### Personalized Learning

Create a custom learning experience based on your strengths and weaknesses. Interactive and dynamic content reinforces learning to help you make the connections and master key Med-Surg topics.

### Davis Edge Quizzing

Master course content and improve your scores on classroom exams by completing instructor assignments or creating your own practice quizzes. Detailed rationales for all answer options help prepare you for success.

### eBook

Access your text online anytime, anywhere for study, review, and reference. Add notes, highlights, and bookmarks.

**Activate your Access Code for Davis Advantage for Medical-Surgical Nursing today!**

1. Scratch off the silver bar below to reveal your unique access code
2. Go to [FADavis.com](http://FADavis.com) and click the **Log in** button at the top of the page
3. Log in or create an account
4. You'll be taken to the **My Products** page where you enter your access code

Scratch off silver bar with care!

PLEASE NOTE: This book cannot be returned for a refund once this code is scratched off. If your code has already been used, visit [FADavis.com](http://FADavis.com) to purchase access. Before activating your code, you will be asked to create a new student account or log into your existing account. If you are using Davis Advantage in a class, you will have the option to enter your Class ID when registering. Your instructor will provide you with your Class ID.

INSTRUCTORS: You don't need a code to access content. Adopters have free access to both Instructor and Student resources.

# Brief Table of Contents

## Unit I Professional Foundations of Medical-Surgical Nursing 1

- 1 Foundations for Medical-Surgical Nursing 1
- 2 Interprofessional Collaboration and Care Coordination 8
- 3 Cultural Considerations 22
- 4 Ethical Concepts 38
- 5 Palliative Care and End-of-Life Issues 52

## Unit II Clinical Principles of Medical-Surgical Nursing 61

- 6 Geriatric Implications for Medical-Surgical Nursing 61
- 7 Oxygen Therapy Management 80
- 8 Fluid and Electrolyte Management 110
- 9 Acid-Base Balance 141
- 10 Overview of Infusion Therapies 155
- 11 Pain Management 174
- 12 Complementary and Alternative Care Initiatives 215
- 13 Overview of Cancer Care 224
- 14 Overview of Shock and Sepsis 255

## Unit III Managing the Surgical Experience 283

- 15 Priorities for the Preoperative Patient 283
- 16 Priorities for the Intraoperative Patient 301
- 17 Priorities for the Postoperative Patient 323

## Unit IV Promoting Health in Patients With Immune Disorders 339

- 18 Assessment of Immune Function 339
- 19 Coordinating Care for Patients With Immune Disorders 356
- 20 Coordinating Care for Patients With Connective Tissue Disorders 380
- 21 Coordinating Care for Patients With Multidrug-Resistant Organism Infectious Disorders 408
- 22 Coordinating Care for Patients With HIV 425

## Unit V Promoting Health in Patients With Oxygenation Disorders 439

- 23 Assessment of Respiratory Function 439
- 24 Coordinating Care for Patients With Infectious Respiratory Disorders 459
- 25 Coordinating Care for Patients With Upper Airway Disorders 476
- 26 Coordinating Care for Patients With Lower Airway Disorders 495
- 27 Coordinating Care for Critically Ill Patients With Respiratory Dysfunction 515

## Unit VI Promoting Health in Patients With Circulatory or Perfusion Disorders 539

- 28 Assessment of Cardiovascular Function 539
- 29 Coordinating Care for Patients With Cardiac Dysrhythmia 560
- 30 Coordinating Care for Patients With Cardiac Disorders 592
- 31 Coordinating Care for Patients With Vascular Disorders 619
- 32 Coordinating Care for Critically Ill Patients With Cardiovascular Dysfunction 653

## Unit VII Promoting Health in Patients With Hematological Disorders 683

- 33 Assessment of Hematological Function 683
- 34 Coordinating Care for Patients With Hematological Disorders 710

## Unit VIII Promoting Health in Patients With Neurological Disorders 749

- 35 Assessment of Neurological Function 749
- 36 Coordinating Care for Patients With Brain Disorders 779
- 37 Coordinating Care for Patients With Spinal Cord Disorders 812

38 Coordinating Care for Patients With Peripheral Nervous System Disorders 844

39 Coordinating Care for Critically Ill Patients With Neurological Dysfunction 862

## Your journey to success begins here!

Davis Advantage for Medical-Surgical Nursing combines your textbook with an interactive, personalized learning and quizzing experience that makes this challenging, but must-know content easier to master.

Follow the instructions on the inside front cover.  
**UNLOCK YOUR RESOURCES TODAY!**

# LEARNING

Connecting concepts from the written word to the real world *Medical-Surgical Nursing, 2nd Edition* helps you to make the connections between concepts and patient care to prepare you for real-world nursing practice.

## STEP #1 Build a solid foundation.

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Describing the epidemiology of lower airway disorders
2. Correlating clinical manifestations to pathophysiological processes of:
  - a. Asthma
  - b. Chronic obstructive pulmonary disease
  - c. Cystic fibrosis
  - d. Lung cancer
3. Describing the diagnostic results used to confirm the diagnosis of lower airway disorders
4. Discussing the medical management of:
  - a. Asthma
  - b. Chronic obstructive pulmonary disease
  - c. Cystic fibrosis
  - d. Lung cancer
5. Developing a comprehensive plan of nursing care for patients with lower airway disorders

**Learning Outcomes** at the beginning of each chapter guide your reading and highlight the information you'll need to know, while **Connection Checks** throughout the chapters test how well you've mastered the material.

### Making Connections

#### CASE STUDY: WRAP-UP

Clifford continues to be short of breath and to wheeze. His SpO<sub>2</sub> remains acceptable while he receives oxygen via the nasal cannula. After the first three nebulizer treatments, his peak flow reading is repeated. It is slightly improved but not back to baseline. Clifford then receives Prednisone 60 mg intramuscularly (IM). The symptoms slowly begin to subside. A repeat of the peak flow reading reveals continued improvement. When Clifford's symptoms are fully resolved, he is discharged from the emergency department with a prescription for an oral prednisone taper. Before he leaves, hospital personnel ensure that he has an appointment with his primary care provider to review this hospital visit and update his asthma action plan.

#### Case Study Questions

1. What is the most important component of the medical management of Mr. Davis?
  - A. Breathing techniques
  - B. Disease management through education
  - C. Use of "rescue" medications
  - D. Use of a peak flow meter
2. If there are no wheezes and diminished breath sounds upon reassessment, what conclusion can the nurse make?
  - A. Mr. Davis has resolved his respiratory condition.
  - B. Mr. Davis has responded to the bronchodilator therapy.
  - C. Mr. Davis has a partially obstructed airway.

### Connection Check 26.2

What is the primary difference between emphysema and chronic bronchitis?

- A. Chronic bronchitis predominately affects the large airways.
- B. Emphysema predominately affects the large airways.
- C. Emphysema predominately affects the alveoli.
- D. Chronic bronchitis predominately affects the alveoli.

### Finding Connections

#### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Clifford Davis is a 39-year-old male with a history of asthma who presents to the emergency department with shortness of breath and inability to carry on a conversation. He is assuming a tripod position and exhibits pursed-lip breathing. He has a nonproductive cough. He woke up coughing, followed by chest tightness, which prompted a call to the rescue services. His vital signs are blood pressure (BP), 121/65 mm Hg; heart rate (HR), 150 bpm; respiratory rate (RR), 40. He has audible wheezes bilaterally. He has been a one-pack/day smoker for 15 years.

**Finding Connections** are case studies that illustrate key points and bring the content to life. Follow each case study as it unfolds throughout the chapter to see how the theory you're learning applies to practice. Then, answer the critical-thinking questions at the end of **Making Connections Case Study: Wrap-Up**.

**Safety Alert** If a patient with COPD experiencing an exacerbation is on oxygen therapy, SpO<sub>2</sub> and respiratory rate must be monitored continuously until the condition is stabilized. If the patient is receiving too much oxygen, it may “blunt” the respiratory drive. The respiratory effort in a patient with COPD is triggered by the decrease in oxygen, not an increase in carbon dioxide, which is different from the patient with healthy lungs. Therefore, too much oxygen and high PaO<sub>2</sub> and SpO<sub>2</sub> may cause a decreased respiratory effort.

**Safety Alerts** focus on potential hazardous or high-risk issues related to the specific chapter content.

**Nursing Management** provides clear and well-defined nursing care guidance to help you to understand the nurse’s role. Begin with scientific explanations for presenting clinical manifestations, then follow the nursing process to prioritize care. For easy reference, **Nursing Interventions** are formatted into **Assessments**, **Actions**, and **Teaching** categories with bulleted rationales that explain the ‘hows’ and ‘whys’ of treatment.

To explore learning resources for this chapter, go to **Davis Advantage** and find...

- Answers to in-text questions
- Chapter Resources and Activities
- NCLEX®-Style Chapter Review Questions
- Bibliography

Additional learning resources and activities are available for every chapter on **Davis Advantage**.

## Nursing Management

### Assessment and Analysis

The clinical manifestations presented by the patient are due to increased airway resistance, increased work of breathing, and increased sputum production. They include:

- Cough
- Increased sputum production
- Dyspnea
- Use of accessory muscles
- Tripod positioning
- Inability to talk in full sentences
- Pursed-lip breathing
- Changes in skin coloring
- Anxiety

### Nursing Diagnoses

- **Impaired gas exchange** related to altered oxygen delivery and alveoli destruction
- **Ineffective airway clearance** related to decreased energy, dyspnea, ineffective cough
- **Activity intolerance** related to fatigue and dyspnea
- **Anxiety** related to breathlessness

### Nursing Interventions

#### Assessments

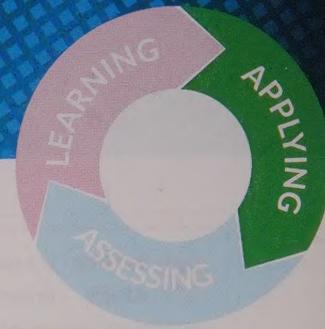

- Oxygen saturation  
*An SpO<sub>2</sub> of less than 90% indicates a significant oxygenation problem. The goal is to maintain the SpO<sub>2</sub> at 90% or above.*
- Respiratory rate  
*Monitor respiratory rate to avoid hypoventilation—the respiratory drive in COPD is hypoxemia, not hypercapnia. See Safety Alert.*
- Breath sounds  
*The presence of crackles and wheezes may indicate airway obstruction. Crackles indicate the premature closing of the airways.*
- Pursed-lip breathing  
*Patients with COPD display pursed-lip breathing to keep the airways open longer and prolong exhalation, allowing for increased time for oxygen and carbon dioxide exchange.*
- Cough  
*Cough is a cardinal sign of pulmonary disease. It is a protective mechanism for the tracheobronchial tree.*
- Temperature  
*Increased temperature is a sign of an infectious trigger.*
- Dyspnea  
*Use of the visual analog dyspnea scale allows the patient to identify his or her own level of dyspnea because dyspnea is a subjective experience.*
- Weight  
*Monitoring weight identifies nutritional deficiencies—with prolonged increased work of breathing and decreased energy, the ability to eat decreases.*

#### Actions

- Administer bronchodilators as ordered.  
*Bronchodilators are bronchial smooth muscle relaxants that help open the airway. Beta<sub>2</sub>-agonists (short-acting beta-agonists [SABAs] and long-acting beta-agonists [LABAs]) relax the smooth muscles of the airway by stimulating beta-adrenergic receptors, resulting in antagonism to bronchoconstriction. Anticholinergics relax and enlarge the airways in the lungs, making breathing easier. Also, anticholinergics can also protect the airways from bronchospasm and may reduce the amount of mucus produced by the airways.*
- Provide oxygen.  
*Increase the SpO<sub>2</sub> to 90%. Patients may be placed on continuous oxygen therapy if the SpO<sub>2</sub> is less than or equal to 88% or the PaO<sub>2</sub> is less than or equal to 60 mm Hg.*
- Position—semi-Fowler’s  
*The semi-Fowler’s position increases oxygenation by allowing adequate lung expansion.*
- Provide small, frequent meals with dietary supplements.  
*Small, frequent meals take less energy to consume and avoid excessive pressure on the diaphragm that may be associated with a large meal.*

#### Teaching

- Breathing techniques—pursed-lip breathing (Box 26.3)  
*Pursed-lip breathing keeps the airways open longer and prolongs exhalation, allowing for increased time for oxygen and carbon dioxide exchange.*
- Pacing of activities  
*Pacing decreases the work of breathing and conserves energy.*

# APPLYING

**A personalized learning experience tailored to your needs**

Put a study plan to work that's based on your strengths and weaknesses. Engaging, interactive content helps you make the connections and master key Med-Surg topics.

**Pre-Assessment for COPD**

Question 1 of 5

The nurse is caring for a client with secondary spontaneous pneumothorax. The client develops sudden shortness of breath and chest pain with a tracheal shift after harsh coughing. What should the nurse do next?

- Assess a blood pressure reading.
- Provide supplemental oxygen.**
- Deliver a bronchodilator medication.
- Prepare for chest tube insertion.

Animated mini-lecture videos make key concepts easier to understand, while interactive learning activities allow you to apply your knowledge and make the connections.

After working through the video and activity, a Post-Assessment quiz tests your mastery. The results feed into your Personalized Learning Plan, where your instructor is able to view them.

COPD

Video

Activity

Post-Assessment

Question 1 of 8

**This or That?** For each topic, select the answer which best classifies the following vocabulary term or patient data.

Caused by the destruction of alveoli

Chronic Bronchitis
  Emphysema
  Both

**INCORRECT.** Hypoxemia refractory to the administration of oxygen therapy is common in patients who are diagnosed with ARDS; therefore, the priority nursing action is to monitor pulse oximetry readings. A decrease in pulse oximetry readings from the baseline occurs due to intrapulmonary shunting. While auscultating heart sounds may be required, it is more appropriate to auscultate lung sounds as crackles may be present due to fluid buildup or lung sounds may be diminished due to atelectasis and fibrotic changes in the lungs.

Post-Assessment for COPD

Question 1 of 5

The client with emphysema comes to the emergency department with difficulty breathing. What assessment finding should the nurse anticipate?

- Excess mucous production
- Barrel shaped chest
- Hypoventilation
- Blueish skin tones

# ASSESSING

Building mastery and improving test scores with Personalized Quizzing

NCLEX®-style Q&A provides the additional practice you need to master Med-Surg content and improve your scores on classroom exams.

## STEP #3 Study smarter, not harder with Davis Edge quizzing.

**edge** COPD  
Start Date: 10/1/19 • End Date: 10/20/19

Question 1 of 10

The nurse is evaluating the effectiveness of a small volume nebulizer bronchodilator treatment for a patient with emphysema. Which assessment change indicates an effective outcome of the therapy? *Select all that apply.*

- Pulse oximetry reading goes from 92% to 94%.
- Audible wheezes are diminished.
- Heart rate increases from 98 to 110 beats per minute.
- The client states "my breathing is the same."
- Facial complexion is a ruddier color.

**Submit**

**NCLEX®-style questions** assess your understanding and challenge you to think critically. Practice with standard format questions like **multiple choice**, as well as more difficult format types such as **select all that apply**.

Immediate feedback with **comprehensive rationales** explains why your responses are **correct** or **incorrect**. Page-specific references direct you to the relevant content in your *Medical-Surgical Nursing* text, while **Test-Taking Tips** improve your test-taking skills.

**Feedback**

You answered 9 out of 10 correctly.  
Review the questions, answers and rationales below.

---

**Question 1**  
The nurse is evaluating the effectiveness of a small volume nebulizer bronchodilator treatment for a patient with emphysema. Which assessment change indicates an effective outcome of the therapy? *Select all that apply.*

**Answer Options:**

- Pulse oximetry reading goes from 92% to 94%.**  
Rationale: An increase in the pulse oximetry indicates increased oxygenation.
- Audible wheezes are diminished.**  
Rationale: Wheezes are a sign of restrictive airway, so a decrease is an encouraging sign.
- Heart rate increases from 98 to 110 beats per minute.  
Rationale: This is a side effect and not a sign of an effective outcome.
- The client states "my breathing is the same."  
Rationale: The patient should have an improvement of their breathing.
- Facial complexion is a ruddier color.  
Rationale: This is a side effect, not an effective outcome.

**Question ID:** ADE-31546  
**Course Topic:** Lower Airway Disorders: COPD  
**Concept:** Oxygenation; Critical Thinking  
**Cognitive:** Analysis [Analyzing]  
**Difficulty Level:** Easy  
**Client Need:** Physiological integrity  
**Chapter:** 26  
**Page reference:** 26-10

---

**Question 2**  
The nurse is caring for a patient with COPD who is on ventilator therapy. Which test is most beneficial to evaluate the patient's response to ventilator therapy?

**Answer Options:**

- Spirometry**  
Rationale: Spirometry measures airflow and lung volumes.
- Pulse oximetry  
Rationale: Pulse oximetry (SpO2) is a noninvasive method of measuring oxygen saturation that helps determine the severity of the respiratory distress.
- Arterial blood gases (ABG)  
Rationale: ABG measures oxygenation of the blood, acid-base balance, and the partial pressure of carbon dioxide, and it identifies the patient's response to oxygen and ventilation therapy and medications.
- Forced expiratory volume (FEV1)  
Rationale: FEV1 measures the amount of air that can be forced out of the lungs after a full inspiration in one second.

**Question ID:** ADE-31546  
**Course Topic:** Lower Airway Disorders: COPD  
**Concept:** Oxygenation  
**Cognitive:** Application [Applying]  
**Difficulty Level:** Medium  
**Client Need:** Physiological integrity  
**Chapter:** 26  
**Page reference:** 26-10

# About the Authors

**Janice J. Hoffman,  
PhD, RN, ANEF**

Dr. Hoffman began her nursing career on active duty as a United States Navy Nurse Corps Officer. She transitioned to the Navy Reserves after 7 years and retired in 2005 as a captain. Her experiences in the U.S. Navy were the start of her interest in

and passion for teaching, as she served as a staff development officer involved in medical corps, nurse corps, and hospital corps training.

With a nursing career spanning over 40 years, she has taught in graduate, baccalaureate, associate, and diploma nursing programs, as well as serving in staff-development positions in acute care and military facilities. Dr. Hoffman's areas of expertise include clinical decision making, new graduate transition, preceptor development, curriculum development; and teaching strategies. She has presented nationally and internationally on effective teaching and learning strategies, curriculum development, and new graduate nurse transition. Dr. Hoffman is a member of the editorial board and a manuscript reviewer for *Nurse Educator* and also serves as a reviewer for the *Journal of Nursing Education* and *Journal of Professional Nursing*.

She completed her Bachelor of Science in Nursing from the University of North Carolina at Chapel Hill. While she was receiving her Master of Science in Nursing Education from California State University Fresno, her master's thesis investigated self-directed learning among registered nurses. She obtained her PhD in Nursing from the University of Maryland School of Nursing, Baltimore, where she studied critical thinking in undergraduate students. An expert in new graduate transition, she has developed and implemented nurse internship and residency programs in large academic health centers, military facilities, and community hospitals.

In addition to this textbook, Dr. Hoffman has been a contributing author to several nursing fundamentals, pathophysiology, pharmacology, and critical care nursing textbooks. She has published manuscripts on new graduate transition, teaching strategies, and nursing care of patients with neurological disorders. An expert in test development, she has served as an item writer and item reviewer for the National Council of State Boards of Nursing. Dr. Hoffman has received more than \$1.8 million in grant funding to support seamless academic progression, particularly in RN-to-BSN programs.

**Nancy J. Sullivan,  
DNP, RN**

Dr. Sullivan's career has spanned over 40 years, which has allowed her the opportunity to experience a tremendous variety of nursing roles. She began her career in critical care/trauma nursing with both adult and pediatric patients. These experiences

sparked an interest in critical care nursing that remains today. She also has nurse management experience and 11 years of experience in a nurse educator role working with new graduate nurses. Since 2005, she has held several faculty positions, such as clinical instructor, clinical course coordinator, and theory course coordinator for both critical care and medical-surgical nursing courses.

She received her Bachelor of Science in Nursing from the University of Maryland, Baltimore, in 1975 and her Master of Science in Trauma/Critical Care Nursing from the same school in 1992. In 2013, she received her DNP from the Johns Hopkins University School of Nursing after completing a project focusing on rapid-cycle deliberate practice simulation.

Dr. Sullivan has authored manuscripts and presented locally, nationally, and internationally on the topics of the use of simulation in nursing education and resuscitation. She was also a contributing author in a nursing pharmacology textbook, writing a chapter focusing on antiarrhythmic drugs.

Presently, Dr. Sullivan is an assistant professor and the clinical simulation director for the Johns Hopkins University School of Nursing. She has primary responsibility for the simulation program for the prelicensure program as well as overseeing the integration of simulation into the advanced practice DNP programs. She is also presently the theory course coordinator for the last in a series of three medical-surgical nursing courses. Her research interests include using simulation in nursing education and resuscitation training.

The Sigma Theta Tau International Honor Society of Nursing acknowledged the first edition of Dr. Hoffman's and Dr. Sullivan's text with the Capstone International Nursing Book Award.

## **ACKNOWLEDGMENTS**

Both authors would like to acknowledge the many students and faculty who have provided feedback to the first edition of our book. It has been so gratifying and humbling to hear how you are using our book to facilitate your teaching and learning. To the students, a special thank you for your feedback, as this book was written with you, the students, in mind!

### **BOTH AUTHORS DEDICATE THIS BOOK TO:**

The dedicated and resourceful people at F. A. Davis Company who have been instrumental in the development of the first and second editions of this medical-surgical textbook. It was through their guidance, support, patience, and expertise that this textbook has become a reality. Thank you to Terri, Adrienne, Beth, and all the other reviewers, editors, and others involved. We also would like to thank the many contributing authors who shared their expertise and time in the development of this book. It is only their sharing of their expertise and experience that this book is a reality.

### **JANICE HOFFMAN ALSO DEDICATES THIS BOOK TO:**

My husband, Paul, who has unselfishly given up weekend activities and vacation days to allow me to devote time to this work! Hopefully, we will have more time to explore Virginia now!

My two sons, Bryan and Joshua, and their wives, Erika and Kaitlyn, who have been unconditionally supportive and patient as I worked on “THE BOOK.” Their love and encouragement are a constant source of joy in my life, and their children (my grandchildren—Lilly, Benton, and Joey Rose) are such great diversions!

A special tribute to my parents, Wallace and Lorraine Joyce, who were always a great source of love, support, and encouragement.

A special acknowledgment to Dr. Anne Belcher and Dr. Marilyn Oermann, who have consistently supported my academic career over the years and provided valuable mentoring.

Finally, heartfelt thanks to my coauthor, Dr. Nancy Sullivan! We have been friends and colleagues for years, and there is no one with whom I would rather have shared this journey. I hope you and Mark now have more time to enjoy your spectacular home!

### **NANCY SULLIVAN ALSO DEDICATES THIS BOOK TO:**

My wonderful husband, Mark, who has contributed steadfast support and invaluable advice during the hours spent in the writing and revising of this book. A true partner.

My parents, Charles and Lydia, whose love and support I will always cherish, and a special tribute to my mother, who inspired me to become a nurse. It was through her example that I realized from a very early age that I wanted to be a nurse—just like her!

Finally, warmest thanks to my coauthor, Dr. Janice Hoffman! In addition to her friendship, she has been a mentor guiding me through my career, providing support and opportunities that have helped move me forward. Thank you, Janice!

The title of this book is important because it describes the approach to the design and pedagogy of this nursing textbook. We believe that it is the connections that nurses make between the clinical presentation of the patient, the nursing actions, and *most importantly*, the rationales for those actions that promote clinical judgment and clinical decision making. *Medical-Surgical Nursing: Making Connections to Practice* is a concise, focused medical-surgical nursing text designed to prepare contemporary nursing students for adult health practice areas. This text is designed to teach associate degree (ADN), baccalaureate degree (BSN), and entry-level master's degree (MSN) nursing students. It is designed to serve as the primary text for medical-surgical and/or acute care courses.

According to the Nursing Executive Center of the Advisory Board (2008), there is a growing academic–practice gap demonstrated by recent nursing school graduates. In particular, nursing executives surveyed in these studies prioritized the following as areas in which new graduates lack expected knowledge and competency:

- Knowledge of pathophysiology of patient conditions (34%)\*
- Knowledge of pharmacological implications of medications (28%)\*
- Decision making based upon the nursing process (20%)\*
- Interpretation of assessment data (18%)\*

(The asterisks indicate the percentage of frontline nurse leaders' satisfaction with the specific new graduate nurses' proficiency.)

*Medical-Surgical Nursing: Making Connections to Practice* not only provides content related to pathophysiology and pharmacology but also presents it in a format that fosters an understanding of the relationships between the physiology, pathophysiology, clinical manifestations, and management of these disorders. This approach fosters a more accurate interpretation of data and better clinical judgment and decision making.

## ORGANIZATION

*Medical-Surgical Nursing: Making Connections to Practice* introduces a contemporary, student-centered learning approach to nursing education. With its concise content and explicit correlations between pathophysiology, clinical presentation, medical management, and nursing management, learners' thinking will be focused on understanding and applying the underlying principles to the management of disorders seen in adult patients. The consistent structure and organization in each of the chapters support learning and mastery of content.

The beginning of the text presents current professional issues/content pertinent to the medical-surgical population

(cultural considerations, ethical principles, interprofessional implications, etc.). The second unit provides the foundational clinical concepts that are woven throughout the text (geriatric considerations, pain management, oncology overview, fluid and electrolyte balance, etc.). Perioperative content is the focus of Unit III, which describes the management of patients in pre-, intra- and postoperative settings. This unit provides a broad overview of the operative experience that supports the specific discussions of surgical procedures presented in the disorder chapters.

The heart of the book is the chapters focusing on body system units. Consistent with the *Healthy People 2020* recommendations, there is comprehensive content on decreasing the risk and managing the complications of diseases such as heart disease, stroke, diabetes mellitus, chronic kidney disease, and cancer. The *Healthy People 2020* objectives are also used to guide content related to genomics and interprofessional care management. The final section of the book focuses on special populations and again incorporates those conditions outlined in *Healthy People 2020*, including obesity and substance use disorders. There are also chapters related to environmental injuries and trauma as well as management of mass casualties. In this second edition, based on the opioid crises in the United States, we have expanded this content, particularly in the chapters on pain and substance use disorders.

With an emphasis on health and wellness, each body system unit includes an assessment chapter, which is an overview of normal function, followed by chapters detailing selected disorders. The pathophysiology discussed in the disorder chapters is presented with an emphasis on how the clinical manifestations are directly related to alterations in normal function. Again, the focus is on assisting the learner in transferring prior learning in order to better understand the disease process. This approach is also consistent with most nursing programs, which require anatomy and physiology as prerequisites to their programs. The disorder chapters consistently present the epidemiology, pathophysiology, clinical manifestations, and medical and nursing management of selected medical-surgical disorders. With a focus on “making connections,” the rationales for medical, nursing, and interprofessional interventions are directly related to the underlying physiology and/or pathophysiology. Critical thinking and clinical judgment are facilitated with this approach because it requires the learner to consistently address the “whys” and “hows” of clinical presentation and treatment plans for patients with specific disease processes. The nursing care is presented with scientific explanations for the presenting clinical manifestations, and formatted as assessments, actions, and teaching interventions with rationales that correlate directly back to the physiological and/or pathophysiological content in the chapter—again, “making connections.”

Critical care nursing content is integrated into most of the body system units, with a dedicated critical care chapter for the management of patients in cardiovascular, neurological and neurosurgical, respiratory, and burn intensive care units. Additionally, there is a chapter dedicated to the management of patients in various shock states, with guides to hemodynamic monitoring.

## PEDAGOGICAL FEATURES

Numerous pedagogical features are incorporated into the book to facilitate student learning.

- **Learning Outcomes** guide the organization and content of each chapter. A consistent approach is used, with each assessment and disorder chapter having similar learning objectives to support the learner in developing a systematic approach to learning new content.
- **Essential Terms** are introduced at the beginning of each chapter and are highlighted and defined the first time they are used in the chapter.
- **Concepts** are used to guide the presentation of the content and are listed at the beginning of each chapter. These concepts are particularly relevant to nursing programs using a concept-based approach to their nursing curriculum.
- **Connection Checks** are multiple-choice questions incorporated throughout each chapter. Questions are integrated throughout the chapters and align with the chapter objectives. The successful completion of the Connection Checks helps ensure the student's understanding of the material as he or she moves through the chapter. An Answer Key for all of the Connection Check questions is at the end of the book for quick access; answers with rationales for each question are available online in the Davis Advantage Resources.
- **Case Studies** are used in each chapter. At the beginning of the chapter, the case study is titled "Finding Connections" and presents a patient case related to the chapter content. The case is introduced three times in each chapter and supports the learner in applying the chapter content. At the end of the chapter, "Making Connections" provides a wrap-up of the case study.
- **Case Study Questions** are presented at the end of the final "episode" of the case study and include five questions that require the application of the case study content to answer correctly. Answers with detailed rationales for these questions are available online in the Davis Advantage Resources.
- **Nursing Process Approach** is used to present the nursing management, including assessment, action, and teaching interventions and scientific rationales.
- **Evidence-Based Practice Boxes** are included in each chapter and present the latest evidence for a practice discussed in the respective chapter.
- **Safety Alerts** in chapters focus on potential hazardous or high-risk issues related to the specific chapter content.

- **Geriatric/Gerontological Considerations Boxes** present content focused on the special needs of older adults, including assessment findings associated with aging as well as special considerations in the care of this population.
- **Transitional Care Boxes** highlight the coordination required for patients with complex healthcare needs as they transition from different levels of healthcare settings on the basis of their care-coordination needs.
- **Genetic Connections Boxes** are included in chapters where there are genetic links related to the incidence, pathophysiology, or treatment modalities.
- **Figures and Graphics** are included to provide representative art to support student comprehension.

## Online Chapter Resources

- **NCLEX®-Style Chapter Review Questions** are presented online for each chapter for review of the overall chapter content.
- **Finding Connections Assessment Questions** ask the learner to apply anatomy and physiology content. Again, this stresses the importance of understanding anatomy and physiology as the basis of understanding disorders and not merely memorizing signs and symptoms.
- **Prioritization Activities** are included in selected disorder chapters and provide at least two presentations/scenarios that allow the student to prioritize the care for these patients.
- **NANDA-NIC-NOC Tables** are available in selected case studies and support the learner in applying the nursing process to the care of the patient.
- **Concept Maps** are included in selected case studies and have a consistent approach that describes the connections/relationships between normal anatomy and physiology, pathophysiology, clinical manifestations, and management.
- **Community Resource Boxes** are available for selected disorders and other selected chapters and present a list of public and community resources to provide services and information pertaining to selected disorders.

## THE TEXT IN RESPONSE TO STUDENT-CENTERED LEARNING

*Medical-Surgical Nursing: Making Connections to Practice* is a concise textbook that uses an integrated approach that reduces redundancies while at the same time making the important correlations more explicit. The textbook is based on the underlying physiology and pathophysiology of specific disorders generally seen in medical-surgical settings. The consistent focus on explicit correlations between pathophysiology, clinical presentation, and treatment plans facilitates critical thinking and provides the basis for better clinical decisions. Using this

type of framework, which integrates clinical judgment to guide decision making, promotes consistency in approach and provides a more focused discussion. With an emphasis on student-centered learning and technology, this medical-surgical textbook provides nursing students and faculty with the most up-to-date resources and information available through Web/online references.

The consistent approach to each assessment and disorder chapter facilitates student comprehension and fosters a structured approach to learning this complex content. The writing style supports reading comprehension, and the frequent Connection Checks allow students to self-evaluate their progress. Consistent headings and features also support the student in developing a systematic approach to learning complex content. The concise, focused approach of each disorder chapter is presented in a straightforward manner, with all content presented in an organized format from epidemiology to the evaluation of nursing care.

## THE TEACHING AND LEARNING PACKAGE

How students learn is evolving. In this digital age, we consume information in new ways. Online, we are spoon-fed information in bite-size, dynamic chunks.

In order to meet the needs of today's learners, how faculty teach is also evolving. Classroom time is valuable for active learning. This approach makes students responsible for the key concepts, allowing faculty to focus on clinical application. Relying on the textbook alone to support an active classroom leaves a gap. *Davis Advantage Med-Surg* fills that gap with the following resources:

- **A Strong Core Textbook** that provides the foundation of knowledge that today's nursing students need to pass the NCLEX® and enter practice prepared for success.

- **Online Student Tools** to learn and practice the content in an engaging, interactive format. **Pre-Assessment Quizzes** test students on their comprehension of a key topic and then give them a **Personalized Learning Plan** to work through that is based on their strengths and weaknesses. They are engaged in an interactive experience that uses multimedia content to help spark connections and bring concepts to life. Once students complete the interactive experience, **Post-Assessment Quizzes** assess their comprehension of the material.
- **Online Instructor Resources** are aimed at creating a dynamic classroom experience that relies heavily on interactive participation and is tailored to students' needs. Results from the post-assessments are available to faculty, in aggregate or by student, and inform a **Personalized Teaching Plan** that faculty can use to deliver a targeted classroom experience. Faculty will know students' strengths and weaknesses *before* they come to class and can spend class time focusing on where students are struggling. Suggested in-class activities are provided to help create an interactive, hands-on learning environment that helps students connect more deeply with the content. NCLEX-style questions from the **Instructor Test Bank** and **PowerPoint** slides that correspond to the textbook chapters are referenced in the Personalized Teaching Plans.
- **Davis Edge Med-Surg** online quizzing to promote assessment and remediation, using an adaptive format with NCLEX®-style questions. Faculty can set up a review and remediation system to take a constant pulse of classroom performance. The results are provided in real time and feed to a gradebook. Comprehensive rationales for all answer options are provided for students and explain why an answer is correct or incorrect.

Detroit, Michigan

# Reviewers

**Terri Astorino, DEd, MSN, RN**  
Associate Professor of Nursing  
Edinboro University  
Edinboro, Pennsylvania

**Andrietta Wright Barnett, DNP, APRN, FNP-BC**  
Visiting Professor  
Chamberlain University  
Walterboro, South Carolina

**Tracy Blanc, RN, MSN**  
Associate Professor  
Ivy Tech Community College, Terre Haute Campus  
Terre Haute, Indiana

**Tammy Clemens, MSN, RN, NP-C**  
Clinical Instructor/Course Manager  
University of Alabama in Huntsville  
Huntsville, Alabama

**Lorraine S. Collins, MSN, RN, CNOR**  
Associate Professor of Nursing  
Piedmont Virginia Community College  
Charlottesville, Virginia

**Lenore Cortez, MSN, RN-BC**  
Clinical Instructor of Nursing  
Angelo State University  
San Angelo, Texas

**Stacy Flaten, MSN, RN**  
Nursing Instructor  
Minot State University  
Minot, North Dakota

**Kryisia Hudson, DNP, RN, BC**  
Assistant Professor  
Johns Hopkins University School of Nursing  
Baltimore, Maryland

**Susan Irvine, MS, RN**  
Faculty Program Director  
Excelsior College  
Albany, New York

**Neena Tresa John, RN, MSN**  
Assistant Professor  
Ivy Tech Community College  
Lawrenceburg, Indiana

**Lynn Lagasse, MSN, RN, CNE**  
Assistant Clinical Professor of Nursing  
Keene State College  
Keene, New Hampshire

**Mary Jane Larmon, MBA, MSN, RN-BC, CCRN, Alumnus**  
Director  
Sharon Regional School of Nursing  
Sharon, Pennsylvania

**Susan McCarthy, DNP, APRN**  
Professor of Nursing  
Finger Lakes Community College  
Canandaigua, New York

**Janell McKethan, MSN, RN, CMSRN**  
Registered Nurse  
Atlanta VA Medical Center  
Atlanta, Georgia

**Terri Peterson, RN, MSN Ed**  
Nursing Faculty  
Atlanta Technical College  
Atlanta, Georgia

**Kimberlie Rippey, MSN, RNC**  
Instructor of Nursing  
Finger Lakes Community College  
Canandaigua, New York

**Rebecca Rubin, MS**  
Instructor  
South Piedmont Community College  
Monroe, North Carolina

**Suzanne H. Tang, DNP, APRN, FNP-BC, PHN**  
Professor and Assistant Director of Nursing  
Rio Hondo College  
Whittier, California

**Regina Donovan Twigg, DNP, RN, CNE**  
Clinical Associate Professor & Nursing Program Coordinator  
Towson-Hagerstown  
Towson University, Department of Nursing  
Towson, Maryland

**Geraldine Tyrell, DNP, RN, CNE**  
Director & Associate Professor  
Bethel College  
North Newton, Kansas

**Julia Vincente, PhD, MSN, RN, CCRN**  
Clinical Education Consultant, Critical Care Residency Program  
Martin Health System  
Stuart, Florida

**Karol Yundt, MSN, RN**  
Assistant Professor of Nursing  
Northampton Community College  
Bethlehem, Pennsylvania

## SPECIAL THANKS TO OUR CULTURE ADVISORY BOARD REVIEWERS:

**Victoria Haynes, DNP, APRN, FNP-C**  
Coordinator of Diversity & Cultural Competency/Associate Professor  
School of Nursing  
MidAmerica Nazarene University  
Olathe, Kansas

**Marilyn A. Ray, RN, PhD, CTN-A, FSfAA, FAAN, FESPCH (hon.), FNAP**  
Colonel (Ret.), United States Air Force, Nurse Corps  
Professor Emeritus  
The Christine E. Lynn College of Nursing  
Florida Atlantic University  
Boca Raton, Florida

## UNIT I PROFESSIONAL FOUNDATIONS OF MEDICAL-SURGICAL NURSING 1

### Chapter 1: Foundations for Medical-Surgical Nursing 1

#### Introduction 2

#### Competencies in Medical-Surgical Nursing 2 Competencies Related to the Nursing Process 3

#### Evidence-Based Nursing Care 3

#### Patient-Centered Care in the Medical- Surgical Setting 4

#### Patient Safety Outcomes 5

#### Interprofessional Collaboration and Communication 6

### Chapter 2: Interprofessional Collaboration and Care Coordination 8

#### Introduction 9

#### Overview of Transitional Care 9

#### Evidence-Based Models of Transitional Care 10

The Transitional Care Model 10

The Care Transitions Program 11

Project RED and Project BOOST 11

Patient-Centered Medical Home/Guided Care  
Program 11

Transforming Care at the Bedside Model 12

Patient Education 12

#### The Nurse as Patient Care Coordinator 12

#### Interprofessional Collaboration 13

Interprofessional Communication 13

Interprofessional Education 14

#### Composition and Roles of the Interprofessional Care Team 15

Registered Nurse 15

Providers 17

Rehabilitation Therapy 17

Respiratory Therapist 17

Registered Dietitian/Nutritionist 18

Case Manager 18

Home-Care Coordinator 18

Transition Guide 18

Pharmacist 18

Ad Hoc Members 18

#### Unique Patient Situations Requiring or Enhanced by Interprofessional Collaboration 19

### Chapter 3: Cultural Considerations 22

#### Introduction 22

#### Ethnicity, Race, Identity, Culture, and Cultural Belief System 23

#### Cultural Competence, Awareness, and Sensitivity 24

Cultural Competence 24

Cultural Awareness 24

Cultural Sensitivity 25

#### Health Disparities and Health Equity 25

Health Disparities 25

#### Eliminating Disparities and Creating Health Equity 29

Social Determinants of Health 29

Improving Health Literacy 30

#### Cultural Assessment Models 31

Transcultural Nursing 32

#### Assessing Cultural Competence 32

Characteristics of Cultural Diversity 32

### Chapter 4: Ethical Concepts 38

#### The Role of Ethics in Nursing 38

#### Bioethics 39

#### The Belmont Report 40

#### Professional Standards for Ethical Practice: Guidance Documents for Nurses 40

American Nurses Association Code of Ethics 40

ANA Scope and Standards of Practice 41

International Nursing Council Code of Ethics 41

#### Ethical Principles and Theories Relevant to Nursing 41

#### Ethical Theories to Support Nurses in Decision Making 42

Deontology 42

Consequentialism and Utilitarianism 43

Rights	43
Casuistry	43
<b>Ethical Dilemmas</b>	<b>44</b>

Nursing Management for a Mechanically Ventilated Patient	106
Weaning From Mechanical Ventilation	107

## Chapter 8: Fluid and Electrolyte Management 110

### Basic Concepts of Fluids 111

- Fluid Composition 111
- Fluid Intake and Output 112

### Fluid and Electrolyte Regulation 112

- Osmosis 112
- Diffusion 113
- Filtration 113
- Regulatory Mechanisms 113
- Indicators of Fluid Status 115
- Age-Related Changes 116

### Fluid Imbalances 116

- Hypovolemia: Fluid Volume Deficit 117
- Hypervolemia: Fluid Volume Excess 118

### Electrolyte Disorders 121

- Sodium 121
- Chloride 127
- Potassium 128
- Magnesium 132
- Calcium 134
- Phosphorus 137

## Chapter 9: Acid-Base Balance 141

### Acid-Base Balance Overview 141

- Hydrogen Ion Concentration 141
- Acids 142
- Bases 142
- Oxygenation 142
- Carbon Dioxide 142
- Bicarbonate 143

### Regulation of Acid-Base Balance 143

- Chemical Buffers 143
- Respiratory Buffers 143
- Renal Buffers 143

### Respiratory and Renal Compensation 144

- Respiratory Compensation 144
- Renal Compensation 144

### Arterial Blood Gas Interpretation 146

- Obtaining an Arterial Blood Gas 146
- Arterial Blood Gas Assessment 146
- Steps for Interpreting Arterial Blood Gas 147

### Acid-Base Disorders 148

- Respiratory Acidosis 148
- Respiratory Alkalosis 149
- Metabolic Acidosis 150
- Metabolic Alkalosis 151

## Chapter 10: Overview of Infusion Therapies 155

### Introduction 156

### Solutions Used in Infusion Therapy 156

### Veins Used in Infusion Therapy 158

### Types of Intravenous Access Devices 159

- Peripheral Venous Access 159
- Central Venous Access 161

### Equipment Used in Infusion Therapy 164

### Nursing Management of Infusion Therapy 165

- Monitoring and Preventing Complications 165
- Maintaining Intravenous Access 167
- Administration of Intravenous Medications 168
- Administration of Blood Products 169
- Administration of Total Parenteral Nutrition 171
- Patient Teaching 172

## Chapter 11: Pain Management 174

### Introduction 175

### Definitions of Pain 176

- Distinguishing Acute and Chronic Pain 177
- Distinguishing Nociceptive and Neuropathic Pain 178

### Processing Pain Messages 179

- The Processing of Pain Messages in Acute Pain 179
- Dysfunctional Pain Processing Is the Hallmark of Chronic Pain 181

### Factors Shaping the Pain Experience 182

- Sociocultural Determinants of Pain 182
- The Influence of Gender and Genetics 182
- Epigenetics and Pain 184
- Pain and Older Adults 184

### Comprehensive Assessment Strategies for Acute and Chronic Pain 185

- Measuring Pain Intensity 185
- The Focused Pain Assessment 187

### Nursing Management of Pain 188

- Patient and Nurse: The Therapeutic Partnership 188
- The Care-Planning Process for Managing Acute and Chronic Pain 188
- Nursing Diagnoses for Patients in Pain 189
- Measuring the Effectiveness of Care 190

### Pain Management Options 190

- Therapeutic Interventions to Promote Pain Relief 190
- Managing Pain and Pain Relief Expectancy 208

**Managing Pain in Special Populations 209**

- Managing Pain in Older Adults 209
- Managing Pain in Adults With Cognitive or Communication Impairments 210

**Chapter 12: Complementary and Alternative Care Initiatives 215****Introduction 215****Classification of CAM 216**

- Whole Medical Systems/Alternative Medical Systems 216
- Mind/Body Therapies 217
- Manipulative and Body-Based Therapies 219
- Energy Healing Therapy 220
- Dietary Supplements, Herbal Medicine, and Botanicals 220

**Nursing Implications: Assessment, Education, and Research 221****Chapter 13: Overview of Cancer Care 224****Introduction 225****Epidemiology 225**

- Prevalence in the United States 225
- Risk Factors for Cancer 226

**Pathophysiology 226**

- Carcinogenesis 226
- Cancer Characteristics 226
- Metastasis 227

**Types of Cancer 228****Staging 228****Clinical Presentation 228**

- Oncological Emergencies 233

**Prevention 237**

- Primary Prevention 237
- Secondary Prevention 238
- Tertiary Prevention 240

**Diagnosing Cancer 240**

- Diagnostic Evaluation 240

**Treatment 241**

- Treatment Modalities 242

**Nursing Management 247****Chapter 14: Overview of Shock and Sepsis 255****Overview of Shock 256**

- Cardiac Output 256
- Classifications of Shock 256
- Stages of Shock 257

**Assessment and Monitoring of Shock 258**

- Physical Assessment 258
- Hemodynamic Monitoring 260
- Laboratory Analysis 262

**Hypovolemic Shock 263**

- Epidemiology 263
- Pathophysiology 263
- Clinical Manifestations 263
- Management 264

**Cardiogenic Shock 266**

- Epidemiology 266
- Pathophysiology 267
- Clinical Manifestations 267
- Management 267

**Obstructive Shock 270**

- Epidemiology 270
- Pathophysiology 271
- Clinical Manifestations 271
- Management 271

**Distributive Shock 272**

- Neurogenic Shock 273
- Anaphylactic Shock 274
- Sepsis/Septic Shock 275

**UNIT III****MANAGING THE SURGICAL EXPERIENCE 283****Chapter 15: Priorities for the Preoperative Patient 283****Introduction 284****Informed Consent 284**

- Components of an Informed Consent 287
- Advance Directives 289
- Obtaining Informed Consent 289

**Time-Outs/Pause for Cause 290**

- Components of a Time-Out 290

**Patient Assessment 290**

- Patient History 290
- Physical Assessment 295
- Systems Assessment 295

**Patient Preparation for the Surgical Experience 296**

- Laboratory Assessment 296
- Radiological Assessment 296
- Patient Teaching 296
- Physical Preparations 297
- Transfer 297

**Nursing Management 298**

- Nursing Diagnoses 298
- Nursing Interventions 298

**Chapter 16: Priorities for the Intraoperative Patient 301****Overview of the Surgical Experience 302**

- Surgical Settings 302
- Surgical Categories 302

**Overview of the Surgical Team Members 303**

- Sterile Team Members 303
- Nonsterile Team Members 304

**Priority Assessments and Procedures 305**

- Preoperative Assessment 305
- Surgical Pause 305
- Surgical Scrub 306
- Surgical Attire 306

**Anesthesia 306**

- Types of Anesthesia 307

**Airway Management 313****Positioning the Patient in the Operating Room 315**

- Common Intraoperative Positions 315
- Positioning Devices 319
- Positioning Complications 319

**Nursing Management 319**

- Nursing Diagnoses 319
- Nursing Interventions 320

**Chapter 17: Priorities for the Postoperative Patient 323****Introduction 323****The Post-Anesthesia Care Unit 323**

- Post-Anesthesia Care Unit Phases of Care 324
- Post-Anesthesia Care Unit Settings 324

**Patient Care in the Post-Anesthesia Care Unit 325**

- Priority Assessments 325
- Pain Management 327
- Management of Postoperative Nausea and Vomiting (PONV) 328
- Potential Complications 328

**Nursing Management 329**

- Nursing Interventions 329

**Patient Care on the Inpatient Unit 332**

- Potential Postoperative Complications 333

**Nursing Management 334****UNIT IV  
PROMOTING HEALTH IN PATIENTS  
WITH IMMUNE DISORDERS 339****Chapter 18: Assessment  
of Immune Function 339****Introduction 340****Overview of Anatomy and Physiology 340**

- Anatomy of the Immune System 340
- Physiology of the Immune Function 346

**Assessment of the Immune System 349**

- History 349
- Physical Examination 349
- Inspection 350
- Auscultation 350
- Palpation and Percussion 350

**Diagnostic Studies 350****Age-Related Changes 353****Chapter 19: Coordinating  
Care for Patients With Immune  
Disorders 356****Introduction 357****Overview of Primary and Secondary  
Immune Dysfunction 357****Primary Immune Dysfunction: B-Cell  
Deficiencies 357**

- X-Linked Agammaglobulinemia 357
- Other B-Cell Deficiencies 360

**Primary Immune Dysfunction: T-Cell Deficiencies 361**

- DiGeorge's Syndrome 361
- Other T-Cell Immune Deficiencies 365

**Primary Immune Deficiency of Both T Cells and B Cells 365****Secondary Immune Dysfunction: Therapy-Induced Deficiencies 366**

- Epidemiology 366
- Pathophysiology 366
- Management 366

**Excessive Immune Response 367**

- Hypersensitivities 369

**Chapter 20: Coordinating Care for Patients With Connective Tissue Disorders 380****Introduction 381****Osteoarthritis 381**

- Epidemiology 381
- Pathophysiology 381
- Clinical Manifestations 382
- Management 382

**Rheumatoid Arthritis 386**

- Epidemiology 386
- Pathophysiology 387
- Clinical Manifestations 388
- Management 388

**Scleroderma 392**

- Epidemiology 392
- Pathophysiology 393
- Clinical Manifestations 393
- Management 394

**Lupus 396**

- Epidemiology 396
- Pathophysiology 397
- Clinical Manifestations 397
- Management 397

**Gout 400**

- Epidemiology 400
- Pathophysiology 400
- Management 401

**Fibromyalgia 402**

- Epidemiology 402
- Pathophysiology and Clinical Manifestations 403
- Management 403

**Chapter 21: Coordinating Care for Patients With Multidrug-Resistant Organism Infectious Disorders 408****Introduction 409****Multidrug-Resistant Organisms 409**

- Methicillin-Resistant *Staphylococcus Aureus* 409
- Vancomycin-Resistant *Enterococci* 411
- Clostridioides Difficile* 413
- Acinetobacter Baumannii* 414
- Carbapenem-Resistant Enterobacteriaceae (CRE) 415

**Management of Multidrug-Resistant Organisms 416**

- Medical Management 416
- Nursing Management 420

**Chapter 22: Coordinating Care for Patients With HIV 425****Overview of the HIV/AIDS Continuum 425****Human Immunodeficiency Virus (HIV) 426**

- Epidemiology 426
- Pathophysiology 427
- Clinical Manifestations 429
- Management 429

**UNIT V****PROMOTING HEALTH IN PATIENTS WITH OXYGENATION DISORDERS 439****Chapter 23: Assessment of Respiratory Function 439****Introduction 440****Overview of Anatomy and Physiology 440**

- Functions of the Respiratory System 440
- Anatomy of the Respiratory System 440
- Physiology of the Respiratory System 442

**Assessment 445**

- History 445
- Health History 446
- Physical Assessment 447

**Diagnostic Studies 449**

- Arterial Blood Gases 449
- Pulse Oximetry 451
- Capnography and Capnometry 452
- Sputum Analysis 452
- Chest X-rays 453
- Pulmonary Function Test 453
- Bronchoscopy 453
- Thoracentesis 455
- Lung Biopsy 455

**Age-Related Changes of the Respiratory System 456****Chapter 24: Coordinating Care for Patients With Infectious Respiratory Disorders 459****Introduction 460**

- The Upper Respiratory Tract 460
- The Lower Respiratory Tract 460
- Establishment of a Respiratory Tract Infection 461

**Influenza 461**

- Epidemiology 461
- Pathophysiology 461
- Clinical Manifestations 462
- Management 462

**Pneumonia 466**

- Epidemiology 466
- Pathophysiology 467
- Clinical Manifestations 467
- Management 468

**Tuberculosis 470**

- Epidemiology 470
- Pathophysiology and Clinical Manifestations 471
- Management 471

**Chapter 25: Coordinating Care for Patients With Upper Airway Disorders 476****Rhinitis 477**

- Epidemiology 477
- Pathophysiology 477
- Clinical Manifestations 477
- Management 477

**Rhinosinusitis 479**

- Epidemiology 479
- Pathophysiology 479
- Clinical Manifestations 479
- Management 480

**Obstructive Sleep Apnea 481**

- Epidemiology 481
- Pathophysiology 482
- Clinical Manifestations 482
- Management 483

**Laryngitis 485**

- Epidemiology 485
- Pathophysiology and Clinical Manifestations 485
- Management 485

**Laryngeal Cancer 486**

- Epidemiology 486
- Pathophysiology 486
- Clinical Manifestations 486
- Management 486

**Laryngeal Trauma 491**

- Epidemiology 491
- Pathophysiology 491
- Clinical Manifestations 491
- Management 491

**Chapter 26: Coordinating Care for Patients With Lower Airway Disorders 495****Introduction 496****Asthma 496**

- Epidemiology 496
- Pathophysiology 496
- Clinical Manifestations 496
- Management 497

**Chronic Obstructive Pulmonary Disease 500**

- Epidemiology 500
- Pathophysiology 503
- Clinical Manifestations 503
- Management 504

**Cystic Fibrosis 507**

- Epidemiology 507
- Pathophysiology 507
- Clinical Manifestations 509
- Management 509

**Lung Cancer 510**

- Epidemiology 510
- Pathophysiology 510
- Clinical Manifestations 511

## Chapter 27: Coordinating Care for Critically Ill Patients With Respiratory Dysfunction 515

### Pulmonary Embolism 516

- Epidemiology 516
- Pathophysiology 517
- Clinical Manifestations 518
- Management 518

### Acute Respiratory Failure 521

- Epidemiology 521
- Pathophysiology 522
- Clinical Manifestations 522
- Management 523

### Acute Respiratory Distress Syndrome 526

- Epidemiology 526
- Pathophysiology and Clinical Manifestations 526
- Management 527

### Chest Trauma 532

- Epidemiology 532
- Pathophysiology 532
- Clinical Manifestations 533
- Management 533

## UNIT VI

## PROMOTING HEALTH IN PATIENTS WITH CIRCULATORY OR PERFUSION DISORDERS 539

### Chapter 28: Assessment of Cardiovascular Function 539

#### Overview of the Cardiovascular System 540

- Vascular System 540
- Anatomy of the Heart 542
- Blood Supply to the Heart 543

#### Physiology of the Heart 543

- Cardiac Conduction System 544
- Cardiac Cycle 547
- Blood Pressure 548

#### Cardiac Output 549

- Heart Rate 549
- Stroke Volume 549

#### Assessment 550

- History 550
- Current Health Problems 550
- Physical Assessment 550

### Diagnostic Studies 552

- Laboratory Markers as Predictors of Heart Disease 552
- Laboratory Markers of Acute Cardiac Damage or Injury 553
- Diagnostic Imaging Studies 554

### Age-Related Changes 557

## Chapter 29: Coordinating Care for Patients With Cardiac Dysrhythmia 560

### Introduction 561

### Epidemiology 562

### Pathophysiology 562

### ECG Review 562

- Electrocardiogram 562
- Steps in ECG Interpretation 564

### Cardiac Dysrhythmias 565

- Sinus Dysrhythmias 565
- Atrial Dysrhythmias 568
- Junctional Rhythms 576
- Ventricular Rhythms 577
- Asystole 581
- Heart Blocks 581
- Nursing Management 587

## Chapter 30: Coordinating Care for Patients With Cardiac Disorders 592

### Coronary Artery Disease 593

- Epidemiology 593
- Pathophysiology 593
- Clinical Manifestations 595
- Management 595

### Infective Endocarditis 600

- Epidemiology 600
- Pathophysiology 601
- Clinical Manifestations 601
- Management 602

### Myocarditis 603

- Epidemiology 603
- Pathophysiology 603
- Clinical Manifestations 603
- Management 604

### Pericarditis 604

- Epidemiology 604
- Pathophysiology 604

Clinical Manifestations	605
Management	605
<b>Valvular Disease</b>	<b>607</b>

Clinical Manifestations	645
Management	646

## Chapter 32: Coordinating Care for Critically Ill Patients With Cardiovascular Dysfunction 653

### Overview of Hemodynamic Monitoring 654

Cardiac Output	654
Hemodynamic Monitoring Systems	654

### Myocardial Infarction 664

Epidemiology	664
Pathophysiology	664
Clinical Manifestations	665
Management	666

### Cardiomyopathy 672

Epidemiology	672
Pathophysiology	672
Clinical Manifestations	672
Management	673

### Cardiogenic Shock 675

Pathophysiology	676
Clinical Manifestations	676
Management	676

## UNIT VII PROMOTING HEALTH IN PATIENTS WITH HEMATOLOGICAL DISORDERS 683

### Chapter 33: Assessment of Hematological Function 683

#### Introduction 684

#### Overview of Anatomy and Physiology 684

Bone Marrow	684
Blood Cells	684
Plasma	690
Spleen	691

#### Overview of Hematology Function 691

Oxygen Delivery	691
Clotting Cascade	693
Inflammation and Immunity	694

#### Hematological Assessment 694

History	695
Physical Assessment	698

#### Diagnostic Studies 700

Laboratory Profile	700
Examination of the Bone Marrow	706

#### Age-Related Changes to the Hematological System 707

## Chapter 34: Coordinating Care for Patients With Hematological Disorders 710

### Introduction 711

### Red Blood Cell Disorders 711

- Iron-Deficiency Anemia 711
- Vitamin B<sub>12</sub> Anemia 715
- Folic Acid Deficiency 718
- Sickle Cell Anemia 721
- Aplastic Anemia 726
- Glucose-6-Phosphate Dehydrogenase Deficiency 728
- Polycythemia Vera 729

### Bleeding Disorders 733

- Thrombocytopenia 733

### White Blood Cell Disorders 736

- Leukemia 736

### Lymph Disorders 740

- Malignant Lymphomas 740
- Multiple Myeloma 743

## UNIT VIII

## PROMOTING HEALTH IN PATIENTS WITH NEUROLOGICAL DISORDERS 749

## Chapter 35: Assessment of Neurological Function 749

### Introduction 750

### Overview of Anatomy and Physiology 750

- Nerve Cell Types and Functions 750
- The Central Nervous System 753
- The Peripheral Nervous System 761

### Assessment 763

- History and Physical 766
- Vital Signs and Increased Intracranial Pressure 771

### Diagnostic Studies 772

- Radiographic Procedures 772

### Psychosocial Considerations 776

### Age-Related Changes 777

## Chapter 36: Coordinating Care for Patients With Brain Disorders 779

### Introduction 780

### Headache 780

- Epidemiology 780
- Pathophysiology 780
- Clinical Manifestations 780
- Management 782

### Brain Tumors 785

- Primary Brain Tumors 785
- Metastatic Central Nervous System Disease 786

### Seizures 790

- Epidemiology 790
- Pathophysiology 791
- Clinical Manifestations 791
- Management 794

### Meningitis 798

- Epidemiology 798
- Pathophysiology 798
- Clinical Manifestations 799
- Management 799

### Encephalitis 802

- Epidemiology 802
- Pathophysiology 802
- Clinical Manifestations 802
- Management 802

### Parkinson's Disease 803

- Epidemiology 803
- Pathophysiology 804
- Clinical Manifestations 804
- Management 804

### Alzheimer's Disease 806

- Epidemiology 806
- Pathophysiology 807
- Clinical Manifestations 807
- Management 807

## Chapter 37: Coordinating Care for Patients With Spinal Cord Disorders 812

### Introduction 813

### Low-Back Pain 815

- Epidemiology 815
- Pathophysiology 815
- Clinical Manifestations 816
- Management 816

**Herniated Nucleus Pulposus 819**

- Epidemiology 819
- Pathophysiology 819
- Clinical Manifestations 819
- Management 820

**Multiple Sclerosis 823**

- Epidemiology 823
- Pathophysiology 823
- Clinical Manifestations 823
- Management 823

**Amyotrophic Lateral Sclerosis 827**

- Epidemiology 827
- Pathophysiology 827
- Clinical Manifestations 827
- Management 828

**Spinal Cord Injury 830**

- Epidemiology 830
- Pathophysiology 830
- Clinical Manifestations 831
- Management 832

**Spinal Cord Tumors 838**

- Epidemiology 838
- Pathophysiology 838
- Clinical Manifestations 839
- Management 839

**Chapter 38: Coordinating Care for Patients With Peripheral Nervous System Disorders 844****Introduction 845****Peripheral Nervous System 845**

- Autonomic Nervous System 845

**Myasthenia Gravis 846**

- Epidemiology 846
- Pathophysiology 846
- Clinical Manifestations 847
- Management 847

**Guillain-Barré Syndrome 854**

- Epidemiology 854
- Pathophysiology 854
- Clinical Manifestations 855
- Management 855

**Trigeminal Neuralgia 858**

- Epidemiology 858
- Pathophysiology 858
- Clinical Manifestations 858
- Management 859

**Chapter 39: Coordinating Care for Critically Ill Patients With Neurological Dysfunction 862****Introduction 863****Increased Intracranial Pressure 863**

- Pathophysiology and Clinical Manifestations 863
- Intracranial Pressure Monitoring 865
- Management 869

**Stroke 876**

- Epidemiology 876
- Ischemic Stroke 877
- Management 881
- Hemorrhagic Stroke 885

**Traumatic Brain Injury 891**

- Epidemiology 891
- Pathophysiology 891
- Management 896

**Neurogenic Shock 899**

- Pathophysiology and Clinical Manifestations 899
- Management 899

**UNIT IX****PROMOTING HEALTH****IN PATIENTS WITH ENDOCRINE DISORDERS 903****Chapter 40: Assessment of Endocrine Function 903****Introduction 904****Overview of Anatomy and Physiology 904**

- Hypothalamus and Pituitary Gland 907
- Adrenal Glands 908
- Thyroid Gland 909
- Parathyroid Glands 910
- Gonads 910
- Pancreas 911

**Assessment 912**

- History 912
- Physical Assessment 912

**Diagnostic Studies 913**

- Imaging Studies 913

**Age-Related Changes 913**

## Chapter 41: Coordinating Care for Patients With Pituitary Disorders 917

### Introduction 918

### Disorders of the Anterior Pituitary Gland 919

Hypopituitarism 919

Hyperpituitarism 921

### Disorders of the Posterior Pituitary Gland 926

Diabetes Insipidus 926

Syndrome of Inappropriate Antidiuretic

Hormone 928

## Chapter 42: Coordinating Care for Patients With Adrenal Disorders 932

### Introduction 933

### Adrenal Cortical Insufficiency 933

Epidemiology 933

Pathophysiology 933

Clinical Manifestations 934

Management 934

### Adrenal Cortex Hyperfunction 936

Epidemiology 936

Pathophysiology 937

Clinical Manifestations 937

Management 937

### Pheochromocytoma 940

Epidemiology 940

Pathophysiology 940

Clinical Manifestations 940

Management 940

## Chapter 43: Coordinating Care for Patients With Thyroid and Parathyroid Disorders 944

### Introduction 945

### Hypothyroidism 945

Epidemiology 945

Pathophysiology 946

Clinical Manifestations 946

Management 947

### Hyperthyroidism 949

Epidemiology 949

Pathophysiology 949

Clinical Manifestations 949

Management 950

### Thyroid Cancer 953

### Hypoparathyroidism 953

Epidemiology 953

Pathophysiology 954

Clinical Manifestations 954

Management 955

### Hyperparathyroidism 956

Epidemiology 956

Pathophysiology 956

Clinical Manifestations 957

Management 957

## Chapter 44: Coordinating Care for Patients With Diabetes Mellitus 960

### Introduction 961

### Type 1 Diabetes Mellitus 963

Epidemiology 963

Pathophysiology 963

Clinical Manifestations 963

Management 963

### Type 2 Diabetes Mellitus 974

Epidemiology 974

Pathophysiology 974

Clinical Manifestations 975

Management 975

## UNIT X

## PROMOTING HEALTH IN PATIENTS WITH SENSORY SYSTEM DISORDERS 985

## Chapter 45: Assessment of Visual Function 985

### Introduction 986

### Overview of Anatomy and Physiology 986

Internal Structures 986

External Structures 987

Cranial Nerves 988

### Overview of Visual Function 988

### Assessment 989

History 989

Inspection 990

Vision Testing 991

### Diagnostic Studies 993

Computed Tomography 993

Magnetic Resonance Imaging 993

- Ultrasonography 993
- Radioisotope Scanning 994
- Slit-Lamp Testing 994
- Intraocular Pressure Testing 994
- Corneal Staining Test 994
- Fluorescein Angiography 994

## Eye Protection 995

## Age-Related Changes 995

# Chapter 46: Coordinating Care for Patients With Visual Disorders 998

## Introduction 999

## Visual Acuity Disorders 999

- Epidemiology 999
- Pathophysiology 999
- Clinical Manifestations 1001
- Management 1001

## Vision Loss Related to Opioid Use 1003

- Epidemiology and Pathophysiology 1003
- Clinical Manifestations 1004
- Management 1004

## Conjunctivitis 1005

- Epidemiology 1005
- Pathophysiology 1005
- Clinical Manifestations 1005
- Management 1005

## Corneal Abrasion 1007

- Epidemiology 1007
- Pathophysiology 1008
- Clinical Manifestations 1008
- Management 1008

## Cataracts 1010

- Epidemiology 1010
- Pathophysiology 1010
- Clinical Manifestations 1010
- Management 1010

## Glaucoma 1013

- Epidemiology 1013
- Pathophysiology 1013
- Clinical Manifestations 1014
- Management 1014

## Macular Degeneration 1017

- Epidemiology 1017
- Pathophysiology 1017
- Clinical Manifestations 1018
- Management 1018

## Retinal Detachment 1020

- Epidemiology 1020
- Pathophysiology 1020

- Clinical Manifestations 1021
- Management 1021

## Eye Trauma 1023

- Epidemiology 1023
- Pathophysiology 1024
- Clinical Manifestations 1024
- Management 1024

# Chapter 47: Assessment of Auditory Function 1028

## Introduction 1028

## Overview of Anatomy and Physiology 1028

- Anatomy 1028
- Auditory Function 1030

## Assessment of the Auditory System 1030

- History 1030
- Personal Hygiene 1031
- Physical Inspection of the Ear 1032

## Auditory Assessment 1033

- Diagnostic Studies 1033

## Ototoxic Medications 1035

## Hearing Protection 1035

## Age-Related Changes 1036

- Outer Ear 1037
- Middle Ear 1037
- Inner Ear 1037

# Chapter 48: Coordinating Care for Patients With Hearing Disorders 1039

## Introduction 1040

## Hearing Loss 1040

- Epidemiology 1040
- Pathophysiology 1040
- Clinical Manifestations 1041
- Management 1041

## External Otitis 1045

- Epidemiology 1045
- Pathophysiology 1045
- Clinical Manifestations 1046
- Management 1046

## Otitis Media 1047

- Epidemiology 1048
- Pathophysiology 1048
- Clinical Manifestations 1049
- Management 1049

**Tinnitus 1051**

- Epidemiology 1051
- Pathophysiology 1052
- Clinical Manifestations 1052
- Management 1052

**Vertigo 1054**

- Epidemiology 1054
- Pathophysiology 1055
- Management 1055

**Ménière's Disease 1057**

- Epidemiology 1057
- Pathophysiology 1057
- Clinical Manifestations 1057
- Management 1058

**UNIT XI****PROMOTING HEALTH IN PATIENTS WITH INTEGUMENTARY DISORDERS 1063****Chapter 49: Assessment of Integumentary Function 1063****Introduction 1064****Overview of Anatomy, Physiology, and Function 1064**

- Skin 1065
- Hair 1066
- Nails 1066

**Assessment 1068**

- History 1068
- Physical Assessment 1071
- Braden Scale 1081
- Hair Assessment 1081
- Nail Assessment 1082

**Age-Related Skin Changes 1086****Diagnostic Studies and Nursing Considerations 1087**

- Laboratory Studies 1087
- Skin Biopsy 1090

**Chapter 50: Coordinating Care for Patients With Skin Disorders 1094****Introduction 1095****Bacterial Skin Infections 1095**

- Epidemiology 1095
- Pathophysiology and Clinical Manifestations 1098
- Management 1098

**Herpes Simplex Virus 1102**

- Epidemiology 1102
- Pathophysiology and Clinical Manifestations 1102
- Management 1103

**Fungal Infections 1105**

- Epidemiology 1105
- Pathophysiology and Clinical Manifestations 1105
- Management 1111

**Psoriasis 1112**

- Epidemiology 1112
- Pathophysiology and Clinical Manifestations 1113
- Management 1113

**Skin Trauma 1116**

- Epidemiology 1116
- Pathophysiology and Clinical Manifestations 1117
- Management 1120

**Pressure Injuries 1127**

- Epidemiology 1127
- Pathophysiology and Clinical Manifestations 1127
- Management 1129

**Skin Cancer 1139**

- Epidemiology 1139
- Pathophysiology and Clinical Manifestations 1140
- Management 1142

**Reconstructive Surgery 1144**

- Epidemiology 1144
- Pathophysiology 1144
- Management 1145

**Chapter 51: Coordinating Care for Patients With Burns 1148****Introduction 1149****Incidence and Epidemiology 1149****Pathophysiology 1150**

- Classifications 1150
- Anatomical Changes 1156
- Functional Changes 1158

**Systemic Effects of Major Burn Injuries 1158**

- Respiratory 1158
- Cardiovascular 1159
- Fluid and Electrolytes 1160
- Renal 1160
- Gastrointestinal 1160
- Metabolic 1160
- Immunological 1161
- Sepsis 1161

**Special Considerations in the Patient With Burns 1162**

- Inhalation Injuries 1162
- Electrical Injuries 1163
- Chemical Injuries 1163
- Escharotomies and Fasciotomies 1164

**Management of Burn Injuries 1165**

- Emergent Phase 1165
- Intermediate Phase 1171
- Rehabilitative Phase 1178

**Other Conditions Treated in a Burn Center 1180**

- Stevens–Johnson Syndrome and Toxic Epidermal Necrolysis 1180

**UNIT XII****PROMOTING HEALTH IN PATIENTS WITH MUSCULOSKELETAL DISORDERS 1183****Chapter 52: Assessment of Musculoskeletal Function 1183****Overview of Anatomy and Physiology 1184**

- Bones 1184
- Muscles 1186
- Joints 1187
- Ligaments, Tendons, and Fascia 1188

**Assessment 1189**

- Past Medical History and History of Present Illness 1189
- Physical Assessment 1189

**Diagnostic Studies 1192**

- Laboratory Studies 1192
- Imaging Studies 1192
- Arthrocentesis 1195

**Age-Related Changes of the Musculoskeletal System 1195****Chapter 53: Coordinating Care for Patients With Musculoskeletal Disorders 1198****Introduction 1199****Muscular Dystrophies 1199**

- Epidemiology 1199
- Pathophysiology 1200
- Clinical Manifestations 1200
- Management 1201

**Osteoporosis 1204**

- Epidemiology 1204
- Pathophysiology 1205
- Clinical Manifestations 1206
- Management 1206

**Paget's Disease 1209**

- Epidemiology 1209
- Pathophysiology 1210
- Clinical Manifestations 1210
- Management 1210

**Osteomyelitis 1213**

- Epidemiology 1213
- Pathophysiology 1213
- Clinical Manifestations 1214
- Management 1214

**Scoliosis 1216**

- Epidemiology 1216
- Pathophysiology 1216
- Clinical Manifestations 1216
- Management 1216

**Joint Replacement 1218**

- Epidemiology 1218
- Pathophysiology and Clinical Manifestations 1218
- Management 1218

**Bone Cancer 1223**

- Epidemiology 1223
- Pathophysiology 1224
- Clinical Manifestations 1224
- Management 1224

**Chapter 54: Coordinating Care for Patients With Musculoskeletal Trauma 1228****Introduction 1229****Strains and Sprains 1229**

- Epidemiology 1229
- Pathophysiology and Clinical Manifestations 1229
- Management 1230

**Fractures 1231**

- Epidemiology 1231
- Pathophysiology and Clinical Manifestations 1232
- Management 1232

**Amputations 1240**

- Epidemiology 1240
- Pathophysiology and Clinical Manifestations 1241
- Management 1241

**Meniscus Injuries 1244**

- Epidemiology 1244
- Pathophysiology 1244
- Clinical Manifestations 1245
- Management 1245

**Carpal Tunnel Syndrome 1247**

- Epidemiology 1247
- Pathophysiology and Clinical Manifestations 1247
- Management 1247

## **UNIT XIII**

### **PROMOTING HEALTH IN PATIENTS WITH GASTROINTESTINAL DISORDERS 1251**

#### **Chapter 55: Assessment of Gastrointestinal Function 1251**

##### **Introduction 1252**

##### **Overview of Anatomy and Physiology 1252**

- The Mouth 1252
- The Esophagus 1252
- The Stomach 1252
- The Liver 1255
- The Gallbladder 1256
- The Pancreas 1257
- The Small Intestine 1258
- The Large Intestine 1258

##### **Assessment 1259**

- History 1259
- Physical Examination 1261

##### **Diagnostic Studies 1266**

- Laboratory Studies 1266
- Imaging Studies 1266
- Ultrasonography 1269
- Barium Studies 1269
- Endoscopy 1270

##### **Age-Related Changes 1273**

#### **Chapter 56: Coordinating Care for Patients With Oral and Esophageal Disorders 1276**

##### **Introduction 1277**

##### **Oral and Esophageal Diseases 1277**

- Stomatitis 1277
- Hiatal Hernia 1281
- Gastroesophageal Reflux Disease 1285

##### **Oral Cancer 1289**

- Epidemiology 1289
- Pathophysiology 1290
- Clinical Manifestations 1291
- Management 1291

##### **Oral Trauma 1295**

- Epidemiology 1295
- Pathophysiology 1295
- Clinical Manifestations 1295
- Management 1295

##### **Esophageal Cancer 1297**

- Epidemiology 1297
- Pathophysiology 1298
- Clinical Manifestations 1298
- Management 1298

##### **Esophageal Trauma 1302**

- Epidemiology 1302
- Pathophysiology and Clinical Manifestations 1302
- Management 1304

#### **Chapter 57: Coordinating Care for Patients With Stomach Disorders 1308**

##### **Introduction 1309**

##### **Gastritis 1310**

- Types of Gastritis 1310
- Epidemiology 1311
- Pathophysiology 1311
- Clinical Manifestations 1312
- Management 1312

##### **Gastroenteritis 1315**

- Epidemiology 1315
- Pathophysiology 1315
- Clinical Manifestations 1316
- Management 1316

##### **Peptic Ulcer Disease 1317**

- Types of Peptic Ulcers 1317
- Epidemiology 1318
- Pathophysiology 1318
- Clinical Manifestations 1318
- Management 1320

##### **Gastric Cancer 1324**

- Epidemiology 1325
- Pathophysiology 1325
- Clinical Manifestations 1325
- Management 1326

#### **Chapter 58: Coordinating Care for Patients With Intestinal Disorders 1330**

##### **Introduction 1331**

##### **Intestinal Disorders 1331**

- Hernias 1331
- Hemorrhoids 1334
- Irritable Bowel Syndrome 1337
- Inflammatory Bowel Disease 1341
- Celiac Disease 1348
- Diverticulitis 1350
- Appendicitis 1353
- Complications 1354

**Colorectal Cancer 1355**

- Epidemiology 1355
- Pathophysiology 1356
- Clinical Manifestations 1356
- Management 1358

**Abdominal Trauma 1365**

- Epidemiology 1365
- Pathophysiology 1365
- Clinical Manifestations 1365
- Management 1366

**Chapter 59: Coordinating Care for Patients With Hepatic Disorders 1370****Introduction 1371****Hepatitis 1371**

- Epidemiology 1371
- Pathophysiology 1372
- Clinical Manifestations 1372
- Types of Hepatitis 1373
- Management 1374

**Cirrhosis 1378**

- Epidemiology 1378
- Pathophysiology 1378
- Clinical Manifestations 1380
- Management 1380

**Liver Cancer 1385**

- Epidemiology 1385
- Pathophysiology 1385
- Clinical Manifestations 1386
- Management 1386

**Liver Trauma 1388**

- Epidemiology 1388
- Pathophysiology 1388
- Clinical Manifestations 1388
- Management 1388

**Chapter 60: Coordinating Care for Patients With Biliary and Pancreatic Disorders 1392****Introduction 1393****Cholecystitis 1393**

- Epidemiology 1393
- Pathophysiology 1393
- Clinical Manifestations 1393
- Management 1394

**Acute Pancreatitis 1397**

- Epidemiology 1397
- Pathophysiology 1398

Clinical Manifestations 1398

Management 1398

**Chronic Pancreatitis 1404**

- Epidemiology 1404
- Pathophysiology 1404
- Clinical Manifestations 1404
- Management 1404

**Pancreatic Cancer 1406**

- Epidemiology 1406
- Pathophysiology 1407
- Clinical Manifestations 1407
- Management 1407

**UNIT XIV****PROMOTING HEALTH IN PATIENTS WITH RENAL DISORDERS 1413****Chapter 61: Assessment of Renal and Urinary Function 1413****Overview of Anatomy and Physiology 1414**

- Renal Anatomy 1414
- Renal Physiology 1415
- Urinary System Structures 1422

**Assessment 1424**

- History Collection 1424
- Physical Examination 1427

**Diagnostic Studies 1428**

- Laboratory Studies 1428
- Imaging Studies 1432

**Age-Related Changes 1436****Chapter 62: Coordinating Care for Patients With Renal Disorders 1439****Introduction 1440****Polycystic Kidney Disease 1440**

- Epidemiology 1440
- Pathophysiology 1440
- Clinical Manifestations 1441
- Management 1441

**Pyelonephritis 1443**

- Epidemiology 1443
- Pathophysiology 1443
- Clinical Manifestations 1443
- Management 1443

**Acute Glomerulonephritis 1446**

- Epidemiology 1446
- Pathophysiology 1446

- Clinical Manifestations 1446
- Management 1446
- Renal Cancer 1448**
  - Epidemiology 1448
  - Pathophysiology 1448
  - Clinical Manifestations 1448
  - Management 1448
- Renal Trauma 1450**
  - Epidemiology 1450
  - Pathophysiology and Clinical Manifestations 1450
  - Management 1450
- Renal Failure 1452**
- Acute Kidney Injury 1452**
  - Epidemiology 1452
  - Pathophysiology 1452
  - Clinical Manifestations 1454
  - Management 1454
- Chronic Kidney Disease 1457**
  - Epidemiology 1457
  - Pathophysiology 1457
  - Clinical Manifestations 1458
  - Management 1458
- Renal Replacement Therapies 1464**
  - Hemodialysis 1464
  - Continuous Renal Replacement Therapy 1466
  - Peritoneal Dialysis 1467
- Chapter 63: Coordinating Care for Patients With Urinary Disorders 1473**
- Urinary Tract Infections 1474**
  - Epidemiology 1474
  - Pathophysiology 1474
  - Clinical Manifestations 1474
  - Management 1474
- Urolithiasis 1477**
  - Epidemiology 1477
  - Pathophysiology 1477
  - Clinical Manifestations 1477
  - Management 1477
- Incontinence 1480**
  - Epidemiology 1480
  - Pathophysiology and Clinical Manifestations 1480
  - Management 1480
- Bladder Cancer 1484**
  - Epidemiology 1484
  - Pathophysiology and Clinical Manifestations 1484
  - Management 1484

## **UNIT XV PROMOTING HEALTH IN PATIENTS WITH REPRODUCTIVE DISORDERS 1489**

### **Chapter 64: Assessment of Reproductive Function 1489**

- Female Reproductive System 1490**
  - Anatomy of the Female Reproductive System 1490
  - Physiology of the Female Reproductive System 1493

- Male Reproductive System 1495**
  - Anatomy of the Male Reproductive System 1495
  - Physiology of the Male Reproductive System 1497

- Assessment of Male and Female  
Reproductive Systems 1498**
  - Physical Examination of Female Genitalia 1498
  - Physical Examination of Male Genitalia 1501

- Diagnostic Studies 1501**
  - Laboratory Testing 1503

- Age-Related Changes in the Female and  
Male 1504**

### **Chapter 65: Coordinating Care for Female Patients With Reproductive and Breast Disorders 1506**

- Breast Cancer 1507**
  - Epidemiology 1507
  - Pathophysiology 1507
  - Clinical Manifestations 1509
  - Management 1509

- Dysmenorrhea 1513**
  - Epidemiology 1513
  - Pathophysiology 1514
  - Clinical Manifestations 1514
  - Management 1514

- Endometriosis 1515**
  - Epidemiology 1515
  - Pathophysiology 1515
  - Clinical Manifestations 1516
  - Management 1516

- Menopause 1517**
  - Pathophysiology 1517
  - Clinical Manifestations 1517
  - Management 1517

**Fibroids 1519**

- Epidemiology 1519
- Pathophysiology 1519
- Clinical Manifestations 1519
- Management 1519

**Ovarian Cancer 1521**

- Epidemiology 1521
- Pathophysiology 1521
- Clinical Manifestations 1521
- Management 1522

## INTRODUCTION

Medical-surgical nursing has historically been practiced in acute care facilities across the United States. However, with changes in healthcare delivery, legislation, and insurance coverage, medical-surgical nursing is now practiced in many different practice settings, including hospitals, same-day surgical centers, acute rehabilitation centers, ambulatory care settings, long-term care agencies, and patients' homes. No longer considered a "stepping-stone" to more complex patient care settings (intermediate care, critical care, etc.), medical-surgical nursing focuses on the management of acutely ill adult patients. Medical-surgical nurses are the largest group of practicing nursing professionals.

