVERSIBLE CONTRACEPTION: SPECIFIC ISSUES FOR ADOLESCENTS (CLINICAL REPORT)

Seema Menon, MD, and Committee on Adolescence

ABSTRACT. Long-acting reversible contraceptives are the most effective methods to prevent pregnancy and also offer noncontraceptive benefits such as reducing menstrual blood flow and dysmenorrhea. The safety and efficacy of long-acting reversible contraception are well established for adolescents, but the rate of use remains low for this population. The pediatrician can play a key role in increasing access to long-acting reversible contraception for adolescents by providing accurate patient-centered contraception counseling and by understanding and addressing the barriers to use. LONG-TERM FOLLOW-UP CARE FOR CHILDHOOD, ADOLESCENT, AND YOUNG ADULT CANCER SURVIVORS (CLINICAL REPORT)

Melissa M. Hudson, MD; Smita Bhatia, MD, MPH; Jacqueline Casillas, MD, MSHS; Wendy Landier, PhD, RN, CPNP; and Section on Hematology/Oncology (joint with Children's Oncology Group and American Society of Pediatric Hematology/Oncology)

ABSTRACT. Progress in therapy has made survival into adulthood a reality for most children, adolescents, and young adults with a cancer diagnosis today. Notably, this growing population remains vulnerable to a variety of long-term therapy-related sequelae. Systematic ongoing follow-up of these patients is, therefore, important to provide for early detection of and intervention for potentially serious late-onset complications. In addition, health counseling and promotion of healthy lifestyles are important aspects of long-term follow-up care to promote risk reduction for physical and emotional health problems that commonly present during adulthood. Both general and subspecialty health care providers are playing an increasingly important role in the ongoing care of childhood cancer survivors, beyond the routine preventive care, health supervision, and anticipatory guidance provided to all patients. This report is based on the guidelines that have been developed by the Children's Oncology Group to facilitate comprehensive long-term follow-up of childhood, adolescent, and young adult cancer survivors (www.survivorshipguidelines.org). MAINTAINING AND IMPROVING THE ORAL HEALTH OF YOUNG CHILDREN

Section on Oral Health

ABSTRACT. Oral health is an integral part of the overall health of children. Dental caries is a common and chronic disease process with significant short- and long-term consequences. The prevalence of dental caries for the youngest of children has not decreased over the past decade, despite improvements for older children. As health care professionals responsible for the overall health of children, pediatricians frequently confront morbidity associated with dental caries. Because the youngest children visit the pediatrician more often than they visit the dentist, it is important that pediatricians be knowledgeable about the disease process of dental caries, prevention of the disease, and interventions available to the pediatrician and the family to maintain and restore health. (11/14, reaffirmed 1/19)

https://doi.org/10.1542/peds.2014-2984

MALE ADOLESCENT SEXUAL AND REPRODUCTIVE HEALTH CARE (CLINICAL REPORT)

Arik V. Marcell, MD, MPH; Charles Wibbelsman, MD; Warren M. Seigel, MD; and Committee on Adolescence

ABSTRACT. Male adolescents' sexual and reproductive health needs often go unmet in the primary care setting. This report discusses specific issues related to male adolescents' sexual and reproductive health care in the context of primary care, including pubertal and sexual development, sexual behavior, consequences of sexual behavior, and methods of preventing sexually transmitted infections (including HIV) and pregnancy. Pediatricians are encouraged to address male adolescent sexual and reproductive health on a regular basis, including taking a sexual history, performing an appropriate examination, providing patient-centered and age-appropriate anticipatory guidance, and delivering appropriate vaccinations. Pediatricians should provide these services to male adolescent patients in a confidential and culturally appropriate manner, promote healthy sexual relationships and responsibility, and involve parents in age-appropriate discussions about sexual health with their sons. (11/11, reaffirmed 5/15)

https://doi.org/10.1542/peds.2011-2384

MALE CIRCUMCISION (TECHNICAL REPORT)

Task Force on Circumcision

ABSTRACT. Male circumcision consists of the surgical removal of some, or all, of the foreskin (or prepuce) from the penis. It is one of the most common procedures in the world. In the United States, the procedure is commonly performed during the newborn period. In 2007, the American Academy of Pediatrics (AAP) convened a multidisciplinary workgroup of AAP members and other stakeholders to evaluate the evidence regarding male circumcision and update the AAP's 1999 recommendations in this area. The Task Force included AAP representatives from specialty areas as well as members of the AAP Board of Directors and liaisons representing the American Academy of Family Physicians, the American College of Obstetricians and Gynecologists, and the Centers for Disease Control and Prevention. The Task Force members identified selected topics relevant to male circumcision and conducted a critical review of peer-reviewed literature by using the American Heart Association's template for evidence evaluation.

Evaluation of current evidence indicates that the health benefits of newborn male circumcision outweigh the risks; furthermore, the benefits of newborn male circumcision justify access to this procedure for families who choose it. Specific benefits from male circumcision were identified for the prevention of urinary tract infections, acquisition of HIV, transmission of some sexually transmitted infections, and penile cancer. Male circumcision does not appear to adversely affect penile sexual function/sensitivity or sexual satisfaction. It is imperative that those providing circumcision are adequately trained and that both sterile techniques and effective pain management are used. Significant acute complications are rare. In general, untrained providers who perform circumcisions have more complications than well-trained providers who perform the procedure, regardless of whether the former are physicians, nurses, or traditional religious providers.

Parents are entitled to factually correct, nonbiased information about circumcision and should receive this information from clinicians before conception or early in pregnancy, which is when parents typically make circumcision decisions. Parents should determine what is in the best interest of their child. Physicians who counsel families about this decision should provide assistance by explaining the potential benefits and risks and ensuring that parents understand that circumcision is an elective procedure. The Task Force strongly recommends the creation, revision, and enhancement of educational materials to assist parents of male infants with the care of circumcised and uncircumcised penises. The Task Force also strongly recommends the development of educational materials for providers to enhance practitioners' competency in discussing circumcision's benefits and risks with parents.

The Task Force made the following recommendations:

- Evaluation of current evidence indicates that the health benefits of newborn male circumcision outweigh the risks, and the benefits of newborn male circumcision justify access to this procedure for those families who choose it.
- Parents are entitled to factually correct, nonbiased information about circumcision that should be provided before conception and early in pregnancy, when parents are most likely to be weighing the option of circumcision of a male child.
- Physicians counseling families about elective male circumcision should assist parents by explaining, in a nonbiased manner, the potential benefits and risks and by ensuring that they understand the elective nature of the procedure.
- Parents should weigh the health benefits and risks in light of their own religious, cultural, and personal preferences, as the medical benefits alone may not outweigh these other considerations for individual families.
- Parents of newborn boys should be instructed in the care of the penis, regardless of whether the newborn has been circumcised or not.
- Elective circumcision should be performed only if the infant's condition is stable and healthy.
- Male circumcision should be performed by trained and competent practitioners, by using sterile techniques and effective pain management.
- Analgesia is safe and effective in reducing the procedural pain associated with newborn circumcision; thus, adequate analgesia should be provided whenever newborn circumcision is performed.
  - — Nonpharmacologic techniques (eg, positioning, sucrose pacifiers) alone are insufficient to prevent procedural and postprocedural pain and are not recommended as the sole method of analgesia. They should be used only as analgesic adjuncts to improve infant comfort during circumcision.
  - — If used, topical creams may cause a higher incidence of skin irritation in low birth weight infants, compared with infants of normal weight; penile nerve block techniques should therefore be chosen for this group of newborns.
- Key professional organizations (AAP, the American Academy of Family Physicians, the American College of Obstetricians and Gynecologists, the American Society of Anesthesiologists, the American College of Nurse Midwives, and other midlevel clinicians such as nurse practitioners) should work collaboratively to:
  - — Develop standards of trainee proficiency in the performance of anesthetic and procedure techniques, including suturing;
  - — Teach the procedure and analgesic techniques during postgraduate training programs;
  - — Develop educational materials for clinicians to enhance their own competency in discussing the benefits and risks of circumcision with parents;
  - — Offer educational materials to assist parents of male infants with the care of both circumcised and uncircumcised penises.
- The preventive and public health benefits associated with newborn male circumcision warrant third-party reimbursement of the procedure.

The American College of Obstetricians and Gynecologists has endorsed this technical report. (8/12)

https://doi.org/10.1542/peds.2012-1990

MALTREATMENT OF CHILDREN WITH DISABILITIES (CLINICAL REPORT)

Lori A. Legano, MD, FAAP; Larry W. Desch, MD, FAAP; Stephen A. Messner, MD, FAAP; Sheila Idzerda, MD, FAAP; Emalee G. Flaherty, MD, FAAP; Council on Child Abuse and Neglect; and Council on Children With Disabilities

ABSTRACT. Over the past decade, there have been widespread efforts to raise awareness about maltreatment of children. Pediatric providers have received education about factors that make a child more vulnerable to being abused and neglected. The purpose of this clinical report is to ensure that children with disabilities are recognized as a population at increased risk for maltreatment. This report updates the 2007 American Academy of Pediatrics clinical report "Maltreatment of Children With Disabilities." Since 2007, new information has expanded our understanding of the incidence of abuse in this vulnerable population. There is now information about which children with disabilities are at greatest risk for maltreatment because not all disabling conditions confer the same risks of abuse or neglect. This updated report will serve as a resource for pediatricians and others who care for children with disabilities and offers guidance on risks for subpopulations of children with disabilities who are at particularly high risk of abuse and neglect. The report will also discuss ways in which the medical home can aid in early identification and intervene when abuse and neglect are suspected. It will also describe community resources and preventive strategies that may reduce the risk of abuse and neglect. (4/21)

MANAGEMENT OF DENTAL TRAUMA IN A PRIMARY CARE SETTING (CLINICAL REPORT)

Martha Ann Keels, DDS, PhD, and Section on Oral Health

ABSTRACT. The American Academy of Pediatrics and its Section on Oral Health have developed this clinical report for pediatricians and primary care physicians regarding the diagnosis, evaluation, and management of dental trauma in children aged 1 to 21 years. This report was developed through a comprehensive search and analysis of the medical and dental literature and expert consensus. Guidelines published and updated by the International Association of Dental Traumatology (www.dentaltraumaguide.com) are an excellent resource for both dental and nondental health care providers. (1/14)

https://doi.org/10.1542/peds.2013-3792

MANAGEMENT OF FOOD ALLERGY IN THE SCHOOL SETTING (CLINICAL REPORT)

Scott H. Sicherer, MD; Todd Mahr, MD; and Section on Allergy and Immunology

ABSTRACT. Food allergy is estimated to affect approximately 1 in 25 school-aged children and is the most common trigger of anaphylaxis in this age group. School food-allergy management requires strategies to reduce the risk of ingestion of the allergen as well as procedures to recognize and treat allergic reactions and anaphylaxis. The role of the pediatrician or pediatric health care provider may include diagnosing and documenting a potentially life-threatening food allergy, prescribing selfinjectable epinephrine, helping the child learn how to store and use the medication in a responsible manner, educating the parents of their responsibility to implement prevention strategies within and outside the home environment, and working with families, schools, and students in developing written plans to reduce the risk of anaphylaxis and to implement emergency treatment in the event of a reaction. This clinical report highlights the role of the pediatrician and pediatric health care provider in managing students with food allergies. (11/10, reaffirmed 10/20)

https://doi.org/10.1542/peds.2010-2575

MANAGEMENT OF INFANTS AT RISK FOR GROUP B STREPTOCOCCAL DISEASE (CLINICAL REPORT)

Karen M. Puopolo, MD, PhD, FAAP; Ruth Lynfield, MD, FAAP; James J. Cummings, MD, MS, FAAP; Committee on Fetus and Newborn; and Committee on Infectious Diseases

ABSTRACT. Group B streptococcal (GBS) infection remains the most common cause of neonatal early-onset sepsis and a significant cause of late-onset sepsis among young infants. Administration of intrapartum antibiotic prophylaxis is the only currently available effective strategy for the prevention of perinatal GBS early-onset disease, and there is no effective approach for the prevention of late-onset disease. The American Academy of Pediatrics joins with the American College of Obstetricians and Gynecologists to reaffirm the use of universal antenatal microbiologic-based testing for the detection of maternal GBS colonization to facilitate appropriate administration of intrapartum antibiotic prophylaxis. The purpose of this clinical report is to provide neonatal clinicians with updated information regarding the epidemiology of GBS disease as well current recommendations for the evaluation of newborn infants at risk for GBS disease and for treatment of those with confirmed GBS infection. This clinical report is endorsed by the American College of Obstetricians and Gynecologists (ACOG), July 2019, and should be construed as ACOG clinical guidance. (7/19)

https://doi.org/10.1542/peds.2019-1881

MANAGEMENT OF NEONATES BORN AT ≥35 0/7 WEEKS' GESTATION WITH SUSPECTED OR PROVEN EARLY-ONSET BACTERIAL SEPSIS (CLINICAL REPORT)

Karen M. Puopolo, MD, PhD, FAAP; William E. Benitz, MD, FAAP; Theoklis E. Zaoutis, MD, MSCE, FAAP; Committee on Fetus and Newborn; and Committee on Infectious Diseases

ABSTRACT. The incidence of neonatal early-onset sepsis (EOS) has declined substantially over the last 2 decades, primarily because of the implementation of evidence-based intrapartum antimicrobial therapy. However, EOS remains a serious and potentially fatal illness. Laboratory tests alone are neither sensitive nor specific enough to guide EOS management decisions. Maternal and infant clinical characteristics can help identify newborn infants who are at risk and guide the administration of empirical antibiotic therapy. The incidence of EOS, the prevalence and implications of established risk factors, the predictive value of commonly used laboratory tests, and the uncertainties in the risk/benefit balance of antibiotic exposures all vary significantly with gestational age at birth. Our purpose in this clinical report is to provide a summary of the current epidemiology of neonatal sepsis among infants born at ≥35 0/7 weeks' gestation and a framework for the development of evidence-based approaches to sepsis risk assessment among these infants. (11/18)

https://doi.org/10.1542/peds.2018-2894

MANAGEMENT OF NEONATES BORN AT ≤34 6/7 WEEKS' GESTATION WITH SUSPECTED OR PROVEN EARLY-ONSET BACTERIAL SEPSIS (CLINICAL REPORT)

Karen M. Puopolo, MD, PhD, FAAP; William E. Benitz, MD, FAAP; Theoklis E. Zaoutis, MD, MSCE, FAAP; Committee on Fetus and Newborn; and Committee on Infectious Diseases

ABSTRACT. Early-onset sepsis (EOS) remains a serious and often fatal illness among infants born preterm, particularly among newborn infants of the lowest gestational age. Currently, most preterm infants with very low birth weight are treated empirically with antibiotics for risk of EOS, often for prolonged periods, in the absence of a culture-confirmed infection. Retrospective studies have revealed that antibiotic exposures after birth are associated with multiple subsequent poor outcomes among preterm infants, making the risk/benefit balance of these antibiotic treatments uncertain. Gestational age is the strongest single predictor of EOS, and the majority of preterm births occur in the setting of other factors associated with risk of EOS, making it difficult to apply risk stratification strategies to preterm infants. Laboratory tests alone have a poor predictive value in preterm EOS. Delivery characteristics of extremely preterm infants present an opportunity to identify those with a lower risk of EOS and may inform decisions to initiate or extend antibiotic therapies. Our purpose for this clinical report is to provide a summary of the current epidemiology of preterm neonatal sepsis and provide guidance for the development of evidence-based approaches to sepsis risk assessment among preterm newborn infants. (11/18)

MANAGEMENT OF PEDIATRIC TRAUMA

Committee on Pediatric Emergency Medicine; Council on Injury, Violence, and Poison Prevention; Section on Critical Care; Section on Orthopaedics; Section on Surgery; and Section on Transport Medicine (joint with Pediatric Trauma Society and Society of Trauma Nurses Pediatric Committee)

ABSTRACT. Injury is still the number 1 killer of children ages 1 to 18 years in the United States (http://www.cdc.gov/nchs/fastats/children.htm). Children who sustain injuries with resulting disabilities incur significant costs not only for their health care but also for productivity lost to the economy. The families of children who survive childhood injury with disability face years of emotional and financial hardship, along with a significant societal burden. The entire process of managing childhood injury is enormously complex and varies by region. Only the comprehensive cooperation of a broadly diverse trauma team will have a significant effect on improving the care of injured children. (7/16)

https://doi.org/10.1542/peds.2016-1569

MANAGEMENT OF TYPE 2 DIABETES MELLITUS IN CHILDREN AND ADOLESCENTS (TECHNICAL REPORT)

Shelley C. Springer, MD, MBA, MSc, JD, FAAP; Janet Silverstein, MD, FAAP; Kenneth Copeland, MD, FAAP; Kelly R. Moore, MD, FAAP; Greg E. Prazar, MD, FAAP; Terry Raymer, MD, CDE; Richard N. Shiffman, MD, FAAP; Vidhu V. Thaker, MD, FAAP; Meaghan Anderson, MS, RD, LD, CDE; Stephen J. Spann, MD, MBA, FAAFP; and Susan K. Flinn, MA

ABSTRACT. *Objective.* Over the last 3 decades, the prevalence of childhood obesity has increased dramatically in North America, ushering in a variety of health problems, including type 2 diabetes mellitus (T2DM), which previously was not typically seen until much later in life. This technical report describes, in detail, the procedures undertaken to develop the recommendations given in the accompanying clinical practice guideline, "Management of Type 2 Diabetes Mellitus in Children and Adolescents," and provides in-depth information about the rationale for the recommendations and the studies used to make the clinical practice guideline's recommendations.

Methods. A primary literature search was conducted relating to the treatment of T2DM in children and adolescents, and a secondary literature search was conducted relating to the screening and treatment of T2DM's comorbidities in children and adolescents. Inclusion criteria were prospectively and unanimously agreed on by members of the committee. An article was eligible for inclusion if it addressed treatment (primary search) or 1 of 4 comorbidities (secondary search) of T2DM, was published in 1990 or later, was written in English, and included an abstract. Only primary research inquiries were considered; review articles were considered if they included primary data or opinion. The research population had to constitute children and/or

adolescents with an existing diagnosis of T2DM; studies of adult patients were considered if at least 10% of the study population was younger than 35 years. All retrieved titles, abstracts, and articles were reviewed by the consulting epidemiologist.

Results. Thousands of articles were retrieved and considered in both searches on the basis of the aforementioned criteria. From those, in the primary search, 199 abstracts were identified for possible inclusion, 58 of which were retained for systematic review. Five of these studies were classified as grade A studies, 1 as grade B, 20 as grade C, and 32 as grade D. Articles regarding treatment of T2DM selected for inclusion were divided into 4 major subcategories on the basis of type of treatment being discussed: (1) medical treatments (32 studies); (2) nonmedical treatments (9 studies); (3) provider behaviors (8 studies); and (4) social issues (9 studies). From the secondary search, an additional 336 abstracts relating to comorbidities were identified for possible inclusion, of which 26 were retained for systematic review. These articles included the following: 1 systematic review of literature regarding comorbidities of T2DM in adolescents; 5 expert opinions presenting global recommendations not based on evidence; 5 cohort studies reporting natural history of disease and comorbidities; 3 with specific attention to comorbidity patterns in specific ethnic groups (case-control, cohort, and clinical report using adult literature); 3 reporting an association between microalbuminuria and retinopathy (2 case-control, 1 cohort); 3 reporting the prevalence of nephropathy (cohort); 1 reporting peripheral vascular disease (case series); 2 discussing retinopathy (1 case-control, 1 position statement); and 3 addressing hyperlipidemia (American Heart Association position statement on cardiovascular risks; American Diabetes Association consensus statement; case series). A breakdown of grade of recommendation shows no grade A studies, 10 grade B studies, 6 grade C studies, and 10 grade D studies. With regard to screening and treatment recommendations for comorbidities, data in children are scarce, and the available literature is conflicting. Therapeutic recommendations for hypertension, dyslipidemia, retinopathy, microalbuminuria, and depression were summarized from expert guideline documents and are presented in detail in the guideline. The references are provided, but the committee did not independently assess the supporting evidence. Screening tools are provided in the Supplemental Information. (1/13)

https://doi.org/10.1542/peds.2012-3496

MANAGEMENT PRINCIPLES FOR ACUTE ILLNESS IN PATIENTS WITH MEDIUM-CHAIN ACYL-COENZYME A DEHYDROGENASE DEFICIENCY (CLINICAL REPORT)

Tracy L. McGregor, MD; Susan A. Berry, MD, FAAP; Katrina M. Dipple, MD, PhD, FAAP; Rizwan Hamid, MD, PhD, FAAP; and Council on Genetics

ABSTRACT. Medium-chain acyl-coenzyme A dehydrogenase deficiency (MCADD) is a fatty acid oxidation disorder in which the patient is unable to break down fats to produce energy. This disorder places children at risk for metabolic decompensation during periods of stress, such as routine childhood illnesses. The intent of this clinical report is to provide pediatricians with additional information regarding the acute clinical care of patients with MCADD. Although each patient with MCADD will still be expected to have a primary metabolic physician, the involvement of the primary care provider is crucial as well. Appropriate treatment of children with MCADD can lead to avoidance of morbidity and mortality. (12/20)

MARIJUANA USE DURING PREGNANCY AND BREASTFEEDING: IMPLICATIONS FOR NEONATAL AND CHILDHOOD OUTCOMES (CLINICAL REPORT)

Sheryl A. Ryan, MD, FAAP; Seth D. Ammerman, MD, FAAP, FSAHM, DABAM; Mary E. O'Connor, MD, MPH, FAAP; Committee on Substance Use and Prevention; and Section on Breastfeeding

ABSTRACT. Marijuana is one of the most widely used substances during pregnancy in the United States. Emerging data on the ability of cannabinoids to cross the placenta and affect the development of the fetus raise concerns about both pregnancy outcomes and long-term consequences for the infant or child. Social media is used to tout the use of marijuana for severe nausea associated with pregnancy. Concerns have also been raised about marijuana use by breastfeeding mothers. With this clinical report, we provide data on the current rates of marijuana use among pregnant and lactating women, discuss what is known about the effects of marijuana on fetal development and later neurodevelopmental and behavioral outcomes, and address implications for education and policy. (8/18)

https://doi.org/10.1542/peds.2018-1889

MATERNAL-FETAL INTERVENTION AND FETAL CARE CENTERS (CLINICAL REPORT)

Committee on Bioethics (joint with American College of Obstetricians and Gynecologists Committee on Ethics)

ABSTRACT. The past 2 decades have yielded profound advances in the fields of prenatal diagnosis and fetal intervention. Although fetal interventions are driven by a beneficence-based motivation to improve fetal and neonatal outcomes, advancement in fetal therapies raises ethical issues surrounding maternal autonomy and decision-making, concepts of innovation versus research, and organizational aspects within institutions in the development of fetal care centers. To safeguard the interests of both the pregnant woman and the fetus, the American College of Obstetricians and Gynecologists and the American Academy of Pediatrics make recommendations regarding informed consent, the role of research subject advocates and other independent advocates, the availability of support services, the multidisciplinary nature of fetal intervention teams, the oversight of centers, and the need to accumulate maternal and fetal outcome data. (7/11, reaffirmed 2/18)

MEDIA AND YOUNG MINDS

Council on Communications and Media

ABSTRACT. Infants, toddlers, and preschoolers are now growing up in environments saturated with a variety of traditional and new technologies, which they are adopting at increasing rates. Although there has been much hope for the educational potential of interactive media for young children, accompanied by fears about their overuse during this crucial period of rapid brain development, research in this area still remains limited. This policy statement reviews the existing literature on television, videos, and mobile/interactive technologies; their potential for educational benefit; and related health concerns for young children (0 to 5 years of age). The statement also highlights areas in which pediatric providers can offer specific guidance to families in managing their young children's media use, not only in terms of content or time limits, but also emphasizing the importance of parent-child shared media use and allowing the child time to take part in other developmentally healthy activities. (10/16)

https://doi.org/10.1542/peds.2016-2591

MEDIA EDUCATION

Committee on Communications and Media

ABSTRACT. The American Academy of Pediatrics recognizes that exposure to mass media (eg, television, movies, video and computer games, the Internet, music lyrics and videos, newspapers, magazines, books, advertising) presents health risks for children and adolescents but can provide benefits as well. Media education has the potential to reduce the harmful effects of media and accentuate the positive effects. By understanding and supporting media education, pediatricians can play an important role in reducing harmful effects of media on children and adolescents. (9/10)

https://doi.org/10.1542/peds.2010-1636

MEDIA USE IN SCHOOL-AGED CHILDREN AND ADOLESCENTS

Council on Communications and Media

ABSTRACT. This policy statement focuses on children and adolescents 5 through 18 years of age. Research suggests both benefits and risks of media use for the health of children and teenagers. Benefits include exposure to new ideas and knowledge acquisition, increased opportunities for social contact and support, and new opportunities to access health-promotion messages and information. Risks include negative health effects on weight and sleep; exposure to inaccurate, inappropriate, or unsafe content and contacts; and compromised privacy and confidentiality. Parents face challenges in monitoring their children's and their own media use and in serving as positive role models. In this new era, evidence regarding healthy media use does not support a one-size-fits-all approach. Parents and pediatricians can work together to develop a Family Media Use Plan (www.healthychildren.org/MediaUsePlan) that considers their children's developmental stages to individualize an appropriate balance for media time and consistent rules about media use, to mentor their children, to set boundaries for accessing content and displaying personal information, and to implement open family communication about media. (10/16)

MEDIATORS AND ADVERSE EFFECTS OF CHILD POVERTY IN THE UNITED STATES (TECHNICAL REPORT)

John M. Pascoe, MD, MPH, FAAP; David L. Wood, MD, MPH, FAAP; James H. Duffee, MD, MPH, FAAP; Alice Kuo, MD, PhD, MEd, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Council on Community Pediatrics

ABSTRACT. The link between poverty and children's health is well recognized. Even temporary poverty may have an adverse effect on children's health, and data consistently support the observation that poverty in childhood continues to have a negative effect on health into adulthood. In addition to childhood morbidity being related to child poverty, epidemiologic studies have documented a mortality gradient for children aged 1 to 15 years (and adults), with poor children experiencing a higher mortality rate than children from higher-income families. The global great recession is only now very slowly abating for millions of America's children and their families. At this difficult time in the history of our nation's families and immediately after the 50th anniversary year of President Lyndon Johnson's War on Poverty, it is particularly germane for the American Academy of Pediatrics, which is "dedicated to the health of all children," to publish a research-supported technical report that examines the mediators associated with the long-recognized adverse effects of child poverty on children and their families. This technical report draws on research from a number of disciplines, including physiology, sociology, psychology, economics, and epidemiology, to describe the present state of knowledge regarding poverty's negative impact on children's health and development. Children inherit not only their parents' genes but also the family ecology and its social milieu. Thus, parenting skills, housing, neighborhood, schools, and other factors (eg, medical care) all have complex relations to each other and influence how each child's genetic canvas is expressed. Accompanying this technical report is a policy statement that describes specific actions that pediatricians and other child advocates can take to attenuate the negative effects of the mediators identified in this technical report and improve the well-being of our nation's children and their families. (3/16, reaffirmed 4/21)

MEDICAID POLICY STATEMENT

Committee on Child Health Financing

ABSTRACT. Medicaid insures 39% of the children in the United States. This revision of the 2005 Medicaid Policy Statement of the American Academy of Pediatrics reflects opportunities for changes in state Medicaid programs resulting from the 2010 Patient Protection and Affordable Care Act as upheld in 2012 by the Supreme Court. Policy recommendations focus on the areas of benefit coverage, financing and payment, eligibility, outreach and enrollment, managed care, and quality improvement. (4/13, reaffirmed 3/19)

https://doi.org/10.1542/peds.2013-0419

MEDICAL COUNTERMEASURES FOR CHILDREN IN PUBLIC HEALTH EMERGENCIES, DISASTERS, OR TERRORISM

Disaster Preparedness Advisory Council

ABSTRACT. Significant strides have been made over the past 10 to 15 years to develop medical countermeasures (MCMs) to address potential disaster hazards, including chemical, biological, radiologic, and nuclear threats. Significant and effective collaboration between the pediatric health community, including the American Academy of Pediatrics, and federal partners, such as the Office of the Assistant Secretary for Preparedness and Response, Centers for Disease Control and Prevention, Federal Emergency Management Agency, National Institutes of Health, Food and Drug Administration, and other federal agencies, over the past 5 years has resulted in substantial gains in addressing the needs of children related to disaster preparedness in general and MCMs in particular. Yet, major gaps still remain related to MCMs for children, a population highly vulnerable to the effects of exposure to such threats, because many vaccines and pharmaceuticals approved for use by adults as MCMs do not yet have pediatric formulations, dosing information, or safety information. As a result, the nation's stockpiles and other caches (designated supply of MCMs) where pharmacotherapeutic and other MCMs are stored are less prepared to address the needs of children compared with those of adults in the event of a disaster. This policy statement provides recommendations to close the remaining gaps for the development and use of MCMs in children during public health emergencies or disasters. The progress made by federal agencies to date to address the needs of children and the shared commitment of collaboration that characterizes the current relationship between the pediatric health community and the federal agencies responsible for MCMs should encourage all child advocates to invest the necessary energy and resources now to complete the process of remedying the remaining significant gaps in preparedness. (1/16)

MEDICAL EMERGENCIES OCCURRING AT SCHOOL

Council on School Health

ABSTRACT. Children and adults might experience medical emergency situations because of injuries, complications of chronic health conditions, or unexpected major illnesses that occur in schools. In February 2001, the American Academy of Pediatrics issued a policy statement titled "Guidelines for Emergency Medical Care in Schools" (available at: http://aappolicy.

aappublications.org/cgi/content/full/pediatrics;107/2/435). Since the release of that statement, the spectrum of potential individual student emergencies has changed significantly. The increase in the number of children with special health care needs and chronic medical conditions attending schools and the challenges associated with ensuring that schools have access to on-site licensed health care professionals on an ongoing basis have added to increasing the risks of medical emergencies in schools. The goal of this statement is to increase pediatricians' awareness of schools' roles in preparing for individual student emergencies and to provide recommendations for primary care and school physicians on how to assist and support school personnel. (10/08, reaffirmed 9/11, 4/17)
https://doi.org/10.1542/peds.2008-2171

MEDICAL STAFF APPOINTMENT AND DELINEATION OF PEDIATRIC PRIVILEGES IN HOSPITALS (CLINICAL REPORT)

Daniel A. Rauch, MD; Committee on Hospital Care; and Section on Hospital Medicine

ABSTRACT. The review and verification of credentials and the granting of clinical privileges are required of every hospital to ensure that members of the medical staff are competent and qualified to provide specified levels of patient care. The credentialing process involves the following: (1) assessment of the professional and personal background of each practitioner seeking privileges; (2) assignment of privileges appropriate for the clinician's training and experience; (3) ongoing monitoring of the professional activities of each staff member; and (4) periodic reappointment to the medical staff on the basis of objectively measured performance. We examine the essential elements of a credentials review for initial and renewed medical staff appointments along with suggested criteria for the delineation of clinical privileges. Sample forms for the delineation of privileges can be found on the American Academy of Pediatrics Committee on Hospital Care Web site (http://www.aap.org/visit/cmte19.htm). Because of differences among individual hospitals, no 1 method for credentialing is universally applicable. The medical staff of each hospital must, therefore, establish its own process based on the general principles reviewed in this report. The issues of medical staff membership and credentialing have become very complex, and institutions and medical staffs are vulnerable to legal action. Consequently, it is advisable for hospitals and medical staffs to obtain expert legal advice when medical staff bylaws are constructed or revised. (3/12, reaffirmed 2/16)

MEDICAL VERSUS NONMEDICAL IMMUNIZATION EXEMPTIONS FOR CHILD CARE AND SCHOOL ATTENDANCE

Committee on Practice and Ambulatory Medicine, Committee on Infectious Diseases, Committee on State Government Affairs, Council on School Health, and Section on Administration and Practice Management

ABSTRACT. Routine childhood immunizations against infectious diseases are an integral part of our public health infrastructure. They provide direct protection to the immunized individual and indirect protection to children and adults unable to be immunized via the effect of community immunity. All 50 states, the District of Columbia, and Puerto Rico have regulations requiring proof of immunization for child care and school attendance as a public health strategy to protect children in these settings and to secondarily serve as a mechanism to promote timely immunization of children by their caregivers. Although all states and the District of Columbia have mechanisms to exempt school attendees from specific immunization requirements for medical reasons, the majority also have a heterogeneous collection of regulations and laws that allow nonmedical exemptions from childhood immunizations otherwise required for child care and school attendance. The American Academy of Pediatrics (AAP) supports regulations and laws requiring certification of immunization to attend child care and school as a sound means of providing a safe environment for attendees and employees of these settings. The AAP also supports medically indicated exemptions to specific immunizations as determined for each individual child. The AAP views nonmedical exemptions to school-required immunizations as inappropriate for individual, public health, and ethical reasons and advocates for their elimination. (8/16)

MEDICATION-ASSISTED TREATMENT OF ADOLESCENTS WITH OPIOID USE DISORDERS

Committee on Substance Use and Prevention

ABSTRACT. Opioid use disorder is a leading cause of morbidity and mortality among US youth. Effective treatments, both medications and substance use disorder counseling, are available but underused, and access to developmentally appropriate treatment is severely restricted for adolescents and young adults. Resources to disseminate available therapies and to develop new treatments specifically for this age group are needed to save and improve lives of youth with opioid addiction. (8/16)

MENSTRUAL MANAGEMENT FOR ADOLESCENTS WITH DISABILITIES (CLINICAL REPORT)

Elisabeth H. Quint, MD; Rebecca F. O'Brien, MD; and Committee on Adolescence (joint with North American Society for Pediatric and Adolescent Gynecology)

ABSTRACT. The onset of menses for adolescents with physical or intellectual disabilities can affect their independence and add additional concerns for families at home, in schools, and in other settings. The pediatrician is the primary health care provider to explore and assist with the pubertal transition and menstrual management. Menstrual management of both normal and abnormal cycles may be requested to minimize hygiene issues, premenstrual symptoms, dysmenorrhea, heavy or irregular bleeding, contraception, and conditions exacerbated by the menstrual cycle. Several options are available for menstrual management, depending on the outcome that is desired, ranging from cycle regulation to complete amenorrhea. The use of medications or the request for surgeries to help with the menstrual cycles in teenagers with disabilities has medical, social, legal, and ethical implications. This clinical report is designed to help guide pediatricians in assisting adolescent females with intellectual and/or physical disabilities and their families in making decisions related to successfully navigating menarche and subsequent menstrual cycles. MENTAL HEALTH COMPETENCIES FOR PEDIATRIC PRACTICE

Jane Meschan Foy, MD, FAAP; Cori M. Green, MD, MS, FAAP; Marian F. Earls, MD, MTS, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Mental Health Leadership Work Group

ABSTRACT. Pediatricians have unique opportunities and an increasing sense of responsibility to promote healthy social-emotional development of children and to prevent and address their mental health and substance use conditions. In this report, the American Academy of Pediatrics updates its 2009 policy statement, which proposed competencies for providing mental health care to children in primary care settings and recommended steps toward achieving them. This 2019 policy statement affirms the 2009 statement and expands competencies in response to science and policy that have emerged since: the impact of adverse childhood experiences and social determinants on mental health, trauma-informed practice, and team-based care. Importantly, it

also recognizes ways in which the competencies are pertinent to pediatric subspecialty practice. Proposed mental health competencies include foundational communication skills, capacity to incorporate mental health content and tools into health promotion and primary and secondary preventive care, skills in the psychosocial assessment and care of children with mental health conditions, knowledge and skills of evidence-based psychosocial therapy and psychopharmacologic therapy, skills to function as a team member and comanager with mental health specialists, and commitment to embrace mental health practice as integral to pediatric care. Achievement of these competencies will necessarily be incremental, requiring partnership with fellow advocates, system changes, new payment mechanisms, practice enhancements, and decision support for pediatricians in their expanded scope of practice. (10/19)

METABOLIC AND BARIATRIC SURGERY FOR PEDIATRIC PATIENTS WITH SEVERE OBESITY (TECHNICAL REPORT)

Christopher F. Bolling, MD, FAAP; Sarah C. Armstrong, MD, FAAP; Kirk W. Reichard, MD, MBA, FAAP; Marc P. Michalsky, MD, FACS, FAAP, FASMBS; Section on Obesity; and Section on Surgery

ABSTRACT. Severe obesity affects the health and well-being of millions of children and adolescents in the United States and is widely considered to be an "epidemic within an epidemic" that poses a major public health crisis. Currently, few effective treatments for severe obesity exist. Metabolic and bariatric surgery are existing but underuse treatment options for pediatric patients with severe obesity. Roux-en-Y gastric bypass and vertical sleeve gastrectomy are the most commonly performed metabolic and bariatric procedures in the United States and have been shown to result in sustained short-, mid-, and long-term weight loss, with associated resolution of multiple obesity-related comorbid diseases. Substantial evidence supports the safety and effectiveness of surgical weight loss for children and adolescents, and robust best practice guidelines for these procedures exist. (11/19)

THE METABOLIC SYNDROME IN CHILDREN AND ADOLESCENTS: SHIFTING THE FOCUS TO CARDIOMETABOLIC RISK FACTOR CLUSTERING (CLINICAL REPORT)

Sheela N. Magge, MD, MSCE, FAAP; Elizabeth Goodman, MD, MBA, FAAP; Sarah C. Armstrong, MD, FAAP; Committee on Nutrition; Section on Endocrinology; and Section on Obesity

ABSTRACT. Metabolic syndrome (MetS) was developed by the National Cholesterol Education Program Adult Treatment Panel III, identifying adults with at least 3 of 5 cardiometabolic risk factors (hyperglycemia, increased central adiposity, elevated triglycerides, decreased high-density lipoprotein cholesterol, and elevated blood pressure) who are at increased risk of diabetes and cardiovascular disease. The constellation of MetS component risk factors has a shared pathophysiology and many common treatment approaches grounded in lifestyle modification. Several attempts have been made to define MetS in the pediatric population. However, in children, the construct is difficult to define and has unclear implications for clinical care. In this Clinical Report, we focus on the importance of screening for and treating the individual risk factor components of MetS. Focusing attention on children with cardiometabolic risk factor clustering is emphasized over the need to define a pediatric MetS. (7/17)

METRIC UNITS AND THE PREFERRED DOSING OF ORALLY ADMINISTERED LIQUID MEDICATIONS

Committee on Drugs

ABSTRACT. Medication overdoses are a common, but preventable, problem among children. Volumetric dosing errors and the use of incorrect dosing delivery devices are 2 common sources of these preventable errors for orally administered liquid medications. To reduce errors and increase precision of drug administration, milliliter-based dosing should be used exclusively when prescribing and administering liquid medications. Teaspoon- and tablespoon-based dosing should not be used. Devices that allow for precise dose administration (preferably syringes with metric markings) should be used instead of household spoons and should be distributed with the medication. (3/15)

MIND-BODY THERAPIES IN CHILDREN AND YOUTH (CLINICAL REPORT)

Section on Integrative Medicine

ABSTRACT. Mind-body therapies are popular and are ranked among the top 10 complementary and integrative medicine practices reportedly used by adults and children in the 2007–2012 National Health Interview Survey. A growing body of evidence supports the effectiveness and safety of mind-body therapies in pediatrics. This clinical report outlines popular mind-body therapies for children and youth and examines the best-available evidence for a variety of mind-body therapies and practices, including biofeedback, clinical hypnosis, guided imagery, meditation, and yoga. The report is intended to help health care professionals guide their patients to nonpharmacologic approaches to improve concentration, help decrease pain, control discomfort, or ease anxiety. (8/16)
https://doi.org/10.1542/peds.2016-1896

MINORS AS LIVING SOLID-ORGAN DONORS (CLINICAL REPORT)

Lainie Friedman Ross, MD, PhD; J. Richard Thistlethwaite Jr, MD, PhD; and Committee on Bioethics

ABSTRACT. In the past half-century, solid-organ transplantation has become standard treatment for a variety of diseases in children and adults. The major limitation for all transplantation is the availability of donors, and the gap between demand and supply continues to grow despite the increase in living donors. Although rare, children do serve as living donors, and these donations raise serious ethical issues. This clinical report includes a discussion of the ethical considerations regarding minors serving as living donors, using the traditional benefit/burden calculus from the perspectives of both the donor and the recipient. The report also includes an examination of the circumstances under which a minor may morally participate as a living donor, how to minimize risks, and what the informed-consent process should entail. The American Academy of Pediatrics holds that minors can morally serve as living organ donors but only in exceptional circumstances when specific criteria are fulfilled. (8/08, reaffirmed 5/11)

MODEL CONTRACTUAL LANGUAGE FOR MEDICAL NECESSITY FOR CHILDREN

Committee on Child Health Financing

ABSTRACT. The term "medical necessity" is used by Medicare and Medicaid and in insurance contracts to refer to medical services that are generally recognized as appropriate for the diagnosis, prevention, or treatment of disease and injury. There is no consensus on how to define and apply the term and the accompanying rules and regulations, and as a result there has been substantial variation in medical-necessity definitions and interpretations. With this policy statement, the American Academy of Pediatrics hopes to encourage insurers to adopt more consistent medical-necessity definitions that take into account the needs of children. (7/05, reaffirmed 10/11)
https://doi.org/10.1542/peds.2005-0880

MOTOR DELAYS: EARLY IDENTIFICATION AND EVALUATION (CLINICAL REPORT)

Garey H. Noritz, MD; Nancy A. Murphy, MD; and Neuromotor Screening Expert Panel

ABSTRACT. Pediatricians often encounter children with delays of motor development in their clinical practices. Earlier identification of motor delays allows for timely referral for developmental interventions as well as diagnostic evaluations and treatment planning. A multidisciplinary expert panel developed an algorithm for the surveillance and screening of children for motor delays within the medical home, offering guidance for the initial workup and referral of the child with possible delays in motor development. Highlights of this clinical report include suggestions for formal developmental screening at the 9-, 18-, 30-, and 48-month well-child visits; approaches to the neurologic examination, with emphasis on the assessment of muscle tone; and initial diagnostic approaches for medical home providers. Use of diagnostic tests to evaluate children with motor delays are described, including brain MRI for children with high muscle tone, and measuring serum creatine kinase concentration of those with decreased muscle tone. The importance of pursuing diagnostic tests while concurrently referring patients to early intervention programs is emphasized. (5/13, reaffirmed 5/17)

https://doi.org/10.1542/peds.2013-1056

THE NEED TO OPTIMIZE ADOLESCENT IMMUNIZATION (CLINICAL REPORT)

Henry H. Bernstein, DO, MHCM, FAAP; Joseph A. Bocchini Jr, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. The adolescent period heralds the pediatric patient's transition into adulthood. It is a time of dynamic development during which effective preventive care measures can promote safe behaviors and the development of lifelong health habits. One of the foundations of preventive adolescent health care is timely vaccination, and every visit can be viewed as an opportunity to update and complete an adolescent's immunizations.

In the past decade, the adolescent immunization schedule has expanded to include 2 doses of quadrivalent meningococcal conjugate vaccine; 1 dose of tetanus, diphtheria, acellular pertussis, absorbed vaccine; 2 or 3 doses of human papillomavirus vaccine, depending on the child's age; and an annual influenza vaccine. In addition, during adolescent visits, health care providers can determine whether catch-up vaccination is needed to meet early childhood recommendations for hepatitis B; hepatitis A; measles, mumps, rubella; poliovirus; and varicella vaccines. New serogroup B meningococcal vaccines are now available for those at increased risk for meningococcal disease; in addition, these serogroup B meningococcal vaccines received a Category B recommendation for healthy adolescents, where individual counseling and risk–benefit evaluation based on health care provider judgements and patient preferences are indicated. This clinical report focuses on the epidemiology of adolescent vaccine-preventable diseases by reviewing the rationale for the annual universally recommended adolescent immunization schedule of the American Academy of Pediatrics, the American Academy of Family Physicians, the Centers for Disease Control and Prevention, and the American Congress of Obstetricians and Gynecologists. In addition, the barriers that negatively influence adherence to this current adolescent immunization schedule will be highlighted. (2/17)

https://doi.org/10.1542/peds.2016-4186

NEEDS OF KINSHIP CARE FAMILIES AND PEDIATRIC PRACTICE

David Rubin, MD, FAAP; Sarah H. Springer, MD, FAAP; Sarah Zlotnik, MSW, MSPH; Christina D. Kang-Yi, PhD; and Council on Foster Care, Adoption, and Kinship Care

ABSTRACT. As many as 3% of children in the United States live in kinship care arrangements with caregivers who are relatives but not the biological parents of the child. A growing body of evidence suggests that children who cannot live with their biological parents fare better, overall, when living with extended family than with nonrelated foster parents. Acknowledging this, federal laws and public policies increasingly favor kinship care over nonrelative foster care when children are unable to live with their biological parents. Despite overall better outcomes, families providing kinship care experience many hardships, and the children experience many of the same adversities of children in traditional foster care. This policy statement reviews both the strengths and vulnerabilities of kinship families and suggests strategies for pediatricians to use to address the needs of individual patients and families. Strategies are also outlined for community, state, and federal advocacy on behalf of these children and their families. (3/17)

https://doi.org/10.1542/peds.2017-0099

NEONATAL DRUG WITHDRAWAL (CLINICAL REPORT)

Mark L. Hudak, MD; Rosemarie C. Tan, MD, PhD; Committee on Drugs; and Committee on Fetus and Newborn

ABSTRACT. Maternal use of certain drugs during pregnancy can result in transient neonatal signs consistent with withdrawal or acute toxicity or cause sustained signs consistent with a lasting drug effect. In addition, hospitalized infants who are treated with opioids or benzodiazepines to provide analgesia or sedation may be at risk for manifesting signs of withdrawal. This statement updates information about the clinical presentation of infants exposed to intrauterine drugs and the therapeutic options for treatment of withdrawal and is expanded to include evidence-based approaches to the management of the hospitalized infant who requires weaning from analgesics or sedatives. (1/12, reaffirmed 2/16)

https://doi.org/10.1542/peds.2011-3212

NEONATAL OPIOID WITHDRAWAL SYNDROME (CLINICAL REPORT)

Stephen W. Patrick, MD, MPH, MS, FAAP; Wanda D. Barfield, MD, MPH, FAAP; Brenda B. Poindexter, MD, MS, FAAP; Committee on Fetus and Newborn; and Committee on Substance Use and Prevention

ABSTRACT. The opioid crisis has grown to affect pregnant women and infants across the United States, as evidenced by rising rates of opioid use disorder among pregnant women and neonatal opioid withdrawal syndrome among infants. Across the country, pregnant women lack access to evidence-based therapies, including medications for opioid use disorder, and infants with opioid exposure frequently receive variable care. In addition, public systems, such as child welfare and early intervention, are increasingly stretched by increasing numbers of children affected by the crisis. Systematic, enduring, coordinated, and holistic approaches are needed to improve care for the mother-infant dyad. In this statement, we provide an overview of the effect of the opioid crisis on the mother-infant dyad and provide recommendations for management of the infant with opioid exposure, including clinical presentation, assessment, treatment, and discharge. (10/20)

https://doi.org/10.1542/peds.2020-029074

NEONATAL PROVIDER WORKFORCE (TECHNICAL REPORT)

Erin L. Keels, DNP, APRN-CNP, NNP-BC; Jay P. Goldsmith, MD, FAAP; and Committee on Fetus and Newborn

ABSTRACT. This technical report reviews education, training, competency requirements, and scopes of practice of the different neonatal care providers who work to meet the special needs of neonatal patients and their families in the NICU. Additionally, this report examines the current workforce issues of NICU

providers, offers suggestions for establishing and monitoring quality and safety of care, and suggests potential solutions to the NICU provider workforce shortages now and in the future. (11/19)
https://doi.org/10.1542/peds.2019-3147

A NEW ERA IN QUALITY MEASUREMENT: THE DEVELOPMENT AND APPLICATION OF QUALITY MEASURES

Terry Adirim, MD, MPH, FAAP; Kelley Meade, MD, FAAP; Kamila Mistry, PhD, MPH; Council on Quality Improvement and Patient Safety; and Committee on Practice and Ambulatory Medicine

ABSTRACT. Quality measures are used for a variety of purposes in health care, including clinical care improvement, regulation, accreditation, public reporting, surveillance, and maintenance of certification. Most quality measures are 1 of 3 types: structure, process, or outcome. Health care quality measures should address the domains of quality across the continuum of care and reflect patient and family experience. Measure development for pediatric health care has a number of important challenges, including gaps in the evidence base; the fact that measures for most conditions must be age-specific; the long, resourceintensive development process; and the national focus on measure development for adult conditions. Numerous national organizations focus on the development and application of quality measures, including the Pediatric Quality Measures Program, which is focused solely on the development and implementation of pediatric-specific measures. Once a quality measure is developed for use in national measurement programs, the organization that develops and/or "stewards" the measure may submit the measure or set of measures for endorsement, which is recognition of the scientific soundness, usability, and relevance of the measure. Quality measures must then be disseminated and applied to improve care. Although pediatric health care providers and child health care institutions alike must continually balance time and resources needed to address multiple reporting requirements, quality measurement is an important tool for advancing high-quality and safe health care for children. This policy statement provides an overview of quality measurement and describes the opportunities for pediatric health care providers to apply quality measures to improve clinical quality and performance in the delivery of pediatric health care services. (12/16)
https://doi.org/10.1542/peds.2016-3442

NEWBORN SCREENING EXPANDS: RECOMMENDATIONS FOR PEDIATRICIANS AND MEDICAL HOMES—IMPLICATIONS FOR THE SYSTEM (CLINICAL REPORT)

Newborn Screening Authoring Committee

ABSTRACT. Advances in newborn screening technology, coupled with recent advances in the diagnosis and treatment of rare but serious congenital conditions that affect newborn infants, provide increased opportunities for positively affecting the lives of children and their families. These advantages also pose new challenges to primary care pediatricians, both educationally and in response to the management of affected infants. Primary care pediatricians require immediate access to clinical and diagnostic information and guidance and have a proactive role to play in supporting the performance of the newborn screening system. Primary care pediatricians must develop office policies and procedures to ensure that newborn screening is conducted and that results are transmitted to them in a timely fashion; they must also develop strategies to use should these systems fail. In addition, collaboration with local, state, and national partners is essential for promoting actions and policies that will optimize the function of the newborn screening systems and ensure that families receive the full benefit of them. (1/08, reaffirmed 9/16)
https://doi.org/10.1542/peds.2007-3021

NEWBORN SCREENING FOR BILIARY ATRESIA (TECHNICAL REPORT)

Kasper S. Wang, MD, FAAP, FACS; Section on Surgery; and Committee on Fetus and Newborn (joint with Childhood Liver Disease Research Network)

ABSTRACT. Biliary atresia is the most common cause of pediatric end-stage liver disease and the leading indication for pediatric liver transplantation. Affected infants exhibit evidence of biliary obstruction within the first few weeks after birth. Early diagnosis and successful surgical drainage of bile are associated with greater survival with the child's native liver. Unfortunately, because noncholestatic jaundice is extremely common in early infancy, it is difficult to identify the rare infant with cholestatic jaundice who has biliary atresia. Hence, the need for timely diagnosis of this disease warrants a discussion of the feasibility of screening for biliary atresia to improve outcomes. Herein, newborn screening for biliary atresia in the United States is assessed by using criteria established by the Discretionary Advisory Committee on Heritable Disorders in Newborns and Children. Published analyses indicate that newborn screening for biliary atresia by using serum bilirubin concentrations or stool color cards is potentially life-saving and cost-effective. Further studies are necessary to evaluate the feasibility, effectiveness, and costs of potential screening strategies for early identification of biliary atresia in the United States. (11/15)

NICKEL ALLERGIC CONTACT DERMATITIS: IDENTIFICATION, TREATMENT, AND PREVENTION

Nanette B. Silverberg, MD, FAAP, FAAD; Janice L. Pelletier, MD, FAAP; Sharon E. Jacob, MD, FAAP, FAAD; Lynda C. Schneider, MD, FAAP; Section on Dermatology; and Section on Allergy and Immunology

ABSTRACT. Nickel is a ubiquitous metal added to jewelry and metallic substances for its hardening properties and because it is inexpensive. Estimates suggest that at least 1.1 million children in the United States are sensitized to nickel. Nickel allergic contact dermatitis (Ni-ACD) is the most common cutaneous delayed-type hypersensitivity reaction worldwide. The incidence among children tested has almost quadrupled over the past 3 decades. The associated morbidities include itch, discomfort, school absence, and reduced quality of life. In adulthood, individuals with Ni-ACD may have severe disabling hand eczema. The increasing rate of Ni-ACD in children has been postulated to result from early and frequent exposure to metals with high amounts of nickel release (eg, as occurs with ear piercing or with products used daily in childhood such as toys, belt buckles, and electronics).