According to the **Academy of Medical-Surgical Nurses (AMSN)**, the only professional nursing organization dedicated to medical-surgical nursing, the foundation of all nursing practice has its roots in this practice area. The mission of the AMSN is to "promote excellence in medical-surgical nursing" (AMSN, 2018), and the AMSN has an average membership of over 11,000 registered nurses. The strategic plan of the AMSN is in Box 1.1. Over the years, medical-surgical nursing has developed into a specialty practice area, and registered nurses who meet specific requirements are eligible for certification in this practice area through the **Medical-Surgical Nursing Certification Board (MSNCB)**. These nurses earn the credential **Certified Medical-Surgical Registered Nurse® (CMSRN)**. Box 1.2 provides the domains of nursing tested by the MSNCB.

Certification in medical-surgical nursing is also available through the American Nurses Credentialing Center (ANCC); registered nurses with this certification are entitled to the credential of Registered Nurse-Board Certified (RN-BC).

## COMPETENCIES IN MEDICAL-SURGICAL NURSING

Entry-level nursing programs, including associate, baccalaureate, master's (including Clinical Nurse Leader), and doctoral degrees, focus on the preparation of nurses to practice competently in the various medical-surgical settings. Competency in the management and coordination of adult medical-surgical patients requires a strong background in the sciences, including anatomy and physiology, chemistry, microbiology, pathophysiology, and pharmacology. Throughout this text, there is an emphasis on correlating the nursing care of this adult patient population to the physiological and pathophysiological bases of selected disease processes. Promoting an understanding of the relationships between the physiology, pathophysiology, clinical manifestations, and management of these disorders fosters more accurate interpretation of data, enhanced critical thinking, and better clinical decision making.

## Box 1.1 Academy of Medical-Surgical Nurses Strategic Framework

### Mission

The mission of the Academy of Medical-Surgical Nurses (AMSN) is to promote excellence in medical-surgical nursing.

### Vision

Medical-surgical nurses use their powerful voice and focused action to continuously improve patient care.

### Values

Medical-surgical nursing is a distinct specialty with its own body of knowledge. We believe patients receive better care when medical-surgical nurses:

- Engage in ongoing professional development
- Use evidence-based practices
- Speak with a unified voice
- Serve as leaders on healthcare teams
- Have the necessary resources to deliver excellent care
- Practice in a healthy work environment

### Strategic Message

The AMSN is a vibrant community of medical-surgical nurses who care about

- Improving patient care
- Developing personally and professionally
- Advocating for the specialty of medical-surgical nursing
- Connecting with other nurses who share their compassion and commitment

Adapted from American Academy of Medical-Surgical Nurses. (2015). *Strategic plan and initiatives and outcome*. Retrieved from <https://www.amsn.org/sites/default/files/documents/about-amsn/strategic-plan/AMSN-Strategic-Plan.pdf>

## Box 1.2 Domains of Nursing Practice for Medical-Surgical Nursing Certification

1. Helping Role
2. Teaching-Coaching Function
3. Diagnostic and Patient Monitoring
4. Effective Management of Rapidly Changing Situations
5. Administering and Monitoring Therapeutic Interventions and Regimens
6. Monitoring and Ensuring the Quality of Healthcare Practices
7. Organizational and Work Role Competencies

This focus on competency is particularly important because the **Nursing Executive Center of the Advisory Board** has reported that recent nursing school graduates have demonstrated an academic-practice gap. The Nursing Executive Center serves nursing administrators through data collection around best practices, strategic initiatives, and operational issues. In this specific study, nursing executives

described that new graduates lacked the expected knowledge and competency in the following areas:

- Knowledge of pathophysiology of patient conditions (34%)\*
- Knowledge of pharmacological implications of medications (28%)\*
- Decision making based on the nursing process (20%)\*
- Interpretation of assessment data (18%)\*

\*Percentage of front-line nurse leaders who were satisfied with the specific new graduate nurse proficiency.

Although this study was completed in 2008, the issue related to the readiness for practice of new graduate nurses continues, particularly in acute care settings. As a result, there is a growing body of knowledge related to addressing this academic-practice gap through the establishment of academic-practice partnerships. Suggested strategies to better prepare the nurse graduate for the realities of practice include the increased use of simulation in nursing education programs, extended transition to practice and residency programs, as well as the establishment of academic service partnerships.

### Competencies Related to the Nursing Process

Equally important to the practice of medical-surgical nursing are competencies in the **nursing process**, **clinical decision making**, **evidence-based care**, **patient-centered care**, **quality and safety**, and **interprofessional practice**. The nursing process includes assessment, diagnosis, planning, implementation, and evaluation and ultimately guides patient care. Throughout this text, there is a strong emphasis on using the nursing process to guide the delivery of safe, effective, and patient-centered nursing care.

The nursing process is closely associated with the nurse's clinical decision making, and the role of the medical-surgical nurse in key decision making with patients and families is evident in the current healthcare environment. Higher patient acuity and increased complexity of patients' care needs, accompanied by shorter lengths of stay in acute care settings, place the nurse in the vital role of ensuring that patients are prepared for transitions to different levels of care. Facilitating the patient's and family's understanding of treatment plans and discharge teaching is a primary responsibility of the registered nurse.

#### Connection Check 1.1

Which factors have led to the expansion of medical-surgical nursing from traditional acute care facilities to other settings? (Select all that apply.)

- Increases in healthcare complexity
- Shortage of registered nurses
- Changes in insurance coverage
- Shortened hospital lengths of stay
- Low salaries for registered nurses in hospitals

## EVIDENCE-BASED NURSING CARE

**Evidence-based nursing practice** is the foundation of professional nursing practice. Based on a problem-solving approach to healthcare delivery, nursing care practices and protocols are based on the best evidence from research studies and the expertise of clinicians. Medical-surgical nursing incorporates evidence-based practice principles in order to provide the highest-quality and most cost-effective care to patients and families. Evidence-based care is characterized by clinical decisions that are based on the use of the best available evidence, clinical expertise, and patient preferences (see Evidence-Based Practice). The steps of the evidence-based process are listed in Box 1.3.

### Evidence-Based Practice

#### Bedside Shift Reporting

Based on recommendations by The Joint Commission to more actively involve patients in their care, as well as to standardize hand-off communications during a change of care providers, hospitals have implemented nurse-to-nurse bedside shift reporting. In this research, focused on increasing patient involvement in their care and improving patient satisfaction, a quasi-experimental, between-group, pre-implementation and post-implementation study was conducted at a 149-bed hospital to examine compliance with bedside shift reporting. The intervention included a standardized approach to bedside reporting along with a change management strategy that included support from nursing leadership to consistently use this reporting approach. In addition to educating the nurses in the use of SBAR (situation, background, action, and response) to provide the bedside report, consistent monitoring of compliance and leadership support contributed to the effectiveness of this study. Five months after implementation, both patient satisfaction and compliance with nurse-to-nurse bedside reporting had increased.

Scheidenhelm, S., & Reitz, O. E. (2017). Hardwiring bedside shift report. *Journal of Nursing Administration*, 47(3), 147–153.

### Box 1.3 Steps of Evidence-Based Practice

- Develop the question.
- Search and collate the best evidence.
- Evaluate the quality of the evidence.
- Integrate evidence into practice.
- Evaluate outcomes of practice change.
- Disseminate the evidence.

The utilization of the best evidence requires the registered nurse to possess competencies in locating and evaluating the quality of data. Typically, there is a clinical question or problem identified that guides the initiation of an evidence-based project. Once the question has been defined, a literature review is conducted to assess the current state of the science around the question. Skills in conducting effective literature searches and analyzing findings are crucial for the nurse in locating and evaluating the quality of evidence required to guide clinical practice. Increasingly, nursing programs incorporate these search strategies into their curriculum, often in collaboration with college/university libraries.

Once data have been located, the evaluation of the quality of the evidence is the next step in the process. Box 1.4 outlines one process for the evaluation of data and describes the types of data that are used to determine the quality, validity, and reliability of evidence. The lowest numerical rating of the level of evidence in this approach correlates with the highest level of evidence. For example, **systematic reviews** of randomized controlled studies (Level I) are the highest level of evidence because they include data from selected studies that randomly assigned participants to control and experimental groups. **Randomized controlled studies** are considered the gold standard of research, with their findings most valuable. Level II evidence is based on the results of a single randomized controlled study. **Quasi-experimental studies** (Level III) also use the control and experimental groups but lack the random assignment. Research that is designed as a **case-control study** includes two groups, those with a specific disorder and those without, and then comparisons are made between the two groups. **Cohort studies** use a group of people (cohort) who are initially free of disease and are then followed over a period of time to examine whether the development of new cases differs between those with and without exposure to some type of disease, environmental hazard, or other factor. Both case-control and cohort studies are often conducted in epidemiological research and are considered Level IV evidence. Descriptive and qualitative studies do not use an experimental design with control and experimental groups; they provide

findings based on observations of populations and phenomena. Systematic reviews of descriptive studies (Level V), because they include numerous studies as opposed to a single descriptive study (Level VI), provide a higher level of evidence. The lowest level of evidence (Level VII) is expert opinions from individuals and committees. Although higher levels of evidence are preferred, there are not always randomized controlled studies available to answer all questions posed in an evidence-based review of the literature.

The importance of evidence-based care is also reflected in the **American Nursing Credentialing Center (ANCC) Magnet® Recognition program**, in which Magnet status is awarded to healthcare facilities that demonstrate excellence in the recruitment, recognition, and retention of nursing staff as well as excellence in patient care and quality. Because quality patient care is associated with a foundation in evidence-based findings, the AMSN's *Scope of Medical-Surgical Nursing Practice* provides dissemination of evidence-based practice guidelines for medical-surgical nurses.

### Connection Check 1.2

In designing an evidence-based practice guideline for a medical-surgical unit, which source provides the most reliable information?

- A. Content from a textbook
- B. Manuscript in a nursing journal
- C. Results from research studies
- D. Information from a professional activity

### PATIENT-CENTERED CARE IN THE MEDICAL-SURGICAL SETTING

The importance of patient-centered care is highlighted in the **Institute of Medicine's (IOM) 2003 report *Health Professions Education: A Bridge to Quality***. As acute care hospital lengths of stay shorten, the patient's interactions with members of the healthcare team and particularly one-on-one time with the primary healthcare provider are affected. Complicating these patient encounters are greater requirements for documentation and justification for care. From the patient's perspective, the requirements of the system often seem to overshadow the patient's concerns. The results of patient satisfaction surveys that evaluate hospital stays often report dissatisfaction regarding time spent with members of the healthcare team.

Patient-centered care is a benchmark that acute care facilities are evaluated against, and nursing care is an important component of this evaluation. Because nursing care is provided 24 hours a day in acute care settings, patients often base their evaluations of the quality of their care on interactions with nursing staff. Patient-centered care focuses on treating patients and families with dignity and respect and engaging patients and families in decision making about care decisions. Competencies of medical-surgical nurses that are closely associated with patient-centered care

### Box 1.4 Evaluating Levels of Evidence

- **Level I** Evidence from systematic reviews of randomized controlled studies (RCTs)
- **Level II** Evidence from at least one RCT
- **Level III** Evidence from quasi-experimental studies
- **Level IV** Evidence from case-control and cohort studies
- **Level V** Evidence from systematic reviews of descriptive or qualitative studies
- **Level VI** Evidence from a single descriptive or qualitative study
- **Level VII** Evidence from expert individual authorities or committees

include effective communication skills, empathy, caring, and compassion. Equally important are the clinical competency and knowledge base of the registered nurse.

The relevance of patient-centered care is further underscored by the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS), a survey that provides a standardized approach to collecting data from patients about their experiences in hospitals. The nine essential topics included on the HCAHPS survey are listed in Box 1.5.

Patient-centered care and communication are also incorporated into **The Joint Commission (TJC) Standards for Hospitals**. The Joint Commission is an independent, not-for-profit organization that accredits and certifies approximately 77% of hospitals in the United States. Accreditation and certification by TJC are recognized as the standard of patient care, effectiveness, and safety and foster continuous process improvements. Aspects of patient-centered care are incorporated into the accreditation, including data related to patient participation in the plan of care and visitation rights. The vision statement of TJC focuses on promoting safe, high-quality, and best-value healthcare across all healthcare settings.

**The Beryl Institute** is also an organization that fosters patient-centered care through the “patient experience” that is influenced by all the interactions and experiences encountered, based on the organization’s culture and practices. Results from a 2017 study by The Beryl Institute found that efforts focused on supporting patient experiences are expanding, are a top priority for healthcare agencies, and can be tied to positive healthcare outcomes. Consistent with TJC’s mission, The Beryl Institute supports patients and families being well informed and actively involved in all healthcare decisions.

### Connection Check 1.3

The medical-surgical nurse needs to be knowledgeable of which organization that scores patient-centered care via a telephone survey of selected patients after discharge?

- The Joint Commission
- The Beryl Institute
- The Carnegie Institute
- The Hospital Consumer Assessment of Healthcare Providers and Systems

### PATIENT SAFETY OUTCOMES

Providing safe, quality care is a priority for medical-surgical nurses. The Joint Commission annually publishes **National Patient Safety Goals** aimed at improving patient safety through goals that focus on potential problems in the healthcare setting. The 2018 goals identified the following areas to improve patient safety:

- Identify patients correctly
- Improve staff communication

### Box 1.5 Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) Topics

- Communication with providers
- Communication with nurses
- Responsiveness of hospital staff
- Pain management
- Communication about medications
- Discharge information
- Cleanliness of the hospital environment
- Quietness of the hospital environment
- Transition of care

- Use medicines safely
- Use alarms safely
- Prevent infection
- Identify patient safety risks
- Prevent mistakes in surgery

These patient safety goals are integral to safe, quality patient care in the medical-surgical setting.

Accurate patient identification is required throughout the patient experience, especially during assessments, while preparing patients for procedures and surgical procedures, and during medication administration. Effective staff communication is also integral to safe patient care, particularly during “hand-offs,” such as change-of-shift reports, receiving patients, and transferring patients to other departments. The **SBAR** (Box 1.6) is one approach to decreasing communication barriers and focuses on a standard way to state the Situation, Background, Assessment, and Recommendation of patient events. Used to enhance communication with healthcare providers, nurses often use SBAR to report changes in patient conditions. SBAR enhances communication with

### Box 1.6 The SBAR Approach for Effective Communication

SBAR is an acronym that correlates to:

**Situation:** Brief statement of the problem or issue being addressed

**Background:** Data related to the current situation

**Assessment:** Summary of causes, significance, severity of situation

**Recommendation:** Specific actions needed to address the situation

The SBAR method provides a consistent process for communication, particularly in high-risk situations. Of particular value is the focus on making a recommendation that focuses on a definitive approach to addressing the issue or clinical problem.

healthcare providers, and nurses often use SBAR to report changes in patient conditions. Box 1.7 provides an example of SBAR communication between the healthcare provider and nurse around a patient demonstrating difficulty voiding after a surgical procedure. Safety measures around medication administration have been implemented in medical-surgical settings and include practices that prevent interruptions during the preparation and administration of medications. Additionally, the nurse must follow the rights and responsibilities required for safe medication administration and ensure that the rationales for all medications are associated with the patient condition.

Medical-surgical nurses play an integral role in the prevention of infection and surgical errors. Hospital stays may be extended because of infection, particularly those associated with hospital-acquired infections. Many acute care facilities have implemented increased surveillance and evidence-based guidelines to prevent these types of infections, including catheter-associated urinary tract infections and central line infections. Additionally, surgical settings have implemented “time-outs” (requiring all personnel involved in the procedure to stop to make sure that the patient is identified, the correct anatomical site is identified, and all equipment is in working order) and special procedures for marking surgical sites. Better patient outcomes are associated with effective communication and collaboration in patient care settings. The proper use of alarm settings on equipment used for patient monitoring is also essential in the medical-surgical setting. The nurse must ensure that the alarm parameters are

### Box 1.7 SBAR Example

#### Situation:

Hello, Dr. Jones. This is Steve, the registered nurse caring for Ms. Sandra Williams in Room 732 on South Wing. I am contacting you because she arrived from the post-anesthesia care unit (PACU) and has not voided in more than 6 hours.

#### Background:

She was admitted to the hospital this morning, and you performed a lumbar laminectomy this morning for a herniated disc at L4–L5.

#### Assessment:

Ms. Williams is complaining of inability to void. According to her operative reports, she received 1,500 mL of IV fluid during the surgical procedure and in the PACU, and the indwelling catheter was removed prior to transfer from the PACU 6 hours ago; at the time, she had 800 mL of urine output. She has received an additional 250 mL of IV fluid since arriving on the unit.

#### Recommendation:

I recommend that an intermittent catheterization be performed at this time.

individualized to the patient as well as ensuring that the alarms are heard and responded to in a timely manner.

Because of the increased emphasis on quality and safety, in 2005 the Robert Wood Johnson Foundation funded a project focused on educating nursing students on patient safety and healthcare quality. These funds established the Quality and Safety Education for Nurses (QSEN) initiative designed to prepare nurses with the required knowledge, skills, and attitudes to foster continuous improvement of quality and safety in healthcare settings. Based on the Institute of Medicine’s recommendations (Box 1.8), the QSEN initiative developed competencies for both prelicensure and graduate nursing students (Box 1.9).

### Connection Check 1.4

The medical-surgical nurse implements SBAR to promote effectiveness in which aspect of quality and safety in patient care?

- Surveillance
- Communication
- Organization
- Cost-effectiveness

## INTERPROFESSIONAL COLLABORATION AND COMMUNICATION

Because of the complexity and high acuity of most adult patients in medical-surgical settings, interprofessional collaboration is imperative to the promotion of effective patient outcomes. In 1999, the IOM reported in *To Err Is Human: Building a Safer Health System* that between 44,000 and 98,000 deaths occurred in U.S. hospitals because of preventable medical errors. In 2009, another report by the Institute of Healthcare Improvement estimated that there were approximately 40,000 incidences per day in U.S. hospitals that resulted in patient harm. In both of these studies, ineffective communication among the interprofessional healthcare team was identified in a root-cause analysis of

### Box 1.8 Institute of Medicine’s Competencies for Health Professionals

- Provide patient-centered care
- Work in interdisciplinary teams
- Employ evidence-based practice
- Apply quality improvement
- Utilize informatics

From Greiner, A., & Knebel, E. (Eds.). (2003). *Health professions education: A bridge to quality*. Institute of Medicine (US) Committee on the Health Professions Education Summit. Washington, DC: National Academies Press. Retrieved from <http://www.ncbi.nlm.nih.gov/books/NBK221528/>

## Box 1.9 Quality and Safety Education for Nursing (QSEN) Competencies

- Patient-Centered Care
- Teamwork and Collaboration
- Evidence-Based Practice (EBP)
- Quality Improvement (QI)
- Safety
- Informatics

these medical errors. The Joint Commission includes an accreditation standard that addresses the importance of effective communication.

Medical-surgical nurses are members of interprofessional healthcare teams and in acute care settings are often in the role of care coordinator. The nurse participates in interprofessional rounds with the physicians, advanced practice registered nurses, pharmacists, discharge planners, social workers, and other members of the healthcare team. Additionally, because nurses are the primary direct provider in the acute care setting, they are often the key to communication between the various healthcare members as well as with specialists and consultants who may be episodically involved in the patient's care. Effective clinical reasoning and communication skills are crucial to this role of the medical-surgical nurse as a care coordinator. (The roles of care coordinator and interprofessional teams are discussed in Chapter 2.)

With the increased focus on interprofessional patient care teams, attention is also being given to the importance of educating future healthcare providers together. Faculty at schools of medicine, nursing, pharmacy, social work, and other healthcare professional educational settings are working collaboratively to design and implement interprofessional educational programs. The use of patient care simulations using high-fidelity mannequins provides safe environments for these future healthcare team members to practice interprofessional communication and teamwork. This increased

focus on educating future healthcare providers together is based on findings of increased safety and quality in hospitals with effective interprofessional care teams.

### Connection Check 1.5

Which outcome of interprofessional teams is associated with an increased focus on educating health professional students together?

- A. Decreased hospital costs
- B. Increased safety and quality
- C. Decreased length of stay
- D. Increased patient satisfaction

## CHAPTER SUMMARY

Medical-surgical nursing is a specialty area characterized by competencies that are applicable for patients across the healthcare continuum, from acute care hospitals to home settings. As members of the largest subspecialty in nursing, medical-surgical nurses are eligible for certification in this practice area through the AMSN or the ANCC.

Foundational to medical-surgical nursing are evidenced-based practices that foster the delivery of safe, effective care that is based on research findings and clinical expertise and incorporates patient participation. Another growing focus of medical-surgical nursing is patient-centered care, which is also an important benchmark for acute care facilities. Patient-centered care focuses on treating patients and families with dignity and respect and engaging patients and families in decision making about care decisions. The importance of patient-centered care is demonstrated by its incorporation into TJC's Accreditation Standards for Hospitals. Interprofessional coordination and teamwork are also essential to effective patient outcomes in the complex health system in the United States. Medical-surgical nurses work closely in interprofessional teams including providers, social workers, pharmacists, and other disciplines to plan and implement the best evidence-based care.

## Interprofessional Collaboration and Care Coordination

*Laura Syron and Dawn Hohl*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Discussing the importance of successful transitions for medical-surgical patients
2. Describing changes in the healthcare landscape
3. Describing models of transitional care
4. Exploring the role of the registered nurse in patient-centered transitional care programs
5. Defining interprofessional collaboration in the healthcare setting
6. Identifying the roles of healthcare professionals coordinating care for patients
7. Exploring unique patient situations requiring or enhanced by interprofessional collaboration

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Mr. Frank Garfield is a 67-year-old gentleman admitted after an acute cerebrovascular accident (CVA). The patient has a history of well-managed hypertension and atrial fibrillation, lives with his wife of 46 years, and was functionally independent prior to admission. The patient now presents with right-sided weakness and aphasia and has been placed on four new medications, including an anticoagulant. He has been seen by various members of the interprofessional care team (ICT) including the unit-based nurse practitioner (NP). The patient and his wife are Spanish-speaking and are able to carry on simple conversations in English. The nurse recognizes the need to begin interprofessional collaboration (IC) to develop a safe discharge plan to return this patient to an optimal level of function and transition to the next level of care...

## INTRODUCTION

The state of healthcare in the United States is dynamic and very complex. For a patient to safely and effectively navigate through our healthcare system requires coordination among all members of the ICT. However, access to care that is coordinated, safe, and focused on the patient's unique needs across all care settings has eluded many patients, particularly the elderly and chronically ill. The Institute of Medicine (IOM) released two important reports, *To Err Is Human: Building a Safer Health System* (2000) and *Crossing the Quality Chasm: A New Health System for the 21st Century* (2001) that address the quality and fragmentation of healthcare throughout the United States. These documents recommend the necessary transformations in healthcare needed to provide safe, effective, patient-centered, efficient, timely, and equitable care. Nursing practice, which has historically been setting defined rather than patient centered, is part of this transformation. There is an increasing focus on care coordination across settings, particularly for patients with chronic disease who experience frequent changes in health status and require multiple transitions among providers and settings. Vulnerable patients are put at greater risk during transitions if care is not coordinated, communication among professionals is inadequate, socioeconomic factors are inadequately addressed, and the needs of the patient and caregivers are not taken into consideration. Care coordination and managing patient transitions across care settings are integral parts of nursing care and an expanding role for the registered nurse (RN). Medical-surgical nursing quality and safety competencies and targeted knowledge, skills, and attitudes are necessary to prepare the RN to lead care management strategies and transitional care services across the care continuum.

## Connection Check 2.1

Which phase of care is most critical for medical-surgical patients?

- A. Acute hospital phase
- B. Prehospital care phase
- C. Transition phase
- D. Discharge phase

## OVERVIEW OF TRANSITIONAL CARE

The safety of the patient is at risk during transitions between care settings, particularly following an acute hospitalization. The patient's needs may go unmet, and there is the risk for medication errors and adverse clinical events. The readmission rates of hospitalized patients, particularly Medicare beneficiaries, are one driving factor in the call for improved transitional care services. Nearly one in five Medicare patients discharged from a hospital is readmitted within 30 days. Of these readmissions, 76% may be preventable. These readmission rates are often attributed to a lack of coordination of care as patients are discharged to rehabilitation facilities, long-term care agencies, or back to their homes. Without a plan to ensure continuous and coordinated care, these patients may be readmitted with complications. Although all hospital readmissions may not be related to the most recent hospitalization, insurance companies and other payers consider unplanned admissions as wasteful spending and, in some cases, may deny reimbursement or may charge penalties for readmissions within that 30-day window post-discharge. Data trending the numbers of unplanned readmissions after a recent hospital stay are used to measure the quality of hospital care. Focusing on more efficient and effective transitional practices and models should decrease the incidence of unplanned readmissions. The implementation of evidence-based practice to guide post-discharge calls, one important aspect of transitional care, is an example of how readmission rates can be lowered with care coordination (see Evidence-Based Practice).

Increasing access, improving quality and safety, and lowering costs are the basic principles of the Patient Protection and Affordable Care Act (ACA) signed in 2010. Transitional care programs have demonstrated that with the prevention of avoidable readmissions, patient safety and quality of care improve, and costs are lowered. For these reasons, transitional care is a high priority in the act. The Community-Based Care Transitions Program (Section 3026), Centers for Medicare and Medicaid Services (CMS) Innovation (Section 3021), Health Homes (Section 2703), and the Medicare Shared Savings Program (Section 3022) all support transitional care services.

Transitional care programs are patient centered and typically manage the transitions of patients from acute care to post-acute care settings. The goals are to avoid poor health outcomes, ensure continuity of care, and

## Evidence-Based Practice

### Improving Post-Hospital Discharge Telephone Reach Rates Through Pre-Hospital Discharge Face-to-Face Meetings

Calling a patient 24 to 48 hours after hospital discharge is an important component of care-coordination programs aimed at reducing readmission rates. The purpose of the call is to assess the patient's condition, ensure patient understanding of the post-discharge plan of care, and triage the patient as necessary to appropriate providers. A study recently published by Vergara et al (2017) demonstrated that the use of face-to-face meetings by a telephonic case manager with patients prior to discharge improved the rate of post-discharge call reach. The brief pre-hospital discharge meeting assisted patients in understanding the reasons for the call, identified the best times to call using accurate telephone numbers, and instructed patients how to prepare for the call by having their discharge instructions with them. Additionally, the telephonic case manager was no longer a stranger on the telephone but someone the patients had met. These factors combined may have significantly helped to increase post-discharge reach rates.

Vergara, F. H., Davis, J., Sheridan D. J., Sullivan, N. J., & Budhathoki, C. (2017). Improving post-hospital discharge telephone reach rates through pre-hospital discharge face-to-face meetings. *Professional Case Management*, 22(6), 275–283. <http://dx.doi.org/10.1097/NCM.0000000000000243>

facilitate safe transitions between care settings. Unlike disease-management and case-management programs that are ongoing, transitional care is time limited. Emphasis is on the coordinating care, facilitating patient engagement and education, addressing the causes of poor outcomes, and avoiding preventable readmissions, focusing on the 30-day time period following discharge. A meaningful transition plan will include addressing those socioeconomic factors that affect the health of the individual. To support vulnerable patients and address these socioeconomic issues, the transitional care nurse will use a spectrum of community resources and programs. There are many organizations, Web sites, and providers who specifically address the immediate needs of patients out of the hospital and home in their communities. These resources answer questions, provide necessary medical equipment, and suggest community support groups of people who are dealing with similar disorders or issues. Go to [www.DavisAdvantage.com](http://www.DavisAdvantage.com) for a listing of community resources specific to the disorders discussed in this book.

Important strategies in managing the transition from acute to post-acute settings include:

- Initiating care coordination/transition planning at least 24 hours prior to discharge
- Organizing post-discharge follow-up services for patients requiring chronic disease management
- Providing specific discharge teaching related to symptoms requiring immediate treatment
- Coordinating with care providers responsible for management in discharge settings
- Providing a comprehensive medication review

### Connection Check 2.2

What is considered the hospital's span of responsibility for the patient?

- Admission to discharge
- Admission to 30 days post-discharge
- Admission to 15 days post-discharge
- Admission to full recovery

## EVIDENCE-BASED MODELS OF TRANSITIONAL CARE

Several models of transitional care have emerged in response to the call for improved coordination across the care continuum: the transitional care model (TCM), the Care Transitions Program, Project Red, and Project BOOST. Another transitional care plan is the patient-centered medical home (PCMH), a model for comprehensive, patient-centered primary care. A model that focuses on quality and safety in the hospital, Transforming Care at the Bedside (TCAB), was developed as an important first step in ensuring safe transitions across the continuum.

### The Transitional Care Model

The **transitional care model (TCM)** is a nurse-led multi-disciplinary program that was developed by Mary Naylor, an advanced practice nurse at the University of Pennsylvania. **Transitional care nurses (TCNs)** manage patients as they transition across the care continuum from inpatient settings to other settings, including skilled nursing facilities and home. Using evidence-based care-coordination methods, the TCN collaborates with other healthcare team members, including providers, nurses, social workers, discharge planners, and pharmacists, to plan care. The goal of this model is to prevent complications, provide continuity of care, and increase patients' and caregivers' abilities to manage their care. The TCM focuses on chronically ill, high-risk adults. Common medical and surgical conditions often included in this model are heart failure, diabetes mellitus, chronic kidney disease, and postsurgical hip surgery. Because many of these patients have multiple **comorbidities** (two or more coexisting medical conditions or disease processes), coordination

of care is critical to safe, quality care. In this model, the TCN visits the patient in the hospital and, following discharge, visits the patient weekly at home for a month. The TCN then conducts follow-up phone calls during the second month. The patient is followed for approximately 8 weeks. Specific TCN tasks include monitoring symptoms, education, and training and assisting with medication management. Results from National Institute of Health studies demonstrate that the TCM significantly improves patient safety and healthcare outcomes, enhances quality of life and satisfaction with care, and reduces overall healthcare costs.

The TCN can be an advanced practice nurse or a bachelor's level nurse. The typical caseload for most TCNs is 15 to 20 patients. The role of care coordinator or TCN is expected to grow as reimbursement is linked with decreasing admissions to acute care settings and cost-effective care management. Incorporating the competencies of a medical-surgical nurse with those of a care manager and patient advocate, this role requires knowledge of evidence-based care, working in interprofessional teams, quality improvement, and financial issues related to care delivery across multiple episodes of care.

### The Care Transitions Program

Developed by Eric Coleman at the University of Colorado Health Sciences Center, the **Care Transitions Program** employs nurses as “transitions coaches” to manage chronically ill or seriously ill patients as they transition between healthcare settings. The transitions coach does not provide direct skilled care but, rather, uses effective communication to provide education and guidance to ensure a safe transition. In studies using a “coaching” approach, it has been demonstrated that patients who received education, encouragement, and coaching had lower rehospitalization rates. In the Coleman model, transition coaches visit the patient in the hospital and follow up with one home visit and phone calls for a 4-week time period. Patients receive tools to learn self-management skills that include recognizing and responding to “red flags” that indicate worsening of their condition, managing medications, managing their own personal health record, and completing follow-up care with their primary provider.

### Project RED and Project BOOST

**Project RED (Re-engineered Discharge)** and **Project BOOST (Better Outcomes for Older Adults Through Safe Transitions)** are national programs that also seek to improve care as patients transition from acute care settings to post-acute care settings by improving the discharge processes. The objectives of Project BOOST, led by the Society of Hospital Medicine, are to identify patients at risk for readmission on admission, reduce 30-day readmission rates, decrease length of stay, and improve communication of patient care information during discharge. A risk-assessment tool developed by Project BOOST helps to identify patients at risk for adverse events after discharge. Called the *8P Scale*, this assessment tool is completed on admission and identifies

risk factors such as polypharmacy, problem medications, physiological issues, poor health literacy, principal diagnosis, patient support, prior hospitalizations, and palliative care. The *8P Scale* is used by the ICT to determine appropriate post-discharge needs.

Project RED, or Re-Engineered Discharge, is a research group based at Boston University Medical Center that develops and tests strategies that improve hospital discharge processes. The RED is based on 12 interrelated components that promote patient safety and decrease readmissions. The 12 components are as follows:

- Ascertain need for and obtain language assistance.
- Make appointments for follow-up medical appointments and post-discharge tests/labs.
- Plan for the follow-up of results from laboratory tests or studies that are pending at discharge.
- Organize post-discharge outpatient services and medical equipment.
- Identify the correct medicines and a plan for the patient to obtain and take them.
- Reconcile the discharge plan with national guidelines.
- Develop and teach a written discharge plan the patient can understand.
- Educate the patient about his or her diagnosis.
- Assess the degree of the patient's understanding of the diagnosis and discharge plan.
- Review with the patient what to do if a problem arises.
- Expedite transmission of the discharge summary to clinicians accepting care of the patient.
- Provide telephone reinforcement of the discharge plan.

Both Project RED and Project BOOST offer tools, the *8P Scale* and the comprehensive discharge instruction tool, that aid the ICT in safely and appropriately planning for the patient's discharge. These tools also complement the strategies of the TCM and the Care Transitions Program.

### Patient-Centered Medical Home/Guided Care Program

Also included in the Affordable Care Act are programs and initiatives focusing on the **patient-centered medical home (PCMH)**. An enhanced model of primary care, the PCMH engages ICTs to address and care for patients with multiple comorbidities. Specifically, the PCMH promotes care that is patient-centered, comprehensive, interprofessionally coordinated, and accessible on a long-term basis. The **Guided Care Program** is an example of a PCMH that has improved patient outcomes and quality and reduced costs through nursing interventions. Guided care nurses work closely with the interprofessional team to coordinate care for the patient with a chronic illness. They assist in coordinating the transition between sites providing care, assess the patient and caregiver in their home, create an evidence-based care plan, promote self-management, and facilitate access to community resources. As noted, unlike TCNs, the guided care nurse works with the patient on a long-term basis.

## Transforming Care at the Bedside Model

Based on the 2001 IOM report, the **Transforming Care at the Bedside (TCAB)** project was implemented in 2003 to address the recommendations related to improving the quality and safety of patient care on medical-surgical units. Specific aims of this program also address the importance of retention of nurses at the bedside, participation of patients and family in their care experiences, and interprofessional team effectiveness.

The TCAB model focuses on the following themes: (1) safe and reliable care, (2) vitality and teamwork, (3) patient-centered care, (4) value-added processes, and (5) transformational leadership. In this project, front-line nurses and staff work on the development and implementation of action plans to address the overall quality and safety of care. Full participation of patients and families is integral to the project. Other priorities of TCAB include transformative change and continuous learning and discovery as changes in practice are implemented and evaluated. Hospitals participating in the initial phases of this model reported fewer codes, decreased patient injuries secondary to falls, lower readmission rates, reduced nurse turnover, and an increase in the time RNs spent in direct patient-care activities. The development of **rapid response teams** also grew as a result of TCAB efforts. These teams in acute care settings are composed of clinicians who provide critical care expertise at the patient's bedside or point of care and typically include a critical care provider or intensivist, critical care registered nurse, pharmacist, and respiratory therapist. They respond when a patient shows signs of deterioration in an effort to recognize and reverse the problem before a cardiac arrest occurs.

### Patient Education

An essential component of IC and all care models striving for effective in-hospital and transitional care is patient education. Patient teaching can be conducted in any setting (hospital bedside, clinic, or home) by any member of the team. It is essential that the patient demonstrates an understanding of the diagnoses and plan of care in order to safely transition to home and avoid readmission. **Teach-back** is an effective teaching strategy used to enhance patient education (Box 2.1).

### Connection Check 2.3

What is the focus of transitional care programs? (Select all that apply.)

- A. Supporting the patient after hospital discharge
- B. Coaching and teaching to enhance patient understanding
- C. Providing patient-centered discharge instructions
- D. Ensuring evidence-based medical therapy
- E. Providing adequate pain control during hospitalization

## Box 2.1 Teach-Back

Teach-back is a patient education strategy that involves imparting knowledge and then asking for the information to be restated to ensure patient understanding. This teaching should be accompanied by written material for the patient to use as an ongoing resource.

The components of teach-back include:

- Providing patient education in understandable, plain language, avoiding medical jargon
- Asking patients to repeat back what they understood in their own words in a nonshaming fashion—it is *not* a quiz!
- Avoiding the use of close-ended questions, such as “Do you understand?” or “Do you have any questions?”
- Reexplaining any areas of confusion
- Reassessing understanding by asking the patient to repeat back again
- Talking slowly and teaching in chunks, frequently assessing understanding

## THE NURSE AS PATIENT CARE COORDINATOR

The RN providing direct care to patients is directly involved in the coordination and management of care in the acute care setting. Because of the increasing complexity of healthcare and the growing numbers of patients requiring chronic care management, the role of the RN as a **patient care coordinator** is evolving in acute care, rehabilitation, long-term, and home-care settings. Because patients are frequently discharged from acute care settings still in need of follow-up and nursing care, home health nursing is a growing practice area for acute care and medical-surgical nurses. The American Academy of Ambulatory Care Nursing (AACN) developed the Care Coordination and Transition Management (CCTM) Model to standardize the practice of ambulatory nurses as well as acute, subacute, and home health nurses in care-coordination and transition-management roles. The CCTM is grounded in care management and chronic disease management. The RN in care-coordination and transition-management roles practices across the care continuum, applying appropriate evidence-based interventions that focus on patient safety and quality of care during care transitions. To facilitate continuity of care across the care continuum, the RN must use interprofessional collaboration and coordinate healthcare services and community resources. The CCTM Model provides a core curriculum and dimensions or competencies necessary for the RN to be successful in care coordination and transition management roles. Expected knowledge, skills, and attitudes are identified for each dimension, which include advocacy, support for self-management, education and engagement of patient and family, cross-setting communication and transition, coaching and counseling of patients and families, nursing process, teamwork and collaboration, patient-centered care planning, and population health management. Developing the knowledge,

skills, and attitudes needed for each dimension will help the RN meet the needs of patients and families with complex chronic illness and healthcare needs.

### Connection Check 2.4

What roles does the nurse have in transitional care programs? (Select all that apply.)

- A. Directing patient care in the inpatient setting
- B. Coaching the patient after discharge
- C. Managing chronic conditions after discharge
- D. Directing patient care in the clinic setting
- E. Assessing the patient's risk for readmission

### CASE STUDY: EPISODE 2

Mr. Garfield is monitored as he slowly demonstrates signs of recovery. When the care manager meets with the patient's wife, she expresses concern that she is not sure she can care for him at home in his present condition but knows that he has expressed a desire to come home. She asks questions about what to do if his condition takes a turn for the worse because he has told her he "never wants to be on a machine." If she does take him home, she has no equipment in the home and does not know anything about his care or medications. During ICT rounds, the team discusses the need to engage therapists (physical, occupational, and speech), a pharmacist, and a nutritionist. Dual discharge-planning referrals are being made. A consult to the home-care coordinator (HCC) is made to develop a home-care plan. A second referral is made to the social worker for long-term planning should a skilled nursing facility be considered to assist with rehabilitation and advance life-planning decisions...

## INTERPROFESSIONAL COLLABORATION

**Interprofessional collaboration (IC)** occurs when two or more professionals work together to solve problems or coordinate care. The concept that the "whole" is more than the sum of its parts is particularly meaningful when looking at the value of IC. Interprofessional collaboration is a partnership between a team of health professionals and a patient in a participatory and coordinated approach to shared decision making and communication. An important component is the inclusion of the patient and family in care and transition planning. This coordinated effort is ideally done in an atmosphere of mutual respect and shared responsibility for outcomes of care.

When the **interprofessional care team (ICT)** convenes, each individual's professional training and knowledge

are used to optimize the patient's health outcomes. Team members are confident in their knowledge of each other's roles and how they contribute to the patient's care, can activate the team when needed, and hold each other accountable to meet goals. The purpose is to formulate and deliver a plan of care that is goal directed and team focused. **Goal-directed care** focuses on the overall aim for each patient. Daily care objectives remain focused on that overall goal, facilitating the efficient use of time and resources.

The evolving changes in healthcare financing and reimbursement are creating new imperatives for interprofessional teamwork. Well-coordinated collaboration allowing efficient and cost-effective care is not only good but is also essential in meeting contemporary healthcare financial challenges. As an example, a study that explored collaboration between the nurse and pharmacist when reconciling medications at admission and discharge found that preventing one discrepancy in every 290 patient encounters would offset the cost of the intervention. These findings demonstrate that investing in ICT collaboration may be an efficient and cost-effective way to ensure safe care.

### Interprofessional Communication

Team members convene in a variety of ways with the purpose of providing a forum for team communication. This forum provides the opportunity to listen to other team members' assessments and recommendations, provide specific input, and make collaborative decisions. The ICT may convene in a regularly scheduled structure, such as daily rounds, or on an as-needed basis for highly complex patients or for patients who experience frequent readmissions. In a hospital setting, **multidisciplinary "rounds" (MDRs)** may be conducted on nursing units. The goal is to discuss each patient with all ICT members present in order to develop a comprehensive plan of care for both in-hospital and transitional care. This is done in an effort to improve hospital care, reduce unnecessary hospital days (decrease length of stay), and prevent readmissions. Rounds may be in a walking format where the group moves from patient to patient. This format facilitates the timely inclusion of the patient in the care-planning process. This is optimal to the process of **patient-centered care**; however, the length of rounds can be significant, necessitating the need to consider rounding in a conference room setting. Rounds conducted away from the bedside in a conference room can be structured to ensure maximum efficiency. The discussion should be limited to 2 to 5 minutes per patient. On a typical nursing unit, this results in rounds lasting about 1 hour. Included content is designed to cover daily care planning and discharge needs and includes the discussion of:

- Brief overview of the clinical situation
- The overall medical plan/plan for the day
- A risk screen that indicates a patient's potential need for post-acute care needs and complex discharge planning
- Caregiver involvement as applicable
- Patient engagement, teaching needs, and health literacy

- A discussion by each discipline that addresses the plan to prepare the patient for a safe transfer to home, including what needs to be completed prior to discharge (e.g., insulin administration return demonstration, transfer to chair independently, able to safely swallow without choking)
- Planned discharge date
- Specific actions that need to be completed in order for the discharge to occur (e.g., family needs to visit the skilled nursing facility, home infusion company needs to secure authorization, hospital bed and Hoyer lift need to be delivered to the home, provider follow-up appointment within 1 week). If a patient presents with frequent readmissions, the team may reach out to the previous level of care to assess the situation that is not supporting the patient (e.g., may confer with the home health nurse to assess what led to the readmission, such as not taking medications or lack of caregiver support)
- A discussion of required documents for discharge or transfer so that paperwork can be completed in a timely fashion

As discussed, the ideal is to have all team members present for the discussion, but that is not always possible. At these times, the team member facilitating the discussion may need to consult the missing ICT member prior to or after rounds to provide or receive a patient update or seek advice or information about patient plans. **SBAR** (Situation, Background, Assessment, Recommendation) is an effective communication technique used to facilitate concise and accurate communication between members of the team. It is especially useful when attempting to convey a message to a team member not present during rounds. See Box 2.2 for an example of SBAR.

### Connection Check 2.5

Which statement by the nurse indicates an understanding of the benefits of multidisciplinary care? (Select all that apply.)

- "I'm glad the social worker can focus on finding a placement for this patient."
- "I don't have time for this teaching; the nutritionist can go over dietary plans."
- "The occupational therapy evaluation made it clear there are more issues with activities of daily living (ADLs) to resolve before this patient can be discharged."
- "I'm not worried about length of stay. The bean counters can deal with that."
- "Discharge planning is much easier when we talk about it together as a team."

### Interprofessional Education

Future generations of ICTs are being shaped, and **interprofessional education (IPE)** is a part of that development. Interprofessional education is necessary for effective

### Box 2.2 SBAR

An effective form of communication that can be utilized to report changes and problems or provide a report on a patient is SBAR (situation, background, assessment, and recommendation). This is a structured method of communicating important information that needs attention and action. It is commonly used among interprofessional care team members as a standard of practice. This technique assists team members in being succinct, consistent, and thorough when sharing and handing off information or care updates.

#### Example of SBAR (Home-Care Coordinator [HCC] Calling Provider to Request Approval to Set Up Home Care):

##### S = Situation

Dr. XXX, this is XXX. I am the HCC on unit A and am calling you about your patient Mrs. XX. She has experienced two readmissions and expresses concern about her ability to manage her medications.

##### B = Background

She was admitted with dehydration following a prior admission for congestive heart failure (CHF). She reports confusion with her medications, and it is suspected that she double doses on her diuretics. She lives alone and plans to return home; she agrees that she needs more home support and has asked her daughter to more actively participate in her care.

##### A = Assessment

My assessment is that she meets the eligibility criteria for home care and would benefit from and is accepting of services.

##### R = Recommendation

If you are in agreement, I will make all the necessary arrangements. I will need three items from you: an order in the record, a completed face-to-face certification, and Medical Orders for Life-Sustaining Treatment (MOLST). Do you have any questions? Agree with this plan?

IC. It is defined as two or more disciplines learning how they work together in the hospital setting and outpatient settings. In the setting of IC, IPE is focused on each discipline understanding its respective skills, roles, and scope of practice. In doing this, each member can best engage the others appropriately for their expertise in patient care and together provide well-coordinated care. As an example, it is important that the inpatient team understands home-based services and available community services. This helps to ensure that all factors necessary to include in the transitions of care to improve safety are there. This process results in greater efficiency and confidence in managing the discharge process.

There is increasing recognition that IPE holds promise for preparing health professionals as collaborative-ready practitioners. Students who participate in an introductory

IPE course early in their professional preparation develop and maintain positive attitudes toward IC and learning.

The nurse should become knowledgeable about all members of the team and should educate the team as to the nursing role in each unique patient care setting. The nurse should also take responsibility, along with other members of the team, for the education of the patient as to the members of the ICT and their roles. Patients and family can easily become confused on whom to consult for specific questions. If they lack confidence or are hesitant, they may not clarify critically important care needs. Members of the ICT use their respective areas of expertise to educate patients; explain indications for contacting the provider; and coordinate posthospital care, including provider appointments and home care. As noted previously, patient participation in the ICT is essential to ensure that the patient's goals and preferences are integrated into the plan.

### Connection Check 2.6

Which statement by the nurse about discharge planning indicates understanding about the role of the multidisciplinary team?

- "This patient had a fairly uncomplicated hospital admission. There's no need to involve the team in this discharge plan."
- "Our physical therapist is busy today. I'll take care of the physical therapy evaluation."
- "Let's make sure we are all in agreement about the discharge plans for this patient in multidisciplinary rounds today."
- "We need this bed for an emergency admission. I'm okay with discharging this patient before the occupational therapy evaluation."

## COMPOSITION AND ROLES OF THE INTERPROFESSIONAL CARE TEAM

In the healthcare setting, a variety of professionals work directly or indirectly with the patient to help him or her return to optimal health. Each professional has unique training and addresses a particular aspect of patient care. Together, these various healthcare professionals form the ICT and contribute to the development and implementation of a plan of care for the patient throughout the continuum of care (Fig. 2.1). The ICT typically consists of but is not limited to the professionals discussed in the following subsections.

### Registered Nurse

The **registered nurse (RN)** is the professional who utilizes the nursing process to care for the patient: to assess, plan, implement, and evaluate. The nurse performs the patient assessment and formulates the appropriate

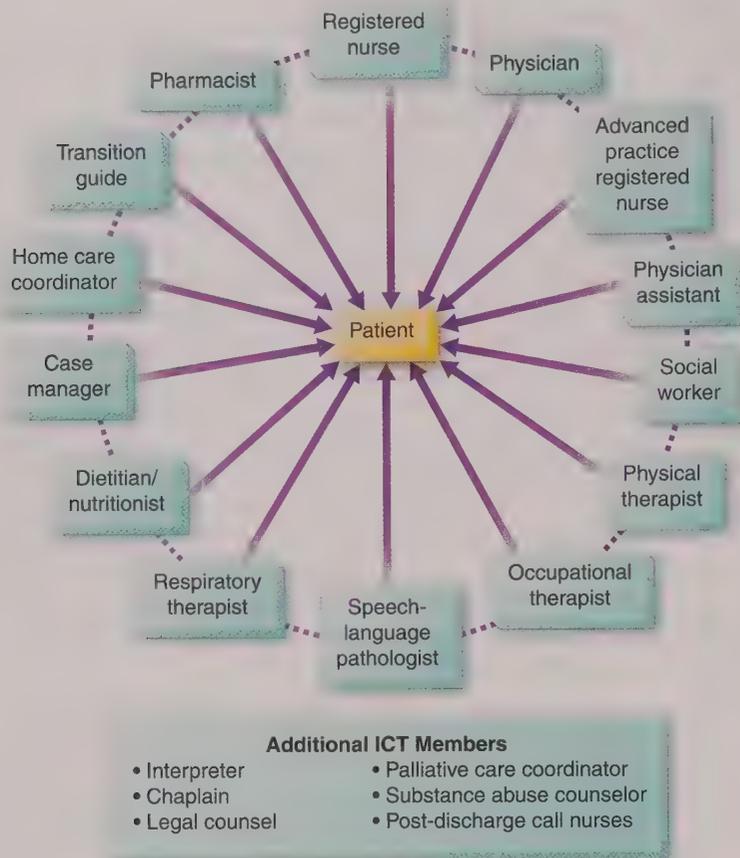

nursing diagnoses. The plan of care is formulated on the basis of the assessment and nursing diagnoses. The plan is implemented and evaluated; revisions are made on the basis of the evaluation. Because of the 24/7, around-the-clock responsibility of RNs, they are the eyes and ears of the healthcare team members. The RN provides feedback to the provider on the efficacy of medical interventions and reports normal and abnormal objective or subjective assessment findings. Most importantly, the RN is the patient advocate, intervening on the patient's behalf to ensure appropriate care and providing patient teaching to facilitate positive outcomes after discharge, including hand-offs to other levels of care. The RN may also function in a charge nurse role. In that role, the nurse's focus broadens from a specific patient assignment to the nursing unit as a whole. That focus includes staffing; patient movement such as discharge, transfer, or admissions; and oversight and support of all staff on the nursing unit, such as new nurses, **licensed practical nurses (LPNs)** or **licensed vocational nurses (LVNs)**, and unlicensed assistive personnel.

The LPN/LVN role functions under the direction of and **delegation** by the nurse. This list is not comprehensive, but as an example, LPNs/VPNs can provide direct patient care that includes helping with activities of daily living, such as bathing, toileting, and feeding. They can also obtain vital signs or laboratory specimens, complete wound care or dressing changes, and administer some medications. Unlike the RN, they do not have the same level of authority or responsibility and cannot make independent decisions.

**Unlicensed assistive personnel (UAP)** is a grouping of paraprofessionals who play a critical role in maintaining safe and accessible care. These paraprofessionals are responsible for the completion of patient care tasks, such as obtaining vital signs, and assisting patients with their personal care needs, such as activities of daily living (ADLs) and personal care. They must receive appropriate training and demonstrate competence before assuming new or expanded responsibilities within the clinical setting. Delegating and monitoring of the UAP is defined in policy and under the Nurse Practice Act. The UAP is accountable to and works under the supervision of the registered nurse when performing a delegated patient care activity and requires ongoing monitoring. With all patient care roles, it is important that communication during the planning and provision of care is maintained to ensure safe, effective care.

### Delegation

Specifics regarding the "Five Rights of Delegation" are included in Table 2.1. It is important for team members to understand the authority of the RNs and the delegatee's scope of practice as it relates to patient care. Also important is understanding the rules within each specific setting because the rules may vary from institution to institution, such as from hospital to home care.

**FIGURE 2.1** The interprofessional care team (ICT).

**Table 2.1 Five Rights of Delegation**

<b>Right Task</b>	The activity falls within the delegatee’s role or in policies of the nursing practice, including expectations and limits of the activity and provision of competency training.
<b>Right Circumstance</b>	The health condition of the patient must be stable. If there is a change, the delegatee must communicate this to the licensed nurse, who reassesses the situation and the appropriateness of the delegation.
<b>Right Person</b>	The licensed nurse, along with the employer and the delegatee, is responsible for ensuring that the delegatee possesses the appropriate skills and knowledge to perform the activity.
<b>Right Directions and Communication</b>	Each delegation situation should be specific to the patient, the licensed nurse, and the delegatee. The licensed nurse is expected to communicate specific instructions for the delegated activity to the delegatee; the delegatee, as part of two-way communication, should ask any clarifying questions. The delegatee must understand the terms of the delegation and must agree to accept the delegated activity. The licensed nurse should ensure that the delegatee understands that she or he cannot make any decisions or modifications in carrying out the activity without first consulting the licensed nurse.
<b>Right Supervision and Evaluation</b>	The licensed nurse is responsible for monitoring and evaluating the delegated activity. The delegatee is responsible for communicating patient information to the licensed nurse during the delegation situation. The licensed nurse should be ready and available to intervene as necessary. The licensed nurse should ensure appropriate documentation of the activity is completed.

From National Council of State Boards of Nursing. (2016). National guidelines for nursing delegation. *Journal of Nursing Regulation*, 7(1), 5–11. Retrieved from [https://www.ncsbn.org/NCSBN\\_Delegation\\_Guidelines.pdf](https://www.ncsbn.org/NCSBN_Delegation_Guidelines.pdf)

## Providers

### Physician

The **physician** (MD) is the healthcare professional who, after reviewing the history and physical examination and results from laboratory and radiology findings, makes a diagnosis and plan for medical care. The physician typically leads the ICT with input from the entire team. Mid-level practitioners or advanced practice providers may also provide leadership of the team under the direction of the physician. They include **certified registered nurse practitioners (CRNPs)** and physician assistants (PAs).

### Certified Registered Nurse Practitioner

Working with and under the direction of a physician, CRNPs can diagnose and manage most common and many chronic illnesses. They perform physical examinations, order and interpret diagnostic tests, provide counseling and education, and write prescriptions. The CRNP role in discharge planning varies by institution, but when involved, this role assists the attending physician in assessing the patient's post-acute care needs; coordinating necessary referrals; ordering important follow-up services; and most importantly, conveying this information to the patient, family, and ICT. The CRNP may attend rounds on behalf of the attending and liaise between the ICT and attending, which is particularly useful for surgeons who may be unavailable when in the operating room. For example, the CRNP may work with the HCC by ordering the home health services and medical equipment, ordering laboratory work, and writing prescriptions for discharge medications. The CRNP may also assist in completing required transition documents, such as those required by specific insurers in order to qualify for care, written orders needed at the next level of care, and discharge instructions forms. A transition call may also be placed to the community physician apprising this physician of the inpatient care experience and post-discharge plan. The CRNP, depending on the model of care within the institution, is typically available for post-discharge calls and possibly for clinic visits. Of note, because this role is a nursing role, the CRNP may be able to assist with making recommendations for specific nursing care as well.

### Physician Assistant

Similar to the NP, PAs obtain medical histories, perform examinations and procedures, prescribe medications and treatments, order and interpret diagnostic tests, diagnose on the basis of those assessments and tests, and assist in the operating room. They typically work with specific physicians, may attend rounds on behalf of the attending, and may also assist with the discharge planning and transition-of-care plan as described previously for the CRNP.

### Social Worker

The **social workers (SWs)** are the professionals who assess the psychosocial functioning of patients and families. They intervene as necessary, connecting patients and families to

necessary supports and resources in the community. They can also provide supportive counseling and help the patient strengthen his or her network of social supports. The SW assists with specific transition care planning, such as guardianship for patients who cannot make sound decisions, facility transfers, and assistance with insurance or medical care provisions.

## Rehabilitation Therapy

### Physical Therapist

The **physical therapist (PT)** is the professional who assesses and provides training and education on physical strength, gait, and mobility for the patient. This professional may also provide wound care and teach transfer techniques, secretion clearance techniques (ways to cough and bring up secretions), and neuromuscular reeducation (re-learning to walk or use an affected limb with maximum function). The PT evaluates and assists the patient in utilizing techniques to maximize his or her safety during and after the hospitalization.

### Occupational Therapist

The **occupational therapist (OT)** is the professional who assesses and retrains the patient to perform ADLs, such as bathing, brushing teeth, dressing, cooking, and doing laundry, and performing skills necessary to return to optimal functions. This professional utilizes adaptive equipment to assist patients in performing these activities, such as a grabber or adaptive utensils. The OT also provides visual and spatial perceptual retraining, such as using a double-vision eye patch and teaching the art of scanning the environment (gathering information about the external environment as an aid in planning a course of action), as well as energy conservation for patients with poor endurance, such as those with chronic respiratory conditions.

### Speech-Language Pathologist

The **speech-language pathologist (SLP)** is the professional who assesses, diagnoses, and treats patients with disorders relating to speech, language, swallowing, voice, and cognitive communication. The SLP develops specific exercises and recommends food consistencies for patients with dysphagia, dysarthria, and a tracheostomy to help prevent complications.

### Respiratory Therapist

The **respiratory therapist (RT)** is the professional who specializes in airway management. As part of and in collaboration with the healthcare team, the RT is responsible for maintaining the airway through the administration of oxygen, nebulized medications, and assessment of respiratory status and lung function (through pulmonary function tests and other assessment methods). The RT cares for patients with all types of respiratory disorders: upper airway disorders such as sinusitis, nasal trauma and fractures, and laryngeal

cancer and lower airway disorders such as chronic obstructive pulmonary disease, asthma, restrictive lung disease, and respiratory distress syndrome. The RT is able to perform arterial blood gases to monitor oxygenation, ventilation, and acid–base balance and also manages ventilators under the direction of the provider.

### Registered Dietitian/Nutritionist

The **registered dietitian/nutritionist (RD)** is the professional who assesses the patient's nutritional needs, develops meal plans, and provides education about dietary modifications related to the individual's disease process. The RD promotes healthy eating habits and assists patients in adapting to acceptable diets according to their healthcare needs, such as recommending a low-sodium diet for patients with congestive heart failure, a low-carbohydrate diet for patients with diabetes, or a low-fat diet for patients with heart disease. The RD also assists in designing enteral and parenteral plans for patients who can no longer eat by mouth and require gastrostomy tubes and central line nutrition.

### Case Manager

The **case manager (CM)** may come from a variety of backgrounds, typically an RN with an advanced nursing degree or a social worker. This team member utilizes the processes of assessing, planning, facilitating, advocating, and providing available resources to meet the individual's health needs with sound quality and cost-effective outcomes in mind. A CM incorporates the input of the ICT to plan in-hospital care and discharge transition care. This professional monitors services to ensure that the patient has the available resources to return to optimal health. This may include conferring with the provider to make a hospice referral for a patient with a terminal illness or assisting a patient in securing medications, which is difficult because of affordability, all while incorporating the patient and family's preference and requests into the plan.

### Home-Care Coordinator

A **home-care coordinator (HCC)**, typically an RN, identifies home-care needs proactively while the patient is in the hospital/skilled nursing facility or emergency department, or in lieu of hospitalization, the HCC may coordinate care from a provider's office. The HCC facilitates the provision of services in the home, including nursing, therapy, infusion, and respiratory care and medical equipment (e.g., hospital bed), and establishes the necessary resources needed for home care prior to discharge.

### Transition Guide

The **transition guide (TG)**, typically an RN with an advanced practice degree, assists patients during and after transitions (such as from hospital to home or a skilled nursing

facility), with the goals of ensuring a smooth transition, identifying and managing readmission risks, and assisting with aligning possible resources to aid in the patient's plan of care. The TG may meet with the patient prior to discharge and reconnect by phone and/or via home visits and is typically accessed when other home-based services are not warranted or when the patient is not eligible. These roles are typically paid by the hospital in a cost-avoidance strategy to minimize readmissions.

### Pharmacist

The **pharmacist** is actively involved in the management of the patient's medications, including:

- Reconciling the patient's medications between transitions of care (from home to the hospital and then from hospital to home)
- Reviewing medication orders for appropriateness and adjustment to the hospital formulary
- Monitoring of medication interactions
- Monitoring of adverse medication reactions
- Monitoring of therapeutic medication levels
- Providing medication counseling to the patient and family members
- Providing patient teaching on new or complex medications

The pharmacist oversees pharmacy technicians who assume responsibility for preparing medications. The pharmacist is an important ICT member because of his or her skills in identifying the best medication regimens for the patient, considering such factors as costs and caregiver skills (e.g., ability to inject medications long term).

 **Safety Alert** A pharmacist should review all medication orders before administration to the patient to ensure that there are no medication interactions, allergies, or other safer alternatives that should be considered.

### Ad Hoc Members

Ad hoc members of the ICT may include:

- Interpreter
- Chaplain
- Community health worker
- Legal counsel
- Palliative care coordinator
- Substance abuse counselor
- Post-discharge call nurses

The **interpreter** is the professional who facilitates the understanding of medical information by translating the information from English to the patient's native tongue, and vice versa. The interpreter needs to have command of the specific

language that he or she translates and should also have the ability to translate the medical terms effectively. Specific competencies are required in order to interpret in the health-care setting. Family members should not be relied on as interpreters because they may not accurately impart all of the information the patient needs to hear and understand.

The **chaplain** is the professional who has an educational background in religion. The chaplain provides spiritual comfort to patients and family members in need.

The **community health worker (CHW)** is an emerging role in the healthcare setting. CHWs serve as a point of connection between the patient's community and the rest of the health system. This role receives basic healthcare training and focuses on behavioral health concepts and important concepts related to patient engagement and motivational factors to promote health. It is important that the ICT understands the specifics of the CHW's role because there are many different types of CHWs. CHWs may address single health issues (e.g., diabetes) or multiple chronic issues, and they have differences in their levels of knowledge, training, and practice settings. Many focus on communities with which they have experience, or where they reside, to heighten credibility with and acceptance by patients.

The **legal counsel** is the professional who has judicial education, particularly in healthcare law, and provides legal perspective and support when resolving legal matters in the healthcare setting. This professional protects the rights of the patients and healthcare professionals in the healthcare system and works to identify safety risks and reduce them.

The **palliative care coordinator** is an advanced practice RN who provides information and support for the patient and family members when the patient needs disease, pain, or symptom management or is in need of hospice care when the patient has a terminal illness. This professional facilitates end-of-life discussions with the patient, family, and healthcare team and helps coordinate the care at home or in a facility.

The **substance abuse counselor** can be an SW, counselor, or RN but is typically a professional with a degree or certificate in addiction counseling. This team member provides counseling, support, and resources for patients who are addicted to substances, most commonly alcohol or prescription or illicit drugs such as heroin, cocaine, or marijuana. This counselor can help facilitate inpatient or outpatient detoxification programs for patients with substance abuse problems.

**Post-discharge call nurses** perform follow-up calls to patients after hospital discharge. They contact the patients who transition home with lower levels of support. Typically, this call is made in the first 24 to 48 hours after discharge to assess how the transition home is progressing. The calls are typically scripted and involve data collection for outcome measures or identification of missed discharge-planning opportunities and activities. The post-discharge call nurse hopes to identify potential challenges early in an attempt to prevent a readmission. Clinical symptom algorithms may be used to make a determination of a stable or unstable condition. An example is inquiring about weight gain, breathing, or fatigue in a patient

with congestive heart failure (CHF). Post-discharge calls can be very helpful in making necessary connections, such as home care for patients who thought they would be comfortable providing their own care at home but, once there, find it to be overwhelming and confusing. The post-discharge call nurse may also have the opportunity to answer questions for a caregiver who was not present during the discharge teaching process. Last, calls may assist with learning about the patient's experience with care in the hospital and give the patient the opportunity to voice complaints and/or compliments.

The patient is the center of the interprofessional effort; however, another important member of the care team is the **Patient and Family Advisory Council (PFAC)**. Most hospitals have PFACs that empower patients and their families and caregivers to participate in the improvement of patient care. PFACs are evolving across the continuum of care. Patients and family members on these councils provide feedback about their experiences of care, review care processes, and evaluate new programs, to name a few areas in which they are involved. The members may also be care mentors and advocates in specific care areas. The team may interact with specific members or access the PFAC through a request to provide input, evaluate a specific care matter, or provide general feedback.

### Connection Check 2.7

The nurse is caring for a patient who has experienced a CVA. Which ICT members should be involved in this patient's care? (Select all that apply.)

- A. Occupational therapist
- B. Physical therapist
- C. Physician
- D. Case manager
- E. Legal counsel

### UNIQUE PATIENT SITUATIONS REQUIRING OR ENHANCED BY INTERPROFESSIONAL COLLABORATION

All patients benefit from IC, but there are several situations where effective collaboration clearly maximizes patient outcomes (Box 2.3). Complex patients with multisystem disease require the expertise of many disciplines. Examples include patients with transplants, those with a chronic disease such as CHF or chronic pulmonary obstructive disease, and patients with cancer. Another example is the patient with catastrophic traumatic injuries involving orthopedic, neurological, cardiovascular, and respiratory issues. These patients require providers from many disciplines working collaboratively with the nurse at the bedside, as well as input from the pharmacist, nutritionist, OT, and PT to design the plan of care. Elderly patients with limited resources or limited caregiver options and patients with impaired mental status are equally challenging. They require collaboration between all members

of the team but especially home care, social work, and CMs to facilitate the availability of the necessary resources in the hospital and at home.

Discharge planning must begin the day of admission; especially with short lengths of stay, it is imperative to discover any issues that may affect a successful transition plan. Key to that is determining the details about the patient's social network, such as:

- Are there family members or friends available to help upon discharge?
- Does the patient have a home to return to, or should the patient return home?
- Can the patient afford the medications ordered? Does the patient have transportation to the provider's office?

An example of a patient who clearly needs and would benefit from effective IC is one going home with a new tracheostomy. There are many questions and issues to be considered. Examples (not an exhaustive list) of the care-planning process/questions for that patient include:

- Who is assuming primary responsibility for managing the tracheostomy? Backup? Third-level backup?
- Has teaching been completed prior to discharge? Can the primary and secondary caregivers successfully demonstrate at least three return demonstrations of tracheostomy care and suctioning?
- When will the patient get the tracheostomy changed? Have the supply sizes been specified so that the proper equipment is ordered?
- What emergency equipment is in place, such as an Ambu bag and suction equipment?
- Has oxygen been ordered? Has the household considered all the oxygen safety factors?
- What other equipment is needed? Hospital bed? Bedside commode? Wheelchair? Suction machine?
- Have home healthcare services been ordered?

### Connection Check 2.8

Which statement by the nurse indicates an understanding of the benefits of interprofessional collaboration in providing care for patients with chronic illness? (*Select all that apply.*)

- A. "Social work can be consulted to assist with long-term counseling."
- B. "Family members need to be included, with the patient's approval, to assess their willingness to assist in the long-term care of the patient."
- C. "Each member of the ICT participates in patient education and can use teach-back as a technique to determine synthesis of the information."
- D. "The ICT is concerned about developing a solid discharge plan that produces positive outcomes for the patient and prevents readmissions."
- E. "Direct care nurses are not involved in long-term care planning for patients with chronic illness."

### Box 2.3 Advantages of Interprofessional Collaboration

- Enhanced communication between members of the team
- Improved understanding of all team members' roles and responsibilities
- More timely discharge and transition planning
- Greater safety in the discharge transition process
- Improved patient satisfaction with the discharge transition process
- Improved team member satisfaction
- Decreased unnecessary hospital days
- Decreased 30-day readmission rates

### Making Connections

#### CASE STUDY: WRAP-UP

Mr. Garfield's discharge plan is discussed in rounds. He continues to be hypertensive during the hospitalization, so he will need to go home with a prescription for an antihypertensive and close monitoring. Social work will work on insurance support for his prescriptions. An interpreter is available to help the nurse, pharmacist, and RD with patient teaching related to his hypertension, diet, and the action/frequency/side effects of the medications. Teach-back is used to ensure that Mrs. Garfield is retaining the teaching provided. Mrs. Garfield decides to take the patient home. On day 3 of the hospitalization, she assists the nurses in delivering his care. On day 4, she provides care all on her own, with supervision, to gain confidence and skills prior to discharge. The HCC works to arrange equipment (hospital bed, bedside commode, and a wheelchair) and home-care services to including nursing, all three therapists (PT, OT, and speech), a SW, and a home health aide. A referral is made to a local skilled nursing facility just in case the plan fails at home. A follow-up provider appointment is made for the first week after discharge.

#### Case Study Questions

1. Which statement by Mr. Garfield indicates that teaching has been effective?
  - A. "I don't need to get lab work when I feel well."
  - B. "I'll take my pill when I don't feel good."
  - C. "I have to take this pill even if I feel good."
  - D. "My blood pressure isn't really that high; it won't cause a problem until it gets really high."
2. Which members of the interprofessional home-care team are necessary for Mr. Garfield's care? (*Select all that apply.*)
  - A. Home-care nurse
  - B. Home health aide
  - C. Speech-language pathologist
  - D. Primary care provider
  - E. Palliative care provider

3. Which statement is true about the follow-up appointment?
  - A. The appointment can be canceled if the patient is doing well.
  - B. The appointment can be delayed if the patient is feeling well.
  - C. It is important to follow up with the provider as planned.
  - D. The appointment is unnecessary if the patient refuses to go.
4. Which statement is *incorrect* about working with a patient who primarily speaks a different language?
  - A. An interpreter is always advised when imparting important information.
  - B. Family members can be used to interpret when necessary.
  - C. Written teaching materials should be in the patient's native language.
  - D. Non-English-speaking patients require advance discharge planning.
5. Excellent interprofessional collaboration in Mr. Garfield's care is evidenced by which of the following statements?
  - A. All members of the team worked according to their specialty to determine an appropriate discharge plan.
  - B. Only the team members necessary were involved in designing Mr. Garfield's discharge plan.
  - C. Only the inpatient team was necessary in developing the discharge plan.
  - D. Only the outpatient team was necessary in developing the discharge plan.

practice. Transitional care models and patient-centered medical homes put nurses in leadership positions to help coordinate care; engage patients, caregivers, and providers; and safely transition patients between care settings. Nurses in these positions easily transition with the patient and become a link to care. The transitional care model (TCM), Care Transitions Program, and guided care are evidence-based practices that utilize nurses in providing patient-centered care coordination across the care continuum. Increasing transitional care and care-management programs is part of the new healthcare landscape, and it will require well-prepared nurses to assist in further development and implementation.

Interprofessional collaboration (IC) is an equal partnership among the varied healthcare professionals and the patient, all working together to provide care to patients. While in the hospital, patients receive care from the IC. When preparing the patient for discharge, the role of the IC is to prepare to transition care to the patient and family. The essential components of this collaboration are coordination, communication, and shared responsibility. The purpose is to formulate and deliver a plan of care that is goal directed and team focused. Goal-directed care focuses on the overall aim for each patient. Daily care objectives remain focused on that overall goal, facilitating the efficient use of time and resources. Patient teaching and teach-back are integral parts of the interprofessional care team (ICT) process.

Members of the team include the registered nurse, physician, social worker, physical therapist, occupational therapist, respiratory therapy, nutritionist, case manager, pharmacist, and speech-language pathologist. Other members of the team include an interpreter, chaplain, legal counsel, home-care coordinator, palliative care coordinator, transition guide, and substance abuse counselor. The ICT may round and review patient care or speak informally but often uses a standardized communication, such as SBAR (see Box 2.2).

Interprofessional collaboration improves the care of the patient by increasing coordination between all healthcare disciplines. Time and resources are utilized more efficiently. Discharge issues are identified early, facilitating a return to home in a timely fashion. Interprofessional collaboration enhances the professional satisfaction of the members of the healthcare team. Ultimately, the outcomes of IC include improved communication, enhanced safety, decreased costs of care, prevention of unnecessary readmissions, and positive patient outcomes. The patient benefits from care delivered by an interprofessional approach, and the practice of the nurse is enhanced.

## CHAPTER SUMMARY

The need for better patient care coordination, particularly smoother transitions of care between different care facilities, is a growing concern in the U.S. healthcare system. Increased medical errors, often resulting in patient harm; increased length of stays in hospital settings; and increased healthcare costs are all driving factors for better care coordination and interprofessional team collaboration.

Patient-centered transitional care and other care-management initiatives are within the nursing scope of

## Cultural Considerations

*Nina Trocky*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Differentiating between cultural competence, awareness, and sensitivity
2. Describing social factors that predispose patients to health disparities
3. Using a cultural competency model to assess knowledge, attitudes, and beliefs
4. Explaining how bias may influence nursing judgment
5. Explaining the social determinants of health

### CONCEPTS

- Assessment
- Communication
- Diversity
- Nursing Roles
- Self

### ESSENTIAL TERMS

Ageism  
Bias  
Conscious (explicit) bias  
Cultural awareness  
Cultural competence  
Cultural sensitivity  
Culture  
Disparity  
Diversity  
Ethnicity  
Ethnocentrism  
Gender identity  
Health disparity  
Health literacy  
Identify  
Implicit bias  
Literacy  
Race  
Social determinants of health  
Stereotype  
Transcultural nursing  
Xenophobia

### Finding Connections

#### CASE STUDY: EPISODE 1

*Follow this patient throughout the chapter.*

Liu Huiwén is a 79-year-old female born in Taiwan. She speaks Mandarin, with limited English. Mrs. Liu recently moved in with her daughter and son-in-law because she requires more assistance to complete activities of daily living. Mrs. Liu's daughter has found her crying during the day and is not sure if Mrs. Liu is taking her Coumadin and other medications prescribed by her primary care physician and cardiologist (Mrs. Liu has heart failure and atrial fibrillation). Mrs. Liu asks her daughter to take her to a Chinese medicine store...

### INTRODUCTION

The ethnic and racial composition of the United States is continually evolving. In the past 25 years, the minority population has been increasing while the majority population has been on the decline. According to the U.S. Census Bureau, African American/black and Asian minority populations have increased, as has the number of Hispanics. Nursing care must be culturally competent in order to best serve the evolving diverse population. **Cultural competence** in healthcare is having the knowledge, abilities, and skills to deliver care congruent with the patient's cultural beliefs and practices. The lack of skills related to cultural competence can make it difficult for nurses to communicate with patients of other cultures and races; therefore, knowledge of other cultures is imperative. In addition to awareness of other cultures, nurses must avoid being ethnocentric and remain bias-free.

**Ethnocentrism** is the universal tendency of human beings to think that their individual ways of thinking, acting, and believing are the only right, proper, and natural ways. Nurses must remain nonjudgmental to optimize relationships and maximize quality care for all patients.

The concepts of ethnicity, culture, race, bias, identity, and inclusion are potential influences on nurses' judgment and behaviors, affecting the ability to deliver culturally competent and patient-centered care. Nurses have no way of knowing an individual's personal values and beliefs, national heritage, feelings about sexual identity, experiences within the healthcare system, or health literacy, based solely on appearance and demographic data. Nurses must develop essential skills in this area, enabling them to work with and care for a cross-cultural and ethnically diverse workforce and patient population. Becoming a competent healthcare professional requires each individual to evaluate and assess his or her knowledge of other cultures and also requires an understanding of personal biases and **stereotypes** (generalized beliefs about a particular category of people) that inhibit the ability to provide compassionate and patient-centered care to all. Moreover, elimination of racial and ethnic disparities in healthcare is needed, and nurses are instrumental in developing care congruent with the principles of a social justice and human rights orientation. The provision of culturally congruent care and sensitivity in developing care based on patients' beliefs and values are core competencies in nursing education.

### ETHNICITY, RACE, IDENTITY, CULTURE, AND CULTURAL BELIEF SYSTEM

Race and ethnicity are related but different concepts. Both terms are associated with how individuals choose to self-identify (**identity** means how a person views him- or herself). Both race and ethnicity place individuals within a social category and begin to establish a personal and group identity.

The American Sociological Association defines **race** as the physical differences that groups and cultures consider socially significant, such as skin color, hair texture, and eye shape or color. The U.S. Office of Management and Budget defines the racial categories that are used in all aspects of our daily lives, including employment applications, official census data, and even Medicaid applications. Self-reporting is the primary method of racial identification, using the following five categories from the U.S. Census Bureau:

- White—a person having origins in any of the original peoples of Europe, the Middle East, or North Africa
- Black or African American—a person having origins in any of the black racial groups of Africa
- American Indian or Alaska Native—a person having origins in any of the original peoples of North and South America (including Central America) and who maintains tribal affiliation or community attachment

- Asian—a person having origins in any of the original peoples of the Far East, Southeast Asia, or the Indian subcontinent, including, for example, Cambodia, China, India, Japan, Korea, Malaysia, Pakistan, the Philippine Islands, Thailand, Taiwan, and Vietnam
- Native Hawaiian or other Pacific Islander—a person having origins in any of the original peoples of Hawaii, Guam, Samoa, or other Pacific Islands

In 2000, the U.S. census offered survey participants the option to select more than one race as the racial category to more accurately describe the changing demographics of the United States and account for the children born to parents of different races. The number of children of two or more races is expected to more than double between 2018 and 2060, from 5% to 11%.

Ethnicity is related to race, but the terms are not synonymous. **Ethnicity** is the perception of oneself as belonging to one or more ethnic groups, including a commitment to cultural customs and rituals. For demographic purposes, the U.S. Census Bureau makes the distinction between people of Hispanic and non-Hispanic origin, and this information may be included in healthcare data. On an admission intake form, for example, the patient may select “White, non-Hispanic,” where “White” is the race and “non-Hispanic” is the ethnicity. However, all patients who self-identify as the same ethnicity may not share all of the same practices or preferences. For example, individuals of Hispanic ethnicity may share a common language (e.g., Spanish) and religion (e.g., Catholic), or they may share a language but not a religion. Another example is an individual who identifies as an Alaskan Native and may refer to him- or herself as a member of a particular tribal community and language group (e.g., Aleut or Eyak). Race and ethnicity are elements of a broader concept called culture. Culture is complex. At first, a person may simply explain that he or she is Irish or Jewish or African in relation to culture. However, that is a very limited view of culture. **Culture** relates to dynamic patterns of behaviors based upon beliefs and values, communication, customs, language, roles and relationships. These interrelated patterns influence expected behaviors associated with ethnic, racial, religious or social groups that are shared and transmitted to following generations.

When thinking about “culture,” individuals consider how much of self is visible to others and how much is kept hidden, yet everything about self—visible or hidden—interacts to create the individual's cultural belief system. Cultural belief systems are personally defined and unique to each individual; they reflect what is valuable and true to that individual, based on ideas and stories individuals tell themselves from a social and personal context.

In healthcare, an individual's belief system influences information processing, including interactions with providers and the overall healthcare system. For example, food may be considered a medicine by certain individuals

because food is used to restore health, whereas others may not see food and diet from such a holistic perspective. As caring professionals, nurses must develop their ability to provide culturally competent care—embracing a patient’s belief system and preferences, ensuring that care is inclusive, just, and respectful.

## CULTURAL COMPETENCE, AWARENESS, AND SENSITIVITY

Cultural competence, awareness, and sensitivity are similar yet different terms. Each term reflects critical knowledge, skills, and abilities that enable nurses to provide care that is appropriate for each patient’s unique set of needs. Learning the differences between each term is the first step. Knowing that differences exist, having the ability to be open to and accepting of these differences, and choosing to avoid judging or assigning value to the differences is the goal.

### Cultural Competence

The term *competence* is not new to nursing and healthcare. Competence refers to a person demonstrating proficiency, knowledge, and/or skill. Registered nurses learn how to take blood pressures and often must complete an annual validation to demonstrate competency for that essential skill, and they are then expected to complete that task correctly, every time. Cultural competence is the ability of healthcare providers and organizations to effectively deliver healthcare services that meet the social, cultural, and linguistic needs of patients. Culturally competent care means that nurses learn about each patient and tailor nursing actions to the individual patient and the patient’s needs.

Culturally competent care is essential to all nursing interventions. In fact, it is a professional expectation set forth by the American Nurses Association (ANA) *Standards of Professional Practice*. Specifically, Standard 8 explains that “the registered nurse practices in a manner that is congruent with cultural diversity and inclusion principles,” which is demonstrated in a number of ways. The elements of Standard 8 explain how nurses apply knowledge of culture and inclusion to develop care that is appropriate, sensitive, and reflective of current nursing practice (Box 3.1).

Total cultural competency requires the recognition that care must be equal, respect **diversity**, and be free of bias. Equal care means that every patient is treated the same, and as a result, patient care outcomes are similar. For example, a nurse provides two different patients information about heart failure. One patient is a college graduate who possesses a high level of literacy, whereas the other patient has less education and a lower level of literacy. The nurse confirms both patients fully understand the material and provides additional literacy support to either patient as necessary. This ensures that both patients receive equal access to the information.

## Box 3.1 American Nurses Association Standards of Professional Practice: Standard 8

The registered nurse practices in a manner that is congruent with cultural diversity and inclusion principles.

Competencies for the registered nurse:

1. Demonstrates respect, equity, and empathy in actions and interactions with all healthcare consumers.
2. Participates in life-long learning to understand cultural preferences, worldview, choices, and decision-making processes of diverse consumers.
3. Creates an inventory of one’s own values, beliefs, and cultural heritage.
4. Applies knowledge of variations in health beliefs, practices, and communication patterns in all nursing practice activities.
5. Identifies the stage of the consumer’s acculturation and oppression in practice within and among vulnerable cultural groups.
6. Considers the effects and impact of discrimination and oppression on practice within and among vulnerable cultural groups.
7. Uses skills and tools that are appropriately vetted for the culture, literacy, and language of the population served.
8. Communicates with appropriate language and behaviors, including the use of medical interpreters and translators in accordance with consumer preferences.
9. Identifies the cultural-specific meaning of interactions, terms, and content.
10. Respects consumer decisions based on age, tradition, beliefs and family influence, and stage of acculturation.
11. Advocates for policies that promote health and prevent harm among culturally diverse, underserved, or underrepresented consumers.
12. Promotes equal access to services, tests, interventions, health promotion programs, enrollment in research, education, and other opportunities.
13. Educates nurse colleagues and other professionals about cultural similarities and differences of healthcare consumers, families, groups, communities, and populations.

From American Nurses Association. (2015). *Nursing scope and standards of practice* (3rd ed.). Washington, DC: Author.

### Cultural Awareness

Realizing that each patient sees and interprets things in his or her own way is the first step toward becoming culturally aware. Awareness may be defined as knowledge or understanding of a subject, issue, or situation, and cultural awareness is rooted in a desire to interact with the patient in a real and authentic fashion. **Cultural awareness**, therefore, is the realization and recognition that personal beliefs and values impact cultural health beliefs and potentially the view of those who are different. It is a critical starting point that nurses choose not to impose personal views on others. Awareness brings humility, further introspection, and empathy, which

can help the nurse develop care that respects each patient's unique needs. To fully respect the differences of individual patients, nurses must actively create an environment and tone that are inclusive and without judgment. A nurse must be culturally aware to provide care that is appropriate for each patient and respectful of each patient's beliefs. For example, in some cultures, it might be appropriate and acceptable to physically stand very close to the person to whom you are speaking. In another cultural, physical space or distance between those in conversation is necessary, fostering comfort. Being culturally aware means that the nurse honors the patient's need for distance and does not force his or her own need to stand close to the patient. Awareness means the nurse is curious, wishing to know more, and choosing to act in a way that honors the patient's needs, not his or her own needs. Acknowledging and understanding the differences among patients and learning from them is the start of a nurse's cultural awareness.

### Cultural Sensitivity

In order to provide culturally competent care, nurses must demonstrate **cultural sensitivity**: an understanding, thoughtfulness, and kindness that leads to inclusiveness and equity. Cultural sensitivity relates to an appreciation of one's personal needs and emotions, as well as to others' cultural practices, that lead to patient-centered care. This is especially important because, no matter the setting, nurses care for patients who come from diverse backgrounds. In fact, The Joint Commission (2017) developed an application, Cultural Sensitivity for Health Care Professionals, to help healthcare professionals improve their ability to deliver culturally sensitive care and strengthen communication skills with patients and families.

As nurses, caring is a hallmark behavior that promotes actions, attitudes, and behaviors that respect all cultures and all patients as individuals. Having a caring mindset and being open to considering and appreciating a patient's culture require time and desire. These are attributes of a professional registered nurse and reflect the ANA's commitment to respecting the human rights of all persons and avoiding personal biases and stereotypes that lead to inequity.

### Connection Check 3.1

Select the statement that reflects a culturally sensitive response to a patient's question.

- Can you try to decrease your smoking while you work?
- How do your religious beliefs impact your healthcare decisions?
- What is the biggest barrier to you making a lifestyle change?
- When do you think it is possible for you to decrease your salt intake?

## HEALTH DISPARITIES AND HEALTH EQUITY

Registered nurses must be committed to reducing health inequities and disparities by customizing patients' plans of care. Applying the *Standards of Professional Practice* ensures that the nurse's role is to fulfill a social contract, based on social justice, modifying care by responding to the needs of patients. Raising awareness is the first step in addressing barriers to health equity. As awareness is raised, nurses improve the ability to recognize actions that perpetuate unjust and unequal care and treatment that contribute to social injustice.

### Health Disparities

A **disparity** is a difference, inequity, discrepancy, or gap. According to the Office of Disease Prevention and Health Promotion, a **health disparity** is a health difference that is closely linked with social, economic, or environmental disadvantages. Health disparities are real and preventable, and they exist in all age groups, cultures, races, ethnic groups, religions, and populations who are vulnerable by virtue of sexual identity.

Any difference in a health outcome that is related to bias, injustice, exclusion, marginalization, and social determinants of health may be viewed as a disparity. For example, in the U.S., infant mortality rates are 2.2 times higher in African Americans compared with non-Hispanic whites, and the rate of postneonatal mortality for non-Hispanic blacks and American Indian/Alaskan Natives is more than twice that of non-Hispanic whites. This may be the result of many social factors (Box 3.2) or may result from the biases and discriminatory behaviors of providers. For the patient, the degree of risk and vulnerability grows as the number of social factors increases.

### Age

A patient's age is an important consideration in the provision of culturally competent care. Age is one of many factors that informs the nurse's actions when developing a plan

### Box 3.2 Social Factors Affecting Healthcare Equity

- Age
- Differences in education
- Disabilities
- Economic instability
- Gender
- Income inequality
- Limited English proficiency
- Limited social support
- Mental illness
- Race
- Sexuality
- Social isolation

of care. However, assuming that patients of the same age, young or old, act and feel the same way is a misperception. **Ageism**, or stereotyping and discriminating based solely on the patient's age, marginalizes the patient and results in dehumanizing and inappropriate care. The following examples show how nurses exhibit ageism:

- When admitting a 79-year-old female for elective surgery, the nurse avoids asking a question about alcohol intake because the likelihood of alcoholism is “pretty low” in her age group. The nurse assumes the female patient does not drink alcohol and misses the opportunity to assess the patient for alcohol use disorder.
- During a health assessment, the nurse notices that the older adult male appears underweight and assumes the patient is malnourished. The nurse fails to ascertain that the patient is a long-distance runner whose weight has been stable for several years. Moreover, upon finding this out, the nurse questions the importance of physical activity in “someone his age.” The nurse dismisses the importance of exercise to the patient's social and spiritual well-being.

Nurses must take steps to avoid judging and stereotyping patients based on age because these actions affect a patient's ability to receive the most appropriate care. These effects may be associated with health disparities because older adults may have limited access to healthcare, whereas in many older adults, the use of healthcare services increases. With the price of medications and other out-of-pocket costs, senior adults are faced with the financial burden of prescription medication use, which may result in delayed healthcare and unmet healthcare needs. Nurses have the opportunity to assess patients using an age-relevant lens that supports the identification of appropriate resources to address patient needs.

### **Race**

To support a healthcare workforce empowered to address and embrace the diversity in the patient population, the U.S. Congress formed the Office of Minority Health (OMH) in 1986. The OMH supports research, projects, and other initiatives to promote a better understanding of health risk factors and successful prevention and intervention strategies for minority populations. Despite the work done by the OMH, there are still problems with health equity for minority populations. The 2010 census noted that although several health indicators (e.g., life expectancy, infant mortality) did improve for the general population, minority groups continued to have a greater incidence of preventable disease, death, and disability compared with nonminorities.

### **Gender and Sexuality**

Gender is defined as the socially constructed characteristics of women and men, such as norms, roles, and relationships of and between groups of women and men. However, how one identifies oneself may be different from how others describe

the person. **Gender identity** is how one defines and sees oneself. For example, a patient appears to be anatomically male, yet the patient identifies as female. This is gender identity and may lead to gender bias in the nurse. The nurse's actions can lead to inappropriate treatment of the patient, such as avoiding contact other than when it is necessary. Gender bias is the end result of negative stereotyping (e.g., assuming all males who are transitioning to a female act in a certain way) and can lead to gender discrimination or the unequal treatment of the patient. Nurses must be able to avoid gender bias and discrimination in order to establish a therapeutic relationship that is free from judgment, personal opinions, or the power to demoralize the patient and/or family. Nurses must develop care based on the acceptance of all patients for who they are, not how the nurse might think they should be, and that care should be both compassionate and equitable.

Sexuality or sexual orientation is linked with gender identity and refers to which individuals a person chooses for romantic and sexual encounters. Both gender identity and sexual orientation are individually and personally defined and may be different from how others may “see” them. A nurse might hold the opinion that men “look” a certain way and women might “act” a certain way; these ideas reflect a broad generalization that is unacceptable and harmful. Holding on to one's personal perceptions regarding sexuality leads to behavior that negatively impacts one's interactions with others, which is called gender stereotyping. The nurse's role is to ensure gender equality and facilitate care that respects all patients' rights and preferences.

In 2016, the National Institute on Minority Health and Health Disparities (NINHD), a part of the U.S. Department of Health and Human Services, designated sexual and gender minorities as a health disparity population. This designation allows the NINHD to specifically address the need for research among lesbian, gay, bisexual, and transgender populations, including those who may be questioning sexual orientation, identity, and expression. Subsequent studies have shown that the social stigma associated with transgender patients plays a role in the degree of patient engagement with medical care. For HIV-positive transgender youth and emerging adults, this was found to result in missed HIV care appointments. Because HIV is a chronic disease, missed HIV visits may lead to greater morbidity and a higher viral load for the individual, which can increase the chance of HIV transmission.

### **Economics**

The possession of adequate financial resources for day-to-day living expenses and to pay for healthcare services greatly impacts an individual's ability to obtain healthcare. The high costs of healthcare services and health insurance create a financial barrier for patients with limited resources. Information related to both past and present financial resources is useful in determining gaps in healthcare or deterioration in health status and function that may be attributable to economic factors. Through a better understanding of the patient's financial needs, the nurse

identifies the support services (e.g., patient assistance programs for prescription medications) that are appropriate for the patient.

When patients face economic and financial barriers to accessing healthcare, there may also be delays in receiving care and/or accessing primary care services that potentially prevent definitive care and hospitalization. Often, income level and employment are associated with health insurance access. Health insurance increases a patient's access to primary care and preventative care. Additionally, the Peterson Center on Healthcare noted that in 2016, an estimated 1 in 10 adults reported that healthcare costs resulted in a delay in seeking care or in avoiding care altogether. Other research, for example, has found that younger black men with healthcare insurance are more likely to participate in prostate cancer screening. As a nurse, understanding the financial barriers and supporting access to healthcare and services for all patients is a vital part of helping patients achieve the highest possible level of health.

### **Language and Literacy**

Communication is a vital part of any patient encounter. The concepts of literacy and health literacy are essential components of providing patient-centered care. **Literacy** is the ability to read, write, speak, and compute and solve problems, and **health literacy** is the ability to appropriately locate, comprehend, and use health information and services. Patients must have an adequate understanding of their treatment plan, medications, and health status in order to make informed decisions. When given teaching materials, patients must be able to read and understand the content accurately, as well as to be able to read printed materials and contact the healthcare provider if experiencing unusual symptoms.

Patients with language barriers or poor levels of health literacy use healthcare services differently compared with patients with higher health literacy and may experience poorer outcomes. Patients with low health literacy are less likely to access preventative services, such as mammograms and influenza vaccinations; are less knowledgeable about their chronic conditions, making them less able to adequately manage disease; have higher hospital admissions and emergency room visits; and have lower medication management capacity (i.e., having the ability to identify, open, and describe the dose and timing of their medications).

### **Geography**

According to the Robert Wood Johnson Foundation, each individual is affected by three interrelated environments either promoting or jeopardizing his or her health: physical, social, and service environments. The physical environment is the "built environment," which includes housing structures, retail shops, and commercial spaces, plus the natural environment, such as parks, trees, and walking trails. The social environment refers to the presence and quality of the relationships and connections individuals have with others,

such as neighbors. Finally, the service environment includes the neighborhood resources associated with education, employment, transportation, healthcare, grocery shopping, recreation, and other services directly or indirectly tied to health.

Where a person lives may create health disparities because an individual's health is directly affected by elements that increase or decrease wellness; a person's immediate neighborhood influences his or her health. Consider the phrase "place matters." When a neighborhood has plenty of green space and parks, crime is low, and streets and sidewalks are in good working order, individuals might feel compelled to enjoy the outside space, embrace exercise, and spend time talking to neighbors. Compare that scenario to a neighborhood where crime is high, city services are marginal, and many homes are vacant and boarded up. Physical safety might be a concern that encourages an individual to stay inside, avoid public spaces, and limit outside hobbies. Consider a neighborhood that has limited public transportation and the ways to access a bus, subway, or train might inhibit one's ability to find work, shop for groceries, and access preventative healthcare services. Likewise, consider a neighborhood where elementary schools lack adequately prepared teachers and sufficient textbooks and do not have a school nurse. Children in this neighborhood may have a foundational education that is inferior compared with children living in a neighborhood where schools are exceptional and have superior teachers and state-of-the-art classroom resources.

Physical geography also influences what the individual breathes (e.g., clean air versus polluted air), the quality of the drinking water, and what diseases people living in that area may be exposed to (e.g., HIV, tuberculosis, alcoholism). Geography and health are very closely linked, and when considered together, they allow the nurse to consider patient risk factors and health needs from a broader perspective. The nurse's role is to identify the degree to which geography negatively impacts health and develop opportunities and provide resources that the patient may access to minimize the risk for disease.

### **Bias and Discrimination**

Every individual has the potential for forming an opinion that is unfair or prejudicial in some way. This perception is termed **bias**. An individual, as well as groups of individuals, may hold multiple biases. There are two aspects to bias that are important to understand because both are associated with inferior, insensitive, and inappropriate healthcare. Implicit or unconscious bias is related to associations outside conscious awareness that foster a negative evaluation of a person on the basis of irrelevant characteristics such as race, gender, age, and so forth. Implicit bias may emanate from negative and positive stereotypes and impact one's judgment and is automatically activated and often unintentional.

**Implicit bias** is subconscious and may be visible through subtle behaviors, such as being more relaxed when addressing one patient while being distant or aloof with another.

Implicit bias explains the potential differences between explicit beliefs and actions to treat everyone equally and the influence of hidden *negative* implicit associations on beliefs and actions.

**Conscious bias**, or **explicit bias**, is blatant, purposeful, targeted, and intentional. For example, conscious bias results when an individual has deliberate thoughts and feelings about an individual, such as an obese male as well as groups of obese individuals. The intent of conscious bias is to demonstrate whether or not the negative aspects or evaluations of the individual or group are true. Bias can lead to stereotyping, which is grouping all individuals in a group together and forming a broad generalization (e.g., “all homeless individuals are illiterate”; “Native Americans are typically obese and live on reservations”).

### Bias and Healthcare Professionals

Healthcare professionals have personal belief systems, values, and attitudes. These personal attitudes, values, and beliefs can impede a provider’s ability to understand and accept patients with different backgrounds or belief systems or patients who may not do things or act in a way that the professional “expects.” This lack of understanding and acceptance can affect patient care and, ultimately, patient outcomes.

In 2002, the Institute of Medicine (now referred to as the National Academy of Medicine) reported that differences in patient care may be related to the behaviors of healthcare professionals, specifically bias, or prejudice directed toward certain groups; greater clinical uncertainty when interacting with minority patients; and beliefs, or stereotypes, held by the provider regarding the behavior or health of minorities. The report *Unequal Treatment: What Healthcare Providers Need to Know About Racial and Ethnic Disparities in Healthcare* explains that there are differences in the way patients respond to treatment and interventions as well as variations in their treatment-seeking behaviors. Despite this and other reports, unequal treatment and health inequity are still evident in the current healthcare environment. Providers must adjust practices to address patient behaviors, attitudes, and care responses, and they must not allow bias to enter into patient care practices.

It has also been found that healthcare providers who stereotype patients based on personal misperceptions and biases negatively influence patient outcomes and contribute to healthcare disparities. Research exploring the impact of the implicit racial and ethnic biases of healthcare professionals and the impact on health outcomes revealed low or moderate levels of implicit bias in healthcare professionals toward people of color. Several studies noted that healthcare professionals characterized African American patients as less cooperative and responsible. Surveys have found that healthcare providers in some Veterans Affairs Medical Centers display bias in relation to patients with mental illness. These findings are based on reports from each provider about the amount of contact with patients with mental illness, as well as with personally known

individuals with mental illness. Stigmatizing attitudes were lower for providers who had more contact with patients and nonpatients with mental illness.

The provider–patient relationship can also create a power dynamic in which the provider has the bulk of the power. This can alter interactions between healthcare providers and patients if providers consider the patients to be “less than” themselves or “beneath” them. The power imbalance fueled by the negative impact of bias and stereotyping can result in actions that are aggressive toward the patient and can lead to unfair treatment by the provider.

When an individual is afraid and demonstrates hatred or exhibits “an attitudinal orientation of hostility against non-natives in a given population,” this is called xenophobia (United Nations Educational and Scientific and Cultural Organization, 2017). **Xenophobia** is often expressed by fear, intolerance, dislike, and prejudice against individuals from other countries.

Biases, conscious or unconscious, are not limited to characteristics such as ethnicity and race; biases may exist toward any social group. Bias, discrimination, stereotyping, and hatred alter judgment, influence behavior, and create isolation and disassociation between nurses and patients and/or family members. The distortions in healthcare provider judgment and decision making are key contributors to patient safety events as well as health inequality and disparities.

### Connection Check 3.2

Select the response that acknowledges that social factors place patients at risk for health disparities.

- A. Anyone can be poor and have limited income; that does not impact access to healthcare.
- B. Having faith and being religious help patients deal with health adversity.
- C. Many patients speak another language, but translations services help them a lot.
- D. Unemployment is a barrier that negatively impacts housing, food, and healthcare access.

### Connection Check 3.3

Which thought by the nurse suggests that the nurse is considering whether unconscious bias is influencing his or her judgment?

- A. “All obese patients just make bad nutritional decisions.”
- B. “I wonder if my feelings about abortion made me say that.”
- C. “Is cultural awareness as important as cultural competency?”
- D. “Why do they all act that way?”

## CASE STUDY: EPISODE 2

Mrs. Liu is admitted to the hospital for rectal bleeding. During the nursing assessment, the nurse learns about Mrs. Liu's recent move to live with her daughter and son-in-law and their visit to the Chinese medicine store. The nurse does not understand why Mrs. Liu went to the Chinese medicine store. Further discussions reveal that Mrs. Liu consulted the local deity (or spiritual leader) when her bleeding first began to ask for guidance. Mrs. Liu brings in her prescriptions, Coumadin and Digoxin, and a vial, without a label, containing blue pills.

The nurse becomes concerned when she learns that the bleeding started 5 days prior to admission and that Mrs. Liu did not contact her primary care physician. Mrs. Liu's daughter explains that her mother values traditional Chinese medicine over Western medicine. Despite that, the nurse recommends some tests to determine the cause of the bleeding. After testing, the nurse determines that Mrs. Liu's rectal bleeding was a consequence of an elevated international normalized ratio (INR). The Coumadin dose is decreased, Mrs. Liu's rectal bleeding resolves. However, the nurse now notices that Mrs. Liu appears withdrawn, avoiding eye contact whenever the nurse enters the room. The nurse considers that Mrs. Liu might feel socially isolated, unable to fully participate in her care management, perhaps because of a language barrier or unfamiliarity with the Western medical system. Mrs. Liu's daughter explains that Mrs. Liu feels fearful...

## ELIMINATING DISPARITIES AND CREATING HEALTH EQUITY

### Social Determinants of Health

The **social determinants of health** (SDOH) consist of a variety of circumstances and conditions “in the environments in which people are born, live, learn, work, play, worship, and age that affect a wide range of health, functioning, and quality-of-life outcomes and risks” (Office of Disease Prevention and Health Promotion, 2018c). The SDOH include specific factors, such as socioeconomic status; level of education; neighborhood and physical environment where one resides; employment, unemployment, or underemployment; presence of social support networks; and ability to access healthcare. Healthcare providers must consider the relevant SDOH for each patient and address those SDOH relevant to improving health and reducing disparities in health and healthcare.

The SDOH model (Fig. 3.1) serves as a visual representation framework for the *Healthy People 2020* population health indicators. These indicators show high-priority issues that impact the health and well-being of all individuals

**FIGURE 3.1** The social determinants of health (SDOH) model

but especially those who are vulnerable, marginalized, and burdened by social factors. Examples of leading health indicators are suicide, obesity, and substance abuse. Additionally, genetics plays an important role in one's ability to maintain health, and given that genetic makeup cannot be altered, nursing efforts must focus on modifiable elements contributing to the individual determinants of health (e.g., homelessness or low literacy).

The SDOH model has five key elements:

- Economic stability
- Education
- Social and community context
- Health and healthcare
- Neighborhood and built environment

Box 3.3 shows the social factors that are included in each of the five SDOH elements. The care provided to the patient must acknowledge the influence of each SDOH element on the current health situation as well as the role of each determinant in the patient's pathway to improved health. Failing to consider the SDOH when providing care is a barrier to providing patient-centered care.

### Healthy People Initiative

The United States has a national initiative centered on creating health equity by focusing on health promotion, disease prevention, and quality of life. According to the Office of Disease Prevention and Health Promotion, the *Healthy People* initiative focuses on 10-year national objectives meant to improve the health of all Americans by utilizing science-based initiatives. Three key goals serve as the foundation:

- Encourage collaborations across communities and sectors.
- Empower individuals toward making informed health decisions.
- Measure the impact of prevention activities.

## Box 3.3 Social Determinants of Health (SDOH)

### Economic Stability

- Employment
- Food insecurity
- Housing instability
- Poverty

### Education

- Early childhood education and development
- Enrollment in higher education
- High school graduation
- Language and literacy

### Social and Community Context

- Civic participation
- Discrimination
- Incarceration
- Social cohesion

### Health and Healthcare

- Access to healthcare
- Access to primary care
- Health literacy

### Neighborhood and Built Environment

- Access to foods that support healthy eating patterns
- Crime and violence
- Environmental conditions
- Quality of housing

Based on Office of Disease Prevention and Health Promotion. (2018). *Determinants of health*. Retrieved from <https://www.healthypeople.gov/2020/about/foundation-health-measures/Determinants-of-Health>.

In each of the 10-year goals, the focus is on addressing health for all and reducing inequities and health disparities for some social groups over another. In *Healthy People 2000*, the goal was to reduce health disparities for Americans. In *Healthy People 2010*, the goal was to eliminate health disparities. In *Healthy People 2020*, the goal is more specific and direct: to achieve health equity, eliminate disparities, and improve the health of all groups. *Healthy People 2020* also covers more vulnerable groups, including LGBTQ populations, as well as those with special needs and considerations. *Healthy People 2030* objectives are in development. Preliminary discussions suggest adding more objectives to develop interventions specifically focused on eliminating health disparities by addressing the SDOH and improving access to quality healthcare.

When nurses develop culturally competent care, conscious decisions are made to minimize barriers to care, including all determinants of health conditions and factors. Although each patient presents unique needs, nurses may use the *Healthy People* framework and the learning health indicators to develop patient, family, and community interventions that contribute to the improved health of the nation.

## Improving Health Literacy

There are several evidence-based interventions that may be incorporated into a healthcare provider's practice to improve health literacy, thereby minimizing the potential barrier of the patient's ability to understand the plan of care. These interventions include:

- Incorporating technology and Web sites with realistic pictures and clear captions to improve comprehension
- Integrating teach-back and plain language into instructions to improve knowledge retention
- Using simple language and photograph- and pictogram-based care plans to improve patients' disease management abilities
- Developing print materials to be at the seventh- to eighth-grade reading level

### Language and Literacy

It is important to assess patients for individual language needs and for healthcare providers to adjust their communication style to meet these needs. Patients with limited ability to speak, write, or read English (individuals with limited English proficiency [LEP]) face additional barriers. Additional safeguards must be in place within healthcare organizations to prevent or minimize potential discrimination. Specifically, Title VI of the Civil Rights Act of 1964 states: "no person in the United States shall, on the ground of race, color, or national origin, be excluded from participation in, be denied the benefits of, or be subjected to discrimination under any program or activity receiving Federal financial assistance." Applicable to all facets of life in the United States, this law is also relevant to supportive services in healthcare, such as medical translators and language resources. Per the Civil Rights Act, printed materials in languages other than English must be available for patients based on the patient population being served. Patients deemed LEP must be provided with services that support their ability to access healthcare and services, communicate with healthcare providers, and receive information in a manner that facilitates their understanding. These practices reflect the incorporation of cultural awareness principles in the provision of individualized care.

### Culturally and Linguistically Appropriate Services (CLAS)

The Office of Minority Health (OMH) formed the Center for Linguistic and Cultural Competency in Health Care (CLCCHC) to address the unmet needs of patients seeking healthcare and to decrease barriers to healthcare literacy. The CLCCHC developed Culturally and Linguistically Appropriate Services (CLAS) as national standards for healthcare facilities to use when developing services, policies, and educational materials to mitigate health inequities and disparities related to individuals with LEP. The CLAS focus is respect and responsiveness, which translates into respecting the wholeness of each individual and responding to each individual's needs, preferences, and desires in order to provide services that reflect an individual's culture and language preferences. The goal of these services is to support healthcare professionals

in facilitating positive health outcomes for diverse populations. The 15 CLAS standards are listed in Box 3.4.

### Connection Check 3.4

What is the most accurate description of the social determinants of health?

- Biological, socioeconomic, psychosocial, behavioral, or social factors influencing an individual's health
- Factors that contribute to health inequity, discrimination, and healthcare professional bias
- National standards that are used to develop culturally competent and linguistically appropriate patient care
- Services used within healthcare facilities to identify which patients require culturally competent care

## CULTURAL ASSESSMENT MODELS

Models of cultural competence serve as a framework to meet the increasing heterogeneity of patient populations. These theories and models exist to assist nurses in developing culturally and linguistically appropriate healthcare that is free of behaviors, attitudes, and judgments influenced by fear, discrimination, and bias. Each model offers healthcare professionals a means to understand personal uncertainties and knowledge gaps related to patients with different experiences, needs, beliefs systems, and cultures. All of the theories and models highlight the importance of developing an authentic connection based on acceptance, understanding, and respect for human life.

### Box 3.4 National Standards for Culturally and Linguistically Appropriate Services (CLAS) in Health and Healthcare Standards

#### Principal Standard:

- Provide effective, equitable, understandable, and respectful quality care and services that are responsive to diverse cultural health beliefs and practices, preferred languages, health literacy, and other communication needs.

#### Governance, Leadership, and Workforce Standards:

- Advance and sustain organizational governance and leadership that promotes CLAS and health equity through policy, practices, and allocated resources.
- Recruit, promote, and support a culturally and linguistically diverse governance, leadership, and workforce that are responsive to the population in the service area.
- Educate and train governance, leadership, and workforce in culturally and linguistically appropriate policies and practices on an ongoing basis.

#### Communication and Language Assistance Standard:

- Offer language assistance to individuals who have limited English proficiency and/or other communication needs, at no cost to them, to facilitate timely access to all healthcare and services.
- Inform all individuals of the availability of language assistance services clearly and in their preferred language, verbally and in writing.
- Ensure the competence of individuals providing language assistance, recognizing that the use of untrained individuals and/or minors as interpreters should be avoided.
- Provide easy-to-understand print and multimedia materials and signage in the languages commonly used by the populations in the service area.

#### Engagement, Continuous Improvement, and Accountability:

- Establish culturally and linguistically appropriate goals, policies, and management accountability, and infuse them throughout the organization's planning and operations.
- Conduct ongoing assessments of the organization's CLAS and related activities, and integrate CLAS and related measures into measurement and continuous quality improvement activities.
- Collect and maintain accurate and reliable demographic data to monitor and evaluate the impact of CLAS on health equity and outcomes and to inform service delivery.
- Conduct regular assessments of community health assets and needs and use the results to plan and implement services that respond to the cultural and linguistic diversity of populations in the service area.
- Partner with the community to design, implement, and evaluate policies, practices, and services to ensure cultural and linguistic appropriateness.
- Create conflict and grievance resolution processes that are culturally and linguistically appropriate to identify, prevent, and resolve conflicts or complaints.
- Communicate the organization's progress in implementing and sustaining CLAS to all stakeholders, constituents, and the general public.

## Transcultural Nursing

**Transcultural nursing** acknowledges that nurses meet and care for patients who are different from themselves, and these differences may present a challenge. Learning about patients' cultural backgrounds, experiences, and desires requires nurses to enter into meaningful conversations about how patients' cultures affect their lives, thereby decreasing discrimination and bias. The recognition by the nurse of how culture influences an individual's values, beliefs, and worldviews reflects cultural awareness. This also underscores the importance of nurses acknowledging that these differences exist and respecting these differences.

### Transcultural Nursing Model

Nursing theorist Madeline Leininger based the Transcultural Nursing (TCN) cultural assessment model on a humanistic approach that broadly supports individuals, organizations, communities, and societies and linking caring within the context of culture. In her work, Leininger blended concepts from both nursing and anthropology to explain caring as the central link between the human being (the patient) and the nurse (provider of care). The concept of caring is considered as assisting, supporting, or enabling the patient's behaviors while also helping the patient improve health and performance. A nurse who practices humanistic care seeks to understand and know the person, the human being, in order to improve health and ameliorate suffering.

### Culture Care Diversity and Universality Theory

Leininger's Culture Care Diversity and Universality Theory explains that nurses must first know the patients they are caring for—individual patterns, beliefs, practices, and personal expressions. The nurse is then informed and able to provide care that is congruent with the belief systems of the patients. The term *transcultural nursing* refers to the nurse's desire to cross the divide and meet the patient where he or she is, as an individual in a global and diverse patient population. Culturally competent care only occurs when culture care values are known and serve as the foundation for meaningful and just care, shifting from less aware to more aware. Moreover, Leininger explains that nurses must be educated and immersed in learning about the nuances of a patient's cultural beliefs and values so that the care provided does not harm or prevent the patient from attaining the highest degree of possible health. The Culture Care Diversity and Universality Theory focuses on examining and addressing the differences and similarities of global cultural care.

### Sunrise Model

Leininger depicts the Culture Care Diversity and Universality Theory using the Sunrise Model (Fig. 3.2), which shows the factors and conditions that influence care. The concept of a sunrise is one that is most fitting to represent

the process of cultural awakening; the rising sun begins first with a dim light but soon becomes bright. In a similar way, the professional nurse may begin with little cultural knowledge but strives to become aware and to expand knowledge and practice to better develop culturally focused interventions for the most vulnerable patients.

In the model, the outermost “ring” represents cultural care and the worldview, the way in which the nurse views the world. This worldview informs the nurse's knowledge about patients, families, and/or communities within the healthcare system. Nurses use their education to learn more about the next ring, which includes cultural and social dimensions that influence each patient: technological, religious/philosophical, kinship/social, cultural values and lifeways, political and legal, economic, and education. By addressing the language and environmental barriers, nurses create pathways that respect patients' experiences, patterns, and practices, leading each to a state of holistic health. Finally, the nurses integrate patients' folk or traditional health beliefs with the professional healthcare systems to devise care that is respectful, just, and patient centered.

## ASSESSING CULTURAL COMPETENCE

### Characteristics of Cultural Diversity

Cultural specifics affect individual health beliefs and behaviors. Knowledge of the cultural specifics of the groups in a community helps explain why patients from different cultures have different expectations of healthcare. The six cultural specifics that influence health are communication, space, time orientation, social organization, environmental control, and biological variations.

### Communication

Communication is an exchange of information, ideas, and feelings, including verbal and nonverbal language (i.e., spoken language, gestures, eye contact, and even silences). Language differences present one of the most difficult obstacles to providing individualized, patient-centered care. Even when the nurse and the patient speak the same language, culture influences how feelings and thoughts are expressed and which verbal and nonverbal expressions are appropriate to use.

### Assessment and Strategies

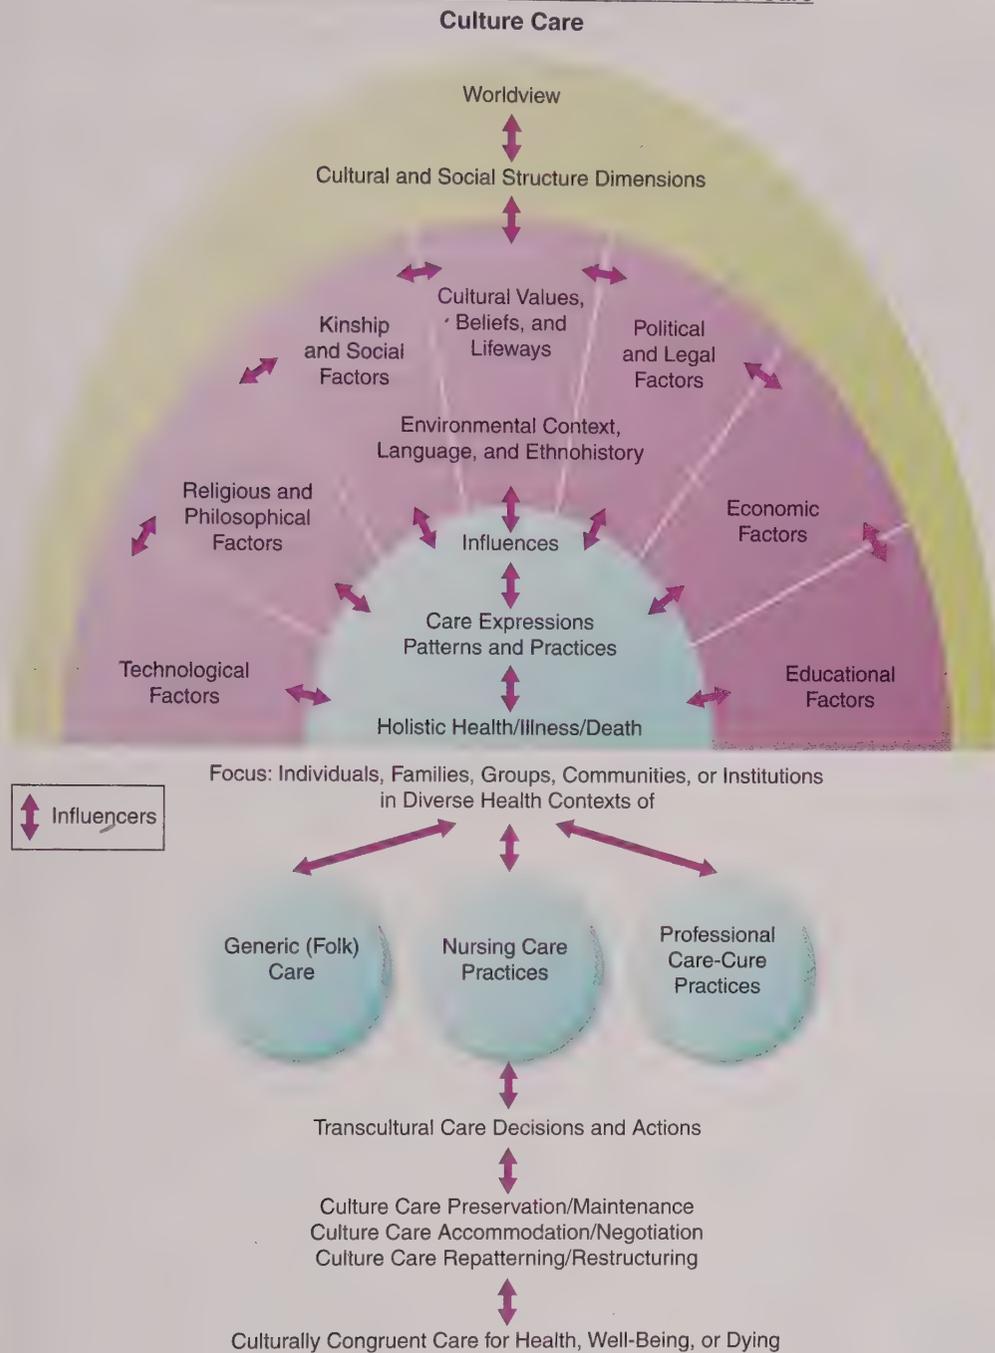

Ask the following questions:

- By what name do you prefer to be called?
- What language do you speak at home?
- Are you able to read and write in English?
- If not, what language is preferred?

Incorporate the following actions:

- Be an active listener, and become comfortable with silence.
- Avoid appearing rushed.
- Be formal with greetings until told to do otherwise.

### Leininger's Sunrise Enabler to Discover Culture Care

**FIGURE 3.2** Leininger's Culture Care Diversity and Universality Theory—The Sunrise Enabler Model.

- Take greeting cues from the patient.
- Speak slowly and clearly. Do not speak loudly or with exaggerated mouthing.
- Explain why you are asking specific questions.
- Give reasons for treatments.
- Repeat questions as needed.
- Provide written instructions in the patient's preferred language.
- Obtain an interpreter if needed.

Nurses should refrain from relying on untrained individuals to interpret, especially family members. Although it may seem logical that a patient's best advocate is a family member, it is risky to rely on family members to

interpret medical or health information for the following reasons:

- Family members may not be proficient in medical terminology.
- They may not possess the skills needed to interpret.
- They may unintentionally or intentionally omit or alter important information.
- Using family members to interpret may raise privacy issues protected by the Health Insurance Portability and Accountability Act of 1996 (HIPAA).
- If children are used as translators, they may not be emotionally mature enough to handle the information being conveyed.

## Space

Space refers to a person's personal space, or the boundaries that determine how close one person can be to another person. A person's comfort level is related to space. When you invade another's personal space, a common reaction is for the person to move away from you. A similar concept is territoriality, which is related to the geographic space a person views as owned or claimed, such as an area or room. When an individual's personal space is protected, there are feelings of safety, security, control, and reduced anxiety.

Within all cultural groups, personal space varies depending on the relationship between the people speaking: intimates versus acquaintances, people of the same versus opposite sex, and people of a different position within the social hierarchy.

## Assessment and Strategies

Ask the following questions:

- Are you comfortable?
- Do you have any concerns you would like to discuss?

Incorporate the following actions:

- Ensure patients are comfortable before interviewing them.
- Maintain appropriate physical distances while also observing for cues.
- Be aware of cultural differences.
- Be aware of physical objects that may be a barrier to comfort.
- Make sure that the patient's physical environment is arranged to ensure safety, security, confidentiality, and familiarity.

## Time Orientation

Time orientation varies among people of different cultures, and the perception of time has two dimensions. The first dimension is related to clock time versus social time. For example, some cultures have a flexible orientation to time and events, and appointments take place when the person arrives. For others, time is less flexible, and appointments and social events are expected to start at the agreed-upon time. For many, social events may be flexible, whereas medical appointments and business engagements start on time.

The second dimension of time relates to whether the culture is predominantly concerned with the past, present, or future. Past-oriented individuals maintain traditions that were meaningful in the past and may worship ancestors. Present-oriented people accept the day as it comes, with little regard for the past; the future is unpredictable. Future-oriented people anticipate a bigger and better future and place a high value on change. Some people balance all three views—they respect the past, enjoy living in the present, and plan for the future.

Differences in time orientation are important considerations when planning nursing interventions. It is important to understand patients' time orientation to best prepare them for the timing of appointments, tests, and treatments.

In addition, an assessment of the patient's usual routines is necessary in order to incorporate these as much as possible into the daily care.

## Assessment and Strategies

Ask the following questions to understand patients' time orientation:

- Are you normally on time for appointments?
- Are there any routines you need to follow?
- What time do you usually eat your meals? Take your bath?

Incorporate the following actions:

- Have a clock in the patient's room.
- Assess for orientation and reorient to time as needed.
- Prepare patients before a procedure or test.
- Give time options when appropriate (e.g., "Would you like to take a walk now or in an hour?").

## Social Organization

Social organization includes the family unit (e.g., nuclear, single parent, or extended family) and the wider organizations (e.g., community, religious, ethnic) with which the individual or family identifies.

Family organization includes the perceived head of the household, gender roles, and roles of the older and extended family members. The household may be patriarchal (male dominated), matriarchal (female dominated), or egalitarian (shared equally between men and women). An awareness of the family dominance pattern is important for determining which family member to speak to when healthcare decisions are made. Confidentiality issues can complicate this issue. Be sure to follow the institution's policies when communicating with family members. The patient's permission may be needed before planning care with family members.

In some cultures, specific roles are outlined for men and women. Men are expected to protect and provide for the family, manage finances, and deal with the outside world. Women are expected to maintain the home environment, including childcare and household tasks. Not all societies share or even desire an egalitarian family structure.

Roles for older adults and extended family vary among culturally diverse groups. In some cultures, adults are seen as being wise, are deferred to for making decisions, and are held in high esteem. Children are expected to provide for older family members when they are no longer able to care for themselves. In other cultures, although older people may be loved by family members, they may not be given such high regard and may be cared for outside the home when self-care or assistance with daily activities becomes a concern.

The extended family is very important in some groups, and a single household may include several generations living together out of desire rather than out of necessity. The extended family may include both blood-related and non-blood-related persons who are given family status. In other families, each generation lives in a separate home or living space.

## Assessment and Strategies

Ask the following questions:

- Who makes the decisions in your household?
- Who takes care of money matters, does the cooking, or is responsible for childcare?
- Who decides when it is time to visit a healthcare provider?
- Who lives in your household?

Incorporate the following actions:

- Observe the use of touch between family members.
- Let family members decide where they want to stand or sit for comfort.

## Environmental Control

Environmental control consists of three major concepts: people's perception of the ability to control what happens to them and their health, beliefs about health and illness, and beliefs in alternative healthcare therapies such as folk medicine. For example, if individuals do not believe they have control of their health, they may not be receptive to nursing interventions that require self-confidence, such as self-administration of insulin. Regarding health beliefs, if individuals believe that illness is due to a spiritual cause and not bacteria or believe in folk healing practices, they may not understand the need to take antibiotics. Nurses need to consider their patients' cultural values and beliefs, especially when they differ from those of the dominant Western healthcare view.

Distinctions are made between health and illness and what people do to promote or maintain health and to prevent and treat illnesses. Not all patients use a Western healthcare system or provider. Many people try some form of alternative therapy before seeking treatment. People also use alternative therapies and religious systems, such as prayer, in combination with the scientific medical system.

## Assessment and Strategies

Ask the following questions:

- How do you define health? Illness?
- Do you have any special beliefs about health and illness?
- What do you do to keep well?
- When you feel ill, what is the first thing you do to get better?
- How do you deal with pain?
- How do you and your family express grief?
- Are there any cultural beliefs or practices that I need to know about to plan your care?

Incorporate the following actions:

- Be aware of possible cultural beliefs and practices.
- Never stereotype based on what you know about different cultures; always ask for specific information.
- Perform a cultural assessment on all of your patients.

- Ask if patients have received treatments of any kind for their illness.
- Ask about religious beliefs and practices.
- Encourage helpful practices and discourage those that are harmful.

## Biological Variations

Biological variations include ways in which people are different genetically and physiologically, including body variations and medication metabolism. Biological variations create susceptibility to certain diseases and injuries and explain differences in response to treatment. Consequently, clinical trials (medication studies) now recommend incorporating biological variations.

Biological variations also refer to differences in nutritional practices, including the personal meaning of food, food choices and rituals, food taboos, and how food and food substances are used for health promotion and wellness. Cultural beliefs influence what people eat or avoid. In addition to being important for survival, food offers security and acceptance, plays a significant role in socialization, and can serve as an expression of love.

Culturally congruent dietary counseling, such as adapting preparation practices and including ethnic food choices, can reduce health risks. Whenever possible, determine a patient's current dietary practices. Counseling about food group requirements or dietary restrictions must respect an individual's cultural background. Most cultures have nutritional practices for health promotion and disease prevention. For many, a balance of different types of foods is important for maintaining health and preventing illness.

## Assessment and Strategies

Ask the following questions:

- Are there any genetic disorders or diseases related to your cultural background?
- Are you satisfied with your weight?
- Are you active? What is your normal exercise pattern?
- Do you protect your eyes and skin from the sun? From possible injuries?
- Do you have any medication or food allergies?
- Has anyone in your family had any major illnesses?
- What do you eat to stay healthy?
- What do you eat when you are ill?
- Are there certain foods you do not eat? Why?
- Do certain foods cause you to become ill? What are they?
- Who purchases the food in your household?
- Who prepares the food in your household?

Incorporate the following actions:

- Teach about biological variations that may pertain to the patient.
- Determine and respect usual eating patterns whenever possible.
- Teach good nutrition habits, taking into account patient preferences. Refer to a dietitian if appropriate.

### Connection Check 3.5

Which action by the nurse reflects the use of a cultural competency model to assess knowledge, beliefs, and attitudes?

- Acknowledging that education level plays a role in the ability to buy a home
- Believing that patients bring on their own illness by making poor choices
- Considering how similar spiritual beliefs are to those of another nurse
- Thinking about how one American Indian tribe member looks like another

## Making Connections

### CASE STUDY: WRAP-UP

The nurse requests an interprofessional team meeting to discuss and develop a discharge plan addressing Mrs. Liu's care needs. A medical interpreter is assigned to Mrs. Liu and will follow her as both an inpatient and outpatient. This consistency is important to establish trust and to give the interpreter the opportunity to assess Mrs. Liu's health literacy needs. Social workers will work with Mrs. Liu to identify a Taiwanese community center, helping her to build a social group of friends and peers. The nurse working in the Coumadin Clinic will contact Mrs. Liu, with the assistance of the interpreter, to perform medication reconciliation and symptom management and will also determine if Mrs. Liu has visited the Chinese medicine practitioner. If Mrs. Liu has visited the Chinese medicine practitioner, the nurses plan to gently probe her to determine if she began any new complementary therapies. All communications, assessments, and interventions will be documented in the electronic medical record, allowing the primary care physician and cardiologist to access critical patient information during Mrs. Liu's medical visits.

#### Case Study Questions

- Mrs. Liu is challenged by a low level of health literacy; what interventions might the nurse suggest to the interprofessional care team?
  - Ask if she wants to continue to see the Chinese medicine practitioner.
  - Locate a family member who can translate all healthcare documents for her.
  - Secure relevant patient teaching materials written in her native language.
  - Talk only to her daughter and son-in-law to expedite all communications.
- The nurse verbalizes annoyance and fear when learning about the visit to the Chinese medicine practitioner. This attitude best reflects which characteristic?
  - Bigotry
  - Discrimination
  - Hatred
  - Xenophobia
- What resources might the nurse secure to improve the nurse's knowledge of the cultural beliefs and values of Taiwanese patients?
  - Calling the nurse manager to discuss the situation
  - Consulting with the care coordination manager to discuss CLAS standards
  - Discussing the patients with other staff nurses during hourly rounds
  - Managing all communications quickly through the patient's daughter
- How might feelings of social isolation influence Mrs. Liu's ability to adapt to her new living environment?
  - Attributing loneliness to food items she has never eaten
  - Developing new hobbies and interests to fill up her day
  - Fearing engagement with Western healthcare providers
  - Making long-term plans with her daughter and son-in-law
- Which strategy reflects a nurse's ability to apply communication to culturally specific influences in an encounter with Mrs. Liu?
  - Actively listening following a question placed to Mrs. Liu
  - Increasing the tone of voice after Mrs. Liu appears confused
  - Nodding to Mrs. Liu when she is speaking
  - Quickly calling in the interpreter, then walking out of the room

## CHAPTER SUMMARY

Nurses care for patients who are diverse, different, and complex, and this is the reality of the world. It is of utmost importance that nurses are aware that differences exist while remaining open to assessing all factors contributing to each patient's ability to strive for the highest level of health. All this must be done without assigning judgment, stereotyping, and displaying bias.

Becoming a culturally competent healthcare provider means demonstrating care, compassion, and tolerance to all human beings. This process requires the nurse to acknowledge differences and similarities among patients, groups, and populations. Understanding key terminology

and concepts helps to minimize barriers that prevent the nurse from providing care that is free of bias, judgment, stereotypes, and the cultural bias of the nurse and other members of the healthcare team to facilitate the provision of individualized and patient-centered care.

There are several cultural competence models to assist nurses in assessing their knowledge, skills, and abilities so that they may appropriately guide their actions, ensuring culturally competent and appropriate healthcare. Nurses

may apply the Culture Care Diversity and Universality Theory and Sunrise Enabler Model of Leininger to help them assess their knowledge, skills, and attitudes toward becoming culturally competent professionals and to enhance care delivery for diverse populations. Additionally, consideration of the six cultural specifics that influence health ensures the nurse's actions are focused on minimizing health disparities and maximizing care based on the unique needs of each patient.

# Chapter 4

## Ethical Concepts

JoAnn Conroy

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Identifying professional standards that guide ethical nursing practice
2. Defining ethical principles
3. Describing ethical theories
4. Addressing ethical dilemmas associated with the care of the acutely ill adult
5. Discussing how ethical principles guide decision making for the registered nurse

### CONCEPTS

- Assessment
- Collaboration
- Communication
- Ethics
- Nursing Roles

### Finding Connections

#### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Joseph Michaels is a 45-year-old male who is attending a 4th of July picnic when he suddenly feels dizzy, with loss of balance, trouble speaking, and a sudden headache. Family members assist Mr. Michaels in lying down, blame the symptoms on the hot day, and wonder if he has consumed too much alcohol. After a short while, he feels better and returns to the party. On the way home that evening, he again experiences the dizziness and headache, and his wife decides to take him to the local emergency department. Because he also demonstrates right-sided hemiplegia, global aphasia, and dysphagia, he undergoes a diagnostic evaluation and is diagnosed with a cerebrovascular accident, admitted to the intensive care unit, and started on anticoagulant therapy...

### ESSENTIAL TERMS

Sanctity of life  
Self-determination  
Veracity  
Virtue

### THE ROLE OF ETHICS IN NURSING

As nurses gain autonomy in their professional roles, their responsibility and accountability for sound clinical judgment grow as well. Today's complex healthcare environment presents a myriad of ethical and bioethical challenges to all healthcare providers. Nurses spend a disproportionately large amount of time with patients and serve as their advocates, protectors, and trusted confidantes. In many instances, nurses must guide patients and families in making difficult choices, and in some cases, they must make decisions on their behalf, in consultation with other members of the interdisciplinary team. These decisions are often complex and sometimes controversial. Ethical theories and principles provide a moral framework for sound decision making. In many cases, there is no apparent *good* decision, only a list of the *best possible* options, which speaks to the challenging moral relativity that often accompanies ethical decision making. Ethical principles also guide the moral traditions, values, and behaviors of professional nursing, which are outlined in the *Code of Ethics for Nurses* ("the Code") we use today (Box 4.1).

## Box 4.1 Guide to the *Code of Ethics for Nurses: Interpretation and Application*

### Provision 1

The nurse practices with compassion and respect for the inherent dignity, worth, and unique attributes of every person.

### Provision 2

The nurse's primary commitment is to the patient, whether an individual, family, group, community, or population.

### Provision 3

The nurse promotes, advocates for, and protects the rights, health, and safety of the patient.

### Provision 4

The nurse has authority, accountability, and responsibility for nursing practice; makes decisions; and takes action consistent with the obligation to promote health and to provide optimal care.

### Provision 5

The nurse owes the same duties to self as to others, including the responsibility to promote health and safety, preserve wholeness of character and integrity, maintain competence, and continue personal and professional growth.

### Provision 6

The nurse, through individual and collective effort, establishes, maintains, and improves the ethical environment of the work setting and conditions of employment that are conducive to safe, quality healthcare.

### Provision 7

The nurse, in all roles and settings, advances the profession through research and scholarly inquiry, professional standards development, and the generation of both nursing and health policy.

### Provision 8

The nurse collaborates with other health professionals and the public to protect human rights, promote health diplomacy, and reduce health disparities.

### Provision 9

The profession of nursing, collectively through its professional organizations, must articulate nursing values, maintain the integrity of the profession, and integrate principles of social justice into nursing and health policy.

From American Nurses Association. (2015). *Code of ethics for nurses with interpretive statements*. Silver Spring, MD: Author.

## BIOETHICS

The field of bioethics is similar to ethics but is broader in scope. It is both a concept and a movement that considers our past missteps as well as the breadth and consequences of our technological advances; just because we can, should we? It is an interdisciplinary shared consideration of moral philosophy as it relates to standards and methods of treatment of disease in individuals. Bioethics is an ongoing public conversation that manifests through the formation of health policy, through media coverage, at professional conferences, on the pages of professional journals, and in numerous other venues. It often considers questions engendered by the moral consequences of our technological advances, such as cloning and genetic testing (see Evidence-Based Practice). Its history stems from earlier events, both good, such as Watson and Crick's paper about DNA in 1953 and the first heart transplant in 1967, and bad, such as the syphilis research performed on African American males by the U.S. Public Health Service in Tuskegee, Alabama. All of these events, both positive and negative, signaled increasing complexity and the need for a new way of thinking and greater input from a more diverse body of knowledge and pool of disciplines.

### Evidence-Based Practice

#### Ethics Related to Genetic Testing in Patients with Cancer

Genetic testing and genomics are rapidly expanding practices in the management of patients with cancer. Nurses working in oncology may face ethical issues, and this case study examined the impact of cancer genetics and ethics on patients and families with familial adenomatous polyposis (FAP). Because genetic testing can provide information about the impact of a hereditary cancer syndrome, like FAP, this case study considered ethical issues, particularly those related to an individual's rights. In this case study, there were differences in opinion among family members about whether they wanted to know the results related to their risk of future cancer development. The case study includes a discussion about the differences between legal obligations to share genetic information and the moral obligation to share genetic testing results. Nurses working in areas where genetic testing and genomics are growing need to consider how these advances affect their practice, as well as their responsibilities regarding the ethical issues of cancer genetics.

Beamer, L. C. (2017). Ethics and genetics: Examining a crossroads in nursing through a case study. *Clinical Journal of Oncology Nursing*, 21(6), 730–737.

## THE BELMONT REPORT

Due to the past harm caused to individuals in the name of research in places like Tuskegee and Nuremberg, a commission was formed in 1976 to create a set of principles to govern the use of human subjects in research. The commission met at the Smithsonian Institute in the Belmont Conference Center. The resultant document, entitled the *Belmont Report*, is used to this day. The report describes three basic ethical principles to be applied to any research involving human subjects: respect for persons, beneficence, and justice. These are broad terms that need increased specificity when applied to a particular situation. For example, the principle of beneficence means to “do good,” but does it also mean to “do no harm”? The *Belmont Report* outlines requirements for such situational specificity. Since the time of its publication, the *Belmont Report* has engendered the inclusion of additional ethical principles, such as **nonmaleficence** (do no harm) and autonomy (individual right to choose for oneself).

Two important developments came out of the report’s publication, each with direct implications for current nursing practice. First, any research involving human subjects, which may be conducted on nursing units, must be approved by the organization’s institutional review board (IRB) to ensure that the proposed research methodologies will not cause any harm to the research subjects.

In consideration of the principle of autonomy, which states that a mentally competent individual of legal age (therefore not a child) has the right to choose for him- or herself, the practice of informed consent was created. This practice protects patients’ rights to decide what is best for themselves once they are provided with key information about the risks and benefits of a diagnostic test, treatment, surgical procedure, and other diagnostic or treatment modalities. The informed-consent process must contain all of the needed elements (information, voluntary participation, and mental competence) in order to be considered legal. It is imperative for nurses to know that the provider is responsible for obtaining patient consent. Nurses cannot obtain informed consent on behalf of a surgeon, anesthesiologist, or other direct-care provider performing a procedure, but they may witness the consent form.

## PROFESSIONAL STANDARDS FOR ETHICAL PRACTICE: GUIDANCE DOCUMENTS FOR NURSES

The *Code of Ethics for Nurses* and *Nursing: Scope and Standards of Practice* are separate documents; however, both provide a framework for the practice of nursing where ethical decision making and care are the expected norm rather than the exception.

## American Nurses Association Code of Ethics

One of the distinguishing characteristics of any profession is its code of ethics. The code of ethics for the profession is the social contract with the public concerning the moral behaviors of the members of the profession. Nursing first began to discuss a code of ethics in 1896, when a group of nursing leaders met to discuss the practice of nursing in the United States. The forerunners to the official code of ethics were generally based on the (Florence) Nightingale Pledge, which was and still is administered to graduating nurses. That first organization to address the code of ethics for nurses eventually became the American Nurses Association (ANA), and the first official code of ethics for nurses, the Code for Professional Nurses, was accepted by the ANA House of Delegates in 1950.

The Code for Professional Nurses has been updated and revised over the years to the *Code of Ethics for Nurses* (“the Code”) we use today (see Box 4.1). It reflects the social contract that nursing has with the public, encompassing the moral traditions, values, and trust that the public has come to associate with nursing. The obligations that nurses have toward themselves, patients, and communities are all guided by ethical principles. There are no right or wrong behaviors identified in ethical principles, only guidelines for the moral practice of nursing.

Throughout the *Code*, the predominating principle is **justice**. Registered nurses have been voted the most trusted healthcare professionals again and again in public opinion polls. Nursing has a strong and long-standing commitment to social justice at every level, for both the individual as well as the community. Social justice relates to the equal treatment of all persons irrespective of race, ethnicity, gender, social status, or religion. Today’s nurse must be culturally competent and attuned to the needs of vulnerable populations.

In order to practice sound ethical decision making, nurses must know and understand their own personal value systems. The value system of the nurse and the values of the organization in which the registered nurse is employed are fundamental to ethical behavior. However, these are not always compatible. What is considered ethical behavior in one situation may not apply in another. When a nurse is seeking employment, it is important that he or she examine the stated beliefs of the organization before accepting a position. Most organizations set forth a framework for ethical decision making. However, there may be moral conflicts encountered by a nurse involving certain reproductive services provided by the employer if these are not consistent with the nurse’s personal moral position on birth control and abortion.

Many situations in healthcare are ambiguous, morally confronting, and have no clear-cut solution. The *Code* serves as a guide for the nurse; it does not tell the nurse what the *right* answer is in situations calling for ethical decision making. The first three provisions of the *Code*

speak to the individual nurse and the responsibilities and commitment of the nurse in building a relationship with the patient. These provisions are based on equal **respect** for the patient and the need to advocate for the patient's rights regardless of race, gender, or culture. Provisions 4, 5, and 6 provide guidance for the nurse in the workplace environment, focusing on personal and professional accountability for the nursing care provided, professional behavior, and maintaining professional practice competency.

### Connection Check 4.1

The initial nursing code of ethics was based on which work?

- A. The Bill of Rights
- B. The Nightingale Pledge
- C. The Hippocratic Oath
- D. The International Council of Nurses

### ANA Scope and Standards of Practice

The ANA first published the *Standards of Nursing Practice* in 1973. This document defined a generic level of competency common to all practicing nurses and used the nursing process as the framework. Since that time, there have been revisions and updates. In 2015, *Nursing: Scope and Standards of Practice* (3rd ed.) was published to guide nursing practice.

The scope of nursing practice describes the who, what, when, where, why, and how of nursing practice. Nursing today is practiced in many different settings requiring knowledge and skill in the biological, physical, social, and behavioral sciences. Registered nurses are licensed by the state in which they practice and work collaboratively with other healthcare professionals.

Nursing is both an art and a science that includes caring, compassion, and respect for human dignity. The natural sciences are foundational to nursing practice. Through the use of critical thinking, nurses gather pertinent information, which is turned into action in the form of the nursing process. The nursing process is identified as the primary decision-making method for registered nurses and entails the collection of both subjective and objective data, analysis of the data to determine an appropriate nursing diagnosis, formulation of desired patient outcomes, creation of a plan to accomplish the outcomes, provision of care, and evaluation of the patient response.

There are 16 standards of professional nursing practice divided into two subsets: the 6 standards of practice and the 10 standards of professional performance, both of which are based on the nursing process. The first six standards define the practice of nursing for the registered nurse (RN) as well as the graduate-level-prepared advanced practice registered nurse (APRN). The remaining

10 standards define the roles and responsibilities of professional performance. Again, the registered nurse and the graduate-level advanced/specialty nurse roles and responsibilities are defined. Standard 7 addresses ethical nursing practice.

### International Nursing Council Code of Ethics

The International Council of Nurses (ICN) is an organization that promotes ethical nursing practices throughout the world. The standards, guidelines, and policies of the ICN are accepted globally for the basis of nursing practice and policy. The ANA is the representative member for the United States.

The goals of the ICN are to (1) influence global health policy by (2) advancing nurses and nursing practice and (3) bring nursing together worldwide. The code of ethics of the ICN guides registered nurses worldwide in setting priorities, making ethical judgments, and taking action when faced with an ethical dilemma. The core values of the ICN promote ethical practice through (1) visionary leadership, (2) innovativeness, (3) solidarity, (4) accountability, and (5) social justice. The ICN code of ethics describes what nurses are held accountable for in terms of their core values, making nurses responsible for promoting health, preventing illness, and alleviating suffering on a global level.

### ETHICAL PRINCIPLES AND THEORIES RELEVANT TO NURSING

The study of ethics is a branch of philosophy. Ethics assumes that individuals have choices for their decisions and behaviors. The choices are concerned with right and wrong; in other words, there are good choices and bad choices. The decision-making process for choosing a behavior or making a certain decision is complex and can be controversial. Although the ethical theories used in nursing are prescriptive and provide a framework for decision making, no single theory or principle is sufficient for every instance.

The most common ethical principles that provide the foundation of ethical practice and decision making for nurses:

1. **Beneficence** concerns people acting positively on behalf of the perceived well-being of others.
2. **Autonomy** involves the individual's personal right to make decisions concerning him- or herself. Nurses must provide support and advocacy for the individual patient's choices, regardless of whether they agree with them.
3. **Justice** requires fair and equal treatment for everyone regardless of race, religion, or gender. At the level of community, questions of equitability are taken

into account in decision making, such as the greatest good for the greatest number and the allocation of scarce resources during times of disasters or emergency.

4. **Fidelity** expects the nurse to be accountable for commitments made to others, to the self, and to the profession, based on the **virtue** of caring.
5. Nonmaleficence examines issues related to who may be harmed by actions and how any harm can be minimized or averted. This also relates to nurses' need to remain competent in their practice and exercise moral courage in reporting suspected/observed incidents of malpractice, abuse, or diversion.
6. **Veracity** is the requirement to tell the truth and to refrain from intentionally misleading or deceiving a patient to influence decisions (related to paternalism, described in item 8). Veracity or truth telling is also part of nonmaleficence, described in item 5.
7. **Confidentiality** requires that information is not shared beyond those who have a need to know. Nurses must remain vigilant regarding their use of social media, as outlined in later this chapter.
8. **Paternalism** is the inappropriate intention to protect individuals from their own involuntary actions or choices in the name of beneficence, which actually violates their right to self-determination (autonomy). Paternalism is often seen in the care of the older adult and in male-dominant cultures.

## ETHICAL THEORIES TO SUPPORT NURSES IN DECISION MAKING

Ethical decision making can be highly complex and often ambiguous. The following ethical theories offer some foundational perspective and are provided as a guide to how individuals decide the relative moral “rightness or wrongness” of a decision or behavior. Because the human condition is so variable in both personal circumstance and situational elements, it is important to remain mindful of the term *relative* when engaging in ethical decision making. There are no absolutes; nurses must strive to make the *best possible* decision for a specific individual patient given the variables at hand while respecting and supporting the patient's autonomy.

An example of this is the concept of the **common good**, which considers what decision will be most beneficial for the greatest number of people and relates to the theory of utilitarianism. This theory is often associated with matters of social justice, the allocation of scarce resources, and emergency and disaster response. Another example is the concept of the **sanctity of life**. Healthcare providers are taught early and consistently that anything that will cause a patient to die is harmful. Although

the principle of nonmaleficence states that healthcare providers must do no harm, there are times when forcing life and enforcing lifesaving measures may be considered harmful. Respecting the wishes of the patients and their families can be difficult for healthcare providers if those wishes conflict with the basic value system of the provider. There are no right or wrong answers when working through ethical dilemmas, only the *best possible* solutions for the patient encountering a particular set of circumstances. In these situations, there are resources, such as hospital-based ethics committees (discussed later in this chapter), that can provide support, shared wisdom, and consultation to patients, family members, and providers.

### Connection Check 4.2

Which ethical principle deals with ensuring truthfulness and commitment?

- A. Autonomy
- B. Beneficence
- C. Justice
- D. Veracity

## Deontology

The deontological perspective of determining the rightness or wrongness of behavior is derived from the Greek term *deontos*, which means “a duty to obey.” **Deontology** is most frequently associated with the philosopher Immanuel Kant, who felt that a moral individual, although self-determined, must base his or her actions on duty, which he saw as superior to actions based on love. Those who use deontology as their ethical framework inherently believe there is a right and a wrong for all acts based on fixed laws. Neither the situation in which the act occurs nor the consequences resulting from the act are considered. There are no exceptions, and any characteristics of the environment or situation are not considered when making decisions. Using purely this perspective, a patient in a vegetative state will not be removed from life support if the removal of the assistive device will hasten death. The healthcare team has a duty to do no harm, and removing life support would result in death.

This example considers the concept of the sanctity of life. Traditional healthcare education teaches providers that anything that will cause a patient to die is harmful. Although the principle of nonmaleficence states that healthcare providers must do no harm, there are times when forcing life and enforcing lifesaving measures may indeed be considered harmful. Respecting the wishes of the patients and their families can be difficult for healthcare providers if those wishes conflict with the deontological value system of the provider. In these situations, there are resources such as hospital-based ethics committees that can share the decision-making burden.

## Consequentialism and Utilitarianism

In contrast to deontology, **consequentialism** determines the rightness or wrongness of a decision or behavior by the end result of the action. The utilitarian perspective is sometimes called the *greater-good perspective* and is based on the work of two British philosophers, Jeremy Bentham and John Stuart Mill. Utilitarianism aims at maximizing desired positive outcomes, such as lives saved, and minimizing harm, such as lives lost. The characteristics of the environment and the situation, as well as the consequences of the action, are an essential part of the decision-making process.

Using the utilitarian perspective, that same patient in a vegetative state on life support considered through the lens of deontology in the previous section can be removed from the ventilator and allowed to die. This is based on the decision meeting with the wishes of the patient and family, who view the death as a greater good than lingering and suffering in a vegetative state.

In addition, there are two similar theories to consider: act utilitarianism and rule utilitarianism. *Act utilitarianism* theory states that the consequences of an act are predictable and that the choice that yields the greatest benefit for the most people is the right and ethical choice. Act utilitarianism does not take into account personal feelings or societal constraints and is not concerned with justice, beneficence, or individual autonomy but with what will benefit the most individuals even if individual rights are infringed. Examples of act utilitarian-based actions include the potential enforcement of mandatory quarantine in times of epidemic and mandatory vaccination laws aimed to prevent such an epidemic. *Rule utilitarianism* theory is similar to act utilitarianism but takes into account any fairness laws that may exist, which sometimes come up in persons unable to receive certain vaccines due to allergies, for example. Therefore, justice and beneficence are valued. However, there can be the possibility of conflicting rules, resulting in no ethically correct answer. The theory itself poses potential dilemmas for both society and the individual.

### CASE STUDY: EPISODE 2

Because of persistent swallowing problems, video fluoroscopy is conducted, and the findings indicate a severe swallowing disorder. Because of the danger of aspiration, the provider orders a nasogastric tube inserted for feeding purposes, with plans for possible gastrostomy tube placement if the dysphagia does not resolve. The family members tell the nurse they do not want any type of permanent feeding tube placed in the patient...

If the deontological perspective is used in the decision as to whether to place the device as described in the case study, the device will be placed because of the duty to do no harm.

Leaving the nasogastric tube in place may result in irritation to the nasal passages and oropharyngeal area, skin irritation from the tape and tube around the outside of the nares, and a potential for placement errors that result in fluid being introduced into the lungs. So the right action would be to place a more permanent feeding device directly into Mr. Michaels's stomach because it is safer for the patient. However, the patient's family does not want a permanent feeding tube.

## Rights

The rights theory can be useful if it is used in conjunction with another ethical theory; it cannot stand alone. This theory states the rights set by society are to be afforded the highest priority and protected at all cost. Individuals can also give rights to others if they are in a position to do so. The primary issue with this theory is that society has to determine the rights it wishes to uphold; but in order to do this, society must determine its priorities and goals, and these priorities must be backed with laws or legislation. One example is the right for all citizens to be provided healthcare. Although a vehicle for this has been created in the form of the Affordable Care Act, it is at risk due to its associated costs to business, and there is no guarantee that society will continue to uphold and support it.

## Casuistry

The term **casuistry** is derived from the Latin word for *case*. It examines the outcomes and lessons learned from earlier benchmark or *paradigm* cases to make ethical decisions. It uses inductive reasoning to examine significant facts and outcomes in past similar cases as a means to project possible future outcomes on which to base ethical decision making. Casuistry has a more holistic and personal focus than the more all-or-nothing approaches of deontology and utilitarianism. Although it is not considered to be flawless, it is a highly valued addition to the ethical toolbox in today's complex bioethical environment where healthcare providers are faced with coming to terms with the unintended consequences of technological advancements.

There are many other theories that have characteristics that are useful in ethical decision making. However, no single theory is applicable in all situations. By using a combination of theories, it is oftentimes possible to arrive at the *most ethical* decision. For nurses interested in further study, there are philosophy courses and continuing education opportunities that focus on ethical decision making.

### Connection Check 4.3

Which ethical theory is based on obeying laws?

- A. Autonomy
- B. Deontology
- C. Rights
- D. Consequentialism

## ETHICAL DILEMMAS

The complexity of today's nursing practice cannot be understated. Nursing ethics considers situations where there are no clear right or wrong answers; what may be right for one patient may be very wrong for another. Today's nursing practice takes place in many different settings, increasingly outside of the traditional acute care hospital, where there is an environment of support from other healthcare providers. Practice settings such as community health fairs, schools, private homes, shopping malls, homeless shelters, and soup kitchens are the new norm. Often, the nurse is the only healthcare provider at the site and has to independently work through an ethical dilemma.

As previously discussed, the predominating principle of the ANA's *Code* is justice, and although there are nine provisions to guide the nurse, there is no step-by-step process for nurses to use to solve ethical dilemmas. There is, however, a process that nurses use every day, the *nursing process*, that when applied to ethical decision making can assist the nurse in making a complex decision (Box 4.2).

Today, nursing is emerging in many states as an autonomous and independent profession by virtue of being a licensed profession. This is exemplified in the 2010 Institute of Medicine report *The Future of Nursing: Leading Change*,

*Advancing Health*, which includes recommendations to increase the numbers of baccalaureate-prepared nurses to 80% by 2020, to double the number of nurses with a doctorate by 2020, and to remove scope-of-practice barriers for APRNs. In the past, practice within the hospital setting saw the typically male physician in charge of the patient's care and the typically female nurse following physician orders. There was an unspoken attitude that nurses were subservient members of the healthcare team due to sexist views of the place of females in society and the gaps in educational preparation between physicians and nurses. In today's practice environment, there are more male nurses, more APRNs functioning as providers, and improved interdisciplinary communication across healthcare teams. The nurse who chooses to practice within a hospital setting is no longer considered subservient. Each healthcare organization has a stated mission and vision that govern the roles and responsibilities of nurses and other healthcare team members. Nurses are expected to practice ethically within the scope and standards of practice and to be vocal and involved when ethical dilemmas present themselves.

Nurses are frequently placed in situations where decisions require an examination of ethical issues. They have a duty (fidelity) to the patient to provide care that is competent and respectful of each patient's individual situation. Sometimes this may be in conflict with the nurse's own beliefs, the organization's beliefs and protocols, or the provider's/practitioner's beliefs.

A *dilemma* can be defined as a problem with one or more alternative solutions where each of the alternative solutions presents ethical or practicality problems and where all solutions are equally unpleasant. Almost all ethical dilemmas in nursing involve the right to **self-determination** (autonomy) of the patient and relate to the patient's right to make his or her own decisions about treatment. Although nursing practice has many such dilemmas, the following discussion is limited to some of the more commonly seen scenarios related to healthcare.

### Box 4.2 Suggested Ethical Decision-Making Process

#### Assess/Diagnose

Determine exactly what must be decided. Sometimes the issue is hidden within the emotional or cultural/ethnic/religious characteristics of the patient and family. The nurse must determine how these factors affect or define the issue.

#### Plan

Formulate at least three alternatives to solve the issue. Each alternative must be examined for practicality, legal issues, patient and family characteristics such as personal wants and desires, the social and environmental aspects of the alternative, financial considerations, and the long- and short-term viability and consequences of each alternative. Ideally, the alternative is chosen by the healthcare team (which includes the nurse) and the family. Sometimes ethics committees assist in choosing the alternative.

#### Implement

Once the alternative is chosen, actions to achieve the greatest benefit with the least amount of risk are carried out.

#### Evaluate

Determine if the desired effect has occurred or new information is available that might alter the plan and/or implementation.

### Connection Check 4.4

In addressing an ethical dilemma, which principle guides decision making focused on minimizing harm to the patient?

- Beneficence
- Justice
- Nonmaleficence
- Fidelity

### Informed Consent

As discussed earlier regarding the *Belmont Report*, **informed consent** simply means that the patient has been fully informed by the provider responsible for the treatment or procedure. This consent includes information related to necessity, what is physically involved in the treatment or procedure, and the associated risks and benefits. This allows

the patient to make a knowledgeable determination as to whether to agree to have the proposed treatment or procedure. The patient who is giving consent for the procedure must be mentally competent to make this decision. For patients who are minors or deemed mentally incompetent, the parent(s) or appointed guardian must give consent following the same informed-consent procedure.

Informed consent is required for all invasive treatments/procedures. All information must be provided in a language or format that the patient understands, with an opportunity for the patient to ask questions. The information is provided by the person who will be performing the treatment/procedure. Neither the healthcare provider nor any member of the healthcare team is allowed to coerce the patient to give consent for the treatment/procedure. Although it is not the responsibility of the nurse to obtain informed consent on behalf of an absent or unwilling provider, the nurse may be asked to witness a consent process. In this case, the nurse is validating *only* that the patient, parent, or guardian/surrogate was observed signing the consent form.

The patient has the right to refuse a treatment/procedure, refuse receipt of the information about the treatment/procedure, or waive the informed consent and still have the procedure. Whenever a patient refuses any part of the informed consent, there must be comprehensive documentation of the refusal in the patient's medical record.

There are instances when informed consent by the patient, parent, or guardian is not required, and almost all of these are in emergency situations where withholding or delaying the treatment/procedure to seek consent would be deleterious to the patient. Healthcare organizations have policies that guide the actions of the provider performing an emergency treatment/procedure because it is necessary to "save life or limb." In addition, parental consent is not needed for minors seeking treatment for sexually transmitted infections. In some states, minors may be considered emancipated (those who are married, pregnant, or financially independent), allowing them to give consent. In other instances, the treatment/procedure can be ordered by the courts or other legal authority, and the patient, parent, or guardian does not need to give consent.

Registered nurses participating in research are often involved with human subjects. As outlined in the *Belmont Report*, any individual who takes part in a research study must be informed of the study's goals, any known benefits and risks associated with participation, what the individual can expect by being a participant, and that he or she has the right to refuse or withdraw at any time without consequences. All research studies using human subjects must be approved by the agency's institutional review board (IRB).

### Do-Not-Resuscitate Directives

The customary definition of death is the absence of a heart-beat and respiration. However, with today's technological advances in healthcare, there are situations where patients

may have significant and irreversible brain injuries, but because the brainstem is still intact, the patient still has a pulse and respirations. This damage to the brain may lead to an irreversible loss of consciousness or a persistent vegetative state, but there are unassisted heartbeats and respirations. Decisions regarding life-sustaining procedures raise many ethical questions, and these decisions require communication between the healthcare providers, the patient, and the family.

Patients have the right to refuse or accept life-sustaining treatment. The primary issue is to determine whether the patient is mentally competent to make that decision. Once competency is determined, the information needed by the patient to make this decision revolves around whether (1) by accepting treatment, the patient will return to an acceptable state of health; (2) by accepting treatment, the patient will continue in a compromised health state with no hope of returning to an acceptable state of health for an indefinite period; or (3) by accepting treatment for a terminal illness, the dying process will be prolonged. All of these situations bring up ethical issues. What is in the best interest of the patient is the question that must be posed.

Most healthcare organizations have policies related to do-not-resuscitate (DNR) orders, and it is up to the patient and the provider to follow the procedures set forth in the policy for the particular agency. A DNR order must be displayed in a visible spot in a patient's room because it is the exception to the rule in healthcare agencies that mandate that in the event of cardiac or respiratory arrest, cardiopulmonary resuscitation must be initiated by a competent person. Consultation between the patient (or patient's family in the case of an unconscious or incompetent patient) and the provider should precede any written DNR orders and usually revolves around issues of quality of life. A DNR order should be reviewed periodically and updated as the patient's condition changes. With the increased use of palliative care to maximize the quality of life, for some patients and families, prolonging life may not be a welcome option. Nurses who have personal belief systems related to DNR orders that would compromise their ability to enforce a DNR order should transfer the care of that patient to another nurse and consider changing their practice setting if this type of dilemma is frequently encountered.

A relatively new program called the physician order for life-sustaining treatment (POLST) is based on effective communication between patients with life-threatening illnesses and providers. Although similar to an advanced directive (discussed in the next section), which everyone should have, a POLST is created at the time a patient develops a condition that is seen as life-threatening. It contains documentation of agreed-upon orders and a promise by providers to honor the patient's wishes for treatment concerning procedures such as intubation, feeding tubes, and the use of specific medications. In essence, the program provides a DNR order that is independent of a specific healthcare organization. POLST programs have been implemented at some level in all 50 states and the District of

Columbia. However, levels of usage and incorporation as a standard of care vary widely from state to state. How the program is administered and what it is called (e.g., medical orders for life-sustaining treatment [MOLST], physician orders for scope of treatment [POST], and clinician orders for life-sustaining treatment [COLST]) varies from state to state as well. Decisions on determining resuscitation status are informed by documents optimally created by patients before they become seriously ill. They include the advance directive and living will.

### Advance Directives

An **advance directive** is a document that is designed to communicate the final wishes of patients in the event they cannot speak for themselves and is created when the patient is competent and in open communication with the provider, family, and close friends. Sometimes religious leaders are also a part of these conversations. The directive is a set of precise instructions for the type and duration of care the patient wants. Different scenarios may be presented with the circumstances outlined regarding life-sustaining procedures and treatments.

### Living Wills

A **living will** is a legal document created by a competent person that provides the person's desires for medical care in the event the person is unable to independently make decisions regarding care. The requirements for living wills vary by state and may also be referred to as a type of advance directive, healthcare directive, or a provider's directive. This document describes specifics about life-prolonging treatments the person will allow and those that will not be allowed and becomes effective only when the person becomes incapacitated to the point that he or she cannot make decisions for him- or herself.

### Withdrawal of Fluids and Nutrition

The decision to withdraw fluids and nutrition is one of the most challenging ethical dilemmas that a nurse may confront. The patient, family, and provider ultimately make this decision collaboratively. Withdrawal of fluids and nutrition to patients is commonly referred to the healthcare agency's ethics committee for review and input. The decision to withdraw fluids and nutrition is not made lightly because it violates the responsibility of the provider and the nurse to promote comfort. It is often difficult for the family to understand and accept. Nurses exhibit beneficence and fidelity by explaining the rationale for withdrawing nutrition to anxious patient families and reassuring them of the comfort and benefit derived from these measures. Patients who are in the dying phase do not need fluid or nutrition in the amounts that are necessary to sustain life, and the addition or forcing of fluids or nutrition may be detrimental to the patient's comfort. The dying phase varies by individual patient and may take several days or a relatively short

period. Often, there is a tendency for the family to request fluids and nutrition at levels the patient had in the past. However, as the body begins to shut down, the circulation becomes slower, so the addition of extra fluid may cause increased fluid in the lungs, causing difficulty breathing, peripheral edema, ascites, or vomiting. The addition of nutrition from either enteral feedings or IV sources may cause vomiting, constipation, or bowel obstruction from the reduced gastric emptying. In addition, there is the chance of aspiration because of the reduced gag reflex.