To reduce exposure to metal sources with high nickel release by prolonged and direct contact with human skin, Denmark and the European Union legislated a directive several decades ago with the goal of reducing high nickel release and the incidence of Ni-ACD. Since then, there has been a global reduction in incidence of Ni-ACD in population-based studies of adults and studies of children and young adults being tested for allergic contact dermatitis. These data point to nickel exposure as a trigger for elicitation of Ni-ACD and, further, provide evidence that legislation can have a favorable effect on the economic and medical health of a population.

This policy statement reviews the epidemiology, history, and appearances of Ni-ACD. Examples of sources of high nickel release are discussed to highlight how difficult it is to avoid this metal in modern daily lives. Treatments are outlined, and

avoidance strategies are presented. Long-term epidemiological interventions are addressed. Advocacy for smarter nickel use is reviewed. The American Academy of Pediatrics supports US legislation that advances safety standards (as modeled by the European Union) that protect children from early and prolonged skin exposure to high–nickel-releasing items. Our final aim for this article is to aid the pediatric community in developing nickel-avoidance strategies on both individual and global levels. (4/20)

NICOTINE AND TOBACCO AS SUBSTANCES OF ABUSE IN CHILDREN AND ADOLESCENTS (TECHNICAL REPORT)

Lorena M. Siqueira, MD, MSPH, FAAP, FSAHM, and Committee on Substance Use and Prevention

ABSTRACT. Nicotine is the primary pharmacologic component of tobacco, and users of tobacco products seek out its effects. The highly addictive nature of nicotine is responsible for its widespread use and difficulty with quitting. This technical report focuses on nicotine and discusses the stages of use in progression to dependence on nicotine-containing products; the physiologic characteristics, neurobiology, metabolism, pharmacogenetics, and health effects of nicotine; and acute nicotine toxicity. Finally, some newer approaches to cessation are noted. (12/16)
https://doi.org/10.1542/peds.2016-3436

NONDISCRIMINATION IN PEDIATRIC HEALTH CARE

Committee on Pediatric Workforce

ABSTRACT. This policy statement is a revision of a 2001 statement and articulates the positions of the American Academy of Pediatrics on nondiscrimination in pediatric health care. It addresses both pediatricians who provide health care and the infants, children, adolescents, and young adults whom they serve. (10/07, reaffirmed 6/11, 1/15, 5/21)
https://doi.org/10.1542/peds.2007-2334

NONEMERGENCY ACUTE CARE: WHEN IT'S NOT THE MEDICAL HOME

Gregory P. Conners, MD, MPH, MBA, FAAP; Susan J. Kressly, MD, FAAP; James M. Perrin, MD, FAAP; Julia E. Richerson, MD, FAAP; Usha M. Sankrithi, MBBS, MPH, FAAP; Committee on Practice and Ambulatory Medicine; Committee on Pediatric Emergency Medicine; Section on Telehealth Care; Section on Emergency Medicine; Subcommittee on Urgent Care; and Task Force on Pediatric Practice Change

ABSTRACT. The American Academy of Pediatrics (AAP) affirms that the optimal location for children to receive care for acute, nonemergency health concerns is the medical home. The medical home is characterized by the AAP as a care model that "must be accessible, family centered, continuous, comprehensive, coordinated, compassionate, and culturally effective." However, some children and families use acute care services outside the medical home because there is a perceived or real benefit related to accessibility, convenience, or cost of care. Examples of such acute care entities include urgent care facilities, retail-based clinics, and commercial telemedicine services. Children deserve high-quality, appropriate, and safe acute care services wherever they access the health care system, with timely and complete communication with the medical home, to ensure coordinated and continuous care. Treatment of children under established, new, and evolving practice arrangements in acute care entities should adhere to the core principles of continuity of care and communication, best practices within a defined scope of services, pediatric-trained staff, safe transitions of care, and continuous improvement. In support of the medical home, the AAP urges stakeholders, including payers, to avoid any incentives (eg, reduced copays) that encourage visits to external entities for acute issues as a preference over the medical home. NONINITIATION OR WITHDRAWAL OF INTENSIVE CARE FOR HIGH-RISK NEWBORNS

Committee on Fetus and Newborn

ABSTRACT. Advances in medical technology have led to dilemmas in initiation and withdrawal of intensive care of newborn infants with a very poor prognosis. Physicians and parents together must make difficult decisions guided by their understanding of the child's best interest. The foundation for these decisions consists of several key elements: (1) direct and open communication between the health care team and the parents of the child with regard to the medical status, prognosis, and treatment options; (2) inclusion of the parents as active participants in the decision process; (3) continuation of comfort care even when intensive care is not being provided; and (4) treatment decisions that are guided primarily by the best interest of the child. (2/07, reaffirmed 5/10, 6/15)

NONINVASIVE RESPIRATORY SUPPORT (CLINICAL REPORT)

James J. Cummings, MD, FAAP; Richard A. Polin, MD, FAAP; and Committee on Fetus and Newborn

ABSTRACT. Mechanical ventilation is associated with increased survival of preterm infants but is also associated with an increased incidence of chronic lung disease (bronchopulmonary dysplasia) in survivors. Nasal continuous positive airway pressure (nCPAP) is a form of noninvasive ventilation that reduces the need for mechanical ventilation and decreases the combined outcome of death or bronchopulmonary dysplasia. Other modes of noninvasive ventilation, including nasal intermittent positive pressure ventilation, biphasic positive airway pressure, and high-flow nasal cannula, have recently been introduced into the NICU setting as potential alternatives to mechanical ventilation or nCPAP. Randomized controlled trials suggest that these newer modalities may be effective alternatives to nCPAP and may offer some advantages over nCPAP, but efficacy and safety data are limited. (12/15)
https://doi.org/10.1542/peds.2015-3758

NONORAL FEEDING FOR CHILDREN AND YOUTH WITH DEVELOPMENTAL OR ACQUIRED DISABILITIES (CLINICAL REPORT)

Richard C. Adams, MD, FAAP; Ellen Roy Elias, MD, FAAP; and Council on Children With Disabilities

ABSTRACT. The decision to initiate enteral feedings is multifaceted, involving medical, financial, cultural, and emotional considerations. Children who have developmental or acquired disabilities are at risk for having primary and secondary conditions that affect growth and nutritional well-being. This clinical report provides (1) an overview of clinical issues in children who have developmental or acquired disabilities that may prompt a need to consider nonoral feedings, (2) a systematic way to support the child and family in clinical decisions related to initiating nonoral feeding, (3) information on surgical options that the family may need to consider in that decision-making process, and (4) pediatric guidance for ongoing care after initiation of nonoral feeding intervention, including care of the gastrostomy tube and skin site. Ongoing medical and psychosocial support is needed after initiation of nonoral feedings and is best provided through the collaborative efforts of the family and a team of professionals that may include the pediatrician, dietitian, social worker, and/or therapists. (11/14, reaffirmed 6/19)

NONTHERAPEUTIC USE OF ANTIMICROBIAL AGENTS IN ANIMAL AGRICULTURE: IMPLICATIONS FOR PEDIATRICS (TECHNICAL REPORT)

Jerome A. Paulson, MD, FAAP; Theoklis E. Zaoutis, MD, MSCE, FAAP; Council on Environmental Health; and Committee on Infectious Diseases

ABSTRACT. Antimicrobial resistance is one of the most serious threats to public health globally and threatens our ability to treat infectious diseases. Antimicrobial-resistant infections are associated with increased morbidity, mortality, and health care costs. Infants and children are affected by transmission of susceptible and resistant food zoonotic pathogens through the food supply, direct contact with animals, and environmental pathways. The overuse and misuse of antimicrobial agents in veterinary and human medicine is, in large part, responsible for the emergence of antibiotic resistance. Approximately 80% of the overall tonnage of antimicrobial agents sold in the United States in 2012 was for animal use, and approximately 60% of those agents are considered important for human medicine. Most of the use involves the addition of low doses of antimicrobial agents to the feed of healthy animals over prolonged periods to promote growth and increase feed efficiency or at a range of doses to prevent disease. These nontherapeutic uses contribute to resistance and create new health dangers for humans. This report describes how antimicrobial agents are used in animal agriculture, reviews the mechanisms of how such use contributes to development of resistance, and discusses US and global initiatives to curb the use of antimicrobial agents in agriculture. (11/15, reaffirmed 6/21)

OFFICE-BASED CARE FOR LESBIAN, GAY, BISEXUAL, TRANSGENDER, AND QUESTIONING YOUTH

Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics issued its last statement on homosexuality and adolescents in 2004. Although most lesbian, gay, bisexual, transgender, and questioning (LGBTQ) youth are quite resilient and emerge from adolescence as healthy adults, the effects of homophobia and heterosexism can contribute to health disparities in mental health with higher rates of depression and suicidal ideation, higher rates of substance abuse, and more sexually transmitted and HIV infections. Pediatricians should have offices that are teen-friendly and welcoming to sexual minority youth. Obtaining a comprehensive, confidential, developmentally appropriate adolescent psychosocial history allows for the discovery of strengths and assets as well as risks. Referrals for mental health or substance abuse may be warranted. Sexually active LGBTQ youth should have sexually transmitted infection/HIV testing according to recommendations of the Sexually Transmitted Diseases Treatment Guidelines of the Centers for Disease Control and Prevention based on sexual behaviors. With appropriate assistance and care, sexual minority youth should live healthy, productive lives while transitioning through adolescence and young adulthood. (6/13, reaffirmed 4/21)

https://doi.org/10.1542/peds.2013-1282

OFFICE-BASED CARE FOR LESBIAN, GAY, BISEXUAL, TRANSGENDER, AND QUESTIONING YOUTH (TECHNICAL REPORT)

David A. Levine, MD, and Committee on Adolescence

ABSTRACT. The American Academy of Pediatrics issued its last statement on homosexuality and adolescents in 2004. This technical report reflects the rapidly expanding medical and psychosocial literature about sexual minority youth. Pediatricians should be aware that some youth in their care may have concerns or questions about their sexual orientation or that of siblings, friends, parents, relatives, or others and should provide factual, current, nonjudgmental information in a confidential manner. Although most lesbian, gay, bisexual, transgender, and questioning (LGBTQ) youth are quite resilient and emerge from adolescence as healthy adults, the effects of homophobia and heterosexism can contribute to increased mental health issues for sexual minority youth. LGBTQ and MSM/WSW (men having sex with men and women having sex with women) adolescents, in comparison with heterosexual adolescents, have higher rates of depression and suicidal ideation, higher rates of substance abuse, and more risky sexual behaviors. Obtaining a comprehensive, confidential, developmentally appropriate adolescent psychosocial history allows for the discovery of strengths and assets as well as risks. Pediatricians should have offices that are teen-friendly and welcoming to sexual minority youth. This includes having supportive, engaging office staff members who ensure that there are no barriers to care. For transgender youth, pediatricians should provide the opportunity to acknowledge and affirm their feelings of gender dysphoria and desires to transition to the opposite gender. Referral of transgender youth to a qualified mental health professional is critical to assist with the dysphoria, to educate them, and to assess their readiness for transition. With appropriate assistance and care, sexual minority youth should live healthy, productive lives while transitioning through adolescence and young adulthood. (6/13, reaffirmed 4/21)

OFFICE-BASED COUNSELING FOR UNINTENTIONAL INJURY PREVENTION (CLINICAL REPORT)

H. Garry Gardner, MD, and Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Unintentional injuries are the leading cause of death for children older than 1 year. Pediatricians should include unintentional injury prevention as a major component of anticipatory guidance for infants, children, and adolescents. The content of injury-prevention counseling varies for infants, preschool-aged children, school-aged children, and adolescents. This report provides guidance on the content of unintentional injury-prevention counseling for each of those age groups. (1/07)

https://doi.org/10.1542/peds.2006-2899

OFF-LABEL USE OF DRUGS IN CHILDREN

Committee on Drugs

ABSTRACT. The passage of the Best Pharmaceuticals for Children Act and the Pediatric Research Equity Act has collectively resulted in an improvement in rational prescribing for children, including more than 500 labeling changes. However, off-label drug use remains an important public health issue for infants, children, and adolescents, because an overwhelming number of drugs still have no information in the labeling for use in pediatrics. The purpose of off-label use is to benefit the individual patient. Practitioners use their professional judgment to determine these uses. As such, the term "off-label" does not imply an improper, illegal, contraindicated, or investigational use. Therapeutic decision-making must always rely on the best available evidence and the importance of the benefit for the individual patient. (2/14, reaffirmed 11/20)

https://doi.org/10.1542/peds.2013-4060

OFF-LABEL USE OF MEDICAL DEVICES IN CHILDREN

Section on Cardiology and Cardiac Surgery and Section on Orthopaedics

ABSTRACT. Despite widespread therapeutic needs, the majority of medical and surgical devices used in children do not have approval or clearance from the Food and Drug Administration (FDA) for use in pediatric populations. The clinical need for devices to diagnose and treat diseases or conditions occurring

in children has led to the widespread and necessary practice in pediatric medicine and surgery of using approved devices for "off-label" or "physician-directed" applications that are not included in FDA-approved labeling. This practice is common and often appropriate, even with the highest-risk (class III) devices. The legal and regulatory framework used by the FDA for devices is complex, and economic or market barriers to medical and surgical device development for children are significant. Given the need for pediatric medical and surgical devices and the challenges to pediatric device development, off-label use is a necessary and appropriate part of care. In addition, because of the relatively uncommon nature of pediatric conditions, FDA clearance or approval often requires other regulatory pathways (eg, Humanitarian Device Exemption), which can cause confusion among pediatricians and payers about whether a specific use, even of an approved device, is considered experimental. This policy statement describes the appropriateness of off-label use of devices in children; the use of devices approved or cleared through the FDA regulatory processes, including through the Humanitarian Device Exemption; and the important need to increase pediatric device labeling information for all devices and especially those that pose the highest risk to children. (12/16)

ONGOING PEDIATRIC HEALTH CARE FOR THE CHILD WHO HAS BEEN MALTREATED (CLINICAL REPORT)

Emalee Flaherty, MD, FAAP; Lori Legano, MD, FAAP; Sheila Idzerda, MD, FAAP; and Council on Child Abuse and Neglect

ABSTRACT. Pediatricians provide continuous medical care and anticipatory guidance for children who have been reported to state child protection agencies, including tribal child protection agencies, because of suspected child maltreatment. Because families may continue their relationships with their pediatricians after these reports, these primary care providers are in a unique position to recognize and manage the physical, developmental, academic, and emotional consequences of maltreatment and exposure to childhood adversity. Substantial information is available to optimize follow-up medical care of maltreated children. This new clinical report will provide guidance to pediatricians about how they can best oversee and foster the optimal physical health, growth, and development of children who have been maltreated and remain in the care of their biological family or are returned to their care by Child Protective Services agencies. The report describes the pediatrician's role in helping to strengthen families' and caregivers' capabilities and competencies and in promoting and maximizing high-quality services for their families in their community. Pediatricians should refer to other reports and policies from the American Academy of Pediatrics for more information about the emotional and behavioral consequences of child maltreatment and the treatment of these consequences. (3/19)

OPHTHALMOLOGIC EXAMINATIONS IN CHILDREN WITH JUVENILE RHEUMATOID ARTHRITIS (CLINICAL REPORT)

James Cassidy, MD; Jane Kivlin, MD; Carol Lindsley, MD; James Nocton, MD; Section on Rheumatology; and Section on Ophthalmology

ABSTRACT. Unlike the joints, ocular involvement with juvenile rheumatoid arthritis is most often asymptomatic; yet, the inflammation can cause serious morbidity with loss of vision. Scheduled slit-lamp examinations by an ophthalmologist at specific intervals can detect ocular disease early, and prompt treatment can prevent vision loss. (5/06, reaffirmed 10/12, 7/18)

OPTIMIZING BONE HEALTH IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Neville H. Golden, MD; Steven A. Abrams, MD; and Committee on Nutrition

ABSTRACT. The pediatrician plays a major role in helping optimize bone health in children and adolescents. This clinical report reviews normal bone acquisition in infants, children, and adolescents and discusses factors affecting bone health in this age group. Previous recommended daily allowances for calcium and vitamin D are updated, and clinical guidance is provided regarding weight-bearing activities and recommendations for calcium and vitamin D intake and supplementation. Routine calcium supplementation is not recommended for healthy children and adolescents, but increased dietary intake to meet daily requirements is encouraged. The American Academy of Pediatrics endorses the higher recommended dietary allowances for vitamin D advised by the Institute of Medicine and supports testing for vitamin D deficiency in children and adolescents with conditions associated with increased bone fragility. Universal screening for vitamin D deficiency is not routinely recommended in healthy children or in children with dark skin or obesity because there is insufficient evidence of the cost–benefit of such a practice in reducing fracture risk. The preferred test to assess bone health is dual-energy x-ray absorptiometry, but caution is advised when interpreting results in children and adolescents who may not yet have achieved peak bone mass. For analyses, *z* scores should be used instead of T scores, and corrections should be made for size. Office-based strategies for the pediatrician to optimize bone health are provided. This clinical report has been endorsed by American Bone Health. (9/14)

OPTIMIZING RESOURCES IN CHILDREN'S SURGICAL CARE: AN UPDATE ON THE AMERICAN COLLEGE OF SURGEONS' VERIFICATION PROGRAM (TECHNICAL REPORT)

Kasper S. Wang, MD, FAAP; James Cummings, MD, FAAP; Ann Stark, MD, FAAP; Constance Houck, MD, MPH, FAAP; Keith Oldham, MD, FAAP; Catherine Grant, BSN, RN; Mary Fallat, MD, FAAP; Section on Surgery; Committee on Fetus and Newborn; and Section on Anesthesiology and Pain Medicine

ABSTRACT. Surgical procedures are performed in the United States in a wide variety of clinical settings and with variation in clinical outcomes. In May 2012, the Task Force for Children's Surgical Care, an ad hoc multidisciplinary group comprising physicians representing specialties relevant to pediatric perioperative care, was convened to generate recommendations to optimize the delivery of children's surgical care. This group generated a white paper detailing the consensus opinions of the involved experts. Following these initial recommendations, the American College of Surgeons (ACS), Children's Hospital Association, and Task Force for Children's Surgical Care, with input from all related perioperative specialties, developed and published specific and detailed resource and quality standards designed to improve children's surgical care (https://www.facs.org/quality-programs/childrens-surgery/childrens-surgery-verification). In 2015, with the endorsement of the American Academy of Pediatrics (https://pediatrics.aappublications.org/content/135/6/e1538), the ACS established a pilot verification program. In January 2017, after completion of the pilot program, the ACS Children's Surgery Verification Quality Improvement Program was officially launched. Verified sites are listed on the program Web site at https://www.facs.org/quality-programs/childrens-surgery/childrens-surgery-verification/centers, and more than 150 are interested in verification. This report provides an update on the ACS Children's Surgery Verification Quality Improvement Program as it continues to evolve. (4/20)

OPTIONS COUNSELING FOR THE PREGNANT ADOLESCENT PATIENT

Laurie L. Hornberger, MD, MPH, FAAP, and Committee on Adolescence

ABSTRACT. Each year, more than 500 000 girls and young women younger than 20 years become pregnant. It is important for pediatricians to have the ability and the resources in their offices to make a timely pregnancy diagnosis in their adolescent patients and provide them with nonjudgmental pregnancy options counseling. Counseling includes an unbiased discussion of the adolescent's legal options to either continue or terminate her pregnancy, supporting the adolescent in the decision-making process, and referring the adolescent to appropriate resources and services. Pediatricians who choose not to provide such discussions should promptly refer pregnant adolescent patients to a health care professional who will offer developmentally appropriate pregnancy options counseling. This approach to pregnancy options counseling has not changed since the original 1989 American Academy of Pediatrics statement on this issue. (8/17)

https://doi.org/10.1542/peds.2017-2274

ORAL AND DENTAL ASPECTS OF CHILD ABUSE AND NEGLECT (CLINICAL REPORT)

Susan A. Fisher-Owens, MD, MPH, FAAP; James L. Lukefahr, MD, FAAP; Anupama Rao Tate, DMD, MPH; Section on Oral Health; and Committee on Child Abuse and Neglect (joint with American Academy of Pediatric Dentistry Council on Clinical Affairs, Council on Scientific Affairs, and Ad Hoc Work Group on Child Abuse and Neglect)

ABSTRACT. In all 50 states, health care providers (including dentists) are mandated to report suspected cases of abuse and neglect to social service or law enforcement agencies. The purpose of this report is to review the oral and dental aspects of physical and sexual abuse and dental neglect in children and the role of pediatric care providers and dental providers in evaluating such conditions. This report addresses the evaluation of bite marks as well as perioral and intraoral injuries, infections, and diseases that may raise suspicion for child abuse or neglect. Oral health issues can also be associated with bullying and are commonly seen in human trafficking victims. Some medical providers may receive less education pertaining to oral health and dental injury and disease and may not detect the mouth and gum findings that are related to abuse or neglect as readily as they detect those involving other areas of the body. Therefore, pediatric care providers and dental providers are encouraged to collaborate to increase the prevention, detection, and treatment of these conditions in children. (7/17)

https://doi.org/10.1542/peds.2017-1487

ORAL HEALTH CARE FOR CHILDREN WITH DEVELOPMENTAL DISABILITIES (CLINICAL REPORT)

Kenneth W. Norwood Jr, MD; Rebecca L. Slayton, DDS, PhD; Council on Children With Disabilities; and Section on Oral Health

ABSTRACT. Children with developmental disabilities often have unmet complex health care needs as well as significant physical and cognitive limitations. Children with more severe conditions and from low-income families are particularly at risk with high dental needs and poor access to care. In addition, children with developmental disabilities are living longer, requiring continued oral health care. This clinical report describes the effect that poor oral health has on children with developmental disabilities as well as the importance of partnerships between the pediatric medical and dental homes. Basic knowledge of the oral health risk factors affecting children with developmental disabilities is provided. Pediatricians may use the report to guide their incorporation of oral health assessments and education into their well-child examinations for children with developmental disabilities. This report has medical, legal, educational, and operational implications for practicing pediatricians. (2/13, reaffirmed 6/18)

https://doi.org/10.1542/peds.2012-3650

ORGANIC FOODS: HEALTH AND ENVIRONMENTAL ADVANTAGES AND DISADVANTAGES (CLINICAL REPORT)

Joel Forman, MD; Janet Silverstein, MD; Committee on Nutrition; and Council on Environmental Health

ABSTRACT. The US market for organic foods has grown from $3.5 billion in 1996 to $28.6 billion in 2010, according to the Organic Trade Association. Organic products are now sold in specialty stores and conventional supermarkets. Organic products contain numerous marketing claims and terms, only some of which are standardized and regulated.

In terms of health advantages, organic diets have been convincingly demonstrated to expose consumers to fewer pesticides associated with human disease. Organic farming has been demonstrated to have less environmental impact than conventional approaches. However, current evidence does not support any meaningful nutritional benefits or deficits from eating organic compared with conventionally grown foods, and there are no well-powered human studies that directly demonstrate health benefits or disease protection as a result of consuming an organic diet. Studies also have not demonstrated any detrimental or disease-promoting effects from an organic diet. Although organic foods regularly command a significant price premium, well-designed farming studies demonstrate that costs can be competitive and yields comparable to those of conventional farming techniques. Pediatricians should incorporate this evidence when discussing the health and environmental impact of organic foods and organic farming while continuing to encourage all patients and their families to attain optimal nutrition and dietary variety consistent with the US Department of Agriculture's MyPlate recommendations.

This clinical report reviews the health and environmental issues related to organic food production and consumption. It defines the term "organic," reviews organic food-labeling standards, describes organic and conventional farming practices, and explores the cost and environmental implications of organic production techniques. It examines the evidence available on nutritional quality and production contaminants in conventionally produced and organic foods. Finally, this report provides guidance for pediatricians to assist them in advising their patients regarding organic and conventionally produced food choices. (10/12)

https://doi.org/10.1542/peds.2012-2579

ORGANIZED SPORTS FOR CHILDREN, PREADOLESCENTS, AND ADOLESCENTS (CLINICAL REPORT)

Kelsey Logan, MD, MPH, FAAP; Steven Cuff, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. Interest and participation in organized sports for children, preadolescents, and adolescents continue to grow. Because of increased participation, and younger entry age, in organized sports, appropriate practice, game schedules, and content become more important, taking into account athlete developmental stage and skills. Parental support for organized sports in general, with focus on development and fun instead of winning, has emerged as a key factor in the athlete's enjoyment of sports. Schools and community sports organizations who support multiple levels of sport (eg, recreational, competitive, elite) can include more youth who want to play sports and combat sport dropout. This report reviews the benefits and risks of organized sports as well as the roles of schools, community organizations, parents, and coaches in organized sports. It is designed to complement the American Academy of Pediatrics clinical reports "Physical Activity Assessment and Counseling

in Pediatric Clinical Settings" and "Sports Specialization and Intensive Training in Young Athletes" by reviewing relevant literature on healthy organized sports for youth and providing guidance on organized sport readiness and entry. The report also provides guidance for pediatricians on counseling parents and advocating for healthy organized sports participation. (5/19)
https://doi.org/10.1542/peds.2019-0997

OUT-OF-HOME PLACEMENT FOR CHILDREN AND ADOLESCENTS WITH DISABILITIES (CLINICAL REPORT)

Sandra L. Friedman, MD, MPH, FAAP; Miriam A. Kalichman, MD, FAAP; and Council on Children With Disabilities

ABSTRACT. The vast majority of children and youth with chronic and complex health conditions who also have intellectual and developmental disabilities are cared for in their homes. Social, legal, policy, and medical changes through the years have allowed for an increase in needed support within the community. However, there continues to be a relatively small group of children who live in various types of congregate care settings. This clinical report describes these settings and the care and services that are provided in them. The report also discusses reasons families choose out-of-home placement for their children, barriers to placement, and potential effects of this decision on family members. We examine the pediatrician's role in caring for children with severe intellectual and developmental disabilities and complex medical problems in the context of responding to parental inquiries about out-of-home placement and understanding factors affecting these types of decisions. Common medical problems and care issues for children residing outside the family home are reviewed. Variations in state and federal regulations, challenges in understanding local systems, and access to services are also discussed. (9/14, reaffirmed 2/19)
https://doi.org/10.1542/peds.2014-2279

OUT-OF-HOME PLACEMENT FOR CHILDREN AND ADOLESCENTS WITH DISABILITIES—ADDENDUM: CARE OPTIONS FOR CHILDREN AND ADOLESCENTS WITH DISABILITIES AND MEDICAL COMPLEXITY (CLINICAL REPORT)

Sandra L. Friedman, MD, MPH, FAAP; Kenneth W. Norwood Jr, MD, FAAP; and Council on Children With Disabilities

ABSTRACT. Children and adolescents with significant intellectual and developmental disabilities and complex medical problems require safe and comprehensive care to meet their medical and psychosocial needs. Ideally, such children and youth should be cared for by their families in their home environments. When this type of arrangement is not possible, there should be exploration of appropriate, alternative noncongregate community-based settings, especially alternative family homes. Government funding sources exist to support care in the community, although there is variability among states with regard to the availability of community programs and resources. It is important that families are supported in learning about options of care. Pediatricians can serve as advocates for their patients and their families to access community-based services and to increase the availability of resources to ensure that the option to live in a family home is available to all children with complex medical needs. (11/16, reaffirmed 2/19)
https://doi.org/10.1542/peds.2016-3216

OUT-OF-SCHOOL SUSPENSION AND EXPULSION

Council on School Health

ABSTRACT. The primary mission of any school system is to educate students. To achieve this goal, the school district must maintain a culture and environment where all students feel safe, nurtured, and valued and where order and civility are expected standards of behavior. Schools cannot allow unacceptable behavior to interfere with the school district's primary mission. To this end, school districts adopt codes of conduct for expected behaviors and policies to address unacceptable behavior. In developing these policies, school boards must weigh the severity of the offense and the consequences of the punishment and the balance between individual and institutional rights and responsibilities. Out-of-school suspension and expulsion are the most severe consequences that a school district can impose for unacceptable behavior. Traditionally, these consequences have been reserved for offenses deemed especially severe or dangerous and/or for recalcitrant offenders. However, the implications and consequences of out-of-school suspension and expulsion and "zero-tolerance" are of such severity that their application and appropriateness for a developing child require periodic review. The indications and effectiveness of exclusionary discipline policies that demand automatic or rigorous application are increasingly questionable. The impact of these policies on offenders, other children, school districts, and communities is broad. Periodic scrutiny of policies should be placed not only on the need for a better understanding of the educational, emotional, and social impact of out-of-school suspension and expulsion on the individual student but also on the greater societal costs of such rigid policies. Pediatricians should be prepared to assist students and families affected by out-of-school suspension and expulsion and should be willing to guide school districts in their communities to find more effective and appropriate alternatives to exclusionary discipline policies for the developing child. A discussion of preventive strategies and alternatives to out-of-school suspension and expulsion, as well as recommendations for the role of the physician in matters of out-of-school suspension and expulsion are included. School-wide positive behavior support/positive behavior intervention and support is discussed as an effective alternative. (2/13)

OVERCROWDING CRISIS IN OUR NATION'S EMERGENCY DEPARTMENTS: IS OUR SAFETY NET UNRAVELING?

Committee on Pediatric Emergency Medicine

ABSTRACT. Emergency departments (EDs) are a vital component in our health care safety net, available 24 hours a day, 7 days a week, for all who require care. There has been a steady increase in the volume and acuity of patient visits to EDs, now with well over 100 million Americans (30 million children) receiving emergency care annually. This rise in ED utilization has effectively saturated the capacity of EDs and emergency medical services in many communities. The resulting phenomenon, commonly referred to as ED overcrowding, now threatens access to emergency services for those who need them the most. As managers of the pediatric medical home and advocates for children and optimal pediatric health care, there is a very important role for pediatricians and the American Academy of Pediatrics in guiding health policy decision-makers toward effective solutions that promote the medical home and timely access to emergency care. https://doi.org/10.1542/peds.2004-1287

OVERUSE INJURIES, OVERTRAINING, AND BURNOUT IN CHILD AND ADOLESCENT ATHLETES (CLINICAL REPORT)

Joel S. Brenner, MD, MPH, and Council on Sports Medicine and Fitness

ABSTRACT. Overuse is one of the most common etiologic factors that lead to injuries in the pediatric and adolescent athlete. As more children are becoming involved in organized and recreational athletics, the incidence of overuse injuries is increasing. Many children are participating in sports year-round and sometimes on multiple teams simultaneously. This overtraining can lead to burnout, which may have a detrimental effect on the child participating in sports as a lifelong healthy activity. One contributing factor to overtraining may be parental pressure to

compete and succeed. The purpose of this clinical report is to assist pediatricians in identifying and counseling at-risk children and their families. This report supports the American Academy of Pediatrics policy statement on intensive training and sport specialization. (6/07, reaffirmed 3/11, 6/14, 2/21)
https://doi.org/10.1542/peds.2007-0887

OXYGEN TARGETING IN EXTREMELY LOW BIRTH WEIGHT INFANTS (CLINICAL REPORT)

James J. Cummings, MD, FAAP; Richard A. Polin, MD, FAAP; and Committee on Fetus and Newborn

ABSTRACT. The use of supplemental oxygen plays a vital role in the care of the critically ill preterm infant, but the unrestricted use of oxygen can lead to unintended harms, such as chronic lung disease and retinopathy of prematurity. An overly restricted use of supplemental oxygen may have adverse effects as well. Ideally, continuous monitoring of tissue and cellular oxygen delivery would allow clinicians to better titrate the use of supplemental oxygen, but such monitoring is not currently feasible in the clinical setting. The introduction of pulse oximetry has greatly aided the clinician by providing a relatively easy and continuous estimate of arterial oxygen saturation, but pulse oximetry has several practical, technical, and physiologic limitations. Recent randomized clinical trials comparing different pulse oximetry targets have been conducted to better inform the practice of supplemental oxygen use. This clinical report discusses the benefits and limitations of pulse oximetry for assessing oxygenation, summarizes randomized clinical trials of oxygen saturation targeting, and addresses implications for practice. (7/16)

PAIN ASSESSMENT AND TREATMENT IN CHILDREN WITH SIGNIFICANT IMPAIRMENT OF THE CENTRAL NERVOUS SYSTEM (CLINICAL REPORT)

Julie Hauer, MD, FAAP; Amy J. Houtrow, MD, PhD, MPH, FAAP; Section on Hospice and Palliative Medicine; and Council on Children With Disabilities

ABSTRACT. Pain is a frequent and significant problem for children with impairment of the central nervous system, with the highest frequency and severity occurring in children with the greatest impairment. Despite the significance of the problem, this population remains vulnerable to underrecognition and undertreatment of pain. Barriers to treatment may include uncertainty in identifying pain along with limited experience and fear with the use of medications for pain treatment. Behavioral pain-assessment tools are reviewed in this clinical report, along with other strategies for monitoring pain after an intervention. Sources of pain in this population include acute-onset pain attributable to tissue injury or inflammation resulting in nociceptive pain, with pain then expected to resolve after treatment directed at the source. Other sources can result in chronic intermittent pain that, for many, occurs on a weekly to daily basis, commonly attributed to gastroesophageal reflux, spasticity, and hip subluxation. Most challenging are pain sources attributable to the impaired central nervous system, requiring empirical medication trials directed at causes that cannot be identified by diagnostic tests, such as central neuropathic pain. Interventions reviewed include integrative therapies and medications, such as gabapentinoids, tricyclic antidepressants, α-agonists, and opioids. This clinical report aims to address, with evidence-based guidance, the inherent challenges with the goal to improve comfort throughout life in this vulnerable group of children. (5/17)

PARENTAL LEAVE FOR RESIDENTS AND PEDIATRIC TRAINING PROGRAMS

Section on Medical Students, Residents, and Fellowship Trainees and Committee on Early Childhood

ABSTRACT. The American Academy of Pediatrics (AAP) is committed to the development of rational, equitable, and effective parental leave policies that are sensitive to the needs of pediatric residents, families, and developing infants and that enable parents to spend adequate and good-quality time with their young children. It is important for each residency program to have a policy for parental leave that is written, that is accessible to residents, and that clearly delineates program practices regarding parental leave. At a minimum, a parental leave policy for residents and fellows should conform legally with the Family Medical Leave Act as well as with respective state laws and should meet institutional requirements of the Accreditation Council for Graduate Medical Education for accredited programs. Policies should be well formulated and communicated in a culturally sensitive manner. The AAP advocates for extension of benefits consistent with the Family Medical Leave Act to all residents and interns beginning at the time that pediatric residency training begins. The AAP recommends that regardless of gender, residents who become parents should be guaranteed 6 to 8 weeks, at a minimum, of parental leave with pay after the infant's birth. In addition, in conformance with federal law, the resident should be allowed to extend the leave time when necessary by using paid vacation time or leave without pay. Coparenting, adopting, or fostering of a child should entitle the resident, regardless of gender, to the same amount of paid leave (6–8 weeks) as a person who takes maternity/paternity leave. Flexibility, creativity, and advanced planning are necessary to arrange schedules that optimize resident education and experience, cultivate equity in sharing workloads, and protect pregnant residents from overly strenuous work experiences at critical times of their pregnancies. PARENTAL PRESENCE DURING TREATMENT OF EBOLA OR OTHER HIGHLY CONSEQUENTIAL INFECTION (CLINICAL REPORT)

H. Dele Davies, MD, MS, MHCM, FAAP; Carrie L. Byington, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. This clinical report offers guidance to health care providers and hospitals on options to consider regarding parental presence at the bedside while caring for a child with suspected or proven Ebola virus disease (Ebola) or other highly consequential infection. Options are presented to help meet the needs of the patient and the family while also posing the least risk to providers and health care organizations. The optimal way to minimize risk is to limit contact between the person under investigation or treatment and family members/caregivers whenever possible while working to meet the emotional support needs of both patient and family. At times, caregiver presence may be deemed to be in the best interest of the patient, and in such situations, a strong effort should be made to limit potential risks of exposure to the caregiver, health care providers, and the community. The decision to allow parental/caregiver presence should be made in consultation with a team including an infectious diseases expert and state and/or local public health authorities and should involve consideration of many factors, depending on the stage of investigation and management, including (1) a careful history, physical examination, and investigations to elucidate the likelihood of the diagnosis of Ebola or other highly consequential infection; (2) ability of the facility to offer appropriate isolation for the person under investigation and family members and to manage Ebola; (3) ability to recognize and exclude people at increased risk of worse outcomes (eg, pregnant women); and

(4) ability of parent/caregiver to follow instructions, including appropriate donning and doffing of personal protective equipment. (8/16, reaffirmed 3/21)

PARTICIPATION OF CHILDREN AND ADOLESCENTS IN LIVE CRISIS DRILLS AND EXERCISES

David J. Schonfeld, MD, FAAP; Marlene Melzer-Lange, MD, FAAP; Andrew N. Hashikawa, MD, MS, FAAP; Peter A. Gorski, MD, MPA, FAAP; Council on Children and Disasters; Council on Injury, Violence, and Poison Prevention; and Council on School Health

ABSTRACT. Children and adolescents should be included in exercises and drills to the extent that their involvement advances readiness to meet their unique needs in the event of a crisis and/or furthers their own preparedness or resiliency. However, there is also a need to be cautious about the potential psychological risks and other unintended consequences of directly involving children in live exercises and drills. These risks and consequences are especially a concern when children are deceived and led to believe there is an actual attack and not a drill and/or for high-intensity active shooter drills. High-intensity active shooter drills may involve the use of real weapons, gunfire or blanks, theatrical makeup to give a realistic image of blood or gunshot wounds, predatory and aggressive acting by the individual posing to be the shooter, or other means to simulate an actual attack, even when participants are aware that it is a drill. This policy statement outlines some of the considerations regarding the prevalent practice of live active shooter drills in schools, including the recommendations to eliminate children's involvement in high-intensity drills and exercises (with the possible exception of adolescent volunteers), prohibit deception in drills and exercises, and ensure appropriate accommodations during drills and exercises based on children's unique vulnerabilities. (8/20)

PATENT DUCTUS ARTERIOSUS IN PRETERM INFANTS (CLINICAL REPORT)

William E. Benitz, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Despite a large body of basic science and clinical research and clinical experience with thousands of infants over nearly 6 decades, there is still uncertainty and controversy about the significance, evaluation, and management of patent ductus arteriosus in preterm infants, resulting in substantial heterogeneity in clinical practice. The purpose of this clinical report is to summarize the evidence available to guide evaluation and treatment of preterm infants with prolonged ductal patency in the first few weeks after birth. (12/15)

PATIENT- AND FAMILY-CENTERED CARE AND THE PEDIATRICIAN'S ROLE

Committee on Hospital Care and Institute for Patient- and Family-Centered Care

ABSTRACT. Drawing on several decades of work with families, pediatricians, other health care professionals, and policy makers, the American Academy of Pediatrics provides a definition of patient- and family-centered care. In pediatrics, patient- and family-centered care is based on the understanding that the family is the child's primary source of strength and support. Further, this approach to care recognizes that the perspectives and information provided by families, children, and young adults are essential components of high-quality clinical decision-making, and that patients and family are integral partners with the health care team. This policy statement outlines the core principles of patient- and family-centered care, summarizes some of the recent literature linking patient- and family-centered care to improved health outcomes, and lists various other benefits to be expected when engaging in patient- and family-centered pediatric practice. The statement concludes with specific recommendations for how pediatricians can integrate patient- and family-centered care in hospitals, clinics, and community settings, and in broader systems of care, as well. (1/12, reaffirmed 2/18)
https://doi.org/10.1542/peds.2011-3084

PATIENT- AND FAMILY-CENTERED CARE AND THE ROLE OF THE EMERGENCY PHYSICIAN PROVIDING CARE TO A CHILD IN THE EMERGENCY DEPARTMENT

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians)

ABSTRACT. Patient- and family-centered care is an approach to health care that recognizes the role of the family in providing medical care; encourages collaboration between the patient, family, and health care professionals; and honors individual and family strengths, cultures, traditions, and expertise. Although there are many opportunities for providing patient- and family-centered care in the emergency department, there are also challenges to doing so. The American Academy of Pediatrics and the American College of Emergency Physicians support promoting patient dignity, comfort, and autonomy; recognizing the patient and family as key decision-makers in the patient's medical care; recognizing the patient's experience and perspective in a culturally sensitive manner; acknowledging the interdependence of child and parent as well as the pediatric patient's evolving independence; encouraging family-member presence; providing information to the family during interventions; encouraging collaboration with other health care professionals; acknowledging the importance of the patient's medical home; and encouraging institutional policies for patient- and family-centered care. (11/06, reaffirmed 6/09, 10/11, 9/15, 10/19)
https://doi.org/10.1542/peds.2006-2588

PATIENT- AND FAMILY-CENTERED CARE COORDINATION: A FRAMEWORK FOR INTEGRATING CARE FOR CHILDREN AND YOUTH ACROSS MULTIPLE SYSTEMS

Council on Children With Disabilities and Medical Home Implementation Project Advisory Committee

ABSTRACT. Understanding a care coordination framework, its functions, and its effects on children and families is critical for patients and families themselves, as well as for pediatricians, pediatric medical subspecialists/surgical specialists, and anyone providing services to children and families. Care coordination is an essential element of a transformed American health care delivery system that emphasizes optimal quality and cost outcomes, addresses family-centered care, and calls for partnership across various settings and communities. High-quality, cost-effective health care requires that the delivery system include elements for the provision of services supporting the coordination of care across settings and professionals. This requirement of supporting coordination of care is generally true for health systems providing care for all children and youth but especially for those with special health care needs. At the foundation of an efficient and effective system of care delivery is the patient-/family-centered medical home. From its inception, the medical home has had care coordination as a core element. In general, optimal outcomes for children and youth, especially those with special health care needs, require interfacing among multiple care systems and individuals, including the following: medical, social, and behavioral professionals; the educational system; payers; medical equipment providers; home care agencies; advocacy groups; needed supportive therapies/services; and families. Coordination of care across settings permits an integration of services that is centered on the comprehensive needs of

the patient and family, leading to decreased health care costs, reduction in fragmented care, and improvement in the patient/family experience of care. (4/14, reaffirmed 4/18)

PATIENT- AND FAMILY-CENTERED CARE OF CHILDREN IN THE EMERGENCY DEPARTMENT (TECHNICAL REPORT)

Nanette Dudley, MD, FAAP; Alice Ackerman, MD, MBA, FAAP; Kathleen M. Brown, MD, FACEP; Sally K. Snow, BSN, RN, CPEN, FAEN; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. Patient- and family-centered care is an approach to the planning, delivery, and evaluation of health care that is grounded in a mutually beneficial partnership among patients, families, and health care professionals. Providing patient- and family-centered care to children in the emergency department setting presents many opportunities and challenges. This revised technical report draws on previously published policy statements and reports, reviews the current literature, and describes the present state of practice and research regarding patient- and family-centered care for children in the emergency department setting as well as some of the complexities of providing such care. (12/14, reaffirmed 10/19)
https://doi.org/10.1542/peds.2014-3424

PATIENT SAFETY IN THE PEDIATRIC EMERGENCY CARE SETTING

Committee on Pediatric Emergency Medicine

ABSTRACT. Patient safety is a priority for all health care professionals, including those who work in emergency care. Unique aspects of pediatric care may increase the risk of medical error and harm to patients, especially in the emergency care setting. Although errors can happen despite the best human efforts, given the right set of circumstances, health care professionals must work proactively to improve safety in the pediatric emergency care system. Specific recommendations to improve pediatric patient safety in the emergency department are provided in this policy statement. (12/07, reaffirmed 6/11, 7/14, 8/18)
https://doi.org/10.1542/peds.2007-2902

PEDESTRIAN SAFETY

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Each year, approximately 900 pediatric pedestrians younger than 19 years are killed. In addition, 51000 children are injured as pedestrians, and 5300 of them are hospitalized because of their injuries. Parents should be warned that young children often do not have the cognitive, perceptual, and behavioral abilities to negotiate traffic independently. Parents should also be informed about the danger of vehicle back-over injuries to toddlers playing in driveways. Because posttraumatic stress syndrome commonly follows even minor pedestrian injury, pediatricians should screen and refer for this condition as necessary. The American Academy of Pediatrics supports community- and school-based strategies that minimize a child's exposure to traffic, especially to high-speed, high-volume traffic. Furthermore, the American Academy of Pediatrics supports governmental and industry action that would lead to improvements in vehicle design, driver manuals, driver education, and data collection for the purpose of reducing pediatric pedestrian injury. (7/09, reaffirmed 8/13, 5/19)
https://doi.org/10.1542/peds.2009-1143

PEDIATRIC AND ADOLESCENT MENTAL HEALTH EMERGENCIES IN THE EMERGENCY MEDICAL SERVICES SYSTEM (TECHNICAL REPORT)

Margaret A. Dolan, MD; Joel A. Fein, MD, MPH; and Committee on Pediatric Emergency Medicine

ABSTRACT. Emergency department (ED) health care professionals often care for patients with previously diagnosed psychiatric illnesses who are ill, injured, or having a behavioral crisis. In addition, ED personnel encounter children with psychiatric illnesses who may not present to the ED with overt mental health symptoms. Staff education and training regarding identification and management of pediatric mental health illness can help EDs overcome the perceived limitations of the setting that influence timely and comprehensive evaluation. In addition, ED physicians can inform and advocate for policy changes at local, state, and national levels that are needed to ensure comprehensive care of children with mental health illnesses. This report addresses the roles that the ED and ED health care professionals play in emergency mental health care of children and adolescents in the United States, which includes the stabilization and management of patients in mental health crisis, the discovery of mental illnesses and suicidal ideation in ED patients, and approaches to advocating for improved recognition and treatment of mental illnesses in children. The report also addresses special issues related to mental illness in the ED, such as minority populations, children with special health care needs, and children's mental health during and after disasters and trauma. (4/11, reaffirmed 7/14, 4/20)
https://doi.org/10.1542/peds.2011-0522

PEDIATRIC ANTHRAX CLINICAL MANAGEMENT (CLINICAL REPORT)

John S. Bradley, MD, FAAP, FIDSA, FPIDS; Georgina Peacock, MD, MPH, FAAP; Steven E. Krug, MD, FAAP; William A. Bower, MD, FIDSA; Amanda C. Cohn, MD; Dana Meaney-Delman, MD, MPH, FACOG; Andrew T. Pavia, MD, FAAP, FIDSA; Committee on Infectious Diseases; and Disaster Preparedness Advisory Council

ABSTRACT. Anthrax is a zoonotic disease caused by *Bacillus anthracis,* which has multiple routes of infection in humans, manifesting in different initial presentations of disease. Because *B anthracis* has the potential to be used as a biological weapon and can rapidly progress to systemic anthrax with high mortality in those who are exposed and untreated, clinical guidance that can be quickly implemented must be in place before any intentional release of the agent. This document provides clinical guidance for the prophylaxis and treatment of neonates, infants, children, adolescents, and young adults up to the age of 21 (referred to as "children") in the event of a deliberate *B anthracis* release and offers guidance in areas where the unique characteristics of children dictate a different clinical recommendation from adults. (4/14)
https://doi.org/10.1542/peds.2014-0563

PEDIATRIC ANTHRAX CLINICAL MANAGEMENT: EXECUTIVE SUMMARY

John S. Bradley, MD, FAAP, FIDSA, FPIDS; Georgina Peacock, MD, MPH, FAAP; Steven E. Krug, MD, FAAP; William A. Bower, MD, FIDSA; Amanda C. Cohn, MD; Dana Meaney-Delman, MD, MPH, FACOG; Andrew T. Pavia, MD, FAAP, FIDSA; Committee on Infectious Diseases; and Disaster Preparedness Advisory Council

ABSTRACT. The use of *Bacillus anthracis* as a biological weapon is considered a potential national security threat by the US government. *B anthracis* has the ability to be used as a biological weapon and to cause anthrax, which can rapidly progress to systemic disease with high mortality in those who are untreated. Therefore, clear plans for managing children after a *B anthracis*

bioterror exposure event must be in place before any intentional release of the agent. This document provides a summary of the guidance contained in the clinical report (appendices cited in this executive summary refer to those in the clinical report) for diagnosis and management of anthrax, including antimicrobial treatment and postexposure prophylaxis (PEP), use of antitoxin, and recommendations for use of anthrax vaccine in neonates, infants, children, adolescents, and young adults up to the age of 21 years (referred to as "children"). (4/14)

PEDIATRIC APPLICATION OF CODING AND VALUATION SYSTEMS

David M. Kanter, MD, MBA, FAAP; Richard Lander, MD, FAAP, CIC; Richard A. Molteni, MD, FAAP; Committee on Coding and Nomenclature; and Private Payer Advocacy Advisory Committee

ABSTRACT. The American Academy of Pediatrics provides this revised policy statement to address health care changes that impact procedural and visit coding and valuation as well as the incorporation of coding principles into innovative, newer payment models. This policy statement focuses solely on recommendations, and an accompanying technical report provides supplemental coding and valuation background. (9/19)
https://doi.org/10.1542/peds.2019-2496

PEDIATRIC APPLICATION OF CODING AND VALUATION SYSTEMS (TECHNICAL REPORT)

David M. Kanter, MD, MBA, FAAP; Richard A. Molteni, MD, FAAP; and Committee on Coding and Nomenclature

ABSTRACT. The American Academy of Pediatrics provides this technical report as supplemental background to the accompanying coding and valuation system policy statement. The rapid evolution in health care payment modeling requires that clinicians have a current appreciation of the mechanics of service representation and valuation. The accompanying policy statement provides recommendations relevant to this area, and this technical report provides a format to outline important concepts that allow for effective translation of bedside clinical events into physician payment. (9/19)
https://doi.org/10.1542/peds.2019-2498

PEDIATRIC ASPECTS OF INPATIENT HEALTH INFORMATION TECHNOLOGY SYSTEMS (TECHNICAL REPORT)

Christoph U. Lehmann, MD, FAAP, FACMI, and Council on Clinical Information Technology

ABSTRACT. In the past 3 years, the Health Information Technology for Economic and Clinical Health Act accelerated the adoption of electronic health records (EHRs) with providers and hospitals, who can claim incentive monies related to meaningful use. Despite the increase in adoption of commercial EHRs in pediatric settings, there has been little support for EHR tools and functionalities that promote pediatric quality improvement and patient safety, and children remain at higher risk than adults for medical errors in inpatient environments. Health information technology (HIT) tailored to the needs of pediatric health care providers can improve care by reducing the likelihood of errors through information assurance and minimizing the harm that results from errors. This technical report outlines pediatric-specific concepts, child health needs and their data elements, and required functionalities in inpatient clinical information systems that may be missing in adult-oriented HIT systems with negative consequences for pediatric inpatient care. It is imperative that inpatient (and outpatient) HIT systems be adapted to improve their ability to properly support safe health care delivery for children. (2/15)
https://doi.org/10.1542/peds.2014-4148

PEDIATRIC CONSIDERATIONS BEFORE, DURING, AND AFTER RADIOLOGICAL OR NUCLEAR EMERGENCIES

Jerome A. Paulson, MD, FAAP, and Council on Environmental Health

ABSTRACT. Infants, children, and adolescents can be exposed unexpectedly to ionizing radiation from nuclear power plant events, improvised nuclear or radiologic dispersal device explosions, or inappropriate disposal of radiotherapy equipment. Children are likely to experience higher external and internal radiation exposure levels than adults because of their smaller body and organ size and other physiologic characteristics, by picking up contaminated items, and through consumption of contaminated milk or foodstuffs. This policy statement and accompanying technical report update the 2003 American Academy of Pediatrics policy statement on pediatric radiation emergencies by summarizing newer scientific knowledge from studies of the Chernobyl and Fukushima Daiichi nuclear power plant events, use of improvised radiologic dispersal devices, exposures from inappropriate disposal of radiotherapy equipment, and potential health effects from residential proximity to nuclear plants. Policy recommendations are made for providers and governments to improve future responses to these types of events. (11/18)
https://doi.org/10.1542/peds.2018-3000

PEDIATRIC CONSIDERATIONS BEFORE, DURING, AND AFTER RADIOLOGICAL OR NUCLEAR EMERGENCIES (TECHNICAL REPORT)

Martha S. Linet, MD, MPH; Ziad Kazzi, MD; Jerome A. Paulson, MD, FAAP; and Council on Environmental Health

ABSTRACT. Infants, children, and adolescents can be exposed unexpectedly to ionizing radiation from nuclear power plant events, improvised nuclear or radiologic dispersal device explosions, or inappropriate disposal of radiotherapy equipment. Children are likely to experience higher external and internal radiation exposure levels than adults because of their smaller body and organ size and other physiologic characteristics as well as their tendency to pick up contaminated items and consume contaminated milk or foodstuffs. This technical report accompanies the revision of the 2003 American Academy of Pediatrics policy statement on pediatric radiation emergencies by summarizing newer scientific data from studies of the Chernobyl and the Fukushima Daiichi nuclear power plant events, use of improvised radiologic dispersal devices, exposures from inappropriate disposal of radiotherapy equipment, and potential health effects from residential proximity to nuclear plants. Also included are recommendations from epidemiological studies and biokinetic models to address mitigation efforts. The report includes major emphases on acute radiation syndrome, acute and long-term psychological effects, cancer risks, and other late tissue reactions after low-to-high levels of radiation exposure. Results, along with public health and clinical implications, are described from studies of the Japanese atomic bomb survivors, nuclear plant accidents (eg, Three Mile Island, Chernobyl, and Fukushima), improper disposal of radiotherapy equipment in Goiania, Brazil, and residence in proximity to nuclear plants. Measures to reduce radiation exposure in the immediate aftermath of a radiologic or nuclear disaster are described, including the diagnosis and management of external and internal contamination, use of potassium iodide, and actions in relation to breastfeeding. (11/18)
https://doi.org/10.1542/peds.2018-3001

PEDIATRIC INTEGRATIVE MEDICINE (CLINICAL REPORT)

Hilary McClafferty, MD, FAAP; Sunita Vohra, MD, FAAP; Michelle Bailey, MD, FAAP; Melanie Brown, MD, MSE, FAAP; Anna Esparham, MD, FAAP; Dana Gerstbacher, MD, FAAP; Brenda Golianu, MD, FAAP; Anna-Kaisa Niemi, MD, PhD, FAAP, FACMG; Erica Sibinga, MD, FAAP; Joy Weydert, MD, FAAP; Ann Ming Yeh, MD; and Section on Integrative Medicine

ABSTRACT. The American Academy of Pediatrics is dedicated to optimizing the well-being of children and advancing family-centered health care. Related to this mission, the American Academy of Pediatrics recognizes the increasing use of complementary and integrative therapies for children and the subsequent need to provide reliable information and high-quality clinical resources to support pediatricians. This Clinical Report serves as an update to the original 2008 statement on complementary medicine. The range of complementary therapies is both extensive and diverse. Therefore, in-depth discussion of each therapy or product is beyond the scope of this report. Instead, our intentions are to define terms; describe epidemiology of use; outline common types of complementary therapies; review medicolegal, ethical, and research implications; review education and training for select providers of complementary therapies; provide educational resources; and suggest communication strategies for discussing complementary therapies with patients and families. (8/17)

https://doi.org/10.1542/peds.2017-1961

PEDIATRIC MEDICATION SAFETY IN THE EMERGENCY DEPARTMENT

Lee Benjamin, MD, FAAP, FACEP; Karen Frush, MD, FAAP; Kathy Shaw, MD, MSCE, FAAP; Joan E. Shook, MD, MBA, FAAP; Sally K. Snow, BSN, RN, CPEN, FAEN; and Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Emergency Medicine Committee)

ABSTRACT. Pediatric patients cared for in emergency departments (EDs) are at high risk of medication errors for a variety of reasons. A multidisciplinary panel was convened by the Emergency Medical Services for Children program and the American Academy of Pediatrics Committee on Pediatric Emergency Medicine to initiate a discussion on medication safety in the ED. Top opportunities identified to improve medication safety include using kilogram-only weight-based dosing, optimizing computerized physician order entry by using clinical decision support, developing a standard formulary for pediatric patients while limiting variability of medication concentrations, using pharmacist support within EDs, enhancing training of medical professionals, systematizing the dispensing and administration of medications within the ED, and addressing challenges for home medication administration before discharge. (2/18)

https://doi.org/10.1542/peds.2017-4066

PEDIATRIC MENTAL HEALTH EMERGENCIES IN THE EMERGENCY MEDICAL SERVICES SYSTEM

Committee on Pediatric Emergency Medicine (joint with American College of Emergency Physicians)

ABSTRACT. Emergency departments are vital in the management of pediatric patients with mental health emergencies. Pediatric mental health emergencies are an increasing part of emergency medical practice because emergency departments have become the safety net for a fragmented mental health infrastructure that is experiencing critical shortages in services in all sectors. Emergency departments must safely, humanely, and in a culturally and developmentally appropriate manner manage pediatric patients with undiagnosed and known mental illnesses, including those with mental retardation, autistic spectrum disorders, and attention-deficit/hyperactivity disorder and those experiencing a behavioral crisis. Emergency departments also manage patients with suicidal ideation, depression, escalating aggression, substance abuse, posttraumatic stress disorder, and maltreatment and those exposed to violence and unexpected deaths. Emergency departments must address not only the physical but also the mental health needs of patients during and after mass-casualty incidents and disasters. The American Academy of Pediatrics and the American College of Emergency Physicians support advocacy for increased mental health resources, including improved pediatric mental health tools for the emergency department, increased mental health insurance coverage, and adequate reimbursement at all levels; acknowledgment of the importance of the child's medical home; and promotion of education and research for mental health emergencies. (10/06, reaffirmed 6/09, 4/13, 4/20)

PEDIATRIC METABOLIC AND BARIATRIC SURGERY: EVIDENCE, BARRIERS, AND BEST PRACTICES

Sarah C. Armstrong, MD, FAAP; Christopher F. Bolling, MD, FAAP; Marc P. Michalsky, MD, FACS, FAAP, FASMBS; Kirk W. Reichard, MD, MBA, FAAP, FACS; Section on Obesity; and Section on Surgery

ABSTRACT. Severe obesity among youth is an "epidemic within an epidemic" and portends a shortened life expectancy for today's children compared with those of their parents' generation. Severe obesity has outpaced less severe forms of childhood obesity in prevalence, and it disproportionately affects adolescents. Emerging evidence has linked severe obesity to the development and progression of multiple comorbid states, including increased cardiometabolic risk resulting in end-organ damage in adulthood. Lifestyle modification treatment has achieved moderate short-term success among young children and those with less severe forms of obesity, but no studies to date demonstrate significant and durable weight loss among youth with severe obesity. Metabolic and bariatric surgery has emerged as an important treatment for adults with severe obesity and, more recently, has been shown to be a safe and effective strategy for groups of youth with severe obesity. However, current data suggest that youth with severe obesity may not have adequate access to metabolic and bariatric surgery, especially among underserved populations. This report outlines the current evidence regarding adolescent bariatric surgery, provides recommendations for practitioners and policy makers, and serves as a companion to an accompanying technical report, "Metabolic and Bariatric Surgery for Pediatric Patients With Severe Obesity," which provides details and supporting evidence. (11/19)

https://doi.org/10.1542/peds.2019-3223

PEDIATRIC OBSERVATION UNITS (CLINICAL REPORT)

Gregory P. Conners, MD, MPH, MBA; Sanford M. Melzer, MD, MBA; Committee on Hospital Care; and Committee on Pediatric Emergency Medicine

ABSTRACT. Pediatric observation units (OUs) are hospital areas used to provide medical evaluation and/or management for health-related conditions in children, typically for a well-defined, brief period. Pediatric OUs represent an emerging alternative site of care for selected groups of children who historically may have received their treatment in an ambulatory setting, emergency department, or hospital-based inpatient unit. This clinical report provides an overview of pediatric OUs, including the definitions and operating characteristics of different types of OUs, quality considerations and coding for observation services, and the effect of OUs on inpatient hospital utilization. (6/12, reaffirmed 9/15)

https://doi.org/10.1542/peds.2012-1358

PEDIATRIC ORGAN DONATION AND TRANSPLANTATION

Committee on Hospital Care, Section on Surgery, and Section on Critical Care

ABSTRACT. Pediatric organ donation and organ transplantation can have a significant life-extending benefit to the young recipients of these organs and a high emotional impact on donor and recipient families. Pediatricians, pediatric medical specialists, and pediatric transplant surgeons need to be better acquainted with evolving national strategies that involve organ procurement and organ transplantation to help acquaint families with the benefits and risks of organ donation and transplantation. Efforts of pediatric professionals are needed to shape public policies to provide a system in which procurement, distribution, and cost are fair and equitable to children and adults. Major issues of concern are availability of and access to donor organs; oversight and control of the process; pediatric medical and surgical consultation and continued care throughout the organ-donation and transplantation process; ethical, social, financial, and follow-up issues; insurance-coverage issues; and public awareness of the need for organ donors of all ages. (3/10, reaffirmed 3/14, 4/19)

https://doi.org/10.1542/peds.2010-0081

PEDIATRIC PALLIATIVE CARE AND HOSPICE CARE COMMITMENTS, GUIDELINES, AND RECOMMENDATIONS

Section on Hospice and Palliative Medicine and Committee on Hospital Care

ABSTRACT. Pediatric palliative care and pediatric hospice care (PPC-PHC) are often essential aspects of medical care for patients who have life-threatening conditions or need end-of-life care. PPC-PHC aims to relieve suffering, improve quality of life, facilitate informed decision-making, and assist in care coordination between clinicians and across sites of care. Core commitments of PPC-PHC include being patient centered and family engaged; respecting and partnering with patients and families; pursuing care that is high quality, readily accessible, and equitable; providing care across the age spectrum and life span, integrated into the continuum of care; ensuring that all clinicians can provide basic palliative care and consult PPC-PHC specialists in a timely manner; and improving care through research and quality improvement efforts. PPC-PHC guidelines and recommendations include ensuring that all large health care organizations serving children with life-threatening conditions have dedicated interdisciplinary PPC-PHC teams, which should develop collaborative relationships between hospital- and community-based teams; that PPC-PHC be provided as integrated multimodal care and practiced as a cornerstone of patient safety and quality for patients with life-threatening conditions; that PPC-PHC teams should facilitate clear, compassionate, and forthright discussions about medical issues and the goals of care and support families, siblings, and health care staff; that PPC-PHC be part of all pediatric education and training curricula, be an active area of research and quality improvement, and exemplify the highest ethical standards; and that PPC-PHC services be supported by financial and regulatory arrangements to ensure access to high-quality PPC-PHC by all patients with life-threatening and life-shortening diseases. (10/13, reaffirmed 4/19)

PEDIATRIC PRIMARY HEALTH CARE

Committee on Pediatric Workforce

ABSTRACT. Primary health care is described as accessible and affordable, first contact, continuous and comprehensive, and coordinated to meet the health needs of the individual and the family being served.

Pediatric primary health care encompasses health supervision and anticipatory guidance; monitoring physical and psychosocial growth and development; age-appropriate screening; diagnosis and treatment of acute and chronic disorders; management of serious and life-threatening illness and, when appropriate, referral of more complex conditions; and provision of first contact care as well as coordinated management of health problems requiring multiple professional services.

Pediatric primary health care for children and adolescents is family centered and incorporates community resources and strengths, needs and risk factors, and sociocultural sensitivities into strategies for care delivery and clinical practice. Pediatric primary health care is best delivered within the context of a "medical home," where comprehensive, continuously accessible and affordable care is available and delivered or supervised by qualified child health specialists.

The pediatrician, because of training (which includes 4 years of medical school education, plus an additional 3 or more years of intensive training devoted solely to all aspects of medical care for children and adolescents), coupled with the demonstrated interest in and total professional commitment to the health care of infants, children, adolescents, and young adults, is the most appropriate provider of pediatric primary health care. (1/11, reaffirmed 10/13, 5/17, 4/20)

PEDIATRIC READINESS IN EMERGENCY MEDICAL SERVICES SYSTEMS

Brian Moore, MD, FAAP; Manish I. Shah, MD, MS, FAAP; Sylvia Owusu-Ansah, MD, MPH, FAAP; Toni Gross, MD, MPH, FAAP; Kathleen Brown, MD, FAAP; Marianne Gausche-Hill, MD, FACEP, FAAP, FAEMS; Katherine Remick, MD, FACEP, FAAP, FAEMS; Kathleen Adelgais, MD, MPH, FAAP; John Lyng, MD, FAEMS, FACEP, NRP; Lara Rappaport, MD, MPH, FAAP; Sally Snow, RN, BSN, CPEN, FAEN; Cynthia Wright-Johnson, MSN, RNC; Julie C. Leonard, MD, MPH, FAAP; Committee on Pediatric Emergency Medicine; Section on Emergency Medicine; and EMS Subcommittee (joint with American College of Emergency Physicians Emergency Medical Services Committee; Emergency Nurses Association Pediatric Committee; National Association of Emergency Medical Services Physicians Standards and Clinical Practice Committee; and National Association of Emergency Medical Technicians Medical Technicians Emergency Pediatric Care Committee)

ABSTRACT. Prehospital emergency care typically involves emergency medical technicians, paramedics, and other licensed medical providers who work in emergency medical services (EMS) systems in ground ambulances and fixed- or rotor-wing aircraft that are dispatched to an emergency when either a bystander calls 9-1-1 or when a patient requires interfacility transport for a medical illness or traumatic injury. Because prehospital emergency care of children plays a critical role in the continuum of health care, which also involves primary prevention, hospital-based acute care, rehabilitation, and return to the medical home, the unique needs of children must be addressed by EMS systems. Pediatric readiness encompasses the presence of equipment and medications, usage of guidelines and policies, availability of education and training, incorporation of performance-improvement practices, and integration of EMS physician medical oversight to equip EMS systems to deliver optimal care to children. It has been shown that emergency departments are more prepared to care for children when a pediatric emergency care coordinator is responsible for championing and making recommendations for policies, training, and resources pertinent to the emergency care of children. The specialty of EMS medicine has the potential to derive similar benefits when members of the EMS community are personally invested in pediatric patient care. Although a critical aspect of pediatric readiness in EMS involves strong EMS physician oversight of these investments, a discussion of physician oversight of pediatric care in EMS is outside the scope of this article. This topic is, however, well addressed in the National

Association of Emergency Medical Services Physicians position statement "Physician Oversight of Pediatric Care in Emergency Medical Services." This policy statement is accompanied by a technical report published simultaneously in this issue of *Pediatrics*. (12/19)
https://doi.org/10.1542/peds.2019-3307

PEDIATRIC READINESS IN EMERGENCY MEDICAL SERVICES SYSTEMS (TECHNICAL REPORT)

Sylvia Owusu-Ansah, MD, MPH, FAAP; Brian Moore, MD, FAAP; Manish I. Shah, MD, MS, FAAP; Toni Gross, MD, MPH, FAAP; Kathleen Brown, MD, FAAP; Marianne Gausche-Hill, MD, FACEP, FAAP, FAEMS; Katherine Remick, MD, FACEP, FAAP, FAEMS; Kathleen Adelgais, MD, MPH, FAAP; Lara Rappaport, MD, MPH, FAAP; Sally Snow, RN, BSN, CPEN, FAEN; Cynthia Wright-Johnson, MSN, RNC; Julie C. Leonard, MD, MPH, FAAP; John Lyng, MD, FAEMS, FACEP, NRP; Mary Fallat, MD, FACS, FAAP; Committee on Pediatric Emergency Medicine; Section on Emergency Medicine; EMS Subcommittee; and Section on Surgery

ABSTRACT. Ill and injured children have unique needs that can be magnified when the child's ailment is serious or life-threatening. This is especially true in the out-of-hospital environment. Providing high-quality out-of-hospital care to children requires an emergency medical services (EMS) system infrastructure designed to support the care of pediatric patients. As in the emergency department setting, it is important that all EMS agencies have the appropriate resources, including physician oversight, trained and competent staff, education, policies, medications, equipment, and supplies, to provide effective emergency care for children. Resource availability across EMS agencies is variable, making it essential that EMS medical directors, administrators, and personnel collaborate with outpatient and hospital-based pediatric experts, especially those in emergency departments, to optimize prehospital emergency care for children. The principles in the policy statement "Pediatric Readiness in Emergency Medical Services Systems" and this accompanying technical report establish a foundation on which to build optimal pediatric care within EMS systems and serve as a resource for clinical and administrative EMS leaders. (12/19)
https://doi.org/10.1542/peds.2019-3308

PEDIATRIC READINESS IN THE EMERGENCY DEPARTMENT

Katherine Remick, MD, FAAP, FACEP, FAEMS; Marianne Gausche-Hill, MD, FAAP, FACEP, FAEMS; Madeline M. Joseph, MD, FAAP, FACEP; Kathleen Brown, MD, FAAP, FACEP; Sally K. Snow, BSN, RN, CPEN, FAEN; Joseph L. Wright, MD, MPH, FAAP; Committee on Pediatric Emergency Medicine; and Section on Surgery (joint with American College of Emergency Physicians Pediatric Emergency Medicine Committee and Emergency Nurses Association Pediatric Committee)

ABSTRACT. This is a revision of the previous joint Policy Statement titled "Guidelines for Care of Children in the Emergency Department." Children have unique physical and psychosocial needs that are heightened in the setting of serious or life-threatening emergencies. The majority of children who are ill and injured are brought to community hospital emergency departments (EDs) by virtue of proximity. It is therefore imperative that all EDs have the appropriate resources (medications, equipment, policies, and education) and capable staff to provide effective emergency care for children. In this Policy Statement, we outline the resources necessary for EDs to stand ready to care for children of all ages. These recommendations are consistent with the recommendations of the Institute of Medicine (now called the National Academy of Medicine) in its report "The Future of Emergency Care in the US Health System." Although resources within emergency and trauma care systems vary locally, regionally, and nationally, it is essential that ED staff, administrators, and medical directors seek to meet or exceed these recommendations to ensure that high-quality emergency care is available for all children. These updated recommendations are intended to serve as a resource for clinical and administrative leadership in EDs as they strive to improve their readiness for children of all ages. (10/18)

PEDIATRIC SUDDEN CARDIAC ARREST

Section on Cardiology and Cardiac Surgery

ABSTRACT. Pediatric sudden cardiac arrest (SCA), which can cause sudden cardiac death if not treated within minutes, has a profound effect on everyone: children, parents, family members, communities, and health care providers. Preventing the tragedy of pediatric SCA, defined as the abrupt and unexpected loss of heart function, remains a concern to all. The goal of this statement is to increase the knowledge of pediatricians (including primary care providers and specialists) of the incidence of pediatric SCA, the spectrum of causes of pediatric SCA, disease-specific presentations, the role of patient and family screening, the rapidly evolving role of genetic testing, and finally, important aspects of secondary SCA prevention. This statement is not intended to address sudden infant death syndrome or sudden unexplained death syndrome, nor will specific treatment of individual cardiac conditions be discussed. This statement has been endorsed by the American College of Cardiology, the American Heart Association, and the Heart Rhythm Society. (3/12)
https://doi.org/10.1542/peds.2012-0144

PEDIATRICIAN GUIDANCE IN SUPPORTING FAMILIES OF CHILDREN WHO ARE ADOPTED, FOSTERED, OR IN KINSHIP CARE (CLINICAL REPORT)

Veronnie F. Jones, MD, MSPH, FAAP; Elaine E. Schulte, MD, MPH, FAAP; Douglas Waite, MD, FAAP; and Council on Foster Care, Adoption, and Kinship Care

ABSTRACT. The child welfare system strives to provide children and adolescents in foster care with a safe, nurturing environment through kinship and nonkinship foster care placement with the goal of either reunification with birth parents or adoption. Pediatricians can support families who care for children and adolescents who are fostered and adopted while attending to children's medical needs and helping each child attain their developmental potential. Although this report primarily focuses on children in the US child welfare system, private and internationally adopted children often have similar needs. (11/20)

PEDIATRICIAN WORKFORCE POLICY STATEMENT

Committee on Pediatric Workforce

ABSTRACT. This policy statement reviews important trends and other factors that affect the pediatrician workforce and the provision of pediatric health care, including changes in the pediatric patient population, pediatrician workforce, and nature of pediatric practice. The effect of these changes on pediatricians and the demand for pediatric care are discussed. The American Academy of Pediatrics (AAP) concludes that there is currently a shortage of pediatric medical subspecialists in many fields, as well as a shortage of pediatric surgical specialists. In addition, the AAP believes that the current distribution of primary care pediatricians is inadequate to meet the needs of children living in rural and other underserved areas, and more primary care pediatricians will be needed in the future because of the increasing number of children who have significant chronic health problems, changes in physician work hours, and implementation of current health reform efforts that seek to improve access to comprehensive patient- and family-centered care for all children in a medical home. The AAP is committed to being an active

participant in physician workforce policy development with both professional organizations and governmental bodies to ensure a pediatric perspective on health care workforce issues. The overall purpose of this statement is to summarize policy recommendations and serve as a resource for the AAP and other stakeholders as they address pediatrician workforce issues that ultimately influence the quality of pediatric health care provided to children in the United States. (7/13)

PEDIATRICIAN-FAMILY-PATIENT RELATIONSHIPS: MANAGING THE BOUNDARIES

Committee on Bioethics

ABSTRACT. All professionals are concerned about maintaining the appropriate limits in their relationships with those they serve. Pediatricians should be aware that, under normal circumstances, caring for one's own children presents significant ethical issues. Pediatricians also must strive to maintain appropriate professional boundaries in their relationships with the family members of their patients. Pediatricians should avoid behavior that patients and parents might misunderstand as having sexual or inappropriate social meaning. Romantic and sexual involvement between physicians and patients is unacceptable. The acceptance of gifts or nonmonetary compensation for medical services has the potential to affect the professional relationship adversely. (11/09, reaffirmed 1/14, 10/20)
https://doi.org/10.1542/peds.2009-2147

THE PEDIATRICIAN'S ROLE IN CHILD MALTREATMENT PREVENTION (CLINICAL REPORT)

Emalee G. Flaherty, MD; John Stirling Jr, MD; and Committee on Child Abuse and Neglect

ABSTRACT. It is the pediatrician's role to promote the child's well-being and to help parents raise healthy, well-adjusted children. Pediatricians, therefore, can play an important role in the prevention of child maltreatment. Previous clinical reports and policy statements from the American Academy of Pediatrics have focused on improving the identification and management of child maltreatment. This clinical report outlines how the pediatrician can help to strengthen families and promote safe, stable, nurturing relationships with the aim of preventing maltreatment. After describing some of the triggers and factors that place children at risk for maltreatment, the report describes how pediatricians can identify family strengths, recognize risk factors, provide helpful guidance, and refer families to programs and other resources with the goal of strengthening families, preventing child maltreatment, and enhancing child development. (9/10, reaffirmed 1/14, 7/20)
https://doi.org/10.1542/peds.2010-2087

THE PEDIATRICIAN'S ROLE IN FAMILY SUPPORT AND FAMILY SUPPORT PROGRAMS

Committee on Early Childhood, Adoption, and Dependent Care

ABSTRACT. Children's social, emotional, and physical health; their developmental trajectory; and the neurocircuits that are being created and reinforced in their developing brains are all directly influenced by their relationships during early childhood. The stresses associated with contemporary American life can challenge families' abilities to promote successful developmental outcomes and emotional health for their children. Pediatricians are positioned to serve as partners with families and other community providers in supporting the well-being of children and their families. The structure and support of families involve forces that are often outside the agenda of the usual pediatric health supervision visits. Pediatricians must ensure that their medical home efforts promote a holistically healthy family environment for all children. This statement recommends opportunities for pediatricians to develop their expertise in assessing the strengths and stresses in families, in counseling families about strategies and resources, and in collaborating with others in their communities to support family relationships. (11/11, reaffirmed 12/16)
https://doi.org/10.1542/peds.2011-2664

THE PEDIATRICIAN'S ROLE IN OPTIMIZING SCHOOL READINESS

Council on Early Childhood and Council on School Health

ABSTRACT. School readiness includes not only the early academic skills of children but also their physical health, language skills, social and emotional development, motivation to learn, creativity, and general knowledge. Families and communities play a critical role in ensuring children's growth in all of these areas and thus their readiness for school. Schools must be prepared to teach all children when they reach the age of school entry, regardless of their degree of readiness. Research on early brain development emphasizes the effects of early experiences, relationships, and emotions on creating and reinforcing the neural connections that are the basis for learning. Pediatricians, by the nature of their relationships with families and children, may significantly influence school readiness. Pediatricians have a primary role in ensuring children's physical health through the provision of preventive care, treatment of illness, screening for sensory deficits, and monitoring nutrition and growth. They can promote and monitor the social-emotional development of children by providing anticipatory guidance on development and behavior, by encouraging positive parenting practices, by modeling reciprocal and respectful communication with adults and children, by identifying and addressing psychosocial risk factors, and by providing community-based resources and referrals when warranted. Cognitive and language skills are fostered through timely identification of developmental problems and appropriate referrals for services, including early intervention and special education services; guidance regarding safe and stimulating early education and child care programs; and promotion of early literacy by encouraging language-rich activities such as reading together, telling stories, and playing games. Pediatricians are also well positioned to advocate not only for children's access to health care but also for high-quality early childhood education and evidence-based family supports such as home visits, which help provide a foundation for optimal learning. (8/16)
https://doi.org/10.1542/peds.2016-2293

THE PEDIATRICIAN'S ROLE IN SUPPORTING ADOPTIVE FAMILIES (CLINICAL REPORT)

Veronnie F. Jones, MD, PhD, MSPH; Elaine E. Schulte, MD, MPH; Committee on Early Childhood; and Council on Foster Care, Adoption, and Kinship Care

ABSTRACT. Each year, more children join families through adoption. Pediatricians have an important role in assisting adoptive families in the various challenges they may face with respect to adoption. The acceptance of the differences between families formed through birth and those formed through adoption is essential in promoting positive emotional growth within the family. It is important for pediatricians to be aware of the adoptive parents' need to be supported in their communication with their adopted children. (9/12, reaffirmed 12/16)
https://doi.org/10.1542/peds.2012-2261

THE PEDIATRICIAN'S ROLE IN THE EVALUATION AND PREPARATION OF PEDIATRIC PATIENTS UNDERGOING ANESTHESIA

Section on Anesthesiology and Pain Medicine

ABSTRACT. Pediatricians play a key role in helping prepare patients and families for anesthesia and surgery. The questions to be answered by the pediatrician fall into 2 categories. The first

involves preparation: is the patient in optimal medical condition for surgery, and are the patient and family emotionally and cognitively ready for surgery? The second category concerns logistics: what communication and organizational needs are necessary to enable safe passage through the perioperative process? This revised statement updates the recommendations for the pediatrician's role in the preoperative preparation of patients. (8/14, reaffirmed 2/21)

PEDIATRICIANS AND PUBLIC HEALTH: OPTIMIZING THE HEALTH AND WELL-BEING OF THE NATION'S CHILDREN

Alice A. Kuo, MD, PhD, FAAP; Pauline A. Thomas, MD, FAAP; Lance A. Chilton, MD, FAAP; Laurene Mascola, MD, MPH; Council on Community Pediatrics; and Section on Epidemiology, Public Health, and Evidence

ABSTRACT. Ensuring optimal health for children requires a population-based approach and collaboration between pediatrics and public health. The prevention of major threats to children's health (such as behavioral health issues) and the control and management of chronic diseases, obesity, injury, communicable diseases, and other problems cannot be managed solely in the pediatric office. The integration of clinical practice with public health actions is necessary for multiple levels of disease prevention that involve the child, family, and community. Although pediatricians and public health professionals interact frequently to the benefit of children and their families, increased integration of the 2 disciplines is critical to improving child health at the individual and population levels. Effective collaboration is necessary to ensure that population health activities include children and that the child health priorities of the American Academy of Pediatrics (AAP), such as poverty and child health, early brain and child development, obesity, and mental health, can engage federal, state, and local public health initiatives. In this policy statement, we build on the 2013 AAP Policy Statement on community pediatrics by identifying specific opportunities for collaboration between pediatricians and public health professionals that are likely to improve the health of children in communities. In the statement, we provide recommendations for pediatricians, public health professionals, and the AAP and its chapters. (1/18)

PERSONAL WATERCRAFT USE BY CHILDREN AND ADOLESCENTS

Committee on Injury and Poison Prevention

ABSTRACT. The use of personal watercraft (PWC) has increased dramatically during the past decade as have the speed and mobility of the watercraft. A similar dramatic increase in PWC-related injury and death has occurred simultaneously. No one younger than 16 years should operate a PWC. The operator and all passengers must wear US Coast Guard-approved personal flotation devices. Other safety recommendations are suggested for parents and pediatricians. (2/00, reaffirmed 5/04, 1/07, 6/10)
https://doi.org/10.1542/peds.105.2.452

PESTICIDE EXPOSURE IN CHILDREN

Council on Environmental Health

ABSTRACT. This statement presents the position of the American Academy of Pediatrics on pesticides. Pesticides are a collective term for chemicals intended to kill unwanted insects, plants, molds, and rodents. Children encounter pesticides daily and have unique susceptibilities to their potential toxicity. Acute poisoning risks are clear, and understanding of chronic health implications from both acute and chronic exposure are emerging. Epidemiologic evidence demonstrates associations between early life exposure to pesticides and pediatric cancers, decreased cognitive function, and behavioral problems. Related animal toxicology studies provide supportive biological plausibility for these findings. Recognizing and reducing problematic exposures will require attention to current inadequacies in medical training, public health tracking, and regulatory action on pesticides. Ongoing research describing toxicologic vulnerabilities and exposure factors across the life span are needed to inform regulatory needs and appropriate interventions. Policies that promote integrated pest management, comprehensive pesticide labeling, and marketing practices that incorporate child health considerations will enhance safe use. (11/12)
https://doi.org/10.1542/peds.2012-2757

PESTICIDE EXPOSURE IN CHILDREN (TECHNICAL REPORT)

James R. Roberts, MD, MPH; Catherine J. Karr, MD, PhD; and Council on Environmental Health

ABSTRACT. Pesticides are a collective term for a wide array of chemicals intended to kill unwanted insects, plants, molds, and rodents. Food, water, and treatment in the home, yard, and school are all potential sources of children's exposure. Exposures to pesticides may be overt or subacute, and effects range from acute to chronic toxicity. In 2008, pesticides were the ninth most common substance reported to poison control centers, and approximately 45% of all reports of pesticide poisoning were for children. Organophosphate and carbamate poisoning are perhaps the most widely known acute poisoning syndromes, can be diagnosed by depressed red blood cell cholinesterase levels, and have available antidotal therapy. However, numerous other pesticides that may cause acute toxicity, such as pyrethroid and neonicotinoid insecticides, herbicides, fungicides, and rodenticides, also have specific toxic effects; recognition of these effects may help identify acute exposures. Evidence is increasingly emerging about chronic health implications from both acute and chronic exposure. A growing body of epidemiological evidence demonstrates associations between parental use of pesticides, particularly insecticides, with acute lymphocytic leukemia and brain tumors. Prenatal, household, and occupational exposures (maternal and paternal) appear to be the largest risks. Prospective cohort studies link early-life exposure to organophosphates and organochlorine pesticides (primarily DDT) with adverse effects on neurodevelopment and behavior. Among the findings associated with increased pesticide levels are poorer mental development by using the Bayley index and increased scores on measures assessing pervasive developmental disorder, inattention, and attention-deficit/hyperactivity disorder. Related animal toxicology studies provide supportive biological plausibility for these findings. Additional data suggest that there may also be an association between parental pesticide use and adverse birth outcomes including physical birth defects, low birth weight, and fetal death, although the data are less robust than for cancer and neurodevelopmental effects. Children's exposures to pesticides should be limited as much as possible. (11/12)
https://doi.org/10.1542/peds.2012-2758

PHOTOTHERAPY TO PREVENT SEVERE NEONATAL HYPERBILIRUBINEMIA IN THE NEWBORN INFANT 35 OR MORE WEEKS OF GESTATION (TECHNICAL REPORT)

Vinod K. Bhutani, MD, and Committee on Fetus and Newborn

ABSTRACT. *Objective.* To standardize the use of phototherapy consistent with the American Academy of Pediatrics clinical practice guideline for the management of hyperbilirubinemia in the newborn infant 35 or more weeks of gestation.

Methods. Relevant literature was reviewed. Phototherapy devices currently marketed in the United States that incorporate fluorescent, halogen, fiber-optic, or blue light-emitting diode light sources were assessed in the laboratory.

Results. The efficacy of phototherapy units varies widely because of differences in light source and configuration. The fol-

lowing characteristics of a device contribute to its effectiveness: (1) emission of light in the blue-to-green range that overlaps the in vivo plasma bilirubin absorption spectrum (~460–490 nm); (2) irradiance of at least 30 μW·cm–2·nm–1 (confirmed with an appropriate irradiance meter calibrated over the appropriate wavelength range); (3) illumination of maximal body surface; and (4) demonstration of a decrease in total bilirubin concentrations during the first 4 to 6 hours of exposure.

Recommendations. The intensity and spectral output of phototherapy devices is useful in predicting potential effectiveness in treating hyperbilirubinemia (group B recommendation). Clinical effectiveness should be evaluated before and monitored during use (group B recommendation). Blocking the light source or reducing exposed body surface should be avoided (group B recommendation). Standardization of irradiance meters, improvements in device design, and lower-upper limits of light intensity for phototherapy units merit further study. Comparing the in vivo performance of devices is not practical, in general, and alternative procedures need to be explored. (9/11, reaffirmed 7/14)

https://doi.org/10.1542/peds.2011-1494

PHYSICAL ACTIVITY ASSESSMENT AND COUNSELING IN PEDIATRIC CLINICAL SETTINGS (CLINICAL REPORT)

Felipe Lobelo, MD, PhD; Natalie D. Muth, MD, MPH, FAAP, FACSM; Sara Hanson, PhD; Blaise A. Nemeth, MD, FAAP; Council on Sports Medicine and Fitness; and Section on Obesity

ABSTRACT. Physical activity plays an important role in children's cardiovascular health, musculoskeletal health, mental and behavioral health, and physical, social, and cognitive development. Despite the importance in children's lives, pediatricians are unfamiliar with assessment and guidance regarding physical activity in children. With the release of the 2018 Physical Activity Guidelines by the US Department of Health and Human Services, pediatricians play a critical role in encouraging physical activity in children through assessing physical activity and physical literacy; providing guidance toward meeting recommendations by children and their families; advocating for opportunities for physical activity for all children in schools, communities, and hospitals; setting an example and remaining physically active personally; advocating for the use of assessment tools and insurance coverage of physical activity and physical literacy screening; and incorporating physical activity assessment and prescription in medical school curricula. (2/20)

https://doi.org/10.1542/peds.2019-3992

PHYSICIAN HEALTH AND WELLNESS (CLINICAL REPORT)

Hilary McClafferty, MD, FAAP; Oscar W. Brown, MD, FAAP; Section on Integrative Medicine; and Committee on Practice and Ambulatory Medicine

ABSTRACT. Physician health and wellness is a critical issue gaining national attention because of the high prevalence of physician burnout. Pediatricians and pediatric trainees experience burnout at levels equivalent to other medical specialties, highlighting a need for more effective efforts to promote health and well-being in the pediatric community. This report will provide an overview of physician burnout, an update on work in the field of preventive physician health and wellness, and a discussion of emerging initiatives that have potential to promote health at all levels of pediatric training.

Pediatricians are uniquely positioned to lead this movement nationally, in part because of the emphasis placed on wellness in the Pediatric Milestone Project, a joint collaboration between the Accreditation Council for Graduate Medical Education and the American Board of Pediatrics. Updated core competencies calling for a balanced approach to health, including focus on nutrition, exercise, mindfulness, and effective stress management, signal a paradigm shift and send the message that it is time for pediatricians to cultivate a culture of wellness better aligned with their responsibilities as role models and congruent with advances in pediatric training.

Rather than reviewing programs in place to address substance abuse and other serious conditions in distressed physicians, this article focuses on forward progress in the field, with an emphasis on the need for prevention and anticipation of predictable stressors related to burnout in medical training and practice. Examples of positive progress and several programs designed to promote physician health and wellness are reviewed. Areas where more research is needed are highlighted. (9/14)

https://doi.org/10.1542/peds.2014-2278

PHYSICIAN REFUSAL TO PROVIDE INFORMATION OR TREATMENT ON THE BASIS OF CLAIMS OF CONSCIENCE

Committee on Bioethics

ABSTRACT. Health care professionals may have moral objections to particular medical interventions. They may refuse to provide or cooperate in the provision of these interventions. Such objections are referred to as conscientious objections. Although it may be difficult to characterize or validate claims of conscience, respecting the individual physician's moral integrity is important. Conflicts arise when claims of conscience impede a patient's access to medical information or care. A physician's conscientious objection to certain interventions or treatments may be constrained in some situations. Physicians have a duty to disclose to prospective patients treatments they refuse to perform. As part of informed consent, physicians also have a duty to inform their patients of all relevant and legally available treatment options, including options to which they object. They have a moral obligation to refer patients to other health care professionals who are willing to provide those services when failing to do so would cause harm to the patient, and they have a duty to treat patients in emergencies when referral would significantly increase the probability of mortality or serious morbidity. Conversely, the health care system should make reasonable accommodations for physicians with conscientious objections. (11/09, reaffirmed 1/14, 6/18)

https://doi.org/10.1542/peds.2009-2222

PHYSICIAN'S ROLE IN COORDINATING CARE OF HOSPITALIZED CHILDREN (CLINICAL REPORT)

Daniel A. Rauch, MD, FAAP; Committee on Hospital Care; and Section on Hospital Medicine

ABSTRACT. The hospitalization of a child is a stressful event for the child and family. The physician responsible for the admission has an important role in directing the care of the child, communicating with the child's providers (medical and primary caregivers), and advocating for the safety of the child during the hospitalization and transition out of the hospital. These challenges remain constant across the varied facilities in which children are hospitalized. The purpose of this revised clinical report is to update pediatricians about principles to improve the coordination of care and review expectations and practice. (7/18)

https://doi.org/10.1542/peds.2018-1503

PLANNED HOME BIRTH

Committee on Fetus and Newborn

ABSTRACT. The American Academy of Pediatrics concurs with the recent statement of the American College of Obstetricians and Gynecologists affirming that hospitals and birthing centers are the safest settings for birth in the United States while respecting the right of women to make a medically informed decision about delivery. This statement is intended to help pediatricians provide supportive, informed counsel to women considering home birth while retaining their role as child advocates and to summarize the standards of care for newborn infants born at home, which are consistent with standards for infants born in

a medical care facility. Regardless of the circumstances of his or her birth, including location, every newborn infant deserves health care that adheres to the standards highlighted in this statement, more completely described in other publications from the American Academy of Pediatrics, including *Guidelines for Perinatal Care.* The goal of providing high-quality care to all newborn infants can best be achieved through continuing efforts by all participating health care providers and institutions to develop and sustain communications and understanding on the basis of professional interaction and mutual respect throughout the health care system. (4/13, reaffirmed 12/16)
https://doi.org/10.1542/peds.2013-0575

POINT-OF-CARE ULTRASONOGRAPHY BY PEDIATRIC EMERGENCY MEDICINE PHYSICIANS

Committee on Pediatric Emergency Medicine (joint with Society for Academic Emergency Medicine Academy of Emergency Ultrasound, American College of Emergency Physicians Pediatric Emergency Medicine Committee, and World Interactive Network Focused on Critical Ultrasound)

ABSTRACT. Point-of-care ultrasonography is increasingly being used to facilitate accurate and timely diagnoses and to guide procedures. It is important for pediatric emergency medicine (PEM) physicians caring for patients in the emergency department to receive adequate and continued point-of-care ultrasonography training for those indications used in their practice setting. Emergency departments should have credentialing and quality assurance programs. PEM fellowships should provide appropriate training to physician trainees. Hospitals should provide privileges to physicians who demonstrate competency in point-of-care ultrasonography. Ongoing research will provide the necessary measures to define the optimal training and competency assessment standards. Requirements for credentialing and hospital privileges will vary and will be specific to individual departments and hospitals. As more physicians are trained and more research is completed, there should be one national standard for credentialing and privileging in point-of-care ultrasonography for PEM physicians. (3/15, reaffirmed 9/19)
https://doi.org/10.1542/peds.2015-0342

POINT-OF-CARE ULTRASONOGRAPHY BY PEDIATRIC EMERGENCY MEDICINE PHYSICIANS (TECHNICAL REPORT)

Jennifer R. Marin, MD, MSc; Resa E. Lewiss, MD; and Committee on Pediatric Emergency Medicine (joint with Society for Academic Emergency Medicine Academy of Emergency Ultrasound, American College of Emergency Physicians Pediatric Emergency Medicine Committee, and World Interactive Network Focused on Critical Ultrasound)

ABSTRACT. Emergency physicians have used point-of-care ultrasonography since the 1990s. Pediatric emergency medicine physicians have more recently adopted this technology. Point-of-care ultrasonography is used for various scenarios, particularly the evaluation of soft tissue infections or blunt abdominal trauma and procedural guidance. To date, there are no published statements from national organizations specifically for pediatric emergency physicians describing the incorporation of point-of-care ultrasonography into their practice. This document outlines how pediatric emergency departments may establish a formal point-of-care ultrasonography program. This task includes appointing leaders with expertise in point-of-care ultrasonography, effectively training and credentialing physicians in the department, and providing ongoing quality assurance reviews.

Point-of-care ultrasonography (US) is a bedside technology that enables clinicians to integrate clinical examination findings with real-time sonographic imaging. General emergency physicians and other specialists have used point-of-care US for many years, and more recently, pediatric emergency medicine (PEM) physicians have adopted point-of-care US as a diagnostic and procedural adjunct. This technical report and accompanying policy statement provide a framework for point-of-care US training and point-of-care US integration into pediatric care by PEM physicians. (3/15, reaffirmed 9/19)
https://doi.org/10.1542/peds.2015-0343

POSTDISCHARGE FOLLOW-UP OF INFANTS WITH CONGENITAL DIAPHRAGMATIC HERNIA (CLINICAL REPORT)

Section on Surgery and Committee on Fetus and Newborn

ABSTRACT. Infants with congenital diaphragmatic hernia often require intensive treatment after birth, have prolonged hospitalizations, and have other congenital anomalies. After discharge from the hospital, they may have long-term sequelae such as respiratory insufficiency, gastroesophageal reflux, poor growth, neurodevelopmental delay, behavior problems, hearing loss, hernia recurrence, and orthopedic deformities. Structured follow-up for these patients facilitates early recognition and treatment of these complications. In this report, follow-up of infants with congenital diaphragmatic hernia is outlined. (3/08, reaffirmed 5/11)
https://doi.org/10.1542/peds.2007-3282

POSTNATAL CORTICOSTEROIDS TO PREVENT OR TREAT BRONCHOPULMONARY DYSPLASIA

Kristi L. Watterberg, MD, and Committee on Fetus and Newborn

ABSTRACT. The purpose of this revised statement is to review current information on the use of postnatal glucocorticoids to prevent or treat bronchopulmonary dysplasia in the preterm infant and to make updated recommendations regarding their use. High-dose dexamethasone (0.5 mg/kg per day) does not seem to confer additional therapeutic benefit over lower doses and is not recommended. Evidence is insufficient to make a recommendation regarding other glucocorticoid doses and preparations. The clinician must use clinical judgment when attempting to balance the potential adverse effects of glucocorticoid treatment with those of bronchopulmonary dysplasia. (9/10, reaffirmed 1/14, 9/20)
https://doi.org/10.1542/peds.2010-1534

POSTNATAL GLUCOSE HOMEOSTASIS IN LATE-PRETERM AND TERM INFANTS (CLINICAL REPORT)

David H. Adamkin, MD, and Committee on Fetus and Newborn

ABSTRACT. This report provides a practical guide and algorithm for the screening and subsequent management of neonatal hypoglycemia. Current evidence does not support a specific concentration of glucose that can discriminate normal from abnormal or can potentially result in acute or chronic irreversible neurologic damage. Early identification of the at-risk infant and institution of prophylactic measures to prevent neonatal hypoglycemia are recommended as a pragmatic approach despite the absence of a consistent definition of hypoglycemia in the literature. POVERTY AND CHILD HEALTH IN THE UNITED STATES

Council on Community Pediatrics

ABSTRACT. Almost half of young children in the United States live in poverty or near poverty. The American Academy of Pediatrics is committed to reducing and ultimately eliminating child poverty in the United States. Poverty and related social determinants of health can lead to adverse health outcomes in childhood and across the life course, negatively affecting physical health, socioemotional development, and educational achievement. The American Academy of Pediatrics advocates for programs and policies that have been shown to improve the quality of life and health outcomes for children and families living in poverty. With an awareness and understanding of the

effects of poverty on children, pediatricians and other pediatric health practitioners in a family-centered medical home can assess the financial stability of families, link families to resources, and coordinate care with community partners. Further research, advocacy, and continuing education will improve the ability of pediatricians to address the social determinants of health when caring for children who live in poverty. Accompanying this policy statement is a technical report that describes current knowledge on child poverty and the mechanisms by which poverty influences the health and well-being of children. (3/16, reaffirmed 4/21)

THE POWER OF PLAY: A PEDIATRIC ROLE IN ENHANCING DEVELOPMENT IN YOUNG CHILDREN (CLINICAL REPORT)

Michael Yogman, MD, FAAP; Andrew Garner, MD, PhD, FAAP; Jeffrey Hutchinson, MD, FAAP; Kathy Hirsh-Pasek, PhD; Roberta Michnick Golinkoff, PhD; Committee on Psychosocial Aspects of Child and Family Health; and Council on Communications and Media

ABSTRACT. Children need to develop a variety of skill sets to optimize their development and manage toxic stress. Research demonstrates that developmentally appropriate play with parents and peers is a singular opportunity to promote the social-emotional, cognitive, language, and self-regulation skills that build executive function and a prosocial brain. Furthermore, play supports the formation of the safe, stable, and nurturing relationships with all caregivers that children need to thrive.