### Pain Control

Pain is often referred to as the "fifth vital sign" and should be assessed by the nurse upon each patient encounter. The perception of pain is a personal experience for every individual, and only the patient can describe its location, duration, and intensity. Every report of pain, either by the patient or the family/significant other/surrogate on the patient's behalf, should be evaluated by the nurse, and what the patient reports about the pain, including intensity, characteristics, and past effective methods of relief, is to be accepted by the healthcare provider. Patients who are experiencing pain need to be shown empathy and respect and given choices for pain relief. The alternatives for pain relief should be explained, including the advantages and disadvantages, benefits, and risks. The nurse should accept the patient's decision for pain management regardless of personal beliefs. Once the patient has chosen the method of pain relief, it should be implemented and evaluated by the nurse. This evaluation includes a dialogue with the patient concerning the effectiveness of the measure and what the nurse has observed in relation to the relief of pain.

Nurses must be self-aware of and vigilant against any bias, organizational or social pressure regarding patients labeled as "drug-seeking" or "hypochondriacal," or any other factors that may inhibit sound clinical judgment and the provision of appropriate pain control. Further, nurses must display moral courage to advocate for proper pain management from providers who may be hesitant to provide the higher doses of medication required to properly control pain in the suffering patient.

### Genetic Testing, Reproductive Technology, and Selective Abortion

New ethical dilemmas arise from advances in the knowledge and techniques of genetic testing and human reproduction. Mendelian laws of heredity state that there is a one in four chance of a child being affected with a disorder if both parents are carriers of an *autosomal-recessive* gene, a one in two chance the child will be a carrier, and a one in four chance the child will not have the disorder or be a carrier. For *autosomal-dominant* disorders, there is a one in two chance the child will inherit the gene. A child inheriting this gene will have the disorder.

The sex chromosomes also present the possibility of a child inheriting a disorder. X-linked disorders depend on the chromosome, X or Y, on which the mutant gene is attached. Females can contribute only X chromosomes to conception, whereas a male can contribute an X or a Y. If the male contributes an X, the result will be a female child, whereas if the male contributes a Y, the child will be a male. Mutant genes carried on the X chromosome result in the child being affected with the disorder if the child is a male but only a one in two chance of the child being affected if the child is a girl. It would take two X chromosomes with the mutant gene attached for a female to be affected.

There are techniques that detect the presence of genetic disorders in addition to a blood test for individual genetic mapping. Amniocentesis is a procedure that withdraws amniotic fluid from the pregnant uterus that allows testing for certain genetic disorders. This test is not performed before the 15th or 16th week of gestation, and results may not be available until the 20th week of gestation, when selective abortion is more problematic. Chorionic villi sampling, which can be completed in the first trimester, tests placental tissue for genetic disorders, and selective abortion can be done in the first trimester. However, there is a higher risk of spontaneous abortion with this procedure. Prenatal diagnosis of genetic disorders is completed, and then comes the ethical dilemma about whether to decide to abort (selective abortion) the fetus if a disorder is detected.

There are many ethical issues regarding abortion in general and selective abortion specifically. There is a group of disability rights advocates who claim that selective abortion is discrimination. There are also well-known religious and cultural objections to abortion for any reason. The nurse who practices in a setting where abortions are performed must define individual values in relation to abortion and selective abortion, but the nurse's individual values must not be allowed to impact the patient's right to self-determination (autonomy).

Genetic testing does not affect only pregnant women. Individuals who have a history of a disorder in their family may also be tested. There are some disorders that do not produce clinical manifestations until middle age. Huntington's disease is an adult-onset problem but is transmitted genetically. Clearly devastating disorders such as Huntington's, Tay-Sachs, sickle cell anemia, and cystic fibrosis can be detected through genetic testing before conception, thereby preventing transmission. It is considered wrong to coerce individuals to undergo genetic testing for social control over reproductive decisions. Coercive measures for selective abortion after testing are an invasion of rights and a form of paternalism.

Advances in reproduction technology are making it possible for women who have been diagnosed as infertile to become pregnant or to donate the ovum to a surrogate mother who will carry the fetus. Other options include artificial insemination of the ovum with sperm from a sperm bank and in vitro fertilization, in which the sperm fertilizes the ovum in a laboratory and then the embryo is inserted

into the uterus of the woman. Couples can elect to have the woman's ovum fertilized with the man's sperm and frozen for later use. As reproductive technology continues to advance, there are ethical concerns that may arise for the nurse.

The ethical questions that arise in reproductive technology are complex and often revolve around religious values and legal issues. Many religious ethicists say that the use of reproductive technology for the purpose of producing a baby is morally wrong, and if a third party has donated either the ovum or sperm, adultery has been committed. On the other hand, if the wife donated the ovum and the husband donated the sperm, some of these same ethicists contend that this is within the bounds of a marital framework and is permissible. However, if more than one embryo is produced for implantation, or if unneeded or unsuitable embryos are discarded, this can create issues regarding the morality of discontinuing life. Nurses who practice in fertilization centers are frequently confronted with these matters.

In cases where there is a surrogate mother, there can be legal issues concerning who is the mother of the child: the genetic mother or the gestational mother? Where there have been ovum or sperm donors with no relation to the mother, in the case of a single woman or the couple in a husband/wife situation, who is the legal parent? Surrogacy contracts differ from state to state, with various approaches to the social policy aspects. There are no definitive answers for the nurse.

## Experimental Therapies

As with genetics, knowledge and technology in treating disease are rapidly advancing and lead to issues related to research involving human beings. Human subjects research is divided into two categories: therapeutic and nontherapeutic research. Nontherapeutic research, primarily for the advancement of knowledge, results in outcomes not intended to be of benefit to the human subject. In therapeutic research, the human subject is expected to benefit from the treatment, vaccine, new medication, or diagnostic procedure that is being investigated. However, the distinctions between the two categories are often difficult to discern. Therapeutic research may not have the intended beneficial result, and there may be unintended consequences of nontherapeutic research that do benefit the subject. In any kind of research using human subjects, the concern for informed consent is an issue. The person who becomes a research subject must be fully informed of the risks and benefits of participating, consent must be voluntary, and the person must be allowed to withdraw from the study at any time with no repercussions. But in some research, the risks and benefits might not be known.

Biomedical research enhances the advancement of medical treatment by investigating various alternatives in medications, procedures, and treatments so that healthcare practices are evidence based. Ethical issues arise when the

rights of the human subjects are examined. Do patients who have a certain disease have a duty to participate in a study even though they may not want to, even though the results may provide help for others? Is it ever ethical to give a participant a disease so that the effects of various treatments or medication can be studied? There are those who contend that the answer to the previous questions is yes, as long as only minimal risk is involved. But how does one define *minimal risk*? The nurse who practices in the field of research must define personal values that could be challenged by specific research studies.

### Inability to Afford Prescribed Care

There is ongoing debate in the United States about whether access to healthcare is a fundamental human right. Healthcare in the United States is not available to all citizens on an equal basis. Those who have health insurance or can afford to pay healthcare costs enjoy a level of care that may lead to a longer life expectancy and increased quality of life. However, many people cannot afford healthcare because of a lack of health insurance or the inability to pay for care. The Affordable Care Act (ACA) of 2010 was initially designed to close the gap between those who can afford healthcare and those who cannot. Due to many complicating factors and the perceived inordinate cost of healthcare, it is unclear how long the ACA will remain in effect or in its current form.

Does society have an obligation to its citizens to provide healthcare for all? If so, does the individual person have an obligation to participate in behaviors that decrease health risks? The theories of justice give some insight into the issues involved in the ethics of care. The libertarian viewpoint is that citizens have a right to individual liberty, life, and property and that governments cannot take those away to give to someone else. A socialist viewpoint is that all individuals of a society are equal and that governments have an obligation to ensure that equality is maintained, so those who have more must provide for those who have less. The liberal point of view is that those who have more should help those who have less.

There are agencies in most communities that assist those who cannot afford healthcare or who cannot afford treatment. There is a difference in those who cannot afford healthcare and those who cannot afford treatment. Insurance may give the individual the ability to seek healthcare, but insurance may pay for only a portion of the prescribed treatment or none at all.

### Organ and Tissue Donation

The issue of organ donation and transplantation has many considerations. Organ transplantation has been performed since 1954, when the first kidney was transplanted into the donor's twin. There have been many advances since then, but there is also a scarcity of donor organs, which creates an ethical dilemma concerning the allocation of scarce

resources and "who" receives the organ or tissue. There is a great deal of fear about becoming an organ donor among people due to a general mistrust of the medical profession and how death is defined and determined. Public education programs are aimed at dispelling misconceptions and clarifying organ procurement criteria.

Organ donors are solicited in many ways. Many people indicate they are an organ donor through a special decal on their driver's license or by indicating the desire to donate in a will. Although this may be the wish of the individual, the family of the patient can overturn this decision at the time of death of the potential donor. Individuals who are victims of trauma may become donors when the physician determines that the patient is brain dead and requests a donation of unaffected organs from the family. The donor is placed or continued on mechanical ventilation, which keeps the organs oxygenated but also gives the appearance to the family of the donor still being alive, which can make an already difficult decision even more agonizing. Organ procurement teams are specially trained to work with families to encourage organ donation. Although some families are willing to share their loved one's organs with another, some have religious or cultural edicts against this. The nurse may be from a religious or cultural background that prohibits organ donation, but these beliefs cannot interfere with the patient's or family's decisions.

When a person needing a transplant is identified, he or she is added to a national list, created by the National Organ Transplant Act of 1984, to await an organ with the right specifications to become available. The severity of disease is a determinant in where the patient is placed on this list, leading to the sickest patients being placed higher on the list. Many people die before their desired organ or tissue becomes available. The ethical issue of justice arises when there is more than one person needing the same organ when it becomes available. The decision as to which patient gets which organ, or any organ, is based on criteria established by the Organ Procurement and Transplantation Network (OPTN), a division of the U.S. Department of Health and Human Services (HHS).

## ETHICAL ISSUES IN PROFESSIONAL PRACTICE

### Moral Courage

Truth telling has its costs and involves moral courage, and it takes moral courage for nurses to stay strong and resilient in the face of many forms of adversity in today's practice settings. Moral courage involves actions that stand up to wrongdoing. It requires the willingness to be honest in the face of personal risk. For many nurses, it is a fundamental part of their fabric and a key reason they sought out the profession. There is ample reason to celebrate the moral courage of nurses, for in many cases, they go to extremes and expose themselves to personal harm in order to advocate for and protect the rights of their patients. No wonder

that nurses are consistently voted the most trustworthy professionals.

## Discernment

Moral courage requires the practice of discernment. As nurses practice over time, they gain clinical and practical wisdom and the quality of discernment, which allows them to gather pertinent data in a given situation and create informed conclusions based on their accumulated practice-based wisdom. Although the role of bias and burnout, among other factors, must also be considered, experienced nurses know intuitively when they must speak up about certain conditions, behaviors, or situations that violate patient or professional ethical standards. Although there are clear-cut situations—for example, when a colleague is observed diverting medications or abusing a patient, or a surgeon refuses to honor a “time-out” in the operating room, or an informed consent was witnessed as being subtly coerced—many situations requiring moral courage are murky and uncertain.

## Nurse–Patient Communication

Nurses spend proportionately more time with their patients than do other healthcare providers and have more opportunities to connect and form trusting relationships with them. This is not to minimize the trusted relationship that many providers have with their patients. However, when patients receive difficult or complex information from their providers, questions evolve, often when the provider is no longer available, leaving the nurse to answer them. Nurses must learn to carefully navigate the line between what they can and cannot divulge to a patient, based on both scope-of-practice and professional and organizational guidelines. This can be an ethically challenging situation when a patient and/or family is desperate for information that the nurse cannot (but wishes to) divulge to the patient. It takes just as much moral courage and discernment to speak, or refrain from speaking, as it does to report an injustice. However, the nurse can advocate for the patient by discussing the patient’s wishes for more information with the direct healthcare provider.

## Social Media, Computers, and HIPAA

There is a saying about the paradox of your best feature also being your worst. This has never been truer than at the intersection of social media and healthcare. Nurses can access and share knowledge with colleagues and create professional relationships and communities of interest with nurses in other cities and countries. Social media has also brought many patients into closer and more frequent contact with their providers via encrypted virtual private networks (VPNs). Patients can search for health information online, although not all of it is reliable. As consumers, potential patients having elective procedures can review

Medicare’s Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) to decide which hospital best meets their care needs and expectations. These data, accessible via the Internet and disseminated through social media, have made hospitals more accountable for their patient outcomes.

However, a tragic number of nurses, physicians, and students have seen a promising career go by the wayside due to the indiscriminate use of social media sites, upon which they have, often unwittingly, posted information that proved to be sensitive and/or damaging to their patients and organizations. Some mistakenly think that by not mentioning the patient or organization’s name, they are not violating anyone’s privacy. This is not accurate. Social media users are savvy and clever and can piece together information nurses are unaware they are providing. The best practice is for nurses to refrain from even the smallest mention of patient- and workplace-related events in their social media use.

In other computer-related, career-ending events, nurses have violated Health Insurance Portability and Accountability Act (HIPAA) and organizational guidelines prohibiting them from seeking access to charts of patients they know from other aspects of their lives, such as neighbors or their children’s teachers. In other words, they did not access the patient’s medical record on a “need-to-know” basis but, rather, in a self-satisfying inquiry that does not reflect fidelity, veracity, or beneficence toward any patient.

A relatively new phenomenon called “patient-targeted Googling” (PTG), initially used by psychiatrists, citing the need to locate and reconnect with at-risk patients inconsistent in their appointments, has become a greater issue among nurses and providers. The ethical principle of fidelity, which encompasses confidentiality and the right to patient privacy, suggests that to “Google” someone with whom one is in a caregiver–patient or provider–patient relationship, where a power imbalance in favor of the provider already exists, is a violation of professional boundaries and of the patient’s privacy, unless there is urgent concern over the patient’s well-being. Nurses are all human and therefore possess a native inquisitiveness; however, as professionals, curiosity must be curtailed in the name of veracity and fidelity to patients, families, and their privacy.

## Duty to Warn

Although Provision 3 of the ANA *Code* states that the nurse will promote and protect the right to patient confidentiality, there are exceptions to this rule. When a patient shares information with a nurse or provider that indicates that the patient is a danger to him- or herself or others, or contains disclosure of certain past crimes, such as rape or incest, or any other vital information that is critical to the well-being of another, the nurse may disclose the information to outside parties, optimally with the guidance and support of the institution’s organizational leadership.

The exception for disclosure of this type of information came out of a landmark 1976 court case known as *Tarasoff v. Board of Regents of the University of California*. In the case, a psychiatric outpatient who was also enrolled as a student at the university and receiving counseling at the student health center told his therapist of plans to kill his girlfriend. The therapist reported this to the campus police, who did not take appropriate action and warn the victim of the threat, who was later killed by the student. Her parents sued the involved staff and the school's board of regents. This case fundamentally changed the practice and definition of confidentiality.

### Workplace Incivility and Horizontal Violence

Although the phrase “Nurses eat their young” is both negative to the profession and widely known to many, it wasn't until 2015 that the ANA published a position statement on workplace incivility. Nurse-on-nurse aggression is not a new phenomenon. In some ways, there is an inherent setup for this condition by the widely disparate variation in professional preparation. No other profession has as many approved levels of “entry into practice” educational preparation as does nursing. This includes associate degree, diploma (hospital based), baccalaureate, as well as entry master's degree programs, including the clinical nurse leader, all leading to eligibility to seek the licensure to be a registered nurse. If one also considers age, race, and gender biases, by combining all of these “nurses” on a unit, under the pressures of understaffing or high-acuity patients, with good, bad, or uncertain leadership, it is easy to see a prescription for conflict.

### Connection Check 4.5

In managing care for competent patients, which interventions or activities require the patient's informed consent? (Select all that apply.)

- A. Participation in a research study
- B. Change in room/unit
- C. Invasive diagnostic studies
- D. Operative procedures
- E. Discharge time and day

### ETHICS COMMITTEES: SUPPORT FOR ETHICAL DECISION MAKING

Ethical decision making is not easy and usually involves conflicting beliefs and priorities. One of the primary roles for the nurse in a situation where there may be conflicting solutions is to recognize that there may be a question of ethics involved and to get the appropriate personnel involved.

### Role of Interprofessional Care

Interprofessional teams include physicians, APRNs, clinical nurse specialists, staff nurses, social workers, pharmacists, dietitians, chaplains, and physical and occupational therapists and are responsible for addressing issues or concerns beyond a strictly medical focus. For instance, a treatment that may seem in the best interest of the patient could be examined by the team of professionals in relation to quality of life following the treatment, the time the treatment may take and any long-term consequences that may result, the cost of the treatment, or the recovery time associated with the treatment. The team must be able to present a wider range of options for the same problem.

### Ethics Committees

An ethics committee consists of healthcare providers from many different disciplines. Ethics committees are similar to an interprofessional team, but an ethics committee examines ethical dilemmas as they arise in an agency and creates policies to assist with decision making. An ethics committee also provides guidelines for potential ethical problems, serves as a forum for open discussion of the problem, and acts as the patient's advocate, as needed. Ethics committees usually have one of three distinct structures but can blend these structures as needed:

1. The autonomy model facilitates decision making for the competent patient.
2. The patient benefit model uses substituted judgment and facilitates decision making for the incompetent patient.
3. The social justice model considers broad social issues and is accountable to the institution.

The ethics committee is responsible for creating the policies by which ethical decisions are made so that the rights of the patients are protected. The committee also describes the roles of each member of the healthcare team and the patients and families in making decisions.

## Making Connections

### CASE STUDY: WRAP-UP

The family has stated they do not want a gastrostomy tube placed. It is the responsibility of the nurse and the healthcare team in general to provide enough information about the entire issue of the feeding tubes, both nasogastric and a skin-level device. Informed consent or dissent can be made only when the family has as much information about the benefits of each feeding device and the consequences of each device. In the case of Mr. Michaels, part of the information needed is that his hemiplegia is improving, and

he responds appropriately to commands and the surrounding environment. The decision is made to hold a conference to discuss whether a permanent tube should be placed. Additionally, a competency evaluation is scheduled for Mr. Michaels to determine his ability to make informed decisions based on his improving level of consciousness.

### Case Study Questions

- To begin to assist this patient and family with decision making concerning a gastrostomy tube, which action should the nurse do first?
  - Report the family's decision to the prescriber.
  - Inform the family that the provider will make the best decision.
  - Offer to have another patient who has a gastrostomy tube talk with the family.
  - Check the patient's chart for an advance directive or living will.
- In checking for the presence of a living will for Mr. Michaels, the nurse is using which ethical principle?
  - Autonomy
  - Beneficence
  - Justice
  - Nonmaleficence
- As Mr. Michaels's level of consciousness improves and he is following commands, what must be evaluated prior to making the decision about placement of the gastrostomy tube?
  - Mental competency
  - Swallowing
  - Psychomotor abilities
  - Vision and hearing screening
- Mr. Michaels is found to be mentally competent, but the family still does not want the gastrostomy tube placed. In the event the tube is not placed, this could be considered a violation of which ethical principle?
  - Veracity
  - Beneficence
  - Self-determination
  - Confidentiality

- As a result of the difference between the family members' and Mr. Michaels's wishes, the nurse should request which consultation?
  - Ethics committee
  - Interprofessional meeting
  - Hospital chaplain
  - Family lawyer

## CHAPTER SUMMARY

Registered nurses in today's world face ethical challenges almost daily. Knowing the guidelines provided by professional organizations, understanding individual value systems, and enlisting the available support systems assist in helping the nurse to make choices that are in the best interest of the patients. Nurses must be familiar with essential ethical principles that guide decision making in the clinical setting. It is important that the nurse be knowledgeable of the role of autonomy, beneficence, confidentiality, fidelity, justice, nonmaleficence, veracity, and paternalism in providing care. These ethical principles are used in assisting patients and families in making difficult decisions related to advance directives, living wills, organ transplantation, life-prolonging procedures, and genetic testing. Ethics committees are available in most acute care settings to support the patient, family, and healthcare team in resolving potential ethical dilemmas.

# Chapter 5

## Palliative Care and End-of-Life Issues

*Jennifer Wenzel and Maya Zumstein-Shaba*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Discussing the meaning of palliative care and hospice care
2. Listing the domains of palliative care
3. Analyzing the nursing care priorities for patients near the end of life
4. Developing communication and support strategies for family members
5. Explaining moral distress in end-of-life issues
6. Identifying nursing self-care strategies

### CONCEPTS

- Assessment
- Comfort
- Communication
- Ethics
- Grief and Loss
- Legal

### ESSENTIAL TERMS

Advanced care planning (ACP)  
Hospice care  
Moral distress  
Palliative care (PC)  
Postmortem care

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Mrs. Kelso is a 79-year-old female with hypertension, past myocardial infarction, chronic obstructive pulmonary disease (COPD), congestive heart failure, and peptic ulcer disease. She had been living in her own home and was able to bathe and feed herself and perform light housework until she fell at home and suffered a subdural hematoma. The hematoma was surgically evacuated. Since the surgery, she has lost the ability to walk and has had ongoing changes in her mental status. She is not oriented to person, time, or place and does not interact with her caregivers. She sleeps most of the day, with only occasional periods of wakefulness. These changes in her mental status have resulted in the loss of full decisional capacity. Mrs. Kelso's daughter, Nancy, has become her surrogate decision maker with the input of other family members. They elect to continue fully aggressive care because their primary goal is Mrs. Kelso's survival. She is eventually discharged to a rehabilitation facility in an attempt to improve her mobility...

## HISTORICAL BACKGROUND

Early in the last century, the focus of healthcare was on the provision of comfort, mostly at the time of death. With an average life expectancy of 47 years in the United States, patients usually died at home, surrounded by loved ones, following a sudden acute illness such as an infectious disease or an accident. As the century progressed, standard public health interventions such as water and sewage treatment and mass inoculation helped prevent and manage disease outbreaks. Injuries sustained during World Wars I and II brought about advances in preventing and treating infections and improved surgical techniques. Today, the United States has an average life expectancy of 78 years. Millions of Americans have benefited from innovations, including organ transplantation; advances in cardiac care involving pacemakers, vessel stents, coronary bypass surgery, and implanted defibrillators; gene therapy; cancer treatment; perinatal and neonatal care; laparoscopic surgery; imaging techniques; antibiotics; and immunotherapy.

Even though people are living longer with chronic illnesses that are better managed by scientific advances, they are also living longer with disability. There is ample evidence that patients with advanced disease have inadequate knowledge about illness progression, receive inappropriate or inadequate care, have poorly managed symptoms, and experience spiritual distress and financial worries. Disease progression and the aging process can result in treatment efforts that have marginal benefits, do not improve function, and can cause suffering. This

results in death from a chronic illness that follows exacerbations over many years. Seventy percent of these deaths occur in hospitals and institutional settings. The economic consequences of this care are significant. The number of Americans aged 65 and older is expected to double to more than 71 million by 2030, and more than 25% of Medicare expenditures account for care provided at the end of life.

## PALLIATIVE CARE

**Palliative care (PC)** is a specialized form of care that focuses on relief of pain and other symptoms and stress associated with a severe illness. It includes, but is not limited to, **hospice care**, which focuses on the care of a patient with a terminal illness who has less than 6 months to live. Palliative care was developed in response to the poorly met needs of an increasingly aging population. Many patients benefit from PC, which focuses on the relief of suffering and maximizing the quality of life for patients with a serious, life-threatening illness and their families. Provided by an interprofessional team, PC is given concurrently with curative treatment that meets the patient's goals (Fig. 5.1). This care serves patients in all situations, including those who depend on technology such as dialysis or artificial ventilation, as well as those with chronic progressive conditions; acute, serious, and life-threatening illness; and terminal illness. Having basic proficiency in PC skills is the responsibility of all professional healthcare providers. Specialty training and certification are available for nurses and providers.

Palliative care has been shown to improve symptom management and patient and family satisfaction. In a randomized study of patients with non-small cell lung cancer, those who received PC experienced a better quality of life. They were less depressed and received fewer aggressive interventions at the end of life. They also survived longer than those who received standard care. Palliative care is provided in hospital, outpatient, and community settings. It is also provided for patients under hospice care with a projected prognosis of 6 months or less. Palliative care provides continuity of care across healthcare settings, including the outpatient clinic, hospital, rehabilitation or nursing facility, home, and hospice.

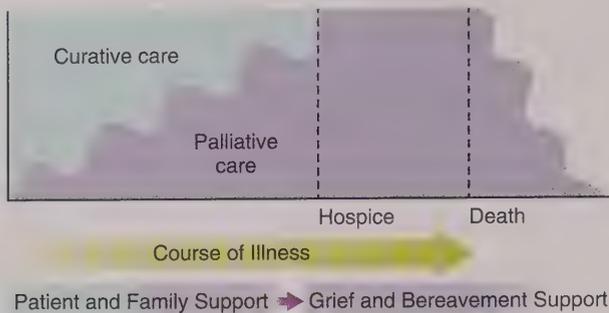

### Connection Check 5.1

Hospice care is *not* appropriate in which of these circumstances?

- The patient decides to forego curative treatment.
- The patient's prognosis is 3 to 6 months.
- The patient is undergoing experimental chemotherapy.
- The patient is receiving palliative chemotherapy.

## Domains of Palliative Care

In 2004, the National Consensus Project published clinical practice guidelines to promote quality PC across all care settings. These guidelines, or domains of care, provide a useful structure for discussing nursing implications for PC.

**FIGURE 5.1** Integrated palliative care model.

### Domain 1: Structure and Process of Care

The structure and process of care domain addresses the plan of care provided by nurses and providers with advanced PC training. The plan should incorporate the patient's goals, preferences, and values while recognizing that they may change over time. The plan of care should travel with the patient across healthcare settings. Patients and families should be educated about hospice care when death may occur within the year (Table 5.1). The topic should be

reintroduced as the patient declines. The healthcare team should assess and improve, as necessary, patient and family knowledge about the disease course, prognosis, and benefits and risks/burdens of diagnostic evaluation and treatments.

### Domain 2: Physical Aspects of Care

Physical aspects of care address the need to assess, treat, and document symptoms such as pain, dyspnea, constipation, and nausea using standardized scales to evaluate the effectiveness of the interventions. Patient outcomes should be documented. There should be follow-up with provider colleagues for continuing orders to provide effective symptom management.

### Domain 3: Psychological and Psychiatric Aspects of Care

Psychological and psychiatric aspects of care state that the PC plan should assess and document the presence of anxiety, depression, and delirium using available standardized scales such as the Memorial Symptom Assessment Scale and the Edmonton Symptom Assessment Scale. The patient's symptoms should be managed in a safe and timely manner

**Table 5.1** Hospice Care

Frequently Asked Question	Answer
<b>Who can receive hospice?</b>	Anyone, regardless of diagnosis, with a prognosis of 6 months or less who has decided not to pursue curative treatment (exceptions may be made for time-limited palliative treatment such as radiation or artificial nutrition; also, Affordable Care Act [ACA] pediatric patients are not required to forgo curative treatment)
<b>What are the levels of care under hospice?</b>	<ol style="list-style-type: none"> <li>1. Routine home care</li> <li>2. Continuous home care</li> <li>3. Inpatient respite care</li> <li>4. General inpatient care</li> </ol>
<b>How is hospice provided?</b>	<ul style="list-style-type: none"> <li>● In the home by a team of nurses, health aides, social workers, and others</li> <li>● In an inpatient hospice unit with 24-hour nursing and other caregivers</li> <li>● In a nursing home with intermittent visits provided by the home hospice team</li> </ul>
<b>Who can contact hospice?</b>	The patient, the family, the attending provider, or any member of the team can contact hospice; the hospice will contact the patient's primary care provider to sign orders for hospice.
<b>When should hospice be contacted?</b>	When the patient does not want to pursue curative therapy; when life expectancy is 6 months or less
<b>How long can a patient receive hospice care?</b>	As long as the provider certifies the patient is terminally ill with a life expectancy of 6 months or less if the disease runs its expected course
<b>What services are provided?</b>	Intermittent nursing; home health aide; social work; pastoral care; physical therapy; nutrition services; provider visits; volunteers; bereavement services; medical equipment; medications to manage symptoms; short-term acute inpatient care, including respite care, counseling, and pain and symptom management
<b>How is it paid for?</b>	Medicare A, Medical Assistance, and most major health insurance plans provide hospice coverage.
<b>What is not covered?</b>	Treatment for the terminal illness that is not for symptom relief; care given by another provider that was not arranged for by the hospice; care from another provider that duplicates the care hospice is required to provide

that is acceptable to the patient and his or her family. The patient and family should be assisted with their emotional or psychological reactions to functional impairment and loss. They should be connected with coping resources such as grief and bereavement services.

#### **Domain 4: Social Aspects of Care, Including Advanced Care Planning**

Social aspects of care address the need to facilitate regularly scheduled patient and family conferences with the interprofessional team to discuss the goals of care, prognosis, and advance care planning and to offer support. It includes assessment of patient and family social networks; cultural, legal, and financial concerns; caregiver availability; and coping skills, as well as access to medications and equipment. These aspects should be incorporated into the plan of care.

Nurses are important in **advanced care planning (ACP)**, a process in which patients, with support from care providers, family, and important others, make decisions about future healthcare. The concept of ACP is based on the premise that persons with life-threatening chronic diseases or polymorbidity and their families need to be assisted by healthcare professionals to identify and determine preferences and wishes about end of life and respective decision making. As part of ACP, a person may elaborate an advance directive to indicate his or her preferences about the end of life. ACP can be employed for any illness but is specifically recommended in the context of chronic diseases or polymorbidity with a potentially fatal outcome; the recommendation is to initiate this early in the disease process, well before any issues of incompetency or incapacity may arise. ACP includes three main aspects: ensuring full comprehension about the disease and its treatment; clarifying expectations about proposed treatments; and determining therapeutic goals, preferences, and wishes.

#### **Domain 5: Spiritual, Religious, and Existential Aspects of Care**

Spiritual, religious, and existential aspects of care incorporate the patient's religious, spiritual, and existential concerns and practices into the plan of care. Spiritual care is based on the patient's preferences.

#### **Domain 6: Cultural Aspects of Care**

Caring for patients, families, and communities within increasingly diverse practice settings necessitates cultural sensitivity and cultural competency. This is especially true when issues arise that elicit cultural, philosophical, and personal views surrounding death and dying and how to appropriately intervene or manage care. Being confronted with the end of life is challenging in most cultures around the world, and healthcare providers need to be well prepared to manage cultural aspects of care.

Cultural humility may be an especially effective framework for navigating highly sensitive and emotionally charged discussions and interactions surrounding palliative care or end-of-life decisions. Awareness of power imbalances and an inclusive and open approach to incorporating a variety of perspectives and practices are important components of provider training, communication, and practice,

promoting mutual empowerment, respect, partnership, and optimal care outcomes.

Consideration of the cultural aspects of PC should address the patient and family's cultural beliefs about care, such as:

- How healthcare decisions are made
- Preferences for how and to whom information is disclosed
- Dietary preferences
- Family communication
- Perspectives on death, suffering, and grieving
- Funeral/burial preferences

#### **Domain 7: Care of the Imminently Dying**

Care of the imminently dying addresses the need to recognize, document, and inform family and other team members of the transition to the active dying phase. It addresses the need to educate the family about the signs and symptoms of dying (Table 5.2) and to appropriately treat

**Table 5.2 Physical and Psychological Changes Prior to Death**

Stage	Description
1. Early stage: acceptance that death is approaching	The patient may begin to withdraw. There may be a loss of interest in social contacts. As the body slows, there may be a loss of appetite because the body has decreased needs; however, the patient does not experience hunger or thirst. The patient decreases participation in activities and begins to sleep more.
2. Middle stage: weeks before death	There is a decline in mental status; the patient will become confused and disoriented, sleeping most of the time. Physical changes include decreases in body temperature and blood pressure. The pulse rate may become irregular. Respirations become labored and rapid. Skin color begins to change as circulation is diminished. Speaking slows or ceases altogether.
3. Late stage: days or hours before death	The patient may experience a very brief and limited surge of energy in a last effort at physical exertion and expression. Afterward, previously noted symptoms worsen. Coma ensues, extremities become cool and mottled, and the respiratory pattern becomes more rapid and labored (Cheyne–Stokes respiration). There is a loss of ability to manage secretions because of loss of the swallow reflex. Congestion in the airways causes respirations to sound loud and wet. Death follows.
	Hearing is thought to be one of the last senses to lapse before death, so care should be taken to act as if the dying person is aware and able to hear even if he or she is unresponsive.

the patient. The family should be supported throughout this process.

### Symptom Management

Symptom management in the dying patient includes being aware of and treating the typical signs of distress that occur during the dying process. Several of the most common symptoms include pain/general discomfort, respiratory distress, and delirium. If the patient is unable to express his or her pain, an observational pain scale will note the presence of facial grimacing, moaning/groaning, and restlessness. Opiates, such as morphine, and adjuvant medications are often the treatment of choice. However, nonpharmacologic ways to address pain or to manage symptoms should also be explored. These can include acupressure, essential oils, sea bands, the use of fans for dyspnea, and other emerging complementary and alternative therapies (see, for example, <http://www.caresearch.com.au>).

Respiratory signs/symptoms can include dyspnea, tachypnea, upper airway “gurgle,” and the use of accessory muscles for breathing. Anticholinergic medications help dry the secretions, lessening the gurgle. Other treatment modalities for respiratory distress during the active dying phase include elevating the head of the bed and the use of opiates. Concomitant use of sedatives with opiates acts synergistically to relax the patient, calm the breathing, and alleviate pain. Nurses, at times, express the fear that administering opiates to a dying patient may hasten death. The ethical principle of double effect states that a nurse’s conduct is moral and ethical if the primary intent is to ease pain and respiratory distress (Box 5.1).

Delirium can be managed by calm verbal reassurance. Surrounding the patient with familiar sights, sounds, and smells is also beneficial. Haloperidol or benzodiazepines (lorazepam, midazolam) can be used to manage hyperactive delirium in dying patients. Causes of delirium such as medications, constipation, or a full bladder should be ruled out before other measures are tried.

### Connection Check 5.2

Mrs. Jones is receiving hospice care in the nursing home. During the assessment, the nurse observes the patient is unconscious and has wet, noisy respirations and cool, mottled extremities. The nurse understands which of the following actions are indicated? (*Select all that apply.*)

- A. Notifying the patient’s family
- B. Requesting an order for an anticholinergic medication
- C. Notifying the patient’s provider
- D. Performing a sternal rub to assess the patient’s response
- E. Performing a full systems assessment

### Family Support

Family support (Box 5.2) includes offering the family an opportunity to participate in the patient’s care. This may include providing mouth care and applying lip balm, bathing, massaging aching joints, or reading to the patient. Maintaining

### Box 5.1 Principle of Double Effect

The principle of double effect, often invoked concerning the effect of opiates at the end of life, implies that an intended good effect such as pain management is ethically permissible even if it produces an unintended secondary effect, hastening death. There is no evidence to support this cause-and-effect relationship in pain management at the end of life. There is a wide margin of safety with the use of opiates and sedating medications to manage symptoms.

### Box 5.2 Care of the Family

- Assess family understanding of the patient’s diagnosis and dying.
- Inform family members that the patient is dying. Open a space for them to express grief.
- Invite family members to care for the patient as they feel comfortable: bathing, massaging bony prominences, applying lip balm, or reading to the patient.
- Bring in the patient’s favorite music; use headphones.
- Bring in favorite quilts or family pictures.
- If young children cannot visit, have them write a note that can be shared with the patient. Alternatively, have them call on the phone.
- Have family members record stories from the past and share them with the patient. This can become a family legacy.
- If family members are unable to visit, have them call the patient’s room. Other family members or nursing staff can hold the phone to the patient’s ear. This can be done even if the patient is comatose.

communication with the family is of paramount importance. Nurses are not always sure of what to say to the family of a dying patient. Expressing concern and understanding of their distress is one simple way to begin to establish a bond. The use of reflective listening is a technique to help family members process their experience (Box 5.3). When possible, incorporate patient and family preferences for the site of dying: home or inpatient hospice. Assure everyone that effective pain and symptom management is being provided.

Encourage the family to communicate with the patient prior to death. Allow each family member, as desired, private time with the patient to express his or her final thoughts. Sometimes family members are unsure about what to say. Providing simple suggestions helps facilitate the process. Some feel that actually saying a final good-bye allows the patient to go on his or her final journey. See Box 5.4 for suggested communications with the dying patient.

Offering the family private time in the room to view the patient’s body after death can help facilitate the grieving process. Some families may decline the viewing, preferring to remember the person as he or she was when still alive. Foot traffic near the patient’s room should be monitored for noise so that a respectful presence is maintained. Incorporate a bereavement care plan that includes follow-up after the death.

### Box 5.3 Communication With the Family

Use reflective listening to help the family process the dying experience:

- How are you doing?
- What are you worried or anxious about?
- What questions do you have?
- I can see this is difficult for you.
- How did you hear the news?
- How are other family members coping?
- What are some of your favorite memories of the patient?
- What will you miss most about the patient?
- Do you think the patient is comfortable?
- Do you need anything at this time?

### Box 5.4 Communication With the Dying Patient

Talking with a loved one as death approaches is difficult. The following phrases may help guide the conversation and make it meaningful for both the patient and the family member or friend. These phrases may also be used by the dying patient to help express important thoughts and feelings before dying.

- “Thank you for . . .”
- “I forgive you for . . .”
- “Please forgive me for . . .”
- “I love you.”
- “Good-bye.”

#### Connection Check 5.3

Mr. Smith’s wife is in the terminal stage of chronic obstructive pulmonary disease (COPD). He is very anxious that his wife be comfortable during her last hours. The nurse finds him tearful in the hall outside the room. Which communication should the nurse use first?

- A. “My aunt had COPD, and she died on a ventilator. Count your blessings that your wife is not on a machine.”
- B. “I can see you’re upset, Mr. Smith. Would you like to talk about it?”
- C. “Is your family here?”
- D. “Do you think your wife would like a visit from pastoral care?”

#### Postmortem Care

**Postmortem care** involves preparing the body for eventual disposition to the funeral home. The body should be treated with respect, incorporating the family’s religious and cultural practices. Practices vary by state and/or local jurisdiction, but if there is to be an autopsy, tubes and catheters

usually must remain in place. If no autopsy is planned, remove tubes and cleanse soiled areas of the body. Taking the time to involve other nurses in this care provides an opportunity for the staff to engage in a ritual of farewell. After completing the care, each nurse/staff member can pause for a moment to say good-bye to the patient before the body is transported to the morgue or funeral home.

#### Domain 8: Ethical and Legal Aspects of Care

Important to this domain is addressing the patient’s decisional capacity (Box 5.5) and determining who the patient’s surrogate decision maker is if the patient is unable to make decisions for himself or herself. This domain also addresses the nurse’s role as patient advocate, assuring the patient or surrogate that preferences are known and will be honored and that ethical care will be provided. This includes the patient’s right to full disclosure of information and refusal of treatment. The ethical principle of beneficence is demonstrated by providing care that benefits the patient, such as good symptom management. Addressing the patient’s spiritual distress and respecting wishes for the use of life-sustaining treatment are examples of nonmaleficence, or not doing harm to the patient. Providing equitable access to hospice and PC for all patients is an example of the principle of justice.

After the goals of care are determined, the team translates them into medical orders. Usually, the attending provider recommends appropriate interventions that promote comfort. Decisions need to be made regarding the use of life-sustaining treatments, including cardiopulmonary resuscitation, artificial ventilation, dialysis, artificial hydration and nutrition, antibiotics, and vasopressors. Ongoing discussions of these interventions should consider the benefits and burdens or risks they pose in meeting the patient care goals (Box 5.6).

#### Connection Check 5.4

The nurse asks the patient and family members if they have any questions about the patient’s diagnosis and plan of care. This is an example of which PC domain?

- A. Physical aspects of care
- B. Psychological and emotional aspects of care
- C. Ethical and legal aspects of care
- D. Structure and process of care

### Box 5.5 Decisional Capacity

The patient is deemed to have decisional capacity if these criteria are met:

- Ability to understand the nature and consequences of the proposed treatment
- Ability to rationally evaluate the burdens, benefits, and risks of treatment
- Ability to communicate a decision

## Box 5.6 A Well-Managed Death

- Appropriate pain and symptom management
- Avoiding a prolonged dying process
- Clear communication about decisions by patient, family, and provider
- Adequate preparation for death for both the patient and loved ones
- Feeling a sense of control
- Finding a spiritual or emotional sense of completion
- Affirming the patient as a unique and worthy person
- Strengthening relationships with loved ones
- Not being alone

### CASE STUDY: EPISODE 2

While in rehabilitation, Mrs. Kelso develops a urinary tract infection and sacral decubitus ulcers. Unable to participate in intensive physical therapy, she is discharged home bedbound after 10 days, with 24-hour caregivers. After 1 week at home, her home-care nurse notes that she is hypotensive and tachycardic. She is taken to the emergency department, where she is intubated and subsequently admitted to the intensive care unit with a diagnosis of sepsis. Cultures reveal an infected central line, pneumonia, and osteomyelitis related to the decubitus ulcers. Her respiratory status eventually stabilizes, and she is extubated. She is often delirious, calling out and speaking in a confused manner. Although she is unable to tell the staff she is in pain, her discomfort is clear as she moans when turned and screams when her sacral dressings are changed...

## ETHICAL IMPLICATIONS AND MORAL DISTRESS

Nurses deliver highly technological and complex care, with an expectation that all of their actions will work toward enhancing the patient's well-being in all domains: physiological, psychological, relational, social, and spiritual. Nurses correctly feel they have an ethical obligation to advocate for the patient.

Unfortunately, sometimes the valuation of “doing well” and “the patient's best interest” can differ among the patient, his or her family members, and members of the healthcare team. Disagreements often occur over the choice of treatments, patient prognosis, and acknowledgment that the patient is dying. At times, the nurse may believe the patient's best interest is being violated. However, nurses often have difficulty acting according to their

values and goals for the patient and difficulty voicing their concerns in practice. This may be due to working in a traditional power structure that lacks collaborative relationships with providers. Sometimes, nurses feel ignored or not respected as professionals. Thus, they often feel caught between the patient and the provider's decisions for patient care. In this context, nurses are regularly confronted with decisions they do not agree with but are expected to implement. This can lead to a sense of disintegration of the nurse's personal integrity.

Nurses who regularly face these situations can suffer **moral distress**, which involves the inability to do the morally correct thing because of situational factors. Factors that contribute to creating moral distress include high stress in the work environment; time and resource pressures; high-technology care situations; and differences in values, attitudes, and cultural or religious beliefs among patients, families, and staff.

Unaddressed moral distress has serious consequences. Nurses begin to feel disengaged from patients, resulting in poor patient care. Feelings of anger, frustration, powerlessness, dissatisfaction, and emotional and physical exhaustion can lead to burnout. There is no longer a sense of joy in working with patients and families. Moral distress also results in decreased job satisfaction, increased staff turnover, and ultimately, nurses choosing to leave the profession.

Nurses cope with moral distress by talking with other nurses about the situation and sharing their feelings and values with their peers. They also share with and receive support from nurse managers and chaplains. They share decisions with colleagues, sometimes acceding to the majority opinion. Such discussions enable the nurse to consider alternatives in the situation. Providing education in ethical decision making and instituting ethics rounds can help manage moral distress. Nurses who have developed expertise, experience, problem-solving skills, and an ability to take risks tend to take action in an ethical manner when confronted with moral dilemmas. These nurses may act as role models and are a valuable resource for new nurses.

Healthcare organizations must also be responsive by developing and implementing processes that help nurses recognize and name moral distress. Nurse leaders and administrators need to recognize factors that contribute to moral distress. Monitoring of mechanisms that produce moral distress allows the organization to address moral distress in a systematic fashion. Initiatives to promote open dialogue about ethical concerns among team members can transform the care environment so that nurses and others feel safe voicing their concerns and are empowered to act in an ethical manner. The organization's ethics committee may be helpful in addressing conflicts regarding the goals of care, healthcare decisions, and

advance care planning. The ethics committee may also model behaviors of respectful listening that encourage dialogue.

### Connection Check 5.5

The nurse understands that moral distress may result in which of the following? (*Select all that apply.*)

- A. Physical exhaustion
- B. Disagreements among staff
- C. Anger at family
- D. Anger at providers
- E. Feelings of undeserved power

### Nurse Self-Care

Nurses are in the privileged position of caring for patients when they are perhaps most vulnerable: the time preceding their death. While advocating for patients so that their values, goals, and preferences are heard and honored, nurses may also feel a sense of loss and grief over the impending death. When involved in stressful care situations, nurses may not take the time to process the experience with trusted friends or professionals. The end result may be a walling off of emotions in an effort to protect from feelings of distress. Nurses do not have to settle for this result.

As individuals, nurses can build self-care activities into their daily schedules. Talking with trusted friends or nursing colleagues, journaling, engaging in aerobic exercise, gardening, practicing yoga, meditating, and praying can help recharge emotional batteries.

As a team, nurses can employ stress-reducing strategies, such as:

- Performing postmortem care together
- Pausing for a moment of silence during the monthly staff meeting to remember those who have died in care
- Sending the family a bereavement card

Nursing management should plan regularly scheduled unit debriefings facilitated by crisis intervention staff, pastoral care, or social workers. Managers should take advantage of employer-provided counseling services to help staff process stressful care situations.

Again, as individuals, nurses should reflect on their role as the final caregivers who make a difference for patients at a crucial time in their lives. The nurse is sometimes the only person who attends a dying patient. It should be remembered that this is a privilege and an honor. Appropriating the experiences of death and loss deepens a sense of shared humanity and forms a sense of compassion and the ability to be more fully present for future patients and families in care.

### Connection Check 5.6

The nurse understands that appropriate actions to take after a distressing discussion with a provider over end-of-life issues for a patient include which of the following?

- A. Avoid communicating with the provider except through the electronic medical record
- B. Having a drink after work to calm frazzled nerves
- C. Arguing with colleagues who disagree
- D. Soliciting support from a nurse manager or ethics consultation

## Making Connections

### CASE STUDY: WRAP-UP

As Mrs. Kelso's condition continues to deteriorate despite aggressive care, the need to discuss healthcare goals, expectations, and hopes for recovery becomes clear. The healthcare team believes that the patient is dying. As family members discuss their hopes and fears for the patient with the nurse, they become tearful. Using active listening, the nurse encourages the family to talk about the patient's past life, her relationships with her family, her love for gardening, and her involvement in church activities. The nurse asks the family if the patient ever expressed her wishes about end-of-life care. They state simply, "Our mother did not want to suffer." The healthcare team discusses Mrs. Kelso's potential and actual suffering—physically, emotionally, and spiritually—and, with the family, develops a plan that includes palliative and hospice care.

They develop a plan for the management of pain and respiratory distress. Morphine sulfate is ordered. The patient ceases moaning, her facial muscles relax, and her respiratory rate decreases to 18 per minute with no use of accessory muscles. The nurse documents her findings and incorporates symptom management into the care plan. Mrs. Kelso is transferred to inpatient hospice. She dies 2 days later.

#### Case Study Questions

1. The nurse caring for Mrs. Kelso understands that her first priority should be to do which of the following?
  - A. Call the chaplain
  - B. Ask family members for their understanding of the situation
  - C. Address the patient's pain
  - D. Call the ethics committee

2. Efforts to support family members include which of the following? (*Select all that apply.*)
  - A. Assuring them that the end is near and that it is okay to go home
  - B. Encouraging final private conversations with the patient
  - C. Asking them to bring a few of the patient's favorite things to her room
  - D. Telling them to encourage the patient to hold on for them
  - E. Encouraging active discussions about favorite family memories
3. The nurse understands that the use of morphine sulfate to treat symptoms may result in which of the following? (*Select all that apply.*)
  - A. Improved mobility
  - B. Relief of pain
  - C. Slowing of respirations
  - D. Relief of nausea
  - E. Improved appetite
4. As an experienced palliative care nurse, your response to Mrs. Kelso's nurse when expressing concern that giving pain medication and sedatives may hasten patient death is which of the following?
  - A. "Don't worry—we do this all of the time."
  - B. "We are covered ethically by the principle of double effect."
  - C. "Don't worry—we have a doctor's order."
  - D. "We are covered ethically by the principle of beneficence."
5. Mrs. Kelso's death can be described as a well-managed death for which reason?
  - A. It allowed enough time for the family to accept it was coming.
  - B. It occurred in the hospice unit.
  - C. There was appropriate pain and symptom management.
  - D. The family accepted the care team's decisions.

## CHAPTER SUMMARY

The need for PC arose as advances in healthcare brought about not only longevity but also increased chances of surviving with long-term disability. Palliative care addresses the needs of patients with chronic illness and their families in order to alleviate and prevent suffering in all its forms and promote the best possible quality of life.

The domains of PC include the structure and process of care, physical aspects of care, psychological and psychiatric aspects of care, social aspects of care, spiritual and religious aspects of care, cultural aspects of care, care of the imminently dying, and ethical and legal issues. Ensuring that the patient and family have needed information about the diagnosis and prognosis is part of the structure and process of care. Symptom management and family support are also essential in the care of the imminently dying patient.

As care providers who spend the most time at the bedside, nurses play a pivotal role in providing PC by advocating for patient preferences, educating the patient and family about the disease process, and assisting them in processing the experience by engaging them in advanced care planning as well as reflective listening and by probing what is important to them. Often, the nurse provides a supportive presence, bearing silent witness in the midst of an experience that inspires awe: the death of the beloved. Nurses may experience moral distress as they try to advocate for the patient's best interest while being expected to carry out treatments they find morally distressing. Moral distress may result in staff turnover, anger, frustration, and extreme fatigue. Interventions at both the individual and organizational levels can help manage moral distress.

## Clinical Principles of Medical-Surgical Nursing

### Chapter 6

## Geriatric Implications for Medical-Surgical Nursing

*Denise Cost*

#### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Defining the demographics of the aging population
2. Discussing age-related physiological changes
3. Identifying common healthcare issues of older adults
4. Analyzing care priorities for geriatric patients
5. Developing support strategies for older adults

#### CONCEPTS

- Assessment
- Cognition
- Fluids and Electrolytes
- Nutrition
- Perfusion
- Safety

#### ESSENTIAL TERMS

Activities of daily living (ADLs)  
Adaptation  
Advance directives  
Ageism  
Aging in place  
Alzheimer's dementia  
Atrophy  
Cachexia  
Calcification  
Cognitive  
Deconditioning  
Delirium  
Dementia  
Depression  
Homeostasis  
Homeostenosis  
Instrumental activities of daily living (IADLs)  
Living will  
Polypharmacy  
Sarcopenia  
Sclerosis  
Senescence  
Stenosis

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Mrs. Gomez is an 87-year-old Hispanic woman with a history of hypertension and arthritis. She developed new-onset shortness of breath and was hospitalized. In the hospital, she was diagnosed as having heart failure and was discharged to home with six new medications, oxygen therapy, and a sodium-restricted diet. Mrs. Gomez is a widow and lives alone in her apartment. She has extended family members who live in the same apartment building. She speaks some English but mostly Spanish. She has been referred for home-care services and has been assigned a primary nurse...

## OVERVIEW OF AGING

### Demographics

The process of aging is universal and inevitable and affects all species. Interest in and study of aging is peaking as the number of people who are considered elderly has rapidly increased. Presently, *old age* is defined by three stages. The age range of 65 to 75 is considered “young-old,” the range of 75 to 85 is “old,” and from 85 upward is termed the “old-old” or “oldest old.” As Americans live longer, the growth in the number of older adults is unprecedented. The dramatic growth is due in part to the so-called “baby boomer” population, those people born between the years 1946 and 1963, who have started to turn 65. Over the past 10 years, the population 65 and over increased from 36.6 million in 2005 to 47.8 million in 2015 (a 30% increase) and is projected to more than double to 98 million. In 2016, 23% of persons age 65 and over were members of racial or ethnic minority populations; 9% were African Americans (not Hispanic), 4% were Asian or Pacific Islander (not Hispanic), 0.5% were Native American (not Hispanic), 0.1% were Native Hawaiian/Pacific Islander (not Hispanic), and 0.7% of persons 65+ identified themselves as being of two or more races. Persons of Hispanic origin (who may be of any race) represented 8% of the older population (Box 6.1).

U.S. Census Bureau statistics show that women continue to live longer than men. Based on the 2012 census, there are approximately 22.9 million older women and 17.3 million older men. The overall life expectancy for the U.S. population is 77.2 years. Older men are much more likely to be married. Forty-two percent of older women are widows, and of women 75 and older, 49% live alone. The financial status of older persons reveals a median income of \$25,877 for men and \$15,282 for women. Their major sources of income are reported to be Social Security (reported by 87%), assets

## Box 6.1 Health Disparities in the Geriatric Population

- *Healthy People 2020* defines a *health disparity* as “a particular type of health difference that is closely linked with social, economic, and/or environmental disadvantage.” Minority populations are increasing overall in the United States. They are among the leading victims of hypertension and diabetes. Disparities occur when differences in outcomes are related to bias and a system of care that is not culturally sensitive.
- The Census Bureau predicts that racial and ethnic minority populations will grow to half of the U.S. population in 3 decades. The National Institutes of Health has a research agenda in place to address the increasing health needs of populations suffering from inequities. Some health disparities are demonstrated in the following facts:
  - A comparison of rates by race reveals that black women and men have much higher rates of death from coronary heart disease in the 45-to-74 age-group.
  - The same black-white difference was seen among women and men who died of stroke.
  - Older adults, non-Hispanic blacks, U.S.-born adults, and adults with lower family income, less education, public health insurance, diabetes, obesity, or a disability all have a higher prevalence of hypertension than their counterparts.
  - The disparity by race/ethnicity, socioeconomic status, disability status, and education level is still substantial. Non-Hispanic blacks have the highest percentage of householders living in inadequate, unhealthy housing, followed by Hispanics and American Indians/Alaska Natives.
  - As of 2015, whereas 20% of measures showed disparities getting smaller for blacks and Hispanics, most disparities have not changed significantly for any racial and ethnic groups.

From Agency for Healthcare Research and Quality. (2017). *2016 national healthcare quality and disparities report*. Retrieved from <http://www.ahrq.gov/research/findings/nhqdr/nhqdr16/summary.html>

income (54%), private pensions (28%), government employee pensions (14%), and earnings (25%). Almost 8.9% of older adults live below the poverty line.

### Connection Check 6.1

The nurse is preparing a discharge plan for a 78-year-old woman. Which likely scenario should the nurse anticipate?

- The patient will drive herself home.
- The patient lives in a homeless shelter.
- The patient is a widow and lives alone.
- The patient receives a government pension.

## AGE-RELATED CHANGES AND COMMON HEALTH ISSUES

Death in advanced years is not caused by “old age” but by disease processes or infections. Older adults are at greater risk for illness because of the normal decline in adaptation

that occurs in the body. Most of the changes of aging become apparent when the body is placed under stress. **Homeostasis** is the body's ability to adapt to or return to a normal state of balance after being subjected to a threat or stress. Such stressors include injury, exposure to pathogenic organisms, changes in fluid and nutritional intake, and the effects of medication. The failure of homeostasis is termed **homeostenosis**. This is defined as the characteristic progressive decrease in homeostatic reserve that occurs in every organ system with aging. The physiological reserves are present, but they are being used to maintain homeostasis. Therefore, when a challenge occurs, there is less reserve to call upon for compensation.

**Senescence** refers to normal age-related changes in the organ systems. Individual humans age differently, but there are changes that affect all people in a similar manner. In general, there are several processes that affect all body systems. **Sclerosis** is the hardening of tissue due to fibrous tissue overgrowth. **Stenosis** is the narrowing or constricting of a passage or orifice. **Atrophy** is defined as a wasting away or decrease in the size of an organ. **Calcification** occurs normally as part of bone formation. However, calcium and calcium salts can be deposited abnormally in other organs, including blood vessels. On a functional level, there is a general tendency for slowing, shrinking, and stiffening. Gait slows down, height is diminished, and range of motion decreases. Organ systems develop these changes at differing rates between individuals and within an individual. Mobility and strength in an 85-year-old man may be good while he suffers from cataracts and markedly diminished hearing. His 85-year-old neighbor may need to use a walker but has excellent vision and hearing.

These processes do not necessarily bring on disease, but they create limitations in normal activities. Healthy aging entails compensation for these limitations by way of healthy lifestyle choices and interventions in factors that can be controlled.

The following sections and accompanying tables describe the body systems and the physiological alterations that occur.

### Common Cardiovascular Health Issues

Age-related cardiovascular changes are listed in Table 6.1. They include a decreased number of pacemaker cells, stenosis of the heart valves, and stiffening and narrowing of arterial walls.

### Heart and Vascular Diseases

Heart and vascular diseases, such as *hypertension (HTN)*, *coronary artery disease (CAD)*, and *myocardial infarction (MI)*, occur as a result of sclerotic changes in blood vessels and heart wall muscle tissues, particularly coronary arteries. Systolic blood pressure rises because of the stiffening of systemic arteries. When blood flow is decreased to the heart muscle, death of the tissue (infarction) occurs.

### Heart Failure

Heart failure (HF) is most often caused by MI or HTN. Damaged heart muscle results in weakened contractility. The pumping function of the heart becomes impaired, and fluid accumulation develops in the lungs and tissues. Pulmonary edema (fluid in the lungs) causes shortness of breath and the inability to breathe while lying flat and can be life threatening. Edema in dependent areas of the body, most often the feet and legs, can develop as well and is an early sign of heart failure. One in every 100 people over age 65 has heart failure, and 80% of those hospitalized with heart failure are over 65.

### Atrial Fibrillation

Changes in the pacemaker cells in the atrium contribute to the development of atrial fibrillation (AF). The pacemaker cells fire sporadically, resulting in a rapid twitching of the atria. This produces inefficient filling of the ventricles and a backup of blood in the atria. The main danger of AF is the formation of blood clots in the right atrium, which puts the patient at risk for systemic embolization. Stroke is the

**Table 6.1 Age-Related Cardiovascular Changes**

Change	Consequence
<ul style="list-style-type: none"> <li>● Reduced number of pacemaker cells in the sinoatrial (SA) node</li> </ul>	<ul style="list-style-type: none"> <li>● Decrease in maximum heart rate with age</li> </ul>
<ul style="list-style-type: none"> <li>● Decreased cardiac responsiveness to beta-adrenergic stimuli</li> </ul>	<ul style="list-style-type: none"> <li>● Increased tendency for arrhythmias, atrial fibrillation</li> <li>● Reduced heart-rate control that impairs ability to adapt to stressors</li> </ul>
<ul style="list-style-type: none"> <li>● Left atrial enlargement</li> </ul>	<ul style="list-style-type: none"> <li>● Fourth heart sound heard normally in older adults</li> <li>● Increased risks of hypertension and heart failure</li> </ul>
<ul style="list-style-type: none"> <li>● Stenosis (narrowing or constriction) of heart valves</li> </ul>	<ul style="list-style-type: none"> <li>● Rise in systolic blood pressure</li> </ul>
<ul style="list-style-type: none"> <li>● Increased fibrosis and calcification of heart chambers and valves</li> </ul>	
<ul style="list-style-type: none"> <li>● Stiffening of artery walls</li> </ul>	
<ul style="list-style-type: none"> <li>● Narrowed arteries and weakened venous valves</li> </ul>	<ul style="list-style-type: none"> <li>● Slowed venous return, resulting in edema</li> </ul>
<ul style="list-style-type: none"> <li>● Formation of atherosclerotic plaques that can block blood flow</li> </ul>	<ul style="list-style-type: none"> <li>● Increased risk of venous thrombosis and stroke</li> </ul>
<ul style="list-style-type: none"> <li>● Decline in baroreflex response to arterial pressure</li> </ul>	<ul style="list-style-type: none"> <li>● Diminished blood pressure responses</li> <li>● Orthostatic hypotension</li> </ul>

most common complication of atrial fibrillation and the resultant embolization.

### Heart Disease

Heart disease continues to be the number one cause of death in those over 65. Stroke is the third-leading cause of death. Risk factors that can be modified to prevent heart disease and stroke include HTN, high cholesterol levels, diabetes, smoking, obesity, poor diet, and physical inactivity. According to *Healthy People 2020*, addressing and improving these factors could substantially reduce the number of deaths from cardiovascular disease.

### CASE STUDY: EPISODE 2

The goal is to have Ms. Gomez safely age in place: to remain living where she has lived for years, a familiar place in which she is comfortable (Box 6.2). The primary nurse from the home healthcare service will assess her needs and determine which services are necessary for Ms. Gomez to remain safely at home. Before the first home visit, the primary nurse needs to arrange for a Spanish interpreter and a family member to be present so that they can support and assist the patient during the assessment. An informed consent form for home-care services must also be obtained before the nurse can conduct an assessment. A complete physical and psychosocial assessment, a home safety assessment, and an assessment of the patient's medications are needed in order to develop nursing diagnoses and a plan of care to address Ms. Gomez's needs. In addition, the nurse will need to prioritize educating Ms. Gomez on home oxygen use and safety and assess her risk of falling as part of the home safety assessment. On the basis of the assessment findings, the nurse will determine what other support services are needed. The nurse will communicate with the primary health provider to obtain medical orders for all anticipated services and to confirm medications. A plan of care based on the problems identified and nursing interventions to address them will then be implemented...

**Safety Alert** The Joint Commission identified five safety goals for home care for 2018:

1. **Correctly identifying the patient.** Use at least two ways of identifying the patient, such as the patient's name and date of birth, for example. Even in the home environment, it is possible to visit or examine the wrong person, especially if there are many other family members present. Verification of the patient's first and last name and having another family member present to confirm the identity will prevent misidentification.

2. **Using medications safely.** Record and communicate correct information about a patient's medications. Compare new medications with the medications being taken previously. In the home, the nurse must use communication, teaching, and organizational skills to educate the patient about his or her medications. This includes indications, side effects, and dosing intervals. The nurse helps the patient develop a system for organizing the medications, usually accomplished with a "mediplanner" pill container (Fig. 6.1). This is a major priority for home care in order to avoid dangerous medication interactions and side effects.
3. **Preventing infection.** The home-care nurse must follow accepted practices of hand washing and maintenance of the equipment carried into each visit in order to prevent the spread of pathogens into the home and outside to the community. Use the hand-cleaning guidelines from the Centers for Disease Control and Prevention (CDC) or the World Health Organization (WHO) when washing hands. Use accepted maintenance practices for equipment brought into the home in order to prevent the spread of pathogens in the home and outside to the community.
4. **Preventing falls.** Older adults are at increased risk for falls. A careful review of medications that may have side effects of dizziness, weakness, or sleepiness is a priority, as is education of the individual about fall prevention.
5. **Identifying safety risks.** These risks include environmental hazards such as loose carpeting, damaged electrical connections, or clutter and trash that pose a fire hazard. If there is oxygen in the home, safety measures to prevent the risk of fire must be taught, and the residence must be identified at the entrance as having oxygen on the premises.

FIGURE 6.1 Typical mediplanner container.

## Box 6.2 Aging at Home

The Centers for Disease Control and Prevention defines **aging in place** as independently and comfortably remaining in one's own home regardless of income, age, or disabilities. An assessment is completed to determine the resources necessary to safely remain at home. Occupational therapy, physical therapy, and home healthcare are resources to support aging in place. Overall, this process has been aided by legislation that supports older adults staying at home, assistive technologies such as telehealth for remote health and wellness monitoring, and technologies that support safety and home security. Also built into this model are communities and activities designed to decrease isolation and increase involvement with others. Group social activities and potluck dinners are examples. Volunteers or family members who can help with shopping and home maintenance are key ingredients for successful aging in place.

## Common Respiratory Health Issues

Age-related respiratory changes are listed in Table 6.2. They include stiffening and calcification of the cartilage that separates the bones within the rib cage (costochondral cartilage), atrophy of the intercostal muscles, and loss of lung elastic recoil. As a result of the homeostatic changes previously discussed, there is an increased risk of respiratory failure from all causes. Combined, lower respiratory diseases are the fourth-leading cause of death in people aged 65 and over. Nonpulmonary conditions such as malnutrition, stroke, heart failure, Parkinson's disease, and **delirium** impact pulmonary issues. For example, gastrostomy tube feeding has a significant risk for aspiration. Tube feedings are commonly administered in older adult patients with dementia who can no longer eat or swallow safely.

### Pneumonia

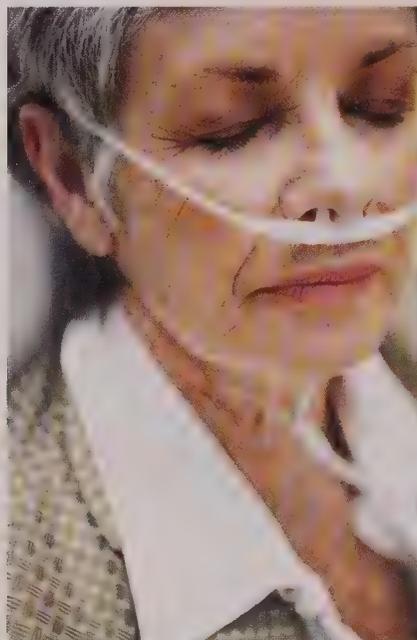

Pneumonias include bacterial, viral, and aspiration as well as diffuse aspiration bronchiolitis. A decrease in the lung's **elastic recoil and diminished compliance** cause decreased **alveolar expansion**. Weakened cough reflex and diaphragm strength allow secretions to pool in the lungs, contributing to infections. In addition, older adults tend to have impaired swallowing, which puts them at risk for aspiration and pneumonia. The use of thickening agents in liquids helps decrease the risk of aspiration by making liquids thicker and easier to swallow.

### Chronic Obstructive Pulmonary Disease/Asthma

Chronic obstructive pulmonary disease (COPD) is a term used to refer to two conditions, **emphysema** and **chronic bronchitis** (Fig. 6.2). Smoking is the primary

**Table 6.2** Age-Related Respiratory Changes

Change	Consequence
● Ossification of laryngeal cartilage (becomes bony)	● Voice becomes weak, breathy, rough, and hoarse.
● Less mobile vocal fold movement	
● Atrophy of vocalis muscle	
● Costochondral cartilage calcification	● By age 65, inspiration becomes dependent on the abdominal muscles.
● Decreased chest wall compliance	
● Atrophy of intercostal muscles	
● Progressive loss of lung elastic recoil, decreasing lung compliance, and decreasing surface area for gas exchange	● Decline in PaO <sub>2</sub>
● Diminished laryngeal and cough reflexes	● Increased risk of aspiration and aspiration pneumonia
● Reduced diaphragm strength	● Increased risk of respiratory failure
● Decreased pulmonary reserves	

**FIGURE 6.2** Older adult patients with chronic obstructive pulmonary disease often need continuous oxygen.

risk factor for COPD. Those aged 65 and over have the highest rate of chronic bronchitis. Asthma affects 5% to 7% of the over-65 population, and this age-group accounts for 60% of all asthma-related fatalities. Indoor allergens are more likely to be triggers for asthma because older adults spend more time in the home than outside.

**Common Neurological Health Issues**

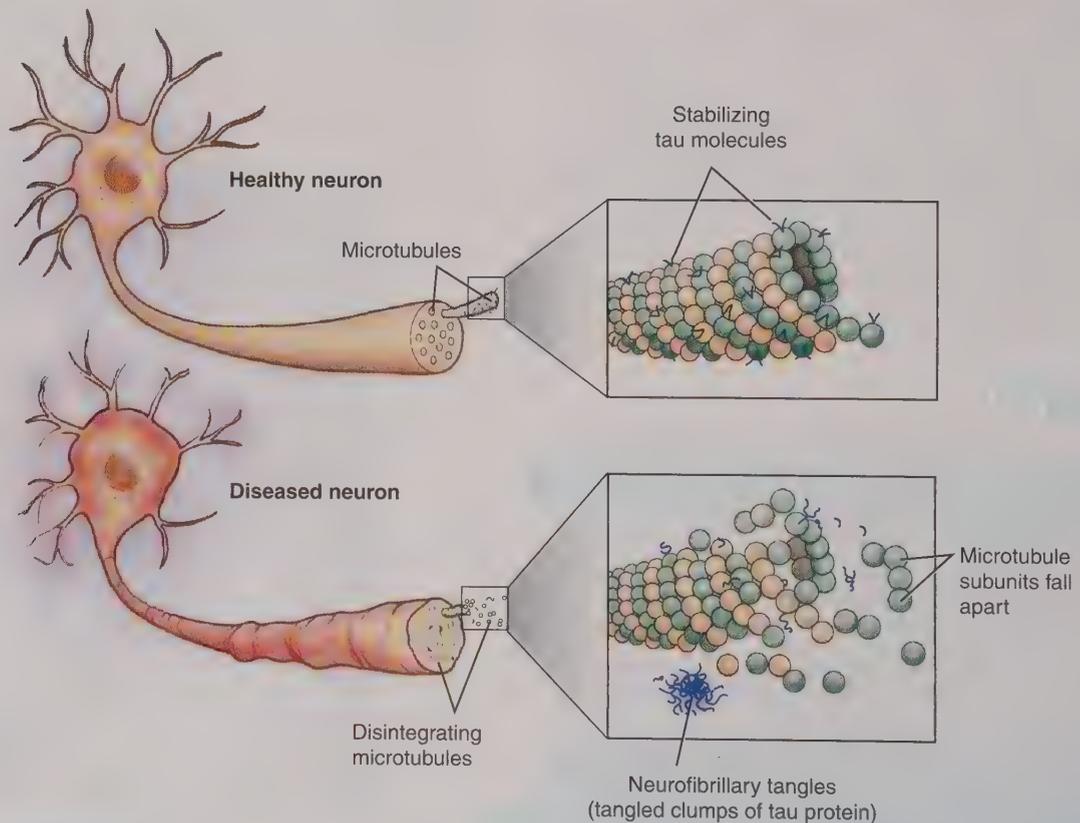

Age-related neurological changes are noted in Table 6.3. They include atrophy of the brain, decreased numbers of neuronal cells, and reduced cerebral white matter and blood flow.

**Dementia**

Dementia is defined as a progressive cognitive decline that affects a person’s social and occupational functioning (Fig. 6.4). Loss of the ability to think, reason, and remember interferes with communicating and relating to others. In addition, dementia prevents accomplishing **instrumental activities of daily living (IADLs)**, such as paying bills, making appointments, shopping, and maintaining a household. It can become severe enough to affect the individual’s ability to perform **activities of**

**Table 6.3 Age-Related Neurological Changes**

Change	Consequence
● Atrophy of the brain, occurring mainly in the cerebrum	● These anatomic changes may not have direct clinical consequences; new synapses continue to form to compensate for neuronal losses.
● Decreased number of neuronal cells, which varies from one region to another	● Decreases in information processing
● Reduced cerebral white-matter volume	● Slower working memory
● Decrease of 20% in cerebral blood flow	● Increased response time
● Synaptic loss and decreased dendritic connections	● Decreased reaction time
● Slowed nerve conduction time in peripheral nervous system shows	● Decreased motor time is task specific; familiar tasks are not affected.
● Formation of neurofibrillary tangles (aggregates of “tau” protein; see Figure 6.3) and senile plaque (can be present without dementia)	● Development of Alzheimer’s dementia

**FIGURE 6.3** Neurofibrillary tangles.

**FIGURE 6.4** Older adult woman with dementia.

daily living (ADLs), such as dressing, bathing, eating, and walking.

Dementia stems from a variety of pathological conditions. The most common is **Alzheimer's dementia**, which occurs in 50% to 80% of cases. According to the Alzheimer's Association, 5.7 million Americans are living with Alzheimer's, and by 2020, this number will rise to nearly 14 million. It is the sixth-leading cause of death in the United States. One in three seniors dies with Alzheimer's or another form of dementia. It kills more people than breast cancer and prostate cancer combined.

Some other causes of dementia are Parkinson's disease, Lewy body dementia, multi-infarct dementia, and vascular dementia. Delirium is the short-term, acute loss of some cognitive abilities. Differentiating dementia from delirium is a major clinical challenge when caring for older adults. Table 6.4 notes the differences between dementia and delirium.

### Depression

It is a myth that depression is a normal part of aging. However, it is a common problem for older adults, and it needs to be treated so that the individual can have the best quality of life. The normal emotional changes that accompany aging can develop into clinical depression. It has been found that older adults with depression are underdiagnosed and undertreated. The National Institutes of Health has reported that depression in people aged 65 and older is a major public health problem. The suicide rate of people 80 to 84 years of age is twice that of the general population.

Some symptoms of depression are similar to naturally occurring changes of aging and make diagnosis more challenging. For instance, lower energy levels, difficulty sleeping, less appetite, aches and pains, and difficulty remembering details are some of the symptoms shared by depression and the aging body. The symptoms of a major depressive episode are the same regardless of age—the presence of five or more of the following symptoms during a 2-week period

**Table 6.4** Differentiating Dementia and Delirium

Feature	Dementia	Delirium
<b>Course</b>	Chronic, gradual onset	Acute; onset often in the evening
<b>Progression</b>	Slow but even	Abrupt
<b>Duration</b>	Months to years	Hours to less than 1 month
<b>Awareness</b>	Clear	Reduced
<b>Alertness</b>	Generally normal	Fluctuating, lethargic, or hypervigilant
<b>Orientation</b>	May be impaired	Generally impaired; fluctuates in severity
<b>Memory</b>	Recent and remote impairment	Recent and immediate impairment
<b>Thinking</b>	Impaired judgment; word finding and abstraction are difficult.	Disorganized, distorted, fragmented; speech is incoherent.
<b>Perception</b>	Misperceptions can be absent.	Illusions, delusions, and hallucinations are present; patient has difficulty distinguishing reality.
<b>Psychomotor behavior</b>	Normal; may have loss of some previously learned skills	Variable; can be hypokinetic or hyperkinetic
<b>Sleep/wake cycle</b>	Fragmented; frequent naps	Disturbed; day–night reversal

that represents a change from previous functioning *and* at least one of the symptoms is depressed mood or loss of pleasure or interest:

1. Depressed mood most of the day nearly every day
2. Markedly diminished interest or pleasure in all or most activities
3. Significant, unintentional weight loss or decreased appetite nearly every day
4. Insomnia or hypersomnia (sleeping too much)
5. Psychomotor agitation or retardation (slowness or speed of movement)
6. Fatigue or loss of energy
7. Feelings of worthlessness or excessive guilt feelings
8. Diminished ability to think or concentrate
9. Recurrent thoughts of death, recurrent suicidal ideation

Once depression is identified, treatment must be prompt and aggressive, using pharmacological and nonpharmacological measures. Most antidepressants are effective for older adults. Care must be taken with the older class of antidepressants, such as amitriptyline, because these medications can cause lowered blood pressure and sedation.

Most depressed people find that support from family and friends, involvement in self-help and support groups, and psychotherapy are helpful. Psychotherapy is especially beneficial for those who prefer not to take medicine. It also is helpful for older adults who cannot take medications because of side effects, interactions with other medicines, or other medical illnesses. Psychotherapy in older adults can address a broad range of functional and social consequences of depression. The nurse is in a key position to identify possible clinical depression and to place a psychiatric referral.

### Parkinson's Disease

Parkinson's disease is a degenerative condition that primarily affects movement. It causes tremor, rigidity, and gait disturbances and can also adversely affect speech.

### Cerebrovascular Accident

Cerebrovascular accident (stroke) is primarily a vascular disease with neurological consequences. Paralysis, weakness, and speech and vision impairments can range from minor to devastating. If treated immediately, neurological damage can be minimized or prevented.

### Common Cognitive Issues

Age-related cognitive changes are noted in Table 6.5. They include mostly changes in memory and information processing. The Mini-Cog screening tool described in Box 6.3 can be used to assess cognitive impairment.

Cardiovascular health is the best physical predictor of intellectual ability in old age. In the absence of disease, older adults who keep mentally and physically active retain their mental and cognitive skills. When tasks do not require

**Table 6.5 Age-Related Cognitive Changes**

Change	Consequence
● Episodic memory diminishes with age.	● Evident in tasks requiring learning and recall of items that are not meaningful, for example, phone numbers
● Free recall diminishes.	● The ability to recall unrelated words from a list decreases.
● Working memory ability decreases.	● The ability to multitask successfully declines with aging, along with reduced ability to process complex incoming information.
● Semantic memory is maintained or may increase.	● Memory of facts and meanings and intellectual ability are unchanged.
● Processing speed decreases.	● If speed is not crucial, information is retrieved as well as in younger people.

### Box 6.3 Mini-Cog Assessment for Cognitive Impairment

The Mini-Cog is a validated, quick, simple screening tool for assessing cognitive impairment. It can be administered in 3 minutes. The assessment is completed through evaluation of memory and the ability to accurately draw a specific time on a clock. Specifically, after the patient's attention has been gained, he or she is asked to remember three unrelated words. The patient is then asked to draw the face of a clock and then draw in the hands of the clock depicting a specific time, such as 11:10. Scoring is based on how many words the patient is able to remember and whether or not the clock and time are drawn correctly.

From Borson, S., Scanlan, J. M., Chen, P., & Ganguli, M. (2003). The Mini-Cog as a screen for dementia: Validation in a population-based sample. *JAGS*, 51(10), 1451-1454.t

speed, older people perform as well as younger people. The older adult's ability to solve practical problems is generally higher than that of young adults. New learning may be more difficult, and it takes more time to store new knowledge in accessible memory. This can impact health education for older adults.

### Common Renal Issues

Age-related renal changes are noted in Table 6.6. In general, all of the changes in the renal system together result in the consequences noted.

**Table 6.6 Age-Related Renal Changes**

Change	Consequence
● Decrease in the size of the renovascular bed	● Impaired tubular reabsorption
● Decreased renal blood flow	● Reduced ability to conserve and excrete sodium
● Selective loss of cortical vasculature	● Impaired concentrating ability
● Sclerosis of glomeruli	● Reduced response to antidiuretic hormone
● Loss of glomeruli	● Inability to excrete an acid load
● Decrease in tubular size and number	● Greatly increased risk for fluid and electrolyte imbalances of many types
● Exaggerated renal vasoconstrictive response to sympathetic stimulation	● Decline in creatinine clearance

Common health issues include:

- Greatly increased risk of dehydration, not only from renal changes but also from a delayed and less-intense thirst response
- Decreased excretion of drugs and toxins, with an associated increase in side effects and morbidity
- Hyponatremia and hypernatremia related to impaired renal-diluting capacity and concentrating ability
- Both hypokalemia and hyperkalemia, which can occur from gastrointestinal losses and diuretic use. Hyperkalemia is more common in older adults

### Common Genitourinary and Reproductive Changes

Age-related genitourinary and reproductive changes are noted in Table 6.7. Changes include a general decline in bladder function and capacity, uterine and vaginal atrophy, and decreased reproductive hormone levels.

Incontinence is a problem in both men and women. Stress incontinence is more common in women. Male urinary dysfunction is characterized by hesitancy, a weak urinary stream, and a feeling of incomplete bladder emptying as a result of benign prostatic hypertrophy. Sexual dysfunction occurs in both sexes as a result of hormone decreases, organ atrophy, and decreased sexual fluids.

**Table 6.7 Age-Related Genitourinary and Reproductive Changes**

Change	Consequence
● Decline in bladder capacity, contractility, and control	● Incontinence of urine
● Decline in urethral length and sphincter strength	● Increased risk of urinary infection
● Prostate hypertrophy	● Narrowing of the urethral lumen with incomplete bladder emptying, incontinence
● Detrusor muscle instability	● Risk of uterine prolapse in females
● Pelvic floor muscle weakness	● Cessation of reproductive capacity
● Atrophy of uterus and vagina	● Decreased libido
● Markedly reduced production of estrogen and ovarian fibrosis	● Erectile dysfunction
● Decreased testosterone levels	

### Connection Check 6.2

The nurse is performing a cardiovascular assessment of an older adult patient. Which physical signs of normal aging can be expected?

- Irregular pulse and diminished lung sounds
- Heart rate of 88 bpm and a heart murmur
- Systolic blood pressure of 150 mm Hg and a fourth heart sound
- Productive cough and hoarseness

### Common Gastrointestinal Changes

Age-related gastrointestinal changes are noted in Table 6.8. Typical changes include slowed gastric emptying, delayed transport through the colon, increases in acid secretion, and a decrease in the organ size of the liver and pancreas.