Play is not frivolous: it enhances brain structure and function and promotes executive function (ie, the process of learning, rather than the content), which allow us to pursue goals and ignore distractions.

When play and safe, stable, nurturing relationships are missing in a child's life, toxic stress can disrupt the development of executive function and the learning of prosocial behavior; in the presence of childhood adversity, play becomes even more important. The mutual joy and shared communication and attunement (harmonious serve and return interactions) that parents and children can experience during play regulate the body's stress response. This clinical report provides pediatric providers with the information they need to promote the benefits of play and to write a prescription for play at well visits to complement reach out and read. At a time when early childhood programs are pressured to add more didactic components and less playful learning, pediatricians can play an important role in emphasizing the role of a balanced curriculum that includes the importance of playful learning for the promotion of healthy child development. PRACTICAL APPROACHES TO OPTIMIZE ADOLESCENT IMMUNIZATION (CLINICAL REPORT)

Henry H. Bernstein, DO, MHCM, FAAP; Joseph A. Bocchini Jr, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. With the expansion of the adolescent immunization schedule during the past decade, immunization rates notably vary by vaccine and by state. Addressing barriers to improving adolescent vaccination rates is a priority. Every visit can be viewed as an opportunity to update and complete an adolescent's immunizations. It is essential to continue to focus and refine the appropriate techniques in approaching the adolescent patient and parent in the office setting. Health care providers must continuously strive to educate their patients and develop skills that can help parents and adolescents overcome vaccine hesitancy. Research on strategies to achieve higher vaccination rates is ongoing, and it is important to increase the knowledge and implementation of these strategies. This clinical report focuses on increasing adherence to the universally recommended vaccines in the annual adolescent immunization schedule of the American Academy of Pediatrics, the American Academy of Family Physicians, the Centers for Disease Control and Prevention, and the American Congress of Obstetricians and Gynecologists. This will be accomplished by (1) examining strategies that heighten confidence in immunizations and address patient and parental concerns to promote adolescent immunization and (2) exploring how best to approach the adolescent and family to improve immunization rates. PREMEDICATION FOR NONEMERGENCY ENDOTRACHEAL INTUBATION IN THE NEONATE (CLINICAL REPORT)

Praveen Kumar, MD; Susan E. Denson, MD; Thomas J. Mancuso, MD; Committee on Fetus and Newborn; and Section on Anesthesiology and Pain Medicine

ABSTRACT. Endotracheal intubation is a common procedure in newborn care. The purpose of this clinical report is to review currently available evidence on use of premedication for intubation, identify gaps in knowledge, and provide guidance for making decisions about the use of premedication. (2/10, reaffirmed 8/13, 5/18)

THE PRENATAL VISIT (CLINICAL REPORT)

Michael Yogman, MD, FAAP; Arthur Lavin, MD, FAAP; George Cohen, MD, FAAP; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. A pediatric prenatal visit during the third trimester is recommended for all expectant families as an important first step in establishing a child's medical home, as recommended by *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents, Fourth Edition*. As advocates for children and their families, pediatricians can support and guide expectant parents in the prenatal period. Prenatal visits allow general pediatricians to establish a supportive and trusting relationship with both parents, gather basic information from expectant parents, offer information and advice regarding the infant, and may identify psychosocial risks early and high-risk conditions that may require special care. There are several possible formats for this first visit. The one used depends on the experience and preference of the parents, the style of the pediatrician's practice, and pragmatic issues of payment. (6/18)

PREPARATION FOR EMERGENCIES IN THE OFFICES OF PEDIATRICIANS AND PEDIATRIC PRIMARY CARE PROVIDERS

Committee on Pediatric Emergency Medicine

ABSTRACT. High-quality pediatric emergency care can be provided only through the collaborative efforts of many health care professionals and child advocates working together throughout a continuum of care that extends from prevention and the medical home to prehospital care, to emergency department stabilization, to critical care and rehabilitation, and finally to a return to care in the medical home. At times, the office of the pediatric primary care provider will serve as the entry site into the emergency care system, which comprises out-of-hospital emergency medical services personnel, emergency department nurses and physicians, and other emergency and critical care providers. Recognizing the important role of pediatric primary care providers in the emergency care system for children and understanding the capabilities and limitations of that system are essential if pediatric primary care providers are to offer the best chance at intact survival for every child who is brought to the office with an emergency. Optimizing pediatric primary care provider office readiness for emergencies requires consideration of the unique aspects of each office practice, the types of patients and

emergencies that might be seen, the resources on site, and the resources of the larger emergency care system of which the pediatric primary care provider's office is a part. Parent education regarding prevention, recognition, and response to emergencies, patient triage, early recognition and stabilization of pediatric emergencies in the office, and timely transfer to an appropriate facility for definitive care are important responsibilities of every pediatric primary care provider. In addition, pediatric primary care providers can collaborate with out-of-hospital and hospital-based providers and advocate for the best-quality emergency care for their patients. PRESCRIBING ASSISTIVE-TECHNOLOGY SYSTEMS: FOCUS ON CHILDREN WITH IMPAIRED COMMUNICATION (CLINICAL REPORT)

Larry W. Desch, MD; Deborah Gaebler-Spira, MD; and Council on Children With Disabilities

ABSTRACT. This clinical report defines common terms of use and provides information on current practice, research, and limitations of assistive technology that can be used in systems for communication. The assessment process to determine the best devices for use with a particular child (ie, the best fit of a device) is also reviewed. The primary care pediatrician, as part of the medical home, plays an important role in the interdisciplinary effort to provide appropriate assistive technology and may be asked to make a referral for assessment or prescribe a particular device. This report provides resources to assist pediatricians in this role and reviews the interdisciplinary team functional evaluation using standardized assessments; the multiple funding opportunities available for obtaining devices and ways in which pediatricians can assist families with obtaining them; the training necessary to use these systems once the devices are procured; the follow-up evaluation to ensure that the systems are meeting their goals; and the leadership skills needed to advocate for this technology. The American Academy of Pediatrics acknowledges the need for key resources to be identified in the community and recognizes that these resources are a shared medical, educational, therapeutic, and family responsibility. Although this report primarily deals with assistive technology specific for communication impairments, many of the details in this report also can aid in the acquisition and use of other types of assistive technology. (6/08, reaffirmed 1/12, 6/18)

PRESCRIBING PHYSICAL, OCCUPATIONAL, AND SPEECH THERAPY SERVICES FOR CHILDREN WITH DISABILITIES (CLINICAL REPORT)

Amy Houtrow, MD, PhD, MPH, FAAP, FAAPMR; Nancy Murphy, MD, FAAP, FAAPMR; and Council on Children With Disabilities

ABSTRACT. Pediatric health care providers are frequently responsible for prescribing physical, occupational, and speech therapies and monitoring therapeutic progress for children with temporary or permanent disabilities in their practices. This clinical report will provide pediatricians and other pediatric health care providers with information about how best to manage the therapeutic needs of their patients in the medical home by reviewing the International Classification of Functioning, Disability and Health; describing the general goals of habilitative and rehabilitative therapies; delineating the types, locations, and benefits of therapy services; and detailing how to write a therapy prescription and include therapists in the medical home neighborhood. (3/19)
https://doi.org/10.1542/peds.2019-0285

PREVENTING CHILDHOOD TOXIC STRESS: PARTNERING WITH FAMILIES AND COMMUNITIES TO PROMOTE RELATIONAL HEALTH

Andrew Garner, MD, PhD, FAAP; Michael Yogman, MD, FAAP; Committee on Psychosocial Aspects of Child and Family Health; Section on Developmental and Behavioral Pediatrics; and Council on Early Childhood

ABSTRACT. By focusing on the safe, stable, and nurturing relationships (SSNRs) that buffer adversity and build resilience, pediatric care is on the cusp of a paradigm shift that could reprioritize clinical activities, rewrite research agendas, and realign our collective advocacy. Driving this transformation are advances in developmental sciences as they inform a deeper understanding of how early life experiences, both nurturing and adverse, are biologically embedded and influence outcomes in health, education, and economic stability across the life span. This revised policy statement on childhood toxic stress acknowledges a spectrum of potential adversities and reaffirms the benefits of an ecobiodevelopmental model for understanding the childhood origins of adult-manifested disease and wellness. It also endorses a paradigm shift toward relational health because SSNRs not only buffer childhood adversity when it occurs but also promote the capacities needed to be resilient in the future. To translate this relational health framework into clinical practice, generative research, and public policy, the entire pediatric community needs to adopt a public health approach that builds relational health by partnering with families and communities. This public health approach to relational health needs to be integrated both vertically (by including primary, secondary, and tertiary preventions) and horizontally (by including public service sectors beyond health care). The American Academy of Pediatrics asserts that SSNRs are biological necessities for all children because they mitigate childhood toxic stress responses and proactively build resilience by fostering the adaptive skills needed to cope with future adversity in a healthy manner. PREVENTING HOME MEDICATION ADMINISTRATION ERRORS

H. Shonna Yin, MD, MSc, FAAP; Daniel R. Neuspiel, MD, MPH, FAAP; Ian M. Paul, MD, MSc, FAAP; Council on Quality Improvement and Patient Safety; and Committee on Drugs

ABSTRACT. Medication administration errors that take place in the home are common, especially when liquid preparations are used and complex medication schedules with multiple medications are involved; children with chronic conditions are disproportionately affected. Parents and other caregivers with low health literacy and/or limited English proficiency are at higher risk for making errors in administering medications to children in their care. Recommended strategies to reduce home medication errors relate to provider prescribing practices; health literacy–informed verbal counseling strategies (eg, teachback and showback) and written patient education materials (eg, pictographic information) for patients and/or caregivers across settings (inpatient, outpatient, emergency care, pharmacy); dosing-tool provision for liquid medication measurement; review of medication lists with patients and/or caregivers (medication reconciliation) that includes prescription and over-the-counter medications, as well as vitamins and supplements; leveraging the medical home; engaging adolescents and their adult caregivers; training of providers; safe disposal of medications; regulations related to medication dosing tools, labeling, packaging, and informational materials; use of electronic health records and other technologies; and research to identify novel ways to support safe home medication administration. PREVENTING OBESITY AND EATING DISORDERS IN ADOLESCENTS (CLINICAL REPORT)

Neville H. Golden, MD, FAAP; Marcie Schneider, MD, FAAP; Christine Wood, MD, FAAP; Committee on Nutrition; Committee on Adolescence; and Section on Obesity

ABSTRACT. Obesity and eating disorders (EDs) are both prevalent in adolescents. There are concerns that obesity prevention efforts may lead to the development of an ED. Most adolescents who develop an ED did not have obesity previously, but some teenagers, in an attempt to lose weight, may develop an ED. This clinical report addresses the interaction between obesity prevention and EDs in teenagers, provides the pediatrician with evidence-informed tools to identify behaviors that predispose to both obesity and EDs, and provides guidance about obesity and ED prevention messages. The focus should be on a healthy lifestyle rather than on weight. Evidence suggests that obesity prevention and treatment, if conducted correctly, do not predispose to EDs. (8/16)

PREVENTION AND MANAGEMENT OF PROCEDURAL PAIN IN THE NEONATE: AN UPDATE

Committee on Fetus and Newborn and Section on Anesthesiology and Pain Medicine

ABSTRACT. The prevention of pain in neonates should be the goal of all pediatricians and health care professionals who work with neonates, not only because it is ethical but also because repeated painful exposures have the potential for deleterious consequences. Neonates at greatest risk of neurodevelopmental impairment as a result of preterm birth (ie, the smallest and sickest) are also those most likely to be exposed to the greatest number of painful stimuli in the NICU. Although there are major gaps in knowledge regarding the most effective way to prevent and relieve pain in neonates, proven and safe therapies are currently underused for routine minor, yet painful procedures. Therefore, every health care facility caring for neonates should implement (1) a pain-prevention program that includes strategies for minimizing the number of painful procedures performed and (2) a pain assessment and management plan that includes routine assessment of pain, pharmacologic and nonpharmacologic therapies for the prevention of pain associated with routine minor procedures, and measures for minimizing pain associated with surgery and other major procedures. (1/16, reaffirmed 7/20)

PREVENTION OF AGRICULTURAL INJURIES AMONG CHILDREN AND ADOLESCENTS

Committee on Injury and Poison Prevention and Committee on Community Health Services

ABSTRACT. Although the annual number of farm deaths to children and adolescents has decreased since publication of the 1988 American Academy of Pediatrics statement, "Rural Injuries," the rate of nonfatal farm injuries has increased. Approximately 100 unintentional injury deaths occur annually to children and adolescents on US farms, and an additional 22 000 injuries to children younger than 20 years occur on farms. Relatively few adolescents are employed on farms compared with other types of industry, yet the proportion of fatalities in agriculture is higher than that for any other type of adolescent employment. The high mortality and severe morbidity associated with farm injuries require continuing and improved injury-control strategies. This statement provides recommendations for pediatricians regarding patient and community education as well as public advocacy related to agricultural injury prevention in childhood and adolescence. (10/01, reaffirmed 1/07, 11/11)

PREVENTION OF CHILDHOOD LEAD TOXICITY

Council on Environmental Health

ABSTRACT. Blood lead concentrations have decreased dramatically in US children over the past 4 decades, but too many children still live in housing with deteriorated lead-based paint and are at risk for lead exposure with resulting lead-associated cognitive impairment and behavioral problems. Evidence continues to accrue that commonly encountered blood lead concentrations, even those below 5 μg/dL (50 ppb), impair cognition; there is no identified threshold or safe level of lead in blood. From 2007 to 2010, approximately 2.6% of preschool children in the United States had a blood lead concentration ≥5 μg/dL (≥50 ppb), which represents about 535 000 US children 1 to 5 years of age. Evidence-based guidance is available for managing increased lead exposure in children, and reducing sources of lead in the environment, including lead in housing, soil, water, and consumer products, has been shown to be cost-beneficial. Primary prevention should be the focus of policy on childhood lead toxicity. (6/16, reaffirmed 4/21)

https://doi.org/10.1542/peds.2016-1493

PREVENTION OF CHOKING AMONG CHILDREN

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Choking is a leading cause of morbidity and mortality among children, especially those aged 3 years or younger. Food, coins, and toys are the primary causes of choking-related injury and death. Certain characteristics, including shape, size, and consistency, of certain toys and foods increase their potential to cause choking among children. Childhood choking hazards should be addressed through comprehensive and coordinated prevention activities. The US Consumer Product Safety Commission (CPSC) should increase efforts to ensure that toys that are sold in retail store bins, vending machines, or on the Internet have appropriate choking-hazard warnings; work with manufacturers to improve the effectiveness of recalls of products that pose a choking risk to children; and increase efforts to prevent the resale of these recalled products via online auction sites. Current gaps in choking-prevention standards for children's toys should be reevaluated and addressed, as appropriate, via revisions to the standards established under the Child Safety Protection Act, the Consumer Product Safety Improvement Act, or regulation by the CPSC. Prevention of food-related choking among children in the United States has been inadequately addressed at the federal level. The US Food and Drug Administration should establish a systematic, institutionalized process for examining and addressing the hazards of food-related choking. This process should include the establishment of the necessary surveillance, hazard evaluation, enforcement, and public education activities to prevent food-related choking among children. While maintaining its highly cooperative arrangements with the CPSC and the US Department of Agriculture, the Food and Drug Administration should have the authority to address choking-related risks of all food products, including meat products that fall under the jurisdiction of the US Department of Agriculture. The existing National Electronic Injury Surveillance System–All Injury Program of the CPSC should be modified to conduct more-detailed surveillance of choking on food among children. Food manufacturers should design new foods and redesign existing foods to avoid shapes, sizes, textures, and other characteristics that increase choking risk to children, to the extent possible. Pediatricians, dentists, and other infant and child health care providers should provide choking-prevention counseling to parents as an integral part of anticipatory guidance activities. (2/10, reaffirmed 10/19)

https://doi.org/10.1542/peds.2009-2862

PREVENTION OF DROWNING (TECHNICAL REPORT)

Sarah A. Denny, MD, FAAP; Linda Quan, MD, FAAP; Julie Gilchrist, MD, FAAP; Tracy McCallin, MD, FAAP; Rohit Shenoi, MD, FAAP; Shabana Yusuf, MD, Med, FAAP; Jeffrey Weiss, MD, FAAP; Benjamin Hoffman, MD, FAAP; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. Drowning is a leading cause of injury-related death in children. In 2018, almost 900 US children younger than 20 years died of drowning. A number of strategies are available to prevent these tragedies. As educators and advocates, pediatricians can play an important role in prevention of drowning. (7/21)

THE PREVENTION OF UNINTENTIONAL INJURY AMONG AMERICAN INDIAN AND ALASKA NATIVE CHILDREN: A SUBJECT REVIEW (CLINICAL REPORT)

Committee on Native American Child Health and Committee on Injury and Poison Prevention

ABSTRACT. Among ethnic groups in the United States, American Indian and Alaska Native (AI/AN) children experience the highest rates of injury mortality and morbidity. Injury mortality rates for AI/AN children have decreased during the past quarter century, but remain almost double the rate for all children in the United States. The Indian Health Service (IHS), the federal agency with the primary responsibility for the health care of AI/AN people, has sponsored an internationally recognized injury prevention program designed to reduce the risk of injury death by addressing community-specific risk factors. Model programs developed by the IHS and tribal governments have led to successful outcomes in motor vehicle occupant safety, drowning prevention, and fire safety. Injury prevention programs in tribal communities require special attention to the sovereignty of tribal governments and the unique cultural aspects of health care and communication. Pediatricians working with AI/AN children on reservations or in urban environments are strongly urged to collaborate with tribes and the IHS to create community-based coalitions and develop programs to address highly preventable injury-related mortality and morbidity. Strong advocacy also is needed to promote childhood injury prevention as an important priority for federal agencies and tribes. (12/99, reaffirmed 12/02 COIVPP, 5/03 CONACH, 1/06, 9/08)

THE PRIMARY CARE PEDIATRICIAN AND THE CARE OF CHILDREN WITH CLEFT LIP AND/OR CLEFT PALATE (CLINICAL REPORT)

Charlotte W. Lewis, MD, MPH, FAAP; Lisa S. Jacob, DDS, MS; Christoph U. Lehmann, MD, FAAP, FACMI; and Section on Oral Health

ABSTRACT. Orofacial clefts, specifically cleft lip and/or cleft palate (CL/P), are among the most common congenital anomalies. CL/P vary in their location and severity and comprise 3 overarching groups: cleft lip (CL), cleft lip with cleft palate (CLP), and cleft palate alone (CP). CL/P may be associated with one of many syndromes that could further complicate a child's needs. Care of patients with CL/P spans prenatal diagnosis into adulthood. The appropriate timing and order of specific cleft-related care are important factors for optimizing outcomes; however, care should be individualized to meet the specific needs of each patient and family. Children with CL/P should receive their specialty cleft-related care from a multidisciplinary cleft or craniofacial team with sufficient patient and surgical volume to promote successful outcomes. The primary care pediatrician at the child's medical home has an essential role in making a timely diagnosis and referral; providing ongoing health care maintenance, anticipatory guidance, and acute care; and functioning as an advocate for the patient and a liaison between the family and the craniofacial/cleft team. This document provides background on CL/P and multidisciplinary team care, information about typical timing and order of cleft-related care, and recommendations for cleft/craniofacial teams and primary care pediatricians in the care of children with CL/P. PRINCIPLES OF CHILD HEALTH CARE FINANCING

Mark L. Hudak, MD, FAAP; Mark E. Helm, MD, MBA, FAAP; Patience H. White, MD, MA, FAAP, FACP; and Committee on Child Health Financing

ABSTRACT. After passage of the Patient Protection and Affordable Care Act, more children and young adults have become insured and have benefited from health care coverage than at any time since the creation of the Medicaid program in 1965. From 2009 to 2015, the uninsurance rate for children younger than 19 years fell from 9.7% to 5.3%, whereas the uninsurance rate for young adults 19 to 25 years of age declined from 31.7% to 14.5%. Nonetheless, much work remains to be done. The American Academy of Pediatrics (AAP) believes that the United States can and should ensure that all children, adolescents, and young adults from birth through the age of 26 years who reside within its borders have affordable access to high-quality and comprehensive health care, regardless of their or their families' incomes. Public and private health insurance should safeguard existing benefits for children and take further steps to cover the full array of essential health care services recommended by the AAP. Each family should be able to afford the premiums, deductibles, and other cost-sharing provisions of the plan. Health plans providing these benefits should ensure, insofar as possible, that families have a choice of professionals and facilities with expertise in the care of children within a reasonable distance of their residence. Traditional and innovative payment methodologies by public and private payers should be structured to guarantee the economic viability of the pediatric medical home and of other pediatric specialty and subspecialty practices to address developing shortages in the pediatric specialty and subspecialty workforce, to promote the use of health information technology, to improve population health and the experience of care, and to encourage the delivery of evidence-based and quality health care in the medical home, as well as in other outpatient, inpatient, and home settings. All current and future health care insurance plans should incorporate the principles for child health financing outlined in this statement. Espousing the core principle to do no harm, the AAP believes that the United States must not sacrifice any of the hard-won gains for our children. Medicaid, as the largest single payer of health care for children and young adults, should remain true to its origins as an entitlement program; in other words, future fiscal or regulatory reforms of Medicaid should not reduce the eligibility and scope of benefits for children and young adults below current levels nor jeopardize children's access to care. Proposed Medicaid funding "reforms" (eg, institution of block grant, capped allotment, or per-capita capitation payments to

states) will achieve their goal of securing cost savings but will inevitably compel states to reduce enrollee eligibility, trim existing benefits (such as Early and Periodic Screening, Diagnostic, and Treatment), and/or compromise children's access to necessary and timely care through cuts in payments to providers and delivery systems. In fact, the AAP advocates for increased Medicaid funding to improve access to essential care for existing enrollees, fund care for eligible but uninsured children once they enroll, and accommodate enrollment growth that will occur in states that choose to expand Medicaid eligibility. The AAP also calls for Congress to extend funding for the Children's Health Insurance Program, a plan vital to the 8.9 million children it covered in fiscal year 2016, for a minimum of 5 years. (8/17)

PRINCIPLES OF FINANCING THE MEDICAL HOME FOR CHILDREN

Jonathan Price, MD, FAAP; Mary L. Brandt, MD, FACS, FAAP; Mark L. Hudak, MD, FAAP; and Committee on Child Health Financing

ABSTRACT. A well-implemented and adequately funded medical home not only is the best approach to optimize the health of the individual patient but also can function as an effective instrument for improving population health. Key financing elements to providing quality, effective, comprehensive care in the pediatric medical home include the following: (1) first dollar coverage without deductibles, copays, or other cost-sharing for necessary preventive care services as recommended by *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents;* (2) adoption of a uniform definition of medical necessity across payers that embraces services that promote optimal growth and development and prevent, diagnose, and treat the full range of pediatric physical, mental, behavioral, and developmental conditions, in accord with evidence-based science or evidence-informed expert opinion; (3) payment models that promote appropriate use of pediatric primary care and pediatric specialty services and discourage inappropriate, inefficient, or excessive use of medical services; and (4) payment models that strengthen the patient- and family-physician relationship and do not impose additional administrative burdens that will only erode the effectiveness of the medical home. These goals can be met by designing payment models that provide adequate funding of the cost of medical encounters, care coordination, population health services, and quality improvement activities; provide incentives for quality and effectiveness of care; and ease administrative burdens. (12/19)

PRINCIPLES OF PEDIATRIC PATIENT SAFETY: REDUCING HARM DUE TO MEDICAL CARE

Brigitta U. Mueller, MD, MHCM, CPPS, CPHQ, FAAP; Daniel Robert Neuspiel, MD, MPH, FAAP; Erin R. Stucky Fisher, MD, FAAP; Council on Quality Improvement and Patient Safety; and Committee on Hospital Care

ABSTRACT. Pediatricians render care in an increasingly complex environment, which results in multiple opportunities to cause unintended harm. National awareness of patient safety risks has grown since the National Academy of Medicine (formerly the Institute of Medicine) published its report "To Err Is Human: Building a Safer Health System" in 1999. Patients and society as a whole continue to challenge health care providers to examine their practices and implement safety solutions. The depth and breadth of harm incurred by the practice of medicine is still being defined as reports continue to reveal a variety of avoidable errors, from those that involve specific high-risk medications to those that are more generalizable, such as patient misidentification and diagnostic error. Pediatric health care providers in all practice environments benefit from having a working knowledge of patient safety language. Pediatric providers should serve as advocates for best practices and policies with the goal of attending to risks that are unique to children, identifying and supporting a culture of safety, and leading efforts to eliminate avoidable harm in any setting in which medical care is rendered to children. In this Policy Statement, we provide an update to the 2011 Policy Statement "Principles of Pediatric Patient Safety: Reducing Harm Due to Medical Care." (1/19)

PROBIOTICS AND PREBIOTICS IN PEDIATRICS (CLINICAL REPORT)

Dan W. Thomas, MD; Frank R. Greer, MD; Committee on Nutrition; and Section on Gastroenterology, Hepatology, and Nutrition

ABSTRACT. This clinical report reviews the currently known health benefits of probiotic and prebiotic products, including those added to commercially available infant formula and other food products for use in children. Probiotics are supplements or foods that contain viable microorganisms that cause alterations of the microflora of the host. Use of probiotics has been shown to be modestly effective in randomized clinical trials (RCTs) in (1) treating acute viral gastroenteritis in healthy children; and (2) preventing antibiotic-associated diarrhea in healthy children. There is some evidence that probiotics prevent necrotizing enterocolitis in very low birth weight infants (birth weight between 1000 and 1500 g), but more studies are needed. The results of RCTs in which probiotics were used to treat childhood *Helicobacter pylori* gastritis, irritable bowel syndrome, chronic ulcerative colitis, and infantile colic, as well as in preventing childhood atopy, although encouraging, are preliminary and require further confirmation. Probiotics have not been proven to be beneficial in treating or preventing human cancers or in treating children with Crohn disease. There are also safety concerns with the use of probiotics in infants and children who are immunocompromised, chronically debilitated, or seriously ill with indwelling medical devices.

Prebiotics are supplements or foods that contain a nondigestible food ingredient that selectively stimulates the favorable growth and/or activity of indigenous probiotic bacteria. Human milk contains substantial quantities of prebiotics. There is a paucity of RCTs examining prebiotics in children, although there may be some long-term benefit of prebiotics for the prevention of atopic eczema and common infections in healthy infants. Confirmatory well-designed clinical research studies are necessary. (11/10, reaffirmed 3/21)

PROCEDURES FOR THE EVALUATION OF THE VISUAL SYSTEM BY PEDIATRICIANS (CLINICAL REPORT)

Sean P. Donahue, MD, PhD, FAAP; Cynthia N. Baker, MD, FAAP; Committee on Practice and Ambulatory Medicine; and Section on Ophthalmology (joint with American Association of Certified Orthoptists, American Association for Pediatric Ophthalmology and Strabismus, and American Academy of Ophthalmology)

ABSTRACT. Vision screening is crucial for the detection of visual and systemic disorders. It should begin in the newborn nursery and continue throughout childhood. This clinical report provides details regarding methods for pediatricians to use for screening. (12/15)
https://doi.org/10.1542/peds.2015-3597

PROFESSIONALISM IN PEDIATRICS (TECHNICAL REPORT)

Mary E. Fallat, MD; Jacqueline Glover, PhD; and Committee on Bioethics

ABSTRACT. The purpose of this report is to provide a concrete overview of the ideal standards of behavior and professional practice to which pediatricians should aspire and by which students and residents can be evaluated. Recognizing that the

ideal is not always achievable in the practical sense, this document details the key components of professionalism in pediatric practice with an emphasis on core professional values for which pediatricians should strive and that will serve as a moral compass needed to provide quality care for children and their families. (10/07, reaffirmed 5/11)
https://doi.org/10.1542/peds.2007-2230

PROFESSIONALISM IN PEDIATRICS: STATEMENT OF PRINCIPLES

Committee on Bioethics

ABSTRACT. The purpose of this statement is to delineate the concept of professionalism within the context of pediatrics and to provide a brief statement of principles to guide the behavior and professional practice of pediatricians. (10/07, reaffirmed 5/11)
https://doi.org/10.1542/peds.2007-2229

PROMOTING EDUCATION, MENTORSHIP, AND SUPPORT FOR PEDIATRIC RESEARCH

Committee on Pediatric Research

ABSTRACT. Pediatricians play a key role in advancing child health research to best attain and improve the physical, mental, and social health and well-being of all infants, children, adolescents, and young adults. Child health presents unique issues that require investigators who specialize in pediatric research. In addition, the scope of the pediatric research enterprise is transdisciplinary and includes the full spectrum of basic science, translational, community-based, health services, and child health policy research. Although most pediatricians do not directly engage in research, knowledge of research methodologies and approaches promotes critical evaluation of scientific literature, the practice of evidence-based medicine, and advocacy for evidence-based child health policy. This statement includes specific recommendations to promote further research education and support at all levels of pediatric training, from premedical to continuing medical education, as well as recommendations to increase support and mentorship for research activities. Pediatric research is crucial to the American Academy of Pediatrics' goal of improving the health of all children. The American Academy of Pediatrics continues to promote and encourage efforts to facilitate the creation of new knowledge and ways to reduce barriers experienced by trainees, practitioners, and academic faculty pursuing research. (4/14, reaffirmed 2/18)
https://doi.org/10.1542/peds.2014-0448

PROMOTING FOOD SECURITY FOR ALL CHILDREN

Council on Community Pediatrics and Committee on Nutrition

ABSTRACT. Sixteen million US children (21%) live in households without consistent access to adequate food. After multiple risk factors are considered, children who live in households that are food insecure, even at the lowest levels, are likely to be sick more often, recover from illness more slowly, and be hospitalized more frequently. Lack of adequate healthy food can impair a child's ability to concentrate and perform well in school and is linked to higher levels of behavioral and emotional problems from preschool through adolescence. Food insecurity can affect children in any community, not only traditionally underserved ones. Pediatricians can play a central role in screening and identifying children at risk for food insecurity and in connecting families with needed community resources. Pediatricians should also advocate for federal and local policies that support access to adequate healthy food for an active and healthy life for all children and their families. (10/15)

PROMOTING HEALTHY SEXUALITY FOR CHILDREN AND ADOLESCENTS WITH DISABILITIES

Amy Houtrow, MD, PhD, MPH, FAAP; Ellen Roy Elias, MD, FAAP, FACMG; Beth Ellen Davis, MD, MPH, FAAP; and Council on Children With Disabilities

ABSTRACT. This clinical report updates a 2006 report from the American Academy of Pediatrics titled "Sexuality of Children and Adolescents With Developmental Disabilities." The development of a healthy sexuality best occurs through appropriate education, absence of coercion and violence, and developmental acquisition of skills to navigate feelings, desires, relationships, and social pressures. Pediatric health care providers are important resources for anticipatory guidance and education for all children and youth as they understand their changing bodies, feelings, and behaviors. Yet, youth with disabilities and their families report inadequate education and guidance from pediatricians regarding sexual health development. In the decade since the original clinical report was published, there have been many advancements in the understanding and care of children and youth with disabilities, in part because of an increased prevalence and breadth of autism spectrum disorder as well as an increased longevity of individuals with medically complex and severely disabling conditions. During this same time frame, sexual education in US public schools has diminished, and there is emerging evidence that the attitudes and beliefs of all youth (with and without disability) about sex and sexuality are being formed through media rather than formal education or parent and/or health care provider sources. This report aims to provide the pediatric health care provider with resources and tools for clinical practice to address the sexual development of children and youth with disabilities. The report emphasizes strategies to promote competence in achieving a healthy sexuality regardless of physical, cognitive, or socioemotional limitations. (6/21)

https://doi.org/10.1542/peds.2021-052043

PROMOTING HUMAN MILK AND BREASTFEEDING FOR THE VERY LOW BIRTH WEIGHT INFANT (CLINICAL REPORT)

Margaret G. Parker, MD, MPH; Lisa M. Stellwagen, MD; Lawrence Noble, MD; Jae H. Kim, MD, PhD; Brenda B. Poindexter, MD; Karen M. Puopolo, MD, PhD; AAP Section on Breastfeeding; Committee on Nutrition; and Committee on Fetus and Newborn

ABSTRACT. Provision of mother's own milk for hospitalized very low birth weight (VLBW) (≤1500 g) infants in the NICU provides short- and long-term health benefits. Mother's own milk, appropriately fortified, is the optimal nutrition source for VLBW infants. Every mother should receive information about the critical importance of mother's own milk to the health of a VLBW infant. Pasteurized human donor milk is recommended when mother's own milk is not available or sufficient. Neonatal health care providers can support lactation in the NICU and potentially reduce disparities in the provision of mother's own milk by providing institutional supports for early and frequent milk expression and by promoting skin-to-skin contact and direct breastfeeding, when appropriate. Promotion of human milk and breastfeeding for VLBW infants requires multidisciplinary and system-wide adoption of lactation support practices. (10/21)

PROMOTING OPTIMAL DEVELOPMENT: IDENTIFYING INFANTS AND YOUNG CHILDREN WITH DEVELOPMENTAL DISORDERS THROUGH DEVELOPMENTAL SURVEILLANCE AND SCREENING (CLINICAL REPORT)

Paul H. Lipkin, MD, FAAP; Michelle M. Macias, MD, FAAP; Council on Children With Disabilities; and Section on Developmental and Behavioral Pediatrics

ABSTRACT. Early identification and intervention for developmental disorders are critical to the well-being of children and are the responsibility of pediatric professionals as an integral function of the medical home. This report models a universal system of developmental surveillance and screening for the early identification of conditions that affect children's early and long-term development and achievement, followed by ongoing care. These conditions include autism, deafness/hard-of-hearing, intellectual and motor disabilities, behavioral conditions, and those seen in other medical conditions. Developmental surveillance is supported at every health supervision visit, as is as the administration of standardized screening tests at the 9-, 18-, and 30-month visits. Developmental concerns elicited on surveillance at any visit should be followed by standardized developmental screening testing or direct referral to intervention and specialty medical care. Special attention to surveillance is recommended at the 4- to 5-year well-child visit, prior to entry into elementary education, with screening completed if there are any concerns. Developmental surveillance includes bidirectional communication with early childhood professionals in child care, preschools, Head Start, and other programs, including home visitation and parenting, particularly around developmental screening. The identification of problems should lead to developmental and medical evaluations, diagnosis, counseling, and treatment, in addition to early developmental intervention. Children with diagnosed developmental disorders are identified as having special health care needs, with initiation of chronic condition management in the pediatric medical home. (12/19)
https://doi.org/10.1542/peds.2019-3449

PROMOTING OPTIMAL DEVELOPMENT: SCREENING FOR BEHAVIORAL AND EMOTIONAL PROBLEMS (CLINICAL REPORT)

Carol Weitzman, MD, FAAP; Lynn Wegner, MD, FAAP; Section on Developmental and Behavioral Pediatrics; Committee on Psychosocial Aspects of Child and Family Health; and Council on Early Childhood (joint with Society for Developmental and Behavioral Pediatrics)

ABSTRACT. By current estimates, at any given time, approximately 11% to 20% of children in the United States have a behavioral or emotional disorder, as defined in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition.* Between 37% and 39% of children will have a behavioral or emotional disorder diagnosed by 16 years of age, regardless of geographic location in the United States. Behavioral and emotional problems and concerns in children and adolescents are not being reliably identified or treated in the US health system. This clinical report focuses on the need to increase behavioral screening and offers potential changes in practice and the health system, as well as the research needed to accomplish this. This report also (1) reviews the prevalence of behavioral and emotional disorders, (2) describes factors affecting the emergence of behavioral and emotional problems, (3) articulates the current state of detection of these problems in pediatric primary care, (4) describes barriers to screening and means to overcome those barriers, and (5) discusses potential changes at a practice and systems level that are needed to facilitate successful behavioral and emotional screening. Highlighted and discussed are the many factors at the level of the pediatric practice, health system, and society contributing to these behavioral and emotional problems. (1/15, reaffirmed 12/20)
https://doi.org/10.1542/peds.2014-3716

PROMOTING THE PARTICIPATION OF CHILDREN AND ADOLESCENTS WITH DISABILITIES IN SPORTS, RECREATION, AND PHYSICAL ACTIVITY (CLINICAL REPORT)

Paul S. Carbone, MD, FAAP; Peter J. Smith, MD, MA, FAAP; Charron Lewis, MD, FAAP; Claire LeBlanc, MD, FAAP; Council on Children With Disabilities; and Council on Sports Medicine and Fitness

ABSTRACT. The benefits of physical activity are likely universal for all children, including children and adolescents with disabilities (CWD). The participation of CWD in physical activity, including adaptive or therapeutic sports and recreation, promotes inclusion, minimizes deconditioning, optimizes physical functioning, improves mental health as well as academic achievement, and enhances overall well-being. Despite these benefits, CWD face barriers to participation and have lower levels of fitness, reduced rates of participation, and a higher prevalence of overweight and obesity compared with typically developing peers. Pediatricians and caregivers may overestimate the risks or overlook the benefits of physical activity in CWD, which further limits participation. Preparticipation evaluations often include assessment of health status, functional capacity, individual activity preferences, availability of appropriate programs, and safety precautions. Given the complexity, the preparticipation evaluation for CWD may not occur in the context of a single office visit but rather over a period of time with input from the child's multidisciplinary team (physicians, coaches, physical education teachers, school nurses, adaptive recreation specialists, physical and occupational therapists, and others). Some CWD may desire to participate in organized sports to experience the challenge of competition, and others may prefer recreational activities for enjoyment. To reach the goal of inclusion in appropriate physical activities for all children with disabilities, child, family, financial, and societal barriers to participation need to be identified and addressed. Health care providers can facilitate participation by encouraging physical activity among CWD and their families during visits. Health care providers can create "physical activity prescriptions" for CWD on the basis of the child's preferred activities, functional status, need for adaptation of the activity and the recreational opportunities available in the community. This clinical report discusses the importance of participation in sports, recreation, and physical activity for CWD and offers practical suggestions to health care providers. (11/21)

PROMOTING THE WELL-BEING OF CHILDREN WHOSE PARENTS ARE GAY OR LESBIAN

Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. To promote optimal health and well-being of all children, the American Academy of Pediatrics (AAP) supports access for all children to (1) civil marriage rights for their parents and (2) willing and capable foster and adoptive parents, regardless of the parents' sexual orientation. The AAP has always been an advocate for, and has developed policies to support, the optimal physical, mental, and social health and well-being of all infants, children, adolescents, and young adults. In so doing, the AAP has supported families in all their diversity, because the family has always been the basic social unit in which children develop the supporting and nurturing relationships with adults that they need to thrive. Children may be born to, adopted by, or cared for temporarily by married couples, nonmarried couples, single parents, grandparents, or legal guardians, and any of these may be heterosexual, gay or lesbian, or of another orientation. Children need secure and enduring relationships with committed and nurturing adults to enhance their life experiences for optimal social-emotional and cognitive development. Scientific evidence affirms that children have similar developmental and

emotional needs and receive similar parenting whether they are raised by parents of the same or different genders. If a child has 2 living and capable parents who choose to create a permanent bond by way of civil marriage, it is in the best interests of their child(ren) that legal and social institutions allow and support them to do so, irrespective of their sexual orientation. If 2 parents are not available to the child, adoption or foster parenting remain acceptable options to provide a loving home for a child and should be available without regard to the sexual orientation of the parent(s). (3/13)
https://doi.org/10.1542/peds.2013-0376

PROMOTING THE WELL-BEING OF CHILDREN WHOSE PARENTS ARE GAY OR LESBIAN (TECHNICAL REPORT)

Ellen C. Perrin, MD, MA; Benjamin S. Siegel, MD; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Extensive data available from more than 30 years of research reveal that children raised by gay and lesbian parents have demonstrated resilience with regard to social, psychological, and sexual health despite economic and legal disparities and social stigma. Many studies have demonstrated that children's well-being is affected much more by their relationships with their parents, their parents' sense of competence and security, and the presence of social and economic support for the family than by the gender or the sexual orientation of their parents. Lack of opportunity for same-gender couples to marry adds to families' stress, which affects the health and welfare of all household members. Because marriage strengthens families and, in so doing, benefits children's development, children should not be deprived of the opportunity for their parents to be married. Paths to parenthood that include assisted reproductive techniques, adoption, and foster parenting should focus on competency of the parents rather than their sexual orientation. (3/13)

PROMOTION OF HEALTHY WEIGHT-CONTROL PRACTICES IN YOUNG ATHLETES (CLINICAL REPORT)

Rebecca L. Carl, MD, MS, FAAP; Miriam D. Johnson, MD, FAAP; Thomas J. Martin, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. Children and adolescents may participate in sports that favor a particular body type. Some sports, such as gymnastics, dance, and distance running, emphasize a slim or lean physique for aesthetic or performance reasons. Participants in weight-class sports, such as wrestling and martial arts, may attempt weight loss so they can compete at a lower weight class. Other sports, such as football and bodybuilding, highlight a muscular physique; young athletes engaged in these sports may desire to gain weight and muscle mass. This clinical report describes unhealthy methods of weight loss and gain as well as policies and approaches used to curb these practices. The report also reviews healthy strategies for weight loss and weight gain and provides recommendations for pediatricians on how to promote healthy weight control in young athletes. (8/17)
https://doi.org/10.1542/peds.2017-1871

PROTECTING CHILDREN FROM SEXUAL ABUSE BY HEALTH CARE PROVIDERS

Committee on Child Abuse and Neglect

ABSTRACT. Sexual abuse or exploitation of children is never acceptable. Such behavior by health care providers is particularly concerning because of the trust that children and their families place on adults in the health care profession. The American Academy of Pediatrics strongly endorses the social and moral prohibition against sexual abuse or exploitation of children by health care providers. The academy opposes any such sexual abuse or exploitation by providers, particularly by the academy's members. Health care providers should be trained to recognize and abide by appropriate provider-patient boundaries. Medical institutions should screen staff members for a history of child abuse issues, train them to respect and maintain appropriate boundaries, and establish policies and procedures to receive and investigate concerns about patient abuse. Each person has a responsibility to ensure the safety of children in health care settings and to scrupulously follow appropriate legal and ethical reporting and investigation procedures. https://doi.org/10.1542/peds.2011-1244

PROTECTING CHILDREN FROM TOBACCO, NICOTINE, AND TOBACCO SMOKE (TECHNICAL REPORT)

Harold J. Farber, MD, MSPH, FAAP; Judith Groner, MD, FAAP; Susan Walley, MD, FAAP; Kevin Nelson, MD, PhD, FAAP; and Section on Tobacco Control

ABSTRACT. This technical report serves to provide the evidence base for the American Academy of Pediatrics' policy statements "Clinical Practice Policy to Protect Children From Tobacco, Nicotine, and Tobacco Smoke" and "Public Policy to Protect Children From Tobacco, Nicotine, and Tobacco Smoke." Tobacco use and involuntary exposure are major preventable causes of morbidity and premature mortality in adults and children. Tobacco dependence almost always starts in childhood or adolescence. Electronic nicotine delivery systems are rapidly gaining popularity among youth, and their significant harms are being documented. In utero tobacco smoke exposure, in addition to increasing the risk of preterm birth, low birth weight, stillbirth, placental abruption, and sudden infant death, has been found to increase the risk of obesity and neurodevelopmental disorders. Actions by pediatricians can help to reduce children's risk of developing tobacco dependence and reduce children's involuntary tobacco smoke exposure. Public policy actions to protect children from tobacco are essential to reduce the toll that the tobacco epidemic takes on our children. (10/15, reaffirmed 6/20)
https://doi.org/10.1542/peds.2015-3110

PROVIDING A PRIMARY CARE MEDICAL HOME FOR CHILDREN AND YOUTH WITH CEREBRAL PALSY (CLINICAL REPORT)

Gregory S. Liptak, MD, MPH; Nancy A. Murphy, MD; and Council on Children With Disabilities

ABSTRACT. All primary care providers will care for children with cerebral palsy in their practice. In addition to well-child and acute illness care, the role of the medical home in the management of these children includes diagnosis, planning for interventions, authorizing treatments, and follow-up. Optimizing health and well-being for children with cerebral palsy and their families entails family-centered care provided in the medical home; comanagement is the most common model. This report reviews the aspects of care specific to cerebral palsy that a medical home should provide beyond the routine health care needed by all children. (10/11, reaffirmed 11/14, 8/18)
https://doi.org/10.1542/peds.2011-1468

PROVIDING A PRIMARY CARE MEDICAL HOME FOR CHILDREN AND YOUTH WITH SPINA BIFIDA (CLINICAL REPORT)

Robert Burke, MD, MPH; Gregory S. Liptak, MD, MPH; and Council on Children With Disabilities

ABSTRACT. The pediatric primary care provider in the medical home has a central and unique role in the care of children with spina bifida. The primary care provider addresses not only the typical issues of preventive and acute health care but also the needs specific to these children. Optimal care requires communication and comanagement with pediatric medical and developmental subspecialists, surgical specialists, therapists, and community providers. The medical home provider is essen-

tial in supporting the family and advocating for the child from the time of entry into the practice through adolescence, which includes transition and transfer to adult health care. This report reviews aspects of care specific to the infant with spina bifida (particularly myelomeningocele) that will facilitate optimal medical, functional, and developmental outcomes. (11/11, reaffirmed 2/15, 7/18)
https://doi.org/10.1542/peds.2011-2219

PROVIDING CARE FOR CHILDREN AND ADOLESCENTS FACING HOMELESSNESS AND HOUSING INSECURITY

Council on Community Pediatrics

ABSTRACT. Child health and housing security are closely intertwined, and children without homes are more likely to suffer from chronic disease, hunger, and malnutrition than are children with homes. Homeless children and youth often have significant psychosocial development issues, and their education is frequently interrupted. Given the overall effects that homelessness can have on a child's health and potential, it is important for pediatricians to recognize the factors that lead to homelessness, understand the ways that homelessness and its causes can lead to poor health outcomes, and when possible, help children and families mitigate some of the effects of homelessness. Through practice change, partnership with community resources, awareness, and advocacy, pediatricians can help optimize the health and well-being of children affected by homelessness. (5/13, reaffirmed 10/16)
https://doi.org/10.1542/peds.2013-0645

PROVIDING CARE FOR CHILDREN IN IMMIGRANT FAMILIES

Julie M. Linton, MD, FAAP; Andrea Green, MDCM, FAAP; and Council on Community Pediatrics

ABSTRACT. Children in immigrant families (CIF), who represent 1 in 4 children in the United States, represent a growing and ever more diverse US demographic that pediatric medical providers nationwide will increasingly encounter in clinical care. Immigrant children are those born outside the United States to non–US citizen parents, and CIF are defined as those who are either foreign born or have at least 1 parent who is foreign born. Some families immigrate for economic or educational reasons, and others come fleeing persecution and seeking safe haven. Some US-born children with a foreign-born parent may share vulnerabilities with children who themselves are foreign born, particularly regarding access to care and other social determinants of health. Therefore, the larger umbrella term of CIF is used in this statement. CIF, like all children, have diverse experiences that interact with their biopsychosocial development. CIF may face inequities that can threaten their health and well-being, and CIF also offer strengths and embody resilience that can surpass challenges experienced before and during integration. This policy statement describes the evolving population of CIF in the United States, briefly introduces core competencies to enhance care within a framework of cultural humility and safety, and discusses barriers and opportunities at the practice and systems levels. Practice-level recommendations describe how pediatricians can promote health equity for CIF through careful attention to core competencies in clinical care, thoughtful community engagement, and system-level support. Advocacy and policy recommendations offer ways pediatricians can advocate for policies that promote health equity for CIF. (8/19)
https://doi.org/10.1542/peds.2019-2077

PROVIDING CARE FOR INFANTS BORN AT HOME

Kristi Watterberg, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. The American Academy of Pediatrics (AAP) believes that current data show that hospitals and accredited birth centers are the safest settings for birth in the United States. The AAP does not recommend planned home birth, which has been reported to be associated with a twofold to threefold increase in infant mortality in the United States. The AAP recognizes that women may choose to plan a home birth. This statement is intended to help pediatricians provide constructive, informed counsel to women considering home birth while retaining their role as child advocates and to summarize appropriate care for newborn infants born at home that is consistent with care provided for infants born in a medical care facility. Regardless of the circumstances of his or her birth, including location, every newborn infant deserves health care consistent with that highlighted in this statement, which is more completely described in other publications from the AAP, including *Guidelines for Perinatal Care* and the *Textbook of Neonatal Resuscitation.* All health care clinicians and institutions should promote communications and understanding on the basis of professional interaction and mutual respect. (4/20)
https://doi.org/10.1542/peds.2020-0626

PROVIDING PSYCHOSOCIAL SUPPORT TO CHILDREN AND FAMILIES IN THE AFTERMATH OF DISASTERS AND CRISES (CLINICAL REPORT)

David J. Schonfeld, MD, FAAP; Thomas Demaria, PhD; Disaster Preparedness Advisory Council; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Disasters have the potential to cause short- and long-term effects on the psychological functioning, emotional adjustment, health, and developmental trajectory of children. This clinical report provides practical suggestions on how to identify common adjustment difficulties in children in the aftermath of a disaster and to promote effective coping strategies to mitigate the impact of the disaster as well as any associated bereavement and secondary stressors. This information can serve as a guide to pediatricians as they offer anticipatory guidance to families or consultation to schools, child care centers, and other child congregate care sites. Knowledge of risk factors for adjustment difficulties can serve as the basis for mental health triage. The importance of basic supportive services, psychological first aid, and professional self-care are discussed. Stress is intrinsic to many major life events that children and families face, including the experience of significant illness and its treatment. The information provided in this clinical report may, therefore, be relevant for a broad range of patient encounters, even outside the context of a disaster. Most pediatricians enter the profession because of a heartfelt desire to help children and families most in need. If adequately prepared and supported, pediatricians who are able to draw on their skills to assist children, families, and communities to recover after a disaster will find the work to be particularly rewarding. (9/15, reaffirmed 12/20)
https://doi.org/10.1542/peds.2015-2861

PSYCHOLOGICAL MALTREATMENT (CLINICAL REPORT)

Roberta Hibbard, MD; Jane Barlow, DPhil; Harriet MacMillan, MD; Committee on Child Abuse and Neglect (joint with American Academy of Child and Adolescent Psychiatry Child Maltreatment and Violence Committee)

ABSTRACT. Psychological or emotional maltreatment of children may be the most challenging and prevalent form of child abuse and neglect. Caregiver behaviors include acts of omission (ignoring need for social interactions) or commission (spurning, terrorizing); may be verbal or nonverbal, active or passive, and with or without intent to harm; and negatively affect the child's cognitive, social, emotional, and/or physical development. Psychological maltreatment has been linked with disorders of attachment, developmental and educational problems, socialization problems, disruptive behavior, and later psychopathology. Although no evidence-based interventions that can prevent psychological maltreatment have been identified to date, it is

possible that interventions shown to be effective in reducing overall types of child maltreatment, such as the Nurse Family Partnership, may have a role to play. Furthermore, prevention before occurrence will require both the use of universal interventions aimed at promoting the type of parenting that is now recognized to be necessary for optimal child development, alongside the use of targeted interventions directed at improving parental sensitivity to a child's cues during infancy and later parent-child interactions. Intervention should, first and foremost, focus on a thorough assessment and ensuring the child's safety. Potentially effective treatments include cognitive behavioral parenting programs and other psychotherapeutic interventions. The high prevalence of psychological abuse in advanced Western societies, along with the serious consequences, point to the importance of effective management. Pediatricians should be alert to the occurrence of psychological maltreatment and identify ways to support families who have risk indicators for, or evidence of, this problem. (7/12, reaffirmed 4/16)

PSYCHOSOCIAL FACTORS IN CHILDREN AND YOUTH WITH SPECIAL HEALTH CARE NEEDS AND THEIR FAMILIES (CLINICAL REPORT)

Gerri Mattson, MD, MSPH, FAAP; Dennis Z. Kuo, MD, MHS, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Council on Children With Disabilities

ABSTRACT. Children and youth with special health care needs (CYSHCN) and their families may experience a variety of internal (ie, emotional and behavioral) and external (ie, interpersonal, financial, housing, and educational) psychosocial factors that can influence their health and wellness. Many CYSHCN and their families are resilient and thrive. Medical home teams can partner with CYSHCN and their families to screen for, evaluate, and promote psychosocial health to increase protective factors and ameliorate risk factors. Medical home teams can promote protective psychosocial factors as part of coordinated, comprehensive chronic care for CYSHCN and their families. A team-based care approach may entail collaboration across the care spectrum, including youth, families, behavioral health providers, specialists, child care providers, schools, social services, and other community agencies. The purpose of this clinical report is to raise awareness of the impact of psychosocial factors on the health and wellness of CYSHCN and their families. This clinical report provides guidance for pediatric providers to facilitate and coordinate care that can have a positive influence on the overall health, wellness, and quality of life of CYSHCN and their families. (12/18)
https://doi.org/10.1542/peds.2018-3171

PSYCHOSOCIAL SUPPORT FOR YOUTH LIVING WITH HIV (CLINICAL REPORT)

Jaime Martinez, MD, FAAP; Rana Chakraborty, MD, FAAP; and Committee on Pediatric AIDS

ABSTRACT. This clinical report provides guidance for the pediatrician in addressing the psychosocial needs of adolescents and young adults living with HIV, which can improve linkage to care and adherence to life-saving antiretroviral (ARV) therapy. Recent national case surveillance data for youth (defined here as adolescents and young adults 13 to 24 years of age) revealed that the burden of HIV/AIDS fell most heavily and disproportionately on African American youth, particularly males having sex with males. To effectively increase linkage to care and sustain adherence to therapy, interventions should address the immediate drivers of ARV compliance and also address factors that provide broader social and structural support for HIV-infected adolescents and young adults. Interventions should address psychosocial development, including lack of future orientation, inadequate educational attainment and limited health literacy, failure to focus on the long-term consequences of near-term risk behaviors, and coping ability. Associated challenges are closely linked to the structural environment. Individual case management is essential to linkage to and retention in care, ARV adherence, and management of associated comorbidities. Integrating these skills into pediatric and adolescent HIV practice in a medical home setting is critical, given the alarming increase in new HIV infections in youth in the United States. (2/14)

A PUBLIC HEALTH RESPONSE TO OPIOID USE IN PREGNANCY

Stephen W. Patrick, MD, MPH, MS, FAAP; Davida M. Schiff, MD, FAAP; and Committee on Substance Use and Prevention

ABSTRACT. The use of opioids during pregnancy has grown rapidly in the past decade. As opioid use during pregnancy increased, so did complications from their use, including neonatal abstinence syndrome. Several state governments responded to this increase by prosecuting and incarcerating pregnant women with substance use disorders; however, this approach has no proven benefits for maternal or infant health and may lead to avoidance of prenatal care and a decreased willingness to engage in substance use disorder treatment programs. A public health response, rather than a punitive approach to the opioid epidemic and substance use during pregnancy, is critical, including the following: a focus on preventing unintended pregnancies and improving access to contraception; universal screening for alcohol and other drug use in women of childbearing age; knowledge and informed consent of maternal drug testing and reporting practices; improved access to comprehensive obstetric care, including opioid-replacement therapy; gender-specific substance use treatment programs; and improved funding for social services and child welfare systems. The American College of Obstetricians and Gynecologists supports the value of this clinical document as an educational tool (December 2016). (2/17)

PUBLIC POLICIES TO REDUCE SUGARY DRINK CONSUMPTION IN CHILDREN AND ADOLESCENTS

Natalie D. Muth, MD, MPH, RDN, FAAP; William H. Dietz, MD, PhD, FAAP; Sheela N. Magge, MD, MSCE, FAAP; Rachel K. Johnson, PhD, MPH, RD, FAHA; Section on Obesity; and Committee on Nutrition (joint with American Heart Association)

ABSTRACT. Excess consumption of added sugars, especially from sugary drinks, poses a grave health threat to children and adolescents, disproportionately affecting children of minority and low-income communities. Public policies, such as those detailed in this statement, are needed to decrease child and adolescent consumption of added sugars and improve health. (3/19)
https://doi.org/10.1542/peds.2019-0282

PUBLIC POLICY TO PROTECT CHILDREN FROM TOBACCO, NICOTINE, AND TOBACCO SMOKE

Section on Tobacco Control

ABSTRACT. Tobacco use and tobacco smoke exposure are among the most important health threats to children, adolescents, and adults. There is no safe level of tobacco smoke exposure. The developing brains of children and adolescents are particularly vulnerable to the development of tobacco and nicotine dependence. Tobacco is unique among consumer products in that it causes disease and death when used exactly as intended. Tobacco continues to be heavily promoted to children and young adults. Flavored and alternative tobacco products, including little cigars, chewing tobacco, and electronic nicotine delivery systems, are gaining popularity among youth. This statement describes important evidence-based public policy actions that, when implemented, will reduce tobacco product use and tobacco

smoke exposure among youth and, by doing so, improve the health of children and young adults. (10/15, reaffirmed 6/20)

QUALITY EARLY EDUCATION AND CHILD CARE FROM BIRTH TO KINDERGARTEN

Elaine A. Donoghue, MD, FAAP, and Council on Early Childhood

ABSTRACT. High-quality early education and child care for young children improves physical and cognitive outcomes for the children and can result in enhanced school readiness. Preschool education can be viewed as an investment (especially for at-risk children), and studies show a positive return on that investment. Barriers to high-quality early childhood education include inadequate funding and staff education as well as variable regulation and enforcement. Steps that have been taken to improve the quality of early education and child care include creating multidisciplinary, evidence-based child care practice standards; establishing state quality rating and improvement systems; improving federal and state regulations; providing child care health consultation; and initiating other innovative partnerships. Pediatricians have a role in promoting quality early education and child care for all children not only in the medical home but also at the community, state, and national levels. (7/17)

RACE, ETHNICITY, AND SOCIOECONOMIC STATUS IN RESEARCH ON CHILD HEALTH

Tina L. Cheng, MD, MPH, FAAP; Elizabeth Goodman, MD, FAAP; and Committee on Pediatric Research

ABSTRACT. An extensive literature documents the existence of pervasive and persistent child health, development, and health care disparities by race, ethnicity, and socioeconomic status (SES). Disparities experienced during childhood can result in a wide variety of health and health care outcomes, including adult morbidity and mortality, indicating that it is crucial to examine the influence of disparities across the life course. Studies often collect data on the race, ethnicity, and SES of research participants to be used as covariates or explanatory factors. In the past, these variables have often been assumed to exert their effects through individual or genetically determined biologic mechanisms. However, it is now widely accepted that these variables have important social dimensions that influence health. SES, a multidimensional construct, interacts with and confounds analyses of race and ethnicity. Because SES, race, and ethnicity are often difficult to measure accurately, leading to the potential for misattribution of causality, thoughtful consideration should be given to appropriate measurement, analysis, and interpretation of such factors. Scientists who study child and adolescent health and development should understand the multiple measures used to assess race, ethnicity, and SES, including their validity and shortcomings and potential confounding of race and ethnicity with SES. The American Academy of Pediatrics (AAP) recommends that research on eliminating health and health care disparities related to race, ethnicity, and SES be a priority. Data on race, ethnicity, and SES should be collected in research on child health to improve their definitions and increase understanding of how these factors and their complex interrelationships affect child health. Furthermore, the AAP believes that researchers should consider both biological and social mechanisms of action of race, ethnicity, and SES as they relate to the aims and hypothesis of the specific area of investigation. It is important to measure these variables, but it is not sufficient to use these variables alone as explanatory for differences in disease, morbidity, and outcomes without attention to the social and biologic influences they have on health throughout the life course. The AAP recommends more research, both in the United States and internationally, on measures of race, ethnicity, and SES and how these complex constructs affect health care and health outcomes throughout the life course. RADIATION RISK TO CHILDREN FROM COMPUTED TOMOGRAPHY (CLINICAL REPORT)

Alan S. Brody, MD; Donald P. Frush, MD; Walter Huda, PhD; Robert L. Brent, MD, PhD; and Section on Radiology

ABSTRACT. Imaging studies that use ionizing radiation are an essential tool for the evaluation of many disorders of childhood. Ionizing radiation is used in radiography, fluoroscopy, angiography, and computed tomography scanning. Computed tomography is of particular interest because of its relatively high radiation dose and wide use. Consensus statements on radiation risk suggest that it is reasonable to act on the assumption that low-level radiation may have a small risk of causing cancer. The medical community should seek ways to decrease radiation exposure by using radiation doses as low as reasonably achievable and by performing these studies only when necessary. There is wide agreement that the benefits of an indicated computed tomography scan far outweigh the risks. Pediatric health care professionals' roles in the use of computed tomography on children include deciding when a computed tomography scan is necessary and discussing the risk with patients and families. Radiologists should be a source of consultation when forming imaging strategies and should create specific protocols with scanning techniques optimized for pediatric patients. Families and patients should be encouraged to ask questions about the risks and benefits of computed tomography scanning. The information in this report is provided to aid in decision-making and discussions with the health care team, patients, and families. (9/07)

RECOGNITION AND MANAGEMENT OF IATROGENICALLY INDUCED OPIOID DEPENDENCE AND WITHDRAWAL IN CHILDREN (CLINICAL REPORT)

Jeffrey Galinkin, MD, FAAP; Jeffrey Lee Koh, MD, FAAP; Committee on Drugs; and Section on Anesthesiology and Pain Medicine

ABSTRACT. Opioids are often prescribed to children for pain relief related to procedures, acute injuries, and chronic conditions. Round-the-clock dosing of opioids can produce opioid dependence within 5 days. According to a 2001 consensus paper from the American Academy of Pain Medicine, American Pain Society, and American Society of Addiction Medicine, dependence is defined as "a state of adaptation that is manifested by a drug class specific withdrawal syndrome that can be produced by abrupt cessation, rapid dose reduction, decreasing blood level of the drug, and/or administration of an antagonist." Although the experience of many children undergoing iatrogenically induced withdrawal may be mild or goes unreported, there is currently no guidance for recognition or management of withdrawal for this population. Guidance on this subject is available only for adults and primarily for adults with substance use disorders. The guideline will summarize existing literature and provide readers with information currently not available in any single source specific for this vulnerable pediatric population. (12/13)
https://doi.org/10.1542/peds.2013-3398

RECOGNITION AND MANAGEMENT OF MEDICAL COMPLEXITY (CLINICAL REPORT)

Dennis Z. Kuo, MD, MHS, FAAP; Amy J. Houtrow, MD, PhD, MPH, FAAP; and Council on Children With Disabilities

ABSTRACT. Children with medical complexity have extensive needs for health services, experience functional limitations, and are high resource utilizers. Addressing the needs of this

population to achieve high-value health care requires optimizing care within the medical home and medical neighborhood. Opportunities exist for health care providers, payers, and policy makers to develop strategies to enhance care delivery and to decrease costs. Important outcomes include decreasing unplanned hospital admissions, decreasing emergency department use, ensuring access to health services, limiting out-of-pocket expenses for families, and improving patient and family experiences, quality of life, and satisfaction with care. This report describes the population of children with medical complexity and provides strategies to optimize medical and health outcomes. (11/16)

https://doi.org/10.1542/peds.2016-3021

RECOGNIZING AND RESPONDING TO MEDICAL NEGLECT (CLINICAL REPORT)

Carole Jenny, MD, MBA, and Committee on Child Abuse and Neglect

ABSTRACT. A caregiver may fail to recognize or respond to a child's medical needs for a variety of reasons. An effective response by a health care professional to medical neglect requires a comprehensive assessment of the child's needs, the parents' resources, the parents' efforts to provide for the needs of the child, and options for ensuring optimal health for the child. Such an assessment requires clear, 2-way communication between the family and the health care professional. Physicians should consider the least intrusive options for managing cases of medical neglect that ensure the health and safety of the child. (12/07, reaffirmed 1/11, 2/16)

RECOMMENDATIONS FOR PREVENTION AND CONTROL OF INFLUENZA IN CHILDREN, 2021–2022

Committee on Infectious Diseases

ABSTRACT. This statement updates the recommendations of the American Academy of Pediatrics for the routine use of influenza vaccine and antiviral medications in the prevention and treatment of influenza in children during the 2021–2022 influenza season. A detailed review of the evidence supporting these recommendations is published in the accompanying technical report. The American Academy of Pediatrics recommends annual influenza immunization of all children without medical contraindications, starting at 6 months of age. Influenza vaccination is an important intervention to protect vulnerable populations and reduce the burden of respiratory illnesses during circulation of severe acute respiratory syndrome coronavirus, which is expected to continue during the 2021–2022 influenza season. Any licensed, recommended, age-appropriate vaccine available can be administered, without preference for one product or formulation over another. Antiviral treatment of influenza with any licensed, recommended, age-appropriate influenza antiviral medication is recommended for children with suspected or confirmed influenza who are hospitalized, have severe or progressive disease, or have underlying conditions that increase their risk of complications of influenza. Antiviral treatment may be considered for any previously healthy, symptomatic outpatient not at high risk for influenza complications, in whom an influenza diagnosis is confirmed or suspected, if treatment can be initiated within 48 hours of illness onset and for children whose siblings or household contacts either are younger than 6 months or have a high-risk condition that predisposes them to complications of influenza. (9/21)

RECOMMENDATIONS FOR PREVENTION AND CONTROL OF INFLUENZA IN CHILDREN, 2021–2022 (TECHNICAL REPORT)

Committee on Infectious Diseases

ABSTRACT. This technical report accompanies the recommendations of the American Academy of Pediatrics for the routine use of the influenza vaccine and antiviral medications in the prevention and treatment of influenza in children during the 2021–2022 season. Influenza vaccination is an important intervention to protect vulnerable populations and reduce the burden of respiratory illnesses during circulation of severe acute respiratory syndrome coronavirus 2, which is expected to continue during this influenza season. In this technical report, we summarize recent influenza seasons, morbidity and mortality in children, vaccine effectiveness, vaccination coverage, and detailed guidance on storage, administration, and implementation. We also provide background on inactivated and live attenuated influenza vaccine recommendations, vaccination during pregnancy and breastfeeding, diagnostic testing, and antiviral medications for treatment and chemoprophylaxis. (9/21)

RECOMMENDATIONS FOR SEROGROUP B MENINGOCOCCAL VACCINE FOR PERSONS 10 YEARS AND OLDER

Committee on Infectious Diseases

ABSTRACT. This policy statement provides recommendations for the prevention of serogroup B meningococcal disease through the use of 2 newly licensed serogroup B meningococcal vaccines: MenB-FHbp (Trumenba; Wyeth Pharmaceuticals, a subsidiary of Pfizer, Philadelphia, PA) and MenB-4C (Bexsero; Novartis Vaccines, Siena, Italy). Both vaccines are approved for use in persons 10 through 25 years of age. MenB-FHbp is licensed as a 2- or 3-dose series, and MenB-4C is licensed as a 2-dose series for all groups. Either vaccine is recommended for routine use in persons 10 years and older who are at increased risk of serogroup B meningococcal disease (category A recommendation). Persons at increased risk of meningococcal serogroup B disease include the following: (1) persons with persistent complement component diseases, including inherited or chronic deficiencies in C3, C5–C9, properdin, factor D, or factor H, or persons receiving eculizumab (Soliris; Alexion Pharmaceuticals, Cheshire, CT), a monoclonal antibody that acts as a terminal complement inhibitor by binding C5 and inhibiting cleavage of C5 to C5A; (2) persons with anatomic or functional asplenia, including sickle cell disease; and (3) healthy persons at increased risk because of a serogroup B meningococcal disease outbreak. Both serogroup B meningococcal vaccines have been shown to be safe and immunogenic and are licensed by the US Food and Drug Administration for individuals between the ages of 10 and 25 years. On the basis of epidemiologic and antibody persistence data, the American Academy of Pediatrics agrees with the Advisory Committee on Immunization Practices of the Centers for Disease Control and Prevention that either vaccine may be administered to healthy adolescents and young adults 16 through 23 years of age (preferred ages are 16 through 18 years) to provide short-term protection against most strains of serogroup B meningococcal disease (category B recommendation). RECOMMENDED ESSENTIAL EQUIPMENT FOR BASIC LIFE SUPPORT AND ADVANCED LIFE SUPPORT GROUND AMBULANCES 2020: A JOINT POSITION STATEMENT

John Lyng, MD, NRP; Kathleen Adelgais, MD, MPH; Rachael Alter, BA; Justin Beal, RN; Bruce Chung, MD; Toni Gross, MD; Marc Minkler, NRP; Brian Moore, MD; Tim Stebbins, MD; Sam Vance, NRP; Ken Williams, MD; and Allen Yee, MD

ABSTRACT. The National Association of EMS Physicians, along with these coauthoring associations: American Academy of Pediatrics, American College of Surgeons Committee on Trauma, EMS for Children Innovation and Improvement Center, Emergency Nurses Association, and National Association of State EMS Officials and as also endorsed by the National Association of Emergency Medical Technicians, believes that the delivery of high-quality and effective EMS care is dependent on several factors, including but not limited to the presence of the following:

— providers who have been credentialed to ensure they demonstrate appropriate cognitive knowledge, affective ability, psychomotor skills, and critical thinking;
— clinical protocols or guidelines that are supported by the best available scientific evidence; and
— equipment and supplies necessary to deliver appropriate care as directed by clinical protocols and/or guidelines for patients of all ages.

Several documents, including previous versions of this joint position statement, the National Model EMS Clinical Guidelines Version 2.2, the 2018 National EMS Scope of Practice Model, the Clinical Credentialing of EMS Providers, Physician Oversight of Pediatric Care in Emergency Medical Services, Pediatric Readiness in Emergency Medical Services Systems, and core performance measures from the US Department of Health and Human Services Health Resources and Services Administration EMS for Children (EMSC) Program have been developed to lay the foundation of several of the concepts noted above. REDUCING INJURY RISK FROM BODY CHECKING IN BOYS' YOUTH ICE HOCKEY

Council on Sports Medicine and Fitness

ABSTRACT. Ice hockey is an increasingly popular sport that allows intentional collision in the form of body checking for males but not for females. There is a two- to threefold increased risk of all injury, severe injury, and concussion related to body checking at all levels of boys' youth ice hockey. The American Academy of Pediatrics reinforces the importance of stringent enforcement of rules to protect player safety as well as educational interventions to decrease unsafe tactics. To promote ice hockey as a lifelong recreational pursuit for boys, the American Academy of Pediatrics recommends the expansion of nonchecking programs and the restriction of body checking to elite levels of boys' youth ice hockey, starting no earlier than 15 years of age. (5/14, reaffirmed 7/18)

https://doi.org/10.1542/peds.2014-0692

REDUCING THE NUMBER OF DEATHS AND INJURIES FROM RESIDENTIAL FIRES

Committee on Injury and Poison Prevention

ABSTRACT. Smoke inhalation, severe burns, and death from residential fires are devastating events, most of which are preventable. In 1998, approximately 381 500 residential structure fires resulted in 3250 non-firefighter deaths, 17 175 injuries, and approximately $4.4 billion in property loss. This statement reviews important prevention messages and intervention strategies related to residential fires. It also includes recommendations for pediatricians regarding office anticipatory guidance, work in the community, and support of regulation and legislation that could result in a decrease in the number of fire-related injuries and deaths to children. (6/00)

https://doi.org/10.1542/peds.105.6.1355

REFERRAL TO PEDIATRIC SURGICAL SPECIALISTS

Surgical Advisory Panel

ABSTRACT. The American Academy of Pediatrics, with the collaboration of the Surgical Sections of the American Academy of Pediatrics, has created referral recommendations intended to serve as voluntary practice parameters to assist general pediatricians in determining when and to whom to refer their patients for pediatric surgical specialty care. It is recognized that these recommendations may be difficult to implement, because communities vary in terms of access to major pediatric medical centers. Limited access does not negate the value of the recommendations, however, because the child who needs specialized surgical and anesthetic care is best served by the skills of the appropriate pediatric surgical team. Major congenital anomalies, malignancies, major trauma, and chronic illnesses (including those associated with preterm birth) in infants and children should be managed by pediatric medical subspecialists and pediatric surgical specialists at pediatric referral centers that can provide expertise in many areas, including the pediatric medical subspecialties and surgical specialties of pediatric radiology, pediatric anesthesiology, pediatric pathology, and pediatric intensive care. The optimal management of the child with complex problems, chronic illness, or disabilities requires coordination, communication, and cooperation of the pediatric surgical specialist with the child's primary care pediatrician or physician. (1/14)

https://doi.org/10.1542/peds.2013-3820

RELIEF OF PAIN AND ANXIETY IN PEDIATRIC PATIENTS IN EMERGENCY MEDICAL SYSTEMS (CLINICAL REPORT)

Joel A. Fein, MD, MPH; William T. Zempsky, MD, MPH; Joseph P. Cravero, MD; Committee on Pediatric Emergency Medicine; and Section on Anesthesiology and Pain Medicine

ABSTRACT. Control of pain and stress for children is a vital component of emergency medical care. Timely administration of analgesia affects the entire emergency medical experience and can have a lasting effect on a child's and family's reaction to current and future medical care. A systematic approach to pain management and anxiolysis, including staff education and protocol development, can provide comfort to children in the emergency setting and improve staff and family satisfaction. (10/12, reaffirmed 9/15, 12/20)

https://doi.org/10.1542/peds.2012-2536

RESCUE MEDICINE FOR EPILEPSY IN EDUCATION SETTINGS (CLINICAL REPORT)

Adam L. Hartman, MD, FAAP; Cynthia Di Laura Devore, MD; Section on Neurology; and Council on School Health

ABSTRACT. Children and adolescents with epilepsy may experience prolonged seizures in school-associated settings (eg, during transportation, in the classroom, or during sports activities). Prolonged seizures may evolve into status epilepticus. Administering a seizure rescue medication can abort the seizure and may obviate the need for emergency medical services and subsequent care in an emergency department. In turn, this may save patients from the morbidity of more invasive interventions and the cost of escalated care. There are significant variations in prescribing practices for seizure rescue medications, partly because of inconsistencies between jurisdictions in legislation and professional practice guidelines among potential first responders (including school staff). There also are potential liability issues for prescribers, school districts, and unlicensed

assistive personnel who might administer the seizure rescue medications. This clinical report highlights issues that providers may consider when prescribing seizure rescue medications and creating school medical orders and/or action plans for students with epilepsy. Collaboration among prescribing providers, families, and schools may be useful in developing plans for the use of seizure rescue medications. (12/15)

RESISTANCE TRAINING FOR CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Paul R. Stricker, MD, FAAP; Avery D. Faigenbaum, EdD, FACSM, FNSCA; Teri M. McCambridge, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. Resistance training is becoming more important as an integral part of comprehensive sport training regimens, school physical education classes, and after-school fitness programs. The increasing number of youth who are involved in sport activities, coupled with the health problems of inactivity and being overweight, have resulted in increased interest in resistance training. Secular declines in measures of muscular fitness in modern-day youth highlight the need for participation in youth resistance training for nonathletes as well as athletes. Parents often ask pediatricians to offer advice regarding the safety, benefits, and implementation of an effective resistance-training program. This report is a revision of the 2008 American Academy of Pediatrics policy statement and reviews current information and research on the benefits and risks of resistance training for children and adolescents. (5/20)

RESOURCES RECOMMENDED FOR THE CARE OF PEDIATRIC PATIENTS IN HOSPITALS (CLINICAL REPORT)

Kimberly D. Ernst, MD, MSMI, FAAP, and Committee on Hospital Care

ABSTRACT. It is crucial that all children are provided with high-quality and safe health care. Pediatric inpatient needs are unique in regard to policies, equipment, facilities, and personnel. The intent of this clinical report is to provide recommendations for the resources necessary to provide high-quality and safe pediatric inpatient medical care. (3/20)
https://doi.org/10.1542/peds.2020-0204

RESPIRATORY SUPPORT IN PRETERM INFANTS AT BIRTH

Committee on Fetus and Newborn

ABSTRACT. Current practice guidelines recommend administration of surfactant at or soon after birth in preterm infants with respiratory distress syndrome. However, recent multicenter randomized controlled trials indicate that early use of continuous positive airway pressure with subsequent selective surfactant administration in extremely preterm infants results in lower rates of bronchopulmonary dysplasia/death when compared with treatment with prophylactic or early surfactant therapy. Continuous positive airway pressure started at or soon after birth with subsequent selective surfactant administration may be considered as an alternative to routine intubation with prophylactic or early surfactant administration in preterm infants. (12/13)
https://doi.org/10.1542/peds.2013-3442

RESPONDING TO PARENTAL REFUSALS OF IMMUNIZATION OF CHILDREN (CLINICAL REPORT)

Douglas S. Diekema, MD, MPH, and Committee on Bioethics

ABSTRACT. The American Academy of Pediatrics strongly endorses universal immunization. However, for childhood immunization programs to be successful, parents must comply with immunization recommendations. The problem of parental refusal of immunization for children is an important one for pediatricians. The goal of this report is to assist pediatricians in understanding the reasons parents may have for refusing to immunize their children, review the limited circumstances under which parental refusals should be referred to child protective services agencies or public health authorities, and provide practical guidance to assist the pediatrician faced with a parent who is reluctant to allow immunization of his or her child. (5/05, reaffirmed 1/09, 11/12)
https://doi.org/10.1542/peds.2005-0316

RESPONSIBLE INNOVATION IN CHILDREN'S SURGICAL CARE

Section on Surgery and Committee on Bioethics (joint with American Pediatric Surgical Association New Technology Committee)

ABSTRACT. Advances in medical care may occur when a change in practice incorporates a new treatment or methodology. In surgery, this may involve the translation of a completely novel concept into a new procedure or device or the adaptation of existing treatment approaches or technology to a new clinical application. Regardless of the specifics, innovation should have, as its primary goal, the enhancement of care leading to improved outcomes from the patient's perspective. This policy statement examines innovation as it pertains to surgical care, focusing on some of the definitions that help differentiate applied innovation or innovative therapy from research. The ethical challenges and the potential for conflict of interest for surgeons or institutions seeking to offer innovative surgical therapy are examined. The importance of engaging patients and families as "innovation partners" to ensure complete transparency of expectations from the patient's and provider's perspectives is also examined, with specific emphasis on cultural competence and mutually respectful approaches. A framework for identifying, evaluating, and safely implementing innovative surgical therapy in children is provided. (12/16)
https://doi.org/10.1542/peds.2016-3437

RETURNING TO LEARNING FOLLOWING A CONCUSSION (CLINICAL REPORT)

Mark E. Halstead, MD, FAAP; Karen McAvoy, PsyD; Cynthia D. Devore, MD, FAAP; Rebecca Carl, MD, FAAP; Michael Lee, MD, FAAP; Kelsey Logan, MD, FAAP; Council on Sports Medicine and Fitness; and Council on School Health

ABSTRACT. Following a concussion, it is common for children and adolescents to experience difficulties in the school setting. Cognitive difficulties, such as learning new tasks or remembering previously learned material, may pose challenges in the classroom. The school environment may also increase symptoms with exposure to bright lights and screens or noisy cafeterias and hallways. Unfortunately, because most children and adolescents look physically normal after a concussion, school officials often fail to recognize the need for academic or environmental adjustments. Appropriate guidance and recommendations from the pediatrician may ease the transition back to the school environment and facilitate the recovery of the child or adolescent. This report serves to provide a better understanding of possible factors that may contribute to difficulties in a school environment after a concussion and serves as a framework for the medical home, the educational home, and the family home to guide the student to a successful and safe return to learning. (10/13, reaffirmed 7/18)

THE ROLE OF INTEGRATED CARE IN A MEDICAL HOME FOR PATIENTS WITH A FETAL ALCOHOL SPECTRUM DISORDER (CLINICAL REPORT)

Renee M. Turchi, MD, MPH, FAAP; Vincent C. Smith, MD, MPH, FAAP; Committee on Substance Use and Prevention; and Council on Children With Disabilities

ABSTRACT. Fetal alcohol spectrum disorder (FASD) is an umbrella term used to describe preventable birth defects and intellectual and/or developmental disabilities resulting from prenatal alcohol exposure. The American Academy of Pediatrics has a previous clinical report in which diagnostic criteria for a child with an FASD are discussed and tools to assist pediatricians with its management can be found. This clinical report is intended to foster pediatrician awareness of approaches for screening for prenatal alcohol exposure in clinical practice, to guide management of a child with an FASD after the diagnosis is made, and to summarize available resources for FASD management. (9/18)

THE ROLE OF PEDIATRICIANS IN GLOBAL HEALTH

Parminder S. Suchdev, MD, MPH, FAAP; Cynthia R. Howard, MD, MPHTM, FAAP; Section on International Child Health

ABSTRACT. Ninety percent of the world's children live in low- and middle-income countries, where barriers to health contribute to significant child morbidity and mortality. The American Academy of Pediatrics is dedicated to the health and well-being of *all* children. To fulfill this promise, this policy statement defines the role of the pediatrician in global health and provides a specific set of recommendations directed to all pediatricians, emphasizing the importance of global health as an integral function of the profession of pediatrics. (11/18)

https://doi.org/10.1542/peds.2018-2997

ROLE OF PULSE OXIMETRY IN EXAMINING NEWBORNS FOR CONGENITAL HEART DISEASE: A SCIENTIFIC STATEMENT FROM THE AHA AND AAP

William T. Mahle, MD; Jane W. Newburger, MD, MPH; G. Paul Matherne, MD; Frank C. Smith, MD; Tracey R. Hoke, MD; Robert Koppel, MD; Samuel S. Gidding, MD; Robert H. Beekman III, MD; Scott D. Grosse, PhD; on behalf of Section on Cardiology and Cardiac Surgery and Committee of Fetus and Newborn (joint with American Heart Association Congenital Heart Defects Committee of the Council on Cardiovascular Disease in the Young, Council on Cardiovascular Nursing, and Interdisciplinary Council on Quality of Care and Outcomes Research)

ABSTRACT. *Background.* The purpose of this statement is to address the state of evidence on the routine use of pulse oximetry in newborns to detect critical congenital heart disease (CCHD).

Methods and Results. A writing group appointed by the American Heart Association and the American Academy of Pediatrics reviewed the available literature addressing current detection methods for CCHD, burden of missed and/or delayed diagnosis of CCHD, rationale of oximetry screening, and clinical studies of oximetry in otherwise asymptomatic newborns. MEDLINE database searches from 1966 to 2008 were done for English-language papers using the following search terms: congenital heart disease, pulse oximetry, physical examination, murmur, echocardiography, fetal echocardiography, and newborn screening. The reference lists of identified papers were also searched. Published abstracts from major pediatric scientific meetings in 2006 to 2008 were also reviewed. The American Heart Association classification of recommendations and levels of evidence for practice guidelines were used. In an analysis of pooled studies of oximetry assessment performed after 24 hours of life, the estimated sensitivity for detecting CCHD was 69.6%, and the positive predictive value was 47.0%; however, sensitivity varied dramatically among studies from 0% to 100%. False-positive screens that required further evaluation occurred in only 0.035% of infants screened after 24 hours.

Conclusions. Currently, CCHD is not detected in some newborns until after their hospital discharge, which results in significant morbidity and occasional mortality. Furthermore, routine pulse oximetry performed on asymptomatic newborns after 24 hours of life, but before hospital discharge, may detect CCHD. Routine pulse oximetry performed after 24 hours in hospitals that have on-site pediatric cardiovascular services incurs very low cost and risk of harm. Future studies in larger populations and across a broad range of newborn delivery systems are needed to determine whether this practice should become standard of care in the routine assessment of the neonate. (8/09)

https://doi.org/10.1542/peds.2009-1397

THE ROLE OF THE PEDIATRICIAN IN PRIMARY PREVENTION OF OBESITY (CLINICAL REPORT)

Stephen R. Daniels, MD, PhD, FAAP; Sandra G. Hassink, MD, FAAP; and Committee on Nutrition

ABSTRACT. The adoption of healthful lifestyles by individuals and families can result in a reduction in many chronic diseases and conditions of which obesity is the most prevalent. Obesity prevention, in addition to treatment, is an important public health priority. This clinical report describes the rationale for pediatricians to be an integral part of the obesity-prevention effort. In addition, the 2012 Institute of Medicine report "Accelerating Progress in Obesity Prevention" includes health care providers as a crucial component of successful weight control. Research on obesity prevention in the pediatric care setting as well as evidence-informed practical approaches and targets for prevention are reviewed. Pediatricians should use a longitudinal, developmentally appropriate life-course approach to help identify children early on the path to obesity and base prevention efforts on family dynamics and reduction in high-risk dietary and activity behaviors. They should promote a diet free of sugar-sweetened beverages, of fewer foods with high caloric density, and of increased intake of fruits and vegetables. It is also important to promote a lifestyle with reduced sedentary behavior and with 60 minutes of daily moderate to vigorous physical activity. This report also identifies important gaps in evidence that need to be filled by future research. (6/15)

https://doi.org/10.1542/peds.2015-1558

THE ROLE OF THE PEDIATRICIAN IN RURAL EMERGENCY MEDICAL SERVICES FOR CHILDREN

Committee on Pediatric Emergency Medicine

ABSTRACT. In rural America, pediatricians can play a key role in the development, implementation, and ongoing supervision of emergency medical services for children (EMSC). Pediatricians may represent the only source of pediatric expertise for a large region and are a vital resource for rural physicians (eg, general and family practice, emergency medicine) and other rural health care professionals (physician assistants, nurse practitioners, and emergency medical technicians), providing education about management and prevention of pediatric illness and injury; appropriate equipment for the acutely ill or injured child; and acute, chronic, and rehabilitative care. In addition to providing clinical expertise, the pediatrician may be involved in quality assurance, clinical protocol development, and advocacy, and may serve as a liaison between emergency medical services and other entities working with children (eg, school nurses, child care centers, athletic programs, and programs for children with special health care needs). (10/12, reaffirmed 9/15)

https://doi.org/10.1542/peds.2012-2547

ROLE OF THE PEDIATRICIAN IN YOUTH VIOLENCE PREVENTION

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Youth violence continues to be a serious threat to the health of children and adolescents in the United States. It is crucial that pediatricians clearly define their role and develop the appropriate skills to address this threat effectively. From a clinical perspective, pediatricians should become familiar with *Connected Kids: Safe, Strong, Secure,* the American Academy of Pediatrics' primary care violence prevention protocol. Using this material, practices can incorporate preventive education, screening for risk, and linkages to community-based counseling and treatment resources. As advocates, pediatricians may bring newly developed information regarding key risk factors such as exposure to firearms, teen dating violence, and bullying to the attention of local and national policy makers. This policy statement refines the developing role of pediatricians in youth violence prevention and emphasizes the importance of this issue in the strategic agenda of the American Academy of Pediatrics. ROLE OF THE SCHOOL NURSE IN PROVIDING SCHOOL HEALTH SERVICES

Council on School Health

ABSTRACT. The American Academy of Pediatrics recognizes the important role school nurses play in promoting the optimal biopsychosocial health and well-being of school-aged children in the school setting. Although the concept of a school nurse has existed for more than a century, uniformity among states and school districts regarding the role of a registered professional nurse in schools and the laws governing it are lacking. By understanding the benefits, roles, and responsibilities of school nurses working as a team with the school physician, as well as their contributions to school-aged children, pediatricians can collaborate with, support, and promote school nurses in their own communities, thus improving the health, wellness, and safety of children and adolescents. (5/16)

ROLE OF THE SCHOOL PHYSICIAN

Council on School Health

ABSTRACT. The American Academy of Pediatrics recognizes the important role physicians play in promoting the optimal biopsychosocial well-being of children in the school setting. Although the concept of a school physician has existed for more than a century, uniformity among states and school districts regarding physicians in schools and the laws governing it are lacking. By understanding the roles and contributions physicians can make to schools, pediatricians can support and promote school physicians in their communities and improve health and safety for children. ROUTINE NEUROIMAGING OF THE PRETERM BRAIN (CLINICAL REPORT)

Ivan L. Hand, MD, FAAP; Renée A. Shellhaas, MD, MS, FAAP; Sarah S. Milla, MD, FAAP; Committee on Fetus and Newborn; Section on Neurology; and Section on Radiology

ABSTRACT. Neuroimaging of the preterm infant is a common assessment performed in the NICU. Timely and focused studies can be used for diagnostic, therapeutic, and prognostic information. However, significant variability exists among neonatal units as to which modalities are used and when imaging studies are obtained. Appropriate timing and selection of neuroimaging studies can help identify neonates with brain injury who may require therapeutic intervention or who may be at risk for neurodevelopmental impairment. This clinical report reviews the different modalities of imaging broadly available to the clinician. Evidence-based indications for each modality, optimal timing of examinations, and prognostic value are discussed. (10/20)

RUNAWAY YOUTH: CARING FOR THE NATION'S LARGEST SEGMENT OF MISSING CHILDREN (CLINICAL REPORT)

Thresia B. Gambon, MD, MPH, MBA, FAAP; Janna R. Gewirtz O'Brien, MD, FAAP; Committee on Psychosocial Aspects of Child and Family Health; and Council on Community Pediatrics

ABSTRACT. The largest segment of missing children in the United States includes runaways, children who run away from home, and thrownaways, children who are told to leave or stay away from home by a household adult. Although estimates vary, as many as 1 in 20 youth run away from home annually. These unaccompanied youth have unique health needs, including high rates of trauma, mental illness, substance use, pregnancy, and sexually transmitted infections. While away, youth who run away are at high risk for additional trauma, victimization, and violence. Runaway and thrownaway youth have high unmet health care needs and limited access to care. Several populations are at particular high risk for runaway episodes, including victims of abuse and neglect; lesbian, gay, bisexual, transgender, and questioning youth; and youth in protective custody. Pediatricians and other health care professionals have a critical role to play in supporting runaway youth, addressing their unique health needs, fostering positive relationships within their families and with other supportive adults, and connecting them with available community resources. This report provides clinical guidance for pediatricians and other health care professionals regarding (1) the identification of adolescents who are at risk for running away or being thrown away and (2) the management of the unique medical, mental health, and social needs of these youth. In partnership with national, state, and local resources, pediatricians can significantly reduce risk and improve long-term outcomes for runaway youth. (1/20)

SAFE SLEEP AND SKIN-TO-SKIN CARE IN THE NEONATAL PERIOD FOR HEALTHY TERM NEWBORNS (CLINICAL REPORT)

Lori Feldman-Winter, MD, MPH, FAAP; Jay P. Goldsmith, MD, FAAP; Committee on Fetus and Newborn; and Task Force on Sudden Infant Death Syndrome

ABSTRACT. Skin-to-skin care (SSC) and rooming-in have become common practice in the newborn period for healthy newborns with the implementation of maternity care practices that support breastfeeding as delineated in the World Health Organization's "Ten Steps to Successful Breastfeeding." SSC and rooming-in are supported by evidence that indicates that the implementation of these practices increases overall and exclusive breastfeeding, safer and healthier transitions, and improved maternal-infant bonding. In some cases, however, the practice of SSC and rooming-in may pose safety concerns, particularly with regard to sleep. There have been several recent case reports and case series of severe and sudden unexpected postnatal collapse in the neonatal period among otherwise healthy newborns and near fatal or fatal events related to sleep, suffocation, and falls from adult hospital beds. Although these are largely case reports, there are potential dangers of unobserved SSC immediately after birth and throughout the postpartum hospital period as well as with unobserved rooming-in for at-risk situations. Moreover, behaviors that are modeled in the hospital after birth, such as sleep position, are likely to influence sleeping practices after discharge. Hospitals and birthing centers have found it difficult to develop policies that will allow SSC and rooming-in to continue in a safe manner. This clinical report is intended for birthing centers and delivery hospitals caring for healthy newborns to assist

in the establishment of appropriate SSC and safe sleep policies. (8/16)

SAFE TRANSPORTATION OF PRETERM AND LOW BIRTH WEIGHT INFANTS AT HOSPITAL DISCHARGE (CLINICAL REPORT)

Marilyn J. Bull, MD; William A. Engle, MD; Committee on Injury, Violence, and Poison Prevention; and Committee on Fetus and Newborn

ABSTRACT. Safe transportation of preterm and low birth weight infants requires special considerations. Both physiologic immaturity and low birth weight must be taken into account to properly position such infants. This clinical report provides guidelines for pediatricians and other caregivers who counsel parents of preterm and low birth weight infants about car safety seats. (4/09, reaffirmed 8/13, 6/18)

SCHOOL BUS TRANSPORTATION OF CHILDREN WITH SPECIAL HEALTH CARE NEEDS

Joseph O'Neil, MD, MPH, FAAP; Benjamin D. Hoffman, MD, FAAP; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. School systems are responsible for ensuring that children with special needs are safely transported on all forms of federally approved transportation provided by the school system. A plan to provide the most current and proper support to children with special transportation needs should be developed by the Individualized Education Program team, including the parent, school transportation director, and school nurse, in conjunction with physician orders and recommendations. With this statement, we provide current guidance for the protection of child passengers with specific health care needs. Guidance that applies to general school transportation should be followed, inclusive of staff training, provision of nurses or aides if needed, and establishment of a written emergency evacuation plan as well as a comprehensive infection control program. Researchers provide the basis for recommendations concerning occupant securement for children in wheelchairs and children with other special needs who are transported on a school bus. Pediatricians can help their patients by being aware of guidance for restraint systems for children with special needs and by remaining informed of new resources. Pediatricians can also play an important role at the state and local level in the development of school bus specifications. (4/18)
https://doi.org/10.1542/peds.2018-0513

SCHOOL READINESS (TECHNICAL REPORT)

P. Gail Williams, MD, FAAP; Marc Alan Lerner, MD, FAAP; Council on Early Childhood; and Council on School Health

ABSTRACT. School readiness includes the readiness of the individual child, the school's readiness for children, and the ability of the family and community to support optimal early child development. It is the responsibility of schools to meet the needs of all children at all levels of readiness. Children's readiness for kindergarten should become an outcome measure for a coordinated system of community-based programs and supports for the healthy development of young children. Our rapidly expanding insights into early brain and child development have revealed that modifiable factors in a child's early experience can greatly affect that child's health and learning trajectories. Many children in the United States enter kindergarten with limitations in their social, emotional, cognitive, and physical development that might have been significantly diminished or eliminated through early identification and attention to child and family needs. A strong correlation between social-emotional development and school and life success, combined with alarming rates of preschool expulsion, point toward the urgency of leveraging opportunities to support social-emotional development and address behavioral concerns early. Pediatric primary care providers have access to the youngest children and their families. Pediatricians can promote and use community supports, such as home visiting programs, quality early care and education programs, family support programs and resources, early intervention services, children's museums, and libraries, which are important for addressing school readiness and are too often underused by populations who can benefit most from them. When these are not available, pediatricians can support the development of such resources. The American Academy of Pediatrics affords pediatricians many opportunities to improve the physical, social-emotional, and educational health of young children, in conjunction with other advocacy groups. This technical report provides an updated version of the previous iteration from the American Academy of Pediatrics published in 2008. (7/19)

SCHOOL START TIMES FOR ADOLESCENTS

Adolescent Sleep Working Group, Committee on Adolescence, and Council on School Health

ABSTRACT. The American Academy of Pediatrics recognizes insufficient sleep in adolescents as an important public health issue that significantly affects the health and safety, as well as the academic success, of our nation's middle and high school students. Although a number of factors, including biological changes in sleep associated with puberty, lifestyle choices, and academic demands, negatively affect middle and high school students' ability to obtain sufficient sleep, the evidence strongly implicates earlier school start times (ie, before 8:30 AM) as a key modifiable contributor to insufficient sleep, as well as circadian rhythm disruption, in this population. Furthermore, a substantial body of research has now demonstrated that delaying school start times is an effective countermeasure to chronic sleep loss and has a wide range of potential benefits to students with regard to physical and mental health, safety, and academic achievement. The American Academy of Pediatrics strongly supports the efforts of school districts to optimize sleep in students and urges high schools and middle schools to aim for start times that allow students the opportunity to achieve optimal levels of sleep (8.5–9.5 hours) and to improve physical (eg, reduced obesity risk) and mental (eg, lower rates of depression) health, safety (eg, drowsy driving crashes), academic performance, and quality of life. (8/14)
https://doi.org/10.1542/peds.2014-1697

SCHOOL TRANSPORTATION SAFETY

Committee on Injury, Violence, and Poison Prevention and Council on School Health

ABSTRACT. This policy statement replaces the previous version published in 1996. It provides new information, studies, regulations, and recommendations related to the safe transportation of children to and from school and school-related activities. Pediatricians can play an important role at the patient/family, community, state, and national levels as child advocates and consultants to schools and early education programs about transportation safety. (7/07, reaffirmed 10/11)
https://doi.org/10.1542/peds.2007-1278

SCHOOL-AGED CHILDREN WHO ARE NOT PROGRESSING ACADEMICALLY: CONSIDERATIONS FOR PEDIATRICIANS (CLINICAL REPORT)

Celiane Rey-Casserly, PhD; Laura McGuinn, MD, FAAP; Arthur Lavin, MD, FAAP; Committee on Psychosocial Aspects of Child and Family Health; Section on Developmental and Behavioral Pediatrics

ABSTRACT. Pediatricians and other pediatric primary care providers may be consulted when families have concerns that their child is not making expected progress in school. Pediatricians care not only for an increasingly diverse population of children who may have behavioral, psychological, and learning difficulties but also for increasing numbers of children with complex and chronic medical problems that can affect the development of the central nervous system and can present with learning and academic concerns. In many instances, pediatric providers require additional information about the nature of cognitive, psychosocial, and educational difficulties that affect their school-aged patients. Our purpose for this report is to describe the current state of the science regarding educational achievement to inform pediatricians' decisions regarding further evaluation of a child's challenges. In this report, we review commonly available options for psychological evaluation and/or treatment, medical referrals, and/or recommendations for referral for eligibility determinations at school and review strategies for collaborating with families, schools, and specialists to best serve children and families. (9/19)

https://doi.org/10.1542/peds.2019-2520

SCHOOL-BASED HEALTH CENTERS AND PEDIATRIC PRACTICE

Chris Kjolhede, MD, MPH, FAAP; April C. Lee, MD, FAAP; and Council on School Health

ABSTRACT. School-based health centers (SBHCs) are unique health care settings for our nation's school-aged children and adolescents. SBHCs represent the collaboration between the health and school communities to support the health and mental health needs and the academic achievements of children and adolescents, particularly students with health disparities or poor access to health care. SBHCs improve access to health care services for students by decreasing financial, geographic, age, and cultural barriers. This policy statement provides an overview of SBHCs, including the scope of services as well as some of the documented benefits and challenges. This policy statement also reviews the role of SBHCs in working with the pediatric medical home and provides recommendations that support the coordination of SBHCs with pediatric primary care providers and the pediatric medical home. SCOPE OF HEALTH CARE BENEFITS FOR CHILDREN FROM BIRTH THROUGH AGE 26

Committee on Child Health Financing

ABSTRACT. The optimal health of all children is best achieved with access to appropriate and comprehensive health care benefits. This policy statement outlines and defines the recommended set of health insurance benefits for children through age 26. The American Academy of Pediatrics developed a set of recommendations concerning preventive care services for children, adolescents, and young adults. These recommendations are compiled in the publication *Bright Futures: Guidelines for Health Supervision of Infants, Children, and Adolescents,* third edition. The Bright Futures recommendations were referenced as a standard for access and design of age-appropriate health insurance benefits for infants, children, adolescents, and young adults in the Patient Protection and Affordable Care Act of 2010 (Pub L No. 114–148). (12/11)

https://doi.org/10.1542/peds.2011-2936

SCOPE OF PRACTICE ISSUES IN THE DELIVERY OF PEDIATRIC HEALTH CARE

Committee on Pediatric Workforce

ABSTRACT. The American Academy of Pediatrics (AAP) believes that optimal pediatric health care depends on a team-based approach with supervision by a physician leader, preferably a pediatrician. The pediatrician, here defined to include not only pediatric generalists but all pediatric medical subspecialists, all surgical specialists, and internal medicine/pediatric physicians, is uniquely qualified to manage, coordinate, and supervise the entire spectrum of pediatric care, from diagnosis through all stages of treatment, in all practice settings. The AAP recognizes the valuable contributions of nonphysician clinicians, including nurse practitioners and physician assistants, in delivering optimal pediatric care. However, the expansion of the scope of practice of nonphysician pediatric clinicians raises critical public policy and child health advocacy concerns. Pediatricians should serve as advocates for optimal pediatric care in state legislatures, public policy forums, and the media and should pursue opportunities to resolve scope of practice conflicts outside state legislatures. The AAP affirms the importance of appropriate documentation and standards in pediatric education, training, skills, clinical competencies, examination, regulation, and patient care to ensure safety and quality health care for all infants, children, adolescents, and young adults. (5/13, reaffirmed 10/15)

SCREENING EXAMINATION OF PREMATURE INFANTS FOR RETINOPATHY OF PREMATURITY

Walter M. Fierson, MD, FAAP, and Section on Ophthalmology (joint with American Academy of Ophthalmology, American Association for Pediatric Ophthalmology and Strabismus, and American Association of Certified Orthoptists)

ABSTRACT. This policy statement revises a previous statement on screening of preterm infants for retinopathy of prematurity (ROP) that was published in 2013. ROP is a pathologic process that occurs in immature retinal tissue and can progress to a tractional retinal detachment, which may then result in visual loss or blindness. For more than 3 decades, treatment of severe ROP that markedly decreases the incidence of this poor visual outcome has been available. However, severe, treatment-requiring ROP must be diagnosed in a timely fashion to be treated effectively. The sequential nature of ROP requires that infants who are at-risk and preterm be examined at proper times and intervals to detect the changes of ROP before they become destructive. This statement presents the attributes of an effective program to detect and treat ROP, including the timing of initial and follow-up examinations. (11/18)

https://doi.org/10.1542/peds.2018-3061

SCREENING FOR NONVIRAL SEXUALLY TRANSMITTED INFECTIONS IN ADOLESCENTS AND YOUNG ADULTS

Committee on Adolescence (joint with Society for Adolescent Health and Medicine)

ABSTRACT. Prevalence rates of many sexually transmitted infections (STIs) are highest among adolescents. If nonviral STIs are detected early, they can be treated, transmission to others can be eliminated, and sequelae can be averted. The US Preventive Services Task Force and the Centers for Disease Control and Prevention have published chlamydia, gonorrhea, and syphilis screening guidelines that recommend screening those at risk on the basis of epidemiologic and clinical outcomes data. This policy statement specifically focuses on these curable, nonviral STIs and

reviews the evidence for nonviral STI screening in adolescents, communicates the value of screening, and outlines recommendations for routine nonviral STI screening of adolescents. (6/14)
https://doi.org/10.1542/peds.2014-1024

SCREENING FOR RETINOPATHY IN THE PEDIATRIC PATIENT WITH TYPE 1 DIABETES MELLITUS (CLINICAL REPORT)

Gregg T. Lueder, MD; Janet Silverstein, MD; Section on Ophthalmology; and Section on Endocrinology (joint with American Association for Pediatric Ophthalmology and Strabismus)

ABSTRACT. Diabetic retinopathy (DR) is the leading cause of blindness in young adults in the United States. Early identification and treatment of DR can decrease the risk of vision loss in affected patients. This clinical report reviews the risk factors for the development of DR and screening guidance for pediatric patients with type 1 diabetes mellitus. (7/05, reaffirmed 1/09, 7/14, 11/19)
https://doi.org/10.1542/peds.2005-0875

SELECTING APPROPRIATE TOYS FOR YOUNG CHILDREN IN THE DIGITAL ERA (CLINICAL REPORT)

Aleeya Healey, MD, FAAP; Alan Mendelsohn, MD, FAAP; and Council on Early Childhood

ABSTRACT. Play is essential to optimal child development because it contributes to the cognitive, physical, social, and emotional well-being of children and youth. It also offers an ideal and significant opportunity for parents and other caregivers to engage fully with children using toys as an instrument of play and interaction. The evolution of societal perceptions of toys from children's playthings to critical facilitators of early brain and child development has challenged caregivers in deciding which toys are most appropriate for their children. This clinical report strives to provide pediatric health care providers with evidence-based information that can be used to support caregivers as they choose toys for their children. The report highlights the broad definition of a toy; consideration of potential benefits and possible harmful effects of toy choices on child development; and the promotion of positive caregiving and development when toys are used to engage caregivers in play-based interactions with their children that are rich in language, pretending, problem-solving, and creativity. The report aims to address the evolving replacement of more traditional toys with digital media–based virtual "toys" and the lack of evidence for similar benefits in child development. Furthermore, this report briefly addresses the role of toys in advertising and/or incentive programs and aims to bring awareness regarding safety and health hazards associated with toy availability and accessibility in public settings, including some health care settings. (12/18)

SENSORY INTEGRATION THERAPIES FOR CHILDREN WITH DEVELOPMENTAL AND BEHAVIORAL DISORDERS

Section on Complementary and Integrative Medicine and Council on Children With Disabilities

ABSTRACT. Sensory-based therapies are increasingly used by occupational therapists and sometimes by other types of therapists in treatment of children with developmental and behavioral disorders. Sensory-based therapies involve activities that are believed to organize the sensory system by providing vestibular, proprioceptive, auditory, and tactile inputs. Brushes, swings, balls, and other specially designed therapeutic or recreational equipment are used to provide these inputs. However, it is unclear whether children who present with sensory-based problems have an actual "disorder" of the sensory pathways of the brain or whether these deficits are characteristics associated with other developmental and behavioral disorders. Because there is no universally accepted framework for diagnosis, sensory processing disorder generally should not be diagnosed. Other developmental and behavioral disorders must always be considered, and a thorough evaluation should be completed. Difficulty tolerating or processing sensory information is a characteristic that may be seen in many developmental behavioral disorders, including autism spectrum disorders, attention-deficit/hyperactivity disorder, developmental coordination disorders, and childhood anxiety disorders.