Common health issues include:

- Increased risk of gastric and duodenal ulcers and atrophic gastritis
- Gastroesophageal reflux disease
- Vitamin B<sub>12</sub> deficiency and resultant anemia
- Increased feeling of fullness after a meal, with resultant reduced intake and possible nutritional deficiency
- Bone loss
- Constipation and fecal impaction. These are frequent and major problems for seniors. Delayed colon transit time and decreased strength of contraction, a tendency toward dehydration, and

**Table 6.8 Age-Related Gastrointestinal Changes**

Change	Consequence
<ul style="list-style-type: none"> <li>● Slowed gastric emptying</li> <li>● Gastric mucosal atrophy</li> </ul>	<ul style="list-style-type: none"> <li>● Gastric distention and anorexia</li> </ul>
<ul style="list-style-type: none"> <li>● Increased secretion of gastrin (hormone that increases gastric acid secretion)</li> </ul>	<ul style="list-style-type: none"> <li>● Risk of ulcer formation</li> </ul>
<ul style="list-style-type: none"> <li>● Impaired gastric mucosal barrier function</li> </ul>	
<ul style="list-style-type: none"> <li>● Reduced secretion of intrinsic factor, a protein necessary for the absorption of vitamin B<sub>12</sub></li> </ul>	<ul style="list-style-type: none"> <li>● Impaired vitamin B<sub>12</sub> absorption</li> </ul>
<ul style="list-style-type: none"> <li>● Delayed colonic transit</li> </ul>	<ul style="list-style-type: none"> <li>● Constipation</li> </ul>
<ul style="list-style-type: none"> <li>● Decreased rectal wall sensitivity</li> </ul>	
<ul style="list-style-type: none"> <li>● Decreased colonic contraction strength</li> </ul>	
<ul style="list-style-type: none"> <li>● Decreased calcium absorption</li> </ul>	<ul style="list-style-type: none"> <li>● Contributes to bone loss</li> </ul>
<ul style="list-style-type: none"> <li>● Decrease in liver size and blood flow</li> </ul>	<ul style="list-style-type: none"> <li>● Impaired clearance of drugs</li> </ul>
<ul style="list-style-type: none"> <li>● Decrease in pancreas mass and enzyme reserves</li> </ul>	<ul style="list-style-type: none"> <li>● Reduced insulin secretion; increased insulin resistance</li> </ul>

side effects from multiple medications all play a contributing role.

- Increased risk of adverse reactions and toxicity from medications as a result of liver changes
- Type 2 diabetes mellitus, also known as adult-onset diabetes, is considered epidemic among older adults. It accounts for 95% of all cases of diabetes in adults. Diagnosed and undiagnosed diabetes occurs in more than 26% of adults aged 65 and over. It can be prevented with a combination of weight loss, exercise, and dietary limitation of fats and calories.

### Nutritional Issues

Related to gastrointestinal status, nutrition in older adults can be less than optimal for a variety of reasons. As part of the aging process, the senses of taste and smell diminish and can make food seem less appetizing. In addition to the previously mentioned changes in feelings of fullness and a tendency toward constipation, there can be problems with dentition and chewing that interfere with eating a well-balanced diet. A contributing factor in malnutrition is the presence of dysphasia, or difficulty swallowing, leading to loss of appetite, dehydration, and weight loss. Dysphasia also sometimes leads seniors to “pocket” food or medication in their cheeks, leading to an increased risk of aspiration.

Medications can have side effects affecting appetite and taste, which can lead to lowered intake of food. Seniors may have more difficulty shopping and cooking because of decreased mobility. Social isolation and having meals alone can decrease the enjoyment of eating and lead to decreased intake. Those with early-onset dementia and short-term memory impairment can simply forget to eat without assistance or reminders.

A comprehensive nutritional assessment is part of the nurse’s responsibility when caring for seniors in any setting (Box 6.4). In addition, the nurse can collaborate with the nutritionist or registered dietitian because this health professional can conduct a detailed nutritional assessment.

Of particular concern is geriatric “failure to thrive,” which is a condition of unintended weight loss in older adults. The term was borrowed from pediatrics in the 1970s. The Institute of Medicine defines *failure to thrive* as “weight loss of >5%, decreased appetite, poor nutrition, physical inactivity often associated with dehydration, depression, immune dysfunction and low cholesterol.” It is a multidimensional problem with four chief characteristics: impaired physical functioning, malnutrition, depression, and cognitive impairment. In 25% to 35% of those affected, there is no identifiable medical cause.

**Cachexia** is the loss of weight and muscle mass and cannot be reversed nutritionally. It is generally associated with cancer, untreated or unsuccessfully treated AIDS, and COPD. This age-related wasting has multiple physical, psychological, and sociological causes. If not treated early, it can lead to rapid physical decline and has a poor prognosis.

### Box 6.4 Mini Nutritional Assessment

The Mini Nutritional Assessment is a screening tool used to assess the nutritional status of those aged 65 and over. The purpose of the tool is to identify individuals who are malnourished or at risk for malnourishment.

It consists of six screening questions and 12 assessment questions that seek to correlate readily available data. Some of the data measured by this tool are appetite, typical foods and liquids consumed, mobility, living situation, number of medications taken, recently experienced psychological stress, midarm and midcalf circumferences, and body weight. One advantage of the tool is that it eliminates the need for blood testing.

The clinician can use this tool along with information regarding the individual’s preferences, cultural influences, and usual mealtime desires to perform a comprehensive nutritional assessment.

The tool and more details on its background and application can be viewed online at the Hartford Institute for Geriatric Nursing Web site (<http://consultgeri.org/try-this/general-assessment/issue-9>).

## Common Musculoskeletal Changes

Age-related musculoskeletal changes are noted in Table 6.9. Decreases in muscle mass, stiffening of tendons and ligaments, decreased bone density, and increased bone loss are common.

Common health issues include:

- Arthritis, with chronic joint and skeletal pain
- Osteoporosis, with risk of fractures caused by trauma and spontaneous fractures
- Limitations in movement and ability to perform tasks, resulting in increasing dependence on others for assistance with all activities
- Development of **sarcopenia**, which is the loss of muscle mass and increase in body fat that occurs with aging. In order to prevent a reduced quality of life due to loss of strength and function, interventions to address dietary needs and exercise are needed. These include increased protein intake and resistance training. Protein supplementation in combination with resistance-training exercises enhances muscle protein synthesis and improves body composition by increasing lean mass in relation to fat mass.

**Table 6.9 Age-Related Musculoskeletal Changes**

Change	Consequence
• Decrease of 30%–40% in muscle mass	• Reduced strength of upper and lower extremities
• Increased intramuscular and subcutaneous fat	• Loss of muscle mass (sarcopenia)
• Decline in tensile strength of ligaments and tendons	• Increased risk of deconditioning; a rapid loss of strength
• Stiffening of ligaments and tendons	• Reduced joint range of motion
• Stiffer collagen in cartilage	
• Decreased bone density and bone remodeling	• Osteopenia and osteoporosis
• Increased bone loss	• Increased risk for fractures
• Decreased vitamin D absorption	
• Decrease in hand and foot movement speed	• Increased risk for falls
• Significant decline in one-legged balance	• Management of activities of daily living and instrumental activities of daily living becomes more challenging, including dressing, bathing, ambulating, doing household chores, shopping, and writing.
• Gait changes, including reduced stride length and walking speed	
• Decreased grip strength	
• Presence of postural tremor	

- Increased risk of falls as well as risk of sustaining injuries when falls occur (Boxes 6.5 and 6.6)

Fall prevention programs in the hospital should include strategies initiated before falls occur, not after a fall has been sustained. Age is a risk factor for falls because of the associated altered or ineffective gait and mobility. A more recent approach accepts that falls cannot be completely prevented. In light of this, emphasis is placed on exercise, strengthening muscles, and gait training and on teaching older adults how to fall safely without developing disabling fear.

**Deconditioning**, a rapid loss of strength, can occur when a patient is hospitalized or bedbound. In this process, bedrest or prolonged immobilization brings about

### Box 6.5 Factors Associated With Increased Risk of Falls

- Confusion and disorientation
- Symptomatic depression
- Altered elimination
- Male gender
- Dizziness or vertigo
- Particular categories of medications: benzodiazepines and antiepileptics
- Higher score on “get-up-and-go test” (see Box 6.6)

From Hendrich, A. (n.d.). *Fall risk assessment for older adults: The Hendrich II Fall Risk Model*. Retrieved from <http://consultgeri.org/try-this/general-assessment/issue-8>

### Box 6.6 Get-Up-and-Go Test

Assessment of poor balance and gait can be accomplished with a portion of the complete Tinetti get-up-and-go test. The assessment can be done by simply asking the patient to rise out of a chair and take several steps in a straight line. Patient steps are observed and should be purposeful and steady. To conduct the test, follow these steps:

- Ask the patient to rise.
  - Remain close in case the patient begins to fall.
  - Ask him or her to walk forward to a specified spot, turn, return to the chair, and sit back down.
  - Look for shuffling gait, lack of arm swing, unequal shoulder or hip height, the ability to turn without support, and the ability to stand and sit in a controlled fashion.
- Score 0 = Patient can rise unassisted/hands-free.  
 Score 1 = Patient rises using arms to push up in one attempt.  
 Score 3 = Patient makes several attempts to push up and succeeds to stand.  
 Score 4 = Patient is unable to stand without assistance.  
 A total accumulative score of 5 or more indicates a higher risk of falls.

From Hendrich, A. (n.d.). *Fall risk assessment for older adults: The Hendrich II Fall Risk Model*. Retrieved from <http://consultgeri.org/try-this/general-assessment/issue-8>

pathological changes in muscles and bones that result in serious disability for older adults. It is estimated that 31% of older adults are discharged from a hospitalization with deconditioning and a significant decrease in ability to perform ADLs.

### CASE STUDY: EPISODE 3

The home-care nurse completes the first visit with the assistance of the Spanish interpreter and the patient's daughter, who lives in the same building. The findings include some shortness of breath with activity, no lower extremity edema, and normal breath sounds. Initial vital signs are as follows:

Heart rate: 95 bpm

Blood pressure: 154/88 mm Hg

Respiratory rate: 22

Temperature: 98.8°F (37.1°C)

The patient's weight is obtained on a home scale. The nurse now has baseline measurements against which to gauge future changes. For patients with HF, weight changes of 2 pounds or greater in 24 hours or 5 pounds in a week require immediate intervention to prevent exacerbation of heart failure or pulmonary edema and rehospitalization. Education on the safe use of home oxygen is conducted by the nurse, and both the patient and her daughter are able to give a correct return demonstration. The home-care nurse sees that Ms. Gomez has come home from the hospital with a decreased ability to ambulate steadily and has suffered a loss of strength and muscle tone. On the basis of all of these findings, the nurse identifies several problems that need to be addressed in the plan of care: decreased activity tolerance, deconditioning, and potential for exacerbation of HF. Interventions to address these findings include directing the patient to maintain her daily weight and providing education on a low-salt diet. A referral for physical therapy is also indicated in order to develop a strength-building program and provide placement of assistive devices (cane, walker, wheelchair) as needed for the provision of safe ambulation. A home health aide is also requested to assist Ms. Gomez with her personal care and her ADLs while she builds her strength and activity tolerance.

The nurse encourages Ms. Gomez to express her concerns and fears related to increasing dependence on others and her changing role in the family. "I'm so tired and weak," she responds. "I'm a useless old lady now. I used to cook for everyone, and now I don't have the energy." It will be important for the nurse to reinforce progress as it develops and to help keep Ms. Gomez focused on her recovery. The nurse will utilize both family and outside social and community agencies to keep Ms. Gomez engaged and supported...

## Common Immunological and Skin Changes

Age-related immunological and skin changes are noted in Table 6.10. There is a general diminishing of immune functioning. The skin's ability to function as a barrier is also diminished.

Common immunological and skin-related health issues include:

- Blunted responses to infection, making diagnosis more difficult. Older adults are less likely to have a fever or elevated white blood cell count or obvious manifestation of symptoms. When older adults develop infections, particularly urinary tract infections, the only sign that may be apparent is a change in their behavior. They may not have any pain or changes in their pattern of urination but will display sudden mood shifts, memory loss, inattention, confusion, or lethargy. These are beginning signs of delirium and need to be investigated immediately (see Table 6.4 on dementia and delirium).

**Table 6.10** Age-Related Immunological and Skin Changes

Change	Consequence
● Decrease in phagocytic activity and bactericidal function	● Increased susceptibility to and mortality from infections
● Decrease in T-cell function	
● Decreased inflammatory responsiveness	● Altered clinical signs of acute infection; absence of fever
● Decreased antibody response to antigen stimulation of 90% by age 75	● Decreased allergic reactions
● Diminished antibody production in response to vaccination or infection	● Reactivation of infectious diseases
● Reduction in humoral immunity	
● Decreased melanocytes	● Increased skin cancer risk
● Decreased collagen	● Dry skin; rough skin
● Progressive loss of elastic tissue	● Low-grade skin infections
● Decreased elasticity	● Slow wound healing; weak scars
● Ineffective DNA repair	
● Loss of dermal thickness	● Decreased barrier function
● Smaller adjoining surface between dermis and epidermis	● "Paper-thin" skin
	● Less resistance to shearing forces
	● Increased potential for skin tears

- Increased risk of skin breakdown from pressure when older persons are sedentary, immobile, or bedbound. Four forces that contribute to skin breakdown are friction, pressure, shearing, and maceration. Prevention or moderation of these mechanisms is essential to avoid skin breakdown.
- Shingles that occurs with a history of herpes zoster (chickenpox). The significance of a shingles outbreak is the risk of developing chronic severe pain even after the shingles lesions have healed. This is termed *postherpetic neuralgia* (PHN) and is most common in older adults. A new shingles vaccine called Shingrix (recombinant zoster vaccine) was licensed by the U.S. Food and Drug Administration (FDA) in 2017. The CDC recommends that healthy adults 50 years and older get two doses of Shingrix, 2 to 6 months apart. Shingrix provides strong protection against shingles and PHN.
- Increased incidence of xeroderma (dry, rough skin) and associated itching
- Intrinsic and extrinsic factors that are responsible for skin problems in older adults. Intrinsic factors are controlled by cellular processes that are programmed by genetic inheritance. Extrinsic aging is the result of external factors such as environmental conditions, smoking, ultraviolet light, medications, and chronic illness. Intrinsic and extrinsic factors can affect the ability of the skin to regenerate and aid in wound healing.

### Common Sensory Changes

Age-related sensory changes are noted in Table 6.11. Decreases in visual acuity and hearing are common. The prevalence of hearing loss doubles with every age decade, and nearly two-thirds of Americans older than 70 years have a clinically significant hearing impairment, according to the Institute of Medicine and the National Research Council. The hearing loss that occurs with age is usually caused by the intrinsic aging of the auditory system. It rarely develops into total deafness. It can most often be managed with a hearing aid. There are many types and varieties from which to choose, and they fit a range of budgets. Hearing loss can be partially prevented by protecting the ears and hearing from excessive noise. The damage from noise is cumulative over a lifetime.

Common health issues related to vision and hearing loss include:

- Safety concerns related to the older adult's ability to navigate his or her environment. Whether older adults are in their homes or outside of them, vision and hearing impairments prevent awareness of obstacles to walking, objects in pathways, oncoming pedestrians or vehicles, and changing traffic signals. Vision impairments can prevent safe medication administration if labels and directions are misread or are unreadable. Safe operation of devices and appliances can be affected as well. In particular, the

**Table 6.11** Age-Related Sensory Changes

Change	Consequence
• Gradual opacity of lens	• Decreased visual acuity
• Increased corneal thickening	• Decreased ability to discriminate between color intensities, particularly blues and greens
• Yellowing of lens	• Decreased ability to focus in dim light; increased sensitivity to glare
• Impaired adaptation to darkness	• Reduced adaptation to changes in light intensity
• Increased rigidity of the pupil	• Presbyopia (failure to bring near objects into focus)
• Decreased elasticity of lens capsule	
• Hardening of the lens	
• Loss of accommodation	
• Reduction in fine oculomotor control	• Decreased dynamic visual acuity
• Reduction depth perception	• Decreased ability to detect movement and judge distances, which can affect driving skills
• Decreased lacrimation	• Dry eyes; increased risk of eye infections
• Presbycusis (age-related hearing loss distinct from other causes of hearing loss) that occurs for unknown reasons	• Loss of high-frequency tones
	• Impaired discrimination in source of sound

question of how long safe driving can continue is a difficult issue. Often, older adults resist giving up the ability to drive because it signals a major loss of independence. The safety concerns of all are a priority in making the decision to stop driving.

- Hearing problems that contribute to miscommunication. Conversations and comments directed to the individual can be misinterpreted. Older adults may begin to avoid social contacts because they cannot really hear what others are saying. When healthcare practitioners are conducting assessments and interviews, incomplete or erroneous information may be collected as a result of the older adult not understanding what is being asked. Lower tones of voice are heard better than high-pitched tones.
- There are long-term and public health implications of sensory impairments, including the risk for costly health outcomes of disability, depression, cognitive impairment, and dementia. Sensory loss impedes self-care and independence and can therefore negatively affect caregivers.

### Connection Check 6.3

When assessing the patient with cognitive impairment, the nurse should be aware that which condition is the most common cause of dementia?

- A. Vascular dementia
- B. Parkinson's disease
- C. Alzheimer's disease
- D. Multi-infarct dementia

## SAFETY AND PSYCHOSOCIAL ISSUES

Care priorities can be broadly discussed as safety and psychosocial issues. Safety considerations are a priority and have been discussed throughout this chapter in relation to the physical changes that naturally occur with aging. They include physical safety and medication safety. Another safety concern is the potential for abuse and being protected from possible abusive situations involving strangers and caregivers alike. Complicating the maintenance of safety for older adults is the fact that they often do not perceive that they are at risk. Psychosocial priorities include successfully navigating the transition into an older adult, attending to the social isolation and loneliness that can accompany old age, attending to housing and financial issues that accompany that transition, and establishing a plan of care or advance directives if the older adult becomes critically ill. When older adults have a chronic illness, an important goal is to prevent hospitalization and maintain care for the individual in his or her home environment. This requires additional services to maintain a safe home environment, with modifications suited to increased needs and the provision of medical equipment needed to treat various conditions.

### Safety Issues

#### Physical Safety

Naturally occurring changes in strength, flexibility, balance, and reflex time combine to put older adults at risk for accidents and falls. If the home environment is not upgraded to compensate for the frailties of age, there can be risks of falling in the bathtub or shower, tripping over rugs and electrical cords, and falling from stepladders and makeshift climbing devices. There is less room for compensation and less margin for safety when a fall does occur. There is a greater chance of serious injury, such as fracture, hemorrhage, or loss of consciousness. Older adults may have fewer social supports and family members available to help or check on them, so they may be injured and unable to move or summon help in a timely manner.

Another important safety issue is driving. Older adult drivers are at risk and put others at risk. Decreased speed of reflex responses and decision making as well as visual and hearing problems can prevent awareness of dangerous traffic situations. Early, unrecognized dementia can impair an older adult's ability to follow traffic lights, directions, and other drivers' signals.

In the hospital setting, older adult patients have safety issues due to the development of behavioral problems as a result of the illness for which they are hospitalized. Sudden severe illness, dehydration, infections, and dementia can result in delirium. Patients with delirium suffer from confusion, disorientation, and altered level of consciousness and sometimes have aggressive behavior. In the past, the use of restraints was common in these circumstances to keep older adults safe, but it is now recognized that the current standard of practice is the avoidance of either physical or chemical (medicating with sedatives or antipsychotics) restraints. The present approach combines investigating possible causes of the behavior; addressing unmet needs and physiological conditions; reducing fall risk by modifying the environment; and providing close, continual observation and assistance (Box 6.7). Included in the approach is the use of the least invasive treatments. The challenge is to balance the patient's rights with his or her safety.

#### Medication Safety

In addition to the dangers of physical trauma from falls and accidents, older persons are at risk of injury from their own medications. The average number of prescription medications taken by those over age 65 is six. The individual may also take a number of over-the-counter medications. Each medication has its own side effects, and the combination of drugs increases the chances for adverse or deleterious effects. Older adults often need education, guidance, and support in order to follow the medication regimens that their primary providers are prescribing. Some of the normal aging changes in visual acuity, memory, and strength can interfere with correct and successful medication management. Problems such as being able to read the prescription label, remembering to take the medication at the right time and the right number of times a day, being able to open the pill bottle or container, and being able to go to the drugstore for refills if the pharmacy does not deliver are all factors that increase the risk of errors in medication management.

### Box 6.7 The 4 Ps

In an effort to increase patient safety and decrease patient falls, many hospitals have implemented the evidence-based practice of hourly rounding. The focus of the hourly rounding is on the 4 Ps: pain, potty, positioning, and possessions. Patients are checked to ensure that their pain needs are met and that their essential possessions (call bell, tissues, glasses) are close at hand. Patients are asked if they need to visit the bathroom or if they need a change of position. In addition to increased patient safety, improved skin integrity or decreased skin breakdown and increased patient satisfaction are outcomes of hourly rounding focusing on the 4 Ps.

### Safety Treatment by Tic Tac

#### Alert

A creative exercise for medical residents at the University of California, Irvine

Medication regimens can be confusing and difficult to follow. Patients often do not take their medications the way they are prescribed. Nonadherence to medication regimens can cause adverse events, sometimes leading to hospitalization, nursing home placement, and death.

A 1-week-long “Mock Medication Compliance Exercise” using different flavors of Tic Tacs was developed. Medical residents were asked to take five mock medications for 7 days:

- “Lisinopril 20 mg” bid
- “Metformin 500 mg” tid
- “Fosamax 70 mg” weekly
- “Coumadin 5 mg,” 1 tablet on Monday, Wednesday, and Friday and 1/2 tablet on Tuesday, Thursday, Saturday, and Sunday
- “Pravastatin 40 mg” at bedtime

The regimen was designed very deliberately to address the multiple issues providers must consider and nurses must monitor before and after prescribing:

1. Five mock prescriptions were given because research indicates that most medication problems start when drug lists are at least five medications long.
2. All “medications” prescribed were given at various times during the day to illustrate the complexities of drug regimens.
3. Each “medication” was to be taken as if it were a real drug.
  - A. “Fosamax,” for example, was to be taken on an empty stomach with a glass of water while in an upright position.
  - B. “Metformin” was to be taken with food to avoid potential gastrointestinal intolerance. Participants were forced to remember to take “metformin” with them to work so that they could take it at lunchtime.
  - C. “Pravastatin” was deliberately prescribed because it is one of the statins less likely to interact with “Coumadin.”
  - D. “Lisinopril” was given because “the patient” was diabetic and would normally take an angiotensin-converting enzyme inhibitor to prevent nephropathy.

There was only one resident who was 100% compliant. He happened to have worked as a pharmacy technician before starting medical school. Most residents were not completely compliant with the medication regimen. The reasons residents did not take the Tic Tacs were

very similar to the reasons patients usually give: forgot them at home, got too busy to take them at home, didn't like the way the Tic Tacs tasted, had difficulty opening a child-resistant prescription vial, or had difficulty cutting the “Coumadin” Tic Tac in half. All residents reported that it was a difficult and very eye-opening experience.

Polypharmacy has been identified as a major problem for older adults. Polypharmacy is generally defined as being prescribed six or more medications and/or using a potentially inappropriate medication. Tools containing criteria for medication evaluation are readily available for the nurse to use. One of the most commonly used tools is the Beers Criteria for Potentially Inappropriate Medication Use in Older Adults.

### Safety Beers criteria

#### Alert

The Beers criteria identify medications that have been determined by an expert consensus panel as having potential risks that outweigh their potential benefits. It was last updated in 2015. The criteria apply to adults aged 65 years and older. This tool helps nurses identify medications that may increase the risk of adverse drug reactions. The purpose is to increase safety in medication use and improve medication monitoring. Part 1 of the tool lists 48 individual medications or classes of medications to avoid in older adults. The following are some of the medications identified in Part 1:

Amitriptyline (Elavil)  
 Barbiturates except phenobarbital  
 Cyclobenzaprine (Flexeril)  
 Diazepam (Valium)  
 Diphenhydramine (Benadryl)  
 Hydroxyzine (Vistaril)  
 Hyoscyamine (Levsin, Anaspaz)  
 Meperidine (Demerol)  
 Naproxen (Aleve, Naprosyn)  
 Promethazine (Phenergan)

The successful treatment of disease depends on compliance with the ordered regimens. People who are in compliance with their medications reduce their risk of rehospitalization and emergency department visits. When seniors have self-care confidence and take the right medication at the right time in the right form and dose, the chances of increased effectiveness and successful treatment of their condition increase greatly (see Evidence-Based Practice).

## Evidence-Based Practice

### Beyond Social Support: Self-Care Confidence Is Key for Adherence in Patients With Heart Failure

A study from 2017 demonstrated that heart failure patients who have confidence in their ability to provide self-care had an improved ability to adhere to their plan of care. Interventions targeting self-care confidence are crucial.

Hammash, M. H., Crawford, T., Shawler, C., Schrader, M., Lin, C. Y., Shewekah, D., & Moser, D. K. (2017). Beyond social support: Self-care confidence is key for adherence in patients with heart failure. *European Journal of Cardiovascular Nursing*, 16(7), 632–637.

### Potential for Abuse

The potential vulnerability of older adults due to increased physical weakness and possible cognitive impairment as well as the stress that they may place on their caregivers makes them unintended and intended targets for abuse. They may suffer physical and emotional abuse at the hands of their caregivers. They may be neglected or abandoned if, for example, the caregiver becomes overly stressed. Older adults can also become victims of scams and financial exploitation by strangers. Their bank accounts are sometimes depleted by the caregivers who have assumed responsibility for their finances. Although the true frequency of elder abuse is not entirely known, a 2010 study published in the *American Journal of Public Health* found that 10% of people over the age of 60 are subject to emotional, physical, or sexual abuse or to neglect. Other studies have determined that elder abuse is vastly underreported, indicating that for every reported case, there are 24 unknown cases. The CDC has released new uniform definitions for elder abuse. Releasing uniform definitions of elder abuse will help guide future research and provide a more accurate depiction of elder abuse cases across the country. This in turn can help increase elder abuse funding at the government level.

#### Safety

#### Alert

● The CDC defines elder abuse as “an intentional act or failure to act by a caregiver or another person in a relationship involving an expectation of trust that causes or creates a risk of harm to an older adult.” In addition, the CDC has identified and defined five types of elder abuse:

- **Physical abuse:** Intentional use of physical force—including hitting, kicking, pushing, slapping, and burning—that causes illness, pain, or injury.
- **Sexual:** Forced or unwanted sexual interaction, including unwanted sexual contact or penetration or noncontact sexual harassment.
- **Emotional or psychological:** Verbal or nonverbal behaviors that inflict anguish, mental pain, fear, or distress, including

name-calling, humiliating, destroying property, or preventing someone from seeing friends or family.

- **Neglect:** Failure to meet basic needs, such as food, water, shelter, clothing, hygiene, and essential medical care.
- **Financial:** Improperly using money, benefits, belongings, property, or assets. Examples of financial abuse include taking money from a bank account or changing a will.

## Psychosocial Issues

### Psychosocial Transition

Those aged 65 and over are entering a unique developmental stage. Becoming old is not only a biological process but also a social and cultural one. As people age, their roles and status in life change, and they acquire another social identity. In the United States, the social identity of older adults is often one of being less valued and less important. Older adults are often neglected, dismissed, or ignored. They can experience a form of discrimination termed **ageism**, where they are treated with less respect and consideration because of their advanced age.

One of the tasks this group faces is how to accept a different and more dependent role after an adult lifetime of independence. Older adults need to adjust to job loss or retirement from a career and physical losses that range from minor vision, hearing, and mobility impairments to major disabilities from the chronic diseases and illnesses of old age. Issues concerning the management of one's material and financial belongings are now evident. There are losses of friends, family, and spouses through death. There is an alteration in self-image as the aging body changes in sometimes drastic ways. Sexual identity and sexual activity are dramatically changed as well. Sometimes complicating this adjustment, older adults commonly live in senior communities, which are designed to provide for their special needs and activities but they also act to segregate this population from the rest of the community and the society around them. All of these changes can increase the potential for social isolation.

There is also the realization of mortality and the associated spiritual, philosophical, and intellectual processes that people face toward the end of life. Eric Erikson described eight developmental stages in life, the last one being late adulthood from age 60 to death. In this stage, the strength of wisdom comes from accumulated experience. As one looks back on life, there is a sense of accomplishment and contentment that the individual has made a contribution to the world in his or her own way. One has acceptance of the life one has lived. Erikson called this *integrity*. There is also the possibility of despair, with the look back showing perceived failures and uncertainty about life's meaning. This can contribute to a fear of death. As with all developmental tasks, older adults learn through a process of awareness and realization, trial and error, adaptation, acceptance, and integration of the newly changed self and new roles

into the personality. As a healthcare provider, the nurse needs to have an awareness of this stage and develop strategies to assist and educate older persons while maintaining their dignity and autonomy as much as possible (Box 6.8).

### Advance Directives

Families are the first source of care and comfort that people look to in times of need. Those who cared for the young must now depend on the young to care for them. When older adults are planning for their future, an open discussion with family members should take place regarding what kind of care they would like to receive if they become incapacitated. **These wishes can be delineated in legal documents referred to as advance directives.** It is most important to have someone older adults trust acting on their behalf if they become unable to speak for themselves. A healthcare proxy is a legally recognized document that outlines who has the authority to act on the older adult's behalf in making medical decisions.

Another important document is a **living will.** The living will outlines acceptable healthcare choices and treatments as well the treatments that are not acceptable. As part of the living will, the person may decide to direct healthcare providers not to perform cardiopulmonary resuscitation (CPR) if he or she should suffer a cardiac arrest. This is termed a *do-not-resuscitate (DNR) order*. These important decisions should be made while the older adult is still able to clearly and accurately communicate his or her desires regarding medical treatment in the event of a serious or terminal illness.

Family members most often fill the role of healthcare proxy as well as serving as legal guardians of the older adult's finances, which is termed a *power of attorney*. When there are no family members alive or willing to assume these responsibilities, friends, neighbors, or any trusted, willing, and capable adult can fulfill these roles. In cases where there is no one available, a court-appointed guardian is necessary.

### Box 6.8 Interventions to Help Decrease Social Isolation

The nurse advocates for and facilitates the following measures:

- Assessment of family and community resources for possible contacts
- Assessment of family members' proximity to the senior and their ability to visit/transport
- Identification of neighbors who are available to help
- Location of community senior centers, volunteer organizations/YMCA, and faith-based organizations able to provide support
- Ensuring safe transport so that seniors can leave the home for activities:
  1. Arrange senior transportation vans.
  2. Locate other local organizations providing care service.
  3. Assist in arranging transportation and senior-discount fares.

The nurse is in an important position to facilitate and encourage these conversations and decisions.

### Housing and Finances

Most people reaching retirement age and beyond hope to be able to live independently for as long as possible. Some of them have homes that are paid for and family members who are willing and able, both physically and geographically, to assist them. Some have retirement income and savings that will be used to supplement their Social Security income. A few will continue to work in some capacity either because they need to or because they want to work and stay active. For others, there will be obstacles if they do not have retirement benefits or have not saved enough money. There may be no family members willing or able to help them. They may not be physically able to live on their own and may have to relocate to a community where help is available or hire assistants to come into their home. Often, the first people who become aware of these circumstances are healthcare practitioners. When older adults are hospitalized and a discharge plan is formulated, it may be discovered that there is no one at home to assist the recovering older adult.

### RESOURCES

With the growing population of aged individuals and the "oldest old" increasing in numbers, the caregivers themselves are advancing in years; a 90-year-old woman might have her 70-year-old daughter as a caregiver who has needs of her own. The "graying" of America is bringing about a crisis in the circumstances of living to old age without the necessary resources. In addition, the increasing numbers of Alzheimer's patients and those suffering from other forms of dementia are placing serious financial and emotional burdens on caregivers. There are growing numbers of agencies that provide information, education, support, and links to other agencies for caregiver assistance. There is very little availability of volunteer assistance in home care for older adults. Most of the agencies that provide aides and home-maker assistants charge an hourly fee for the services.

The first place to seek assistance is the local community or city of residence. Community and government agencies offer support by way of education, referrals to smaller groups, and links to Web sites. In addition, literature can be downloaded or received in the mail, and help with applying for financial assistance can be provided. Community groups often give free assistance on a limited basis and have volunteers available to provide transportation to senior centers, shopping centers, or doctor appointments. There are some groups that provide free meals and food delivery and transportation services. These are usually church- or religion-affiliated organizations.

The Social Security Office can provide information. State governments have a senior citizens department and an office of aging. The federal government also has an Office of Aging.

There are a growing number of geriatric care managers who are experts in knowing about and finding resources. These can include assistance in finding housing; assistance in the home for a range of activities; and management of financial resources, including filing Medicaid applications.

Medicare is the government health insurance program that covers medical expenses for people aged 65 and over. It provides for care in the hospital, provider visits, and limited home-care assistance. Many people are not aware that Medicare does not cover nursing home care and that the coverage for home care does not extend past a few months. After this period, patients and their families must develop a plan using a combination of family and privately hired help.

Medicaid is the government insurance program for those whose incomes are below a certain level at which they are unable to afford the healthcare they need. Medicaid provides for nursing home care or care at an assisted living facility. It also provides for a nursing attendant in the home for 8 or more hours a day if the patient has his or her own home and a caregiver who has assumed responsibility for supervision of his or her affairs.

In order to manage the issues that present themselves in this stage of life, it is usually necessary to put together several strategies that combine the following: a private-pay, supplemental insurance plan; community agencies such as Meals on Wheels or senior centers; Social Security, Medicare, and/or Medicaid; and available family or neighbors. The most active community and government agencies serving as resources for older adults and their caregivers, with links to their Web sites, can be found on [www.DavisAdvantage.com](http://www.DavisAdvantage.com).

### Connection Check 6.4

The nurse caring for an older adult patient with early signs of dementia incorporates which priority nursing diagnosis into the plan of care?

- Altered nutrition, less than nutritional requirements
- Altered nutrition, greater than nutritional requirements
- Risk for injury
- Activity intolerance

### Connection Check 6.5

While assisting family members in finding resources to care for their father, the nurse is aware that which agency can provide assistance with nursing home costs?

- Medicare
- Social Security Administration
- Medicaid
- Department of Health and Human Services

## Making Connections

### CASE STUDY: WRAP-UP

The home-care nurse makes a follow-up visit to Ms. Gomez to evaluate the effectiveness of the plan of care and to continue assessing and monitoring the patient's physical and psychosocial status. Ms. Gomez has weighed herself and recorded the result with the assistance and guidance of her home health aide and her daughter. The nurse provides education to all three about the patient's medications and supervises the daughter in filling the mediplanner. A physical therapist has visited and has initiated a home exercise program with Ms. Gomez. The nurse reviews with the patient her dietary intake for the previous day and reinforces the need for strict salt restriction in order to avoid fluid retention. To promote incentive for maintaining this, the nurse reminds Ms. Gomez that the goal is to prevent rehospitalization. Ms. Gomez continues to express feelings of frustration and hopelessness about her diagnosis and the aging process. The nurse requests a social work referral to provide a more in-depth psychosocial assessment and emotional support. During subsequent visits, the nurse assesses the patient for the absence of symptoms, no weight gain, the absence of edema, reduction of salt intake, and adherence to the medication schedule. Ms. Gomez is evaluated for returning strength and gradual increase in activity tolerance. The goal of aging at home is accomplished through collaboration with a team of people that includes the patient and her family, the provider, the home health aide, the physical therapist, and the social worker.

### Case Study Questions

- Which statement by Ms. Gomez indicates that the teaching has been effective?
  - "I'm not concerned with my weight as long as I take my pills."
  - "Walking too much puts a strain on my heart."
  - "I need to take my medications to stay out of the hospital."
  - "As long as I take my meds, I can use salt."
- The nurse monitors Ms. Gomez for the development of cognitive issues. Which clinical manifestations are early indications of the development of dementia? (*Select all that apply.*)
  - Short-term memory impairment
  - Acute onset of reduced awareness
  - Gradual onset of impaired judgment
  - Fluctuating levels of alertness
  - Personality changes

3. The nurse caring for Ms. Gomez, who is suffering from deconditioning from the recent hospitalization, should add what to the plan of care? (*Select all that apply.*)
  - A. Maintenance of bedrest to prevent a fall
  - B. Range-of-motion exercises
  - C. Limited dietary intake because of decreased activity
  - D. Referral for physical therapy
  - E. Education for safe ambulation and fall prevention
4. The nurse includes which information in the teaching plan about the management of heart failure? (*Select all that apply.*)
  - A. Strict portion control at meals
  - B. Daily weight and record
  - C. Taking stairs instead of elevators
  - D. Avoiding artificial sweeteners
  - E. Salt restriction and salt substitutes
5. Which of these assessment findings will alert the nurse to possible worsening of heart failure? (*Select all that apply.*)
  - A. Sudden inability to breathe while lying flat
  - B. Blurred vision
  - C. Craving for sweets
  - D. Loose bowel movements
  - E. A weight gain of 2.5 pounds in 1 day

of organs. Systolic hypertension and a fourth heart sound are examples of normal consequences of the aging process. Respiratory changes put older adults at higher risk of infection. Gastrointestinal changes can result in decreased appetite and constipation as well as nutritional deficiencies. Renal changes result in a decrease in effective functioning over time. Musculoskeletal changes are evident in the decreased muscle mass of older adults, which is one factor that puts them at an increased risk for falls.

The cognitive changes of aging and the rising incidence of dementia are particularly challenging care issues. Most older adults retain their intellectual abilities but experience decreases in the speed of processing and the amount of information that can be processed at one time. However, the incidence of dementia is growing, with Alzheimer's dementia being the most common form afflicting older adults. This presents an increasingly significant care burden on individuals and on society as a whole.

The safety of older adults is a priority because they are at greater risk of injury as a result of decreases in strength, balance, and reaction time. Fall prevention is a priority of care in all care settings where older adults are seen. Adherence to medication regimens is not only a safety concern, but evidence has also shown that it produces a greater likelihood of positive outcomes and decreased hospitalizations and emergency department visits for patients with heart failure. Another safety priority is protection from abuse, both unintentional and intentional.

Documenting end-of-life wishes with an advance directive and living will after conversations with family members is essential to ensure that the older adult's healthcare priorities are maintained.

Knowledge of how and where to find resources to assist older adults is essential to the nurses who care for older adults in greater numbers. The federal government and individual state governments have established departments of aging that provide extensive information and referral sources for patients, caregivers, and professionals alike. Medicare and Medicaid are government agencies that provide healthcare coverage for older adults. Medicaid is the government program that covers nursing home costs when individual finances have been depleted.

## CHAPTER SUMMARY

The demographics of older adults show that they are an increasingly larger percentage of the U.S. population and are growing rapidly. Older women outnumber older men and are more likely to be widows and live alone. Minority populations are steadily growing and require a culturally sensitive approach in order to achieve positive outcomes. One consequence of increased numbers of older adults is growing pressure on families, communities, and government agencies as they try to meet their care needs.

Age-related changes in each system come primarily as a result of slowing and stiffening processes and the atrophy

# Chapter 7

## Oxygen Therapy Management

Denise Owens

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Reviewing concepts of oxygenation
2. Discussing indications for oxygen therapy
3. Describing methods of oxygen delivery
4. Explaining indications, management, and complications of artificial airways
5. Discussing the rationale, methods, and complications for mechanical ventilation
6. Contrasting various mechanical ventilator modalities
7. Clarifying indications and nursing implications for the following respiratory care modalities:
  - a. Incentive spirometry
  - b. Postural drainage
  - c. Chest physiotherapy
  - d. Nebulizer treatments
  - e. Intermittent positive-pressure breathing

### CONCEPTS

- Assessment
- Communication
- Nursing
- Nursing Roles
- Oxygenation
- pH Regulation
- Safety

### ESSENTIAL TERMS

Atelectasis  
Barotrauma  
Bi-level positive airway pressure (BIPAP)  
Bronchospasm  
Chest physiotherapy (CPT)  
Compliance  
Continuous positive airway pressure (CPAP)  
Decannulation  
Diffusion  
Dyspnea  
Hypercapnia  
Hypercarbia  
Hypoxemia  
Hypoxia  
Incentive spirometer  
Mechanical ventilation  
Mechanical ventilator  
Oxygen concentrator  
Oxygen toxicity  
Oxygenation  
Perfusion  
Pneumothorax  
Postural drainage  
Pressure support  
Pulse oximetry  
Respiration  
Respiratory weaning  
Stridor  
Tidal volume  
Tracheostomy  
Tracheotomy  
Subcutaneous emphysema  
Surfactant  
Ventilation

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Sarah Graham, a 70-year-old Caucasian female, presents to the emergency department with complaints of shortness of breath, chills, weakness, and having a productive cough with yellow/green secretions. At night, she sleeps with two pillows behind her back to make it easier to breathe. Mrs. Graham is having difficulty trying to finish a sentence without stopping to rest to catch her breath. It hurts when she tries to take a deep breath, and the cough gets worse.

History includes chronic obstructive pulmonary disease (COPD), hypertension (HTN), osteoarthritis, and hypothyroidism.

T	101°F (38°C)
Pulse	102 beats per minute
RR	32 breaths per minute
BP	142/84 mm Hg
PO	88% on room air

**History:** She has a history of COPD, HTN, osteoarthritis, and hypothyroidism.

**Social History:** Mrs. Graham states that she smokes one pack of cigarettes per day but has decreased the number of cigarettes because of her difficulty in breathing. She has smoked since she was 16 years old. She has not had much of an appetite the last several days and complains of being tired and weak all the time.

#### Home Medications:

Boniva IV every 3 months  
 Lisinopril 40 mg every day  
 Potassium 20 mEq every day  
 Vitamin D 1,000 units every day  
 Synthroid 0.1 mg every day  
 Fish oil every day  
 Colace 100 mg as needed  
 Spiriva 1 capsule inhalation daily...

## OVERVIEW OF OXYGEN THERAPY

### Physiology

The human body requires oxygen in order to sustain life. The inhaled air consists of 21% oxygen, 78% nitrogen, and 1% miscellaneous gases. Through ventilation, perfusion, and diffusion, oxygen is delivered to the cells and carbon dioxide (CO<sub>2</sub>) is removed to maintain proper oxygenation and tissue perfusion. **Ventilation** is the movement of air in and out of the lungs. **Perfusion** is the gas exchange of

oxygen and CO<sub>2</sub> at the alveoli-capillary membrane. **Diffusion** is the movement of solutes from an area of high concentration to an area of low concentration. **Oxygenation** is the process of oxygen passively diffusing from the alveoli to the blood, where the oxygen attaches to the hemoglobin or dissolves in the plasma. This process of the transport of oxygen from the inhaled air to the cells and the transport of CO<sub>2</sub> in the opposite direction is called **respiration**. The main function of the respiratory system is to deliver oxygen to the lungs (ventilation) where, through diffusion, oxygen is released into the blood at the alveolar-capillary membrane (perfusion); the oxygen is then transported to the tissues, and CO<sub>2</sub> is transported by the blood to the lungs and released at the alveolar-capillary membrane through diffusion and then released as a gas.

The respiratory system consists of the upper respiratory tract and the lower respiratory tract. As air enters the body through the upper airways (the nose, mouth, pharynx, nasopharynx, oropharynx, laryngopharynx, and larynx), the air is warmed, humidified, and filtered as it passes through these structures into the lower respiratory tract. As the air enters the lower respiratory tract (the trachea, bronchi, bronchioles, and into the alveoli), the air continues to be filtered by hairlike cilia that line the respiratory tract. In some patients who are unable to maintain a normal airway, a **tracheotomy** (surgical opening of the trachea) may be performed to create a **tracheostomy** (an opening/stoma directly into the trachea). The care of patients with tracheostomies is discussed throughout this chapter.

The alveoli surface area has two types of cells that make gas exchange possible. Type I cells (squamous) are thin, flat cells that allow for rapid gas exchange between the alveoli and the blood. Type II cells (pneumocytes) secrete **surfactant**, a phospholipid and protein substance that covers the alveoli to prevent the alveoli from collapsing by reducing surface tension in the alveoli, allowing for gas exchange to take place. Surface tension is the force present within the alveoli of the lungs that causes the alveoli to collapse. The surfactant reduces the surface tension, therefore reducing the tendency of the alveoli to collapse. When the lungs have improved **compliance** (ease of expansion of the lungs), less effort is needed to expand the lungs. Oxygen diffuses across the capillary bed that surrounds the alveoli from an area of higher concentration to the blood, the area of lower concentration. Oxygen is carried to the tissue in two ways: 97% of the oxygen is attached to hemoglobin, and 3% is dissolved in plasma. Carbon dioxide is carried by the circulatory system to the lungs, where it is removed from the blood through diffusion into the alveoli and is exhaled as gas.

The normal PaO<sub>2</sub> (partial pressure of oxygen in arterial blood) level, the part of total blood gas pressure exerted by oxygen gas, is 80 to 95 mm Hg, and the normal SaO<sub>2</sub> (percentage of oxygen saturation of arterial blood) level is 95% to 100%. When these levels are sustained, there is adequate oxygenation for the body.

The disruption in oxygenation can be either in ventilation or perfusion, causing **hypoxia** and **hypoxemia**. Hypoxia

occurs secondary to insufficient oxygen to meet the metabolic demands of the cells, tissues, and organs. Hypoxemia develops when there are low levels of oxygen in the arterial blood. When there is a disruption in oxygenation, the cells may become hypoxic (decreased oxygen) because of an inadequate amount of oxygen in the system, causing a decrease in tissue oxygenation.

Hypoxemia is manifested when the PaO<sub>2</sub> level in the blood becomes less than 60 mm Hg or the SaO<sub>2</sub> level becomes less than 90% when breathing room air. Hypoxemia also occurs when the PaO<sub>2</sub> level and/or SaO<sub>2</sub> is less than a desirable amount for specific clinical situations, particularly when supplemental oxygen is administered. Trauma, acute myocardial infarction, and surgery are examples of acute care situations in which hypoxemia may develop.

The patient who does not have adequate oxygenation may experience early signs of hypoxia, including a change in mental status, anxiety, restlessness, and/or confusion, because the cells in the brain are not receiving an adequate supply of oxygen. Other clinical manifestations include increased respiratory and heart rates, as well as **dyspnea** (subjective feeling of difficulty breathing). On the basis of the clinical presentation, these patients may require supplemental oxygen to maintain proper oxygenation to the cells.

Oxygen therapy is initiated when an oxygenation concentration higher than room air (21%) is needed to treat or prevent the hypoxia. Oxygen is a medication and requires an order from a healthcare provider. When a patient is receiving oxygen therapy, the patient must be closely monitored to prevent complications associated with oxygen therapy. When evaluating the oxygen order, the nurse adheres to the six rights of medication administration and continuously monitors the concentration of oxygen that is prescribed by the healthcare provider.

### Connection Check 7.1

The nurse includes which nursing diagnosis in the plan of care for the patient admitted with pneumonia?

- A. Anxiety related to hypoxia
- B. Deficient knowledge related to cause of disorder
- C. Fear related to the threat of pain
- D. Ineffective breathing pattern related to decreased surfactant

### Age-Related Considerations

Through the aging process, the pulmonary function of the older adult undergoes changes, which are not the same in every aging adult and may vary in each individual person. These changes include the loss of lung elasticity, an enlargement and rigidity of the chest wall, a decrease in muscle strength, and a decrease in alveolar surface area. Elastin and collagen changes cause a loss of lung elasticity. Intercostal cartilage calcifies, causing the chest wall to enlarge and become rigid. Respiratory muscles weaken because of the

increased loss of mobility of the chest wall. The decrease in alveolar surface area causes a decrease in the diffusion capacity for oxygen, causing lower oxygen levels in the older adult. These changes can lead to decreased expansion of the lungs, less depth with breathing, less effective cough, a decrease in gas exchange, and alveolar collapse, all of which affect ventilation and perfusion in the aging adult. Older adults who have a significant history of smoking, a sedentary lifestyle, obesity, and a diagnosis of chronic disease, along with the changes in pulmonary function associated with the aging process, are at greater risk for developing hypoxia and hypoxemia (see Geriatric/Gerontological Considerations).

## Geriatric/Gerontological Considerations

### The Older Population

Between 2010 and 2050, the United States is projected to experience rapid growth in the older population. In 2050, the number of Americans 65 and older is projected to be 88.5 million. The baby boomers are largely responsible for the increase in the older population.

With the aging population growing and people living longer, more of the aging population will have health problems. The older adult is at risk for aspiration and infection due to the aging process and other health issues, including pulmonary conditions and pulmonary diseases. Patient education is needed and should include adequate nutrition and leading a healthy lifestyle.

National Center for Health Statistics. (2016). *Chapter 1: Introduction. Healthy People 2020 midcourse review*. Retrieved from [https://www.cdc.gov/nchs/healthy\\_people/index.htm](https://www.cdc.gov/nchs/healthy_people/index.htm)

### Indications for Supplemental Oxygen

Oxygen therapy is initiated with the intent of treating and preventing the clinical manifestations of hypoxia. Indications for oxygen therapy include PaO<sub>2</sub> less than 60 mm Hg or SaO<sub>2</sub> less than 90% in a patient breathing room air or a PaO<sub>2</sub> and/or SaO<sub>2</sub> below the indicated or prescribed range for the patient's clinical situation. Conditions that result in low PaO<sub>2</sub> or SaO<sub>2</sub> levels include respiratory, cardiac, and/or central nervous system disorders. Oxygen therapy may be indicated when there is an increased need for oxygen, such as a patient with a fever, infection, anxiety, and/or anemia, to meet the metabolic demands of these conditions. These conditions cause an increase in the work of breathing and an increased workload of the heart to meet the metabolic demands at the cellular level. The oxygen needs are unmet because of ventilation (intake) and/or perfusion (delivery) problems, and the cells become hypoxic, which can lead to the death of the cell. The body at this time requires an

oxygen concentration greater than 21%. Through oxygen therapy, the patient can receive the higher concentration of oxygen that the body requires.

In order to prevent the cells, tissues, and organs from dying, supplemental oxygen may be required to meet the needs of the body and to sustain life. Oxygen therapy is ordered to maintain a PaO<sub>2</sub> level greater than 80 mm Hg and an SaO<sub>2</sub> level greater than 95%, to decrease the workload of the heart, and to decrease the work required by the patient to maintain optimal oxygen levels. Oxygen therapy is used for both acute and chronic medical conditions.

### Contraindications to Oxygen Administration

Generally, there are no contraindications to oxygen therapy when appropriate assessment, including a history of respiratory disease, and indications are present. Use extreme caution with patients who are hypoxic and have chronic **hypercapnia** or **hypercarbia** (increased PaCO<sub>2</sub> levels in the blood), which is often observed in patients with COPD. In a patient with COPD, a low PaO<sub>2</sub> level (hypoxia) is the patient's primary drive for breathing. Oxygen therapy should be started with caution in patients with COPD because delivering too much oxygen may interfere with the hypoxic drive for breathing, leading to decreased respiratory effort and ultimately rate.

### Oxygen Monitoring and Measurement

The need for and the effectiveness of oxygen therapy are assessed and monitored by physical assessment of the patient, pulse oximetry, and arterial blood gas (ABG) analysis. **Pulse oximetry** is a noninvasive method that can be used in any setting to obtain the oxygen saturation of hemoglobin (SpO<sub>2</sub>) in the blood. The pulse oximeter is the device used to perform the measurement. It uses a light sensor that has two sources of light (red and infrared) that pass through the skin to measure the amount of hemoglobin saturated with oxygen. The light is absorbed by the hemoglobin in the blood; the more hemoglobin saturated with oxygen, the higher the oxygen saturation. The measurement is converted to a digital value representing the percentage of hemoglobin saturated with oxygen. Normal SpO<sub>2</sub> levels are 95% to 99%.

The pulse oximeter can be used as an intermittent assessment or as a continuous monitoring measurement. When used intermittently, the pulse oximeter can be used on an as-needed (prn) basis for patients who may be at risk for hypoxemia. Examples include patients on a medical-surgical floor who are admitted with pneumonia who may experience hypoxia or patients after surgery who may be at risk for hypoxia because of the depressant effects of anesthesia. The pulse oximeter can be used continuously on the patient who is being weaned from oxygen therapy or the patient who is intubated and requires a continuous display

of the oxygen saturation. In addition to the SpO<sub>2</sub> level, many pulse oximeters display the pulse rate. Many health-care facilities use the pulse oximeter when assessing the vital signs of the patient to monitor the patient's SpO<sub>2</sub> level.

The pulse oximeter is most often applied to the finger, but the earlobe, bridge of the nose, or the toe also can be used. The accuracy in the reading of the pulse oximetry depends on several variables, including the hemoglobin level of the patient, adequate perfusion to the area where the pulse oximeter is placed, the temperature of the area where the pulse oximeter is placed, and the patient's ability to oxygenate. The pulse oximeter does not have the ability to measure ventilation or the PaCO<sub>2</sub> and can lead to a potential delay in the detection of hypercapnia. Pulse oximetry is one part of a complete assessment of the patient's oxygenation status and is not a substitute for the need to obtain ABGs. When documenting the results of the patient's pulse oximetry, the nurse should include the SpO<sub>2</sub> level, the amount of oxygen the patient is receiving, and the patient's respiratory rate.

Arterial blood gas analysis is used to measure the pH, PaO<sub>2</sub>, PaCO<sub>2</sub>, HCO<sub>3</sub><sup>-</sup> (bicarbonate), and SaO<sub>2</sub> levels of the blood. The ABG sample is obtained through an arterial puncture, usually via the radial or femoral artery, or through an indwelling arterial line or pulmonary artery catheter. Obtaining an ABG provides the most accurate measurement of cellular oxygenation, and the results guide the management and treatment for patients with oxygenation and acid-base disorders. See Table 7.1 for normal ABG values.

### NONINVASIVE OXYGEN DELIVERY METHODS

There are a number of different noninvasive oxygen delivery devices available for the treatment of patients with oxygenation issues, and several factors are considered when ordering oxygen therapy. These factors include the patient's age, disease process (acute or chronic), degree of hypoxia, and the ability of the patient to tolerate the oxygen device that is ordered.

**Table 7.1 Normal Arterial Blood Gas Values**

Arterial Blood Gas	Normal Range
pH	7.35–7.45
PaO <sub>2</sub>	80–95 mm Hg
PaCO <sub>2</sub>	35–45 mm Hg
HCO <sub>3</sub> <sup>-</sup>	22–26 mEq/L
SaO <sub>2</sub>	95%–100%

**CASE STUDY: EPISODE 2**

A physical examination reveals a frail woman who complains of shortness of breath, chills, and weakness, and she has a productive cough of yellow/green sputum. She states that at night she has to use two pillows to make her breathing easier. Now she has problems trying to finish a sentence without stopping to take a breath. It hurts when she tries to take a deep breath, and she notices the coughing gets worse. Mrs. Graham is alert and oriented times 3, crackles are noted in the lower bases of the lungs with an occasional expiratory wheeze, and her peripheral pulses are palpable but weak. Her abdomen is flat with bowel sounds present. An indwelling urinary (Foley) catheter is placed, with 80 mL of amber-colored urine noted in the urinary drainage bag. Her skin is warm to the touch and pink in color. She is placed on the cardiac monitor, which reveals a heart rate of 102 bpm with occasional premature ventricular contractions. A peripheral IV line is started with 0.9% normal saline at 80 mL an hour.

The following diagnostic results are received:

**Chest x-ray** indicates consolidation in the lower lobes of the lungs.

**ABGs:**

pH	7.32
PaO <sub>2</sub>	56 mm Hg
PaCO <sub>2</sub>	52 mm Hg
HCO <sub>3</sub> <sup>-</sup>	30 mEq/L
SaO <sub>2</sub>	88%

**Hematology results:**

A **sputum culture** is sent to the laboratory.

**Blood cultures** x2 are sent to the laboratory.

Because of these findings, Mrs. Graham is started on a Venturi mask at 28% oxygen...

## Low-Flow Delivery Devices

Low-flow delivery devices include the nasal cannula, simple face mask, partial rebreather mask, and nonrebreather mask. These low-flow delivery systems provide oxygen in concentrations that vary with the patient's respiratory pattern. The supplemental oxygen is mixed with the room air, which lowers the oxygen level that is actually delivered to the patient. The true amount of oxygen that is delivered to the patient, known as the fraction of inspired oxygen (FiO<sub>2</sub>), cannot be determined and can vary according to the

patient's ability to breathe (see Table 7.2 for details on obtaining an oxygen saturation reading).

### Nasal Cannula

The nasal cannula device delivers oxygen through tubing that has two soft prongs on one end that are placed into the patient's nares (Fig. 7.1); the other end of the tubing is connected to an oxygen source. This is the most commonly used delivery system because it is more comfortable, mobile, easy to use, and less expensive than other delivery systems. The nasal cannula is used for patients who require low levels of oxygen to maintain adequate oxygenation, and it works well for the patient who has adequate ventilation but requires a higher oxygen concentration than what is available in room air. This delivery device of supplemental oxygen is used most commonly with patients in the hospital, long-term care units, and home settings. The oxygen concentrations of 24% (1 L/min) to 44% (6 L/min) are administered via the nasal cannula. Patients with chronic lung disease or those who require long-term oxygen therapy find the nasal cannula easy to use and comfortable to wear. The patient who retains CO<sub>2</sub>, such as the patient with COPD, will use the lower amount of oxygen (1–2 L/min) so that the patient does not lose the hypoxic drive to breathe. The oxygen can be humidified when it is passed through a bubbling humidifier of sterile water to decrease the risk of irritation to the nasal passage and drying of the mucous membranes. The area behind the ears where the oxygen tubing is placed, as well as the nasal septum, should be assessed for skin breakdown.

### Face Masks

Face masks are used when a patient requires a higher oxygen concentration. There are several different types of masks used, including simple, partial rebreather, and nonrebreather masks. The mask should fit properly on the patient's face, covering the patient's mouth and nose, and is kept in place with elastic straps that go around the head. This delivery system is hard to use on a patient who is anxious or claustrophobic. Assess for skin breakdown under the mask and behind the ears. The disadvantage to the face mask is that it must be removed for the patient to eat. The patient is placed on a nasal cannula when eating, and the mask is replaced after eating.

### Simple Face Mask

The simple face mask (Fig. 7.2) is used when the patient needs a moderate amount of oxygen to maintain an adequate PaO<sub>2</sub> level. This device uses oxygen flow rates between 5 and 10 L/min and can deliver oxygen concentrations from 40% to 60%. The amount of oxygen that the patient receives depends on the patient's respiratory pattern and proper fitting of the mask. The higher flow rate (5–10 L/min) assists the patient in preventing rebreathing of exhaled CO<sub>2</sub> that can be retained in the mask, thus delivering more oxygen. Rebreathing exhaled CO<sub>2</sub> may lead to complications such as hypoxemia because the patient does not receive an adequate supply of oxygen. This device is used for short-term oxygen therapy and is useful when transporting a patient.

**Table 7.2 Obtaining an Oxygen Saturation Reading**

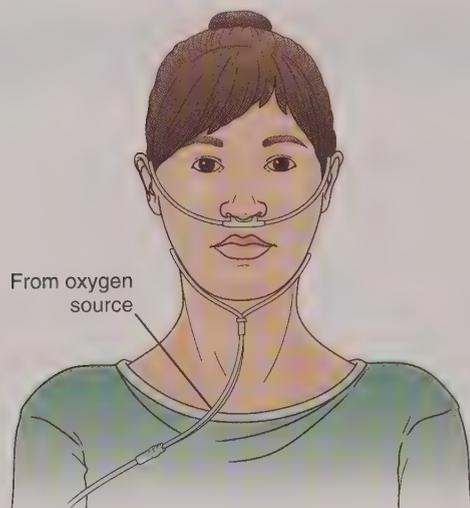

Action	Rationale
Wash hands.	Decreases transmission of microorganisms
Explain the procedure to the patient and/or family members.	Informs patient and family of the purpose of procedure and decreases anxiety and apprehension about procedure
Select a sensor site; the finger is used most frequently. Remove nail polish.	Nail polish decreases light transmission and alters reading of the pulse oximeter.
Choose a site that has signs of adequate perfusion (warm skin, adequate capillary refill) and is free of moisture.	Peripheral vasoconstriction, edema, and moisture can interfere with the SpO <sub>2</sub> reading because of decreased circulation to these areas.
Apply the sensor to allow the light source to be directly opposite the light detector.	This allows for proper determination of the pulse oximetry reading.
Turn device on when sensor is in place.	Allows time for self-testing and detection of the waveforms before values are displayed
Determine accuracy of detected waveform by comparing the displayed pulse rate on the device to the simultaneously assessed heart rate of the patient.	If the pulse rate detected by the oximeter does not correlate with the patient's actual heart rate, the oximeter is not detecting sufficient arterial blood flow. Consider reapplying the sensor again or attaching the sensor to another area such as the earlobe.
Leave sensor in place until oximeter displays constant value and pulse display reaches full strength.	Reading usually takes 10–30 seconds depending on the site used.
Monitor for excessive movement.	Movement may result in a false reading; ask the patient to rest the hand on a flat surface.
If monitoring oxygen saturation continuously, assess the SpO <sub>2</sub> alarm limits that are set. The alarms are usually preset by the manufacturer.	Alarms should be set to alert the nurse of any changes in the patient's condition.
Assess skin integrity under the sensor every 4 hours and adjust pulse oximeter as needed.	The sensor can cause skin irritation or tissue ischemia.
If SpO <sub>2</sub> is assessed intermittently, remove probe and turn device off.	Allows for the patient to continue with activities. Batteries will not last if device is left on.
Wash hands.	Decreases transmission of microorganisms
Documentation includes the SpO <sub>2</sub> results, type and amount of oxygen therapy delivered, vital signs, and education provided to patient and/or family.	Readings are one segment of a complete evaluation of the patient. This allows for comparing of patient data and monitoring for any changes in the patient's condition.

### Partial Rebreather Mask

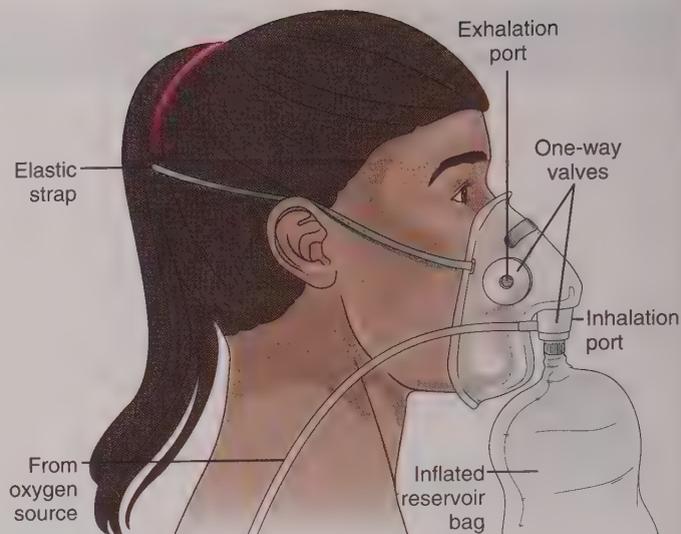

A partial rebreather is a simple mask with a reservoir bag attached (Fig. 7.3). The patient breathes in the oxygen from the reservoir bag; on exhalation, the bag refills with oxygen, and the exhaled gases exit through small holes on both sides of the mask. This allows for a greater concentration of oxygen to be delivered to the patient than with the simple face mask. Oxygen flow must be maintained to keep the reservoir bag one-third to one-half full on inspiration. Maintaining a flow rate of 8 to 10 L/min to this device can provide 50% to 75% oxygen to the patient. This device is useful for short-term oxygen therapy.

### Nonrebreather Mask

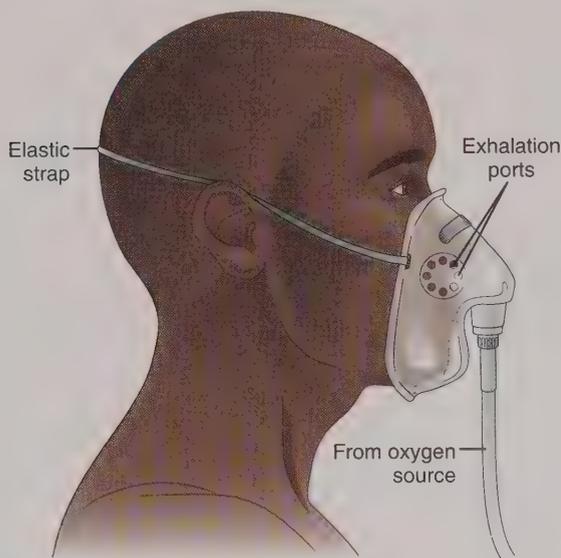

A nonrebreather mask is similar to the partial rebreather mask except this mask has one-way valves (Fig. 7.4). There is a one-way valve between the bag and the mask that prevents the exhaled air from entering the bag, thus ensuring a higher/more accurate oxygen concentration in the reservoir. This device also has one-way valves on both sides of the mask to prevent room air from entering the mask on inhalation. The reservoir bag must be kept inflated at one-third to one-half full on inspiration so that the patient receives the optimal amount of oxygen, and there should be a minimal flow rate of 10 L/min to maintain bag inflation. The nonrebreather mask can provide up to 90% oxygen to the patient.

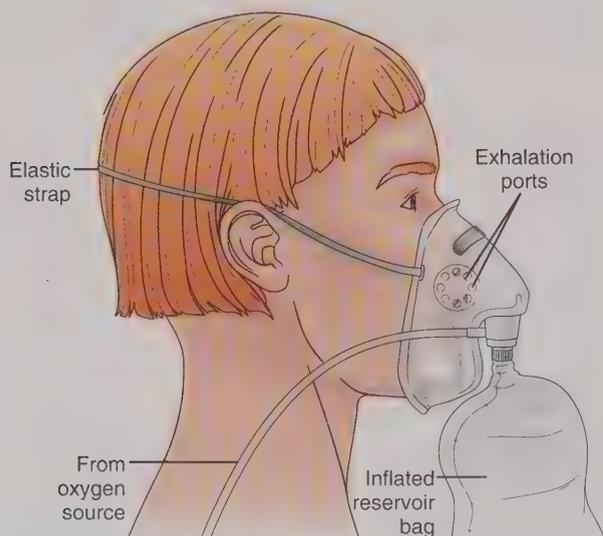

**FIGURE 7.1** Nasal cannula.

**FIGURE 7.4** Nonrebreather mask.

**FIGURE 7.2** Simple face mask.

**FIGURE 7.3** Partial rebreather.

## High-Flow Delivery Devices

High-flow delivery devices include the Venturi mask, aerosol mask, tracheostomy collar, T-piece adapter, and face tent. These high-flow devices deliver set oxygen concentrations regardless of the patient's breathing pattern. Humidity is provided with the oxygen with specific devices. The oxygen source is passed through a humidifier that allows the oxygen concentration to be humidified before reaching the patient. The humidifier has a dial that is used to adjust the oxygen concentration being delivered to the patient. This provides the patient with oxygen concentrations of 24% to 100% with a minimal flow of 10 L/min.

### Venturi Mask

The Venturi mask is the most commonly used high-flow delivery device because this device delivers the most accurate oxygen concentration (Fig. 7.5). This device can deliver oxygen concentrations of 24% to 60% by using different adapters and by adjusting the oxygen flow from 2 to 15 L/min. The adapter indicates the flow rate of oxygen that should be maintained to provide the prescribed percentage of oxygen to the patient. The mask is fitted to the face, and an adapter is attached to the bottom of mask; the other end of the adapter is attached to the oxygen tubing, and then the tubing is connected to the oxygen source. There are Venturi masks that have an adapter with a dial to determine the oxygen concentration to be delivered to the patient. The patient with a chronic lung disorder benefits from this device because this device delivers a more accurate oxygen concentration to the patient on inspiration.

### Aerosol Mask

The aerosol mask is indicated for the patient who requires high-humidity oxygen concentrations. The patients who benefit from aerosol masks are those who have been extubated (discontinuation of an endotracheal tube [ETT]), those who have had upper airway surgery, or those with thick secretions. This device delivers aerosol therapy that

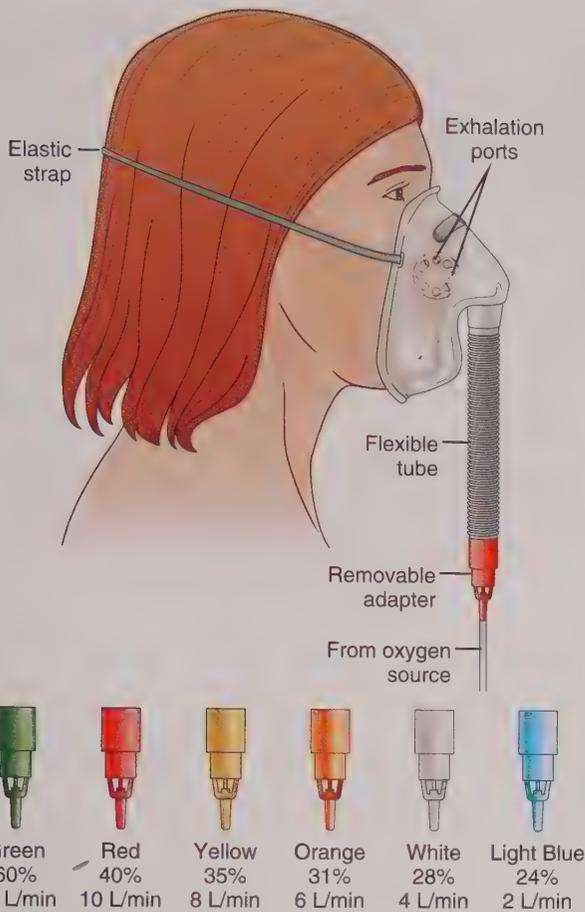

FIGURE 7.5 Venturi mask.

includes humidification and/or medications in order to liquefy secretions for easier removal. It is also used to humidify the respiratory tract, relieve **bronchospasm** (contraction of the smooth muscles of the bronchioles), and reduce edema of the respiratory tract.

### Tracheostomy Collar

The tracheostomy collar is used for patients with a tracheostomy. This device allows humidified oxygen to be delivered to the patient via the tracheostomy collar because the air is inhaled directly through the tracheostomy and bypasses the usual humidification and filtration processes provided by the nose and mouth. This collar fits over the tracheostomy site, and there are adjustable straps that fit around the patient's neck (Fig. 7.6). The device provides high humidity with the prescribed oxygen concentration.

### T-Piece Adapter

The T-piece adapter, much like the tracheostomy collar, is a device that may be used when weaning a patient from the **mechanical ventilator** who still has an endotracheal, nasotracheal, or tracheostomy tube in place. This device connects an oxygen source with humidification to the ETT or tracheostomy tube. The T-piece adaptor provides high humidity with the desired oxygen concentration and allows a spontaneous breathing trial (SBT) to be performed prior to extubating the patient. The SBT requires the patient to

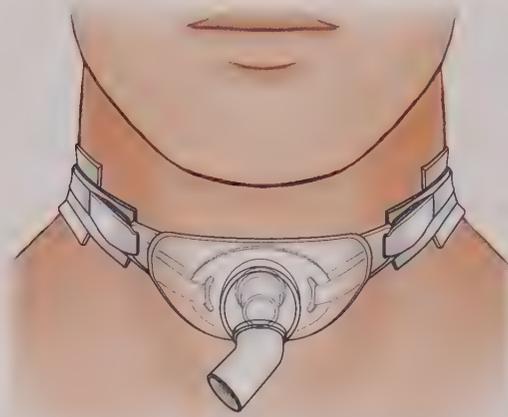

FIGURE 7.6 Tracheostomy collar.

maintain spontaneous breathing through the T-piece adapter.

### Face Tent

The face tent is a device used for patients who have facial trauma, have burns, or have had upper airway surgery. The device fits under the chin and extends just above the ears. This device allows the delivery of oxygen mixed with a mist.

### High-Flow Nasal Cannula

High-flow nasal cannula uses an air-oxygen blender (blends  $O_2$  with compressed air), active humidifier, single heated tube, and nasal cannula to deliver heated and humidified medical gas up to 60 L/min. The advantages include reduced anatomical dead space, positive end-expiratory pressure (PEEP), constant  $FIO_2$ , and humidification. Soft and flexible nasal prongs are used for the comfort of the patient.

## Connection Check 7.2

The nurse is reviewing orders on the patient who is to receive supplemental oxygen. It is a priority for the nurse to follow up with the provider about which order?

- Nasal cannula at 2 L/min
- Venturi mask at 24% concentration
- Nasal cannula at 8 L/min
- Venturi mask at 50% concentration

## Noninvasive Positive-Pressure Ventilation

Noninvasive positive-pressure ventilation (NPPV) delivers positive pressure to the airway without the use of an artificial airway to keep the alveoli open and decreases the risk of nosocomial infections. The positive pressure is delivered to the patient using a nasal mask, a full face mask, or nasal pillows. The patient can receive **continuous positive airway pressure (CPAP)** or **bi-level positive airway pressure (BIPAP)**. Continuous positive airway pressure provides the patient with a preset, continuous positive pressure throughout

the respiratory cycle. The positive pressure is delivered continuously with each breath and is used to keep the alveoli open and to increase the amount of oxygen delivered. The constant pressure keeps the alveoli open during inspiration and exhalation. Bi-level positive airway pressure provides the patient with two preset pressures; one preset pressure is delivered during inspiration, and the other preset pressure is delivered during exhalation. This modality provides positive pressure at the end of exhalation along with a higher positive airway pressure during inhalation, which allows for better oxygenation and ventilation. A ventilator may be used as a backup for patients with periods of apnea.

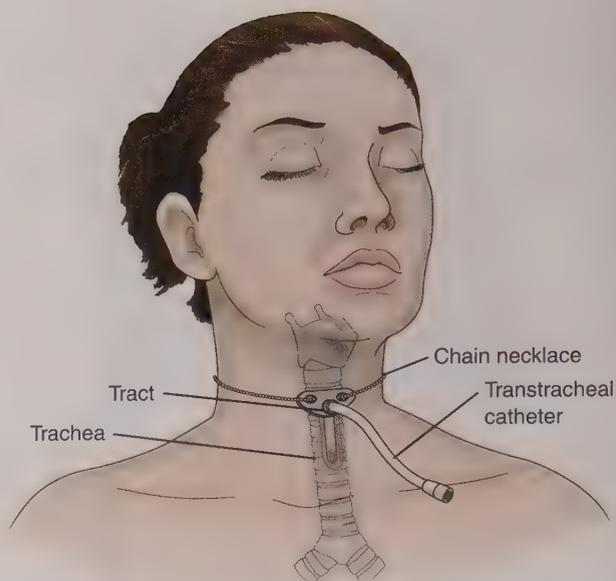

### Long-Term Oxygen Therapy

Long-term oxygen therapy may be indicated for the treatment of hypoxemia in patients with a diagnosis of COPD or with specific clinical conditions associated with hypoxemia, such as heart failure, cystic fibrosis, or sleep apnea. Indications for long-term oxygen therapy include a  $\text{PaO}_2$  level less than or equal to 55 mm Hg or an  $\text{SaO}_2$  level less than or equal to 88% in patients breathing room air or a  $\text{PaO}_2$  of 55 to 59 mm Hg or  $\text{SaO}_2$  less than or equal to 89% with specific clinical conditions such as cor pulmonale, heart failure, or polycythemia greater than 55%. Some of these patients may not meet the criteria for continuous home oxygen therapy but may develop hypoxemia during exercise, ambulation, or during sleep. The indication for oxygen therapy during specific activities, but not continuously, includes an  $\text{SaO}_2$  level falling to levels less than or equal to 90%. The nasal cannula can be used for continuous or intermittent oxygen therapy in the home.

Transtracheal oxygen therapy (TTOT) is another option for long-term oxygen therapy for patients and delivers oxygen directly into the trachea using a small, flexible, plastic catheter (Fig. 7.7). Surgical placement can be done as an outpatient under local anesthesia (modified Seldinger technique), or placement can be done as an inpatient using conscious sedation anesthesia. Advantages to using TTOT over a nasal cannula include less nasal and ear irritation and the catheter being less visible. Some patients have been shown to have a reduction in oxygen flow requirements by 50% to 60% in resting oxygen flow rate and a 30% decrease with activity. The patient and caregiver must be educated on the TTOT procedure, care of the tracheal stoma (opening into the trachea created by the tracheostomy), replacement of the catheter, home oxygen use, and mucus problems that may develop when using TTOT. The TTOT team provides the education and support for the patient and caregiver.

#### Oxygen Delivery

The nurse instructs the patient and/or caregiver in oxygen safety and informs the patient and/or caregiver of the different ways oxygen is available. Oxygen is available in liquid oxygen, compressed oxygen, or as an oxygen concentrator. Liquid oxygen is made by cooling the oxygen gas, changing it to a liquid. Liquid oxygen is often used for people who are more active because large amounts of oxygen can be stored

**FIGURE 7.7** Transtracheal oxygen therapy.

in smaller portable units. These smaller units can be refilled from a large reservoir canister. The disadvantage is that there is an evaporation loss when the canisters are not used.

An **oxygen concentrator** is an electrical device that produces oxygen by removing nitrogen, water vapor, and hydrocarbons that are in the air and extracts the oxygen. The advantage of this system is that it does not need to be resupplied and is less expensive than liquid oxygen. Oxygen concentrators can deliver oxygen at concentrations of 85% or greater and include stationary devices, portable devices, and systems that can transfill oxygen cylinders. This method is less expensive and easy to maintain, and the concentrator runs on electricity or a battery. The disadvantages are that some devices are noisy, and people may need a backup source of oxygen in case of a power failure.

Compressed oxygen is stored under pressure and can be supplied in large cylinders to be used as stationary units in the home. The large tanks are heavy and can be used only in a stationary manner. Smaller units are available for portability and as backup units in case of a power failure or equipment malfunction. See Box 7.1 for instructions for in-home oxygen use.

A respiratory therapist is involved in the transition from the hospital to the use of long-term oxygen in the home. Respiratory therapists assess, treat, and evaluate patients with respiratory or cardiopulmonary disorders. They consult with other healthcare professionals and practice under the direction of the healthcare provider.

**Safety Alert** The Joint Commission's 2014 National Patient Safety Goals require a home safety risk assessment that includes a functional smoke detector, fire extinguisher, and home safety plan.

## Box 7.1 Education for Patients Receiving Home Oxygen

- The referral agency for home oxygen equipment contacts the patient and/or caregiver to set a delivery time for oxygen equipment and supplies to the home.
- The agency sends a respiratory therapist or a home health nurse to demonstrate the use, care, and cleaning of the equipment.
- There are three types of oxygen sources that are available: liquid oxygen, compressed gas, and an oxygen concentrator.
- The education starts in the hospital and continues on discharge to home.
- Explain and educate the patient and caregiver.
- Oxygen is a fire hazard. Oxygen makes a flame burn hotter and faster.
- Never smoke or let anyone smoke while oxygen is in use.
- Place “No Smoking” signs within the home.
- Keep oxygen at least 6 feet away from flames or heat sources, such as gas stoves, space heaters, candles, and fireplaces.
- Check all electrical equipment that is within the same room as the oxygen for frayed cords.
- Keep a fire extinguisher in the home near the oxygen source.
- Store and keep oxygen tanks in an upright position.
- Do not change the settings of the oxygen without the health-care provider’s permission.
- Check the amount of oxygen in the tank and order more in advance so that it does not run out.
- Always have extra equipment and supplies in case of an emergency.
- Discuss an emergency plan; in case of power failure, call 9-1-1.
- Observe the tops of the ears and behind the ears for skin breakdown; the ears may be padded if irritation is noted.
- Assess oral and nasal passages for dryness and/or irritation; water-based gel may be used for protection.

## COMPLICATIONS OF OXYGEN THERAPY

### Oxygen Toxicity

**Oxygen toxicity** can develop as a result of the administration of an oxygen concentration equal to or greater than 50% over 24 to 48 hours. The high levels of oxygen can cause damage to the alveolar-capillary membrane and inactivate surfactant production in the lungs. Loss of surfactant production can result in the walls of the alveoli sticking together and collapsing. The collapse of the alveoli makes it very difficult to reinflate the alveoli, and they can become filled with fluid or blood if there is damage to the alveoli. This can lead to pulmonary edema, **atelectasis** (collapse of alveoli), and hemorrhage and can progress to acute respiratory distress syndrome (ARDS). Prevention of oxygen toxicity is essential for patients who are receiving oxygen therapy and can be facilitated by administering the lowest oxygen concentration to maintain the PaO<sub>2</sub> level within the patient’s normal range.