Occupational therapy with the use of sensory-based therapies may be acceptable as one of the components of a comprehensive treatment plan. However, parents should be informed that the amount of research regarding the effectiveness of sensory integration therapy is limited and inconclusive. Important roles for pediatricians and other clinicians may include discussing these limitations with parents, talking with families about a trial period of sensory integration therapy, and teaching families how to evaluate the effectiveness of a therapy. (5/12)
https://doi.org/10.1542/peds.2012-0876

SEXUAL AND REPRODUCTIVE HEALTH CARE SERVICES IN THE PEDIATRIC SETTING (CLINICAL REPORT)

Arik V. Marcell, MD, MPH; Gale R. Burstein, MD, MPH; and Committee on Adolescence

ABSTRACT. Pediatricians are an important source of health care for adolescents and young adults and can play a significant role in addressing their patients' sexual and reproductive health needs, including preventing unintended pregnancies and sexually transmitted infections (STIs), including HIV, and promoting healthy relationships. STIs, HIV, and unintended pregnancy are all preventable health outcomes with potentially serious permanent sequelae; the highest rates of STIs, HIV, and unintended pregnancy are reported among adolescents and young adults. Office visits present opportunities to provide comprehensive education and health care services to adolescents and young adults to prevent STIs, HIV, and unintended pregnancies. The American Academy of Pediatrics, other professional medical organizations, and the government have guidelines and recommendations regarding the provision of sexual and reproductive health information and services. However, despite these recommendations, recent studies have revealed that there is substantial room for improvement in actually delivering the recommended services. The purpose of this clinical report is to assist pediatricians to operationalize the provision of various aspects of sexual and reproductive health care into their practices and to provide guidance on overcoming barriers to providing this care routinely while maximizing opportunities for confidential health services delivery in their offices. (10/17)
https://doi.org/10.1542/peds.2017-2858

SEXUALITY EDUCATION FOR CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Cora C. Breuner, MD, MPH, FAAP; Gerri Mattson, MD, MSPH, FAAP; Committee on Adolescence; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. The purpose of this clinical report is to provide pediatricians updated research on evidence-based sexual and reproductive health education conducted since the original clinical report on the subject was published by the American Academy of Pediatrics in 2001. Sexuality education is defined as teaching about human sexuality, including intimate relationships, human sexual anatomy, sexual reproduction, sexually transmitted infections, sexual activity, sexual orientation, gender identity, abstinence, contraception, and reproductive rights and responsibilities. Developmentally appropriate and evidence-based education about human sexuality and sexual reproduction over time provided by pediatricians, schools, other professionals, and parents is important to help children and adolescents

make informed, positive, and safe choices about healthy relationships, responsible sexual activity, and their reproductive health. Sexuality education has been shown to help to prevent and reduce the risks of adolescent pregnancy, HIV, and sexually transmitted infections for children and adolescents with and without chronic health conditions and disabilities in the United States. (7/16)
https://doi.org/10.1542/peds.2016-1348

SHARED DECISION-MAKING AND CHILDREN WITH DISABILITIES: PATHWAYS TO CONSENSUS (CLINICAL REPORT)

Richard C. Adams, MD, FAAP; Susan E. Levy, MD, MPH, FAAP; and Council on Children With Disabilities

ABSTRACT. Shared decision-making (SDM) promotes family and clinician collaboration, with ultimate goals of improved health and satisfaction. This clinical report provides a basis for a systematic approach to the implementation of SDM by clinicians for children with disabilities. Often in the discussion of treatment plans, there are gaps between the child's/family's values, priorities, and understanding of perceived "best choices" and those of the clinician. When conducted well, SDM affords an appropriate balance incorporating voices of all stakeholders, ultimately supporting both the child/family and clinician. With increasing knowledge of and functional use of SDM skills, the clinician will become an effective partner in the decision-making process with families, providing family-centered care. The outcome of the process will support the beneficence of the physician, the authority of the family, and the autonomy and well-being of the child. (5/17)
https://doi.org/10.1542/peds.2017-0956

SHOPPING CART–RELATED INJURIES TO CHILDREN

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Shopping cart–related injuries to children are common and can result in severe injury or even death. Most injuries result from falls from carts or cart tip-overs, and injuries to the head and neck represent three fourths of cases. The current US standard for shopping carts should be revised to include clear and effective performance criteria to prevent falls from carts and cart tip-overs. Pediatricians have an important role as educators, researchers, and advocates to promote the prevention of these injuries. (8/06, reaffirmed 4/09, 8/13)
https://doi.org/10.1542/peds.2006-1215

SHOPPING CART–RELATED INJURIES TO CHILDREN (TECHNICAL REPORT)

Gary A. Smith, MD, DrPH, for Committee on Injury, Violence, and Poison Prevention

ABSTRACT. An estimated 24 200 children younger than 15 years, 20 700 (85%) of whom were younger than 5 years, were treated in US hospital emergency departments in 2005 for shopping cart–related injuries. Approximately 4% of shopping cart–related injuries to children younger than 15 years require admission to the hospital. Injuries to the head and neck represent three fourths of all injuries. Fractures account for 45% of all hospitalizations. Deaths have occurred from falls from shopping carts and cart tip-overs. Falls are the most common mechanism of injury and account for more than half of injuries associated with shopping carts. Cart tip-overs are the second most common mechanism, responsible for up to one fourth of injuries and almost 40% of shopping cart–related injuries among children younger than 2 years. Public-awareness initiatives, education programs, and parental supervision, although important, are not enough to prevent these injuries effectively. European Standard EN 1929-1:1998 and joint Australian/New Zealand Standard AS/NZS 3847.1:1999 specify requirements for the construction, performance, testing, and safety of shopping carts and have been implemented as national standards in 21 countries. A US performance standard for shopping carts (ASTM [American Society for Testing and Materials] F2372-04) was established in July 2004; however, it does not adequately address falls and cart tip-overs, which are the leading mechanisms of shopping cart–related injuries to children. The current US standard for shopping carts should be revised to include clear and effective performance criteria for shopping cart child-restraint systems and cart stability to prevent falls from carts and cart tip-overs. This is imperative to decrease the number and severity of shopping cart–related injuries to children. Recommendations from the American Academy of Pediatrics regarding prevention of shopping cart–related injuries are included in the accompanying policy statement. (8/06, reaffirmed 4/09, 8/13)

SIDS AND OTHER SLEEP-RELATED INFANT DEATHS: EVIDENCE BASE FOR 2016 UPDATED RECOMMENDATIONS FOR A SAFE INFANT SLEEPING ENVIRONMENT (TECHNICAL REPORT)

Rachel Y. Moon, MD, FAAP, and Task Force on Sudden Infant Death Syndrome

ABSTRACT. Approximately 3500 infants die annually in the United States from sleep-related infant deaths, including sudden infant death syndrome (SIDS), ill-defined deaths, and accidental suffocation and strangulation in bed. After an initial decrease in the 1990s, the overall sleep-related infant death rate has not declined in more recent years. Many of the modifiable and nonmodifiable risk factors for SIDS and other sleep-related infant deaths are strikingly similar. The American Academy of Pediatrics recommends a safe sleep environment that can reduce the risk of all sleep-related infant deaths. Recommendations for a safe sleep environment include supine positioning, use of a firm sleep surface, room-sharing without bed-sharing, and avoidance of soft bedding and overheating. Additional recommendations for SIDS risk reduction include avoidance of exposure to smoke, alcohol, and illicit drugs; breastfeeding; routine immunization; and use of a pacifier. New evidence and rationale for recommendations are presented for skin-to-skin care for newborn infants, bedside and in-bed sleepers, sleeping on couches/armchairs and in sitting devices, and use of soft bedding after 4 months of age. In addition, expanded recommendations for infant sleep location are included. The recommendations and strength of evidence for each recommendation are published in the accompanying policy statement, "SIDS and Other Sleep-Related Infant Deaths: Updated 2016 Recommendations for a Safe Infant Sleeping Environment," which is included in this issue. (10/16)
https://doi.org/10.1542/peds.2016-2940

SIDS AND OTHER SLEEP-RELATED INFANT DEATHS: EXPANSION OF RECOMMENDATIONS FOR A SAFE INFANT SLEEPING ENVIRONMENT

Rachel Y. Moon, MD, FAAP, and Task Force on Sudden Infant Death Syndrome

ABSTRACT. Despite a major decrease in the incidence of sudden infant death syndrome (SIDS) since the American Academy of Pediatrics (AAP) released its recommendation in 1992 that infants be placed for sleep in a nonprone position, this decline has plateaued in recent years. Concurrently, other causes of sudden unexpected infant death that occur during sleep (sleep-related deaths), including suffocation, asphyxia, and entrapment, and ill-defined or unspecified causes of death have increased in incidence, particularly since the AAP published its last statement on SIDS in 2005. It has become increasingly important to address these other causes of sleep-related infant death. Many of the modifiable and nonmodifiable risk factors for SIDS and suffocation are strikingly similar. The AAP, therefore, is expanding its recommendations from focusing only on SIDS to

focusing on a safe sleep environment that can reduce the risk of all sleep-related infant deaths, including SIDS. The recommendations described in this policy statement include supine positioning, use of a firm sleep surface, breastfeeding, room-sharing without bed-sharing, routine immunizations, consideration of using a pacifier, and avoidance of soft bedding, overheating, and exposure to tobacco smoke, alcohol, and illicit drugs. The rationale for these recommendations is discussed in detail in the accompanying "Technical Report—SIDS and Other Sleep-Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment," which is included in this issue of *Pediatrics* (www.pediatrics.org/cgi/content/full/128/5/e1341). (4/11, reaffirmed 10/20)
https://doi.org/10.1542/peds.2011-2284

SIDS AND OTHER SLEEP-RELATED INFANT DEATHS: EXPANSION OF RECOMMENDATIONS FOR A SAFE INFANT SLEEPING ENVIRONMENT (TECHNICAL REPORT)

Rachel Y. Moon, MD, FAAP, and Task Force on Sudden Infant Death Syndrome

ABSTRACT. Despite a major decrease in the incidence of sudden infant death syndrome (SIDS) since the American Academy of Pediatrics (AAP) released its recommendation in 1992 that infants be placed for sleep in a nonprone position, this decline has plateaued in recent years. Concurrently, other causes of sudden unexpected infant death occurring during sleep (sleep-related deaths), including suffocation, asphyxia, and entrapment, and ill-defined or unspecified causes of death have increased in incidence, particularly since the AAP published its last statement on SIDS in 2005. It has become increasingly important to address these other causes of sleep-related infant death. Many of the modifiable and nonmodifiable risk factors for SIDS and suffocation are strikingly similar. The AAP, therefore, is expanding its recommendations from being only SIDS-focused to focusing on a safe sleep environment that can reduce the risk of all sleep-related infant deaths including SIDS. The recommendations described in this report include supine positioning, use of a firm sleep surface, breastfeeding, room-sharing without bed-sharing, routine immunization, consideration of a pacifier, and avoidance of soft bedding, overheating, and exposure to tobacco smoke, alcohol, and illicit drugs. The rationale for these recommendations is discussed in detail in this technical report. The recommendations are published in the accompanying "Policy Statement—Sudden Infant Death Syndrome and Other Sleep-Related Infant Deaths: Expansion of Recommendations for a Safe Infant Sleeping Environment," which is included in this issue (www.pediatrics.org/cgi/doi/10.1542/peds.2011-2220). (4/11, reaffirmed 10/20)

SIDS AND OTHER SLEEP-RELATED INFANT DEATHS: UPDATED 2016 RECOMMENDATIONS FOR A SAFE INFANT SLEEPING ENVIRONMENT

Task Force on Sudden Infant Death Syndrome

ABSTRACT. Approximately 3500 infants die annually in the United States from sleep-related infant deaths, including sudden infant death syndrome (SIDS; International Classification of Diseases, 10th Revision [ICD-10], R95), ill-defined deaths (ICD-10 R99), and accidental suffocation and strangulation in bed (ICD-10 W75). After an initial decrease in the 1990s, the overall death rate attributable to sleep-related infant deaths has not declined in more recent years. Many of the modifiable and nonmodifiable risk factors for SIDS and other sleep-related infant deaths are strikingly similar. The American Academy of Pediatrics recommends a safe sleep environment that can reduce the risk of all sleep-related infant deaths. Recommendations for a safe sleep environment include supine positioning, the use of a firm sleep surface, room-sharing without bed-sharing, and the avoidance of soft bedding and overheating. Additional recommendations for SIDS reduction include the avoidance of exposure to smoke, alcohol, and illicit drugs; breastfeeding; routine immunization; and use of a pacifier. New evidence is presented for skin-to-skin care for newborn infants, use of bedside and in-bed sleepers, sleeping on couches/armchairs and in sitting devices, and use of soft bedding after 4 months of age. The recommendations and strength of evidence for each recommendation are included in this policy statement. The rationale for these recommendations is discussed in detail in the accompanying technical report (www.pediatrics.org/cgi/doi/10.1542/peds.2016-2940). (10/16)

SKATEBOARD AND SCOOTER INJURIES

Committee on Injury, Violence, and Poison Prevention

ABSTRACT. Skateboard-related injuries account for an estimated 50 000 emergency department visits and 1500 hospitalizations among children and adolescents in the United States each year. Nonpowered scooter-related injuries accounted for an estimated 9400 emergency department visits between January and August 2000, and 90% of these patients were children younger than 15 years. Many such injuries can be avoided if children and youth do not ride in traffic, if proper protective gear is worn, and if, in the absence of close adult supervision, skateboards and scooters are not used by children younger than 10 and 8 years, respectively. (3/02, reaffirmed 5/05, 10/08, 10/13)
https://doi.org/10.1542/peds.109.3.542

SKIN-TO-SKIN CARE FOR TERM AND PRETERM INFANTS IN THE NEONATAL ICU (CLINICAL REPORT)

Jill Baley, MD, and Committee on Fetus and Newborn

ABSTRACT. "Kangaroo mother care" was first described as an alternative method of caring for low birth weight infants in resource-limited countries, where neonatal mortality and infection rates are high because of overcrowded nurseries, inadequate staffing, and lack of equipment. Intermittent skin-to-skin care (SSC), a modified version of kangaroo mother care, is now being offered in resource-rich countries to infants needing neonatal intensive care, including those who require ventilator support or are extremely premature. SSC significantly improves milk production by the mother and is associated with a longer duration of breastfeeding. Increased parent satisfaction, better sleep organization, a longer duration of quiet sleep, and decreased pain perception during procedures have also been reported in association with SSC. Despite apparent physiologic stability during SSC, it is prudent that infants in the NICU have continuous cardiovascular monitoring and that care be taken to verify correct head positioning for airway patency as well as the stability of the endotracheal tube, arterial and venous access devices, and other life support equipment. SNACKS, SWEETENED BEVERAGES, ADDED SUGARS, AND SCHOOLS

Council on School Health and Committee on Nutrition

ABSTRACT. Concern over childhood obesity has generated a decade-long reformation of school nutrition policies. Food is available in school in 3 venues: federally sponsored school meal programs; items sold in competition to school meals, such as a la carte, vending machines, and school stores; and foods available in myriad informal settings, including packed meals and snacks, bake sales, fundraisers, sports booster sales, in-class parties, or other school celebrations. High-energy, low-nutrient beverages, in particular, contribute substantial calories, but little nutrient content, to a student's diet. In 2004, the American Academy of Pediatrics recommended that sweetened drinks be replaced in school by water, white and flavored milks, or 100% fruit and vegetable beverages. Since then, school nutrition has undergone

a significant transformation. Federal, state, and local regulations and policies, along with alternative products developed by industry, have helped decrease the availability of nutrient-poor foods and beverages in school. However, regular access to foods of high energy and low quality remains a school issue, much of it attributable to students, parents, and staff. Pediatricians, aligning with experts on child nutrition, are in a position to offer a perspective promoting nutrient-rich foods within calorie guidelines to improve those foods brought into or sold in schools. A positive emphasis on nutritional value, variety, appropriate portion, and encouragement for a steady improvement in quality will be a more effective approach for improving nutrition and health than simply advocating for the elimination of added sugars. (2/15)
https://doi.org/10.1542/peds.2014-3902

SNOWMOBILING HAZARDS

Committee on Injury and Poison Prevention

ABSTRACT. Snowmobiles continue to pose a significant risk to children younger than 15 years and adolescents and young adults 15 through 24 years of age. Head injuries remain the leading cause of mortality and serious morbidity, arising largely from snowmobilers colliding, falling, or overturning during operation. Children also were injured while being towed in a variety of conveyances by snowmobiles. No uniform code of state laws governs the use of snowmobiles by children and youth. Because evidence is lacking to support the effectiveness of operator safety certification and because many children and adolescents do not have the required strength and skills to operate a snowmobile safely, the recreational operation of snowmobiles by persons younger than 16 years is not recommended. Snowmobiles should not be used to tow persons on a tube, tire, sled, or saucer. Furthermore, a graduated licensing program is advised for snowmobilers 16 years and older. Both active and passive snowmobile injury prevention strategies are suggested, as well as recommendations for manufacturers to make safer equipment for snowmobilers of all ages. SOCCER INJURIES IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Andrew Watson, MD, MS, FAAP; Jeffrey M. Mjaanes, MD, FAAP; Council on Sports Medicine and Fitness

ABSTRACT. Participation in youth soccer in the United States continues to increase steadily, with a greater percentage of preadolescent participants than perhaps any other youth sport. Despite the wide-ranging health benefits of participation in organized sports, injuries occur and represent a threat to the health and performance of young athletes. Youth soccer has a greater reported injury rate than many other contact sports, and recent studies suggest that injury rates are increasing. Large increases in the incidence of concussions in youth soccer have been reported, and anterior cruciate ligament injuries remain a significant problem in this sport, particularly among female athletes. Considerable new research has identified a number of modifiable risk factors for lower-extremity injuries and concussion, and several prevention programs have been identified to reduce the risk of injury. Rule enforcement and fair play also serve an important role in reducing the risk of injury among youth soccer participants. This report provides an updated review of the relevant literature as well as recommendations to promote the safe participation of children and adolescents in soccer. (10/19)
https://doi.org/10.1542/peds.2019-2759

SPECIAL REQUIREMENTS OF ELECTRONIC HEALTH RECORD SYSTEMS IN PEDIATRICS (CLINICAL REPORT)

S. Andrew Spooner, MD, MS, and Council on Clinical Information Technology

ABSTRACT. Some functions of an electronic health record system are much more important in providing pediatric care than in adult care. Pediatricians commonly complain about the absence of these "pediatric functions" when they are not available in electronic health record systems. To stimulate electronic health record system vendors to recognize and incorporate pediatric functionality into pediatric electronic health record systems, this clinical report reviews the major functions of importance to child health care providers. Also reviewed are important but less critical functions, any of which might be of major importance in a particular clinical context. The major areas described here are immunization management, growth tracking, medication dosing, data norms, and privacy in special pediatric populations. The American Academy of Pediatrics believes that if the functions described in this document are supported in all electronic health record systems, these systems will be more useful for patients of all ages. SPECTRUM OF NONINFECTIOUS HEALTH EFFECTS FROM MOLDS

Committee on Environmental Health

ABSTRACT. Molds are eukaryotic (possessing a true nucleus) nonphotosynthetic organisms that flourish both indoors and outdoors. For humans, the link between mold exposure and asthma exacerbations, allergic rhinitis, infections, and toxicities from ingestion of mycotoxin-contaminated foods are well known. However, the cause-and-effect relationship between inhalational exposure to mold and other untoward health effects (eg, acute idiopathic pulmonary hemorrhage in infants and other illnesses and health complaints) requires additional investigation. Pediatricians play an important role in the education of families about mold, its adverse health effects, exposure prevention, and remediation procedures. (12/06, reaffirmed 9/16)
https://doi.org/10.1542/peds.2006-2828

SPECTRUM OF NONINFECTIOUS HEALTH EFFECTS FROM MOLDS (TECHNICAL REPORT)

Lynnette J. Mazur, MD, MPH; Janice Kim, MD, PhD, MPH; and Committee on Environmental Health

ABSTRACT. Molds are multicellular fungi that are ubiquitous in outdoor and indoor environments. For humans, they are both beneficial (for the production of antimicrobial agents, chemotherapeutic agents, and vitamins) and detrimental. Exposure to mold can occur through inhalation, ingestion, and touching moldy surfaces. Adverse health effects may occur through allergic, infectious, irritant, or toxic processes. The cause-and-effect relationship between mold exposure and allergic and infectious illnesses is well known. Exposures to toxins via the gastrointestinal tract also are well described. However, the cause-and-effect relationship between inhalational exposure to mold toxins and other untoward health effects (eg, acute idiopathic pulmonary hemorrhage in infants and other illnesses and health complaints) is controversial and requires additional investigation. In this report we examine evidence of fungal-related illnesses and the unique aspects of mold exposure to children. Mold-remediation procedures are also discussed. (12/06, reaffirmed 9/16)
https://doi.org/10.1542/peds.2006-2829

SPORT-RELATED CONCUSSION IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Mark E. Halstead, MD, FAAP; Kevin D. Walter, MD, FAAP; Kody Moffatt, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. Sport-related concussion is an important topic in nearly all sports and at all levels of sport for children and adolescents. Concussion knowledge and approaches to management have progressed since the American Academy of Pediatrics published its first clinical report on the subject in 2010. Concussion's definition, signs, and symptoms must be understood to diagnose it and rule out more severe intracranial injury. Pediatric health care providers should have a good understanding of diagnostic evaluation and initial management strategies. Effective management can aid recovery and potentially reduce the risk of long-term symptoms and complications. Because concussion symptoms often interfere with school, social life, family relationships, and athletics, a concussion may affect the emotional well-being of the injured athlete. Because every concussion has its own unique spectrum and severity of symptoms, individualized management is appropriate. The reduction, not necessarily elimination, of physical and cognitive activity is the mainstay of treatment. A full return to activity and/or sport is accomplished by using a stepwise program while evaluating for a return of symptoms. An understanding of prolonged symptoms and complications will help the pediatric health care provider know when to refer to a specialist. Additional research is needed in nearly all aspects of concussion in the young athlete. This report provides education on the current state of sport-related concussion knowledge, diagnosis, and management in children and adolescents. (11/18)

https://doi.org/10.1542/peds.2018-3074

SPORTS DRINKS AND ENERGY DRINKS FOR CHILDREN AND ADOLESCENTS: ARE THEY APPROPRIATE? (CLINICAL REPORT)

Committee on Nutrition and Council on Sports Medicine and Fitness

ABSTRACT. Sports and energy drinks are being marketed to children and adolescents for a wide variety of inappropriate uses. Sports drinks and energy drinks are significantly different products, and the terms should not be used interchangeably. The primary objectives of this clinical report are to define the ingredients of sports and energy drinks, categorize the similarities and differences between the products, and discuss misuses and abuses. Secondary objectives are to encourage screening during annual physical examinations for sports and energy drink use, to understand the reasons why youth consumption is widespread, and to improve education aimed at decreasing or eliminating the inappropriate use of these beverages by children and adolescents. Rigorous review and analysis of the literature reveal that caffeine and other stimulant substances contained in energy drinks have no place in the diet of children and adolescents. Furthermore, frequent or excessive intake of caloric sports drinks can substantially increase the risk for overweight or obesity in children and adolescents. Discussion regarding the appropriate use of sports drinks in the youth athlete who participates regularly in endurance or high-intensity sports and vigorous physical activity is beyond the scope of this report. (5/11, reaffirmed 7/17)

https://doi.org/10.1542/peds.2011-0965

SPORTS SPECIALIZATION AND INTENSIVE TRAINING IN YOUNG ATHLETES (CLINICAL REPORT)

Joel S. Brenner, MD, MPH, FAAP, and Council on Sports Medicine and Fitness

ABSTRACT. Sports specialization is becoming the norm in youth sports for a variety of reasons. When sports specialization occurs too early, detrimental effects may occur, both physically and psychologically. If the timing is correct and sports specialization is performed under the correct conditions, the athlete may be successful in reaching specific goals. Young athletes who train intensively, whether specialized or not, can also be at risk of adverse effects on the mind and body. The purpose of this clinical report is to assist pediatricians in counseling their young athlete patients and their parents regarding sports specialization and intensive training. This report supports the American Academy of Pediatrics clinical report "Overuse Injuries, Overtraining, and Burnout in Child and Adolescent Athletes." (8/16)

https://doi.org/10.1542/peds.2016-2148

STANDARD TERMINOLOGY FOR FETAL, INFANT, AND PERINATAL DEATHS (CLINICAL REPORT)

Wanda D. Barfield, MD, MPH, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Accurately defining and reporting perinatal deaths (ie, fetal and infant deaths) is a critical first step in understanding the magnitude and causes of these important events. In addition to obstetric health care providers, neonatologists and pediatricians should have easy access to current and updated resources that clearly provide US definitions and reporting requirements for live births, fetal deaths, and infant deaths. Correct identification of these vital events will improve local, state, and national data so that these deaths can be better addressed and prevented. (4/16)

https://doi.org/10.1542/peds.2011-0965

STANDARDIZATION OF INPATIENT HANDOFF COMMUNICATION (CLINICAL REPORT)

Jennifer A. Jewell, MD, FAAP, and Committee on Hospital Care

ABSTRACT. Handoff communication is identified as an integral part of hospital care. Throughout medical communities, inadequate handoff communication is being highlighted as a significant risk to patients. The complexity of hospitals and the number of providers involved in the care of hospitalized patients place inpatients at high risk of communication lapses. This miscommunication and the potential resulting harm make effective handoffs more critical than ever. Although hospitalized patients are being exposed to many handoffs each day, this report is limited to describing the best handoff practices between providers at the time of shift change. (10/16)

https://doi.org/10.1542/peds.2016-2681

STANDARDS FOR HEALTH INFORMATION TECHNOLOGY TO ENSURE ADOLESCENT PRIVACY

Committee on Adolescence and Council on Clinical Information Technology

ABSTRACT. Privacy and security of health information is a basic expectation of patients. Despite the existence of federal and state laws safeguarding the privacy of health information, health information systems currently lack the capability to allow for protection of this information for minors. This policy statement reviews the challenges to privacy for adolescents posed by commercial health information technology systems and recommends basic principles for ideal electronic health record systems. This policy statement has been endorsed by the Society for Adolescent Health and Medicine. (10/12, reaffirmed 12/18)

https://doi.org/10.1542/peds.2012-2580

STANDARDS FOR PEDIATRIC CANCER CENTERS

Section on Hematology/Oncology

ABSTRACT. Since the American Academy of Pediatrics–published guidelines for pediatric cancer centers in 1986, 1997, and 2004, significant changes in the delivery of health care have prompted a review of the role of medical centers in the care of pediatric patients. The potential effect of these changes on the treatment and survival rates of children with cancer led to this revision. The intent of this statement is to delineate personnel, capabilities, and facilities that are essential to provide state-of-

the-art care for children, adolescents, and young adults with cancer. This statement emphasizes the importance of board-certified pediatric hematologists/oncologists and appropriately qualified pediatric medical subspecialists and pediatric surgical specialists overseeing patient care and the need for specialized facilities as essential for the initial management and much of the follow-up for pediatric, adolescent, and young adult patients with cancer. For patients without practical access to a pediatric cancer center, care may be provided locally by a primary care physician or adult oncologist but at the direction of a pediatric oncologist. (7/14, reaffirmed 10/18)

STIGMA EXPERIENCED BY CHILDREN AND ADOLESCENTS WITH OBESITY

Stephen J. Pont, MD, MPH, FAAP; Rebecca Puhl, PhD, FTOS; Stephen R. Cook, MD, MPH, FAAP, FTOS; Wendelin Slusser, MD, MS, FAAP; and Section on Obesity (joint with The Obesity Society)

ABSTRACT. The stigmatization of people with obesity is widespread and causes harm. Weight stigma is often propagated and tolerated in society because of beliefs that stigma and shame will motivate people to lose weight. However, rather than motivating positive change, this stigma contributes to behaviors such as binge eating, social isolation, avoidance of health care services, decreased physical activity, and increased weight gain, which worsen obesity and create additional barriers to healthy behavior change. Furthermore, experiences of weight stigma also dramatically impair quality of life, especially for youth. Health care professionals continue to seek effective strategies and resources to address the obesity epidemic; however, they also frequently exhibit weight bias and stigmatizing behaviors. This policy statement seeks to raise awareness regarding the prevalence and negative effects of weight stigma on pediatric patients and their families and provides 6 clinical practice and 4 advocacy recommendations regarding the role of pediatricians in addressing weight stigma. In summary, these recommendations include improving the clinical setting by modeling best practices for nonbiased behaviors and language; using empathetic and empowering counseling techniques, such as motivational interviewing, and addressing weight stigma and bullying in the clinic visit; advocating for inclusion of training and education about weight stigma in medical schools, residency programs, and continuing medical education programs; and empowering families to be advocates to address weight stigma in the home environment and school setting. (11/17)

STRATEGIES FOR PREVENTION OF HEALTH CARE–ASSOCIATED INFECTIONS IN THE NICU (CLINICAL REPORT)

Richard A. Polin, MD; Susan Denson, MD; Michael T. Brady, MD; Committee on Fetus and Newborn; and Committee on Infectious Diseases

ABSTRACT. Health care–associated infections in the NICU result in increased morbidity and mortality, prolonged lengths of stay, and increased medical costs. Neonates are at high risk of acquiring health care–associated infections because of impaired host-defense mechanisms, limited amounts of protective endogenous flora on skin and mucosal surfaces at time of birth, reduced barrier function of their skin, use of invasive procedures and devices, and frequent exposure to broad-spectrum antibiotic agents. This clinical report reviews management and prevention of health care–associated infections in newborn infants. (3/12, reaffirmed 2/16)
https://doi.org/10.1542/peds.2012-0145

SUBSTANCE USE SCREENING, BRIEF INTERVENTION, AND REFERRAL TO TREATMENT

Committee on Substance Use and Prevention

ABSTRACT. The enormous public health impact of adolescent substance use and its preventable morbidity and mortality show the need for the health care sector, including pediatricians and the medical home, to increase its capacity related to substance use prevention, detection, assessment, and intervention. The American Academy of Pediatrics published its policy statement "Substance Use Screening, Brief Intervention, and Referral to Treatment for Pediatricians" in 2011 to introduce the concepts and terminology of screening, brief intervention, and referral to treatment (SBIRT) and to offer clinical guidance about available substance use screening tools and intervention procedures. This policy statement is a revision of the 2011 SBIRT statement. An accompanying clinical report updates clinical guidance for adolescent SBIRT. (6/16)
https://doi.org/10.1542/peds.2016-1210

SUBSTANCE USE SCREENING, BRIEF INTERVENTION, AND REFERRAL TO TREATMENT (CLINICAL REPORT)

Sharon J. L. Levy, MD, MPH, FAAP; Janet F. Williams, MD, FAAP; and Committee on Substance Use and Prevention

ABSTRACT. The enormous public health impact of adolescent substance use and its preventable morbidity and mortality highlight the need for the health care sector, including pediatricians and the medical home, to increase its capacity regarding adolescent substance use screening, brief intervention, and referral to treatment (SBIRT). The American Academy of Pediatrics first published a policy statement on SBIRT and adolescents in 2011 to introduce SBIRT concepts and terminology and to offer clinical guidance about available substance use screening tools and intervention procedures. This clinical report provides a simplified adolescent SBIRT clinical approach that, in combination with the accompanying updated policy statement, guides pediatricians in implementing substance use prevention, detection, assessment, and intervention practices across the varied clinical settings in which adolescents receive health care. (6/16)

SUDDEN DEATH IN THE YOUNG: INFORMATION FOR THE PRIMARY CARE PROVIDER

Christopher C. Erickson, MD, FAAP; Jack C. Salerno, MD; Stuart Berger, MD, FAAP; Robert Campbell, MD, FAAP; Bryan Cannon, MD; James Christiansen, MD; Kody Moffatt, MD, MS, FAAP; Andreas Pflaumer, MD; Christopher S. Snyder, MD, FAAP; Chandra Srinivasan, MD; Santiago O. Valdes, MD, FAAP; Victoria L. Vetter, MD, MPH, FAAP; Frank Zimmerman, MD; and Section on Cardiology and Cardiac Surgery (joint with Pediatric and Congenital Electrophysiology Society [PACES] Task Force on Prevention of Sudden Death in the Young)

ABSTRACT. There are multiple conditions that can make children prone to having a sudden cardiac arrest (SCA) or sudden cardiac death (SCD). Efforts have been made by multiple organizations to screen children for cardiac conditions, but the emphasis has been on screening before athletic competition. This article is an update of the previous American Academy of Pediatrics policy statement of 2012 that addresses prevention of SCA and SCD. This update includes a comprehensive review of conditions that should prompt more attention and cardiology evaluation. The role of the primary care provider is of paramount importance in the evaluation of children, particularly as they enter middle school or junior high. There is discussion about whether screening should find any cardiac condition or just those that are associated with SCA and SCD. This update reviews the 4 main screening questions that are recommended, not just for athletes, but for all children. There is also discussion about how to handle post-SCA and SCD situations as well as discussion about genetic

testing. It is the goal of this policy statement update to provide the primary care provider more assistance in how to screen for life-threatening conditions, regardless of athletic status. (6/21)

https://doi.org/10.1542/peds.2021-052044

SUICIDE AND SUICIDE ATTEMPTS IN ADOLESCENTS (CLINICAL REPORT)

Benjamin Shain, MD, PhD, and Committee on Adolescence

ABSTRACT. Suicide is the second leading cause of death for adolescents 15 to 19 years old. This report updates the previous statement of the American Academy of Pediatrics and is intended to assist pediatricians, in collaboration with other child and adolescent health care professionals, in the identification and management of the adolescent at risk for suicide. Suicide risk can only be reduced, not eliminated, and risk factors provide no more than guidance. Nonetheless, care for suicidal adolescents may be improved with the pediatrician's knowledge, skill, and comfort with the topic, as well as ready access to appropriate community resources and mental health professionals. (6/16, reaffirmed 10/20)

https://doi.org/10.1542/peds.2016-1420

SUPPLEMENTAL SECURITY INCOME (SSI) FOR CHILDREN AND YOUTH WITH DISABILITIES

Council on Children With Disabilities

ABSTRACT. The Supplemental Security Income (SSI) program remains an important source of financial support for low-income families of children with special health care needs and disabling conditions. In most states, SSI eligibility also qualifies children for the state Medicaid program, providing access to health care services. The Social Security Administration (SSA), which administers the SSI program, considers a child disabled under SSI if there is a medically determinable physical or mental impairment or combination of impairments that results in marked and severe functional limitations. The impairment(s) must be expected to result in death or have lasted or be expected to last for a continuous period of at least 12 months. The income and assets of families of children with disabilities are also considered when determining financial eligibility. When an individual with a disability becomes an adult at 18 years of age, the SSA considers only the individual's income and assets. The SSA considers an adult to be disabled if there is a medically determinable impairment (or combination of impairments) that prevents substantial gainful activity for at least 12 continuous months. SSI benefits are important for youth with chronic conditions who are transitioning to adulthood. The purpose of this statement is to provide updated information about the SSI medical and financial eligibility criteria and the disability-determination process. This statement also discusses how pediatricians can help children and youth when they apply for SSI benefits. (11/09, reaffirmed 2/15)

https://doi.org/10.1542/peds.2009-2557

SUPPORTING THE FAMILY AFTER THE DEATH OF A CHILD (CLINICAL REPORT)

Esther Wender, MD, and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. The death of a child can have a devastating effect on the family. The pediatrician has an important role to play in supporting the parents and any siblings still in his or her practice after such a death. Pediatricians may be poorly prepared to provide this support. Also, because of the pain of confronting the grief of family members, they may be reluctant to become involved. This statement gives guidelines to help the pediatrician provide such support. It describes the grief reactions that can be expected in family members after the death of a child. Ways of supporting family members are suggested, and other helpful resources in the community are described. The goal of this guidance is to prevent outcomes that may impair the health and development of affected parents and children. (11/12, reaffirmed 12/16)

https://doi.org/10.1542/peds.2012-2772

SUPPORTING THE GRIEVING CHILD AND FAMILY (CLINICAL REPORT)

David J. Schonfeld, MD, FAAP; Thomas Demaria, PhD; Committee on Psychosocial Aspects of Child and Family Health; and Disaster Preparedness Advisory Council

ABSTRACT. The death of someone close to a child often has a profound and lifelong effect on the child and results in a range of both short- and long-term reactions. Pediatricians, within a patient-centered medical home, are in an excellent position to provide anticipatory guidance to caregivers and to offer assistance and support to children and families who are grieving. This clinical report offers practical suggestions on how to talk with grieving children to help them better understand what has happened and its implications and to address any misinformation, misinterpretations, or misconceptions. An understanding of guilt, shame, and other common reactions, as well an appreciation of the role of secondary losses and the unique challenges facing children in communities characterized by chronic trauma and cumulative loss, will help the pediatrician to address factors that may impair grieving and children's adjustment and to identify complicated mourning and situations when professional counseling is indicated. Advice on how to support children's participation in funerals and other memorial services and to anticipate and address grief triggers and anniversary reactions is provided so that pediatricians are in a better position to advise caregivers and to offer consultation to schools, early education and child care facilities, and other child congregate care sites. Pediatricians often enter their profession out of a profound desire to minimize the suffering of children and may find it personally challenging when they find themselves in situations in which they are asked to bear witness to the distress of children who are acutely grieving. The importance of professional preparation and self-care is therefore emphasized, and resources are recommended. (8/16)

SUPPORTING THE HEALTH CARE TRANSITION FROM ADOLESCENCE TO ADULTHOOD IN THE MEDICAL HOME (CLINICAL REPORT)

Patience H. White, MD, MA, FAAP, FACP; W. Carl Cooley, MD, FAAP; American Academy of Pediatrics (joint with Transitions Clinical Report Authoring Group, American Academy of Family Physicians, and American College of Physicians)

ABSTRACT. Risk and vulnerability encompass many dimensions of the transition from adolescence to adulthood. Transition from pediatric, parent-supervised health care to more independent, patient-centered adult health care is no exception. The tenets and algorithm of the original 2011 clinical report, "Supporting the Health Care Transition from Adolescence to Adulthood in the Medical Home," are unchanged. This updated clinical report provides more practice-based quality improvement guidance on key elements of transition planning, transfer, and integration into adult care for all youth and young adults. It also includes new and updated sections on definition and guiding principles, the status of health care transition preparation among youth, barriers, outcome evidence, recommended health care transition processes and implementation strategies using quality improvement methods, special populations, education and training in pediatric onset conditions, and payment options. The clinical report also includes new recommendations pertaining to infrastructure, education and training, payment, and research. (10/18)

https://doi.org/10.1542/peds.2018-2587

SURFACTANT REPLACEMENT THERAPY FOR PRETERM AND TERM NEONATES WITH RESPIRATORY DISTRESS (CLINICAL REPORT)

Richard A. Polin, MD, FAAP; Waldemar A. Carlo, MD, FAAP; and Committee on Fetus and Newborn

ABSTRACT. Respiratory failure secondary to surfactant deficiency is a major cause of morbidity and mortality in preterm infants. Surfactant therapy substantially reduces mortality and respiratory morbidity for this population. Secondary surfactant deficiency also contributes to acute respiratory morbidity in late-preterm and term neonates with meconium aspiration syndrome, pneumonia/sepsis, and perhaps pulmonary hemorrhage; surfactant replacement may be beneficial for these infants. This statement summarizes the evidence regarding indications, administration, formulations, and outcomes for surfactant-replacement therapy. The clinical strategy of intubation, surfactant administration, and extubation to continuous positive airway pressure and the effect of continuous positive airway pressure on outcomes and surfactant use in preterm infants are also reviewed. (12/13)

https://doi.org/10.1542/peds.2013-3443

TACKLING IN YOUTH FOOTBALL

Council on Sports Medicine and Fitness

ABSTRACT. American football remains one of the most popular sports for young athletes. The injuries sustained during football, especially those to the head and neck, have been a topic of intense interest recently in both the public media and medical literature. The recognition of these injuries and the potential for long-term sequelae have led some physicians to call for a reduction in the number of contact practices, a postponement of tackling until a certain age, and even a ban on high school football. This statement reviews the literature regarding injuries in football, particularly those of the head and neck, the relationship between tackling and football-related injuries, and the potential effects of limiting or delaying tackling on injury risk. (10/15, reaffirmed 7/20)

TARGETED REFORMS IN HEALTH CARE FINANCING TO IMPROVE THE CARE OF ADOLESCENTS AND YOUNG ADULTS

Arik V. Marcell, MD, MPH, FAAP; Cora C. Breuner, MD, MPH, FAAP; Lawrence Hammer, MD, FAAP; Mark L. Hudak, MD, FAAP; Committee on Adolescence; and Committee on Child Health Financing

ABSTRACT. Significant changes have occurred in the commercial and government insurance marketplace after the passage of 2 federal legislation acts, the Patient Protection and Affordable Care Act of 2010 and the Paul Wellstone and Pete Domenici Mental Health Parity and Addiction Equity Act of 2008. Despite the potential these 2 acts held to improve the health care of adolescents and young adults (AYAs), including the financing of care, there are barriers to achieving this goal. In the first quarter of 2016, 13.7% of individuals 18 to 24 years of age still lacked health insurance. Limitations in the scope of benefits coverage and inadequate provider payment can curtail access to health care for AYAs, particularly care related to sexual and reproductive health and mental and behavioral health. Some health plans impose financial barriers to access because they require families to absorb high cost-sharing expenses (eg, deductibles, copayments, and coinsurance). Finally, challenges of confidentiality inherent in the billing and insurance claim practices of some health insurance plans can discourage access to health care in the absence of other obstacles and interfere with provision of confidential care. This policy statement summarizes the current state of impediments that AYA, including those with special health care needs, face in accessing timely and appropriate health care and that providers face in serving these patients. These impediments include limited scope of benefits, high cost sharing, inadequate provider payment, and insufficient confidentiality protections. With this statement, we aim to improve both access to health care by AYAs and providers' delivery of developmentally appropriate health care for these patients through the presentation of an overview of the issues, specific recommendations for reform of health care financing for AYAs, and practical actions that pediatricians and other providers can take to advocate for appropriate payments for providing health care to AYAs. THE TEEN DRIVER

Elizabeth M. Alderman, MD, FAAP, FSAHM; Brian D. Johnston, MD, MPH, FAAP; Committee on Adolescence; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. For many teenagers, obtaining a driver's license is a rite of passage, conferring the ability to independently travel to school, work, or social events. However, immaturity, inexperience, and risky behavior put newly licensed teen drivers at risk. Motor vehicle crashes are the most common cause of mortality and injury for adolescents and young adults in developed countries. Teen drivers (15–19 years of age) have the highest rate of motor vehicle crashes among all age groups in the United States and contribute disproportionately to traffic fatalities. In addition to the deaths of teen drivers, more than half of 8- to 17-year-old children who die in car crashes are killed as passengers of drivers younger than 20 years of age. This policy statement, in which we update the previous 2006 iteration of this policy statement, is used to reflect new research on the risks faced by teen drivers and offer advice for pediatricians counseling teen drivers and their families. TELEHEALTH: IMPROVING ACCESS TO AND QUALITY OF PEDIATRIC HEALTH CARE

Alison L. Curfman, MD, MBA, FAAP; Jesse M. Hackell, MD, FAAP; Neil E. Herendeen, MD, MS, FAAP; Joshua J. Alexander, MD, FAAP; James P. Marcin, MD, MPH, FAAP; William B. Moskowitz, MD, FAAP; Chelsea E. F. Bodnar, MD, MPhil, FAAP; Harold K. Simon, MD, MBA, FAAP; S. David McSwain, MD, FAAP; Section on Telehealth Care; Committee on Practice and Ambulatory Medicine; and Committee on Pediatric Workforce

ABSTRACT. All children and adolescents deserve access to quality health care regardless of their race/ethnicity, health conditions, financial resources, or geographic location. Despite improvements over the past decades, severe disparities in the availability and access to high-quality health care for children and adolescents continue to exist throughout the United States. Economic and racial factors, geographic maldistribution of primary care pediatricians, and limited availability of pediatric medical subspecialists and pediatric surgical specialists all contribute to inequitable access to pediatric care. Robust, comprehensive telehealth coverage is critical to improving pediatric access and quality of care and services, particularly for underresourced populations. (8/21)

TELEMEDICINE FOR EVALUATION OF RETINOPATHY OF PREMATURITY (TECHNICAL REPORT)

Walter M. Fierson, MD, FAAP; Antonio Capone Jr, MD; and Section on Ophthalmology (joint with American Academy of Ophthalmology and American Association of Certified Orthoptists)

ABSTRACT. Retinopathy of prematurity (ROP) remains a significant threat to vision for extremely premature infants despite the availability of therapeutic modalities capable, in most cases, of managing this disorder. It has been shown in many controlled trials that application of therapies at the appropriate time is essential to successful outcomes in premature infants affected by ROP. Bedside binocular indirect ophthalmoscopy has been the standard technique for diagnosis and monitoring of ROP in these patients. However, implementation of routine use of this screening method for at-risk premature infants has presented challenges within our existing care systems, including relative local scarcity of qualified ophthalmologist examiners in some locations and the remote location of some NICUs. Modern technology, including the development of wide-angle ocular digital fundus photography, coupled with the ability to send digital images electronically to remote locations, has led to the development of telemedicine-based remote digital fundus imaging (RDFI-TM) evaluation techniques. These techniques have the potential to allow the diagnosis and monitoring of ROP to occur in lieu of the necessity for some repeated on-site examinations in NICUs. This report reviews the currently available literature on RDFI-TM evaluations for ROP and outlines pertinent practical and risk management considerations that should be used when including RDFI-TM in any new or existing ROP care structure. (12/14, reaffirmed 2/21)

TELEMEDICINE: PEDIATRIC APPLICATIONS (TECHNICAL REPORT)

Bryan L. Burke Jr, MD, FAAP; R. W. Hall, MD, FAAP; and Section on Telehealth Care

ABSTRACT. Telemedicine is a technological tool that is improving the health of children around the world. This report chronicles the use of telemedicine by pediatricians and pediatric medical and surgical specialists to deliver inpatient and outpatient care, educate physicians and patients, and conduct medical research. It also describes the importance of telemedicine in responding to emergencies and disasters and providing access to pediatric care to remote and underserved populations. Barriers to telemedicine expansion are explained, such as legal issues, inadequate payment for services, technology costs and sustainability, and the lack of technology infrastructure on a national scale. Although certain challenges have constrained more widespread implementation, telemedicine's current use bears testimony to its effectiveness and potential. Telemedicine's widespread adoption will be influenced by the implementation of key provisions of the Patient Protection and Affordable Care Act, technological advances, and growing patient demand for virtual visits. TESTING FOR DRUGS OF ABUSE IN CHILDREN AND ADOLESCENTS (CLINICAL REPORT)

Sharon Levy, MD, MPH, FAAP; Lorena M. Siqueira, MD, MSPH, FAAP; and Committee on Substance Abuse

ABSTRACT. Drug testing is often used as part of an assessment for substance use in children and adolescents. However, the indications for drug testing and guidance on how to use this procedure effectively are not clear. The complexity and invasiveness of the procedure and limitations to the information derived from drug testing all affect its utility. The objective of this clinical report is to provide guidance to pediatricians and other clinicians on the efficacy and efficient use of drug testing on the basis of a review of the nascent scientific literature, policy guidelines, and published clinical recommendations. (5/14)

https://doi.org/10.1542/peds.2014-0865

TOPICAL NASAL DECONGESTANT OXYMETAZOLINE: SAFETY CONSIDERATIONS FOR PERIOPERATIVE PEDIATRIC USE (CLINICAL REPORT)

Richard Cartabuke, MD, FAAP; Joseph D. Tobias, MD, FAAP; Kris R. Jatana, MD, FAAP; Section on Anesthesiology and Pain Medicine; and Section on Otolaryngology—Head and Neck Surgery

ABSTRACT. The over-the-counter nasal decongestant oxymetazoline (eg, Afrin) is used in the pediatric population for a variety of conditions in the operating room setting. Given its vasoconstrictive properties, it can have cardiovascular adverse effects when systemically absorbed. There have been several reports of cardiac and respiratory complications related to use of oxymetazoline in the pediatric population. Current US Food and Drug Administration approval for oxymetazoline is for patients ≥6 years of age, but medical professionals may elect to use it short-term and off label for younger children in particular clinical scenarios in which the potential benefit may outweigh risks (eg, active bleeding, acute respiratory distress from nasal obstruction, acute complicated sinusitis, improved surgical visualization, nasal decongestion for scope examination, other conditions, etc). To date, there have not been adequate pediatric pharmacokinetic studies of oxymetazoline, so caution should be exercised with both the quantity of dosing and the technique of administration. In the urgent care setting, emergency department, or inpatient setting, to avoid excessive administration of the medication, medical professionals should use the spray bottle in an upright position with the child upright. In addition, in the operating room setting, both monitoring the quantity used and effective communication between the surgeon and anesthesia team are important. Further studies are needed to understand the systemic absorption and effects in children in both nonsurgical and surgical nasal use of oxymetazoline. (10/21)

TOWARD TRANSPARENT CLINICAL POLICIES

Steering Committee on Quality Improvement and Management

ABSTRACT. Clinical policies of professional societies such as the American Academy of Pediatrics are valued highly, not only by clinicians who provide direct health care to children but also by many others who rely on the professional expertise of these organizations, including parents, employers, insurers, and legislators. The utility of a policy depends, in large part, on the degree to which its purpose and basis are clear to policy users, an attribute known as the policy's transparency. This statement describes the critical importance and special value of transparency in clinical policies, guidelines, and recommendations; helps identify obstacles to achieving transparency; and suggests several approaches to overcome these obstacles. (3/08, reaffirmed 2/14)

https://doi.org/10.1542/peds.2007-3624

TRAMPOLINE SAFETY IN CHILDHOOD AND ADOLESCENCE

Council on Sports Medicine and Fitness

ABSTRACT. Despite previous recommendations from the American Academy of Pediatrics discouraging home use of trampolines, recreational use of trampolines in the home setting continues to be a popular activity among children and adolescents. This policy statement is an update to previous statements, reflecting the current literature on prevalence, patterns, and mechanisms of trampoline-related injuries. Most trampoline injuries occur with multiple simultaneous users on the mat. Cervical spine injuries often occur with falls off the trampoline or with attempts at somersaults or flips. Studies on the efficacy of trampoline safety measures are reviewed, and although there is a paucity of data, current implementation of safety measures have not appeared to mitigate risk substantially. Therefore, the home

use of trampolines is strongly discouraged. The role of trampoline as a competitive sport and in structured training settings is reviewed, and recommendations for enhancing safety in these environments are made. (9/12, reaffirmed 7/15, 3/20)

THE TRANSFER OF DRUGS AND THERAPEUTICS INTO HUMAN BREAST MILK: AN UPDATE ON SELECTED TOPICS (CLINICAL REPORT)

Hari Cheryl Sachs, MD, FAAP, and Committee on Drugs

ABSTRACT. Many mothers are inappropriately advised to discontinue breastfeeding or avoid taking essential medications because of fears of adverse effects on their infants. This cautious approach may be unnecessary in many cases, because only a small proportion of medications are contraindicated in breastfeeding mothers or associated with adverse effects on their infants. Information to inform physicians about the extent of excretion for a particular drug into human milk is needed but may not be available. Previous statements on this topic from the American Academy of Pediatrics provided physicians with data concerning the known excretion of specific medications into breast milk. More current and comprehensive information is now available on the Internet, as well as an application for mobile devices, at LactMed (http://toxnet.nlm.nih.gov). Therefore, with the exception of radioactive compounds requiring temporary cessation of breastfeeding, the reader will be referred to LactMed to obtain the most current data on an individual medication. This report discusses several topics of interest surrounding lactation, such as the use of psychotropic therapies, drugs to treat substance abuse, narcotics, galactagogues, and herbal products, as well as immunization of breastfeeding women. A discussion regarding the global implications of maternal medications and lactation in the developing world is beyond the scope of this report. The World Health Organization offers several programs and resources that address the importance of breastfeeding (see http://www.who.int/topics/breastfeeding/en/). (8/13, reaffirmed 5/18)

TRANSITION TO A SAFE HOME SLEEP ENVIRONMENT FOR THE NICU PATIENT

Michael H. Goodstein, MD, FAAP; Dan L. Stewart, MD, FAAP; Erin L. Keels, DNP, APRN-CNP, NNP-BC; Rachel Y. Moon, MD, FAAP; Committee on Fetus and Newborn; and Task Force on Sudden Infant Death Syndrome

ABSTRACT. Of the nearly 3.8 million infants born in the United States in 2018, 8.3% had low birth weight (ie, weight <2500 g) and 10% were born preterm (ie, gestational age of <37 weeks). Ten to fifteen percent of infants (approximately 500 000 annually), including low birth weight and preterm infants and others with congenital anomalies, perinatally acquired infections, and other diseases, require admission to a NICU. Every year, approximately 3600 infants in the United States die of sudden unexpected infant death (SUID), including sudden infant death syndrome (SIDS), unknown and undetermined causes, and accidental suffocation and strangulation in an unsafe sleep environment. Preterm and low birth weight infants are 2 to 3 times more likely than healthy term infants to die suddenly and unexpectedly. Thus, it is important that health care professionals prepare families to maintain their infant in a safe home sleep environment as per recommendations of the American Academy of Pediatrics. Medical needs of the NICU infant often require practices such as nonsupine positioning, which should be transitioned as soon as medically possible and well before hospital discharge to sleep practices that are safe and appropriate for the home environment. This clinical report outlines the establishment of appropriate NICU protocols for the timely transition of these infants to a safe home sleep environment. The rationale for these recommendations is discussed in the accompanying technical report "Transition to a Safe Home Sleep Environment for the NICU Patient," included in this issue of *Pediatrics.* (6/21)

https://doi.org/10.1542/peds.2021-052045

TRANSITION TO A SAFE HOME SLEEP ENVIRONMENT FOR THE NICU PATIENT (TECHNICAL REPORT)

Michael H. Goodstein, MD, FAAP; Dan L. Stewart, MD, FAAP; Erin L. Keels, DNP, APRN-CNP, NNP-BC; Rachel Y. Moon, MD, FAAP; Committee on Fetus and Newborn; and Task Force on Sudden Infant Death Syndrome

ABSTRACT. Of the nearly 3.8 million infants born in the United States in 2018, 8.3% had low birth weight (<2500 g [5.5 lb]) and 10% were born preterm (gestational age of <37 completed weeks). Many of these infants and others with congenital anomalies, perinatally acquired infections, and other disease require admission to a NICU. In the past decade, admission rates to NICUs have been increasing; it is estimated that between 10% and 15% of infants will spend time in a NICU, representing approximately 500 000 neonates annually. Approximately 3600 infants die annually in the United States from sleep-related deaths, including sudden infant death syndrome *International Classification of Diseases, 10th Revision* (R95), ill-defined deaths (R99), and accidental suffocation and strangulation in bed (W75). Preterm and low birth weight infants are particularly vulnerable, with an incidence of death 2 to 3 times greater than healthy term infants. Thus, it is important for health care professionals to prepare families to maintain their infant in a safe sleep environment, as per the recommendations of the American Academy of Pediatrics. However, infants in the NICU setting commonly require care that is inconsistent with infant sleep safety recommendations. The conflicting needs of the NICU infant with the necessity to provide a safe sleep environment before hospital discharge can create confusion for providers and distress for families. This technical report is intended to assist in the establishment of appropriate NICU protocols to achieve a consistent approach to transitioning NICU infants to a safe sleep environment as soon as medically possible, well before hospital discharge. TRANSPORTING CHILDREN WITH SPECIAL HEALTH CARE NEEDS

Joseph O'Neil, MD, MPH, FAAP; Benjamin Hoffman, MD, FAAP; and Council on Injury, Violence, and Poison Prevention

ABSTRACT. Children with special health care needs should have access to proper resources for safe transportation as do typical children. This policy statement reviews important considerations for transporting children with special health care needs and provides current guidance for the protection of children with specific health care needs, including those with airway obstruction, orthopedic conditions or procedures, developmental delays, muscle tone abnormalities, challenging behaviors, and gastrointestinal disorders. (4/19)

TRAUMA-INFORMED CARE (CLINICAL REPORT)

Heather Forkey, MD, FAAP; Moira Szilagyi, MD, PhD, FAAP; Erin T. Kelly, MD, FAAP, FACP; James Duffee, MD, MPH, FAAP; Council on Foster Care, Adoption, and Kinship Care; Council on Community Pediatrics; Council on Child Abuse and Neglect; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Most children will experience some type of trauma during childhood, and many children suffer from significant adversities. Research in genetics, neuroscience, and epidemiology all provide evidence that these experiences have effects

at the molecular, cellular, and organ level, with consequences on physical, emotional, developmental, and behavioral health across the life span. Trauma-informed care translates that science to inform and improve pediatric care and outcomes. To practically address trauma and promote resilience, pediatric clinicians need tools to assess childhood trauma and adversity experiences as well as practical guidance, resources, and interventions. In this clinical report, we summarize current, practical advice for rendering trauma-informed care across varied medical settings. (7/21)

See full text on page 1135.

https://doi.org/10.1542/peds.2021-052580

TRAUMA-INFORMED CARE IN CHILD HEALTH SYSTEMS

James Duffee, MD, MPH, FAAP; Moira Szilagyi, MD, PhD, FAAP; Heather Forkey, MD, FAAP; Erin T. Kelly, MD, FAAP, FACP; Council on Community Pediatrics; Council on Foster Care, Adoption, and Kinship Care; Council on Child Abuse and Neglect; and Committee on Psychosocial Aspects of Child and Family Health

ABSTRACT. Recent progress in understanding the lifelong effects of early childhood adversities has clarified the need for an organized strategy to identify and intervene with children, adolescents, and families who may be at risk for maladaptive responses. Trauma-informed care (TIC) in child health care operationalizes the biological evidence of toxic stress with the insights of attachment and resilience to enhance health care delivery to mitigate the effects of trauma. The resulting pediatric health care delivery strategy promotes and restores resilience in children and adolescents, partners with families to support relational health, and reduces secondary trauma among pediatric health care clinicians. This policy statement summarizes what policy makers, legislators, and health care organizations need to consider in terms of infrastructure, resources, and financial support to facilitate the integration of TIC principles into all pediatric points of care. The accompanying clinical report describes the elements of TIC in the direct care of children, adolescents, and families and covers the spectrum from prevention to treatment. The recommendations in this statement and the clinical report build on other American Academy of Pediatrics policies that address the needs of special populations (such as children and adolescents in foster or kinship care, in immigrant and refugee families, or in poor or homeless families) and are congruent with American Academy of Pediatrics policies and technical reports concerning the role of pediatric clinicians in the promotion of lifelong health. (7/21)

THE TREATMENT OF NEUROLOGICALLY IMPAIRED CHILDREN USING PATTERNING

Committee on Children With Disabilities

ABSTRACT. This statement reviews patterning as a treatment for children with neurologic impairments. This treatment is based on an outmoded and oversimplified theory of brain development. Current information does not support the claims of proponents that this treatment is efficacious, and its use continues to be unwarranted. (11/99, reaffirmed 11/02, 1/06, 8/10, 4/14, 5/18)

https://doi.org/10.1542/peds.104.5.1149

TRUTH, RECONCILIATION, AND TRANSFORMATION: CONTINUING ON THE PATH TO EQUITY

Board of Directors

ABSTRACT. One year ago, the American Academy of Pediatrics (AAP) published a landmark policy statement identifying racism as a core social determinant of health and a driver of health inequities. Seventy-five years ago, the AAP admitted its first Black members, Drs Alonzo deGrate Smith and Roland Boyd Scott. As the AAP continues to evolve its equity agenda, it is essential that the tortuous experiences of Drs deGrate Smith and Scott on their pathway to AAP membership be truthfully acknowledged and reckoned with. (8/20)

https://doi.org/10.1542/peds.2020-019794

TUBERCULOSIS INFECTION IN CHILDREN AND ADOLESCENTS: TESTING AND TREATMENT (CLINICAL REPORT)

Dawn Nolt, MD, MPH, FAAP; Jeffrey R. Starke, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. Tuberculosis (TB) remains an important problem among children in the United States and throughout the world. There is no diagnostic reference standard for latent tuberculosis infection (also referred to as tuberculosis infection [TBI]). The tuberculin skin test (TST) has many limitations, including difficulty in administration and interpretation, the need for a return visit by the patient, and false-positive results caused by cross-reaction with Mycobacterium bovis–bacille Calmette-Guerin vaccines and many nontuberculous mycobacteria. Interferon-gamma release assays (IGRAs) are blood tests that use antigens specific for M tuberculosis; as a result, IGRAs yield fewer false-positive results than the TST. Both IGRAs and the TST have reduced sensitivity in immunocompromised children, including children with severe TB disease. Both methods have high positive predictive value when applied to children with risk factors for TBI, especially recent contact with a person who has TB disease. The advantages of using IGRAs and diminished experience with the placement and interpretation of the TST favor expanded use of IGRAs in children in the United States. There are now several effective and safe regimens for the treatment of TBI in children. For improved adherence to therapy, the 3 rifamycin-based regimens are preferred because of their short duration. Daily isoniazid can be used if there is intolerance or drug interactions with rifamycins. A TB specialist should be involved when there are questions regarding testing interpretation, selection of an appropriate treatment regimen, or management of adverse effects. (11/21)

ULTRAVIOLET RADIATION: A HAZARD TO CHILDREN AND ADOLESCENTS

Council on Environmental Health and Section on Dermatology

ABSTRACT. Ultraviolet radiation (UVR) causes the 3 major forms of skin cancer: basal cell carcinoma; squamous cell carcinoma; and cutaneous malignant melanoma. Public awareness of the risk is not optimal, overall compliance with sun protection is inconsistent, and melanoma rates continue to rise. The risk of skin cancer increases when people overexpose themselves to sun and intentionally expose themselves to artificial sources of UVR. Yet, people continue to sunburn, and teenagers and adults alike remain frequent visitors to tanning parlors. Pediatricians should provide advice about UVR exposure during health-supervision visits and at other relevant times. Advice includes avoiding sunburning, wearing clothing and hats, timing activities (when possible) before or after periods of peak sun exposure, wearing protective sunglasses, and applying and reapplying sunscreen. Advice should be framed in the context of promoting outdoor physical activity. Adolescents should be strongly discouraged from visiting tanning parlors. Sun exposure and vitamin D status are intertwined. Cutaneous vitamin D production requires sunlight exposure, and many factors, such as skin pigmentation, season, and time of day, complicate efficiency of cutaneous vitamin D production that results from sun exposure. Adequate vitamin D is needed for bone health. Accumulating information suggests a beneficial influence of vitamin D on many health conditions.

Although vitamin D is available through the diet, supplements, and incidental sun exposure, many children have low vitamin D concentrations. Ensuring vitamin D adequacy while promoting sun-protection strategies will require renewed attention to children's use of dietary and supplemental vitamin D. (2/11, reaffirmed 9/16)
https://doi.org/10.1542/peds.2010-3501

ULTRAVIOLET RADIATION: A HAZARD TO CHILDREN AND ADOLESCENTS (TECHNICAL REPORT)

Sophie J. Balk, MD; Council on Environmental Health; and Section on Dermatology

ABSTRACT. Sunlight sustains life on earth. Sunlight is essential for vitamin D synthesis in the skin. The sun's ultraviolet rays can be hazardous, however, because excessive exposure causes skin cancer and other adverse health effects. Skin cancer is a major public health problem; more than 2 million new cases are diagnosed in the United States each year. Ultraviolet radiation (UVR) causes the 3 major forms of skin cancer: basal cell carcinoma; squamous cell carcinoma; and cutaneous malignant melanoma. Exposure to UVR from sunlight and artificial sources early in life elevates the risk of developing skin cancer. Approximately 25% of sun exposure occurs before 18 years of age. The risk of skin cancer is increased when people overexpose themselves to sun and intentionally expose themselves to artificial sources of UVR. Public awareness of the risk is not optimal, compliance with sun protection is inconsistent, and skin-cancer rates continue to rise in all age groups including the younger population. People continue to sunburn, and teenagers and adults are frequent visitors to tanning parlors. Sun exposure and vitamin D status are intertwined. Adequate vitamin D is needed for bone health in children and adults. In addition, there is accumulating information suggesting a beneficial influence of vitamin D on various health conditions. Cutaneous vitamin D production requires sunlight, and many factors complicate the efficiency of vitamin D production that results from sunlight exposure. Ensuring vitamin D adequacy while promoting sun-protection strategies, therefore, requires renewed attention to evaluating the adequacy of dietary and supplemental vitamin D. Daily intake of 400 IU of vitamin D will prevent vitamin D deficiency rickets in infants. The vitamin D supplementation amounts necessary to support optimal health in older children and adolescents are less clear. This report updates information on the relationship of sun exposure to skin cancer and other adverse health effects, the relationship of exposure to artificial sources of UVR and skin cancer, sun-protection methods, vitamin D, community skin-cancer–prevention efforts, and the pediatrician's role in preventing skin cancer. In addition to pediatricians' efforts, a sustained public health effort is needed to change attitudes and behaviors regarding UVR exposure. (2/11, reaffirmed 9/16)

UMBILICAL CORD CARE IN THE NEWBORN INFANT (CLINICAL REPORT)

Dan Stewart, MD, FAAP; William Benitz, MD, FAAP; and Committee on Fetus and Newborn

ABSTRACT. Postpartum infections remain a leading cause of neonatal morbidity and mortality worldwide. A high percentage of these infections may stem from bacterial colonization of the umbilicus, because cord care practices vary in reflection of cultural traditions within communities and disparities in health care practices globally. After birth, the devitalized umbilical cord often proves to be an ideal substrate for bacterial growth and also provides direct access to the bloodstream of the neonate. Bacterial colonization of the cord not infrequently leads to omphalitis and associated thrombophlebitis, cellulitis, or necrotizing fasciitis. Various topical substances continue to be used for cord care around the world to mitigate the risk of serious infection. More recently, particularly in high-resource countries, the treatment paradigm has shifted toward dry umbilical cord care. This clinical report reviews the evidence underlying recommendations for care of the umbilical cord in different clinical settings. (8/16)

UNDERSTANDING LIABILITY RISKS AND PROTECTIONS FOR PEDIATRIC PROVIDERS DURING DISASTERS

Robin L. Altman, MD, FAAP; Karen A. Santucci, MD, FAAP; Michael R. Anderson, MD, MBA, FAAP; William M. McDonnell, MD, JD, FAAP; and Committee on Medical Liability and Risk Management

ABSTRACT. Although most health care providers will go through their careers without experiencing a major disaster in their local communities, if one does occur, it can be life and career altering. The American Academy of Pediatrics has been at the forefront of providing education and advocacy on the critical importance of disaster preparedness. From experiences over the past decade, new evidence and analysis have broadened our understanding that the concept of preparedness is also applicable to addressing the unique professional liability risks that can occur when caring for patients and families during a disaster. In our recommendations in this policy statement, we target pediatric health care providers, advocates, and policy makers and address how individuals, institutions, and government can work together to strengthen the system of liability protections during disasters so that appropriate and timely care can be delivered with minimal fear of legal reprisal or confusion. (2/19)
https://doi.org/10.1542/peds.2018-3892

UNDERSTANDING LIABILITY RISKS AND PROTECTIONS FOR PEDIATRIC PROVIDERS DURING DISASTERS (TECHNICAL REPORT)

Robin L. Altman, MD, FAAP; Karen A. Santucci, MD, FAAP; Michael R. Anderson, MD, MBA, FAAP; William M. McDonnell, MD, JD, FAAP; and Committee on Medical Liability and Risk Management

ABSTRACT. Although most health care providers will go through their careers without experiencing a major disaster in their local communities, if one does occur, it can be life and career altering. The American Academy of Pediatrics has been in the forefront of providing education and advocacy on the critical importance of disaster preparedness. From experiences over the past decade, new evidence and analysis have broadened our understanding that the concept of preparedness is also applicable to addressing the unique professional liability risks that can occur when caring for patients and families during a disaster. Concepts explored in this technical report will help to inform pediatric health care providers, advocates, and policy makers about the complexities of how providers are currently protected, with a focus on areas of unappreciated liability. The timeliness of this technical report is emphasized by the fact that during the time of its development (ie, late summer and early fall of 2017), the United States went through an extraordinary period of multiple, successive, and overlapping disasters within a concentrated period of time of both natural and man-made causes. In a companion policy statement (www.pediatrics.org/cgi/doi/10.1542/peds.2018-3892), recommendations are offered on how individuals, institutions, and governments can work together to strengthen the system of liability protections during disasters so that appropriate and timely care can be delivered with minimal fear of legal reprisal or confusion. (2/19)

UNIQUE NEEDS OF THE ADOLESCENT

Elizabeth M. Alderman, MD, FSAHM, FAAP; Cora C. Breuner, MD, MPH, FAAP; and Committee on Adolescence

ABSTRACT. Adolescence is the transitional bridge between childhood and adulthood; it encompasses developmental milestones that are unique to this age group. Healthy cognitive, physical, sexual, and psychosocial development is both a right and a responsibility that must be guaranteed for all adolescents to successfully enter adulthood. There is consensus among national and international organizations that the unique needs of adolescents must be addressed and promoted to ensure the health of all adolescents. This policy statement outlines the special health challenges that adolescents face on their journey and transition to adulthood and provides recommendations for those who care for adolescents, their families, and the communities in which they live. (11/19)

https://doi.org/10.1542/peds.2019-3150

UPDATE OF NEWBORN SCREENING AND THERAPY FOR CONGENITAL HYPOTHYROIDISM (CLINICAL REPORT)

Susan R. Rose, MD; Section on Endocrinology; and Committee on Genetics (joint with Rosalind S. Brown, MD; American Thyroid Association; and Lawson Wilkins Pediatric Endocrine Society)

ABSTRACT. Unrecognized congenital hypothyroidism leads to mental retardation. Newborn screening and thyroid therapy started within 2 weeks of age can normalize cognitive development. The primary thyroid-stimulating hormone screening has become standard in many parts of the world. However, newborn thyroid screening is not yet universal in some countries. Initial dosage of 10 to 15 μg/kg levothyroxine is recommended. The goals of thyroid hormone therapy should be to maintain frequent evaluations of total thyroxine or free thyroxine in the upper half of the reference range during the first 3 years of life and to normalize the serum thyroid-stimulating hormone concentration to ensure optimal thyroid hormone dosage and compliance.

Improvements in screening and therapy have led to improved developmental outcomes in adults with congenital hypothyroidism who are now in their 20s and 30s. Thyroid hormone regimens used today are more aggressive in targeting early correction of thyroid-stimulating hormone than were those used 20 or even 10 years ago. Thus, newborn infants with congenital hypothyroidism today may have an even better intellectual and neurologic prognosis. Efforts are ongoing to establish the optimal therapy that leads to maximum potential for normal development for infants with congenital hypothyroidism.

Remaining controversy centers on infants whose abnormality in neonatal thyroid function is transient or mild and on optimal care of very low birth weight or preterm infants. Of note, thyroid-stimulating hormone is not elevated in central hypothyroidism. An algorithm is proposed for diagnosis and management.

Physicians must not relinquish their clinical judgment and experience in the face of normal newborn thyroid test results. Hypothyroidism can be acquired after the newborn screening. When clinical symptoms and signs suggest hypothyroidism, regardless of newborn screening results, serum free thyroxine and thyroid-stimulating hormone determinations should be performed. UPDATED GUIDANCE FOR PALIVIZUMAB PROPHYLAXIS AMONG INFANTS AND YOUNG CHILDREN AT INCREASED RISK OF HOSPITALIZATION FOR RESPIRATORY SYNCYTIAL VIRUS INFECTION

Committee on Infectious Diseases and Bronchiolitis Guidelines Committee

ABSTRACT. Palivizumab was licensed in June 1998 by the Food and Drug Administration for the reduction of serious lower respiratory tract infection caused by respiratory syncytial virus (RSV) in children at increased risk of severe disease. Since that time, the American Academy of Pediatrics has updated its guidance for the use of palivizumab 4 times as additional data became available to provide a better understanding of infants and young children at greatest risk of hospitalization attributable to RSV infection. The updated recommendations in this policy statement reflect new information regarding the seasonality of RSV circulation, palivizumab pharmacokinetics, the changing incidence of bronchiolitis hospitalizations, the effect of gestational age and other risk factors on RSV hospitalization rates, the mortality of children hospitalized with RSV infection, the effect of prophylaxis on wheezing, and palivizumab-resistant RSV isolates. (7/14, reaffirmed 2/19)

UPDATED GUIDANCE FOR PALIVIZUMAB PROPHYLAXIS AMONG INFANTS AND YOUNG CHILDREN AT INCREASED RISK OF HOSPITALIZATION FOR RESPIRATORY SYNCYTIAL VIRUS INFECTION (TECHNICAL REPORT)

Committee on Infectious Diseases and Bronchiolitis Guidelines Committee

ABSTRACT. Guidance from the American Academy of Pediatrics (AAP) for the use of palivizumab prophylaxis against respiratory syncytial virus (RSV) was first published in a policy statement in 1998. Guidance initially was based on the result from a single randomized, placebo-controlled clinical trial conducted in 1996–1997 describing an overall reduction in RSV hospitalization rate from 10.6% among placebo recipients to 4.8% among children who received prophylaxis. The results of a second randomized, placebo-controlled trial of children with hemodynamically significant heart disease were published in 2003 and revealed a reduction in RSV hospitalization rate from 9.7% in control subjects to 5.3% among prophylaxis recipients. Because no additional controlled trials regarding efficacy were published, AAP guidance has been updated periodically to reflect the most recent literature regarding children at greatest risk of severe disease. Since the last update in 2012, new data have become available regarding the seasonality of RSV circulation, palivizumab pharmacokinetics, the changing incidence of bronchiolitis hospitalizations, the effects of gestational age and other risk factors on RSV hospitalization rates, the mortality of children hospitalized with RSV infection, and the effect of prophylaxis on wheezing and palivizumab-resistant RSV isolates. These data enable further refinement of AAP guidance to most clearly focus on those children at greatest risk. (7/14)

UPDATES ON AN AT-RISK POPULATION: LATE-PRETERM AND EARLY-TERM INFANTS (CLINICAL REPORT)

Dan L. Stewart, MD, FAAP; Wanda D. Barfield, MD, MPH, FAAP, RADM, USPHS; Committee on Fetus and Newborn

ABSTRACT. The American Academy of Pediatrics published a clinical report on late-preterm (LPT) infants in 2007 that was largely based on a summary of a 2005 workshop convened by the *Eunice Kennedy Shriver* National Institute of Child Health and

Human Development, at which a change in terminology from "near term" to "late preterm" was proposed. This paradigm-shifting recommendation had a remarkable impact: federal agencies (the Centers for Disease Control and Prevention), professional societies (the American Academy of Pediatrics and American College of Obstetricians and Gynecologists), and organizations (March of Dimes) initiated nationwide monitoring and educational plans that had a significant effect on decreasing the rates of iatrogenic LPT deliveries. However, there is now an evolving concern. After nearly a decade of steady decreases in the LPT birth rate that largely contributed to the decline in total US preterm birth rates, the birth rate in LPT infants has been inching upward since 2015. In addition, evidence revealed by strong population health research demonstrates that being born as an early-term infant poses a significant risk to an infant's survival, growth, and development. In this report, we summarize the initial progress and discuss the potential reasons for the current trends in LPT and early-term birth rates and propose research recommendations. (10/19)

USE OF CHAPERONES DURING THE PHYSICAL EXAMINATION OF THE PEDIATRIC PATIENT

Committee on Practice and Ambulatory Medicine

ABSTRACT. Physicians should always communicate the scope and nature of the physical examination to be performed to the pediatric patient and his or her parent. This statement addresses the use of chaperones and issues of patient comfort, confidentiality, and privacy. The use of a chaperone should be a shared decision between the patient and physician. In some states, the use of a chaperone is mandated by state regulations. (4/11, 11/17)

USE OF INHALED NITRIC OXIDE IN PRETERM INFANTS (CLINICAL REPORT)

Praveen Kumar, MD, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Nitric oxide, an important signaling molecule with multiple regulatory effects throughout the body, is an important tool for the treatment of full-term and late-preterm infants with persistent pulmonary hypertension of the newborn and hypoxemic respiratory failure. Several randomized controlled trials have evaluated its role in the management of preterm infants ≤34 weeks' gestational age with varying results. The purpose of this clinical report is to summarize the existing evidence for the use of inhaled nitric oxide in preterm infants and provide guidance regarding its use in this population. (12/13)
https://doi.org/10.1542/peds.2013-3444

THE USE OF NONNUTRITIVE SWEETENERS IN CHILDREN

Carissa M. Baker-Smith, MD, MPH, FAAP; Sarah D. de Ferranti, MD, MPH, FAAP; William J. Cochran, MD, FAAP; Committee on Nutrition; and Section on Gastroenterology, Hepatology, and Nutrition

ABSTRACT. The prevalence of nonnutritive sweeteners (NNSs) in the food supply has increased over time. Not only are more children and adolescents consuming NNSs, but they are also consuming a larger quantity of NNSs in the absence of strong scientific evidence to refute or support the safety of these agents. This policy statement from the American Academy of Pediatrics is intended to provide the pediatric provider with a review of (1) previous steps taken for approved use of NNSs, (2) existing data regarding the safety of NNS use in the general pediatric population, (3) what is known regarding the potential benefits and/or adverse effects of NNS use in children and adolescents, (4) identified gaps in existing knowledge and potential areas of future research, and (5) suggested talking points that pediatricians may use when discussing NNS use with families. (10/19)

USE OF PERFORMANCE-ENHANCING SUBSTANCES (CLINICAL REPORT)

Michele LaBotz, MD, FAAP; Bernard A. Griesemer, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. Performance-enhancing substances (PESs) are used commonly by children and adolescents in attempts to improve athletic performance. More recent data reveal that these same substances often are used for appearance-related reasons as well. PESs include both legal over-the-counter dietary supplements and illicit pharmacologic agents. This report reviews the current epidemiology of PES use in the pediatric population, as well as information on those PESs in most common use. Concerns regarding use of legal PESs include high rates of product contamination, correlation with future use of anabolic androgenic steroids, and adverse effects on the focus and experience of youth sports participation. The physical maturation and endogenous hormone production that occur in adolescence are associated with large improvements in strength and athletic performance. For most young athletes, PES use does not produce significant gains over those seen with the onset of puberty and adherence to an appropriate nutrition and training program. (6/16, reaffirmed 8/20)

USE OF PROBIOTICS IN PRETERM INFANTS (CLINICAL REPORT)

Brenda Poindexter, MD, MS, FAAP, and Committee on Fetus and Newborn

ABSTRACT. Probiotic products in the United States are available for use in the general category of dietary supplements, bypassing the rigor of the US Food and Drug Administration (FDA) approval process in safety, efficacy, and manufacturing standards. As a result, currently available probiotics lack FDA-approved drug labeling and cannot be marketed to treat or prevent disease in preterm infants, including necrotizing enterocolitis and late-onset sepsis. Despite lack of availability of a pharmaceutical-grade product, the number of preterm infants receiving probiotics in the United States and Canada is steadily increasing. According to recent reports from large collaborative databases in the United States, approximately 10% of extremely low gestational age neonates receive a probiotic preparation during their stay in the NICU, with wide variation in practice among units. In sum, more than 10 000 preterm infants have been enrolled in randomized clinical trials of probiotic supplementation worldwide. Methodologic differences among study protocols included different strains and combinations of therapy, masking of trials, and a priori definitions of the primary outcome measure. Large meta-analyses of these trials have demonstrated the efficacy of multiple-strain probiotics in reducing necrotizing enterocolitis and all-cause mortality, whereas the efficacy of single-strain probiotic preparations is less certain. In the absence of an appropriate medical-grade product in the United States, dietary supplement–grade probiotics, some of which have been the subject of recent recalls for contamination, are being prescribed. Given the lack of FDA-regulated pharmaceutical-grade products in the United States, conflicting data on safety and efficacy, and potential for harm in a highly vulnerable population, current evidence does not support the routine, universal administration of probiotics to preterm infants, particularly those with a birth weight of <1000 g. THE USE OF SYSTEMIC AND TOPICAL FLUOROQUINOLONES (CLINICAL REPORT)

Mary Anne Jackson, MD, FAAP; Gordon E. Schutze, MD, FAAP; and Committee on Infectious Diseases

ABSTRACT. Appropriate prescribing practices for fluoroquinolones, as well as all antimicrobial agents, are essential as evolving resistance patterns are considered, additional treatment indications are identified, and the toxicity profile of fluoroquinolones in children has become better defined. Earlier recommendations for systemic therapy remain; expanded uses of fluoroquinolones for the treatment of certain infections are outlined in this report. Prescribing clinicians should be aware of specific adverse reactions associated with fluoroquinolones, and their use in children should continue to be limited to the treatment of infections for which no safe and effective alternative exists or in situations in which oral fluoroquinolone treatment represents a reasonable alternative to parenteral antimicrobial therapy. (10/16, reaffirmed 3/21)

https://doi.org/10.1542/peds.2016-2706

THE USE OF TELEMEDICINE TO ADDRESS ACCESS AND PHYSICIAN WORKFORCE SHORTAGES

Committee on Pediatric Workforce

ABSTRACT. The use of telemedicine technologies by primary care pediatricians, pediatric medical subspecialists, and pediatric surgical specialists (henceforth referred to as "pediatric physicians") has the potential to transform the practice of pediatrics. The purpose of this policy statement is to describe the expected and potential impact that telemedicine will have on pediatric physicians' efforts to improve access and physician workforce shortages. The policy statement also describes how the American Academy of Pediatrics can advocate for its members and their patients to best use telemedicine technologies to improve access to care, provide more patient- and family-centered care, increase efficiencies in practice, enhance the quality of care, and address projected shortages in the clinical workforce. As the use of telemedicine increases, it is likely to impact health care access, quality, and education and costs of care. Telemedicine technologies, applied to the medical home and its collaborating providers, have the potential to improve current models of care by increasing communication among clinicians, resulting in more efficient, higher quality, and less expensive care. Such a model can serve as a platform for providing more continuous care, linking primary and specialty care to support management of the needs of complex patients. In addition, telemedicine technologies can be used to efficiently provide pediatric physicians working in remote locations with ongoing medical education, increasing their ability to care for more complex patients in their community, reducing the burdens of travel on patients and families, and supporting the medical home. On the other hand, telemedicine technologies used for episodic care by nonmedical home providers have the potential to disrupt continuity of care and to create redundancy and imprudent use of health care resources. Fragmentation should be avoided, and telemedicine, like all primary and specialty services, should be coordinated through the medical home. (6/15, reaffirmed 5/19)

VENTRICULAR FIBRILLATION AND THE USE OF AUTOMATED EXTERNAL DEFIBRILLATORS ON CHILDREN

Committee on Pediatric Emergency Medicine and Section on Cardiology and Cardiac Surgery

ABSTRACT. The use of automated external defibrillators (AEDs) has been advocated in recent years as one part of the chain of survival to improve outcomes for adult cardiac arrest victims. When AEDs first entered the market, they had not been tested for pediatric usage and rhythm interpretation. In addition, the presumption was that children do not experience ventricular fibrillation, so they would not benefit from the use of AEDs. Recent literature has shown that children do experience ventricular fibrillation, which has a better outcome than do other cardiac arrest rhythms. At the same time, the arrhythmia software on AEDs has become more extensive and validated for children, and attenuation devices have become available to downregulate the energy delivered by AEDs to allow their use on children. Pediatricians are now being asked whether AED programs should be implemented, and where they are being implemented, pediatricians are being asked to provide guidance on the use of them on children. As AED programs expand, pediatricians must advocate on behalf of children so that their needs are accounted for. For pediatricians to be able to provide guidance and ensure that children are included in AED programs, it is important for pediatricians to know how AEDs work, be up-to-date on the literature regarding pediatric fibrillation and energy delivery, and understand the role of AEDs as life-saving interventions for children. VIRTUAL VIOLENCE

Council on Communications and Media

ABSTRACT. In the United States, exposure to media violence is becoming an inescapable component of children's lives. With the rise in new technologies, such as tablets and new gaming platforms, children and adolescents increasingly are exposed to what is known as "virtual violence." This form of violence is not experienced physically; rather, it is experienced in realistic ways via new technology and ever more intense and realistic games. The American Academy of Pediatrics continues to be concerned about children's exposure to virtual violence and the effect it has on their overall health and well-being. This policy statement aims to summarize the current state of scientific knowledge regarding the effects of virtual violence on children's attitudes and behaviors and to make specific recommendations for pediatricians, parents, industry, and policy makers. VISUAL SYSTEM ASSESSMENT IN INFANTS, CHILDREN, AND YOUNG ADULTS BY PEDIATRICIANS

Committee on Practice and Ambulatory Medicine and Section on Ophthalmology (joint with American Association of Certified Orthoptists, American Association for Pediatric Ophthalmology and Strabismus, and American Academy of Ophthalmology)

ABSTRACT. Appropriate visual assessments help identify children who may benefit from early interventions to correct or improve vision. Examination of the eyes and visual system should begin in the nursery and continue throughout both childhood and adolescence during routine well-child visits in the medical home. Newborn infants should be examined using inspection and red reflex testing to detect structural ocular abnormalities, such as cataract, corneal opacity, and ptosis. Instrument-based screening, if available, should be first attempted between 12 months and 3 years of age and at annual well-child visits until acuity can be tested directly. Direct testing of visual acuity can often begin by 4 years of age, using age-appropriate symbols (optotypes). Children found to have an ocular abnormality or who fail a vision assessment should be referred to a pediatric ophthalmologist or an eye care specialist appropriately trained to treat pediatric patients. (12/15)

WEB SERVICES AND CLOUD COMPUTING IN PEDIATRIC CARE (TECHNICAL REPORT)

Michael G. Leu, MD, MS, MHS, FAAP, FAMIA; Stuart T. Weinberg, MD, FAAP, FAMIA; Craig Monsen, MD, MS; Christoph U. Lehmann, MD, FAAP, FACMI, FIAHSI; and Council on Clinical Information Technology

ABSTRACT. Electronic health record (EHR) systems do not uniformly implement pediatric-supportive functionalities. One method of adding these capabilities across EHR platforms is to integrate Web services and Web applications that may perform decision support and store data in the cloud when the EHR platform is able to integrate Web services. Specific examples of these services are described, such as immunization clinical decision support services, consumer health resources, and bilirubin nomograms. Health care providers, EHR vendors, and developers share responsibilities in the appropriate development, integration, and use of Web services and Web applications as they relate to best practices in the areas of data security and confidentiality, technical availability, audit trails, terminology and messaging standards, compliance with the Health Insurance Portability and Accountability Act, testing, usability, and other considerations. It is desirable for health care providers to have knowledge of Web services and Web applications that can improve pediatric capabilities in their own EHRs because this will naturally inform discussions concerning EHR features and facilitate implementation and subsequent use of these capabilities by clinicians caring for children. (6/21)

WITHHOLDING OR TERMINATION OF RESUSCITATION IN PEDIATRIC OUT-OF-HOSPITAL TRAUMATIC CARDIOPULMONARY ARREST

Committee on Pediatric Emergency Medicine (joint with American College of Surgeons Committee on Trauma and National Association of EMS Physicians)

ABSTRACT. This multiorganizational literature review was undertaken to provide an evidence base for determining whether recommendations for out-of-hospital termination of resuscitation could be made for children who are victims of traumatic cardiopulmonary arrest. Although there is increasing acceptance of out-of-hospital termination of resuscitation for adult traumatic cardiopulmonary arrest when there is no expectation of a good outcome, children are routinely excluded from state termination-of-resuscitation protocols. The decision to withhold resuscitative efforts in a child under specific circumstances (decapitation or dependent lividity, rigor mortis, etc) is reasonable. If there is any doubt as to the circumstances or timing of the traumatic cardiopulmonary arrest, under the current status of limiting termination of resuscitation in the field to persons older than 18 years in most states, resuscitation should be initiated and continued until arrival to the appropriate facility. If the patient has arrested, resuscitation has already exceeded 30 minutes, and the nearest facility is more than 30 minutes away, involvement of parents and family of these children in the decision-making process with assistance and guidance from medical professionals should be considered as part of an emphasis on family-centered care because the evidence suggests that either death or a poor outcome is inevitable. (3/14, reaffirmed 6/20)

YOUTH PARTICIPATION AND INJURY RISK IN MARTIAL ARTS (CLINICAL REPORT)

Rebecca A. Demorest, MD, FAAP; Chris Koutures, MD, FAAP; and Council on Sports Medicine and Fitness

ABSTRACT. The martial arts can provide children and adolescents with vigorous levels of physical exercise that can improve overall physical fitness. The various types of martial arts encompass noncontact basic forms and techniques that may have a lower relative risk of injury. Contact-based sparring with competitive training and bouts have a higher risk of injury. This clinical report describes important techniques and movement patterns in several types of martial arts and reviews frequently reported injuries encountered in each discipline, with focused discussions of higher risk activities. Some of these higher risk activities include blows to the head and choking or submission movements that may cause concussions or significant head injuries. The roles of rule changes, documented benefits of protective equipment, and changes in training recommendations in attempts to reduce injury are critically assessed. This information is intended to help pediatric health care providers counsel patients and families in encouraging safe participation in martial arts. (11/16)

THE 21ST CENTURY CURES ACT & ADOLESCENT CONFIDENTIALITY

North American Society for Pediatric and Adolescent Gynecology and Society for Adolescent Health and Medicine

INTRODUCTION. In 2020 the Office of the National Coordinator for Heath Information Technology (ONC) issued a Final Rule to implement specific requirements of the 21st Century Cures Act. The goal of the Final Rule is to increase access, use, and exchange of electronic health information. The North American Society for Pediatric and Adolescent Gynecology (NASPAG) and the Society for Adolescent Health and Medicine (SAHM) agree that sharing health information with patients and families allows for improved medical care. We believe it is equally important to recognize the right of adolescent minors to access confidential care, which is protected to some degree in every U.S. state. As experts in the care of adolescents, NASPAG and SAHM are in a unique position to inform institutional policies around release of information for this population. (2/21)

ADVANCED PRACTICE REGISTERED NURSE: ROLE, PREPARATION, AND SCOPE OF PRACTICE

National Association of Neonatal Nurses

ABSTRACT. In recent years, the National Association of Neonatal Nurses (NANN) and the National Association of Neonatal Nurse Practitioners (NANNP) have developed several policy statements on neonatal advanced practice registered nurse (APRN) workforce, education, competency, fatigue, safety, and scope of practice. This position paper is a synthesis of previous efforts and discusses the role, preparation, and scope of practice of the neonatal APRN. (1/14)

ANTENATAL CORTICOSTEROID THERAPY FOR FETAL MATURATION

American College of Obstetricians and Gynecologists

ABSTRACT. Corticosteroid administration before anticipated preterm birth is one of the most important antenatal therapies available to improve newborn outcomes. A single course of corticosteroids is recommended for pregnant women between 24 0/7 weeks and 33 6/7 weeks of gestation who are at risk of preterm delivery within 7 days, including for those with ruptured membranes and multiple gestations. It also may be considered for pregnant women starting at 23 0/7 weeks of gestation who are at risk of preterm delivery within 7 days, based on a family's decision regarding resuscitation, irrespective of membrane rupture status and regardless of fetal number. Administration of betamethasone may be considered in pregnant women between 34 0/7 weeks and 36 6/7 weeks of gestation who are at risk of preterm birth within 7 days, and who have not received a previous course of antenatal corticosteroids. A single repeat course of antenatal corticosteroids should be considered in women who are less than 34 0/7 weeks of gestation who are at risk of preterm delivery within 7 days, and whose prior course of antenatal corticosteroids was administered more than 14 days previously. Rescue course corticosteroids could be provided as early as 7 days from the prior dose, if indicated by the clinical scenario. Continued surveillance of long-term outcomes after in utero corticosteroid exposure should be supported. Quality improvement strategies to optimize appropriate and timely antenatal corticosteroid administration are encouraged. (8/17)

APPROPRIATE USE CRITERIA FOR INITIAL TRANSTHORACIC ECHOCARDIOGRAPHY IN OUTPATIENT PEDIATRIC CARDIOLOGY

American College of Cardiology Appropriate Use Task Force

ABSTRACT. The American College of Cardiology (ACC) participated in a joint project with the American Society of Echocardiography, the Society of Pediatric Echocardiography, and several other subspecialty societies and organizations to establish and evaluate Appropriate Use Criteria (AUC) for the initial use of outpatient pediatric echocardiography. Assumptions for the AUC were identified, including the fact that all indications assumed a first-time transthoracic echocardiographic study in an outpatient setting for patients without previously known heart disease. The definitions for frequently used terminology in outpatient pediatric cardiology were established using published guidelines and standards and expert opinion. These AUC serve as a guide to help clinicians in the care of children with possible heart disease, specifically in terms of when a transthoracic echocardiogram is warranted as an initial diagnostic modality in the outpatient setting. They are also a useful tool

for education and provide the infrastructure for future quality improvement initiatives as well as research in healthcare delivery, outcomes, and resource utilization.