### Absorption Atelectasis

Absorption atelectasis occurs when high levels of oxygen are administered and cause the alveoli to collapse. The high levels of oxygen dilute the nitrogen that normally prevents the alveoli from collapsing and replace nitrogen with oxygen in the alveoli. The high level of oxygen causes the nitrogen to be “washed out” of the alveoli. The oxygen diffuses from the alveoli into the bloodstream faster than it is replaced by inhaled oxygen, causing the alveoli to collapse.

### Mucous Membrane Dryness

Oxygen has a drying effect on the mucous membranes because the humidification of the inspired air is lessened for the patient who is receiving oxygen therapy. When oxygen therapy is prescribed at levels greater than 4 L/min via nasal cannula, humidification should be added. The humidification occurs when the oxygen is passed through sterile water, causing bubbling in the container, and then goes through the tubing to the patient’s mask or cannula. This process restores the humidity that is normally present in the room air.

### Infection

Oxygen therapy can be a potential cause of infection. The equipment used to deliver oxygen, such as the humidifier, nebulizer, nasal cannula, oxygen tubing, and/or masks, can be a source of bacteria causing infection due to moisture that may accumulate. Healthcare facilities have protocols and/or policies in place that state when the equipment is to be changed to prevent the cause of infection.

### Precautions in Oxygen Therapy

Delivering oxygen to patients with COPD may inhibit their stimulus to breathe. In patients with chronic lung disease such as COPD, the stimulus for breathing is hypoxia rather than an increase in CO<sub>2</sub> levels. The central chemoreceptors located in the medulla are normally sensitive to the increased arterial carbon dioxide (PaCO<sub>2</sub>) levels. These receptors stimulate breathing and increase the respiratory rate. Patients with chronic lung disease have a gradual increase in PaCO<sub>2</sub> levels; thus, the normal stimulus to breathe is diminished. The respiratory center becomes less sensitive to the elevated CO<sub>2</sub> levels that usually stimulate the respiratory center, and the stimulus to breathe becomes the low arterial oxygen (PaO<sub>2</sub>) levels. The decreased oxygen levels are sensed by the peripheral chemoreceptors located in the aortic arch and the carotid sinuses. These oxygen receptors then take over as the primary drive to breathe in the patient with chronic lung disease; this is called the hypoxic drive. This physiological change requires the nurse to titrate the oxygen to meet the individual needs of the patient with COPD.

In the management of the patient with chronic lung disease receiving oxygen therapy, it is important to frequently assess the patient for any changes in oxygen saturation, level of consciousness, and rate and depth of respirations as well

as to frequently monitor ABG results. Oxygen-induced hypoventilation may be a concern for patients with chronic lung disease, but not treating the hypoxia is a greater threat to the patient. Withholding oxygen therapy can lead to greater hypoxia and can threaten life. Oxygen therapy is ordered at the lowest level of oxygen needed to treat the hypoxemia.

### Connection Check 7.3

What is the most important information for the nurse to include in the teaching plan about the management of home oxygen therapy? (*Select all that apply.*)

- A. Do not change the settings of the oxygen without the healthcare provider's permission.
- B. Place "No Smoking" signs within the home.
- C. Oxygen is a fire hazard.
- D. Others may smoke around you as long as you do not smoke.
- E. Keep a fire extinguisher near the oxygen source.

### Connection Check 7.4

The nurse is caring for a patient who is receiving oxygen therapy via the Venturi mask. Which complications are associated with oxygen therapy? (*Select all that apply.*)

- A. Oxygen toxicity
- B. Cachexia
- C. Bradycardia
- D. Absorption atelectasis
- E. Increased dead space

## INVASIVE OXYGEN DELIVERY

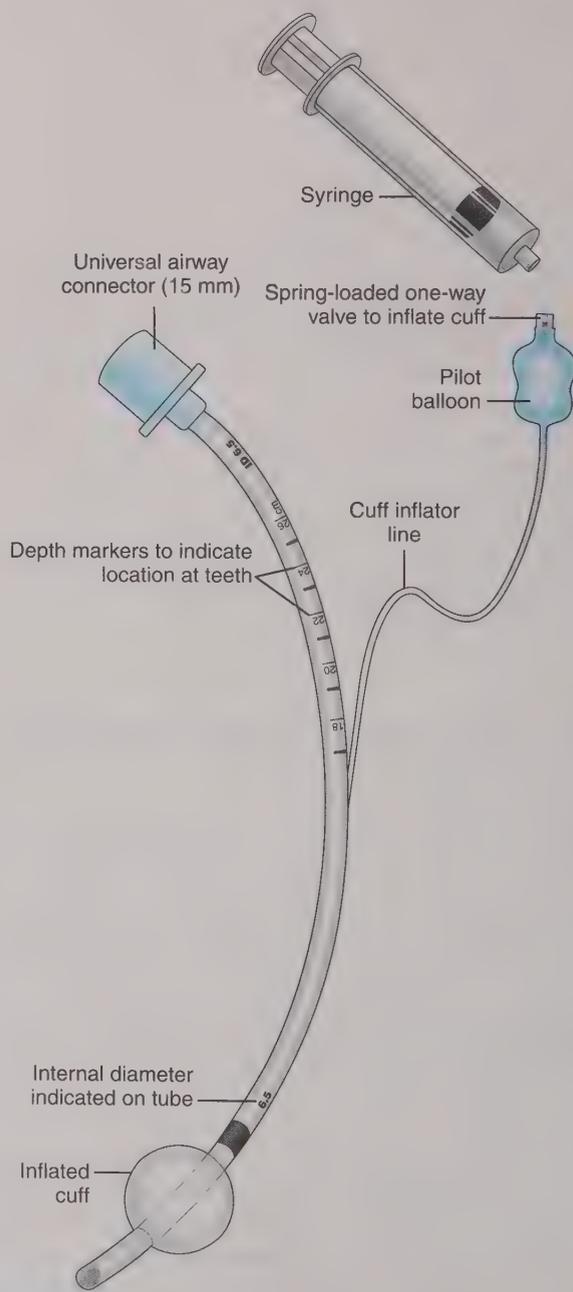

### Artificial Airways

Airway management is the first priority for clinical care and involves maintaining a patent passage for the inhaled air to move through the upper airways to the lower airways to achieve adequate ventilation. The upper and lower airways can become narrowed or blocked as a result of secretions, a foreign object, or constriction of the airways. An airway that is not patent leads to oxygen deprivation. Without oxygen, cells begin to die, and death of the patient may result within minutes. Through the use of artificial airways, the patient can be ventilated and provided with adequate oxygen to maintain tissue perfusion.

#### Endotracheal Tube

An endotracheal tube (ETT) is an artificial airway used to maintain a patent airway when a patient is having respiratory distress. An ETT is a long tube made of polyvinyl chloride that is passed either nasally or orally through the vocal cords into the trachea and is placed just above the carina (the point where the trachea divides into the left and right

mainstem bronchi (Fig. 7.8). The cuff (an inflatable balloon that encircles the lower end of the ETT) is inflated to prevent air from leaking around the ETT, to minimize the risk for aspiration and to secure the ETT in place. Adult sizes range from 7.5 to 9.0 mm. Oral intubation is preferred over nasal intubation because it is quicker and allows visualization of the vocal cords during intubation, as opposed to nasal intubation, which is considered "blind" intubation because the vocal cords cannot be seen during the procedure. Nasal intubation is used when the patient has facial or oral trauma or when oral intubation is not possible. The patient may develop sinusitis after nasal intubation. A certified nurse anesthetist, anesthesiologist, pulmonologist,

**FIGURE 7.8** Endotracheal tube (ETT).

airway, or acute care nurse practitioner usually performs the intubation.

### Indications

Endotracheal tubes are indicated when there is upper airway obstruction, apnea, high risk for aspiration, ineffective airway clearance, and/or respiratory distress. These tubes are also placed to deliver general anesthesia via an endotracheal tube and may be required after the surgical procedure to maintain the airway. In all of these situations, there is a need for assistance to maintain adequate ventilation and perfusion.

### Nursing Considerations

An interprofessional team approach is used when a patient requires intubation. The nurse ensures all needed personnel are at the bedside, including anesthesia, the healthcare provider, the respiratory therapist, and other nurses to assist in the procedure. Considerations include the following:

- Explain the procedure and the reason for intubation to the patient (if patient is able to understand) and family members.

- Maintain proper airway management using a manual resuscitation bag with a face mask connected to 100% oxygen source throughout the intubation procedure.
- Position the intubation tray at the bedside.
- Ensure suction is available throughout the procedure to ensure a patent airway.

During intubation, the nurse coordinates the care of the patient. The nurse continuously monitors the patient, including vital signs; continuous pulse oximetry; and signs of hypoxia, dysrhythmias, and aspiration. If intubation takes longer than 15 to 30 seconds, the intubation needs to stop, the patient is manually ventilated to prevent hypoxia or cardiac arrest, and then a second attempt to place the ETT is initiated (Table 7.3). It is often the responsibility of the nurse to ensure that the procedure is stopped in the event that the attempted intubation exceeds 30 seconds.

Once the patient is intubated, endotracheal placement is verified by an end-tidal CO<sub>2</sub> device, indicating CO<sub>2</sub> is released in expired air from the lungs. If the tube is inadvertently placed in the esophagus, the end-tidal CO<sub>2</sub> is negative. The nurse also verifies proper placement by assessing

**Table 7.3 Process for Endotracheal Intubation**

Action	Rationale
<b>Preparation</b>	
Explain the procedure and the reason for intubation to the patient (if patient is able to understand) and family members.	Allows for cooperation by the patient and less anxiety and apprehension by the family and patient
Maintain proper airway management using a manual resuscitation bag with face mask connected to 100% oxygen source throughout the intubation procedure.	Proper oxygenation prevents hypoxia that can lead to decreased cerebral perfusion and possibly death.
The healthcare provider, nurse, anesthesia provider, and respiratory therapist will all assist in the intubation procedure.	An interprofessional team meets the needs of the patient.
The nurse ensures all equipment is at the bedside and properly functioning. An intubation tray is positioned at the bedside for use by the anesthesia provider during intubation.	Functioning equipment is required for a successful intubation. Most intubation trays include laryngoscopes, endotracheal tubes (ETTs) of different sizes, lubricant, stylet, syringe for balloon inflation, oral airways, Magill forceps, and CO <sub>2</sub> detector; an ETT holder should be available once the ETT is in place. The nurse makes sure all materials are present and functioning.
Respiratory therapy brings the ventilator to the bedside.	Prevents accidental extubation by patient
Restraints may be required; assess need once patient is intubated.	Removes increased secretions to allow for proper oxygenation
Suction setup is ready to be used throughout the procedure to ensure a patent airway: Yankauer for oral secretions and in-line suction once the patient has been intubated.	Decreases transmission of microorganisms and secretions
Personal protective equipment is made available to all the staff members who will be assisting in the intubation procedure.	Decreases transmission of microorganisms
Wash hands.	

*Continued*

**Table 7.3 Process for Endotracheal Intubation—cont'd**

Action	Rationale
<b>Intubation Process</b>	
Premedicate as required with sedation and/or paralytic.	Promotes cooperation by the patient
The patient's head is placed in the "sniff" position.	This allows for easier access/visualization to the vocal cords for intubation.
Prior to intubation, the patient is hyperoxygenated with 100% O <sub>2</sub> .	Provides protection from suction-induced hypoxia
The anesthesia provider inserts the laryngoscope into the patient's mouth until the vocal cords are seen; the ETT is inserted through the vocal cords and stops above the carina.	The ETT is placed above the carina where the trachea branches into the right and left bronchioles; this allows for adequate oxygenation.
The cuff of the ETT is inflated, and either respiratory therapy or the nurse assesses for bilateral lung sounds; a CO <sub>2</sub> detector is used to assist in verifying placement.	To ensure proper placement of the ETT
Secure the ETT with the ETT holder.	Assists in maintaining proper positioning of the ETT
The patient is attached to the ventilator, and settings are ordered by the healthcare provider.	A closed system between the patient and the ventilator allows for proper ventilation for the patient.
Placement of an orogastric tube (OGT) or nasogastric tube (NGT) can be performed at this time. Proper verification of placement can be done.	This allows for proper nutrition and for medication administration.
A portable chest x-ray is ordered, and then daily chest x-rays are ordered.	To ensure proper placement of ETT and OGT/NGT.
Note tube placement at the lip or teeth and chart/report at change of shift.	This information allows for monitoring tube placement. If the tube requires adjustment, the respiratory therapist or registered nurse will adjust.
<b>Management</b>	
Assess frequently for change in vital signs, pulse oximetry (or can place SpO <sub>2</sub> ), respiratory status, cardiac rhythm, and level of consciousness.	The information reflects the patient's status for ventilation and oxygenation.
Monitor ventilator settings and alarm settings.	The priority is proper ventilation and oxygenation of the patient. When alarms are not immediately corrected, disconnect the patient from the ventilator and manually ventilate the patient.
Assess for suctioning needs every 2 hours along with lung sounds bilaterally in all lobes.	Suctioning assists the patient in removing secretions from the airways; assessing lung sounds provides information for the need to suction and proper ETT placement.
Check the water level for proper humidification.	Humidification allows for increases in secretion movement.
Empty the water that collects in the tubing delivering oxygen to the patient into a separate container.	If water collects in the delivery tubing, it leads to increased work for the ventilator to maintain proper oxygen flow. This results in increases in the peak airway (inspiratory) pressure and an area for microorganism production. Water accumulation in the tubing may also make the high-pressure alarm sound.
Check cuff pressure every 4 hours to maintain proper cuff inflation (usually done by respiratory therapy).	Cuff pressure that is too high causes ischemia in surrounding tissue. Cuff pressure that is too low allows for possible accidental extubation and aspiration. Low pressures may also interfere with the delivery of the ordered tidal volume.
Keep HOB elevated at 30 degrees and provide mouth care every 2 hours, daily sedation vacations, GI prophylaxis, and DVT prophylaxis.	These are the ventilator bundles used to decrease ventilator-associated pneumonia (see Evidence-Based Practice: What Is the ABCDEF Bundle?).

DVT = Deep vein thrombosis; GI = gastrointestinal; HOB = head of bed.

## Evidence-Based Practice

### What Is the ABCDEF Bundle?

The ABCDEF bundle is an evidence-based approach to caring for critically ill patients at the bedside, designed to prevent oversedation, prolonged ventilation, delirium, and other complications associated with unwanted outcomes of critically ill patients.

A = Assess, prevent, and manage pain

B = Both spontaneous awakening trials and spontaneous breathing trials

C = Choice of analgesia and sedation

D = Delirium—assess, prevent, and manage

E = Early exercise/ambulation

F = Family engagement and empowerment

Marra, A., Ely, E. W., Pandharipande, P. P., & Patel, M. B. (2017). The ABCDEF bundle in critical care. *Critical Care Clinics*, 33(2), 225–243.

for symmetrical chest rise and fall with ventilation, equal and bilateral lung sounds, no sounds heard over the abdomen, and an order for a portable chest x-ray to confirm placement. If lung sounds and chest wall movement are present only on the right side of the chest, the ETT may have been placed in the right main bronchus. Right mainstem bronchus intubation occurs because the right bronchus has a lesser angle to the trachea and is often wider than the left bronchus. With right mainstem intubation, the ETT needs to be repositioned and reassessed for correct placement.

The ETT is stabilized by inflating the ETT cuff with 20 to 25 mm Hg of air. High cuff pressures can result in ischemia to the surrounding tissue, pressure necrosis, and tracheal bleeding. Low cuff pressures can result in aspiration of secretions, inability to deliver effective ventilations, and unwanted early intubation. An ETT holder device assists in maintaining proper placement of the ETT. The ETT has centimeter markings on the tube, and the nurse documents at what centimeter the ETT is placed at the level of the teeth or lip. If the patient bites the ETT, this will temporarily occlude the tube, and an oral airway may be needed to ensure the patient receives the needed ventilator support by preventing biting.

The administration of a sedative, a paralytic, and an analgesic medication during the intubation procedure of the patient must be considered. This will decrease the risk of aspiration and injury to the patient. The goals for sedation and analgesics in a patient being intubated and placed on a mechanical ventilator are focused on providing comfort for the patient and maintaining synchrony between the patient's breathing and the mechanical ventilator rate.

### ETT Management

The nurse documents the intubation procedure, including a complete assessment of the patient, the ETT size, the ETT position, the location of the ETT (centimeter marking at the lip, teeth, or gum), the ventilator settings, and the patient's response to the procedure.

The role of the nurse is to ensure proper ETT management by maintaining a patent airway, monitoring the patient for complications, maintaining proper cuff inflation, providing oral care and suctioning as needed, maintaining correct tube placement, monitoring oxygenation and vital signs, and educating the patient and family members. This role is shared with the respiratory therapist, who works closely with the nurses in managing the patient who has an ETT and is also being mechanically ventilated. The respiratory therapist maintains the proper cuff pressure, assesses the patient frequently, adjusts the ETT on an as-needed basis, gives ordered respiratory treatments, and obtains the ABGs when ordered. In some settings, the nurse may be the person responsible for repositioning the ETT and obtaining ABG samples.

Communication is often difficult with a mechanically ventilated patient. Using different methods of communication is important to assist the patient in communicating with the interprofessional team and family members. There are various ways to communicate with the patient that can minimize feelings of isolation, frustration, and anxiety about the care and the surroundings. Despite the inability of the patient to speak, there are methods available to assist the patient. Intubated patients can communicate with their family members and the interprofessional team through letter and picture boards, writing paper, gestures, or lip reading. Explain the equipment and the patient's surroundings to the patient to help alleviate stress and anxiety.

### Connection Check 7.5

The nurse is caring for a patient who has just been orally intubated. Which action should the nurse take first?

- Assess for symmetrical chest rise and fall with ventilation.
- Provide mouth care to ensure a clean oral cavity.
- Assess the need for nutritional support through an oral nasogastric tube.
- Provide a communication board for the patient and family.

Suctioning is required in a patient with an artificial airway to remove secretions and to maintain a patent airway, and it allows for optimal ventilation and oxygenation in the patient who is unable to clear secretions. Swallowing is impaired due to the placement of the ETT. An in-line suction system device may be used in a patient who has an artificial airway and is receiving mechanical ventilation. The in-line suction catheter prevents the interruption of ventilation and

oxygenation that the patient is receiving by the ventilator. These devices are known to decrease infection rates and allow for suctioning of the lower airway.

Suctioning increases the risk for hypoxemia and bronchospasm, so suction only as needed. Assess the patient to determine if suctioning is necessary because some patients require suctioning every 1 to 2 hours, whereas other patients

may require less suctioning. To determine if the patient requires suctioning, assess breath sounds for wheezes, crackles, and/or rhonchi; these sounds may indicate a need for suctioning (Table 7.4). Other indications may include coughing, audible secretions, increase in pulse or respirations, decreased  $\text{SaO}_2$  level, visible secretions, and/or restlessness (Table 7.5).

**Table 7.4 Characteristics of Breath Sounds**

	<b>Character</b>	<b>Indication</b>
<b>Wheezes</b>	Musical High pitched Squeaking	Air squeezed through narrowed passages caused by secretions, bronchospasm, edema, inflammation
<b>Crackles</b>	Loud, low-pitched, bubbling, and gurgling sound	On inhalation, air comes in contact with secretions in the trachea and large bronchi.
<b>Rhonchi</b>	Musical Low pitched Snoring/moaning	Airflow obstruction from thick secretions or fluid in the large airways

**Table 7.5 Suctioning Using In-Line or Closed Suction Catheters**

<b>Steps</b>	<b>Rationale</b>
Wash hands and put on protective equipment.	Reduces transmission of microorganisms
Explain procedure to patient and family members if present at the time of the procedure; encourage patient to cough to assist in removing the secretions if patient is alert.	Explaining the procedure will reduce the likelihood of apprehension and anxiety.
Place patient in a semi-Fowler's position.	Elevating the HOB will allow for easier ventilation for the patient.
Continuously monitor patient's cardiac rhythm, BP, pulse, respiration, and $\text{SaO}_2$ level before, during, and after the procedure.	Monitoring the patient for changes in VS can alert the nurse to complications such as dysrhythmias, decreased oxygenation, and vagal response that may occur during this procedure.
Attach the in-line suction catheter or closed suction catheter system to suction.	Attaching the catheter to suction allows for removal of secretions from the airways.
Turn on suction and set suction vacuum up to 160 mm Hg.	This level of suction allows for adequate negative-pressure suctioning.
Hyperoxygenate the patient by activating the 100% oxygen button on the ventilator. The 100% oxygen button that is located on the ventilator provides 100% oxygen for approximately 2 minutes.	Hyperoxygenation assists in providing protection from suction-induced hypoxia.
Insert the catheter quickly without applying suction, far enough to stimulate the cough reflex.	Applying suction during catheter insertion increases the risk of hypoxia and trauma to tissue.
Apply suction and rotate catheter as the catheter is gently withdrawn, with each suctioning event lasting no longer than 10 seconds.	Suctioning for longer than 10 seconds can cause hypoxia, cardiopulmonary compromise, or vagal response.
Hyperoxygenate the patient again with 100% of $\text{FiO}_2$ via the ventilator 100% oxygen button.	Hyperoxygenation assists in providing protection from suction-induced hypoxia.
If secretions are still present, repeat the procedure with a maximum of three passes of catheter; provide a rest period of 10–20 seconds between suction procedures.	Suctioning can produce hypoxia, dysrhythmias, and bronchospasm. Repeated suctioning can remove excessive secretions.

**Table 7.5 Suctioning Using In-Line or Closed Suction Catheters—cont'd**

Steps	Rationale
Rinse the catheter with sterile saline solution while maintaining suction. This allows the saline to rinse the catheter without the saline going into the artificial airway. This is done between passes of the catheter and when the procedure is done.	Secretions that remain in the suction catheter can reduce the catheter's ability to remove excessive secretions.
Suction the patient's mouth and, if indicated, provide mouth care to the patient; use a separate suction line when providing mouth care.	Removes upper airway secretions and microorganisms that may introduce infection
Check the ventilator settings.	Assessing the ventilator settings ensures that the settings are correct.
Assess the patient's breath sounds, VS, cardiac monitor, and SaO <sub>2</sub> and document findings after procedure.	Suctioning can induce cardiac dysrhythmias, hypoxia, and bronchospasm.
If at any time during the suctioning procedure the patient's pulse oximeter decreases or if the patient's heart rate decreases, stop suctioning and give 100% oxygen.	Suctioning can induce hypoxia and stimulate the vagal response.
Document procedure, color, consistency, and amount of secretions noted and patient's response in the medical records.	Provides information about the procedure, information about the secretions that may indicate infection, or change in secretions

BP = Blood pressure; HOB = head of bed; VS = vital signs.

### Complications

Complications of endotracheal intubation include unplanned extubation, aspiration, and infection. Unplanned extubation can be caused by the patient pulling out the ETT or by unwanted movement of the ETT during repositioning or transfer of the patient. To prevent unplanned extubation, provide the patient with adequate sedation and analgesics, use soft wrist restraints only if necessary, and explain the reason for the ETT to the patient and family members. The nurse is responsible for ensuring that the ETT is in the proper position and is secure at all times during repositioning and transferring of the patient. If an unplanned extubation does occur, the nurse calls for assistance, stays with the patient, and provides airway management until assistance arrives and the patient is reintubated as indicated. Airway management includes proper head positioning of the patient to allow an open airway and manually ventilating the patient using a 100% oxygen source, usually a manual resuscitation bag.

During and after placement of an ETT, there is the risk for aspiration of gastric contents or aspiration of secretions because the ETT passes through the epiglottis, and the patient loses the protection of the epiglottis to prevent aspiration. The ETT does have an inflatable cuff, but this does not totally prevent aspiration from occurring. Other ways to prevent aspiration include maintaining the head-of-the-bed elevation above 30 degrees unless contraindicated (this minimizes aspiration of gastric secretions), providing frequent mouth care (this decreases the risk of colonization of the oral secretions that, if aspirated, can lead to an infection), suctioning of the mouth and above the cuff of the ETT (this decreases the likelihood of oral secretions pooling around the ETT), and maintaining proper inflation of the ETT cuff at 20 to 25 mm Hg (this decreases

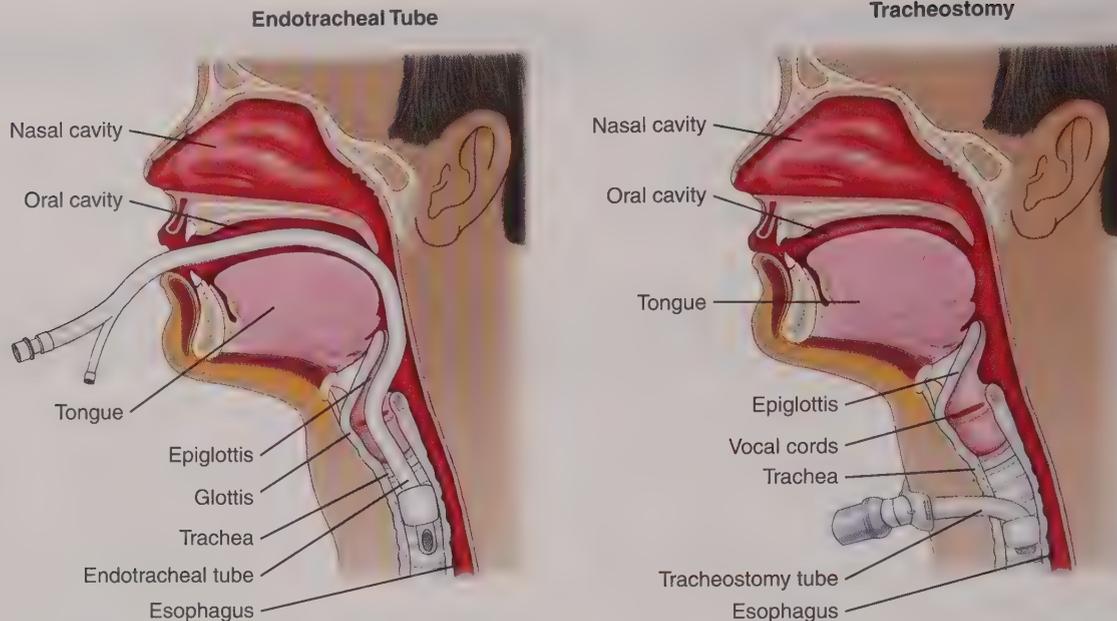

the incidence of oral secretions and/or gastric secretions from being aspirated into the lungs).

An ETT provides an opportunity for infection to occur because it bypasses the natural defenses provided by the upper airway. Continuous or intermittent subglottic suction is available with some ETTs; these ETTs include a subglottic suction adaptor that suction at the area above the cuff to prevent secretions from going into the lungs and causing infection and aspiration.

### Tracheostomy

If a patient requires mechanical ventilation for longer than 7 to 14 days, a tracheostomy is usually performed to prevent the laryngeal and upper airway damage that is associated with the prolonged use of an ETT. A tracheostomy is indicated to provide a stable airway in patients who require long-term ventilator support, to allow access to the lower airway for suctioning, and to relieve upper airway obstructions. The tracheostomy tube replaces the ETT and provides the patient with improved comfort and patient safety.

Advantages of a tracheostomy include decreasing airway resistance; allowing air to enter directly into the trachea and the lungs; allowing for decreased workload of breathing compared with air traveling from the upper airways to the lower airways; and allowing for improved oral care over the ETT, which is passed through the mouth, making oral care more difficult. Other advantages include improved airway security due to the fact that an ETT is not as secure as a tracheostomy tube, improved access for the removal of pulmonary secretions, and improved patient comfort. The tracheostomy tube allows the oral cavity to be free of tubes, making it easier for reading lips, and in time, patients may be able to eat with a tracheostomy in place (Fig. 7.9).

**FIGURE 7.9** Endotracheal tube (ETT) versus tracheostomy.

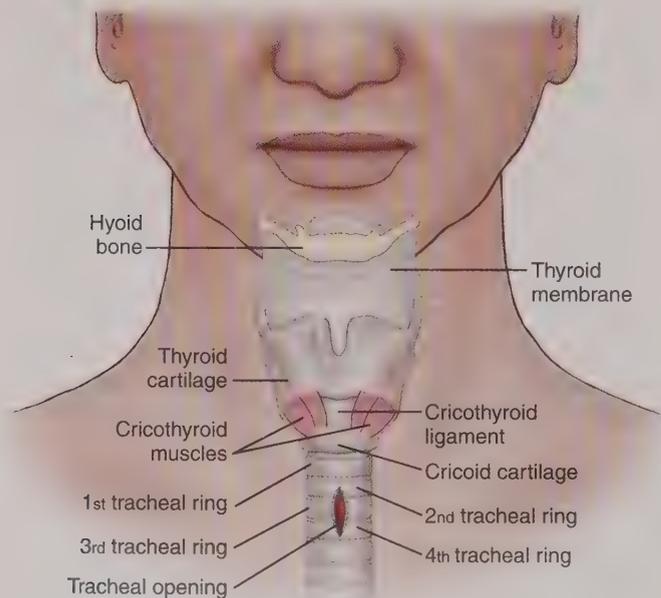

Disadvantages of a tracheostomy are the inability to communicate verbally, similar to the patient with an ETT.

To perform a surgical tracheostomy, the patient's shoulders are elevated, and the head is extended. The skin over the second tracheal ring is identified, and a vertical incision of 2 to 3 cm in length is made (Fig. 7.10). A second incision is made entering the trachea. There are different techniques and incisions used, and they depend on the surgeon and the reason for the tracheostomy. Once the trachea has been entered, the tracheostomy tube is placed and secured with sutures and a tracheostomy tube holder, and a chest

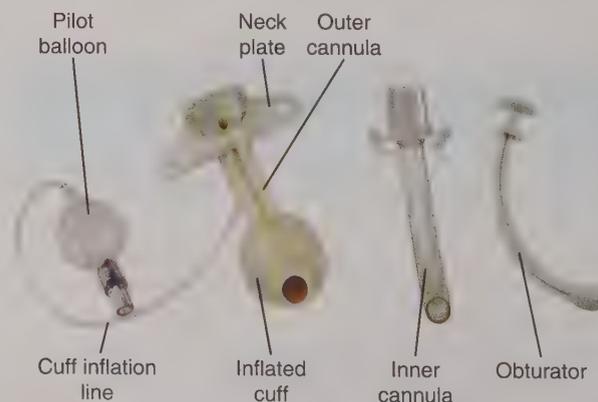

x-ray is ordered to ensure proper placement of the tracheostomy tube.

Tracheostomy tubes are permanent or temporary, and there are a number of different types and sizes of tracheostomy tubes. The type and size of the tracheostomy tube used depend on the patient's size and the rationale. Most tracheostomy tubes consist of an outer cannula with a neck plate, an inner cannula, and an obturator (Fig. 7.11). The outer cannula is the tube that holds the tracheostomy open. The neck plate extends from the sides of the outer tube. There are holes in the neck plate that attach the Velcro strap around the neck. The inner cannula locks inside of the outer cannula. The obturator is used to insert a tracheostomy tube. Most tracheostomy tubes are made of polyvinyl chloride, silicone, or polyurethane; a few are made of metal (silver or stainless steel).

Tracheostomy tubes may have an inner cannula that can be removed for cleaning or a disposable inner cannula. There are also cuffed and uncuffed tracheostomy tubes. A

**FIGURE 7.10** Tracheostomy.

**FIGURE 7.11** Parts of a tracheostomy tube.

cuffed tracheostomy tube is used for the patient who needs continuous mechanical ventilation or a patient who is at risk for aspiration. It is recommended that cuff pressure be maintained at 20 to 30 cm H<sub>2</sub>O to decrease the risk of injury to esophageal tissue and aspiration. An uncuffed tracheostomy tube is used for patients who are ready for **decannulation** (the process of removing the tracheostomy tube) or are not receiving mechanical ventilation. The fenestrated tracheostomy tube is similar to the cuffed tube, with the exception that this tube has small openings above the cuff that allow the patient to speak. The fenestrated tracheostomy tube has a removable inner cannula and a plastic plug. If the inner cannula is removed, the cuff deflated, and the plastic plug in place, the patient is able to speak and breathe through the natural airways. This allows the healthcare provider to assess the patient's ability to breathe using the oral/nasal route in preparing for possible decannulation. The Passy-Muir speaking valve is an example of a one-way speaking valve that attaches to the hub of a nonfenestrated tracheostomy tube. The Passy-Muir valve opens on inhalation, allowing air to pass and enter into the lungs. Then on exhalation, the valve closes, and the air must exit and passes through the vocal cords to produce speech.

### Indications

Indications for the creation of a tracheotomy include the need to provide long-term mechanical ventilation, to bypass upper airway obstruction, to allow removal of

respiratory secretions, to allow for a more secure airway, and to allow oral intake and speech in a patient requiring a long-term tracheostomy tube. A long-term tracheostomy tube also allows for increased mobility for the patient and decreases the risk of aspiration compared with an ET.

### Tracheostomy Care

Tracheostomy care is provided each shift and as needed or as indicated by the facility's policy and protocol. This care is provided to maintain a patent airway and to prevent infection (Table 7.6).

### Suctioning a Tracheostomy

Assess the patient to determine if suctioning is necessary. Some patients require suctioning every 1 to 2 hours, and other patients may require less suctioning. Assess breath sounds for wheezes, crackles, and/or rhonchi; these sounds may indicate a need for suctioning. Other indications may include coughing, audible secretions, an increase in pulse or respirations, or restlessness (Table 7.7).

**Safety Alert** If at any time during the suctioning procedure the patient's oxygen saturation decreases or the heart rate drops, suctioning should be stopped and 100% oxygen administered.

**Table 7.6 Best Practice for Tracheostomy Care**

Actions	Rationale
Gather supplies and prepare for procedure.	Allows for an organized procedure
Provide patient and family, if present, the rationale for the procedure.	Decreases the patient's and family's level of anxiety and apprehension
Wash hands and apply personal protective equipment.	Decreases transmission of microorganisms
Suction the tracheostomy as needed.	Removal of secretions from inner cannula and lower airways allows for better oxygenation and reduces the need for coughing during the procedure.
Remove old dressing; place in biohazard bag along with soiled gloves; put on clean gloves.	Decreases transmission of microorganisms
If patient has disposable inner cannula, remove the old inner cannula and replace with a new inner cannula using aseptic technique. Secure in place. Remove soiled gloves.	Secures inner cannula and decreases transmission of microorganisms
Inspect the tracheostomy site for signs of infection, irritation, and skin breakdown.	Irritation or skin breakdown can lead to infection.
Prepare sterile supplies from tracheostomy cleaning kit.	Decreases transmission of microorganisms
If the patient has a reusable inner cannula, remove and clean the inner cannula; use sterile saline and a small brush to remove secretions.	Normal saline loosens and removes secretions from the inner cannula. Brushing the inner cannula removes the secretions that are not easily removed.

*Continued*

**Table 7.6 Best Practice for Tracheostomy Care—cont'd**

Actions	Rationale
Rinse with sterile saline and replace inner cannula after drying with sterile 4 × 4s.	Rinsing with normal saline cleans the inner cannula.
Replace inner cannula and secure in place.	Secures the inner cannula and reestablishes airway
Clean around the stoma site with sterile cotton-tipped applicators moistened with sterile saline. Cleanse the plate of the tracheostomy with sterile cotton-tipped applicators moistened with sterile saline. Do not allow any solution into the tracheostomy stoma. Using dry 4 × 4 gauze, dry the stoma area.	This removes secretions from stoma/plate site and cleans the area. Drying the area around the stoma/plate decreases microorganism growth and excoriation of the area.
Place a new sterile tracheostomy dressing under the tube plate.	Dry surfaces provide decreased growth of microorganisms and skin excoriation. Dressing absorbs any drainage and prevents pressure from the plate.
Replace the Velcro tracheostomy holder if soiled. The tracheostomy tube holder should be changed with two caregivers.	The use of two caregivers prevents accidental dislodgement of the tracheostomy tube.
Allow room for one to two fingers' width of space between the Velcro tube holder and the neck.	The two-finger method prevents the tube holder from being too tight.
Remove gloves and wash hands.	Decreases transmission of microorganisms
Document procedure, how patient tolerated procedure, education that was done with patient, and assessment of the stoma site.	Allows for interprofessional team to note any changes at the tracheostomy site. Excoriated skin can lead to infection; increased secretions indicate the need for increased tracheostomy site care.

**Table 7.7 Suctioning the Tracheostomy Tube/Nasotracheal**

Actions	Rationales
Wash hands and put on protective equipment.	Decreases transmission of microorganisms and secretions
Explain the procedure to patient and family members if present at the time of the procedure.	Decreases the patient's and family's level of anxiety and apprehension
Encourage the patient to cough to assist in removing the secretions if the patient is alert.	Assists with secretion removal
Place patient in a semi-Fowler's position.	Promotes secretion removal and prevents aspiration
Turn on suction and set suction vacuum up to 120 mm Hg.	This level of suction allows for adequate negative-pressure suctioning.
Open suction catheter kit and place sterile drape on bedside table. Do not allow sterile suction catheter to touch unsterile area.	Decreases transmission of microorganisms
Open sterile saline container and fill with sterile saline solution, approximately 100 mL. Do not touch the inside of the sterile container.	Saline is used to "flush" the tubing after each suction procedure.
Open lubricant and squeeze on sterile field. Lubricant is needed only when suctioning nasotracheal; it is not used for artificial airways.	Lubricant allows for easy passage of the nasotracheal suction catheter.
Apply sterile gloves, pick up suction catheter with dominant hand (keep sterile), and attach the catheter to the suction tubing. Use nondominant hand when touching the suction tubing (this hand will be nonsterile).	Decreases transmission of microorganisms and maintains sterility of suction catheter

**Table 7.7 Suctioning the Tracheostomy Tube/Nasotracheal—cont'd****Actions**

Suction a small amount of saline to make sure the equipment is functioning correctly. Apply small amount of lubricant on catheter if performing nasotracheal suctioning.

Remove oxygen device with nondominant hand and hyperoxygenate the patient by providing 100% oxygen via an Ambu bag that is connected to 100% oxygen. Hyperoxygenate with 4–6 breaths.

Instruct the patient to take a deep breath.

Insert the catheter quickly; do not apply suction on insertion of the catheter. Insert catheter far enough to stimulate the cough reflex.

Apply suction and rotate catheter as the catheter is gently withdrawn over a maximum period of 10 seconds by placing thumb of nondominant hand over the catheter.

Encourage patient to cough.

Reoxygenate the patient again with 100% of  $\text{FiO}_2$  via the Ambu bag for 2–3 breaths.

Rinse the catheter with sterile saline solution while maintaining suction. This will allow the saline to rinse the catheter between suction attempts.

If secretions are still present, repeat procedure for a maximum of three passes of the catheter; provide a rest period of 20–30 seconds between passes of the catheter.

When the procedure is complete, replace oxygen source to patient, clean area, and discard per hospital policy.

Suction patient's mouth and, if indicated, provide mouth care to the patient. Use a separate suction line when providing mouth care.

Assess the patient's breath sounds, vital signs, cardiac rhythm if the patient is on monitor, and  $\text{SaO}_2$  level throughout the procedure and after the procedure.

Document procedure, patient's response, and breath sounds; include color, consistency, and amount of secretions noted and patient's BP, pulse, respirations, and  $\text{SaO}_2$  level before, during, and after the procedure.

**Rationales**

Equipment must be functioning correctly to perform this procedure.

Hyperoxygenation assists in providing protection from suction-induced hypoxia and should provide approximately 2 minutes of 100% oxygen before the procedure.

Insert during inspiration when the epiglottis is open.

Applying suction during catheter insertion increases the risk of hypoxia and trauma to the mucosa.

Suctioning longer than 10 seconds can cause hypoxia, cardiopulmonary compromise, or vagal response and damage to the mucosa.

Allows for easier removal of secretions

Hyperoxygenation assists in providing protection from suction-induced hypoxia.

Secretions that remain in the suction catheter can reduce the catheter's ability to remove excessive secretions.

Suctioning can produce hypoxia, dysrhythmias, and bronchospasm. Repeated suctioning can remove excessive secretions.

Allows proper patient oxygenation after the procedure

Removes upper airway secretions and microorganisms that may introduce infection

Monitoring of the patient's vital signs allows for discontinuation of the procedure if the patient's heart rate or oxygen saturation drops because of hypoxia or vagal stimulation.

Provides information about the procedure and information about the secretions that may indicate infection or change in secretions

BP = Blood pressure.

**Immediate Post-Tracheostomy Complications**

Accidental tracheostomy tube decannulation within the first 72 hours of the surgical procedure is considered a medical emergency because the tracheostomy is not mature, and during reinsertion, there is a greater risk for tissue damage and unsuccessful ventilation. If accidental decannulation occurs, the nurse must stay with the patient, call for assistance from respiratory therapy and a healthcare provider, and provide manual ventilation using a manual resuscitation bag with 100% oxygen. Because the patient will be anxious, offer assurances that help is on the way. When

the respiratory therapist or the healthcare provider arrives, insertion of a new tracheostomy tube will be attempted. Best practices require that replacement tracheostomy tubes are maintained at the bedside; this includes a tube equal in size and a tube that is one size smaller, along with an intubation tray.

Tube obstruction caused by secretions can be prevented by encouraging the patient to deep breathe and cough, suctioning, and providing humidification with the oxygen source. Humidification is often indicated even if the patient does not require supplemental oxygen because

the inspired air is not warmed, filtered, and humidified through the nose and mouth as with normal breathing. The patient with a tracheostomy has less of an effective cough because of the inability to close the glottis. A small amount of bleeding from the tracheostomy site is expected for the first few days. Report moderate to large amounts of bleeding or a continuous oozing of blood to the health-care provider.

A **pneumothorax** is a collection of air in the pleural cavity. This complication may occur during the tracheotomy procedure if the lung is pierced during the procedure, allowing air to enter the chest cavity. A chest x-ray is always ordered after the procedure to verify placement and to assess for a pneumothorax. **Subcutaneous emphysema** can occur if there is a puncture or tear in the trachea and air moves into the surrounding tissue. The air can move into the neck area, chest, or even the face. If this occurs, the skin becomes edematous with air and feels like a crackling sensation when palpated with the fingers and hand. Notify the healthcare provider immediately if this finding is observed.

Infection can occur early or late in a patient with a tracheostomy. While the patient is in the hospital, it is imperative to use aseptic techniques when providing tracheostomy care and when suctioning the patient. Teach the patient and/or caregiver about tracheostomy care before discharge, have the patient or family member return demonstrate the correct procedure, and ensure follow-up with home care once the patient has been discharged.

Long-term complications of a tracheostomy may include infection, tracheal stenosis, or tracheoesophageal fistula. Tracheal stenosis is a narrowing of the trachea due to scar tissue that forms from irritation of the mucosal lining of the trachea from the cuff. To prevent tracheal stenosis, maintain proper cuff pressures, prevent pulling of the tracheostomy tube, and maintain proper positioning of the tracheostomy tube. A tracheoesophageal fistula can develop as a result of overinflation of the tracheostomy cuff. The excessive pressure from the cuff causes a fistula (hole) to occur between the trachea and the esophagus. Prevention includes maintaining proper cuff pressures.

## THERAPEUTIC MODALITIES

### Incentive Spirometry

The **incentive spirometer** (Fig. 7.12) is a handheld respiratory device designed to assist the patient in deep-breathing exercises and encourage the patient to breathe slowly and deeply to allow lung expansion and to prevent or reverse atelectasis. When taking a slow, deep breath in and holding it, the alveoli expand, reducing the risk for collapse and assisting with oxygenation.

#### Indications

The incentive spirometer is ordered by the healthcare provider for patients who have had a surgical procedure and patients diagnosed with chronic breathing problems or

FIGURE 7.12 Incentive spirometer.

pulmonary issues. Patients ordered bedrest or patients with an extended hospital stay associated with decreased or limited mobility may benefit from the use of an incentive spirometer to reduce the possibility of developing atelectasis, which increases the risk for pneumonia.

#### Nursing Implications

Encourage the patient to use this device 5 to 10 times per hour while awake. Set the incentive spirometer goals on the basis of the patient's individual performance. For surgical patients, teaching and setting of incentive spirometer goals are best if completed preoperatively because postoperative pain or sedation may impair respiratory effort. Repeated use of the incentive spirometer can improve lung expansion and assist in removing secretions from the airways (Box 7.2).

### Chest Physiotherapy

**Chest physiotherapy (CPT)** is ordered when the patient requires assistance in removing pulmonary secretions. Chest physiotherapy consists of percussion, vibration, and **postural drainage**. After CPT, the patient is encouraged to breathe deeply and cough to clear the airways. Some patients may require suctioning to assist in removing the secretions if they are unable to produce an effective cough to independently clear the airways. The goal is to move the secretions to the main airways so that the patient is able to produce an effective cough to clear the airways, thus allowing for improved ventilation. Chest physiotherapy is ordered 1 hour before meals or 3 hours after meals, and a bronchodilator may be ordered before CPT to allow for bronchial dilation. Percussion and vibration along with postural drainage assist the patient in removing pulmonary secretions.

## Box 7.2 Use of the Incentive Spirometer

- Explain the correct use and indication for incentive spirometry.
- Assist the patient to a sitting position (semi-Fowler's) if no contraindications are noted. (This allows for optimal lung expansion during this breathing exercise.)
- Instruct the patient to exhale completely.
- Instruct the patient to place the mouthpiece in the mouth and place the lips tightly around the mouthpiece. (This allows for a good seal around the mouthpiece.)
- Instruct the patient to take in a slow, smooth, deep breath, like inhaling through a straw. When the patient has reached maximal inspiration and cannot inhale any more, instruct the patient to hold his or her breath for approximately 3 seconds. Then have the patient exhale smoothly and slowly. (This allows for good expansion of the alveoli to prevent or treat atelectasis.)
- Encourage the patient to use the device 5–10 times per hour while awake or as directed by the healthcare provider. Have the patient rest a few seconds between exercises and cough after each session. (This repeated exercise improves lung expansion and promotes airway clearance of the secretions.)
- Keep the incentive spirometer at the bedside within the patient's reach.
- Document exercises and effectiveness in the patient's medical record.

Postural drainage uses gravity to assist in removing pulmonary secretions. Through percussion and vibration, the secretions become loose and drain into the larger airways so that the patient can cough or the nurse can assist with suctioning the secretions if the patient is unable to independently clear secretions. Postural drainage consists of using different positions that use gravity to allow drainage of different segments of the lungs (Fig. 7.13). The head must be lower than the chest; this allows the secretions to drain toward the trachea, where they can be easily expectorated or suctioned if needed. The position of the patient depends on the segment of the lung that needs to be drained. Bronchodilators and mucolytic medications may be ordered before postural drainage to improve secretion removal. Pillows, a positional hospital bed, or a tilt table may be used to achieve the different positions. Each position should be held for 3 to 15 minutes or longer if ordered by the healthcare provider. Positions are modified if indicated by the patient's condition or tolerance to the treatment. Patients with chronic respiratory and cardiac conditions, for example, COPD or heart failure, may be unable to tolerate having the head lower than the chest.

Chest percussion is performed by lightly striking the chest wall over the area of the lung segment that is being drained. Use cupped hands so that the fingers and thumb are closed, and strike the chest wall while alternating cupped hands (Fig. 7.14). This percussion facilitates the secretions to move into the larger airways and allows the patient to cough and free the airways of secretions. Perform

percussion over the patient's gown or over a thin layer of clothing to protect the skin. Do not perform percussion over buttons, snaps, or zippers. Percussion is performed only to the area of the chest wall ordered by the healthcare provider and can be performed manually or by a mechanical device that is ordered by the healthcare provider.

Vibration is performed with the hands in a flat position. The hand moves repeatedly, causing a vibration to the area of the segment of the lung that needs to be drained. This is performed during exhalation to assist in loosening the secretions and inducing a cough.

Other airway clearance devices can be ordered to clear pulmonary secretions, including the Acapella and the high-frequency chest wall compression device. The Acapella is a handheld device that can be used in any setting to mobilize secretions. Acapella uses positive expiratory pressure and airway vibration and is easier to tolerate than CPT for some patients. The high-frequency chest wall compression device is a vibrating, air-filled vest that causes a continuous, gentle vibrating motion to assist the patient in removing pulmonary secretions. Devices such as the high-frequency chest wall compression device can be used in the home on patients who are discharged from the hospital and require assistance in mobilizing secretions. With proper patient education, the patient and/or caregiver can use the devices without assistance.

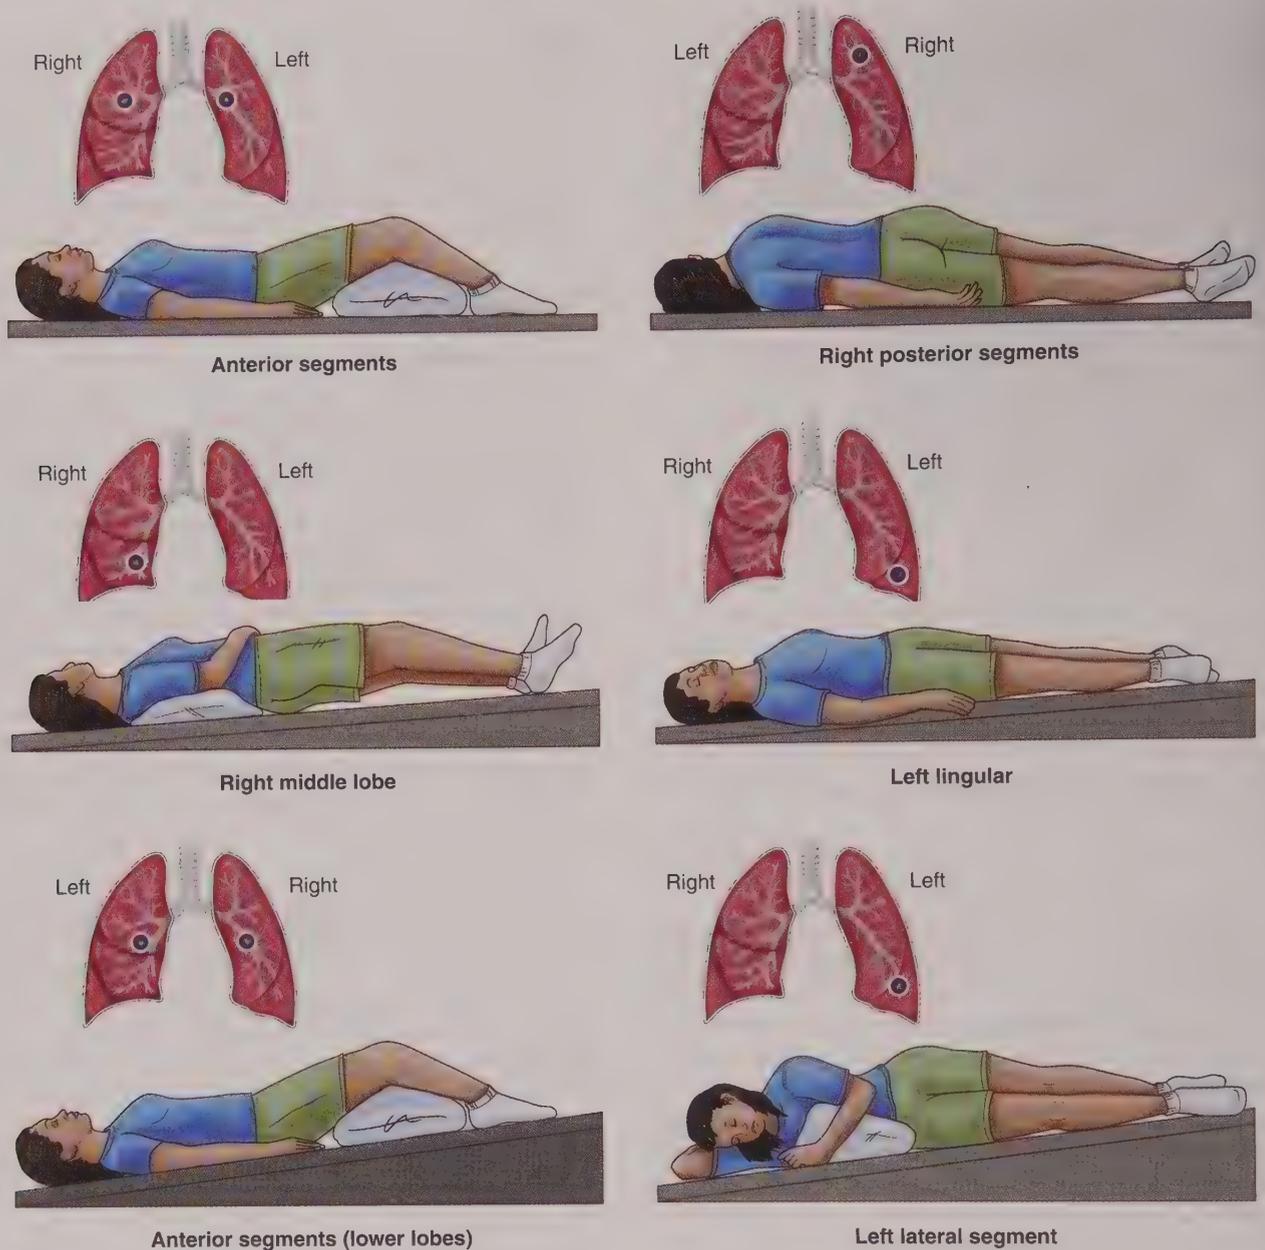

### Connection Check 7.6

When the nurse is performing postural drainage for the patient, which factor promotes the movement of secretions to the upper airways?

- Dilation of alveoli
- Action of the cilia
- Muscle contraction
- Force of gravity

### Nebulizer Treatments

Nebulizer treatments are prescribed by a healthcare provider and are usually administered by a respiratory therapist or another trained healthcare provider. Nebulizer treatments use bronchodilators, corticosteroids, and/or mucolytic agents to assist in thinning secretions, to reduce bronchospasm, and to reduce edema or inflammation of the bronchioles. Some medications that are prescribed may require saline to be added. The nebulizer changes the liquid medication into a mist; this is done either by a compressor machine that creates high air pressure that causes the liquid to become a mist or by an ultrasonic machine that uses high-speed vibration that causes the liquid to become a mist. The mist/medication that is produced is inhaled into the airways and lungs. Auscultation of the breath sounds and monitoring of vital signs are performed before and after each treatment. The breath sounds, vital signs, and patient response to the treatment are noted in the patient record.

**FIGURE 7.13** Common positions for postural drainage.

**FIGURE 7.14** Cupped hand.

**Intermittent Positive-Pressure Breathing**

Intermittent positive-pressure breathing (IPPB) devices are prescribed by the healthcare provider to improve lung expansion, to deliver aerosol medications, or to assist the

patient in ventilation. IPPB is indicated for patients who need to improve lung expansion, patients with pulmonary atelectasis when other therapies have been unsuccessful (incentive spirometry, CPT, and deep-breathing exercises), patients with an inability to clear secretions due to ineffective cough, and patients who require short-term ventilatory support. The patient receives intermittent positive pressure to the airways to maintain adequate gas exchange or to deliver aerosol treatments.

**OVERVIEW OF MECHANICAL VENTILATION**

**Mechanical ventilation** (Fig. 7.15) is required when a patient cannot maintain adequate ventilation and/or perfusion. Indications for mechanical ventilation include acute

**FIGURE 7.15** Mechanical ventilation.

respiratory failure; heart failure; exacerbation of COPD; protection of the airway due to cardiac arrest, drug overdose, or respiratory depression; and spinal cord or neurological trauma. The goal of mechanical ventilation is to support the patient until the underlying pathophysiological process is corrected. Mechanical ventilation is not a cure but is used to support the patient to improve ventilation and perfusion and to decrease the patient's work of breathing until the acute problem is managed. Once the underlying condition is corrected, mechanical ventilation may be discontinued. Patients who cannot support their own ventilatory needs or who cannot maintain optimal oxygenation may require the mechanical ventilation on a permanent basis. For example, patients who suffer a high cervical spinal injury may require permanent mechanical ventilation due to the loss of function of both the diaphragm and the intercostal muscles. When the patient requires mechanical ventilation, interprofessional collaboration is required to meet the needs of the patient. The role of the nurse includes providing continuous monitoring and assessment, preventing complications from mechanical ventilation, monitoring the equipment for any problems, and providing emotional support to the patient and family. Other members of the team may include the primary healthcare provider, respiratory therapist, dietitian, physical therapist, and social worker.

## Types of Mechanical Ventilation

### Negative-Pressure Ventilation

Negative-pressure ventilation is a noninvasive mechanical ventilation modality used for patients with respiratory disorders usually associated with neuromuscular disorders that impede the normal respiratory muscle function, such as muscular dystrophy. During spontaneous breathing, negative pressure is created when the thoracic cavity expands, causing intrapulmonary pressure to drop and air to flow into the lungs. This type of ventilation is similar to natural respiration. The negative-pressure ventilator provides a negative (pulling) pressure on the external chest wall, assisting in ventilation. The patient is fitted with a shell that connects to a ventilator. Through the use of the ventilator, the air is removed from the area between the patient and the shell,

causing negative pressure on the external chest wall. Examples include the iron lung and the chest cuirass ventilator.

### Positive-Pressure Ventilation

Positive-pressure ventilation usually requires placement of either an endotracheal tube (ETT) or a tracheostomy tube. This type of ventilator provides positive-pressure ventilation to support the patient who has impaired ventilation, and it is provided by exerting positive pressure on the airways, pushing air into the lungs, causing the alveoli to participate in gas exchange. Exhalation occurs passively. Positive-pressure ventilation can be delivered by pressure-cycled or volume-cycled ventilators. Pressure-cycled ventilators deliver air into the lungs until a preset air pressure is reached. Exhalation remains passive. One issue with this type of ventilation is that the **tidal volume** (the amount of air delivered per breath) varies depending on lung compliance and resistance. Volume-cycled ventilators deliver air into the lungs until a preset volume is reached. A constant tidal volume is delivered regardless of lung compliance and resistance. The volume of air that is delivered is constant with each breath that is given by the ventilator. There is a preset pressure limit that prevents excessive pressure to the lungs with both pressure- and volume-cycled ventilators.

## Mechanical Ventilator Settings

Patients who require the use of a mechanical ventilator have prescribed ventilator settings that are adjusted on the basis of the patient's response. The nurse and respiratory therapist work collaboratively with the healthcare provider in adjusting the ventilator settings to meet the needs of the patient. Typical ventilator settings include the fraction of inspired oxygen ( $\text{FiO}_2$ ), breath rate ( $f$ ), tidal volume ( $V_t$ ), and flow. Pressure support and PEEP are used if indicated.

### Fraction of Inspired Oxygen

The setting for  $\text{FiO}_2$  indicates the amount of oxygen the patient receives via the mechanical ventilator. The  $\text{FiO}_2$  may be started at 100% if the patient is extremely hypoxic and then decreased on the basis of ABG results. The ventilator can provide  $\text{FiO}_2$  from 21% to 100% depending on the needs of the patient. The goal of this setting is to maintain a  $\text{PaO}_2$  above 60% mm Hg and an  $\text{SaO}_2$  above 90% to 92% at the lowest possible oxygen setting.

### Rate

The rate is the number of respirations the patient receives per minute via the ventilator, and the usual setting is 8 to 12 breaths per minute. The setting depends on the mode selected and whether the patient can breathe spontaneously or whether the ventilator needs to provide mandatory ventilation for the patient. The rate may be gradually decreased in a patient who is breathing spontaneously until the patient is able to maintain adequate ventilation. When the respiratory rate of a patient on a mechanical ventilator is assessed, the number documented includes the numbers of both ventilator and spontaneous breaths.

### Tidal Volume

Tidal volume ( $V_t$ ) is the amount of preset air that is delivered with each breath. The usual setting is 8 to 10 mL/kg, and this setting is based on the patient's ideal body weight. Adjustments are made according to the ABG results. Large amounts of  $V_t$  may cause **barotrauma** (injury to the lungs caused by positive pressure) or increase the risk for ventilator-associated lung injury. Lower amounts of  $V_t$  may be ordered on patients with adult respiratory distress syndrome or acute lung injury. Using a lower  $V_t$  decreases the risk of further injury to the lungs.

### Flow

The flow is the velocity of gas flow or volume of gas per minute.

### Positive End-Expiratory Pressure

Positive end-expiratory pressure (PEEP) is positive pressure applied at the end of expiration to help prevent alveolar collapse, assist patent alveoli, and redistribute fluid from the alveoli. PEEP improves oxygenation, allowing the  $FiO_2$  level to be lowered. This is important because prolonged use of high  $FiO_2$  can cause lung injury. PEEP is often ordered at levels between 3 to 5 cm  $H_2O$  to minimize alveolar collapse and based on the patient's underlying pathophysiology. PEEP is generally indicated in patients who are being mechanically ventilated with ventilator modes such as assist-control ventilation, synchronized intermittent mandatory ventilation, or pressure-control ventilation. PEEP is referred to as CPAP when applied to spontaneously breathing patients.

### Modes

There are different modes of mechanical ventilation available to meet the patient's breathing needs. The mode refers to how the breaths are delivered by the ventilator to the patient.

#### Assist-Control Ventilation

Assist-control (A/C) ventilation, also known as continuous mandatory ventilation (CMV), is the mode used for patients who have weak respiratory muscles and may be unable to maintain adequate ventilation. The respiratory rate and volume of breaths are preset. If the patient does not initiate a breath, the ventilator delivers the breaths at the preset rate and volume. If the patient does initiate a breath, the ventilator delivers the preset volume (assisted breath), allowing the patient to control the rate of breaths. The disadvantage of this mode is that in the hyperventilating patient, respiratory alkalosis can develop if the respiratory rate increases above a normal rate because the ventilator continues to deliver a preset volume with each initiated breath. Causes of hyperventilation can include pain, acid-base imbalance, and/or anxiety.

#### Intermittent Mandatory Ventilation

Intermittent mandatory ventilation provides a combination of ventilator-assisted breaths and spontaneous breaths of

the patient. This mode is used for patients who can breathe spontaneously but at a volume and/or rate that does not meet adequate oxygenation. This mode makes sure that a preset volume and rate of breaths are given per minute regardless of the patient's efforts. This mode allows the patient to initiate a breath, but the volume is limited to what the patient is able to produce, decreasing the risk of barotrauma, but can lead to the patient breathing against the ventilator. As the patient exhales, the ventilator may be delivering a breath. This is called "bucking the ventilator."

#### Synchronized Intermittent Mandatory Ventilation

Synchronized intermittent mandatory ventilation (SIMV) is used for patients who are being weaned from the ventilator and those patients who require some assistance to maintain adequate ventilation. If the patient does not initiate a breath, the ventilator delivers the preset volume and rate per minute to the patient. This mode allows the patient to breathe spontaneously at his or her own volume and rate between the breaths given by the ventilator. This mode synchronizes with the patient's efforts to breathe. When used for weaning, the number of breaths given by the ventilator can be decreased so that the patient takes over and breathes spontaneously, without the assistance of the ventilator. This mode is sometimes used with **pressure support** (continuous positive pressure during inspiration) to decrease the workload of breathing for patients who are able to produce spontaneous breaths because there is increased respiratory effort required for the patient to breathe through the ETT.

#### Airway Pressure-Release Ventilation

Airway pressure-release ventilation is a mode designed for spontaneously breathing patients who require a high level of pressure to effectively recruit alveoli. The high level of pressure forces the alveoli open and contributes to gas exchange. The inflation period is long, and breaths may be initiated spontaneously as well as by the ventilator. This mode allows spontaneous breathing at a preset CPAP that is interrupted by pressure release to a lower pressure. This mode is believed to reduce the risk of ventilator-induced lung injuries such as barotrauma.

#### Pressure-Support Ventilation

Pressure-support ventilation (PSV) may be used as an independent mode or in conjunction with CPAP or SIMV. This mode gives a set positive pressure during spontaneous inspirations. The patient breathes spontaneously with the patient's own volume, rate, and inspiratory time but has continuous positive pressure that is maintained during inspiration. This continuous positive pressure assists in reducing the workload of breathing and keeping the alveoli open. When used for weaning, the pressure support helps the patient to overcome the dead space of the ETT.

**CASE STUDY: EPISODE 3**

Mrs. Graham becomes confused and combative, her SaO<sub>2</sub> drops to 82%, and she pulls off her Venturi mask. Her BP drops to 88/46, and her ABGs are as follows:

**ABGs:**

pH	7.24
PaO <sub>2</sub>	58 mm Hg
PaCO <sub>2</sub>	62 mm Hg
HCO <sub>3</sub> <sup>-</sup>	34 mEq/L
SaO <sub>2</sub>	82%

Mrs. Graham is intubated and given a 1,000-mL bolus of 0.9% NS and is transferred to the medical intensive care unit. Upon arrival, she is given another 1,000-mL bolus of NS, vancomycin 1 g IV ordered STAT, and an order to continue the vancomycin 1 g IV every 12 hours.

Ventilator settings are as follows:

**SIMV:**

Vt	550
FiO <sub>2</sub>	100%
SIMV	12
PEEP	5 cm H <sub>2</sub> O

**Admission orders:**

VS every hour

Continuous ECG and PO monitoring

ABGs 2 hours after intubation

Daily labs: ABGs, CBC, chemical profile

Portable CXR and ECG daily

IV D5<sup>1</sup>/<sub>2</sub> NS with 20 mEq of KCl at 84 mL/hr

Enoxaparin (Lovenox) 40 mg subcutaneous daily

Famotidine (Pepcid) 20 mg intravenous push (IVP) daily

Methylprednisolone (Solu-Medrol) 125 mg IVPB every 8 hours

Nebulizer treatments with albuterol (Ventolin) 2.5 mg every 4 hours and prn

Bedrest

Maintenance of ventilator settings

Strict I/O every hour

HOB elevated at 30 degrees

Mouth care every 4 hours and prn

Daily sedation vacation

Smoking cessation

Place orogastric tube and begin Pulmocare (enteral nutrition formula) @ 20 mL/hr; increase by 10 mL/hr until a goal of 40 mL/hr is established. Hold tube feedings for residual greater than 100 mL.

The following ABG results are obtained after 2 hours on the previously mentioned settings of the ventilator.

**ABGs:**

pH	7.36
PaO <sub>2</sub>	90 mm Hg
PaCO <sub>2</sub>	46 mm Hg
HCO <sub>3</sub> <sup>-</sup>	30 mEq/L
SaO <sub>2</sub>	98%

**Complications Associated With Mechanical Ventilation**

The nurse is responsible for assessing the patient and the ventilator to maintain proper functioning. Complications that are associated with mechanical ventilation include hypotension, infection, barotrauma, aspiration, and ventilator-associated pneumonia (VAP). The ventilator has an alarm system that the nurse is required to monitor. The alarm indicates when there is a need for intervention. The nurse immediately assesses the patient and the ventilator to find out what is interfering with the ventilator and causing the alarm. The alarms that most often are activated are the high-pressure alarm and the low-pressure alarm (Table 7.8).

**Safety Alert**

A ventilator alarm alerts the nurse that something is wrong with the pressure, volume, or rate of air being delivered to the patient. When an alarm is activated, it is the nurse's responsibility to immediately check the patient's ventilation and oxygenation; the priority assessment is the patient first, then the ventilator. If the nurse cannot immediately identify the problem, the nurse disconnects the patient from the ventilator and uses a manual resuscitation bag to ventilate the patient while calling for assistance. Failure to ensure adequate ventilation can result in injury to the patient, such as an anoxic brain injury or death.

**Hypotension**

Hypotension may develop secondary to changes in pressure in the chest cavity and is associated with positive-pressure modalities of mechanical ventilation. Because the delivered breaths are "pushed" into the lungs via positive-pressure ventilations, the pressure in the chest cavity increases. This increased intrathoracic pressure decreases venous return to the right side of the heart and ultimately decreases cardiac output. Fluids may be ordered by the healthcare provider to correct the hypotension; ventilator settings may also need to be adjusted. Sedatives or opioids may be a contributing factor to the hypotension and may need to be adjusted to elevate the blood pressure.

**Table 7.8 Mechanical Ventilator Alarms**

Cause	Intervention
<b>High-Pressure Alarm</b>	
Mucous plug or increased secretions	Suction as needed.
Patient biting the ETT	Insert an oral airway to prevent biting.
Pneumothorax	Assess for asymmetrical chest rise and decreased breath sounds over pneumothorax site; contact healthcare provider immediately.
Patient anxious and fighting the ventilator	Assess the patient, provide emotional support, and reevaluate sedation/analgesic need.
Kink in the tubing	Assess the tubing from ventilator to patient to ensure no kinking of the tube is present.
Water collected in the ventilator tubing	Empty water from the ventilator tubing.
<b>Low-Pressure Alarm</b>	
Cuff leak	Assess for cuff leak, check cuff pressure, and call for respiratory and healthcare provider.
Leak in the ventilator circuit	Assess all connections and tubing.
Patient stops breathing in the pressure support modes or SIMV.	Assess patient; notify the healthcare provider.

ETT = Endotracheal tube; SIMV = synchronized intermittent mandatory ventilation.

### Infection

Infection is a potential complication because the normal defenses of the upper and lower respiratory systems are bypassed. The ETT or the tracheostomy tube can become a direct source to the lungs because both increase the risk of introduction of infectious substances. Normally, the upper and lower airways protect against infection by hair-like cilia that line the respiratory tract and filter the air before it reaches the lungs.

### Barotrauma

Barotrauma is a complication of the mechanical ventilator due to the increased positive pressure applied to the lungs, which can cause alveolar rupture. Overdistention of the alveoli can lead to an excessive amount of air entering into the pleural space, causing a tension pneumothorax. This can be a life-threatening situation for the patient, and the nurse must notify the healthcare provider immediately and prepare for chest tube insertion to allow removal of trapped air in the pleural space.

### Aspiration

Aspiration of gastric secretions and pulmonary secretions is a potential complication because the natural defense of the epiglottis is bypassed when an artificial airway is in place. Elevating the head of the bed (HOB) reduces the risk of aspiration. See the following section for additional nursing measures.

### Ventilator-Associated Pneumonia

Ventilator-associated pneumonia (VAP) is a serious healthcare-associated infection resulting in high morbidity, high mortality, and high costs of treatment. Aspiration of oropharyngeal and/or gastric fluids is presumed to be an essential step in the development of VAP, and it typically develops 48 hours or more after endotracheal intubation.

Guidelines for preventing VAP include (1) minimizing sedation, including daily spontaneous breathing trials (SBTs) for patients without contraindications; (2) facilitating early exercise and mobilization; (3) using ETTs with subglottic secretion drainage ports for patients requiring greater than 48 to 72 hours of intubation; (4) elevating the HOB 30 to 45 degrees; and (5) changing the ventilator circuit only when visibly soiled or malfunctioning (Boxes 7.3 and 7.4).

## Nursing Management for a Mechanically Ventilated Patient

### Nursing Diagnoses

- Ineffective airway clearance
- Ineffective breathing pattern
- Impaired gas exchange
- Risk for trauma
- Decreased cardiac output
- Impaired verbal communication
- Risk for infection

### Nursing Interventions

#### ■ Actions

- HOB elevation between 30 and 45 degrees unless contraindicated  
*Reduces the risk for aspiration of gastric contents*
- Clear airway secretions with suctioning, CPT, frequent position changes, and increasing activity.  
*Reduces the risk of aspiration and clears the airways of secretions*
- Daily “sedation vacation” and a readiness-to-wean assessment  
*Holding sedation is necessary to determine the patient’s potential for readiness to wean from the mechanical ventilator. Excessive sedation may decrease the respiratory rate and effort.*
- Peptic ulcer disease prophylaxis  
*Medications that reduce gastric acidity have been shown to protect patients from developing peptic ulcer disease and gastrointestinal bleeding.*
- Deep vein thrombosis (DVT) prophylaxis  
*Treatments with anticoagulants and sequential compression devices have been shown to reduce the risk for DVT that may develop in patients who require prolonged mechanical ventilation.*

### Box 7.3 The American Association of Critical-Care Nurses (AACN) Practice Alert: Prevention of Ventilator-Associated Pneumonia (VAP) in Adults

#### Alert Statements

Critically ill patients who are intubated are at risk for the development of ventilator-associated pneumonia (VAP). The reported incidence rate of VAP has been steadily declining. It is uncertain whether the decrease is related to prevention efforts, reporting definitions, or a combination of the two.

#### Expected Nursing Practice

Collaborate to identify patients for whom implementation of noninvasive positive-pressure ventilation (NIPPV) may be appropriate to prevent the need for intubation.

Assess readiness to extubate daily through combined spontaneous awakening trials (SATs; sedation interruption/minimization) and spontaneous breathing trials (SBTs), unless clinically contraindicated. Maintain and improve physical conditioning through early exercise and mobility. Elevate the head of the bed (HOB) to 30 to 45 degrees unless clinically contraindicated in patients receiving mechanical ventilation, as well as patients at high risk for aspiration. Minimize pooling of secretions above the endotracheal tube cuff by using an endotracheal tube with subglottic suction capability in patients with anticipated intubation greater than 48 to 72 hours. Change ventilator circuits only if visibly soiled; do not change ventilator circuits routinely. Perform oral care using chlorhexidine. Use ventilator bundles to reduce ventilator-associated events (VAEs) and VAP.

From American Association of Critical-Care Nurses. (2017). AACN practice alert: Prevention of ventilator-associated pneumonia in adults. *Critical Care Nurse*, 37(3), e22–e25.

- Daily oral care with chlorhexidine  
*Oral care using chlorhexidine has been shown to decrease dental plaque that can cause bacterial growth.*

#### Connection Check 7.7

The nurse is screening patients for their risk of developing VAP. The nurse considers which patient at greatest risk?

- A patient who was extubated within 24 hours of being intubated
- A patient intubated and placed on mechanical ventilation less than 72 hours ago
- A patient with the head of the bed elevated 45 degrees
- A patient who was placed on a nasal cannula after being extubated

### Box 7.4 Healthcare-Associated Infections

*Healthy People 2020* has indicated emerging issues in health-care-associated infections (HAIs). Healthcare-associated infections are among the leading causes of preventable deaths in the United States and increase the healthcare costs each year. The goal of *Healthy People 2020* is to reduce, prevent, and eventually eliminate HAIs. Ventilator-associated pneumonia is one of the infections among the HAIs that *Healthy People 2020* is addressing. The group plans to target HAIs through evidence-based strategies that the Institute for Healthcare Improvement has adapted.

#### Weaning From Mechanical Ventilation

When a patient is intubated and placed on a mechanical ventilator, the primary goal is to frequently assess the need for continued intubation and mechanical ventilation. **Respiratory weaning** is a gradual process going from ventilator dependence to spontaneous breathing. The patient is assessed daily to determine readiness for the weaning process and discontinuation of the ventilator. The patient should demonstrate evidence that the underlying cause of respiratory failure has been reversed before the patient can be weaned from the ventilator. Indications that the patient may be ready for the weaning process include the ability to breathe spontaneously, support adequate oxygenation, and maintain hemodynamic stability.

#### Patient Criteria for Weaning

The patient is monitored for stable vital signs/ABGs, minimal secretions, adequate oxygenation, and spontaneous breathing and is free of sedation medications (Box 7.5).

#### Weaning Methods

Once the patient has met the weaning criteria, the patient is assessed with a spontaneous breathing trial (SBT). The

### Box 7.5 Weaning Criteria

#### Criteria for Weaning

The criteria should be individualized for each patient.

Reversal of the underlying cause of respiratory failure

Ability to maintain:

pH greater than or equal to 7.25 during spontaneous ventilation

PEEP less than or equal to 5–8 cm H<sub>2</sub>O

FiO<sub>2</sub> less than or equal to 0.4–0.5

PaO<sub>2</sub>/FiO<sub>2</sub> ratio greater than 150–200

Hemodynamic stability, meaning no active myocardial ischemia or hypotension (patients receiving a low dose of vasopressors may be considered for weaning)

Ability to initiate an acceptable inspiratory effort

PEEP = positive end-expiratory pressure.

SBT is completed using a mode of partial support. The most common methods used in SBT are pressure support or CPAP or via a T-piece (see Evidence-Based Practice: T-Piece or Pressure Support Ventilation for Weaning From Mechanical Ventilation).

- Pressure support is used to assist the patient in overcoming the resistance of the ETT and assists the alveoli with perfusion support. The patient must have the ability to breathe spontaneously.
- CPAP is used to assist the patient in overcoming the ETT resistance because there is constant pressure maintained throughout the respiratory cycle. The patient must have spontaneous breathing because there is no additional inspiratory support.
- The T-piece is used when the ventilator is disconnected and the patient breathes through the ETT. Supplemental oxygen is provided, but there is no support provided by the ventilator. The patient must be monitored closely for an increased work of breathing because the small diameter of the ETT requires more patient effort for inspiration.

If the patient tolerates the SBT for 30 to 120 minutes without tachycardia, hypertension, hypotension, deteriorating ABG results, or arrhythmias, the patient is usually extubated. Following extubation, the patient is placed on oxygen via a face mask or nasal cannula for a period of time, and oxygenation and perfusion are continually assessed.

### Evidence-Based Practice

#### T-Piece or Pressure-Support Ventilation for Weaning From Mechanical Ventilation

Two techniques used for spontaneous breathing trials (SBTs) for patients being weaned from mechanical ventilation are the use of a T-piece or pressure-support ventilation (PSV). Because there is no clearly preferable technique, a systematic review was conducted that included MEDLINE, Embase, SciELO, Google Scholar, CINAHL, ClinicalTrials.gov, and Cochrane CENTRAL databases through June 2015. The review included randomized controlled trials in adult patients being weaned from mechanical ventilation and compared outcomes of T-piece and PSV. The specific outcomes reviewed included weaning failure, reintubation rate, intensive care unit (ICU) mortality, and weaning duration. SBT technique was not found to be related to weaning success, ICU mortality, or reintubation. There were specific subgroup analyses that found that PSV might be superior to T-piece weaning in patients who were classified as “simple to wean.” However, in patients found to require prolonged weaning, the T-piece was associated with shorter weaning duration. Because of the low level of evidence, the

authors recommend further comparison studies related to SBT techniques, particularly in difficult-to-wean patients and those with COPD.

Pellegrini, J. A., Moraes, R. B., Maccari, J. G., de Oliveira, R. P., Savi, A., Burns, K. E., & Teixeira, C. (2016). Spontaneous breathing trials with T-piece or pressure support ventilation. *Respiratory Care*, 61(12), 1693–1703.

### Weaning Complications

Reintubation is the major concern with patients after extubation. The team should be ready with an intubation tray at the bedside in case the patient becomes unstable and requires reintubation. Aspiration is another concern with a patient who is being extubated. As the tube is removed, the patient can breathe in and aspirate secretions in the respiratory tract. The patient is suctioned before extubation, and the patient is instructed to cough as the tube is being removed to reduce the incidence of aspiration. The health-care provider orders oxygen either by nasal cannula or by face mask. The patient requires continuous monitoring after extubation. Monitor vital signs, continuous pulse oximetry, cardiac status, and respiratory status, including respiratory rate and effort. The patient may experience a sore throat and be hoarse after extubation because of the irritation to the vocal cords and throat from the ETT. Encourage deep-breathing and coughing exercises. The use of an incentive spirometer will assist the patient with lung expansion. Monitor the patient for any signs of airway obstruction, such as dyspnea, cyanosis, coughing, and stridor. **Stridor** is an abnormal, high-pitched, crowing sound heard on inspiration that is caused by edema of the glottis or laryngospasm. Notify the healthcare provider immediately for reintubation of the patient.

### Connection Check 7.8

A nursing preceptor is observing a newly hired nurse prioritizing patient rounds. Correct prioritization of assigned patients is indicated if the new nurse assesses which patient first?

- A patient with cellulitis of the right lower leg
- A patient who was extubated 2 hours ago
- A patient who was ordered nebulizer treatments prn
- A patient with an IV of D51/2 NS at 125 mL/hr

### Making Connections

#### CASE STUDY: WRAP-UP

Daily ABGs and chest x-rays are obtained. Mrs. Graham goes through daily sedation vacations, and on the third day, she successfully passes the weaning trial and is extubated and placed on 2LNC of oxygen and maintains a PO of 94%.

Mrs. Graham and her family are provided with teaching on the following to prevent further exacerbations:

- Medication therapy, including reason, action, time, adverse effects
- Importance of making follow-up appointments
- Smoking cessation
- Breathing exercises
- Signs of respiratory infection
- Avoiding exposure to people with infections
- Need to balance rest and exercise

Discharge planning is begun to transfer Mrs. Graham to a short-term rehabilitation facility to focus on reconditioning and maximizing independence.

### Case Study Questions

1. The nurse correlates which clinical manifestations observed in Mrs. Graham to hypoxia?
  - A. Shortness of breath
  - B. Chills
  - C. Productive cough
  - D. Fever
2. The nurse identifies which of the following as benefits to placing Mrs. Graham on a Venturi mask? (*Select all that apply.*)
  - A. It delivers low levels of oxygen.
  - B. It minimizes rebreathing of exhaled CO<sub>2</sub>.
  - C. It does not require high flow rates of oxygen.
  - D. It provides a more precise concentration of oxygen.
  - E. It provides higher concentrations of oxygen.
3. In observing Mrs. Graham for changes in respiratory status, which findings correlate with worsening hypoxia?
  - A. Decreased PaCO<sub>2</sub>
  - B. Decreased respiratory rate
  - C. Decreased heart rate
  - D. Decreased PaO<sub>2</sub>
4. What is the rationale for Mrs. Graham being ordered Pepcid (famotidine) 20 mg IV Push daily when intubated and placed on the mechanical ventilator?
  - A. To decrease inflammation in the airways
  - B. To reduce gastric acidity
  - C. To minimize constipation
  - D. To enhance gastric emptying

5. The nurse correlates which ventilator setting as most important in preventing alveolar collapse in Mrs. Graham while intubated?
  - A. FiO<sub>2</sub> of 100%
  - B. Vt of 550 mL
  - C. PEEP of 5 cm H<sub>2</sub>O
  - D. SIMV with rate of 12

## CHAPTER SUMMARY

The main function of the respiratory system is to deliver oxygen to the lungs, where, through diffusion, oxygen is released at the alveolar-capillary membrane into the blood and CO<sub>2</sub> is removed from the blood through diffusion and is released as a gas that is transported to the atmosphere. Oxygen therapy is initiated when patients require a higher concentration than is found in room air, with the goal of oxygen therapy being to treat or prevent hypoxia. The effectiveness of oxygen therapy can be assessed by monitoring the pulse oximeter and by obtaining arterial blood gases.

Endotracheal tubes are indicated when there is upper airway obstruction, apnea, high risk for aspiration, ineffective airway clearance, and/or respiratory distress. Therapeutic modalities include the use of incentive spirometry, chest physiotherapy, nebulizer treatments, and intermittent positive-pressure breathing.

Indications for the use of a mechanical ventilator include acute respiratory failure; heart failure; exacerbation of COPD; protection of the airway due to cardiac arrest, drug overdose, or respiratory depression; and spinal cord or neurological trauma. Complications associated with mechanical ventilation include hypotension, barotrauma, aspiration, and ventilator-assisted pneumonia (VAP).

## Fluid and Electrolyte Management

Linda Cook

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Reviewing basic concepts related to fluid and electrolyte balance
2. Describing the role of the endocrine, renal, and respiratory systems in the regulation of fluid and electrolyte balance
3. Explaining the significance of osmolality, osmolarity, blood urea nitrogen (BUN), creatinine, and urine specific gravity in relation to fluid and electrolyte status
4. Discussing changes in fluid and electrolyte balance associated with aging
5. Describing the pathophysiology, clinical presentations, and management of dehydration, hypovolemia, and hypervolemia
6. Correlating laboratory data and clinical manifestations related to disorders in:
  - a. Sodium balance
  - b. Chloride balance
  - c. Potassium balance
  - d. Magnesium balance
  - e. Calcium balance
  - f. Phosphorus balance
7. Explaining nursing considerations related to patients with fluid and electrolyte disorders

### CONCEPTS

- Assessment

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Henrietta Morrison is an 80-year-old female admitted with a complaint of shortness of breath. She has a history of coronary artery disease, hypertension, and heart failure. She is complaining of a 2-week weight gain of 15 pounds, swollen ankles, and an inability to lie flat at night to sleep. Her current medications include furosemide (Lasix) 20 mg by mouth daily, K-Tabs 10 mEq by mouth twice daily, digoxin (Lanoxin) 0.25 mg by mouth daily, lisinopril (Prinivil) 10 mg by mouth twice daily, and spironolactone (Aldactone) 25 mg by mouth twice daily. She is waiting for the diagnostic tests to be completed, including a complete blood count (CBC), prothrombin time/international normalized ratio (PT/INR), activated partial thromboplastin time (aPTT), basic metabolic profile (BMP), brain natriuretic peptide (BNP), and a chest x-ray...

## BASIC CONCEPTS OF FLUIDS

Disturbances in fluids and **electrolytes**, electrically charged particles in solution and active chemicals, are seen in patients for a variety of reasons and can have significant impacts on nursing care. Understanding the interactions of fluids and electrolytes is important for nurses as they provide care to patients in a variety of clinical settings.

### Fluid Composition

Fluids and electrolytes exist within the body, are dynamic in nature, and are maintained in constant balance, or **homeostasis**, within the body. Electrolytes are responsible for many chemical reactions that produce energy. Energy generation occurs as **cations** (ions with net positive charge) and **anions** (ions with net negative charge) combine and split, resulting in energy creation for organ-level activity such as cardiac and skeletal muscle contractions. During the process of ionization, anions gain electrons, whereas cations lose electrons. Sodium ( $\text{Na}^+$ ), potassium ( $\text{K}^+$ ), calcium ( $\text{Ca}^{++}$ ), magnesium ( $\text{Mg}^{++}$ ), and hydrogen ( $\text{H}^+$ ) ions are the major cations in body fluid. Chloride ( $\text{Cl}^-$ ), bicarbonate ( $\text{HCO}_3^-$ ), and phosphate ( $\text{HPO}_4^-$ ) ions are the major anions in body fluids (Table 8.1).

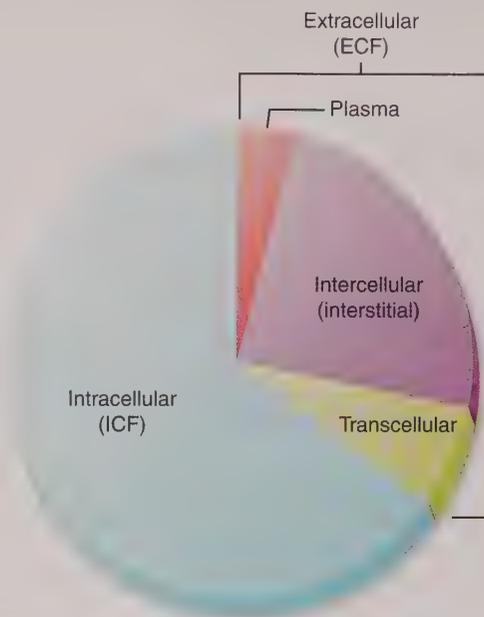

Water is the primary constituent of cells and surrounds each cell. Water is distributed throughout the body, with 55% of the average female body and 65% of the average male body being composed of water. Total body water is distributed between four compartments, the intracellular, extracellular, intercellular, and plasma compartments (Fig. 8.1).

**Intracellular fluid (ICF)** includes all fluid present within the cells, with **extracellular fluid (ECF)** being found outside

**Table 8.1** Ion Concentration of the Intracellular and Extracellular Fluid Compartments

Ion	Intracellular	Extracellular
<b>Sodium</b>	10	140
<b>Potassium</b>	140	4
<b>Chloride</b>	4	104
<b>Bicarbonate</b>	10	24
<b>Biphosphate</b>	100	3
<b>Calcium</b>	1	5

Values are in milliequivalents per liter of water.

**FIGURE 8.1** Compartments of total body water. The extracellular fluid (ECF) is composed of plasma, interstitial fluid, and transcellular fluid.

the cell. Sixty-five percent of total body water is found in ICF, and the remaining 35% is ECF. Extracellular fluid is further divided into intercellular, plasma, and transcellular. Intercellular, or interstitial, fluid is found between cells and is 25% of total body water. Intercellular fluid surrounds all cells, providing nutrients to the cell and facilitating waste removal. **Lymph** fluid is considered interstitial fluid, and as lymph enters the lymphatic system, it returns protein and excess interstitial fluid to the circulatory system. **Plasma** accounts for 8% of total body water and is located in the intravascular system. Total blood volume within the circulatory system is 6 L, of which 3 L is plasma. **Transcellular fluid** is only 2% of total body water and consists of fluids located in the gastrointestinal (GI), respiratory, and urinary tract and glandular, intraocular, and cerebrospinal fluids.

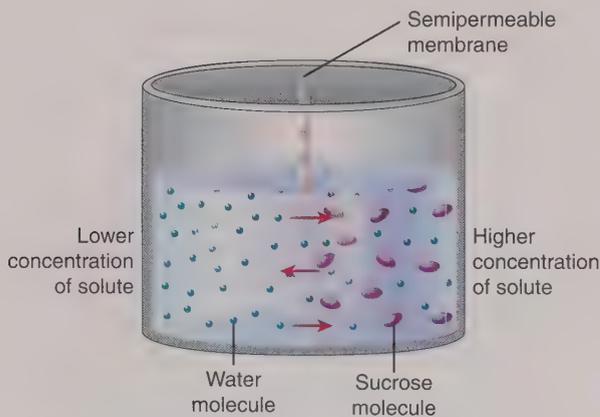

Extracellular and intracellular fluids are separated by the capillary wall and cell membrane. The capillary wall and cell

membrane are permeable membranes allowing water to shift easily between the cells, **interstitial spaces** (area surrounding tissue cells), and plasma. Fluid is drawn back into the intracellular space from the blood through **osmosis**, which is the movement of water through a semipermeable membrane from an area of higher water concentration to an area of lower water concentration (Fig. 8.2). The goal of osmosis is to equalize water and **solute** (substance dissolved in a solution) concentrations on both sides of the membrane. In order to maintain equal distribution of solutes or particles between membranes, diffusion occurs. **Diffusion** moves solutes or particles from an area of higher concentration to an area of lower concentration (Fig. 8.3). The difference in the concentration of solutes or particles between membranes is the **concentration gradient**. A concentration gradient allows for particles to evenly distribute themselves throughout a solution. Osmosis and diffusion are **passive transport**

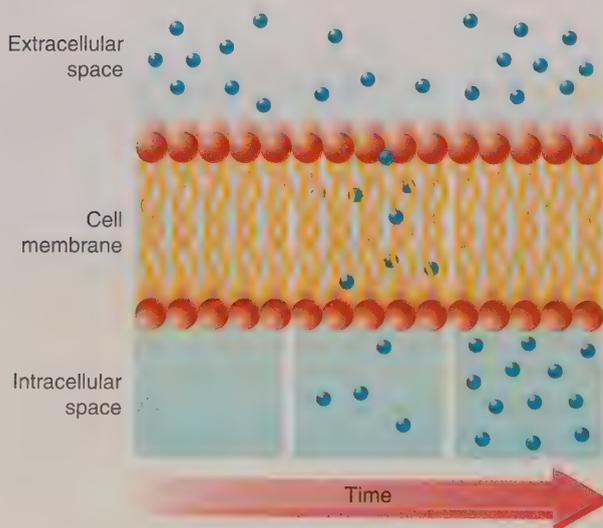

processes because no energy is required for the movement of water or solute through a semipermeable membrane to occur. Larger molecules require energy to move into a cell. This process is called **active transport**. Active transport moves an ion or molecule against a concentration gradient.

### Fluid Intake and Output

Fluid is kept in a balanced state through the intake and output (I&O) of fluid and is achieved through normal physiology. On average, 2,500 mL of fluid is processed daily by the body through gains and losses. Intake of fluid is through solid food, fluid, and cellular anaerobic respiration. Cellular anaerobic respiration uses glucose to create adenosine triphosphate (ATP) for energy, with a by-product being water. The primary loss of body water is in the urine. Additional fluid is lost in the stool, in exhaled air through the respiratory system, and from the skin as perspiration (Fig. 8.4).

**FIGURE 8.2** Osmosis occurs across a semipermeable membrane and reflects the movement of water through a semipermeable membrane from an area of higher water concentration to an area of lower water concentration.

**FIGURE 8.3** Diffusion moves solutes or particles from an area of higher concentration to an area of lower concentration. Solutes move from the extracellular fluid (ECF) through the cell membrane to the intracellular fluid (ICF) over time.

### Connection Check 8.1

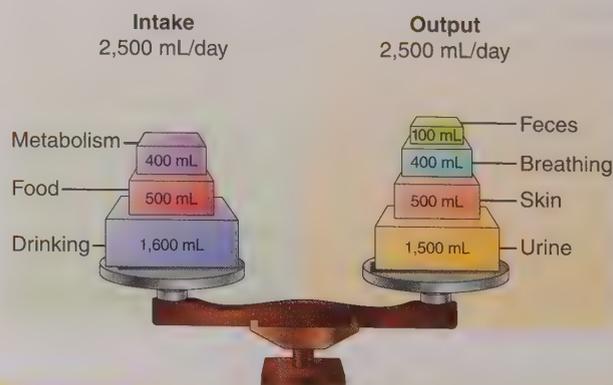

The nurse understands that cerebrospinal fluid is considered which type of fluid?

- A. Intracellular
- B. Interstitial
- C. Transcellular
- D. Plasma

## FLUID AND ELECTROLYTE REGULATION

### Osmosis

Regulation of intracellular and extracellular fluids is based on fluid shifts from a higher concentration of solute to a lower concentration through the membrane separating them. A shift of water occurs until there is a balance in solute concentration and is dependent on the fluid concentration gradient. This process is called osmosis and is dependent on the number of particles in the solution; the number of particles or solutes per unit of solution determines **osmolality** and is measured as the total number of solute

**FIGURE 8.4** Daily intake and output are typically equal. Fluid intake includes fluids, food, and metabolic processes, and output includes urine and fluid loss through the skin, lungs, and bowel.

particles per kilogram. Additional terms associated with osmosis are *osmotic pressure*, *oncotic pressure*, and *osmotic diuresis*.

**Osmotic pressure** is the ability of a solution to draw water across a membrane, and it is affected by the **tonicity** of fluids. Tonicity is the ability of solutes to cause an osmotic driving force that promotes the movement of water across a membrane from one compartment to another. Fluids are classified as **isotonic**, **hypotonic**, or **hypertonic** on the basis of the particle concentration in body fluids. Milliequivalents per liter (mEq/L), milliosmoles per liter (mOsm/L), and millimoles per liter (mmol/L) are how particle concentrations in body fluids are measured. The number of milliosmoles in a kilogram (mOsm/kg) of solution is the osmolality of a solution, whereas **osmolarity** is the number of milliosmoles found in a liter of solution. The normal range for serum osmolality is 275 to 295 mOsm/kg. The normal range for the calculated osmolarity for body fluid and plasma is 270 to 300 mOsm/L, and osmolarity close to 300 mOsm/L is the value at which the body functions best. Isotonic fluids have the same osmolarity as plasma and body fluids, so no fluid is pulled across the cell membrane when these fluids are administered. Hypotonic solutions have a lower concentration of solutes than within the cell, causing fluid movement into cells. Hypertonic solutions have higher concentrations of solutes than within cells, causing fluids to shift out of the cell and into the ECF, causing cells to shrink.

The pressure created by solutes, nondiffusible plasma proteins (primarily albumin) dissolved in fluid, exerts oncotic pressure and pulls fluid toward the solute. **Colloidal osmotic pressure**, also known as oncotic pressure, is a form of osmotic pressure that pulls fluid from the interstitial space back into the intravascular space, increasing the circulating volume. The presence of albumin creates a higher concentration of protein in the intravascular plasma, which exerts colloidal osmotic pressure in the venous end of the capillary, returning fluid to the circulatory system. Plasma protein osmotic function maintains a fluid balance between the interstitial and intravascular spaces. If there is an increase in the intravascular volume from the shifting of fluids from the interstitial space to the intravascular space, there is also an increase in blood volume to the kidneys, leading to an increase in urine output. This resulting increase in urine output is **osmotic diuresis**. Osmotic diuresis also occurs as a result of the body's effort to remove high levels of glucose (hyperglycemia) and in response to mannitol or radiographic contrast media. Hyperglycemia results in increased osmotic pressure within the renal tubules, causing a decreased reabsorption of water back into the intravascular fluid. Mannitol and radiographic contrast media, both of which are administered intravenously, have a high osmolality, leading to osmotic diuresis.

## Diffusion

The movement of molecules from an area of higher concentration to an area of lower concentration is **diffusion**. In any change in the concentration of electrolytes in either the interstitial fluid or plasma, the change is swiftly followed by a shift in electrolytes to restore balance in the

concentration. Once balance is restored, diffusion continues without shifting of electrolytes.

Diffusion occurs as a result of the membrane transport system, which assists with the passage of a specific ion or molecule through the cell membrane. In some instances, the ion or molecule must be moved against a concentration gradient and requires the expenditure of energy. This use of energy is considered active transport and is accomplished through pumps. The sodium–potassium pump is an example of active transport. High concentrations of sodium and potassium are maintained in the ECF and ICF, respectively, because of the active transport of potassium.

## Filtration

**Filtration** is the process by which water and dissolved substances (solutes) cross a membrane as a result of **hydrostatic pressure**, which is the pressure exerted on the walls of blood vessels by fluid, primarily water. Movement of solutes occurs from an area of high hydrostatic pressure to an area of low hydrostatic pressure. Examples of filtration are the glomerular filtration system of the kidneys and the arterial end of the capillary.

## Regulatory Mechanisms

Balance, or homeostasis, of fluid is accomplished by several regulatory mechanisms and processes in the body. Homeostasis between fluids and regulation of I&O are achieved by the renal, endocrine, and respiratory systems.

### Role of the Renal System

The kidneys are the primary organs in regulating fluid volume and electrolyte balance to maintain homeostasis. Through the glomeruli, the renal capillary network, the kidneys process approximately 170 L of plasma daily. Selective reabsorption of water and electrolytes occurs in the glomeruli, maintaining homeostasis of plasma osmolality and fluid (see Geriatric/Gerontological Considerations). Urine output is 1 to 2 L per day.

## Geriatric/Gerontological Considerations

### Renal Changes That Influence Fluid and Electrolyte Balance

With aging, there are renal changes that influence fluid and electrolyte balance. Renal blood flow decreases due to vascular changes, which can result in ischemia and the death of renal cells. Kidney size decreases with age due to cortical tissue loss from **glomerulosclerosis** (hardening of the glomeruli in the kidney). There is a decrease in glomerular filtration rate (GFR) due to reductions in the glomerular capillary plasma flow rate and reabsorption of water. A history of chronic hypertension, heart failure, and diabetes also predisposes the older adult to kidney failure.

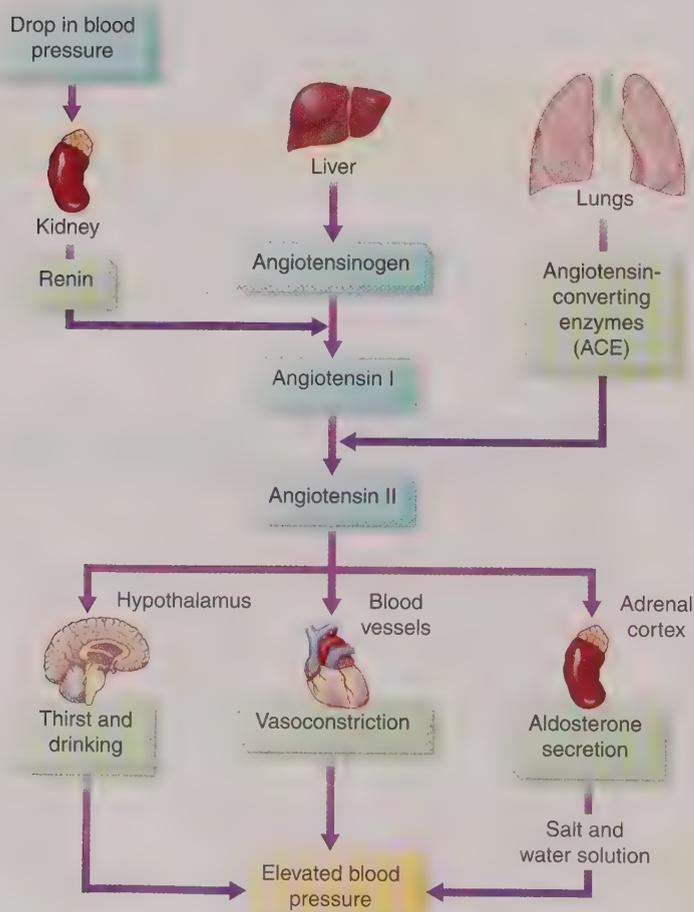

### Role of the Endocrine System

Control of fluid and electrolyte balances is maintained by the renin–angiotensin–aldosterone system (Fig. 8.5), antidiuretic hormone (ADH), and natriuretic peptides. The renin–angiotensin–aldosterone system also assists in maintaining blood pressure and intravascular fluid status. In response to a decrease in blood pressure or blood flow, renin is released from the juxtaglomerular cells of the kidneys and works on angiotensinogen (from the liver), converting it to angiotensin I. Angiotensin I is then converted to angiotensin II in the lungs by angiotensin-converting enzymes. Angiotensin II is a potent vasoconstrictor that also stimulates the release of aldosterone and stimulates the thirst mechanism, increasing fluid intake. Aldosterone release is also stimulated by an increase in urine sodium or a decrease in extracellular sodium and is secreted by the adrenal cortex. Aldosterone promotes the retention of sodium and water in the distal nephrons of the kidney, restoring blood volume.

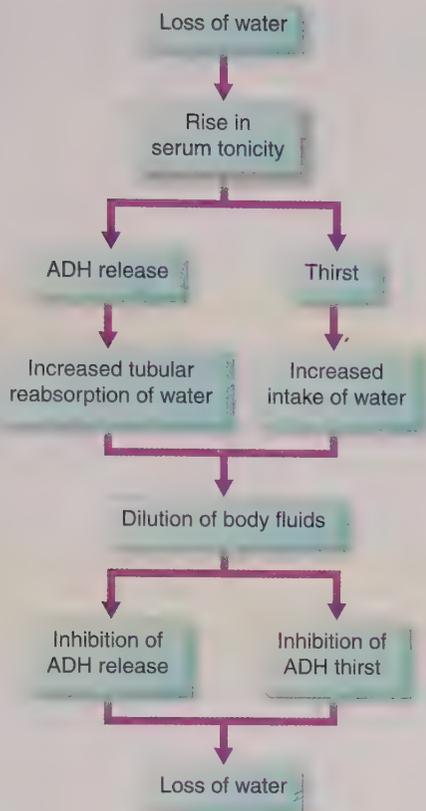

Antidiuretic hormone is synthesized in the hypothalamus and released from the posterior pituitary gland and is released in response to changes in blood osmolality sensed by osmoreceptors located in the hypothalamus. These osmoreceptors are sensitive to blood plasma concentration and

stimulate the release of ADH in response to increases in osmolality. In addition to osmoreceptors, there are baroreceptors, located in the aortic arch, carotid arches, and the left atrium, that also respond to changes in circulating blood volume and blood pressure. If there is a decrease in arterial blood pressure, baroreceptors stimulate the sympathetic nervous system, causing renal arteriole constriction that decreases glomerular filtration and increases the release of aldosterone and reabsorption of sodium and water. Antidiuretic hormone directly influences water reabsorption in the distal tubules and collecting ducts in the kidneys. The reabsorbed water is then returned into the vascular system, reducing serum osmolality and increasing circulating volume. Once serum osmolality returns to normal, 275 to 295 mOsm/kg, the release of ADH is inhibited (Fig. 8.6).

**Natriuretic peptide hormones** are released from specialized cells within the walls of the atrium (atrial natriuretic peptide [ANP]) and ventricles (brain natriuretic peptide [BNP]) in response to increased blood volume and blood pressure. As a result of the release of ANP and BNP, reabsorption of sodium by the kidney and the increase in glomerular filtration rate result in increased urine output that is high in sodium.

**FIGURE 8.5** Fluid and electrolyte balance and blood pressure regulation through the renin–angiotensin system.

**FIGURE 8.6** Role of antidiuretic hormone (ADH) in fluid regulation. ADH secretion increases with thirst and increased serum osmolality and decreases with decreased serum osmolality.

### Role of the Respiratory System

Fluid loss occurs from the lungs through vaporization, which occurs as a result of inspired air being warmed and humidified by the body. With exhalation, the warmed, humidified air is released from the lungs. Approximately 300 mL of water is lost through the lungs daily, and that amount can be higher during hyperventilation or tachypnea or if the patient is receiving mechanical ventilation.

### Invisible Losses

Invisible water loss occurs through the skin, lungs, and stool. Invisible water loss is not controllable and can be significant in the total amount because of the lack of awareness of this fluid loss. Increased invisible water losses can also be seen in hypermetabolic states such as trauma, burns, fever, and thyroid crisis because of fluid loss from impaired skin integrity, an increase in perspiration with fever, and hypermetabolism with thyroid crisis. In a hot, dry environment, invisible water loss increases because of evaporation of body water from the skin. Loss of water through perspiration is variable and is controlled by body temperature, vasodilation, and the autonomic nervous system. With increases in body temperature, the autonomic nervous system is stimulated by the hypothalamus to cause vasodilation. Vasodilation increases blood flow through the periphery, allowing conduction of heat into the environment. Invisible loss of water also increases via the GI tract in severe diarrhea or ulcerative colitis.

### Connection Check 8.2

The nurse correlates which physiological response to the secretion of natriuretic peptide hormones?

- Increase in urine output
- Increase in blood pressure
- Increase in blood volume
- Increase in serum osmolality

### Indicators of Fluid Status

The fluid status of patients is evaluated through a review of body weight, serum osmolality, blood urea nitrogen (BUN), creatinine, and urine specific gravity. Physical assessment findings also contribute to the evaluation of fluid status. Measurement of body weight and comparison to the patient's normal weight provides information regarding fluid loss or retention.

Osmolality is the concentration of a solution as determined by the number of solutes in a kilogram of water in blood and urine. Collection of a blood specimen and a random urine specimen at the same time is the most effective means to evaluate osmolality. The normal ratio between urine and blood osmolality is 3:1, with a normal range of serum osmolality of 275 to 295 mOsm/kg and a random urine specimen osmolality of 50 to 1,200 mOsm/kg of water. Evaluation of urine osmolality is a more exact measurement of urine concentration than specific gravity because it depends on the number of particles of solute found in a unit of solution, which is a better reflection of fluid status. Obtaining urine and serum osmolality levels at the same time provides more information about renal function. Increases in urine osmolality are seen in **fluid volume deficit**, prerenal failure, and heart failure because of the concentration of urine and increase in the number of particle solutes. Decreases in urine osmolality are seen in hyponatremia, **fluid volume excess**, and diabetes insipidus because of the dilution of urine and decrease in the number of particle solutes. Increases in serum osmolality are seen in hyperglycemia, hypernatremia, and severe dehydration, and decreases in serum osmolality are seen with renal failure, diuretic use, and fluid volume excess (Table 8.2).

**Blood urea nitrogen (BUN)** measures the nitrogen portion of urea and serves as a measure of glomerular function. Urea is the end product of protein breakdown by the liver. The normal BUN level is 8 to 21 mg/dL and varies with urine output, which reflects fluid status and renal function. Increases in BUN due to decreased perfusion of the kidneys are seen in impaired renal function secondary to sepsis, shock, stress, and congestive heart failure. In sepsis, shock states, and heart failure, blood is shunted away from the kidneys to maintain perfusion to the heart and brain. Decreases in BUN can be seen in syndrome of inappropriate antidiuretic hormone (SIADH), liver failure, and malnutrition. In patients with SIADH, retention of water occurs, diluting the circulating blood volume, thus decreasing BUN. In liver failure and malnutrition, there is a decrease in protein metabolism, resulting in decreased urea.

**Table 8.2 Serum and Urine Osmolality****Conditions That Increase Osmolality**

Serum	Urine
● Dehydration/sepsis/fever/ sweating/burns	● Dehydration
■ Diabetes mellitus (hyperglycemia)	● SIADH
■ Diabetes insipidus	● Adrenal insufficiency
● Uremia	● Glycosuria
● Hyponatremia	● Hyponatremia
■ Ethanol, methanol, or ethylene glycol ingestion	● High-protein diet
● Mannitol therapy	

**Conditions That Decrease Osmolality**

Serum	Urine
● Excess hydration	● Diabetes insipidus
● Hyponatremia	● Excess fluid intake
● SIADH	● Acute renal insufficiency
	● Glomerulonephritis

SIADH, Syndrome of inappropriate antidiuretic hormone.  
From RnCeus.com. (n.d.). *Serum and urine osmolality*. Retrieved from  
<http://www.rnceus.com/renal/renalosmo.html>

**Creatinine** is the by-product of muscle creatinine phosphate metabolism. Creatinine production is constant as long as muscle mass remains constant and serves as a better indicator of kidney function than BUN. Creatinine values range from 0.5 to 1.2 mg/dL depending on the muscle mass of the individual. The normal ratio of BUN to creatinine is 10:1 to 20:1.

**Specific gravity** is a measurement of dissolved chemicals in urine and reflects the ability of the kidneys to concentrate urine and is affected by the number and size of particles (minerals and salts) in urine. Hydration status, urine volume, and the number of particles impact the normal range of specific gravity. The normal range for specific gravity is 1.005 to 1.030. High values of specific gravity indicate concentrated urine and can be seen in patients with decreased renal perfusion or dehydration or in patients with SIADH. Lower values of specific gravity indicate dilute urine and are seen with diuretic use, diabetes insipidus, and increased fluid intake.

**Connection Check 8.3**

The nurse assesses for which clinical manifestations in the patient with dehydration? (Select all that apply.)

- Increased urine specific gravity
- Increased serum BUN
- Increased serum osmolality
- Decreased serum osmolality
- Decreased BUN-to-creatinine ratio

**Age-Related Changes**

Numerous physiological changes, disease processes and their management, and psychosocial factors occurring with aging impact fluid and electrolyte balance. With aging, there is a decrease in taste, smell, and thirst, which can impact fluid and electrolyte balance because it affects the intake of fluids and food. With aging, there is also a decline in olfactory function due to the decrease in olfactory fibers and receptors. Loss of these fibers and receptors results in a decrease in olfactory function and the ability to discriminate smells. Alterations in smell also affect taste, impacting the oral intake, especially fluids, of older adults. In addition to the loss of taste, the loss of teeth and ill-fitting dentures impact the oral and food intake of older adults, placing them at risk for malnutrition, decreased immunity, weight loss, and deterioration of health status.

Older adults can have numerous health issues, such as arthritis, diabetes mellitus, heart failure, and hypertension, that require complex medication regimens that can influence appetite, food selection, and food absorption. Gastrointestinal motility decreases with age, often requiring the use of cathartics, laxatives, or enemas, which can alter fluid and electrolyte balance. The use of diuretics can result in a fluid volume deficit due to increased urine production. Fluid volume deficits can also occur when older adults limit fluid intake because of problems with bladder control and mobility. Ill-fitting dentures and the absence of teeth can affect food choices, which can result in electrolyte imbalances.

With aging, older adults are at risk for lack of financial resources to purchase and prepare nutritionally balanced meals. Lack of transportation, reduced income, healthcare expenses, and disabilities can limit the older adult's ability to maintain adequate dietary intake. Loneliness and depression can impact the older adult's interest in preparing foods and eating. Cognitive changes associated with dementia and Alzheimer's disease impact the ability to recognize the need for and ability to ingest adequate food and fluid and can result in confusion about the need to eat, swallowing difficulties, and forgetting how to use eating utensils.

**Connection Check 8.4**

In the aging adult, which of the following impacts food and fluid intake?

- Increased sensitivity to smells
- Increased sensitivity to texture in foods
- Decreased manual dexterity
- Decreased olfactory function

**FLUID IMBALANCES**

Alterations in fluid balance occur frequently in patients, and the nurse's role is to identify them, initiate interventions, and evaluate the effects of the intervention. Fluid volume deficit and excess often lead to the need for evaluation and treatment (Table 8.3).

**Table 8.3 Comparison of Fluid Volume Deficit and Fluid Volume Excess**

Assessment Parameters	Fluid Volume Deficit	Fluid Volume Excess
<b>Weight</b>	Decreased	Increased
<b>Vital signs</b>		
<b>Heart rate</b>	Increased	Increased
<b>Blood pressure</b>	Decreased (orthostatic hypotension)	Increased
<b>Respirations</b>	Clear	Crackles or wheezing
<b>Skin turgor</b>	Decreased	Increased
<b>Edema</b>	None	Dependent
<b>Jugular vein</b>	Flat	Possible distention
<b>Urine output</b>	Decreased	Normal or low
<b>Urine specific gravity</b>	Increased	Decreased

### Hypovolemia: Fluid Volume Deficit

A fluid volume deficit is a decrease in fluid in the body and can occur in the interstitial, intravascular, or intracellular spaces. Fluid volume deficits are a common problem and may coexist with acid-base and/or electrolyte imbalances. A fluid volume deficit develops when fluid losses exceed fluid intake.

#### Causes

Fluid volume deficits occur as a result of excessive loss of fluids, insufficient intake of fluid, or fluid shifts. Gastrointestinal loss of fluid through vomiting, diarrhea, and nasogastric suction contributes to excessive loss of fluids. Increased perspiration during strenuous exercise or extreme heat without adequate fluid replacement can contribute to a fluid volume deficit. Additional causes of fluid losses include hemorrhage, diabetes insipidus, diabetic ketoacidosis, and adrenal insufficiency.

Insufficient intake of fluid can occur because of nausea; anorexia; or an inability to swallow as a result of an oral injury, neck trauma, or a cerebrovascular accident (stroke). Altered thirst mechanism can also decrease the recognition of the need to drink. Inability to communicate thirst and to access fluid also contributes to insufficient fluid intake. Aggressive treatment of fluid volume excess with diuretics can also result in a fluid volume deficit.

Fluid shifts into the interstitial space or **third spacing** occurs when fluid leaves the vascular space and enters the space between cells, becoming unavailable to support normal physiological activities. As fluid shifts into the interstitial space, circulating blood volume decreases, resulting in a decrease in blood flow to the organs of the body. Patients

can become hypotensive, tachycardic, or restless and have decreased urine production. Third spacing can be seen in trauma, burns, cirrhosis, or right-sided heart failure and is often related to a decrease in oncotic pressure. Fluid can shift into the abdomen (ascites), pleural space (pleural effusion), or soft tissues (peripheral edema) or be lost through disrupted skin integrity as with burn injuries.

#### Laboratory Values

Routine laboratory studies to evaluate fluid volume status include electrolytes, specifically sodium and potassium; hemoglobin and hematocrit; serum osmolality; BUN in relationship to creatinine; urine specific gravity; and urine osmolality. In a fluid volume deficit, elevations of serum osmolality, urine specific gravity, and urine osmolality are observed as the kidneys work to conserve water. The kidneys conserve water as a result of the role of aldosterone through reabsorption of sodium, and ADH increases water reabsorption in the distal nephrons.

Hemoglobin and hematocrit also may be decreased if the fluid volume deficit is secondary to hemorrhage or elevated with the loss of fluid volume. Hemoglobin is the protein molecule within red blood cells that carries oxygen. Hematocrit is the percentage of red blood cells in the volume of whole blood and is dependent on the number and size of red blood cells. With decreased circulating volume, hematocrit is falsely elevated. Normal values for hemoglobin are 14 to 17.3 g/dL for adult males and 11.7 to 15.5 g/dL for adult females, and hematocrit is 42% to 52% for adult males and 36% to 48% for adult females.

Elevation of the BUN-to-creatinine ratio occurs as a result of decreased renal perfusion and function, which occur in shock states or dehydration. A BUN elevation is seen secondary to dehydration because of the retention of waste products. Serum sodium levels elevate with loss of water. Hypokalemia may occur in severe gastrointestinal (GI) fluid loss such as diarrhea because of the rapid passage of stool through the colon, resulting in the inability of the colon to reabsorb potassium. Gastrointestinal fluids contain sodium, potassium, bicarbonate, and chloride.

#### Clinical Manifestations

Depending on the cause, fluid volume deficits can develop quickly, and if the deficit is severe, patients may exhibit pronounced clinical manifestations. Weight loss, loss of skin turgor, concentrated urine output, **oliguria** (low urine output), thirst, and dry mucous membranes are indications of a fluid volume deficit. Severe, rapid fluid losses may be seen in hemorrhage, burns, or extensive losses from the GI tract. Additional clinical manifestations observed with significant fluid loss may include weak, rapid peripheral pulses; flattened neck veins; hypotension; anxiety; restlessness; and cool, clammy, pale skin.

#### Management

##### Medical Management

Identification of the etiology of the fluid losses and implementation of appropriate interventions are the first steps in correcting fluid volume deficits. Intake of oral fluids is the

preferred method of water replacement if the fluid deficit is not severe. In situations where the patient is unable or it is not feasible to replace fluid orally, or the loss is rapid and severe, alternative methods must be used. Provision of IV isotonic solutions, such as 0.9% normal saline (NaCl) or lactated Ringer's solution, expands plasma volume and corrects hypotension. The rate of infusion is dependent on the severity of fluid loss and patient symptoms. Once hypotension has been corrected, IV solutions and the infusion rate are adjusted to correct electrolyte disturbances and correct deficits in total body water. IV solutions of D5 0.45% NaCl or 0.45% NaCl can replace deficits in total body water and are used as maintenance fluids (Table 8.4).

Close monitoring of patient response to fluid replacement is essential. Assessment of vital signs, pulmonary and neurological function, and urine output identifies improvement in patient status and prevents the development of fluid volume overload. Improvement in neurological status includes a decrease in restlessness and improvement in mental status. Pulmonary clinical manifestations of fluid overload are increased respiratory rate, cough, development of crackles, and decreased oxygen saturation. If urine output continues to be low, further evaluation of fluid status and renal perfusion assists in determining if additional fluid is required.

### Complications

Complications of fluid volume deficit occur with losses of large amounts of fluid volume. Hypovolemic shock can develop, as evidenced by hypotension, tachycardia, and signs of organ hypoperfusion, such as cool and clammy skin, oliguria progressing to **anuria** (lack of urine output), decreased level of consciousness, and tachypnea.

### Nursing Management

Assessment of patients for fluid volume deficit includes collecting a health history, performing a physical assessment, reviewing diagnostic results, and calculating I&O. Collection of a health history focuses on the onset and duration of clinical manifestations, any recent illness, and medication use. Physical assessment findings may include dry mucous membranes, poor skin turgor, weak peripheral pulses, changes in vital signs, and weight loss. Changes in vital signs such as heart rate greater than 100 beats per minute and hypotension can indicate the presence of a significant fluid volume deficit. Hypotension, especially **orthostatic hypotension** (a decrease in blood pressure within 3 minutes of standing when compared with blood pressure from the sitting or supine position), and tachycardia with a weak, thready pulse indicate a fluid volume deficit. Monitoring of vital signs provides information regarding the patient's response to treatment. In addition to vital signs, assessment of mucous membranes; skin turgor; and urine specific gravity, color, and volume provides information about

fluid volume status. Laboratory data may include elevated hemoglobin and hematocrit, serum sodium levels, and BUN. The nurse continues the physical assessment for signs of correction of fluid deficit, such as moist mucous membranes, improved skin integrity, and an increase in urine output.

**Safety Alert** Patients with significant hypovolemia are at risk for orthostatic or postural hypotension.

The nurse needs to monitor the patient closely when changing the patient's position, particularly when sitting or standing, because the patient is at risk for dizziness and falls.

Early recognition of patients at risk for the inability to independently provide an adequate oral intake of fluid assists in preventing the development of fluid volume deficit and is identified through monitoring of output. Ensuring fluid replacement as prescribed assists in correcting a fluid volume deficit. Administering oral liquids or IV fluids as ordered assists in correcting fluid volume deficits. Monitoring I&O is one means to evaluate patient response to interventions to correct fluid volume deficits. Depending on patient status, assessment of I&O is completed in specified hourly increments. Monitoring laboratory results, especially serum electrolytes and osmolality, hemoglobin, and hematocrit, provides information about the patient response to treatment. Obtaining daily weights also provides information about the patient's response to interventions.

## CASE STUDY: EPISODE 2

Henrietta continues to complain of shortness of breath. Physical assessment findings include an irregular heart rate of 124 beats per minute, 3-cm jugular vein distention, bilateral crackles to mid-level of both lungs, 3+ pitting edema to both lower extremities, and abdominal distention. Her chest x-ray shows bilateral pulmonary congestion. Her laboratory work shows hemoglobin 10 g/dL, hematocrit 30%, Na<sup>+</sup> 130 mEq/L, K<sup>+</sup> 4.9 mEq/L, BUN 29 mg/dL, creatinine 0.8 mg/dL, and albumin 3.2 g/dL. A saline lock is inserted, and furosemide (Lasix) 40 mg is administered by IV push...

### Hypervolemia: Fluid Volume Excess

A fluid volume excess occurs as a result of increased water and sodium retention. An increase in sodium always results in an increase in water retention to maintain equilibrium. The presence of excess fluid can lead to increased intravascular fluid volume and interstitial fluid or edema.

**Table 8.4 Common IV Fluids: Crystalloids and Colloids**

	Action/Use	Nursing Considerations
<b>Crystalloid</b>		
<b>Hypotonic:</b> less than 250 mOsm/L	Shifts fluid out of vessels into cells	May worsen hypotension
0.25% NaCl	Hydrates cells	Can increase edema
0.45% NaCl	(D5W spares protein; provides calories and free water; treats hyperkalemia; is a diluent for IV medications)	May cause hyponatremia
5% D5W		(D5W may also irritate veins)
<b>Isotonic:</b> greater than 250 mOsm/L	No fluid shift	May cause fluid overload
0.9% NaCl	Vascular expansion	Generalized edema
Lactated Ringer's (LR)	Electrolyte replacement	Dilutes hemoglobin
		May cause hyperchloremic acidosis
		May cause electrolyte imbalance
		Pro-inflammatory in large doses
<b>Hypertonic:</b> greater than 375 mOsm/L	Shifts fluid back into circulation	Irritating to veins
D5 0.45% NaCl	Vascular expansion	May cause fluid overload
D5 0.9% NaCl	Replaces electrolytes	May cause hypernatremia
HS 3% or 5%		May cause hyperchloremia
		(HS slows inflammation and increases capillary permeability)
<b>Colloid</b>		
Albumin (plasma proteins)	Keeps fluid in vessels	May cause anaphylaxis (watch for hives, fever, chills, headache)
5% or 25%	Maintains volume	May cause fluid overload and pulmonary edema
	Used to replace protein and treat shock and erythroblastosis fetalis	
Dextran (polysaccharide)	Shifts fluids into vessels	May cause fluid overload and hypersensitivity
40 kDa or 70 kDa	Vascular expansion	Increased risk of bleeding
	Prolongs hemodynamic response when given with HS	Contraindicated in bleeding disorders, CHF, and renal failure
HES (synthetic starch)	Shifts fluid into vessels	May cause hypersensitivity and fluid overload
6% or 10%	Vascular expansion	Increased risk of bleeding
		Contraindicated in bleeding disorders, CHF, and renal failure
Mannitol (alcohol sugar)	Oliguric diuresis	May cause fluid overload
5% or 25%	Reduces cerebral edema	May cause electrolyte imbalances
	Eliminates toxins	Cellular dehydration
		Extravasation can cause tissue necrosis

CHF, Congestive heart failure; D5W, dextrose in water; HES, hetastarch; HS, hypertonic saline; NaCl, sodium chloride.

### Causes

Disease processes or conditions that result in retention of sodium and water include cirrhosis, heart failure, stress conditions causing a release of ADH and aldosterone, adrenal gland disorders, and the use of corticosteroids. Patients receiving sodium-containing fluids in excessive amounts are also at risk for fluid volume excess. Ingestion of excessive amounts of salt in the diet also contributes to the development of fluid volume excess.

### Laboratory Values

Laboratory tests that are assessed with suspected fluid volume excess include serum electrolytes, hematocrit, BUN, serum osmolality, and albumin. In fluid volume excess, hematocrit and BUN may be low secondary to dilution. Hypoalbuminemia presents in cirrhosis because of alterations in protein synthesis secondary to liver dysfunction. Hyponatremia and low serum osmolality may be present in chronic renal failure because of the dilution of blood volume.

### Clinical Manifestations

Manifestations of fluid volume excess present in the form of weight gain, ascites, edema, and increased urinary output. Cardiac manifestations of fluid volume excess include hypertension, tachycardia, elevated central venous pressure, development of  $S_3$  heart sounds, and jugular vein distention. In patients with heart failure, cardiac output is not able to meet the oxygen demands of the body. To meet these oxygen demands, the sympathetic nervous system is activated, increasing the heart rate and cardiac contractility, both of which increase blood pressure. As a result of decreased tissue perfusion, activation of the renin-angiotensin system occurs. Angiotensin II stimulates the release of aldosterone, which then promotes sodium and water reabsorption by the kidneys, further increasing the circulating blood volume. An extra heart tone,  $S_3$ , is present because of the large amount of blood volume entering the ventricles during diastole. Jugular vein distention develops as blood backs up in the right side of the heart. Respiratory symptoms develop as fluid leaks from the pulmonary capillaries into the alveoli because of the increased circulating blood volume and the inability of the left heart to pump the blood volume forward into the circulatory system. Respiratory symptoms include cough, tachypnea, adventitious breath sounds (i.e., crackles, wheezing), orthopnea, and decreased oxygen saturation.

### Management

#### Medical Management

Management of fluid volume excess is aimed at prevention, correcting/managing the underlying cause, and treating the clinical manifestations. In patients at risk for fluid volume excess, limiting the daily intake of fluid and sodium and monitoring daily weight assist in preventing fluid retention and facilitating early recognition of fluid overload. Terminating or decreasing the infusion rate of sodium-containing IV fluids assists with fluid volume status. Use of diuretics may

be required to promote excretion of excess fluid volume. In patients with renal compromise who do not respond sufficiently to diuretic therapy, renal dialysis may be required.

### Complications

Worsening heart failure with progressive **pulmonary edema** is a complication of fluid volume excess. As left ventricular function continues to fail, fluid accumulates in the interstitial spaces of the lungs and in the alveoli. Pulmonary edema can occur as a result of an acute exacerbation of chronic heart failure, in the setting of an acute myocardial infarction and acute or chronic renal failure. Pulmonary edema is a potentially life-threatening condition due to progressive hypoxia that develops as oxygen exchange is compromised because of fluid in the alveoli. Emergent interventions include oxygen therapy, diuretics, morphine, and vasodilators.

Oxygen therapy may range from supplemental oxygen via nasal cannula to endotracheal intubation with mechanical ventilation. Mechanical ventilation provides positive end-expiratory pressure that decreases the movement of fluid from the pulmonary capillaries into the alveoli, improving oxygenation. The type of intervention is determined by the patient's arterial blood gas results, oxygen saturation, and signs of respiratory distress. (See Chapter 9 for more information on mechanical ventilation.)

Administration of morphine in small doses of 2 to 3 mg via IV push (IVP) promotes peripheral venous dilation, which reduces preload by redistributing blood volume in the periphery. In addition to peripheral vasodilation, morphine reduces anxiety. This reduction of preload secondary to decreased venous return can minimize the fluid overload of pulmonary edema.

Administration of IV diuretics such as furosemide (Lasix) promotes rapid diuresis, decreasing the circulating blood volume. Close monitoring of urine output to evaluate the patient's response is important. Electrolyte values, particularly potassium, must be monitored with diuretic administration because some of these medications are potassium wasting and others are potassium sparing. Patients with acute or chronic renal failure who develop fluid volume excess may require emergent renal dialysis. Vasodilators such as nitroglycerin or nitroprusside (Nipride) also may be administered intravenously to promote venous dilation and decrease preload. Both medications are titrated to patient response, and the blood pressure is closely monitored.

### Nursing Management

Assessment of patients for fluid volume excess includes collecting a health history, performing a physical assessment, reviewing laboratory data, monitoring weight, and calculating I&O. Collection of a health history focuses on the onset and duration of symptoms, any recent illness, previous health issues, and current medication use and compliance. Physical assessment findings may include adventitious breath sounds (crackles), the presence of the extra heart sound  $S_3$ , abdominal distention or ascites, peripheral edema, a distended jugular vein, and altered mental status. If the

patient status allows, obtain a weight upon admission to assist in evaluating patient response to treatment.

Nursing care is aimed at early recognition of clinical manifestations of fluid volume excess. Monitoring I&O, performing a physical assessment for signs of fluid overload, and evaluating patient response to interventions to resolve fluid volume excess are essential nursing interventions. Obtaining a daily weight provides additional information regarding fluid loss. Each kilogram of weight (2.2 pounds) is equivalent to 1 L of fluid. Providing patient education regarding medications such as diuretics, limiting intake of sodium and fluid, and the importance of daily weight assists patients in preventing the development of fluid volume excess. Patient education also needs to include specific criteria for the patient to contact the healthcare provider regarding clinical manifestations of fluid volume excess.

### Connection Check 8.5

The nurse assesses for which clinical manifestations in the patient with hypervolemia?

- Bradycardia
- S<sub>3</sub> heart sound
- Postural hypotension
- Decreased skin turgor

### CASE STUDY: EPISODE 3

Over the next 3 days, Henrietta has 6 L of urine output. Her breath sounds demonstrate crackles in the bases bilaterally and an SaO<sub>2</sub> of 97% on room air. Follow-up laboratory work shows hemoglobin 15 g/dL, hematocrit 43%, Na<sup>+</sup> 155 mEq/L, K<sup>+</sup> 2.9 mEq/L, BUN 49 mg/dL, creatinine 1.2 mg/dL, and albumin 3.2 g/dL. She is given 40 mEq of potassium chloride, and her diuretics are held for 2 days...

## ELECTROLYTE DISORDERS

Alterations in electrolyte balances are common in patients for a variety of reasons, including acute illnesses or as a result of medication usage. Nurses play a vital role in recognizing these alterations in electrolyte balance and seeking corrective interventions. Electrolyte imbalances place patients at risk for serious negative health outcomes and are found in all healthcare settings (Tables 8.5–8.7).

### Sodium

Sodium is the most prevalent electrolyte in ECF, with 95% of physiologically active sodium located in the ECF. Sodium levels are a key determinant of the osmolality of ECF and control the distribution of water within the body. The

**Table 8.5 Electrolyte Values**

Electrolyte	Normal Value Range
Serum sodium	135–145 mEq/L
Serum chloride	97–107 mEq/L
Serum potassium	3.5–5.0 mEq/L
Serum magnesium	1.6–2.2 mg/dL
Total serum calcium	8.2–10.2 mg/dL
Ionized calcium	4.6–5.3 mg/dL
Serum phosphorus	2.5–4.5 mg/dL
Serum osmolality	275–295 mOsm/kg
Urine osmolality	250–900 mOsm/kg

**Table 8.6 Intracellular Versus Extracellular Electrolytes**

Intracellular	Extracellular
Potassium	Sodium
Magnesium	Chloride
Phosphorus	Bicarbonate

normal range of sodium is 135 to 145 mEq/L. Sodium levels are controlled by thirst, ADH, and the renin–angiotensin–aldosterone system. The thirst mechanism is stimulated, and the release of ADH is seen in patients with elevated sodium levels. Increased oral intake and water reabsorption result in restoring normal serum sodium levels. Excessive free water intake and release of ADH can result in low serum sodium levels. The sodium–potassium pump facilitates transfer of sodium from the ECF to the ICF and transfer of potassium from the ICF to the ECF, creating an action potential. This action potential is responsible for cardiac and skeletal muscle contractions and nerve impulse transmission.

Sodium levels are maintained through the functioning of the kidneys under the influence of ADH, aldosterone, and natriuretic peptide. Sodium ions are positively charged, and chloride ions are negatively charged, and they maintain the balance of positive and negative charges. Sodium intake occurs as a result of the ingestion of food and fluids. The 2015 Dietary Guidelines for Americans report that the Institute of Medicine recommends a daily intake of sodium between 1,500 and 2,300 mg, with the goal to limit sodium intake as much as possible.

Table 8.7 Common Electrolyte Disturbances

Electrolyte	Clinical Manifestations	Treatment
<b>Sodium (Na<sup>+</sup>) 135–145 mEq/L</b>		
<b>Hyponatremia</b> Serum sodium level less than 135 mEq/L	Headache, lethargy, confusion, seizures, nausea/vomiting, coma	<ul style="list-style-type: none"> <li>● Fluid restriction</li> <li>● In severe neurological symptoms, 3% NaCl</li> <li>● Oral sodium supplements</li> <li>● Loop diuretics</li> </ul>

Sodium and water imbalances are common in a variety of patient populations. Changes in water balance, either by intake or loss through excretion, gastrointestinal losses, or illness, impact serum sodium levels and can result in hypernatremia. In patients with hypovolemia (fluid deficit), there is a loss of both water and sodium. Hyponatremia is seen in patients who are not able to eliminate water, resulting in dilution of the intravascular fluid. The presence of edema is primarily the result of the retention of water and sodium as seen in heart failure, liver disease, or renal failure.

### Hyponatremia

Hyponatremia refers to serum sodium values that are less than 135 mEq/L and is the most common electrolyte disorder. Representing the amount of water in relationship to serum sodium, hyponatremia often results from disturbances in water. This disturbance in water balance can result in hypovolemic hyponatremia, euvolemic hyponatremia, or hypervolemic hyponatremia (Table 8.8).

In patients with hypovolemic hyponatremia, there is a decrease in the total body sodium and water in ECF as a result of the renal or extrarenal loss. The use of loop and thiazide diuretics is a cause of renal water loss, with thiazide diuretics being more likely to cause hyponatremia through renal loss of sodium. Sodium may also be lost secondary to diarrhea, vomiting, hyperglycemia with glycosuria, and perspiration. Clinical manifestations of hypovolemic hyponatremia include weight loss, orthostatic hypotension, tachycardia, abdominal cramping, and polydipsia (increased thirst).

Euvolemic hyponatremia occurs when there is an increase in total body water with no evidence of edema or hypovolemia. This can be seen in patients with SIADH and other endocrine disorders, such as severe hypothyroidism or adrenal insufficiency, both of which impair water excretion. Euvolemic hyponatremia also can be seen in psychotic polydipsia (excessive thirst) because antipsychotic medications have an anticholinergic effect, causing dry mouth and increased thirst.

**Table 8.8** Types of Hyponatremia

	Hypervolemic	Euvolemic	Hypovolemic
<b>Total body water</b>	Increased—relative greater water retention	Increased—due to ingestion of large amounts of water	Decreased—loss of water
<b>Total body sodium</b>	Increased	Normal or unchanged value	Decreased—greater loss of sodium
<b>Management</b>	<ul style="list-style-type: none"> <li>● Sodium and water restrictions</li> <li>● Treatment of underlying cause</li> </ul>	<ul style="list-style-type: none"> <li>● Limit free-water intake</li> <li>● Treatment of underlying cause</li> </ul>	<ul style="list-style-type: none"> <li>● Isotonic saline replacement</li> <li>● Treatment of underlying cause</li> </ul>
<b>Causes</b>	<ul style="list-style-type: none"> <li>Congestive heart failure</li> <li>Nephrotic syndrome</li> <li>Cirrhosis</li> <li>Advanced kidney disease</li> <li>Acute kidney injury</li> </ul>	<ul style="list-style-type: none"> <li>Hypothyroidism</li> <li>SIADH</li> <li>Medications               <ul style="list-style-type: none"> <li>● Carbamazepine</li> <li>● Opioids</li> <li>● Barbiturates</li> <li>● Vincristine</li> <li>● Phenytoin</li> <li>● Pantoprazole</li> </ul> </li> </ul>	<ul style="list-style-type: none"> <li>Diuretic excess</li> <li>Salt-losing renal disease</li> <li>Severe diarrhea and vomiting</li> <li>Gastric suctioning</li> <li>Addison's disease</li> <li>Third spacing (burns or pancreatitis)</li> </ul>

SIADH, Syndrome of inappropriate antidiuretic hormone.

Hypervolemic hyponatremia, causing an increase in ECF, occurs secondary to increases in total body water and is seen in patients with heart failure, cirrhosis, and nephrotic syndrome. Hypoperfusion in heart failure results in activation of the renin–angiotensin–aldosterone, norepinephrine, and ADH hormonal compensation mechanisms, leading to water and sodium retention. Hypoalbuminemia, from cirrhosis or nephrotic syndrome, results in a decrease in the osmotic pressure of the intravascular volume, allowing fluid shifts to the interstitial space.

### Clinical Manifestations

Clinical manifestations of hyponatremia are dependent on the severity, cause, and rapidity of onset. In the setting of acute hyponatremia, treatment needs to be started quickly to prevent cerebral edema and neurological decline, whereas slow onset should be treated more conservatively. In acute or severe hyponatremia, serum sodium levels of less than 120 mEq/L develop in less than 48 hours; these patients have the greatest risk for neurological complications. Cerebral edema and higher mortality rates are seen in patients with acute hyponatremia. Neurological clinical manifestations include lethargy, headache, confusion, gait disorders, nausea, and vomiting. Seizures, coma, permanent brain damage, and death may occur because of cerebral edema if severe hyponatremia is not recognized and treated. A slow decline in serum sodium levels may delay the onset of symptoms, and a chronic decrease in sodium can result in adaptation of brain cells to the new osmotic equilibrium, causing fewer symptoms.

**Safety Alert** In the acute onset of sodium levels less than 120 mEq/L, the patient is at high risk for life-threatening neurological changes. These can occur due to brain swelling and intracranial hypertension that can result in brainstem herniation and respiratory arrest. If not treated quickly, this can result in permanent brain damage or death.

### Management

#### Medical Management

Treatment of hyponatremia is based on the etiology of the sodium deficit, speed of development, and assessment for potential causes. Initially, the treatment of hyponatremia is the replacement of sodium via oral, enteral, or parenteral means and restriction of fluid intake. If the patient can tolerate food, intake of a regular diet can provide enough sodium to correct the deficit.

Replacement of volume in patients with hypovolemic hyponatremia with isotonic saline (0.9% NaCl) restores fluid volume and resolves symptoms. In patients with euvolemic hyponatremia, restriction of water intake to less than 1 L per day assists in restoring normal sodium levels but may be difficult to enforce. In patients with chronic hyponatremia, slow correction of sodium levels is important. A correction rate on the average of 0.5 mEq/L/hr for a total of 8 to 12 mEq/L/day is recommended to prevent osmotic demyelination. Osmotic demyelination or central pontine

myelinolysis, leading to severe damage to the myelin sheath, can occur with aggressive or rapid replacement of sodium and can progress to worsening neurological function. Several patient populations, including those with a history of alcohol abuse, burns, or malnourishment and elderly women on thiazide diuretics, are at high risk for the development of osmotic demyelination during the correction of hyponatremia.

In patients exhibiting neurological symptoms, administration of hypertonic saline solution (3% or 5% sodium chloride) intravenously may be required at a rate of about 1 mL/kg/hr. If seizures are present or the patient is exhibiting signs of brain herniation, hypertonic saline may be infused at 2 to 3 mL/kg/hr for the first few hours. Hypertonic saline solution must be administered judiciously because of the potential for developing fluid volume overload. Administration of hypertonic saline solution should take place in a monitored unit with frequent assessments of the patient for indications of improvement in severe neurological symptoms and fluid volume overload. Infused through a central line via an IV pump, hypertonic saline is administered until the resolution of neurological symptoms, and then treatment focuses on management of the underlying disease process causing the hyponatremia. Infusion of hypertonic saline should be terminated prior to reaching normal serum sodium levels to prevent overcorrection of hyponatremia, which can lead to the development of excessive water diuresis, resulting in hypernatremia.

Decreasing circulating volume in hypervolemic hyponatremia is accomplished through the use of loop diuretics, fluid and sodium restriction, and treatment of the underlying fluid retention. In patients with cirrhosis, sodium and water restriction and the use of aldosterone antagonists such as spironolactone (Aldactone) can treat hyponatremia by causing the kidneys to eliminate unneeded water and sodium. With the progression of cirrhosis, liver transplant is the only effective treatment of hyponatremia secondary to hepatic failure (see Table 8.8).

Pharmacological interventions for hyponatremia include demeclocycline (Declomycin), lithium (Eskalith), and vasopressin-receptor antagonists such as conivaptan (Vaprisol) and tolvaptan (Samsca). Inhibition of the kidney's response to vasopressin is accomplished with the administration of demeclocycline (Declomycin) and lithium; both inhibit the reabsorption of water. Beneficial effects of demeclocycline may not be achieved for 1 to 2 weeks. Vasopressin receptor antagonists, referred to as "vaptans," block V2 receptors in the renal tubules, increasing the excretion of water. Tolvaptan (Samsca), lixivaptan (VPA-985), satavaptan (Aquilda), and conivaptan (Vaprisol) are examples of vasopressin-receptor antagonists.

**Complications.** Complications of hyponatremia include neurological symptoms such as lethargy, confusion, weakness, fatigue, muscle cramps, and postural hypotension. In severe acute hyponatremia, seizures, coma, and death can occur.

### Nursing Management

Nursing management focuses on identifying patients at risk for the development of hyponatremia and monitoring sodium levels. Early recognition of hyponatremia can prevent the development of serious consequences such as seizures, decreased level of consciousness, coma, and death. Monitoring of fluid status through obtaining daily weights and measuring I&O can assist with early detection of water-balance issues. Observing the patient for signs of water losses or gain can serve as a warning sign of sodium imbalance. Neurological changes such as confusion, muscle twitching, lethargy, and seizures can indicate low sodium levels, especially in older adults. If hyponatremia is suspected, obtaining orders for urine osmolality and specific gravity can assist with monitoring sodium and water balance.

A key role that nurses play in managing hyponatremia is providing patient education. Goals of patient education include the importance of fluid and sodium intake and patient compliance. Sodium or salt intake increases the reabsorption of water, increasing the risk of redeveloping hyponatremia. Providing education to family members about clinical manifestations of hyponatremia can allow for earlier interventions. The nurse can include patient teaching related to sodium content in foods (Box 8.1).

### Hypernatremia

Hypernatremia refers to serum sodium values greater than 145 mEq/L and often occurs as a direct result of water loss and/or the loss of sodium and water. Unavailability of water or inability to access water can result in water deficits. Changes in mental status, physical disabilities, dementia, or advanced age can limit the ability to verbalize thirst or physically consume water. Without adequate water intake, patients receiving hypertonic enteral feeding are at increased risk of developing hypernatremia. Water losses can also occur from diabetes insipidus, hyperglycemia, neoplasms, hypercalcemia, and hyperkalemia secondary to nephrogenic diabetes insipidus or medications such as lithium, demeclocycline, and amphotericin B. Neoplasms can also affect the hypothalamic osmoreceptors that regulate thirst. Increases in insensible loss of fluids through the respiratory system or skin can also result in water deficits. Losses of fluid

### Box 8.1 Sodium Content of Common Foods

- Frozen pizza, plain cheese: 450–1,200 mg in 4 oz
- Soup (tomato), reconstituted: 700–1,260 mg in 8 oz
- Tomato juice: 340–1,040 mg in 8 oz (approximately 1 cup)
- Pretzels: 290–560 mg in 1 oz (28.4 g)
- Potato chips: 120–180 mg in 1 oz (28.4 g)
- Salsa: 150–240 mg in 2 Tbsp
- Salad dressing, regular fat, all types: 110–505 mg in 2 Tbsp
- Tortilla chips: 105–160 mg in 1 oz (28.4 g)
- Breads, all types: 95–210 mg in 1 oz
- Frozen vegetable, all types: 2–160 mg in 1/2 cup

through the respiratory tract may be secondary to hyperventilation and tracheobronchitis. Burn injuries, febrile states, and exercise can result in loss of fluid through the skin.

Excessive ingestion of sodium also can result in hypernatremia. Use of sodium bicarbonate to correct metabolic acidosis and during cardiopulmonary resuscitation can result in an elevation of serum sodium levels. Close monitoring of sodium levels and prompt termination of sodium bicarbonate infusions after correction of metabolic acidosis minimize the risk of developing hypernatremia.

### Clinical Manifestations

Clinical manifestations of hypernatremia include nonspecific neurological changes such as neuromuscular irritability, agitation, restlessness, lethargy, coma, and seizures. In the setting of severe hypernatremia, hallucinations, delusions, and disorientation may be present. Patients may complain of thirst and demonstrate signs of dehydration, including tachycardia, dry mucous membranes, flushed skin, decreased urine output, and orthostatic hypotension. In healthy persons, thirst serves as the mechanism to prevent the development of hypernatremia. In infants, a high-pitched cry and irritability are present because of brain damage secondary to subarachnoid hemorrhage that may result from hypernatremia.

### Management

#### Medical Management

Medical management is aimed at limiting sodium intake or replacing water deficits through the infusion of hypotonic fluids such as 0.45% NaCl or 5% dextrose in water (D5W). Caution should be taken in order to prevent rapid correction of hypernatremia that may lead to fluid shifts into brain tissue, potentially resulting in cerebral edema. In an effort to correct hypernatremia, intracellular water shifts into the extracellular space, resulting in dehydration of brain cells. As water losses are replaced, water shifts back into brain cells. If rapid correction of water deficit occurs, this shift back into brain cells can result in cerebral edema, increasing the risk of seizures or permanent neurological damage. Termination of IV solutions with isotonic sodium or sodium bicarbonate should be the first step in the correction of hypernatremia. Correction of the water deficit should occur over 48 to 72 hours, preferably by use of enteral means if possible (see Evidence-Based Practice).

### Evidence-Based Practice

#### Free Water Deficit Calculation and Replacement

In patients with hypernatremia, replacement of free water is required to return serum sodium levels to normal. The following formulas are used to calculate the free water deficit and the infusion rate and duration of D5W. In hypernatremia that has developed over days, correction of the

sodium level should occur at a rate not to exceed 0.5 mEq/L/hr and a total of 8 to 10 mEq/d. Rapid correction during this time can result in cerebral edema, which can cause permanent brain damage. If the hypernatremia is accompanied by a volume deficit, the intravascular volume needs to be replaced with isotonic sodium chloride prior to any free-water administration. Correction of a water deficit should occur over a 48- to 72-hour time frame.

Determine water deficit:

1. Total body water (TBW) = correction factor  $\times$  weight in kilograms  
The correction factor is 0.6 for men, 0.5 for women and elderly men, and 0.45 for elderly women.
2. Water deficit (liter) = weight (kg)  $\times$  correction factor
3. Change in serum  $\text{Na}^+$  =  $(\text{Infusate } \text{Na}^+ - \text{serum } \text{Na}^+) / (\text{TBW} + 1)$

As an example of the use of these calculations, consider an 80-year-old male who is admitted with severe dehydration. His weight is 70 kg. His serum sodium level is 165 mEq/L. To reduce his serum sodium, D5W is the infusate to be used ( $\text{Na}^+$  content = 0 in D5W). The calculations are as follows:

1. Total body water =  $0.5 \times 70 = 35\text{L}$
2. Water deficit =  $35 \times 0.5 = 17.5\text{L}$
3. The retention of 1 L of D5W leads to a serum sodium reduction of  $-4.6$ :  $(0 - 165) / (35 + 1) = -4.6$
4. Because the goal is to reduce the serum sodium by no more than 10 mEq/L in 24 hours, then  $10 / 4.6 = 2.17\text{L}$  of D5W is required. To compensate for natural water loss, and additional 1–1.5 L is added to total 3.67 (2.17 + 1.5) over 24 hours.
5. The infusion rate is 153 mL/hour.

D5W, dextrose in water.

Lukitsch, I., & Batuman, V. (2018). *Hypernatremia treatment & management*. Retrieved from <https://emedicine.medscape.com/article/241094-treatment>

**Safety Alert** Correction of hypernatremia must be performed cautiously because of the risk of overcorrection that can lead to life-threatening complications such as cerebral edema secondary to fluid shifting into brain cells.

**Complications.** Complications of mild hypernatremia, sodium levels of 145 to 150 mEq/L, include the development of restlessness, weakness, disorientation, delusions, and hallucinations. With progression to severe hypernatremia,

serum sodium levels greater than 152 mEq/L, seizures, stupor, coma, and potentially death can occur. If hypernatremia is due to fluid volume deficits, cardiac symptoms such as orthostatic hypotension and tachycardia may also be present.

### Nursing Management

Nursing care is aimed at early recognition of patients at risk for hypernatremia through close monitoring of I&O. Close monitoring of patients, specifically those unable to access water independently, receiving enteral feedings, or demonstrating mental status changes or those with physical disabilities, dementia, or advanced age, enables early identification of the actual or potential development of hypernatremia.

Ensuring adequate intake of water in patients receiving enteral nutrition is accomplished by providing a water bolus several times throughout the day. In patients who are unable to access water, providing opportunities to ingest water throughout the day in sufficient quantities is an important role of nursing. If patients are unable to orally ingest adequate amounts of water, collaboration with the healthcare provider regarding alternative routes of fluid administration, such as parenteral or enteral methods (nasogastric or gastrostomy tube), may be required.

Monitoring of daily weights and serum sodium levels assists in providing baseline assessment data to guide interventions. Individuals engaging in strenuous activities are encouraged to ingest adequate amounts of water to prevent water loss and dehydration. Providing patient and family education regarding means to increase water intake can assist in the collaborative management of hypernatremia.

Patients with head injuries, postoperative neurological surgical procedures, or brain tumors are at risk for developing central diabetes insipidus related to decreased production of vasopressin, which promotes water reabsorption in the kidneys. Close monitoring of the hourly urine output volume, urine specific gravity, and serum sodium of patients at risk for the development of diabetes insipidus is an important nursing function.

## Chloride

Chloride is found in the ECF and is the major anion as sodium chloride. The normal serum chloride value range is 97 to 107 mEq/L. Chloride is found in pancreatic and gastric juices as well as saliva, sweat, and bile. In addition to sodium, chloride is important in maintaining the osmotic pressure of ECF. The relationship between serum chloride and bicarbonate levels is an important indicator of the nature of acid-base disturbances because bicarbonate is the anion most often exchanged with chloride. Normal chloride levels are achieved through excretion and reabsorption of chloride in the kidneys.

### Hypochloremia

Hypochloremia refers to serum chloride levels less than 97 mEq/L and occurs as a result of chloride loss. It is observed in patients with severe vomiting, burns, chronic

respiratory acidosis, nasogastric suctioning, metabolic alkalosis, and Addison's disease (adrenal cortex insufficiency). In chronic respiratory acidosis, the buffer systems of the kidney retain bicarbonate and excrete chloride in order to re-establish acid-base balance. Hypochloremia in metabolic alkalosis occurs as a result of increases in plasma bicarbonate concentration due to the loss of hydrogen in the GI tract (nasogastric suctioning, vomiting, or diarrhea) or in the urine.

Administration of IV fluids low in chloride (D5W) or high in bicarbonate, hyponatremia, and decreased sodium intake can also lead to hypochloremia as a result of volume dilution and increases in urine output. Patients can develop hypochloremic metabolic alkalosis as serum chloride levels decrease and increases in sodium and bicarbonate reabsorption compensate for the loss of chloride through the GI tract. In patients with hypochloremia, hypokalemia and hyponatremia may also be present because of the renal loss of potassium and sodium.

### Clinical Manifestations

Patients with hypochloremia may exhibit irritability, hypotension, tetany, shallow respirations, and hyperexcitability of muscles and nerves. If hypokalemia is also present, cardiac dysrhythmias may develop. Because of the relationship of sodium to chloride, hyponatremia may also be present with water excess and, if severe, can lead to seizures and death.

### Management

#### Medical Management

Medical management is aimed at correcting the cause of hypochloremia and replacing chloride through the administration of 0.45% or 0.9% NaCl solution. If metabolic alkalosis is present, ammonium chloride may be prescribed. In metabolic alkalosis, there is an increase in sodium bicarbonate in the blood. Ammonium is used by the kidneys in place of sodium to maintain the acid-base balance. Correcting the metabolic alkalosis restores serum chloride levels.

**Complications.** Hypochloremia can develop as a result of hypokalemia, which can lead to cardiac dysrhythmias. Chloride levels parallel sodium levels, and in the presence of hypochloremia, hyponatremia and water excess can result in seizures and coma.

#### Nursing Management

Nursing care is aimed at early recognition of hypochloremia and implementing actions to assist in the correction of decreased serum chloride levels. Monitor patients for changes in the level of consciousness, respiratory effort, and muscle control, and promptly notify the provider of changes. The provision of patient education regarding foods high in chloride content and replacing fluid losses with electrolyte-containing fluids assists in preventing the reoccurrence of hypochloremia.

### Hyperchloremia

Hyperchloremia is present if the serum chloride level is greater than 107 mEq/L and can result in bicarbonate loss,

resulting in metabolic acidosis and hypernatremia. In hypernatremia, chloride is reabsorbed in the kidneys to maintain ion neutrality. Infusion of excessive levels of chloride relative to sodium can lead to hyperchloremia. Loss of bicarbonate ions through the GI and renal systems, combined with the use of 0.9% NaCl, 0.45% NaCl, and lactated Ringer's solution for fluid intake maintenance, can result in hyperchloremia. With the use of these IV solutions, chloride replaces bicarbonate to correct acidosis, leading to hyperchloremia.

### Clinical Manifestations

Clinical manifestations of hyperchloremia are similar to those observed in fluid volume excess, metabolic acidosis, and hypernatremia. Comparable to hypernatremia, the clinical presentation of hyperchloremia includes deep and rapid respirations, lethargy, tachypnea, decreased cognitive ability, and elevated blood pressure.

### Management

#### Medical Management

Identification and management of the underlying causes and correction of acid-base, fluid, and electrolyte disturbances guide the management of hyperchloremia. Administration of hypotonic IV solutions, such as 0.45% NaCl, to replace fluid losses assists in correcting serum chloride levels. A sodium bicarbonate infusion may be utilized to increase bicarbonate levels to increase the urinary excretion of chloride. In addition to sodium bicarbonate infusions, limiting the intake of fluids containing sodium and chloride and the use of diuretics assist in lowering chloride levels. If metabolic disturbances are present, correction of the underlying cause is essential to correcting hyperchloremia.

**Complications.** If left untreated, patients with hyperchloremia can develop cardiac dysrhythmias, decreased cardiac output, and coma.

#### Nursing Management

Nurses monitor patients for clinical manifestations, including changes in neurological, cardiac, and respiratory status that are typically seen in hyperchloremia, and promptly relay these changes to the healthcare provider. Neurological manifestations include decreases in cognitive ability and lethargy. Cardiac manifestations include hypertension and tachycardia from fluid overload. Deep, rapid respirations are also usually present. Provision of patient education regarding adequate hydration and how to manage hyperchloremia is required prior to discharge. Patient education includes the avoidance of foods high in chloride, such as processed meats, canned vegetables, eggs, bananas, cheese, and milk, and limited intake of free water (water without electrolytes).

### Potassium

Potassium is the major intracellular electrolyte (cation) of the body, with 98% found within the cell. The remaining 2% is extracellular and is essential for neuromuscular

function. The normal range of serum potassium is 3.5 to 5.0 mEq/L. The sodium–potassium pump (Fig. 8.7) controls the movement of potassium into and out of cells as needed for neuromuscular function and to maintain homeostasis. In conjunction with sodium, potassium produces action and resting membrane potentials of muscle and nerve cells. In the function of the sodium–potassium pump, potassium's role is just as important as sodium's for heat production (thermogenesis) and cotransport. Potassium is also important for the metabolic processes of the body and protein synthesis. Normal renal function is required to maintain normal levels of potassium, with 80% of the daily loss of potassium occurring through the kidneys. Daily replacement of potassium loss is easily achieved through daily food intake (Box 8.2).

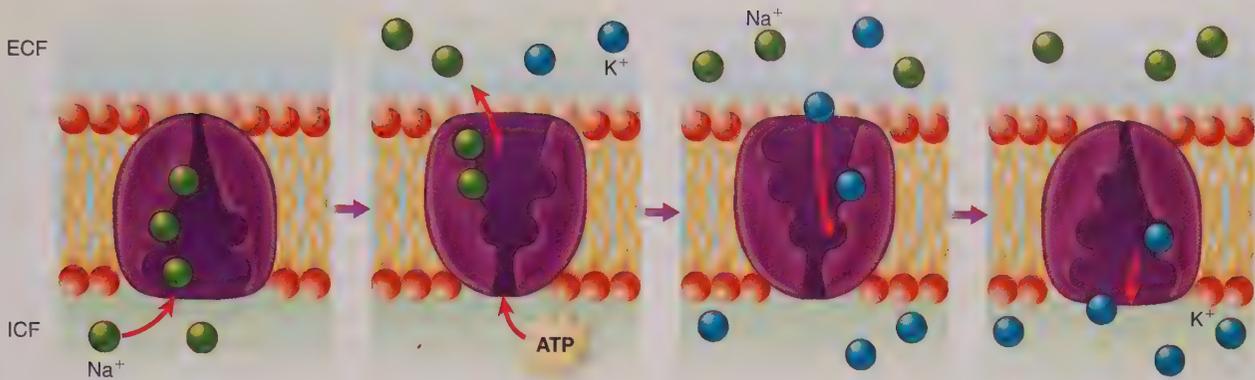

### Hypokalemia

Hypokalemia is associated with serum potassium levels less than 3.5 mEq/L and is further classified as mild (3.0–3.5 mEq/L), moderate (2.5–3.0 mEq/L), and severe (less than 2 mEq/L); it can reflect a real loss of potassium stores or a temporary shift of potassium into the cell. In the patient with respiratory or metabolic alkalosis, potassium ions shift intracellularly as hydrogen ions shift out of the cell in an effort to restore acid-base balance.

Potassium deficit can occur secondary to losses through the GI tract and renal system, actions of medications, transcellular shifts, and inadequate intake of potassium. Gastrointestinal losses of potassium occur as a result of diarrhea, vomiting, and gastric suctioning. Significant potassium loss can occur as a result of the loss of gastric secretions and then as a result of renal excretion of potassium to correct metabolic alkalosis from the gastric secretion loss associated with the loss of hydrochloric acid. Excessive use of enemas or laxatives contributes to potassium loss through the GI tract. Hypokalemia secondary to GI losses can also be seen in patients with anorexia, bulimia, or excessive use of laxatives.

Renal loss of potassium can occur as a result of hyperaldosteronism that leads to increased potassium excretion, resulting in severe potassium depletion. In the patient with hyperaldosteronism, aldosterone secreted from the adrenal cortex stimulates the reabsorption of sodium and the excretion of potassium. As sodium is reabsorbed, increased water is absorbed as well. Renal loss of potassium also occurs with the use of various medications, and diuretics are the most common medication related to hypokalemia. The use of loop diuretics, thiazide diuretics, and ethacrynic acid (Edecrin) with poor intake of potassium can result in hypokalemia. Additional medications that can cause hypokalemia include aminoglycosides, steroids, and beta-adrenergic agonists (albuterol or dobutamine).

Shifts of potassium intracellularly can occur for several reasons. In patients with hyperinsulin secretion, potassium shifts into hepatic and muscular cells are promoted because insulin makes cells more permeable to potassium. The release of catecholamines, such as epinephrine, during periods of

**FIGURE 8.7** High concentrations of sodium and low concentrations of potassium are in the extracellular fluid (ECF), and diffusion occurs through ion channels in the cell membrane. The sodium–potassium pump maintains appropriate concentrations of these ions through active transport (adenosine triphosphate [ATP]).

## Box 8.2 Potassium Content of Common Foods

- Spinach: 839 mg in 1 cup cooked
- Baked potato with skin: 738 mg in 1 small potato
- Tomato juice: 556 mg in 1 cup
- Mushrooms: 555 mg in 1 cup cooked
- Sweet potato: 475 mg in 1/2 cup cooked
- Vegetable juice cocktail: 469 mg in 1 cup
- Banana: 422 mg in 1 medium-sized banana
- Cantaloupe: 417 mg in 1 cup
- Low-fat milk: 407 mg in 1 cup
- Kidney beans: 371 mg in 1/2 cup cooked
- Avocado, California: 345 mg in 1/2 avocado
- Tomato: 292 mg in 1 medium-sized tomato
- Kiwi: 284 mg in 1 kiwi
- Strawberries: 233 mg in 1 cup
- Orange: 232 mg in 1 medium-sized orange

stress, such as acute illness, post-cardiopulmonary resuscitation, and acute head injury, or during episodes of acute coronary ischemia can cause shifting of potassium intracellularly because of increased activity of sodium–potassium adenosine triphosphatase (ATPase).

### Clinical Manifestations

Hypokalemia can result in a variety of physiological alterations, or patients may be asymptomatic if serum potassium levels remain greater than 3 mEq/L. Cardiac, pulmonary, neuromuscular, and GI symptoms can develop as a result of hypokalemia. Patients may experience weakness, lethargy, hyporeflexia, nausea/vomiting, constipation, abdominal cramping and electrocardiogram (ECG) changes (ST depression). In severe hypokalemia, cardiac or respiratory arrest can occur.