To complete the AUC process, the writing group identified 113 indications based on common clinical scenarios and/or published clinical practice guidelines, and each indication was classified into 1 of 9 categories of common clinical presentations, including palpitations, syncope, chest pain, and murmur. A separate, independent rating panel evaluated each indication using a scoring scale of 1 to 9, thereby designating each indication as "Appropriate" (median score 7 to 9), "May Be Appropriate" (median score 4 to 6), or "Rarely Appropriate" (median score 1 to 3). Fifty-three indications were identified as Appropriate, 28 as May Be Appropriate, and 32 as Rarely Appropriate. (11/14)

CHILDREN'S SURGERY VERIFICATION

OPTIMAL RESOURCES FOR CHILDREN'S SURGICAL CARE

American College of Surgeons

EXECUTIVE SUMMARY. The Task Force for Children's Surgical Care, an ad hoc multidisciplinary group of invited leaders in relevant disciplines, assembled initially from April 30 to May 1, 2012, in Rosemont, IL, and subsequently in 2013, 2014, and 2015 to consider approaches to optimize the delivery of children's surgical care in today's competitive national health care environment. Specifically, a mismatch between individual patient needs and available clinical resources for some infants and children receiving surgical care is recognized as a problem in the United States and elsewhere. Although this phenomenon is apparent to most practitioners involved with children's surgical care, comprehensive data are not available, and relevant data are imperfect. The scope of this problem is unknown at present. However, the situation does periodically, and possibly systematically, result in suboptimal patient outcomes.

The composition of the task force is detailed in Appendix 4. The Children's Hospital Association and the American College of Surgeons (ACS) provided support. The group represented key disciplines and perspectives. Published literature and data were used when available, and expert opinion when not, as the basis for these recommendations. The objective was to develop consensus recommendations that would be of use to relevant policymakers and to providers.

Principles regarding resource standards, quality-improvement and safety processes, data collection, and a verification process were initially published in March 2014 [*J Am Coll Surg.* 2014;218(3):479–487]. This document details those principles in a specific manner designed to inform and direct a verification process to be conducted by the ACS and the ACS Children's Surgery Verification Committee.

Notably, there are a number of excellent children's specialty hospitals in the United States whose scope of service is more narrow than delineated in this document. A separate process will be used to develop relevant standards for those institutions to achieve the vision of prospectively matching institutional resources with individual patient needs. (12/15)

COLLABORATION IN PRACTICE: IMPLEMENTING TEAM-BASED CARE

American College of Obstetricians and Gynecologists Task Force on Collaborative Practice

INTRODUCTION. Quality, efficiency, and value are necessary characteristics of our evolving health care system. Team-based care will work toward the Triple Aim of 1) improving the experience of care of individuals and families; 2) improving the health of populations; and 3) lowering per capita costs. It also should respond to emerging demands and reduce undue burdens on health care providers. Team-based care has the ability to more effectively meet the core expectations of the health care system proposed by the Institute of Medicine. These expectations require that care be safe, effective, patient centered, timely, efficient, and equitable. This report outlines a mechanism that all specialties and practices can use to achieve these expectations.

The report was written by the interprofessional Task Force on Collaborative Practice and is intended to appeal to multiple specialties (eg, internal medicine, pediatrics, family medicine, and women's health) and professions (eg, nurse practitioners, certified nurse–midwives/certified midwives, physician assistants, physicians, clinical pharmacists, and advanced practice registered nurses). This document provides a framework for organizations or practices across all specialties to develop team-based care. In doing so, it offers a map to help practices navigate the increasingly complex and continuously evolving health care system. The guidance presented is a result of the task force's work and is based on current evidence and expert consensus. The task force challenges and welcomes all medical specialties to gather additional data on how and what types of team-based care best accomplish the Triple Aim and the Institute of Medicine's expectations of health care. (3/16)

CONFIDENTIALITY PROTECTIONS FOR ADOLESCENTS AND YOUNG ADULTS IN THE HEALTH CARE BILLING AND INSURANCE CLAIMS PROCESS

Society for Adolescent Health and Medicine

ABSTRACT. The importance of protecting confidential health care for adolescents and young adults is well documented. State and federal confidentiality protections exist for both minors and young adults, although the laws vary among states, particularly for minors. However, such confidentiality is potentially violated by billing practices and in the processing of health insurance claims. To address this problem, policies and procedures should be established so that health care billing and insurance claims processes do not impede the ability of providers to deliver essential health care services on a confidential basis to adolescents and young adults covered as dependents on a family's health insurance plan. (3/16)

CONSENSUS COMMUNICATION ON EARLY PEANUT INTRODUCTION AND THE PREVENTION OF PEANUT ALLERGY IN HIGH-RISK INFANTS

Primary contributors: David M. Fleischer, MD; Scott Sicherer, MD; Matthew Greenhawt, MD; Dianne Campbell, MB BS, FRACP, PhD; Edmond Chan, MD; Antonella Muraro, MD, PhD; Susanne Halken, MD; Yitzhak Katz, MD; Motohiro Ebisawa, MD, PhD; Lawrence Eichenfield, MD; Hugh Sampson, MD; Gideon Lack, MB, BCh; and George Du Toit, MB, BCh

INTRODUCTION AND RATIONALE. Peanut allergy is an increasingly troubling global health problem affecting between 1% and 3% of children in many westernized countries. Although multiple methods of measurement have been used and specific estimates differ, there appears to have been a sudden increase in the number of cases in the past 10- to 15-year period, suggesting that the prevalence might have tripled in some countries, such as the United States. Extrapolating the currently estimated prevalence, this translates to nearly 100 000 new cases annually (in the United States and United Kingdom), affecting some 1 in 50 primary school-aged children in the United States, Canada, the United Kingdom, and Australia. A similar increase in incidence is now being noted in developing countries, such as Ghana.

The purpose of this brief communication is to highlight emerging evidence for existing allergy prevention guidelines regarding potential benefits of supporting early rather than delayed peanut introduction during the period of complementary food introduction in infants. A recent study entitled ''Randomized trial of peanut consumption in infants at risk for peanut allergy'' demonstrated a successful 11% to 25% absolute

reduction in the risk of peanut allergy in high-risk infants (and a relative risk reduction of up to 80%) if peanut was introduced between 4 and 11 months of age. In light of the significance of these findings, this document serves to better inform the decision-making process for health care providers regarding such potential benefits of early peanut introduction. More formal guidelines regarding early-life, complementary feeding practices and the risk of allergy development will follow in the next year from the National Institute of Allergy and Infectious Diseases (NIAID)–sponsored Working Group and the European Academy of Allergy and Clinical Immunology (EAACI), and thus this document should be considered interim guidance. CONSENSUS STATEMENT: ABUSIVE HEAD TRAUMA IN INFANTS AND YOUNG CHILDREN

Arabinda Kumar Choudhary; Sabah Servaes; Thomas L. Slovis; Vincent J. Palusci; Gary L. Hedlund; Sandeep K. Narang; Joëlle Anne Moreno; Mark S. Dias; Cindy W. Christian; Marvin D. Nelson Jr; V. Michelle Silvera; Susan Palasis; Maria Raissaki; Andrea Rossi; and Amaka C. Offiah

ABSTRACT. Abusive head trauma (AHT) is the leading cause of fatal head injuries in children younger than 2 years. A multidisciplinary team bases this diagnosis on history, physical examination, imaging and laboratory findings. Because the etiology of the injury is multifactorial (shaking, shaking and impact, impact, etc.) the current best and inclusive term is AHT. There is no controversy concerning the medical validity of the existence of AHT, with multiple components including subdural hematoma, intracranial and spinal changes, complex retinal hemorrhages, and rib and other fractures that are inconsistent with the provided mechanism of trauma. The workup must exclude medical diseases that can mimic AHT. However, the courtroom has become a forum for speculative theories that cannot be reconciled with generally accepted medical literature. There is no reliable medical evidence that the following processes are causative in the constellation of injuries of AHT: cerebral sinovenous thrombosis, hypoxic-ischemic injury, lumbar puncture or dysphagic choking/vomiting. There is no substantiation, at a time remote from birth, that an asymptomatic birth-related subdural hemorrhage can result in rebleeding and sudden collapse. Further, a diagnosis of AHT is a medical conclusion, not a legal determination of the intent of the perpetrator or a diagnosis of murder. We hope that this consensus document reduces confusion by recommending to judges and jurors the tools necessary to distinguish genuine evidence-based opinions of the relevant medical community from legal arguments or etiological speculations that are unwarranted by the clinical findings, medical evidence and evidence-based literature. (5/18)

DEFINING PEDIATRIC MALNUTRITION: A PARADIGM SHIFT TOWARD ETIOLOGY-RELATED DEFINITIONS

American Society for Parenteral and Enteral Nutrition

ABSTRACT. Lack of a uniform definition is responsible for underrecognition of the prevalence of malnutrition and its impact on outcomes in children. A pediatric malnutrition definitions workgroup reviewed existing pediatric age group English-language literature from 1955 to 2011, for relevant references related to 5 domains of the definition of *malnutrition* that were *a priori* identified: anthropometric parameters, growth, chronicity of malnutrition, etiology and pathogenesis, and developmental/functional outcomes. Based on available evidence and an iterative process to arrive at multidisciplinary consensus in the group, these domains were included in the overall construct of a new definition. Pediatric malnutrition (undernutrition) is defined as an imbalance between nutrient requirements and intake that results in cumulative deficits of energy, protein, or micronutrients that may negatively affect growth, development, and other relevant outcomes. A summary of the literature is presented and a new classification scheme is proposed that incorporates chronicity, etiology, mechanisms of nutrient imbalance, severity of malnutrition, and its impact on outcomes. Based on its etiology, malnutrition is either *illness related* (secondary to 1 or more diseases/injury) or *non–illness related,* (caused by environmental/behavioral factors), or both. Future research must focus on the relationship between inflammation and illness-related malnutrition. We anticipate that the definition of malnutrition will continue to evolve with improved understanding of the processes that lead to and complicate the treatment of this condition. A uniform definition should permit future research to focus on the impact of pediatric malnutrition on functional outcomes and help solidify the scientific basis for evidence-based nutrition practices. DELAYED UMBILICAL CORD CLAMPING AFTER BIRTH

American College of Obstetricians and Gynecologists

ABSTRACT. Delayed umbilical cord clamping appears to be beneficial for term and preterm infants. In term infants, delayed umbilical cord clamping increases hemoglobin levels at birth and improves iron stores in the first several months of life, which may have a favorable effect on developmental outcomes. There is a small increase in jaundice that requires phototherapy in this group of infants. Consequently, health care providers adopting delayed umbilical cord clamping in term infants should ensure that mechanisms are in place to monitor for and treat neonatal jaundice. In preterm infants, delayed umbilical cord clamping is associated with significant neonatal benefits, including improved transitional circulation, better establishment of red blood cell volume, decreased need for blood transfusion, and lower incidence of necrotizing enterocolitis and intraventricular hemorrhage. Delayed umbilical cord clamping was not associated with an increased risk of postpartum hemorrhage or increased blood loss at delivery, nor was it associated with a difference in postpartum hemoglobin levels or the need for blood transfusion. Given the benefits to most newborns and concordant with other professional organizations, the American College of Obstetricians and Gynecologists now recommends a delay in umbilical cord clamping in vigorous term and preterm infants for at least 30–60 seconds after birth. The ability to provide delayed umbilical cord clamping may vary among institutions and settings; decisions in those circumstances are best made by the team caring for the mother–infant dyad. (1/17)

EPIDEMIOLOGY IN FIREARM VIOLENCE PREVENTION

Amy B. Davis; James A. Gaudino; Colin L. Soskolne; Wael K. Al-Delaimy; and International Network for Epidemiology in Policy

INTRODUCTION. Firearm violence has reached pandemic levels, with some countries experiencing high injury and death rates

from privately owned guns and firearms (hereinafter collectively referred to as 'firearms'). Significant factors in the increase in deaths and injuries from privately held firearms include the ease of obtaining these arms and, most importantly, the growing lethality of these weapons.

Society cannot be satisfied with reactive responses only in treating victims' physical and psychological wounds after these occurrences; more must be done proactively to prevent firearm violence and address societal circumstances that either facilitate or impede it. Where they exist, well-intended policies fail to adequately protect people from firearm violence, often because they mainly focus on the purchase and illegal uses of guns while neglecting underlying social determinants of the violent uses of firearms.

Laws intended to curb firearm violence are often not enforced, are inadequate or do not address local societal factors of crime, mental well-being, poverty or low education in the relevant communities. These considerations point to the need for a multisectoral approach in which the public health sciences would play a pivotal role in preventing harms relating to firearm violence with a greater focus on its causes. Evidence-based multicomponent interventions, often shown by systematic reviews to be the most effective to address complex, community-level health issues, are needed but are not well-defined to address firearm violence. To both advance understanding of and to guide community-level public health services and actions needed to prevent firearm violence, decision-makers need to rely more on surveillance, research and programme evaluation by public health organizations, schools and universities.

Epidemiologists have unique interdisciplinary tools for addressing the contributors and barriers to preventing and mitigating injury, including firearm violence. These include quantitative, qualitative and social epidemiological methods. Interventions to prevent and mitigate the problem are currently under-developed, under-funded and under-utilized, particularly in the USA. The problem could be addressed by putting in place a robust evidence base to inform policy decisions. Additionally, public health can create, scale up and evaluate interventions designed to address social and behavioural factors associated with firearm violence. We call on governments, community leaders and community members to take meaningful action to support public health in addressing the problem of firearm violence. (4/18)

ETHICAL CONSIDERATION FOR INCLUDING WOMEN AS RESEARCH PARTICIPANTS

American College of Obstetricians and Gynecologists

ABSTRACT. Inclusion of women in research studies is necessary for valid inferences about health and disease in women. The generalization of results from trials conducted in men may yield erroneous conclusions that fail to account for the biologic differences between men and women. Although significant changes in research design and practice have led to an increase in the proportion of women included in research trials, knowledge gaps remain because of a continued lack of inclusion of women, especially those who are pregnant, in premarketing research trials. This document provides a historical overview of issues surrounding women as participants in research trials, followed by an ethical framework and discussion of the issues of informed consent, contraception requirements, intimate partner consent, and the appropriate inclusion of pregnant women in research studies. EVIDENCE-BASED MANAGEMENT OF SICKLE CELL DISEASE: EXPERT PANEL REPORT, 2014

National Heart, Lung, and Blood Institute (2014)

FACULTY COMPETENCIES FOR GLOBAL HEALTH

Academic Pediatric Association Global Health Task Force

International partnerships among medical professionals from different countries are an increasingly common form of clinical and academic collaboration. Global health partnerships can include a variety of activities and serve multiple purposes in the areas of research, medical education and training, health system improvement, and clinical care. Competency domains, introduced by the Accreditation Council for Graduate Medical Education and the American Board of Medical Specialties in 1999, are now widely accepted to provide an organized, structured set of interrelated competencies, mostly for medical trainees. Although there are now competency domains and specific competencies recommended for pediatric trainees pursuing further professional training in global child health, none of these addresses competencies for faculty in global health.

In 2010 the Academic Pediatric Association established a Global Health Task Force to provide a forum for communication and collaboration for diverse pediatric academic societies and groups to advance global child health. Given the burgeoning demand for global health training, and particularly in light of a new global perspective on health education, as outlined in a Lancet Commission Report: *Health Professionals for a New Century: Transforming Education to Strengthen Health Systems in an Interdependent World,* in 2012 the Global Health Task Force noted the lack of defined faculty competencies and decided to develop a set of global health competencies for pediatric faculty engaged in the teaching and practice of global health. Using some of the principles suggested by Milner, et al. to define a competency framework, four domains were chosen, adapted from existing collaborative practice competencies. A fifth domain was added to address some of the unique challenges of global health practice encountered when working outside of one's own culture and health system. The domains are described below and specific competencies are provided for faculty working in global health research, education, administration, and clinical practice. (6/14)

GUIDELINES FOR FIELD TRIAGE OF INJURED PATIENTS

Centers for Disease Control and Prevention (1/12)

IMPORTANCE AND IMPLEMENTATION OF TRAINING IN CARDIOPULMONARY RESUSCITATION AND AUTOMATED EXTERNAL DEFIBRILLATION IN SCHOOLS

American Heart Association Emergency Cardiovascular Care Committee; Council on Cardiopulmonary, Critical Care, Perioperative and Resuscitation; Council on Cardiovascular Diseases in the Young; Council on Cardiovascular Nursing; Council on Clinical Cardiology; and Advocacy Coordinating Committee

ABSTRACT. In 2003, the International Liaison Committee on Resuscitation published a consensus document on education in resuscitation that strongly recommended that "…instruction in CPR [cardiopulmonary resuscitation] be incorporated as a standard part of the school curriculum." The next year the American Heart Association (AHA) recommended that schools "…establish a goal to train every teacher in CPR and first aid and train all students in CPR" as part of their preparation for a response to medical emergencies on campus.

Since that time, there has been an increased interest in legislation that would mandate that school curricula include training in CPR or CPR and automated external defibrillation. Laws or curriculum content standards in 36 states (as of the 2009–2010 school year) now encourage the inclusion of CPR training programs in school curricula. The language in those laws and standards varies greatly, ranging from a suggestion that students "recognize" the steps of CPR to a requirement for certification in CPR. Not surprisingly, then, implementation is not uniform among states,

even those whose laws or standards encourage CPR training in schools in the strongest language. This statement recommends that training in CPR and familiarization with automated external defibrillators (AEDs) should be required elements of secondary school curricula and provides the rationale for implementation of CPR training, as well as guidance in overcoming barriers to implementation. MENSTRUATION IN GIRLS AND ADOLESCENTS: USING THE MENSTRUAL CYCLE AS A VITAL SIGN

American College of Obstetricians and Gynecologists Committee on Adolescent Health Care

ABSTRACT. Despite variations worldwide and within the U.S. population, median age at menarche has remained relatively stable—between 12 years and 13 years—across well-nourished populations in developed countries. Environmental factors, including socioeconomic conditions, nutrition, and access to preventive health care, may influence the timing and progression of puberty. A number of medical conditions can cause abnormal uterine bleeding, characterized by unpredictable timing and variable amount of flow. Clinicians should educate girls and their caretakers (eg, parents or guardians) about what to expect of a first menstrual period and the range for normal cycle length of subsequent menses. Identification of abnormal menstrual patterns in adolescence may improve early identification of potential health concerns for adulthood. It is important for clinicians to have an understanding of the menstrual patterns of adolescent girls, the ability to differentiate between normal and abnormal menstruation, and the skill to know how to evaluate the adolescent girl patient. By including an evaluation of the menstrual cycle as an additional vital sign, clinicians reinforce its importance in assessing overall health status for patients and caretakers. (12/15)

MULTILINGUAL CHILDREN: BEYOND MYTHS AND TOWARD BEST PRACTICES

Society for Research in Child Development

ABSTRACT. Multilingualism is an international fact of life and increasing in the United States. Multilingual families are exceedingly diverse, and policies relevant to them should take this into account. The quantity and quality of a child's exposure to responsive conversation spoken by fluent adults predicts both monolingual and multilingual language and literacy achievement. Contexts supporting optimal multilingualism involve early exposure to high quality conversation in each language, along with continued support for speaking both languages. Parents who are not fluent in English should not be told to speak English instead of their native language to their children; children require fluent input, and fluent input in another language will transfer to learning a second or third language. Messages regarding optimal multilingual practices should be made available to families using any and all available methods for delivering such information, including home visitation programs, healthcare settings, center-based early childhood programs, and mass media. (2013)

NATIONAL ADOPTION CENTER: OPEN RECORDS

National Adoption Center

The National Adoption Center believes that it is an inalienable right of all citizens, including adopted adults, to have unencumbered access to their original birth certificates. In keeping with this position, we believe that copies of both the original and the amended birth certificate should be given to the adoptive family at the time of finalization unless specifically denied by the birthparents. In any case, the National Adoption Center advocates that the adoptee, at age 18, be granted access to his/her original birth certificate. (6/00)

NEONATAL ENCEPHALOPATHY AND NEUROLOGIC OUTCOME, SECOND EDITION

American College of Obstetricians and Gynecologists Task Force on Neonatal Encephalopathy

In the first edition of this report, the Task Force on Neonatal Encephalopathy and Cerebral Palsy outlined criteria deemed essential to establish a causal link between intrapartum hypoxic events and cerebral palsy. It is now known that there are multiple potential causal pathways that lead to cerebral palsy in term infants, and the signs and symptoms of neonatal encephalopathy may range from mild to severe, depending on the nature and timing of the brain injury. Thus, for the current edition, the Task Force on Neonatal Encephalopathy determined that a broader perspective may be more fruitful. This conclusion reflects the sober recognition that knowledge gaps still preclude a definitive test or set of markers that accurately identifies, with high sensitivity and specificity, an infant in whom neonatal encephalopathy is attributable to an acute intrapartum event. The information necessary for assessment of likelihood can be derived from a comprehensive evaluation of all potential contributing factors in cases of neonatal encephalopathy. This is the broader perspective championed in the current report. If a comprehensive etiologic evaluation is not possible, the term hypoxic–ischemic encephalopathy should best be replaced by neonatal encephalopathy because neither hypoxia nor ischemia can be assumed to have been the unique initiating causal mechanism. The title of this report has been changed from *Neonatal Encephalopathy and Cerebral Palsy: Defining the Pathogenesis and Pathophysiology* to *Neonatal Encephalopathy and Neurologic Outcome* to indicate that an array of developmental outcomes may arise after neonatal encephalopathy in addition to cerebral palsy. (4/14)

NEURODEVELOPMENTAL OUTCOMES IN CHILDREN WITH CONGENITAL HEART DISEASE: EVALUATION AND MANAGEMENT; A SCIENTIFIC STATEMENT FROM THE AMERICAN HEART ASSOCIATION

American Heart Association (7/12)

THE NEUROLOGIST'S ROLE IN SUPPORTING TRANSITION TO ADULT HEALTH CARE

Lawrence W. Brown, MD; Peter Camfield, MD, FRCPC; Melissa Capers, MA; Greg Cascino, MD; Mary Ciccarelli, MD; Claudio M. de Gusmao, MD; Stephen M. Downs, MD; Annette Majnemer, PhD, FCAHS; Amy Brin Miller, MSN; Christina SanInocencio, MS; Rebecca Schultz, PhD; Anne Tilton, MD; Annick Winokur, BS; and Mary Zupanc, MD

ABSTRACT. The child neurologist has a critical role in planning and coordinating the successful transition from the pediatric to adult health care system for youth with neurologic conditions. Leadership in appropriately planning a youth's transition and in care coordination among health care, educational, vocational, and community services providers may assist in preventing gaps in care, delayed entry into the adult care system, and/or health crises for their adolescent patients. Youth whose neurologic conditions result in cognitive or physical disability and their families may need additional support during this transition, given the legal and financial considerations that may be required. Eight common principles that define the child neurologist's role in a successful transition process have been outlined by a multidisciplinary panel convened by the Child Neurology Foundation are introduced and described. The authors of this consensus statement recognize the current paucity of evidence for successful transition models and outline areas for future consideration. *Neurology.* 2016;87:1–6. (7/16)

NONINHERITED RISK FACTORS AND CONGENITAL CARDIOVASCULAR DEFECTS: CURRENT KNOWLEDGE

American Heart Association

ABSTRACT. Prevention of congenital cardiovascular defects has been hampered by a lack of information about modifiable risk factors for abnormalities in cardiac development. Over the past decade, there have been major breakthroughs in the understanding of inherited causes of congenital heart disease, including the identification of specific genetic abnormalities for some types of malformations. Although relatively less information has been available on noninherited modifiable factors that may have an adverse effect on the fetal heart, there is a growing body of epidemiological literature on this topic. This statement summarizes the currently available literature on potential fetal exposures that might alter risk for cardiovascular defects. Information is summarized for periconceptional multivitamin or folic acid intake, which may reduce the risk of cardiac disease in the fetus, and for additional types of potential exposures that may increase the risk, including maternal illnesses, maternal therapeutic and nontherapeutic drug exposures, environmental exposures, and paternal exposures. Information is highlighted regarding definitive risk factors such as maternal rubella; phenylketonuria; pregestational diabetes; exposure to thalidomide, vitamin A cogeners, or retinoids; and indomethacin tocolysis. Caveats regarding interpretation of possible exposure-outcome relationships from case-control studies are given because this type of study has provided most of the available information. Guidelines for prospective parents that could reduce the likelihood that their child will have a major cardiac malformation are given. Issues related to pregnancy monitoring are discussed. Knowledge gaps and future sources of new information on risk factors are described. (*Circulation.* 2007;115:2995–3014.) (6/07)

NUSINERSEN USE IN SPINAL MUSCULAR ATROPHY

David Michelson, MD; Emma Ciafaloni, MD; Stephen Ashwal, MD; Elliot Lewis, Pushpa Narayanaswami, MBBS; Maryam Oskoui, MD, MSc; Melissa J. Armstrong, MD, MSc; and American Academy of Neurology

ABSTRACT. *Objective.* To identify the level of evidence for use of nusinersen to treat spinal muscular atrophy (SMA) and review clinical considerations regarding use.

Methods. The author panel systematically reviewed nusinersen clinical trials for patients with SMA and assigned level of evidence statements based on the American Academy of Neurology's 2017 therapeutic classification of evidence scheme. Safety information, regulatory decisions, and clinical context were also reviewed.

Results. Four published clinical trials were identified, 3 of which were rated above Class IV. There is Class III evidence that in infants with homozygous deletions or mutations of *SMN1,* nusinersen improves the probability of permanent ventilation-free survival at 24 months vs a well-defined historical cohort. There is Class I evidence that in term infants with SMA and 2 copies of *SMN2,* treatment with nusinersen started in individuals younger than 7 months results in a better motor milestone response and higher rates of event-free survival than sham control. There is Class I evidence that in children aged 2–12 years with SMA symptom onset after 6 months of age, nusinersen results in greater improvement in motor function at 15 months than sham control. Nusinersen was safe and well-tolerated.

Clinical context. Evidence of efficacy is currently highest for treatment of infantile- and childhood-onset SMA in the early and middle symptomatic phases. While approved indications for nusinersen use in North America and Europe are broad, payer coverage for populations outside those in clinical trials remain variable. Evidence, availability, cost, and patient preferences all influence decision-making regarding nusinersen use. (10/18)

ORTHOPTISTS AS PHYSICIAN EXTENDERS

American Association for Pediatric Ophthalmology and Strabismus (5/15)

PERINATAL PALLIATIVE CARE

American College of Obstetricians and Gynecologists

ABSTRACT. Perinatal palliative care refers to a coordinated care strategy that comprises options for obstetric and newborn care that include a focus on maximizing quality of life and comfort for newborns with a variety of conditions considered to be life-limiting in early infancy. With a dual focus on ameliorating suffering and honoring patient values, perinatal palliative care can be provided concurrently with life-prolonging treatment. The focus of this document, however, involves the provision of exclusively palliative care without intent to prolong life in the context of a life-limiting condition, otherwise known as perinatal palliative comfort care. Once a life-limiting diagnosis is suspected antenatally, the tenets of informed consent require that the pregnant patient be given information of sufficient depth and breadth to make an informed, voluntary choice for her care. Health care providers are encouraged to model effective, compassionate communication that respects patient cultural beliefs and values and to promote shared decision making with patients. Perinatal palliative comfort care is one of several options along a spectrum of care, which includes pregnancy termination (abortion) and full neonatal resuscitation and treatment, that should be presented to pregnant patients faced with pregnancies complicated by life-limiting fetal conditions. If a patient opts to pursue perinatal palliative comfort care, a multidisciplinary team should be identified with the infrastructure and support to administer this care. The perinatal palliative care team should prepare families for the possibility that there may be differences of opinion between family members before and after the delivery of the infant, and that there may be differences between parents and the neonatal care providers about appropriate postnatal therapies, especially if the postnatal diagnosis and prognosis differ substantially from antenatal predictions. Procedures for resolving such differences should be discussed with families ahead of time. (8/19)

A PRACTICAL GUIDE FOR PRIMARY CARE PHYSICIANS: INSTRUMENT-BASED VISION SCREENING IN CHILDREN

Children's Eye Foundation

SUMMARY. In January 2016 a new joint policy statement from the American Academy of Pediatrics (AAP), American Academy of Ophthalmology (AAO), American Association for Pediatric Ophthalmology and Strabismus (AAPOS) and American Association of Certified Orthoptists (AACO) regarding the pediatric eye examination was published. The updated policy statement, published in the journal *Pediatrics,* incorporates earlier and routine visual assessments using instrument-based screening to help identify children who may benefit from early intervention to improve vision (or correct vision problems). Instrument-based screening technology is revolutionizing early detection and prevention of amblyopia by allowing screening of more children and at a younger age.

This guide for primary care physicians is produced by the Children's Eye Foundation of AAPOS to provide information regarding instrument-based screening. Early detection and treatment of amblyopia is key to preventing unnecessary blindness, and primary care physicians play a critical role in its detection through vision screening in the preschool and school age groups. (2016)

PREVENTION AND CONTROL OF MENINGOCOCCAL DISEASE: RECOMMENDATIONS OF THE ADVISORY COMMITTEE ON IMMUNIZATION PRACTICES (ACIP)

Centers for Disease Control and Prevention

SUMMARY. Meningococcal disease describes the spectrum of infections caused by *Neisseria meningitidis,* including meningitidis, bacteremia, and bacteremic pneumonia. Two quadrivalent meningococcal polysaccharide-protein conjugate vaccines that provide protection against meningococcal serogroups A, C, W, and Y (MenACWY-D [Menactra, manufactured by Sanofi Pasteur, Inc., Swiftwater, Pennsylvania] and MenACWY-CRM [Menveo, manufactured by Novartis Vaccines, Cambridge, Massachusetts]) are licensed in the United States for use among persons aged 2 through 55 years. MenACWY-D also is licensed for use among infants and toddlers aged 9 through 23 months. Quadrivalent meningococcal polysaccharide vaccine (MPSV4 [Menommune, manufactured by Sanofi Pasteur, Inc., Swiftwater, Pennsylvania]) is the only vaccine licensed for use among persons aged ≥56 years. A bivalent meningococcal polysaccharide protein conjugate vaccine that provides protection against meningococcal serogroups C and Y along with *Haemophilus influenzae* type b (Hib) (Hib-MenCY-TT [MenHibrix, manufactured by GlaxoSmithKline Biologicals, Rixensart, Belgium]) is licensed for use in children aged 6 weeks through 18 months.

This report compiles and summarizes all recommendations from CDC's Advisory Committee on Immunization Practices (ACIP) regarding prevention and control of meningococcal disease in the United States, specifically the changes in the recommendations published since 2005 (CDC. Prevention and control of meningococcal disease: recommendations of the Advisory Committee on Immunization Practices [ACIP]. *MMWR* 2005;54 Adobe PDF file [No. RR-7]). As a comprehensive summary of previously published recommendations, this report does not contain any new recommendations; it is intended for use by clinicians as a resource. ACIP recommends routine vaccination with a quadrivalent meningococcal conjugate vaccine (MenACWY) for adolescents aged 11 or 12 years, with a booster dose at age 16 years. ACIP also recommends routine vaccination for persons at increased risk for meningococcal disease (i.e., persons who have persistent complement component deficiencies, persons who have anatomic or functional asplenia, microbiologists who routinely are exposed to isolates of *N. meningitidis,* military recruits, and persons who travel to or reside in areas in which meningococcal disease is hyperendemic or epidemic). Guidelines for antimicrobial chemoprophylaxis and for evaluation and management of suspected outbreaks of meningococcal disease also are provided. (3/13)

PREVENTION OF GROUP B STREPTOCOCCAL EARLY-ONSET DISEASE IN NEWBORNS

American College of Obstetricians and Gynecologists Committee on Obstetric Practice

ABSTRACT. Group B streptococcus (GBS) is the leading cause of newborn infection (1). The primary risk factor for neonatal GBS early-onset disease (EOD) is maternal colonization of the genitourinary and gastrointestinal tracts. Approximately 50% of women who are colonized with GBS will transmit the bacteria to their newborns. Vertical transmission usually occurs during labor or after rupture of membranes. In the absence of intrapartum antibiotic prophylaxis, 1–2% of those newborns will develop GBS EOD. Other risk factors include gestational age of less than 37 weeks, very low birth weight, prolonged rupture of membranes, intraamniotic infection, young maternal age, and maternal black race. The key obstetric measures necessary for effective prevention of GBS EOD continue to include universal prenatal screening by vaginal–rectal culture, correct specimen collection and processing, appropriate implementation of intrapartum antibiotic prophylaxis, and coordination with pediatric care providers. The American College of Obstetricians and Gynecologists now recommends performing universal GBS screening between 36 0/7 and 37 6/7 weeks of gestation. All women whose vaginal–rectal cultures at 36 0/7 and 37 6/7 weeks of gestation are positive for GBS should receive appropriate intrapartum antibiotic prophylaxis unless a prelabor cesarean birth is performed in the setting of intact membranes. Although a shorter duration of recommended intrapartum antibiotics is less effective than 4 or more hours of prophylaxis, 2 hours of antibiotic exposure has been shown to reduce GBS vaginal colony counts and decrease the frequency of a clinical neonatal sepsis diagnosis. Obstetric interventions, when necessary, should not be delayed solely to provide 4 hours of antibiotic administration before birth. This Committee Opinion, including Table 1, Box 2, and Figures 1–3, updates and replaces the obstetric components of the CDC 2010 guidelines, "Prevention of Perinatal Group B Streptococcal Disease: Revised Guidelines From CDC, 2010." (6/19)

RECOMMENDED AMOUNT OF SLEEP FOR PEDIATRIC POPULATIONS: A CONSENSUS STATEMENT OF THE AMERICAN ACADEMY OF SLEEP MEDICINE

Shalini Paruthi, MD; Lee J. Brooks, MD; Carolyn D'Ambrosio, MD; Wendy A. Hall, PhD, RN; Suresh Kotagal, MD; Robin M. Lloyd, MD; Beth A. Malow, MD, MS; Kiran Maski, MD; Cynthia Nichols, PhD; Stuart F. Quan, MD; Carol L. Rosen, MD; Matthew M. Troester, DO; and Merrill S. Wise, MD

Background and Methodology. Healthy sleep requires adequate duration, appropriate timing, good quality, regularity, and the absence of sleep disturbances or disorders. Sleep duration is a frequently investigated sleep measure in relation to health. A panel of 13 experts in sleep medicine and research used a modified RAND Appropriateness Method to develop recommendations regarding the sleep duration range that promotes optimal health in children aged 0–18 years. The expert panel reviewed published scientific evidence addressing the relationship between sleep duration and health using a broad set of National Library of Medicine Medical Subject Headings (MeSH) terms and no date restrictions, which resulted in a total of 864 scientific articles. The process was further guided by the Oxford grading system. The panel focused on seven health categories with the best available evidence in relation to sleep duration: general health, cardiovascular health, metabolic health, mental health,

immunologic function, developmental health, and human performance. Consistent with the RAND Appropriateness Method, multiple rounds of evidence review, discussion, and voting were conducted to arrive at the final recommendations. The process to develop these recommendations was conducted over a 10-month period and concluded with a meeting held February 19–21, 2016, in Chicago, Illinois. (6/16)

RESTRICTIVE HOUSING IN JUVENILE CORRECTIONAL SETTINGS

National Commission on Correctional Health Care

INTRODUCTION. NCCHC asserts that "juveniles, mentally ill individuals, and pregnant women should be excluded from solitary confinement of any duration" (NCCHC, 2016). However, the practice of juvenile solitary confinement and broader forms of restrictive housing still occurs today. A 2015 survey of solitary confinement rules in juvenile justice systems revealed that 47% of juvenile detention centers reported locking youth in some type of isolation for more than 4 hours at a time (Lowenstein Center, 2016). Given the widespread use of restrictive housing and the well-understood negative health impacts of these practices, it is imperative that juvenile correctional facilities work to reduce or eliminate the use of restrictive housing and establish clear protocols for the rare instances when isolation is deemed essential (e.g., medical necessity) to ensure safety for youth. (2/21)

SCREENING CHILDREN AT RISK FOR RETINOBLASTOMA: CONSENSUS REPORT FROM THE AMERICAN ASSOCIATION OF OPHTHALMIC ONCOLOGISTS AND PATHOLOGISTS

Alison H. Skalet, MD, PhD; Dan S. Gombos, MD; Brenda L. Gallie, MD; Jonathan W. Kim, MD; Carol L. Shields, MD; Brian P. Marr, MD; Sharon E. Plon, MD, PhD; and Patricia Chévez-Barrios, MD

Purpose: To provide a set of surveillance guidelines for children at risk for development of retinoblastoma.

Design: Consensus panel.

Participants: Expert panel of ophthalmic oncologists, pathologists, and geneticists.

Methods: A group of members of the American Association of Ophthalmic Oncologists and Pathologists (AAOOP) with support of the American Association for Pediatric Ophthalmology and Strabismus and the American Academy of Pediatrics (AAP) was convened. The panel included representative ophthalmic oncologists, pathologists, and geneticists from retinoblastoma referral centers located in various geographic regions who met and discussed screening approaches for retinoblastoma. A patient "at risk" was defined as a person with a family history of retinoblastoma in a parent, sibling, or first- or second-degree relative.

Main Outcome Measures: Screening recommendations for children at risk for retinoblastoma.

Results: Consensus statement from the panel: (1) Dedicated ophthalmic screening is recommended for all children at risk for retinoblastoma above the population risk. (2) Frequency of examinations is adjusted on the basis of expected risk for *RB1* mutation. (3) Genetic counseling and testing clarify the risk for retinoblastoma in children with a family history of the disease. (4) Examination schedules are stratified on the basis of high-, intermediate-, and low-risk children. (5) Children at high risk for retinoblastoma require more frequent screening, which may preferentially be examinations under anesthesia.

Conclusions: Risk stratification including genetic testing and counseling serves as the basis for screening of children at elevated risk for development of retinoblastoma. (10/17)

SCREENING FOR IDIOPATHIC SCOLIOSIS IN ADOLESCENTS—POSITION STATEMENT

American Academy of Orthopedic Surgeons, Scoliosis Research Society, and Pediatric Orthopedic Society of North America

ABSTRACT. The Scoliosis Research Society (SRS), American Academy of Orthopedic Surgeons (AAOS), Pediatric Orthopedic Society of North America (POSNA), and American Academy of Pediatrics (AAP) believe that there has been additional useful research in the early detection and management of adolescent idiopathic scoliosis (AIS) since the review performed by the United States Preventive Services Task Force (USPSTF) in 2004. This information should be available for use by patients, treating health care providers, and policy makers in assessing the relative risks and benefits of the early identification and management of AIS.

The AAOS, SRS, POSNA, and AAP believe that there are documented benefits of earlier detection and non-surgical management of AIS, earlier identification of severe deformities that are surgically treated, and of incorporating screening of children for AIS by knowledgeable health care providers as a part of their care. (9/15)

SKIING AND SNOWBOARDING INJURY PREVENTION

Canadian Paediatric Society

ABSTRACT. Skiing and snowboarding are popular recreational and competitive sport activities for children and youth. Injuries associated with both activities are frequent and can be serious. There is new evidence documenting the benefit of wearing helmets while skiing and snowboarding, as well as data refuting suggestions that helmet use may increase the risk of neck injury. There is also evidence to support using wrist guards while snowboarding. There is poor uptake of effective preventive measures such as protective equipment use and related policy. Physicians should have the information required to counsel children, youth and families regarding safer snow sport participation, including helmet use, wearing wrist guards for snowboarding, training and supervision, the importance of proper equipment fitting and binding adjustment, sun safety and avoiding substance use while on the slopes. (1/12, reaffirmed 1/20)

SPINAL MOTION RESTRICTION IN THE TRAUMA PATIENT—A JOINT POSITION STATEMENT

Peter E. Fischer, MD, MS; Debra G. Perina, MD; Theodore R. Delbridge, MD, MPH; Mary E. Fallat, MD; Jeffrey P. Salomone, MD; Jimm Dodd, MS, MA; Eileen M. Bulger, MD; and Mark L. Gestring, MD

ABSTRACT. The American College of Surgeons Committee on Trauma (ACS-COT), American College of Emergency Physicians (ACEP), and the National Association of EMS Physicians (NAEMSP) have previously offered varied guidance on the role of backboards and spinal immobilization in out-of-hospital situations. This updated consensus statement on spinal motion restriction in the trauma patient represents the collective positions of the ACS-COT, ACEP and NAEMSP. It has further been formally endorsed by a number of national stakeholder organizations. This updated uniform guidance is intended for use by emergency medical services (EMS) personnel, EMS medical directors, emergency physicians, trauma surgeons, and nurses as they strive to improve the care of trauma victims within their respective domains. (8/18)

SUPPLEMENT TO THE JCIH 2007 POSITION STATEMENT: PRINCIPLES AND GUIDELINES FOR EARLY INTERVENTION AFTER CONFIRMATION THAT A CHILD IS DEAF OR HARD OF HEARING

Joint Committee on Infant Hearing

PREFACE. This document is a supplement to the recommendations in the year 2007 position statement of the Joint Committee

on Infant Hearing (JCIH) and provides comprehensive guidelines for early hearing detection and intervention (EHDI) programs on establishing strong early intervention (EI) systems with appropriate expertise to meet the needs of children who are deaf or hard of hearing (D/HH).

EI services represent the purpose and goal of the entire EHDI process. Screening and confirmation that a child is D/HH are largely meaningless without appropriate, individualized, targeted and high-quality intervention. For the infant or young child who is D/HH to reach his or her full potential, carefully designed individualized intervention must be implemented promptly, utilizing service providers with optimal knowledge and skill levels and providing services on the basis of research, best practices, and proven models.

The delivery of EI services is complex and requires individualization to meet the identified needs of the child and family. Because of the diverse needs of the population of children who are D/HH and their families, well-controlled intervention studies are challenging. At this time, few comparative effectiveness studies have been conducted. Randomized controlled trials are particularly difficult for ethical reasons, making it challenging to establish causal links between interventions and outcomes. EI systems must partner with colleagues in research to document what works for children and families and to strengthen the evidence base supporting practices.

Despite limitations and gaps in the evidence, the literature does contain research studies in which all children who were D/HH had access to the same well-defined EI service. These studies indicate that positive outcomes are possible, and they provide guidance about key program components that appear to promote these outcomes. This EI services document, drafted by teams of professionals with extensive expertise in EI programs for children who are D/HH and their families, relied on literature searches, existing systematic reviews, and recent professional consensus statements in developing this set of guidelines.

Terminology presented a challenge throughout document development. The committee noted that many of the frequently occurring terms necessary within the supplement may not reflect the most contemporary understanding and/or could convey inaccurate meaning. Rather than add to the lack of clarity or consensus and to avoid introducing new terminology to stakeholders, the committee opted to use currently recognized terms consistently herein and will monitor the emergence and/or development of new descriptors before the next JCIH consensus statement.

For purposes of this supplement:

- *Language* refers to all spoken and signed languages.
- *Early intervention* (EI), according to part C of the Individuals with Disabilities Education Improvement Act (IDEA) of 2004, is the process of providing services, education, and support to young children who are deemed to have an established condition, those who are evaluated and deemed to have a diagnosed physical or mental condition (with a high probability of resulting in a developmental delay), those who have an existing delay, or those who are at risk of developing a delay or special need that may affect their development or impede their education.
- *Communication* is used in lieu of terms such as communication options, methods, opportunities, approaches, etc.
- *Deaf or hard of hearing* (D/HH) is intended to be inclusive of all children with congenital and acquired hearing loss, unilateral and bilateral hearing loss, all degrees of hearing loss from minimal to profound, and all types of hearing loss (sensorineural, auditory neuropathy spectrum disorder, permanent conductive, and mixed).
- *Core knowledge and skills* is used to describe the expertise needed to provide appropriate EI that will optimize the development and well-being of infants/children and their families. Core knowledge and skills will differ according to the roles of individuals within the EI system (eg, service coordinator or EI provider).

This supplement to JCIH 2007 focuses on the practices of EI providers outside of the primary medical care and specialty medical care realms, rather than including the full spectrum of necessary medical, audiologic, and educational interventions. For more information about the recommendations for medical follow-up, primary care surveillance for related medical conditions, and specialty medical care and monitoring, the reader is encouraged to reference the year 2007 position statement of the JCIH as well as any subsequent revision. When an infant is confirmed to be D/HH, the importance of ongoing medical and audiologic management and surveillance both in the medical home and with the hearing health professionals, the otolaryngologist and the audiologist, cannot be overstated. A comprehensive discussion of those services is beyond the scope of this document. (3/13)

TIMING OF UMBILICAL CORD CLAMPING AFTER BIRTH

American College of Obstetricians and Gynecologists Committee on Obstetric Practice (12/12)

WEIGHING ALL PATIENTS IN KILOGRAMS

Emergency Nurses Association (2021)

YEAR 2007 POSITION STATEMENT: PRINCIPLES AND GUIDELINES FOR EARLY HEARING DETECTION AND INTERVENTION PROGRAMS

Joint Committee on Infant Hearing

ABSTRACT. The Joint Committee on Infant Hearing (JCIH) endorses early detection of and intervention for infants with hearing loss. The goal of early hearing detection and intervention (EHDI) is to maximize linguistic competence and literacy development for children who are deaf or hard of hearing. Without appropriate opportunities to learn language, these children will fall behind their hearing peers in communication, cognition, reading, and social-emotional development. Such delays may result in lower educational and employment levels in adulthood. To maximize the outcome for infants who are deaf or hard of hearing, the hearing of all infants should be screened at no later than 1 month of age. Those who do not pass screening should have a comprehensive audiological evaluation at no later than 3 months of age. Infants with confirmed hearing loss should receive appropriate intervention at no later than 6 months of age from health care and education professionals with expertise in hearing loss and deafness in infants and young children. Regardless of previous hearing-screening outcomes, all infants with or without risk factors should receive ongoing surveillance of communicative development beginning at 2 months of age during well-child visits in the medical home. EHDI systems should guarantee seamless transitions for infants and their families through this process. (10/07)

APPENDIX 1

PPI: AAP Partnership for Policy Implementation

BACKGROUND

The American Academy of Pediatrics (AAP) develops policies that promote optimal physical, mental, and social health and well-being for all infants, children, adolescents, and young adults. These documents are valued highly not only by clinicians who provide direct health care to children but by members of other organizations who share similar goals and by parents, payers, and legislators. To increase clarity and action of AAP clinical guidance and recommendations for physicians at the point of care, the AAP formed the Partnership for Policy Implementation (PPI). The PPI is a group of medical informaticians who partner with authors of AAP clinical practice guidelines and clinical reports to assure that clinical recommendations are stated with the precision needed to implement them in an electronic health record (EHR) system. This also makes recommendations easier for humans to follow. Partnership for Policy Implementation volunteers focus on helping content experts develop clinical guidance that specifies exactly who is to do what, for whom, and under what circumstances.

VISION

The vision of the PPI is that all AAP clinical recommendations include clear guidance on how pediatricians can implement those recommendations into their patient care and that AAP clinical guidance can be easily incorporated within EHR decision-support systems.

MISSION

The mission of the PPI is to facilitate implementation of AAP recommendations at the point of care by ensuring that AAP documents are written in a practical, action-oriented fashion with unambiguous recommendations.

WHAT THE PPI IS

The PPI is a network of pediatric informaticians who work with AAP authors and clinical practice guideline subcommittees throughout the writing process.

Contributions of the PPI to the AAP writing process include disambiguation and specification; development of clear definitions; clearly defined logic; implementation techniques; action-oriented recommendations, including clinical algorithms; transparency of the evidence base for recommendations; and use of health information technology (HIT) standards.

WHAT THE PPI HAS ACCOMPLISHED

Since inception of the PPI, more than 30 statements have been published using the PPI process, covering a wide variety of child health topics, including well-appearing febrile infants (*Pediatrics.* 2021;148[2]:e2021052228), influenza prevention and control (*Pediatrics.* 2021;148[4]:e2021053744), attention-deficit/hyperactivity disorder in children and adolescents (*Pediatrics.* 2019;144[4]:e20192528), infantile hemangiomas (*Pediatrics.* 2019;143[1]:e20183475), maintenance intravenous fluids (*Pediatrics.* 2018;142[6]:e20183083), child passenger safety (*Pediatrics.* 2018;142[5]:e20182460), and high blood pressure in children and adolescents (*Pediatrics.* 2018;142[3]:e20182096).

One example of how a statement developed using the PPI process has gained broader acceptance is the AAP annual influenza statement. Since 2007, the Centers for Disease Control and Prevention has adopted components of the PPI statement (specifically, the clinical algorithm) within its own statement on the same topic.

WHAT THE PPI IS DOING NOW

In addition to creating practical, action-oriented guidance that pediatricians can use at the point of care, the PPI works to make it easier for these recommendations to be incorporated into electronic systems. To date, the PPI has focused its involvement on the statement development process. Involvement of the PPI during the writing process helps produce a clear, more concise document. As these standards of care become well documented, the PPI can begin to focus on building or mapping pediatric vocabulary; once solidified, this vocabulary can be built into EHR systems. The standards of care can also be matched to various logical and functional HIT standards that already exist today. Through this work, the PPI improves AAP policy documents by providing specific guidance to pediatricians at the point of care, helping ensure that EHRs are designed to assist pediatricians in providing optimal care for children. The PPI developed a short video that provides an overview of its mission and process. This video is available on the AAP YouTube channel at www.youtube.com/watch?v=woTfeoNcxn4.

The PPI continues to expand and mentor new members. For more information on the application process and about the PPI, please contact Kymika Okechukwu (kokechukwu@aap.org or 630/626-6317).