Cardiac symptoms in hypokalemia include the development of palpitations; premature atrial or ventricular complexes (PVCs), especially in patients with cardiovascular

disease; cardiac rate disturbances; and hypotension. In severe hypokalemia, sudden death can occur as a result of ventricular fibrillation. Respiratory complications can occur as a result of weakness of accessory muscles of the chest and abdomen, leading to hypoventilation, respiratory distress, and respiratory arrest. Neuromuscular symptoms include skeletal muscle weakness or cramping, paresthesias or paralysis, decreased muscle strength, and weakness of the GI tract. Anorexia, ileus, gaseous distention, abdominal cramping, prolonged gastric emptying, nausea, and vomiting can develop as a result of weakness of the GI muscles.

In the setting of prolonged potassium deficit, the inability of the kidneys to respond to ADH can result in polyuria, nocturia, and polydipsia. The resistance of the kidneys to ADH and increased stimulation of thirst results in polyuria, with potassium being lost with increased urine excretion. Nocturia occurs because of increased fluid intake during waking hours.

### Management

#### Medical Management

Daily intake of potassium is essential for normal homeostasis. If adequate potassium levels are not achieved with dietary intake, supplemental potassium is required. Potassium replacement can be achieved using oral or parenteral routes, with oral being preferred because it is easy to administer, readily absorbed from the GI tract, and safe. In the setting of mild to moderate hypokalemia, oral replacement should suffice. In severe hypokalemia, administration of potassium both orally and parenterally may be required.

#### **! Safety Alert** Parenteral Potassium Administration

Administration of IV potassium is considered a high-alert medication. Potassium is never to be administered as an IVP bolus. The total maximum 24-hour dose is 150 mEq. An infusion pump must be used when administering IV potassium.

Because of the potential for cardiac dysrhythmias, patients with hypokalemia should be placed on cardiac monitoring. IV access is required in the event of life-threatening dysrhythmias and IV replacement of potassium when the patient is not able to take oral replacement. Assessment of respiratory function is also a priority because low potassium levels affect the function of the respiratory muscles. Monitoring of respiratory rate, effort, and oxygen saturation provides information regarding the need for additional interventions.

**Complications.** Complications of hypokalemia can include muscle weakness and cramping, decreased GI motility, cardiac dysrhythmias, respiratory failure, cardiac or respiratory arrest, and death.

### Nursing Management

Because of potentially life-threatening complications, monitoring patients at risk for developing hypokalemia is a key nursing role. This includes an assessment of serum potassium levels and physical assessment findings such as leg cramps and muscle weakness, as well as interpreting cardiac rhythm strips that can assist with early recognition of hypokalemia. Ventricular dysrhythmias are commonly seen in patients with hypokalemia and can progress to ventricular fibrillation, a life-threatening situation. In patients receiving digitalis, hypokalemia can potentiate the effects of digitalis by increasing blood levels of digoxin, leading to digoxin toxicity. Symptoms of digoxin toxicity include loss of appetite, nausea, vomiting, cardiac dysrhythmias, and visual disturbances.

Providing patient education regarding dietary sources of potassium, such as bananas, oranges, and raisins, to patients at risk for developing hypokalemia is an important nursing role. In addition, educating patients about clinical manifestations of hypokalemia can lead to early interventions to replace potassium.

Administration of a potassium replacement is another key nursing action. Oral replacement is the route of choice, with potassium supplements available in liquid, powder, caplet, and tablet forms. Parenteral replacement of potassium should be given slowly and never as an IVP medication because of the risk for cardiac dysrhythmias, cardiac arrest, and death. Potassium chloride can be administered parenterally in concentrated forms, 10 to 20 mEq in 100 mL of fluid over 1 to 2 hours, via an IV pump and preferably through a central access device. Potassium chloride is very irritating to small veins; high concentrations of potassium are not tolerated well by patients. Each institution has guidelines on concentrating and administering concentrated potassium solutions.

### Hyperkalemia

Hyperkalemia is a serum potassium level greater than 5.0 mEq/L and is rarely seen in patients with normal renal function. Hyperkalemia is characterized as mild (5.0–6.0 mEq/L), moderate (6.1–7.0 mEq/L), and severe (greater than 7.0 mEq/L). Hyperkalemia can occur as a result of acute or chronic renal failure, medications, or

excessive intake of foods high in potassium content or through the shift of intracellular potassium to the extracellular space.

Renal excretion is the primary regulation mechanism of potassium. In the setting of acute or chronic renal failure, excretion of potassium is diminished because of decreased potassium filtration due to a reduction in the glomerular filtration rate, resulting in hyperkalemia. Patients with Addison's disease (adrenal cortex insufficiency) can develop hyperkalemia secondary to a decrease in adrenal steroids (hypoaldosteronism), which causes sodium loss and potassium retention. The use of potassium-sparing diuretics, such as spironolactone (Aldactone), which inhibit the effects of aldosterone, allows excretion of water and sodium while retaining potassium. NSAIDs in the setting of renal insufficiency can result in hyperkalemia because these medications decrease renin secretion, which then decreases potassium excretion in the urine.

In addition to potassium-sparing diuretics and NSAIDs, potassium supplements, beta blockers, and digoxin/digitalis glycosides increase potassium levels because of decreased sodium-potassium ATPase activity. Combination medications, including potassium-sparing diuretics, place the patient at risk for hyperkalemia because of the inhibition of aldosterone binding to receptor sites. The use of potassium-based salt substitutes and intake of foods high in potassium, such as bananas, oranges, tomatoes, and high-protein diets, can result in hyperkalemia in patients with renal impairment.

Shifts of intracellular potassium to the ECF occur for several reasons. Metabolic acidosis, soft tissue injury (crush injury or burns), catabolism, and tissue lysis syndrome cause shifts or release of potassium from within the cell. In the setting of metabolic acidosis from acute renal failure, diabetic ketoacidosis, or lactic acidosis, hydrogen ions move into the cell in an attempt to correct acidotic pH levels, thus causing potassium to shift out of the cell. In the diuresis associated with diabetic ketoacidosis, there may be an increased loss of potassium in the urine, and potassium levels require vigilant monitoring as the hyperglycemia and metabolic acidosis resolve. In crush injuries or cellular breakdown, intracellular potassium is released into the bloodstream, leading to hyperkalemia.

In patients for whom hyperkalemia is unlikely, pseudo-hyperkalemia can occur because of hemolysis of blood samples, leukocytosis, thrombosis, and prolonged tourniquet use during phlebotomy. Pseudohyperkalemia occurs as a result of leakage of potassium from the cell, giving a false elevation of serum potassium levels. This disorder should be ruled out prior to intervening in patients with no risk of hyperkalemia.

### Clinical Manifestations

Patients with hyperkalemia may complain of generalized fatigue, muscle cramps, palpitations, paresthesias, or weakness. The clinical presentation may not reflect the true extent of hyperkalemia, placing patients at high risk of cardiac arrest. The most important and potentially life-threatening consequence of hyperkalemia is its effect on the cardiac electrical

conduction system. In patients with serum potassium levels greater than 6 mEq/L, ECG changes may be seen. Patients can develop bradycardia, sinus arrest, heart blocks, or ventricular dysrhythmias. Because of these cardiac rhythm abnormalities, patients can develop symptomatic hypotension. Initial ECG changes are narrow and peaked T waves, ST depression, and shortening of the QT interval (Fig. 8.8). If correction of serum potassium levels does not occur, progression in the severity of cardiac dysrhythmias and sudden cardiac death can occur. In potassium levels ranging from 6.5 to 7.5 mEq/L, there is a progression in the length of the PR, QRS, and QT intervals. In addition, there is a decrease in the amplitude of the R wave, with an increase in the depth of the S wave and depression of the elevation of the ST segment. In potassium levels greater than 7.5 mEq/L, there is a disappearance of the P wave with the development of junctional rhythms. The QRS complex widens and can proceed to the development of idioventricular rhythms. At potassium levels greater than 10 mEq/L, if immediate interventions are not undertaken, the QRS continues to widen to the development of a sine wave, which is preterminal. During assessment of the ECG, the sine wave is associated with the disappearance of the P wave and the merging of the QRS and T waves.

## Management

### Medical Management

Once the presence of hyperkalemia is recognized, an ECG should be obtained to assess for changes in cardiac rate and

rhythm. In situations where pseudohyperkalemia is suspected to be the cause of elevated potassium levels, repeated specimen collection and evaluation may be required. In patients with end-stage renal disease, prompt dialysis removes excessive serum potassium. In patients with hyperkalemia related to increased dietary or supplemental potassium intake, dietary modification and withholding of potassium supplements may be the only interventions required.

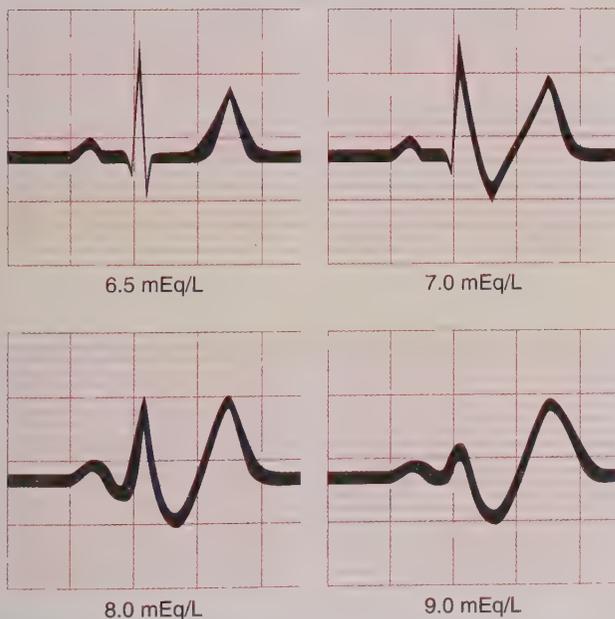

If ECG changes are present in the setting of hyperkalemia, the severity of the ECG changes will determine the priority of interventions. In severe hyperkalemia with widened QRS complexes and loss of P waves, parenteral administration of calcium is indicated. IV-administered calcium will not reduce serum potassium levels but will reverse ECG changes and decrease risks for ventricular dysrhythmias, and the effects from IV calcium are short-lived (30–60 minutes).

In the event of metabolic acidosis, correction of the underlying causes results in shifting of the potassium back into the cell. In diabetic ketoacidosis, correction of hyperglycemia through the use of short-acting IV insulin and volume replacement with normal saline (NS) solution corrects the acidosis, resulting in lowering of serum potassium levels. In metabolic acidosis from acute renal failure or lactic acidosis, the administration of sodium bicarbonate may be required. Sodium bicarbonate elevates the serum pH level by causing intracellular hydrogen to shift outside the cell, leading to potassium moving intracellularly. Sodium bicarbonate may be given as an IV bolus or continuous infusion until sufficient lowering of potassium is achieved.

IV administration of 25 to 40 g of 50% dextrose with 10 units of short-acting insulin promotes the movement of extracellular potassium into the cells. Use of regular insulin shifts glucose into the cell, and potassium follows glucose. The effects of IV 50% dextrose and short-acting insulin have an onset of 20 minutes and last 4 to 6 hours. The use of beta-adrenoceptor agonists such as albuterol (Proventil, Ventolin) in nebulized form can also result in a redistribution of the extracellular potassium intracellularly through activation of the sodium–potassium pump, sending potassium back into the cell. Dosing of albuterol is 4 times normal dosing, with onset of action in 30 minutes and benefits lasting 2 hours.

Elimination of potassium can also be achieved through the use of loop diuretics such as furosemide (Lasix) or bumetanide (Bumex). Loop diuretics inhibit the reabsorption of potassium, sodium, and chloride and the excretion of water. Caution is required with the use of loop diuretics because of the risk of development of a fluid volume deficit. The use of gastrointestinal cation exchangers such as sodium polystyrene sulfonate (Kayexalate) is another means to lower potassium levels. When administered, gastrointestinal cation exchangers cause an exchange of sodium for potassium in the gut, resulting in increased bowel elimination of potassium. Onset is slow, 2 hours, with the desired effect not seen for up to 6 hours.

**K<sup>+</sup> Normal Range 3.5–5**  
**Hyperkalemia Progression**

**FIGURE 8.8** Initial electrocardiogram (ECG) changes are narrow and peaked T waves, ST depression, and shortening of the QT interval. In potassium levels ranging from 6.5 to 7.5 mEq/L, there is a progression in the length of the PR, QRS, and QT intervals. In potassium levels of greater than 7.5 mEq/L, there is a disappearance of the P wave with the development of junctional rhythms. As the potassium level exceeds 9.0 mEq/L, the QRS complex continues to widen.

**Complications.** Complications of hyperkalemia include cardiac dysrhythmias, which can progress to cardiac arrest and death. Muscular weakness with progression to paralysis can occur if hyperkalemia is not corrected. Gastrointestinal symptoms of nausea and diarrhea can also develop.

### Nursing Management

Nurses must be alert to identify and monitor for clinical manifestations of hyperkalemia in high-risk patients, including those with cardiac dysrhythmias and muscle weakness. Monitoring and reporting elevations in BUN and creatinine (a reflection of renal function), serum glucose levels, and potassium and acid-base status also provide earlier identification of hyperkalemia. Elevations of BUN and creatinine indicate decreased renal function, which can result in decreased potassium excretion and hyperkalemia. Providing continuous cardiac monitoring with early recognition of the ECG changes associated with hyperkalemia enables early interventions. Resolution of the ECG changes can provide information about the effectiveness of interventions.

Administering medications as prescribed to lower elevated serum potassium levels and monitoring the results of measures used to lower potassium levels are important nursing roles. After administration of GI cation-exchange agents, it is important to monitor for the onset of GI effects. In patients treated with albuterol, monitor heart rate response for the potential development of tachycardia. The education provided to patients at risk of hyperkalemia should focus on limiting intake of foods high in potassium and potassium-based salt substitutes.

## Magnesium

Magnesium, the fourth most abundant cation in the body, is needed for cellular functioning and has an interrelationship with the sodium–potassium–ATPase pump. Magnesium is also part of DNA and RNA transcription and is required for the production and function of adenosine triphosphate and protein synthesis. Needed for nucleic acid and protein synthesis, magnesium is also required for more than 300 biochemical reactions within the body. Magnesium alters the effects of calcium on smooth muscles, causing them to relax, and also antagonizes calcium ions at the presynaptic junction, reducing the release of acetylcholine. Acetylcholine is a major neurotransmitter of the autonomic nervous system and activates muscle function. Magnesium is needed for healthy bones and teeth, nerve and muscle function, and coagulation. It is also beneficial in preventing myocardial infarction, stroke, and osteoporosis. The normal reference range for magnesium is 1.6 to 2.2 mg/dL.

### Hypomagnesemia

Hypomagnesemia is a serum magnesium level of less than 1.6 mg/dL and is seen in patients with malnutrition and excessive excretion of magnesium via the renal system. Hypokalemia and hypocalcemia may also be present in

patients with hypomagnesemia. Calcium levels are affected by magnesium levels because of the dependence of the production of cyclic adenosine monophosphate on magnesium. Cyclic adenosine monophosphate controls the release of parathyroid hormone (PTH), which controls calcium levels. The relationship of hypomagnesemia and hypokalemia is not fully understood at present; it is thought that hypomagnesemia impairs sodium–potassium–ATPase, contributing to potassium wasting in urine.

People who chronically abuse alcohol are at risk for developing hypomagnesemia because of poor nutritional intake and GI malabsorption issues. Decreased absorption of magnesium in the GI tract can occur from inadequate dietary intake of food containing magnesium, diarrhea, damage to the small intestine resulting in poor absorption, and malnutrition. Malnutrition from low protein and calorie intake, high alcohol intake or chronic alcohol abuse, vomiting and diarrhea, laxative abuse, and dehydration can all result in hypomagnesemia.

Excess renal loss of magnesium in urine can be attributed to increased diuresis caused by loop diuretics, glycosuria, and chronic alcohol use. As urine output increases, increased magnesium loss occurs. In patients with elevated serum glucose levels, increased thirst (polydipsia) is present, resulting in increased urine output (polyuria). Alcohol is a diuretic, increasing urine output and losses of magnesium. Increased secretion of aldosterone, ADH, and administration of IV fluids all increase urine output, which may also lead to hypomagnesemia. Patients receiving certain diuretics (furosemide [Lasix], bumetanide [Bumex], and hydrochlorothiazide), chemotherapy agents (cisplatin), and antibiotics (amphotericin, cyclosporine, and gentamicin) are at risk for developing hypomagnesemia because of increased excretion of magnesium in the urine.

### Clinical Manifestations

Clinical manifestations of hypomagnesemia, if present, are primarily neuromuscular and are associated with symptoms of hyperactivity. Symptoms of hypomagnesemia can be seen in the muscular, central nervous, cardiac, and GI systems. Muscle weakness and cramping, tetany, hyperactive reflex, tremors, and Trousseau and Chvostek signs may be seen in hypomagnesemia. Magnesium, in conjunction with calcium, regulates muscle tone and contraction and serves as a gatekeeper to nerve conduction to prevent overstimulation by calcium. Central nervous system symptoms include disorientation, psychosis, vertigo, irritability, and combativeness. Cardiac symptoms include increases in blood pressure and tachycardia, paroxysmal atrial tachycardia, and ventricular irritability, which can result in premature ventricular contractions (PVCs) and ventricular fibrillation or tachycardia. Anorexia, nausea, and vomiting may also be present. In patients with severe hypomagnesemia, seizures can develop because of alterations in electrical activity in the central nervous system (CNS). Seizures and emotional lability may occur.

## Management

### Medical Management

Because patients may not present with clinical manifestation of low serum magnesium levels, diagnostic laboratory results may be the first identification of hypomagnesemia. If hypomagnesemia is present, evaluation of potassium and calcium levels also needs to occur because magnesium is required to process potassium, and secondary to inhibited release of PTH, hypocalcemia can result. Replacement of magnesium is achieved through dietary increases in foods high in magnesium, such as whole grains and green leafy vegetables. Oral supplementation, such as magnesium oxide or magnesium gluconate, can also be given.

Replacement of magnesium IV may be required if patients are unable to tolerate oral intake or if clinical manifestations are present. IV administration of 2 to 4 grams of 50% magnesium sulfate diluted in D5W or 0.9% NaCl over 30 to 60 minutes is given to treat mild to severe magnesium deficits. In emergency treatment of ventricular fibrillation, 2 to 4 grams of 50% magnesium sulfate is administered as a bolus per Advanced Cardiac Life Support (ACLS) guidelines. During the administration of IV magnesium, monitoring of vital signs for early recognition of hypotension, changes in cardiac rate and rhythm, or the development of respiratory suppression is required.

**Complications.** Cardiac arrest from ventricular fibrillation and seizures can be life-threatening complications of hypomagnesemia. Prompt recognition of decreased serum magnesium, potassium, and calcium, all of which are important in the electrical stimulation and relaxation of smooth muscle, can assist in preventing these life-threatening complications.

### Nursing Management

Recognition of and monitoring for clinical manifestations for patients at risk of hypomagnesemia is a nursing role. Providing safety interventions such as cardiac monitoring because of the risk of cardiac dysrhythmias, seizure precautions because of CNS hyperexcitability, and fall precautions because of muscle weakness and disorientation are examples of nursing interventions. With IV replacement, respiratory rate and effort are also monitored due to magnesium's respiratory-depression effects. Providing patient education regarding foods high in magnesium (Box 8.3) and the correct use of diuretics and laxatives also assists in preventing the reoccurrence of hypomagnesemia. In patients with chronic alcohol abuse-induced hypomagnesemia, nursing can provide counseling and referral to alcohol abstinence programs.

### Hypermagnesemia

Hypermagnesemia is a serum magnesium level greater than 2.2 mg/dL, with the most common causes being over-replacement of magnesium deficits and renal insufficiency or renal failure. Because of the effective excretion of magnesium by the kidneys, hypermagnesemia is uncommon.

## Box 8.3 Food Sources for Magnesium

- Halibut: 90 mg in 3 oz cooked
- Almonds, dry roasted: 80 mg in 1 oz
- Cashews, dry roasted: 75 mg in 1 oz
- Spinach, frozen: 75 mg in 1/2 cup cooked
- Nuts, mixed, dry roasted: 65 mg in 1 oz
- Cereal, shredded wheat: 55 mg in 2 rectangular biscuits
- Oatmeal, instant, fortified: 55 mg in 1 cup prepared with water
- Potato, baked w/skin: 50 mg in 1 medium-sized potato
- Peanuts, dry roasted: 50 mg in 1 oz
- Peanut butter, smooth: 50 mg in 2 Tbsp
- Wheat bran, crude: 45 mg in 2 Tbsp
- Black-eyed peas: 45 mg in 1/2 cup cooked
- Yogurt, plain, skim milk: 45 mg in 8 oz
- Bran flakes: 40 mg in 1/2 cup
- Rice, brown, long grain: 40 mg in 1/2 cup cooked
- Lentils: 35 mg in 1/2 cup cooked
- Avocado, California: 35 mg in 1/2 cup pureed
- Kidney beans: 35 mg in 1/2 cup canned
- Pinto beans: 35 mg in 1/2 cup cooked
- Wheat germ, crude: 35 mg in 2 Tbsp
- Chocolate milk: 33 mg in 1 cup
- Banana: 30 mg in 1 medium-sized banana
- Milk chocolate candy bar: 28 mg in 1.5-oz bar
- Milk, reduced fat (2%) or fat-free: 27 mg in 8 oz
- Bread, whole wheat, commercially prepared: 25 mg in 1 slice
- Raisins: 25 mg in 1/2 cup packed
- Whole milk: 24 mg in 1 cup
- Chocolate pudding: 24 mg in 4-oz ready-to-eat portion

Over-replacement of magnesium in the setting of hypomagnesemia or overuse of medications containing magnesium can lead to hypermagnesemia. Medications containing magnesium include milk of magnesia, magnesium citrate, aluminum-magnesium hydroxide (Maalox), and hydromagnesium aluminate. Older adults are at risk for hypermagnesemia because of decreased renal function and the use of magnesium-containing laxatives and antacids. Lithium toxicity can also result in hypermagnesemia because it decreases renal excretion of magnesium.

Because magnesium levels are affected by both renal and GI function, disorders of each may increase the risk of hypermagnesemia. Acute renal failure results in the inability of the kidneys to excrete magnesium in the urine, resulting in hypermagnesemia. In patients in whom destruction of soft tissue occurs, there is a release of intracellular magnesium. Soft tissue injuries include **rhabdomyolysis** (breakdown of muscle tissue that leads to the release of muscle fiber contents into the blood), burns, sepsis, trauma, and tissue lysis syndrome. Alterations in the GI tract can have an impact on serum magnesium levels. Intestinal hypomotility due to narcotics or anticholinergics and chronic constipation or bowel obstruction results in increased GI absorption and decreased elimination of magnesium through the GI tract.

## Clinical Manifestations

Hypermagnesemia affects the cardiac, central nervous, respiratory, and hematologic systems. Cardiac symptoms in hypermagnesemia include hypotension due to vasodilation and dysrhythmias such as bradycardia, atrial fibrillation, and intraventricular conduction delays exhibited by widening of the QRS complexes. With serum levels greater than 10 mg/dL, heart blocks and asystole can occur. CNS clinical manifestations include drowsiness, lethargy, muscle weakness, loss of deep tendon reflexes, paralysis, and coma. Respiratory signs include a decrease in the respiratory rate that can lead to complete respiratory suppression. Hypermagnesemia is also associated with decreased platelet clumping and delayed formation of thrombin, increasing the risk of bleeding.

## Management

### Medical Management

Correction of hypermagnesemia is aimed at identifying the cause and intervening. If GI hypomotility is identified, the use of agents to promote GI motility, such as cathartics and enemas, stimulates GI loss of magnesium. Cessation of magnesium supplements, if present, and provision of IV hydration and loop diuretics to promote renal excretion of magnesium lower serum magnesium levels. Assessing the airway, breathing, and circulation and providing ventilatory support, treating cardiac dysrhythmias, and correcting hypotension with IV fluids are initial steps in the management of hypermagnesemia. In the setting of severe renal insufficiency or renal failure, hemodialysis with a low-magnesium dialysate may be required to lower serum magnesium levels. Administration of calcium gluconate 100 to 200 mg 10% solution in a continuous IV infusion (2–4 mg/kg/hr) may be required to antagonize the neuromuscular and cardiovascular effects of hypermagnesemia. Calcium reverses the effects of magnesium on smooth muscles, resolving clinical manifestations.

**Complications.** Serum magnesium levels of greater than 10 mg/dL can result in respiratory failure, stupor or coma, cardiac arrest, hypotension refractory to vasopressors, and death.

### Nursing Management

Recognition of and monitoring for clinical manifestations of hypermagnesemia in patients at risk are a nursing priority. Nurses need to monitor vital signs for signs of hypotension, cardiac dysrhythmias, and respiratory depression. Neurological assessment includes monitoring for changes in the level of consciousness and deep tendon reflexes. Loss of deep tendon reflexes occurs because of the blockage of synaptic transmission of nerve impulses that occurs when magnesium levels reach 6 to 10. Older adults need to be provided with patient education focused on limiting the use of magnesium-containing laxatives and antacids. In patients at risk for developing hypermagnesemia due to renal insufficiency or renal failure, education regarding the identification of high-magnesium-content foods and over-the-counter medications is important.

## Connection Check 8.6

The nurse identifies the patient with which electrolyte abnormality as having the greatest risk for ventricular fibrillation?

- Hypochloremia
- Hyponatremia
- Hypocalcemia
- Hypokalemia

## Calcium

Calcium is utilized in processes such as cardiac contraction, blood coagulation, transmission of nerve impulses, and muscular contractions. Calcium is found primarily within bones (99%), with the remaining 1% found in the cells (0.7%) and the ECF (0.3%). The extracellular calcium is either ionized or free (50%); plasma-protein bound (40%); or complexed (10%) or chelated to citrate, phosphate, or sulfate. The ionized form of calcium is the active form of calcium that is involved with cellular functions. The plasma value of calcium is related to changes in plasma albumin, and low levels of albumin result in low levels of total calcium. In patients with low serum calcium levels, it is important for the nurse to also assess the serum albumin level. The ionized calcium levels are the most accurate measurements of active calcium. Normal values for ionized calcium are 4.6 to 5.3 mg/dL and for total calcium are 8.2 to 10.2 mg/dL. Calcium levels are tightly controlled by parathormone (PTH), calcitriol (vitamin D), and calcitonin (secreted by the thyroid gland).

Calcium is regulated on the basis of the functions of the parathyroid and thyroid glands. Parathyroid hormone (parathormone [PTH]) is secreted from the parathyroid glands that are located in the neck area, around the thyroid glands. There is a direct relationship between PTH and serum calcium levels; an increase in PTH leads to an increase in serum calcium. Parathyroid hormone leads to increases in reabsorption of calcium in the urine, in calcium reabsorption from the intestine (vitamin D required), and in osteoclastic (bone-breakdown) activity. Calcitonin, secreted by the thyroid gland, also has a role in calcium regulation. Serum calcium levels decrease as a result of calcitonin because it acts on the kidney to increase calcium excretion.

## Hypocalcemia

Hypocalcemia is serum calcium levels less than 8.2 mg/dL with a normal albumin level or ionized calcium less than 4.6 mg/dL. Hypocalcemia also occurs as a result of vitamin D deficiency, hypoparathyroidism, diarrhea, malnutrition, lactation, pregnancy, chronic renal failure, bone disease, and chronic alcohol abuse. Vitamin D is required for calcium absorption from the GI tract. In patients with hypoparathyroidism, the PTH, which regulates calcium balance, is low, resulting in low serum calcium levels. Hypocalcemia develops from diarrhea, malnutrition, chronic alcohol abuse, inadequate absorption of calcium in the intestines, and inadequate

vitamin D intake. During pregnancy, the fetus requires calcium for mineralization of the skeleton and for normal physiological functions, and lactation provides calcium for continued skeletal growth. In chronic renal failure, there is decreased absorption of calcium because of nonfunctioning kidneys and in response to hyperphosphatemia.

### Clinical Manifestations

Clinical manifestations of hypocalcemia are dependent on the rapidity of onset and severity. There may be no symptoms in patients with chronic hypocalcemia. In acute moderate hypocalcemia, 6 to 7 mg/dL, signs include excitability of nerves and muscles, which can lead to focal numbness, muscle spasms, paresthesias, twitching, tremors, and tetany. Smooth muscle spasms can lead to biliary colic, dysphagia, wheezing, and bronchospasm. Cardiac effects of hypocalcemia include lengthening of the QT interval, which predisposes the patient to ventricular dysrhythmias. In addition, hypocalcemia can cause decreased myocardial contractility, which can lead to hypotension, angina, and congestive heart failure. Calcium is required by cardiac cells for contraction as part of the action potential, and it also prolongs the depolarization phase, making the heart less receptive to further stimulation. Patients may also experience anxiety, confusion, and irritability secondary to low calcium levels. Positive Trousseau (Fig. 8.9) and Chvostek (Fig. 8.10) signs are classic physical assessment findings in hypocalcemia. Depending on the level of hypocalcemia, twitching of the facial muscles is elicited along with carpal spasm. Clinical manifestations of chronic hypocalcemia also include coarse hair, brittle nails, cataracts, chronic pruritus, and dry skin.

**FIGURE 8.9** Positive Trousseau sign. With inflation of the blood pressure cuff, the fingers go into carpal spasm, indicating hypocalcemia.

**FIGURE 8.10** Chvostek sign. Tapping over the facial nerve leads to twitching of the face related to hyperexcitability at the neuromuscular junction due to hypocalcemia.

### Management

#### Medical Management

Acute severe hypocalcemia, serum calcium levels less than 6.5 mg/dL, can produce life-threatening clinical manifestations and is often associated with other complex disease processes such as chronic renal failure, Crohn's disease, and pancreatitis. Initial care includes protection and maintenance of the airway and breathing, implementation of cardiac monitoring, and placement of an IV catheter. Evaluation of diagnostic results establishes the presence of hypocalcemia and other electrolyte abnormalities such as hypomagnesemia, hyperphosphatemia, or hypoalbuminemia. In severe symptomatic hypocalcemia, serum calcium levels less than 6.5 mg/dL, IV replacement of calcium is recommended. Calcium gluconate 0.5 mg/kg/hr IV in D5W over 10 to 15 minutes is administered and may be increased to 2 mg/kg/hr, not to exceed 3 to 4 g IV over 4 hours. The bolus is then followed by a continuous infusion until correction of the calcium deficit has occurred.

Re-evaluation of serum calcium levels should be done every 4 to 6 hours during replacement therapy to prevent hypercalcemia. If hypomagnesemia is present, it should be treated prior to treating hypocalcemia because correction of hypocalcemia is refractory until correction of hypomagnesemia has occurred. Magnesium resistance to PTH diminishes its secretion, affecting calcium concentration in the blood. In chronic hypocalcemia, oral calcium supplements and vitamin D are administered.

**Complications.** Cardiovascular collapse, refractory hypotension, laryngospasm, dysrhythmias, and decompensated heart failure can develop in acute severe hypocalcemia.

#### Nursing Management

Nursing care focuses on monitoring patients at risk for the development of hypocalcemia. Because of the potential for

laryngeal stridor, cardiac dysrhythmias, and seizures, emergency equipment such as intubation equipment, a tracheostomy set, a code/emergency cart, and a defibrillator must be readily available. Severe hypocalcemia causes increased neuromuscular excitability, which can cause tetany and seizures. Provision of a quiet environment is essential to decrease stimulation to prevent seizures in patients with severe hypocalcemia. Patient education regarding the intake of foods that are high in calcium content (Box 8.4) is important. Encourage smoking cessation to decrease excretion of urinary calcium and limiting intake of caffeine and alcohol to improve intestinal absorption of calcium.

### Hypercalcemia

Hypercalcemia is a serum calcium level greater than 10.2 mg/dL with a normal albumin level and ionized calcium levels greater than 5.3 mg/dL. Malignancy and primary hyperparathyroidism are the principal causes of hypercalcemia. Bone metastasis secondary to breast carcinoma, lymphoma, multiple myeloma, and non-small-cell lung cancer can result in hypercalcemia. Humoral hypercalcemia of malignancy can occur as a result of cervical, ovarian, renal, bladder, or esophageal malignancies or head and neck and lung squamous-cell cancer because of increased osteoclastic activity within the bone. Osteoclastic activity results in bone destruction and the release of calcium into the ECF. In hyperparathyroidism, there is an increased release of PTH, resulting in increased release of calcium from bones, increased absorption of calcium in the intestine, and increased reabsorption in the renal system. Medications such as thiazide diuretics, lithium, and calcium carbonate, as well as theophylline toxicity and hypervitaminosis of vitamins A and D, can also cause hypercalcemia. Thiazide diuretics decrease the excretion of calcium in the urine. Lithium increases PTH, which increases serum calcium levels. Theophylline toxicity results in hypercalcemia due to stimulation of beta receptors in the bone, resulting in the release of calcium from the bone. Hypervitaminosis of vitamins A and D causes excessive bone **resorption** (the breakdown of bone resulting in the release of calcium), as well as increased calcium absorption in the intestines.

### Box 8.4 Foods High in Calcium

- Milk: 290–300 mg in 8 oz milk
- Orange or grapefruit juice: 300 mg in 8 oz
- Canned salmon (with bones): 170–210 mg in 3 oz
- American cheese: 165–200 mg in 1-oz slice of cheese
- Broccoli: 160–180 mg in 1 cup
- Soybean curd (tofu): 145–155 mg in 4 oz
- Kale: 90–100 mg in 1/2 cup, cooked
- Ice cream or frozen dessert: 80–100 mg in 1/2 cup
- Egg: 55 mg in 1 medium-sized egg

### Clinical Manifestations

As with hypocalcemia, clinical manifestations of hypercalcemia are related to the rapidity of onset and severity of elevation as well as the overall health status of the patient. The patient's clinical presentation may be nonspecific in hypercalcemia and include clinical manifestations such as bradycardia, hypertension, thirst, lethargy, muscle weakness, abdominal discomfort, constipation, and decreased deep tendon reflexes. Mild and chronic elevation of serum calcium levels may not produce any clinical manifestations. In acute moderate hypercalcemia, calcium levels of 11.5 to 18 mg/dL, anorexia, nausea, vomiting, lethargy, nonspecific joint and muscle aches, and confusion may be present.

Severe elevation in calcium levels can result in coma. Renal calculi, polyuria, dehydration, and, in the setting of calcium levels greater than 13 mg/dL, renal failure may develop. Renal calculi develop as calcium crystals combine to form stones. Renal calculi can obstruct urine flow, leading to renal failure. Calcium deposits within the kidney can impair renal function, resulting in renal failure. Skeletal fractures can occur from osteopenia secondary to calcium loss from the bone.

### Management

#### Medical Management

Initial medical management is dependent on the severity of hypercalcemia and is aimed at stabilization and reduction of calcium levels. Reduction of serum calcium is achieved through increased calcium excretion and decreased resorption of calcium from bone. Discontinuation of medications associated with hypercalcemia and treatment of the underlying causes of hypercalcemia, such as malignancies, hyperparathyroidism, and renal failure, if possible, are additional initial interventions.

In patients with severe hypercalcemia (serum calcium levels above 15–16 mg/dL), hypovolemia is present because of polyuria, nausea, and vomiting. Fluid replacement with 0.9% NaCl should be initiated. Hydration facilitates the renal excretion of calcium, as well as the expansion of ECF. The fluid replacement rate is dependent on the severity of dehydration and the serum calcium levels, with the infusion rate aimed at maintaining a urine output of 100 to 150 mL/hr. Dialysis may be required to correct hypercalcemic states in patients with renal failure. During rehydration, patients must be monitored for clinical manifestations of fluid volume excess. Loop diuretics, which act on the loop of Henle to inhibit sodium, chloride, and water reabsorption, may be used to prevent fluid volume excess as well as to increase calcium excretion.

Administration of IV bisphosphates inhibits bone resorption, the breakdown of bone, and the release of calcium and increases the renal excretion of calcium. Effects of bisphosphonates on serum calcium levels are seen within 2 days, with a peak at 7 days and with benefits lasting 2 weeks. Bisphosphonates inhibit the breakdown of bone by encouraging osteoclasts (cells that destroy bone) to undergo cell death, preventing the release of calcium. Calcitonin also inhibits bone resorption and increases the renal excretion of calcium.

Calcitonin is administered intramuscularly or subcutaneously, with effects within several hours and lasting several days.

In hypercalcemia caused by malignancies, interventions are aimed at the treatment of the malignancies, which cause the release of calcium from the bone, through chemotherapy, surgical removal, or radiation therapy. The use of glucocorticoids in patients with multiple myeloma and hematological malignancies decreases intestinal absorption of calcium and increases renal excretion of calcium. Glucocorticoids inhibit vitamin D–mediated GI absorption of calcium and increase urinary calcium excretions, both of which lower serum calcium levels.

In hyperparathyroidism, treatment is aimed at controlling serum calcium levels and can be achieved through nonsurgical interventions or surgical removal of the parathyroid glands. Nonsurgical interventions include limiting intake of calcium-containing foods, maintaining good hydration, increasing mobilization, engaging in regular exercise activities, and avoiding medications that can impact calcium levels.

**Complications.** Hypercalcemic crisis occurs when serum calcium levels are greater than 14 mg/dL with the presence of clinical manifestations of acute hypercalcemia. Cardiac rhythm changes such as lengthening of PR and QRST intervals, T-wave changes such as flattening or inversion, and varying degrees of heart block can develop, progressing to cardiac arrest. Patients with acute hypercalcemia may have confusion and lethargy with potential progression to coma.

### Nursing Management

Monitoring patients at risk for the development of hypercalcemia is the initial role of nursing. Because of cardiac and neurological clinical manifestations related to hypercalcemia, nurses assess for changes in cardiac rhythm and mental status. Encouraging early and frequent ambulation of patients at risk for hypercalcemia, as well as adequate hydration, assists in preventing elevated serum calcium in patients at risk. Monitor for clinical manifestations of fluid volume excess in patients receiving rehydration therapy in the setting of hypercalcemia. When encouraging oral hydration, provide patients with liquids of choice.

### Connection Check 8.7

Which nursing action is the priority in the patient with a serum calcium of 6.0 mg/dL?

- A. Prepare for placement of a nasogastric tube.
- B. Place an intubation tray at the bedside.
- C. Place an indwelling urinary catheter.
- D. Prepare for emergency dialysis.

## Phosphorus

Phosphorus is primarily found in combination with calcium in bones, with the remainder found inside cells. Phosphorus exists as phosphate in the body and is critical for numerous cellular processes, such as cellular energy metabolism,

production of DNA and RNA, membrane structure, and regulation of enzyme and protein actions. Phosphorus levels are always evaluated in comparison to calcium because of their inverse relationship. Phosphorus levels are maintained with dietary intake and renal excretion. The normal value of serum phosphorus is 2.5 to 4.5 mg/dL.

### Hypophosphatemia

Hypophosphatemia is a serum phosphorus level of less than 2.5 mg/dL, and clinical manifestations appear only when phosphorus levels are less than 1 mg/dL. Hypophosphatemia results from decreased dietary intake, decreased intestinal absorption of phosphorus, and increased renal excretion of phosphorus. Low phosphate levels may also be the result of shifts of phosphate from the intracellular space into the extracellular space, which leads to urinary loss. In respiratory alkalosis, phosphate shifts into the cell and is used for intracellular glycolysis, leading to phosphorus consumption. Hypophosphatemia can be seen in patients with extensive burns, diabetic ketoacidosis, critical illness, malnourishment, refeeding syndrome, alcoholism, and excessive antacid use. In extensive burns, the mechanism of development of hypophosphatemia is unclear, with salt and water diuresis that occurs after burn injury considered to be the cause. In diabetic ketoacidosis, insulin deficiency mobilizes intracellular phosphate, causing phosphate to shift to the extracellular space and leading to urinary loss. Phosphorus levels can also decrease in the treatment of DKA with insulin that moves glucose into the cell and phosphorus is consumed during phosphorylation. Critically ill patients may develop hypophosphatemia because of acid-base disturbances, acute kidney injury, or increased cellular uptake of phosphorus due to catecholamine release. In patients with malnourishment or refeeding syndrome, giving carbohydrates stimulates the release of insulin, which moves glucose and phosphate into the cell. Excessive antacid use results in binding of phosphate in the gut, preventing absorption. Hypophosphatemia may also be caused by hypercalcemia, lack of vitamin D, and hyperparathyroidism.

### Clinical Manifestations

The clinical presentation of hypophosphatemia may include alterations in neurological, cardiac, and musculoskeletal function. Confusion, apprehension, seizures, and coma are neurological symptoms. The most commonly seen manifestation of hypophosphatemia is skeletal or smooth muscle weakness, including weakness in any muscle group. In addition to muscle weakness, respiratory insufficiency can develop from diaphragmatic dysfunction. Clinical manifestations of hypophosphatemia may also include tremors, paresthesias, joint stiffness, and bone pain.

### Management

#### Medical Management

Determining and treating the cause of the intracellular-to-extracellular movement of phosphorus, known as transcellular shift, are the goals of treatment of acute moderate hypophosphatemia if no clinical manifestations are present. Correction of additional electrolyte disturbances

(hypokalemia, hypomagnesemia, and hypocalcemia) facilitates the correction of serum phosphorus transcellular shifts. Hypokalemia and hypomagnesemia increase the renal loss of phosphorus. In the setting of acute severe hypophosphatemia or if the GI tract is nonfunctioning, IV replacement of phosphorus may be required until phosphorus levels are greater than 1.5 mg/dL. Caution must be given to prevent the development of hyperphosphatemia. Management of the phosphorus level focuses on ensuring adequate intake through foods, enteral feedings, and total parenteral nutrition, especially in patients at risk.

**Complications.** Patients with acute severe hypophosphatemia can develop widespread organ-system dysfunction due to depletion of ATP, which is responsible for intracellular energy transfer, and if phosphorus levels are low, energy production converts to glycolysis. Phosphorus is required for the delivery and release of oxygen to cells. In hypophosphatemia, cell dysfunction can occur, resulting in multiple-organ-system disorders. In critically ill patients, respiratory insufficiency and depressed cardiac contractility may be present. Cardiac dysrhythmias, impaired hepatic function, seizures, and depressed function of white blood cells can also occur because of intracellular ATP. Bleeding from platelet dysfunction and hemolysis are rare complications of severe hypophosphatemia.

#### **Nursing Management**

Monitoring and identifying patients at risk for developing hypophosphatemia are the roles of the nurse. Patients at greatest risk for hypophosphatemia are those with a history of chronic alcohol abuse, diabetic ketoacidosis treated with insulin, critical illness, or malnourishment or those with extensive burns. Patients with hypophosphatemia are monitored for clinical manifestations indicating changes in patient status, such as confusion, increased muscle weakness, and myocardial irritability. Nursing care is aimed at the treatment of emergent causes of hypophosphatemia and, with chronic disorders, at patient and family education regarding dietary sources for ensuring adequate intake of phosphorus.

#### **Hyperphosphatemia**

Hyperphosphatemia is defined as a serum phosphate level greater than 4.5 mg/dL. Renal failure is the most frequent cause of hyperphosphatemia and is secondary to decreased renal excretion of phosphorus. Additional causes include shifts from the intracellular to the extracellular space as a result of diabetic ketoacidosis (DKA) and increased ingestion with a decreased output of phosphorus. In DKA, phosphate levels increase secondary to intracellular phosphorus moving in to the extracellular fluid. Shifts of phosphorus can occur as a result of cellular breakdown, secondary to tumor lysis, acute hemolysis, or rhabdomyolysis. Increased intake of phosphorus can be seen in vitamin D intoxication, excessive use of oral saline laxatives, or phosphate replacement. Hyperphosphatemia may also be secondary to hyperthyroidism or hypoparathyroidism.

#### **Clinical Manifestations**

The clinical manifestations of hyperphosphatemia are similar to those seen in hypocalcemia because of the inverse relationship of phosphorus and calcium. Hypocalcemia is caused by phosphorous precipitating calcium and altering bone reabsorption of calcium through stimulation of the PTH, which may result in life-threatening hypocalcemia.

A positive Chvostek or Trousseau sign, hyperreflexia, soft tissue calcification, and tetany may occur with elevated phosphorus levels. Patients may complain of bone and joint pain, muscle weakness, anorexia, and paresthesias. Delirium, convulsions, seizures, and coma may also be noted. Cardiovascular symptoms such as hypotension, heart failure, and a prolonged QT interval on the ECG may be seen. Long-term effects of hyperphosphatemia include the development of calcifications found in soft tissue, the kidneys, the skin, the cornea, and blood vessels. Calcium calcifications play a key role in the development of cardiovascular disease and mitral and aortic stenosis and in the progression of renal disease, resulting in high morbidity and mortality of these patients.

#### **Management**

##### **Medical Management**

Identification of the underlying causes of hyperphosphatemia and treatment are the focus of medical management. Increasing renal excretion of phosphorus through volume replacement with IV normal saline and the use of loop diuretics facilitate the renal excretion of phosphorus. Because of the relationship of phosphorus and calcium, correction of hypocalcemia corrects hyperphosphatemia. In patients with severe renal insufficiency or renal failure, dialysis may be required if hypocalcemia is also present. Limiting the intake of phosphorus-containing foods may be adequate to control hyperphosphatemia. The use of phosphate binders in patients with renal failure is indicated because they inhibit absorption of phosphate through the GI tract.

**Complications.** Short-term complications of hyperphosphatemia include possible tetany from acute hypocalcemia. Long-term effects can be seen in any organ system and can result in vascular wall calcification and arteriosclerosis, kidney disease, bone and joint pain, and fractures.

##### **Nursing Management**

Monitoring and identifying patients at risk for developing hyperphosphatemia are the roles of the nurse. Nursing care is aimed at patient and family education regarding the dietary management of phosphorus intake. Dietary education focuses on foods to avoid, such as meats, nuts, high-protein foods, cheese, and other dairy products. Because of the inverse relationship between phosphorus and calcium, patient education needs to include the symptoms of hypocalcemia.

## Making Connections

### CASE STUDY: WRAP-UP

Henrietta is ready for discharge home. She continues to have fine crackles in her lung bases and trace peripheral edema in her lower extremities. Laboratory work collected today shows hemoglobin 11.7 g/dL, hematocrit 34%, Na<sup>+</sup> 140 mEq/L, K<sup>+</sup> 4.2 mEq/L, BUN 27 mg/dL, and creatinine 0.9 mg/dL. Her discharge medications include furosemide (Lasix) 40 mg by mouth daily, K-Tab 20 mEq by mouth daily, digoxin 0.125 mg by mouth daily, spironolactone (Aldactone) 25 mg by mouth twice daily, and carvedilol (Coreg) 6.25 mg by mouth twice daily. Discharge instructions include taking daily weights, calling her physician if a weight gain of 3 to 4 pounds over 3 days is noted, avoiding salt substitutes, and limiting fluid intake to 1,200 mL per day.

#### Case Study Questions

- The charge nurse is reviewing the admission orders for Henrietta, who has been admitted with heart failure and renal insufficiency. It is a priority for the charge nurse to follow up with the provider about which order?
  - Digoxin 0.125 mg by mouth daily
  - Carvedilol (Coreg) 12.5 mg by mouth twice daily
  - Bumetanide (Bumex) 1 mg by mouth twice daily
  - Spironolactone (Aldactone) 25 mg by mouth three times a day
- Which statement by Henrietta about potassium supplements indicates the need for further teaching?
  - "In addition to the potassium supplement, I will eat a banana every day."
  - "I can liberally use salt substitutes with my meals."
  - "I should stop taking the K-Tab if I have no leg cramps."
  - "Fruits and vegetables are a good source of potassium."
- The nurse is providing discharge instructions to Henrietta regarding dietary sources of potassium. The nurse does not recommend which food as a source of high potassium content?
  - Baked potato
  - Apple
  - Banana
  - Cooked spinach
- When providing discharge instructions for Henrietta, the nurse should include which of the following? (*Select all that apply.*)
  - Weigh herself daily at the same time.
  - Limit fluid intake to 3 L per day.
  - Limit salt intake.
  - Increase the intake of fresh fruits and vegetables.
  - Report a 3-lb weight gain in 2 days to her primary care provider.

- Which statement by Henrietta indicates the need for further teaching about hyperkalemia?
  - "It is normal to have heart palpitations."
  - "Fatigue and weakness are signs of low potassium."
  - "Some of my medications make me at risk for high potassium."
  - "I may have numbness and tingling when my potassium is high."

## CHAPTER SUMMARY

Fluids are categorized as intracellular and extracellular, which includes plasma, intercellular (interstitial) and transcellular fluids. Patients at risk for fluid deficits are those who are unable to access fluids independently; have cognitive changes that diminish the thirst mechanism; or have increased fluid loss due to vomiting, diarrhea, or insensible fluid losses. Clinical manifestations of fluid volume deficits include tachycardia, hypotension, poor skin turgor, and weight loss. Patients at risk for fluid volume excess are older adults with compromised cardiac and renal functions. The clinical presentation of fluid volume excess includes crackles, tachycardia, hypertension, hypoxia, weight gain, and edema.

Sodium is the most prevalent electrolyte in the ECF and is required for many regulatory functions, including fluid and electrolyte balance and neuromuscular activity. The normal range of sodium is 135 to 145 mEq/L. Hyponatremia, a serum sodium level of less than 135 mEq/L, is the most common electrolyte disturbance seen in hospitalized patients. Hyponatremia occurs as a result of increased levels of ADH and aldosterone and fluid volume excess. Clinical manifestations often include neuromuscular manifestations, such as confusion, headache, and muscle cramps.

Hypernatremia, a serum sodium level of greater than 145 mEq/L, is seen in excess loss or decreased intake of water, decreased levels of ADH, and intake of excessive amounts of sodium. Treatment is aimed at the replacement of water. Clinical manifestations of hypernatremia include increased thirst, poor skin turgor, hypotension and tachycardia, confusion, and restlessness.

Chloride is the major ECF anion and works in conjunction with sodium to maintain osmotic pressure. The normal serum chloride value range is 97 to 107 mEq/L. Hypochloremia refers to serum chloride levels of less than 97 mEq/L and occurs as a result of chloride loss. Patients with hypochloremia may exhibit hypotension, tetany, shallow respirations, and hyperexcitability of muscles and nerves. Hyperchloremia is present if the serum chloride level is greater than 107 mEq/L and can result in bicarbonate loss, resulting in metabolic acidosis and hypernatremia. Clinical

manifestations of hyperchloremia include deep and rapid respirations, lethargy, tachypnea, decreased cognitive ability, and increased blood pressure.

Potassium is the most abundant intracellular cation and is essential to neuromuscular function and metabolic processes. The normal range of serum potassium is 3.5 to 5.0 mEq/L. Hypokalemia, a serum potassium level of less than 3.5 mEq/L, is seen in patients with alkalosis, loss due to nasogastric suctioning, diuretic use, and increased renal loss. Treatment includes oral or IV replacement of potassium. Clinical manifestations of hypokalemia include muscle weakness, cardiac dysrhythmias, and altered carbohydrate metabolism. Hyperkalemia, a serum potassium level of greater than 5.0 mEq/L, is seen in patients with acidosis, cell trauma, and renal failure. Treatment is aimed at lowering potassium levels by causing a shift of potassium back into the cell, binding of potassium in the gut, and correction of acidosis. The clinical presentation of hyperkalemia includes muscle weakness and cardiac dysrhythmias.

Magnesium is the fourth most abundant cation in the body and is needed for cellular functioning, healthy bones and teeth, nerve and muscle function, and coagulation. The normal reference range for magnesium is 1.6 to 2.2 mg/dL. Hypomagnesemia is a serum magnesium level of less than 1.6 mg/dL and is seen in patients with malnutrition and excessive excretion of magnesium via the renal system. Clinical manifestations of hypomagnesemia include muscle weakness and cramping, tetany, hyperactive reflexes, and tremors. Hypermagnesemia is a serum magnesium level of greater than 2.2 mg/dL, with the most common causes being over-replacement of magnesium deficits and renal insufficiency or renal failure. Clinical manifestations of high serum magnesium levels include hypotension,

dysrhythmias, muscle weakness, and loss of deep tendon reflexes.

Calcium is utilized in processes such as cardiac contraction, blood coagulation, transmission of nerve impulses, and muscular contractions. Normal values for ionized calcium are 4.6 to 5.3 mg/dL and for total calcium are 8.2 to 10.2 mg/dL. Hypocalcemia is serum calcium levels of less than 8.2 mg/dL with a normal albumin level or ionized calcium less than 4.6 mg/dL. Clinical manifestations of hypocalcemia include positive Trousseau and Chvostek signs, tetany, and laryngospasm. Cardiac signs including lengthening of the QT interval, ventricular dysrhythmias, and hypotension and angina secondary to decreased myocardial contractility. Hypercalcemia is a serum calcium level of greater than 10.2 mg/dL with a normal albumin level and ionized calcium levels greater than 5.3 mg/dL and is often associated with malignancies. Clinical manifestations include bradycardia, hypertension, abdominal discomfort, lethargy, and confusion.

Phosphorus exists as phosphate in the body and is critical for numerous cellular processes, such as cellular energy metabolism. The normal value of serum phosphorus is 2.5 to 4.5 mg/dL. Hypophosphatemia is a serum phosphorus level of less than 2.5 mg/dL. Confusion, apprehension, seizures, coma, and skeletal and smooth muscle weakness are clinical manifestations of hypophosphatemia. Hyperphosphatemia is a serum phosphate level of greater than 4.5 mg/dL, and renal failure is the most frequent cause. Clinical manifestations include positive Chvostek or Trousseau sign, hyperreflexia, soft tissue calcification, tetany, bone and joint pain, muscle weakness, anorexia, and paresthesias. Cardiovascular clinical manifestations may include hypotension, heart failure, and a prolonged QT interval on the ECG.

# Chapter 9

## Acid-Base Balance

Trisha Fronczek

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Describing the significance of acid-base balance for normal function
2. Stating the steps for arterial blood gas interpretation
3. Explaining the meaning of compensation
4. Comparing and contrasting major acid-base disorders
5. Describing the role of the respiratory and renal systems in acid-base balance
6. Explaining nursing considerations related to patients with acid-base disorders

### CONCEPTS

- Assessment
- Fluid and Electrolyte Balance
- Oxygenation
- pH Regulation

### ESSENTIAL TERMS

Acid  
Acid-base balance  
Acid-base imbalance  
Anion gap  
Base  
Base excess  
Bicarbonate  
Bicarbonate buffers  
Carbon dioxide  
Chemical buffers  
Compensation  
Fully compensated  
Hydrogen ion  
Metabolic acidosis  
Metabolic alkalosis  
Oxygenation  
PaO<sub>2</sub>  
Partially compensated  
pH  
Phosphate buffers  
Protein buffers  
Renal buffers  
Respiratory acidosis  
Respiratory alkalosis  
Respiratory buffers  
Uncompensated

### Finding Connections

#### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Cory Nelson, 21 years old, presents via ambulance to the emergency department after a motor vehicle accident (MVA). When the car he was a passenger in struck a tree, Cory was wearing his seat belt. He sustained chest trauma due to the impact and has facial lacerations. The paramedic at the scene noted that Cory had alcohol present on his breath and slurred speech when questioned...

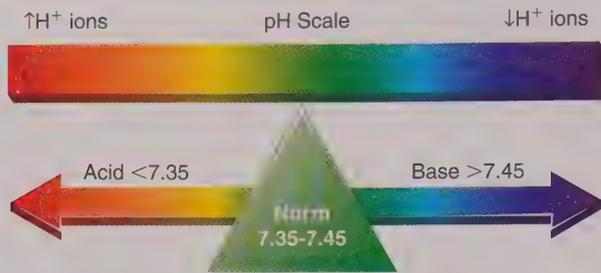

### ACID-BASE BALANCE OVERVIEW

Acid-base balance refers to the homeostasis of the hydrogen ion (H<sup>+</sup>) concentration in body fluids. The body fluid's concentration of hydrogen ions is expressed as the body's pH level (Fig. 9.1). Body fluids are further classified as acids or bases according to their hydrogen ion concentration.

### Hydrogen Ion Concentration

The hydrogen ion concentration of body fluids is vital to acid-base balance. The hydrogen ion concentration is measured in terms of the pH. The pH numerical value is inversely proportional to the number of hydrogen ions in the body fluid:

- ↑ Hydrogen ion concentration, ↓ pH (acid)
- ↓ Hydrogen ion concentration, ↑ pH (base)

**FIGURE 9.1** The relationship between hydrogen ions and the body’s pH. As the hydrogen ion (acid) concentration increases, the pH level decreases, indicating acidosis. As the hydrogen ion concentration decreases, the pH level increases, indicating alkalosis.

The normal arterial blood pH range is 7.35 to 7.45. A pH level below 6.8 or above 7.8 is considered incompatible with life because cell function becomes seriously impaired.

**Safety Alert** Fatal blood pH levels are less than 6.8 and greater than 7.8.

### Acids

Acids are known as hydrogen ion donors. An acidic solution has more hydrogen ions and a pH of less than 7.35. The excess of hydrogen ions can be a result of overproduction of acids that causes the release of hydrogen ions or an under-elimination of acids that causes retention of hydrogen ions. Because hydrogen ions are positively charged ions, hydrogen ion excess in the blood causes imbalances in other electrolytes, such as calcium, potassium, and sodium. These imbalances can lead to disorders of the cardiac, central nervous, neuromuscular, and respiratory systems.

### Bases

Bases are known as hydrogen ion acceptors. A base, or alkaline, solution has fewer hydrogen ions and a pH of greater than 7.45. Alkalosis can result from either an overproduction of base or an under-elimination of base. The most common base is bicarbonate, and the systems affected are the cardiovascular, muscular, and nervous systems.

### Oxygenation

Oxygenation is measured using arterial blood gas (ABG) sampling. The PaO<sub>2</sub> measures the partial pressure of oxygen in arterial blood and is the most important factor in determining how oxygen binds to hemoglobin. If the PaO<sub>2</sub> is high, then more oxygen is able to bind with hemoglobin; if the PaO<sub>2</sub> is low, then less oxygen is able to bind with hemoglobin. The SaO<sub>2</sub> measures the oxygen-carrying capacity of

hemoglobin and can be assessed through the use of pulse oximetry. Primarily, SaO<sub>2</sub> is used to evaluate respiratory function and is not used to evaluate acid-base balance. Higher than normal PaO<sub>2</sub> and SaO<sub>2</sub> values are associated with unnecessarily high levels of supplemental oxygen administration. In contrast, lower than normal PaO<sub>2</sub> and SaO<sub>2</sub> values indicate hypoxemia (Table 9.1).

**Safety Alert** Pulse oximetry is considered accurate for oxygen saturations of greater than 80%. Arterial blood gas analysis is recommended for oxygen saturations of less than 80%.

### Carbon Dioxide

Carbon dioxide (CO<sub>2</sub>) is the natural by-product of cellular metabolism. Carbon dioxide is measured by the PaCO<sub>2</sub> levels, which indicate the partial pressure of CO<sub>2</sub> in the arterial blood. The PaCO<sub>2</sub> is used to evaluate the respiratory component of acid-base balance. Primarily regulated by the ventilatory function of the lungs, normal arterial CO<sub>2</sub> levels are 35 to 45 mm Hg.

- PaCO<sub>2</sub> greater than 45 mm Hg is related to hypoventilation or excessive CO<sub>2</sub> retention, and therefore acidosis.

**Table 9.1 Oxygenation Blood Gas Values**

Level	Normal Value	Interpretation
PaO <sub>2</sub>	80–95 mm Hg	Measurement of partial pressure of oxygen in arterial blood  PaO <sub>2</sub> less than 80 mm Hg = insufficient oxygen present; there is less chance of oxygen binding with hemoglobin  PaO <sub>2</sub> greater than 95 mm Hg = there is more oxygen in the blood than necessary
SaO <sub>2</sub>	>95%	The percentage of oxygen that is bound to hemoglobin  SaO <sub>2</sub> less than 95% = oxygen saturation is insufficient to meet the body’s needs  SaO <sub>2</sub> greater than 95% = oxygen saturation is sufficient for the body’s needs

- PaCO<sub>2</sub> less than 35 mm Hg is related to hyperventilation or excessive CO<sub>2</sub> exhalation, and therefore alkalosis.

## Bicarbonate

Bicarbonate helps the body regulate pH and accomplishes this by its ability to accept a hydrogen ion (H<sup>+</sup>). Regulated by the kidneys, bicarbonate is measured by the arterial blood HCO<sub>3</sub><sup>-</sup> concentration and is used to evaluate the metabolic component of acid-base balance. Normal HCO<sub>3</sub><sup>-</sup> values are between 22 and 26 mEq/L.

- HCO<sub>3</sub><sup>-</sup> less than 22 mEq/L is acidosis.
- HCO<sub>3</sub><sup>-</sup> greater than 26 mEq/L is alkalosis.

### Connection Check 9.1

How does the nurse interpret an arterial pH of 7.47?

- Acidosis
- Alkalosis
- Compensation
- Homeostasis

## REGULATION OF ACID-BASE BALANCE

To maintain the pH of the extracellular fluid within the narrow range, the body has three regulating mechanisms: chemical buffers, respiratory buffers, and renal buffers.

### Chemical Buffers

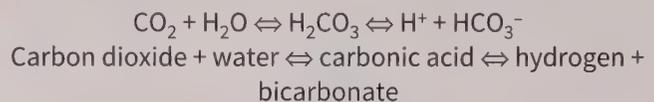

The first line of defense against a change in the body's pH is **chemical buffers**. Chemical buffers include bicarbonate, phosphate, and proteins.

- **Bicarbonate buffers** are mainly responsible for buffering blood and interstitial fluid. They rely on a series of chemical reactions in which pairs of weak acids and bases combine with stronger acids and bases to weaken them. These chemical reactions are assisted by the kidneys and lungs.
- **Phosphate buffers** are found in the intracellular fluids as bicarbonates. They control small fluctuations in pH and respond quickly. They prove especially effective in the renal tubules, where phosphates exist in greater concentration.
- **Protein buffers** are the most abundant buffers in the body. They work both inside and outside of cells: hemoglobin inside the cell and albumin and globulins outside the cell. Protein buffers

work by binding with acids and bases to neutralize them.

## Respiratory Buffers

Acid-base disturbances resulting from primary alterations in the PaCO<sub>2</sub> are regulated by **respiratory buffers**. Any retention of CO<sub>2</sub> or increase in the body's concentration of CO<sub>2</sub> produces an increase in hydrogen ions through the generation of carbonic acid (H<sub>2</sub>CO<sub>3</sub>). This lowers the pH and thus promotes the development of an acidotic state, which is observed in conditions such as chronic obstructive pulmonary disease (COPD). While in the acidotic state, chemoreceptors in the brain respond to the increased CO<sub>2</sub> levels by stimulating the respiratory system to increase the respiratory rate and depth in an effort to excrete CO<sub>2</sub> through the lungs (Table 9.2). Conversely, decreases in CO<sub>2</sub> concentration result in a decrease in hydrogen ions. This leads to a pH rise, and an alkalotic state results, as seen in conditions such as hyperventilation.

## Renal Buffers

The **renal buffers** are the most effective, yet the slowest-acting buffering system and buffer by **regulating bicarbonate levels**. If the body is in a state of alkalosis, then the kidneys excrete HCO<sub>3</sub><sup>-</sup> and reabsorb hydrogen ions (H<sup>+</sup>). This results in urine becoming more alkaline, a drop in the blood bicarbonate levels, and a decrease in pH. If the body is in a state of acidosis, then the kidneys excrete hydrogen ions (H<sup>+</sup>) and reabsorb HCO<sub>3</sub><sup>-</sup>. This results in urine becoming more acidic, bicarbonate levels increasing, and the pH increasing (Table 9.3; Fig. 9.2).

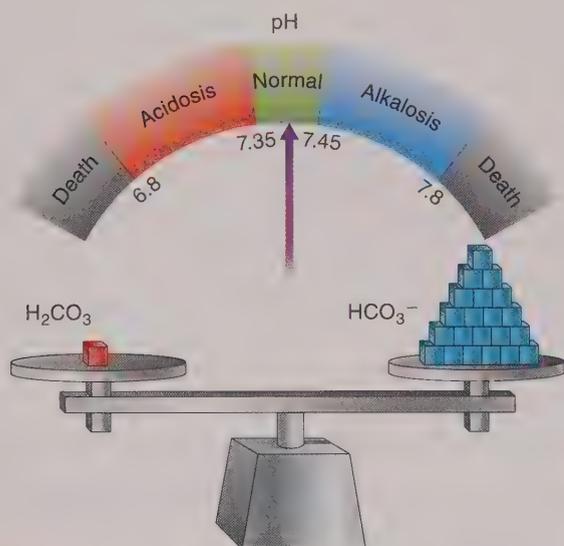

This response to **acid-base imbalances** begins within hours but requires several days to be marginally effective. This is in comparison to the faster changes brought about through the increases or decreases in the respiratory rate.

**Table 9.2 Respiratory System Role in Acid-Base Balance**

CO <sub>2</sub>	H <sup>+</sup> Ions	pH State	Body Response
<i>Retention</i>	↑	↓ pH (acid)	↑ Depth and rate of respirations
<i>Excretion</i>	↓	↑ pH (base)	↓ Rate of respirations

**Table 9.3 Renal System Role in Acid-Base Balance**

Body's State	HCO <sub>3</sub> <sup>-</sup>	H <sup>+</sup> Ions	pH State	Body Response
<b>Alkalosis</b>	Excrete	Reabsorb	Increase	Urine alkaline, ↓ blood HCO <sub>3</sub> <sup>-</sup> , ↓ pH
<b>Acidosis</b>	Absorb	Excrete	Decrease	Urine acidic, ↑ HCO <sub>3</sub> <sup>-</sup> , ↑ pH

**FIGURE 9.2** Normal pH results when the balance between carbonic acid (H<sub>2</sub>CO<sub>3</sub>) and bicarbonate (HCO<sub>3</sub><sup>-</sup>) is maintained. Retention of CO<sub>2</sub> or an increase in the body's concentration of CO<sub>2</sub> produces an increase in hydrogen ions through the generation of carbonic acid (H<sub>2</sub>CO<sub>3</sub>). This lowers the pH and results in an acidotic state. If the body is in a state of alkalosis, then the kidneys excrete HCO<sub>3</sub><sup>-</sup> and reabsorb hydrogen ions (H<sup>+</sup>). This results in urine becoming more alkaline, a drop in blood bicarbonate levels, and decreased pH. If the body is in a state of acidosis, then the kidneys excrete hydrogen ions (H<sup>+</sup>) and reabsorb HCO<sub>3</sub><sup>-</sup>. In all cases, a pH level below 6.8 or above 7.8 is considered incompatible with life, and death will likely ensue.

**Connection Check 9.2**

Which parameter of the ABG result correlates to the assessment of the base component?

- A. pH
- B. PaO<sub>2</sub>
- C. HCO<sub>3</sub><sup>-</sup>
- D. PaCO<sub>2</sub>

**RESPIRATORY AND RENAL COMPENSATION**

**Compensation** describes physiological responses to an acid-base imbalance in an attempt to normalize pH. If the problem is of respiratory origin, then the kidneys work to correct. If the problem is of renal origin, then the lungs work to correct.

**Respiratory Compensation**

If the primary alteration in acid-base balance has resulted from a metabolic disorder, then the respiratory system may compensate by retaining or removing CO<sub>2</sub> while minimizing a change in the pH. The lungs may take as little as 5 to 15 minutes to begin compensation. The respiratory system responds to metabolic-based pH imbalances (Table 9.4) by

- **Metabolic acidosis:** increase in respiratory rate and depth
- **Metabolic alkalosis:** decrease in respiratory rate and depth

In older adults, respiratory compensation may be limited because of physiological changes associated with aging, including barrel chest and kyphosis (spinal curvature) that result in decreased lung compliance and recoil and increased work of breathing.

**Renal Compensation**

If the primary alteration in acid-base balance results from a respiratory disorder, then the renal system may compensate by excreting or retaining hydrogen and bicarbonate. The renal system may take as long as 24 hours to correct a respiratory-induced problem because there are three major renal mechanisms that work to compensate the disorder: tubular kidney movement of bicarbonate, kidney tubule formation of acids, and the formation of ammonium from

**Table 9.4 Metabolic Acidosis and Metabolic Alkalosis**

	Respiratory Compensation	Body Results
<b>Metabolic acidosis:</b> <b>Bicarbonate deficit</b>	↑ Rate and depth of respirations	Greater elimination of CO <sub>2</sub>
<b>Metabolic alkalosis:</b> <b>Bicarbonate excess</b>	↓ Rate and depth of respirations	↑ CO <sub>2</sub> retention and ↑ carbonic acid accumulation

amino acid catabolism. The renal system responds to respiratory-based pH imbalances (Table 9.5) by

- **Respiratory acidosis:** increase in hydrogen excretion and bicarbonate reabsorption
- **Respiratory alkalosis:** decrease in hydrogen excretion and bicarbonate reabsorption

Renal function also changes with aging and includes atrophy of the kidney and decreased blood flow to the kidneys, leading to a decreased glomerular filtration rate. Renal compensation may be affected by these alterations in kidney function.

Arterial blood gases are further defined by their degree of compensation. An ABG can be **uncompensated**, **partially compensated**, or **fully compensated**. To determine the level of compensation, the pH, PaCO<sub>2</sub>, and HCO<sub>3</sub><sup>-</sup> are analyzed.

### Steps to Determine Acid-Base Compensation

1. Does the pH range indicate acidosis or alkalosis? If pH is within the normal range, in which direction does it trend?
2. Has the PaCO<sub>2</sub> or HCO<sub>3</sub><sup>-</sup> changed to account for the acidosis or alkalosis?
3. Has the opposite system worked to correct and shift back toward a normal pH?

### Types of Compensation

The three types of compensation are:

**Uncompensated:** pH is abnormal, and either the PaCO<sub>2</sub> or the HCO<sub>3</sub><sup>-</sup> is also abnormal. There is no indication that the opposite system has tried to correct the imbalance (Table 9.6).

**Partially compensated:** pH is abnormal, and both PaCO<sub>2</sub> and HCO<sub>3</sub><sup>-</sup> are also abnormal (Table 9.7). This indicates that the opposite system has attempted to correct for the other but has not been completely successful.

**Fully compensated:** pH is normal, and both the PaCO<sub>2</sub> and HCO<sub>3</sub><sup>-</sup> are abnormal (Table 9.8). The normal pH indicates that one system has been able to compensate for the other.

**Table 9.5 Respiratory Acidosis and Respiratory Alkalosis**

	Renal Compensation	Body Response
<b>Respiratory acidosis:</b> <b>Carbonic acid excess</b>	↓ H <sup>+</sup> and ↑ HCO <sub>3</sub> <sup>-</sup>	Restore balance
<b>Respiratory alkalosis:</b> <b>Carbonic acid deficit</b>	↑ H <sup>+</sup> and ↓ HCO <sub>3</sub> <sup>-</sup>	Restore balance

**Table 9.6 Example of Blood Gas Results—Respiratory Alkalosis**

Blood Gas 3 Results	Interpretation
pH: 7.51	Alkalosis
PaCO <sub>2</sub> : 26 mm Hg	Alkalosis
HCO <sub>3</sub> <sup>-</sup> : 25 mEq/L	Normal
PaO <sub>2</sub> : 90 mm Hg	Normal

**Table 9.7 Example of Blood Gas Results—Partially Compensated Respiratory Alkalosis**

Blood Gas 4 Results	Interpretation
pH: 7.49	Alkalosis
PaCO <sub>2</sub> : 25 mm Hg	Alkalosis
HCO <sub>3</sub> <sup>-</sup> : 20 mEq/L	Acidosis
PaO <sub>2</sub> : 95 mm Hg	Normal

**Table 9.8 Example of Blood Gas Results—Fully Compensated Respiratory Alkalosis**

Blood Gas 5 Results	Interpretation
pH: 7.44	Normal but greater than 7.4, so tends toward alkalosis
PaCO <sub>2</sub> : 25 mm Hg	Alkalosis, primary problem
HCO <sub>3</sub> <sup>-</sup> : 19 mEq/L	Acidosis, compensatory response
PaO <sub>2</sub> : 95 mm Hg	Normal

Maintaining a homeostatic pH environment is essential for normal body functioning. To achieve this goal, the body must constantly monitor its hydrogen ion concentration. When there is an increase or decrease in this balance, the body must use the blood bicarbonate, proteins, and phosphate buffer body fluids to compensate. There does come a time in the disease process when these buffers can no longer maintain adequate concentrations of hydrogen ions, and outside resources must be used to help the body compensate.

### Connection Check 9.3

What acid-base imbalance does the nurse suspect on the basis of these results?

pH: 7.31

PaCO<sub>2</sub>: 52 mm Hg

HCO<sub>3</sub><sup>-</sup>: 28 mEq/L

- Uncompensated respiratory acidosis
- Partially compensated respiratory acidosis
- Uncompensated metabolic acidosis
- Partially compensated metabolic acidosis

## ARTERIAL BLOOD GAS INTERPRETATION

Arterial blood gas analysis describes the set of values that are assessed to determine an individual's ability to maintain normal acid-base balance. Arterial blood gases are drawn from arteries such as the radial, brachial, or femoral and can also be obtained through an indwelling arterial line that may be present in one of these arteries. Arterial lines also provide continuous blood pressure (BP) monitoring and allow for arterial blood sampling. A patient with an arterial line must be cared for in the intensive care unit (ICU) or a monitored unit because of possible circulatory impairment to the affected limb, risk of hemorrhage, and the need for continuous arterial line monitoring.

### Obtaining an Arterial Blood Gas

Most ABG samples are collected by a respiratory therapist or specially trained registered nurse (see institution's policy). Collection from the femoral artery, however, is usually performed only by a physician or advanced practice registered nurse (APRN). Before a radial puncture is performed, an Allen test should be conducted (Box 9.1). This test is conducted to ensure adequate collateral circulation in the event there is hemorrhage or thrombosis of the radial artery that is punctured.

### Arterial Blood Gas Assessment

There are six parameters included in an ABG measurement:

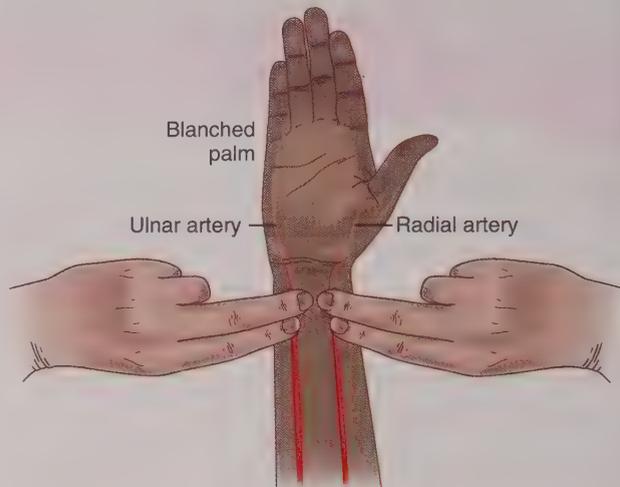

- pH
- PaCO<sub>2</sub>
- HCO<sub>3</sub><sup>-</sup>
- Base excess
- PaO<sub>2</sub>
- SaO<sub>2</sub>

Blood acidity is reflected by pH levels, and the normal range is 7.35 to 7.45. A pH greater than 7.45 indicates alkalosis; a pH less than 7.35 indicates acidosis. If the level is normal or borderline, then the body may be attempting

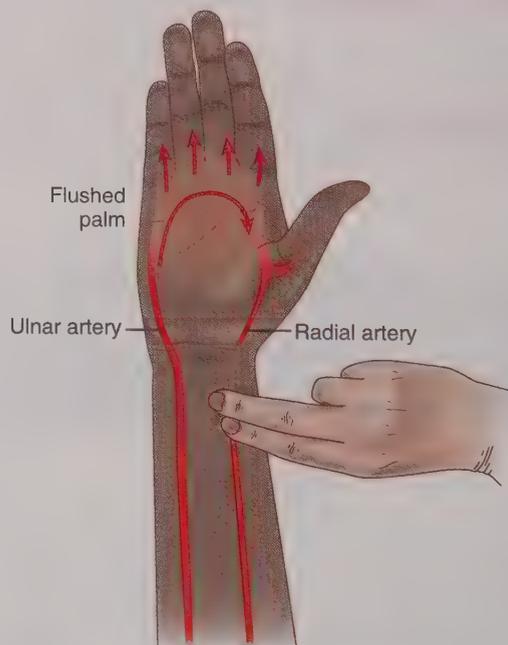

## Box 9.1 Performing an Allen Test

Rest the patient's arm on the mattress or bedside stand and support his wrist with a rolled towel. Tell him to clench his fist. Using your index and middle fingers, press on the radial and ulnar arteries. Hold this position for a few seconds.

Without removing your fingers from the patient's arteries, ask him to unclench his fist and hold his hand in a relaxed position. The palm will be blanched because pressure from your fingers has impaired the normal blood flow.

Release pressure on the patient's ulnar artery. If the hand becomes flushed, which indicates blood filling the vessels, you can safely proceed with the radial artery puncture. If the hand does not flush, select another site for the puncture.

to compensate for a slightly abnormal or chronic acid-base imbalance. Compensation is the way in which the body responds to an acid-base imbalance in an attempt to normalize the pH of the blood.

The  $\text{PaCO}_2$  level reflects the partial pressure of  $\text{CO}_2$  in arterial blood and is adjusted by changes in the rate and depth of respiratory ventilation. The normal range is 35 to 45 mm Hg. A  $\text{PaCO}_2$  greater than 45 mm Hg indicates hypoventilation or excessive  $\text{CO}_2$  retention, as in COPD, drug overdose, or acute respiratory failure, and therefore respiratory acidosis. A  $\text{PaCO}_2$  less than 35 mm Hg indicates hyperventilation or excessive  $\text{CO}_2$  exhalation, and therefore respiratory alkalosis. Respiratory alkalosis may occur with an anxiety attack, pulmonary edema, hepatic failure, or inappropriate mechanical ventilator settings.

The  $\text{HCO}_3^-$  level reflects the arterial blood's  $\text{HCO}_3^-$  concentration and is the renal component of acid-base regulation. The normal range is 22 to 26 mEq/L. An  $\text{HCO}_3^-$  less than 22 mEq/L indicates acidosis and may occur with chronic alcohol abuse, starvation, or acute renal failure. An  $\text{HCO}_3^-$  greater than 26 mEq/L indicates alkalosis and may be the result of gastric drainage, diuretic use, or severe potassium depletion. An **anion gap** calculation may be used to determine the cause of metabolic acidosis and is a way to monitor a person's response to treatments. The calculation of the anion gap is based on the difference between major cations (sodium and potassium) and primary anions (chloride and bicarbonate). The normal reference range for the anion gap is 8 to 16 mEq/L. **Base excess** reflects the level of  $\text{HCO}_3^-$  and other bases such as proteins and hemoglobin, and the normal range is  $-2$  to  $+2$ . A base excess less than  $-2$  indicates an acid excess. A base excess greater than  $+2$  indicates an acid deficit.

The  $\text{PaO}_2$  level reflects the partial pressure of oxygen in arterial blood (Table 9.9). The normal range is 80 to 95 mm Hg. A  $\text{PaO}_2$  level less than 80 mm Hg indicates hypoxemia. The  $\text{SaO}_2$  level reflects hemoglobin's oxygen-carrying capacity. A normal value is anything greater than 95%. This value is not used to evaluate acid-base balance.

**Table 9.9 Normal Arterial Blood Gas Values**

ABG Value	Normal Range
<i>pH</i>	7.35–7.45
<i>PaCO<sub>2</sub></i>	35–45 mm Hg
<i>HCO<sub>3</sub><sup>-</sup></i>	22–26 mEq/L
<b>Base excess</b>	$-2$ to $+2$
<i>PaO<sub>2</sub></i>	80–95 mm Hg
<i>SaO<sub>2</sub></i>	$>95\%$

## Steps for Interpreting Arterial Blood Gas

Step 1: Review the pH result. Is it normal (7.35–7.45), acidosis ( $<7.35$ ), or alkalosis ( $>7.45$ )?

Step 2: Review the  $\text{PaCO}_2$  result. Is it normal (35–45 mm Hg), acidosis ( $>45$  mm Hg), or alkalosis ( $<35$  mm Hg)?

Step 3: Review the  $\text{HCO}_3^-$  result. Is it normal (22–26 mEq/L), acidosis ( $<22$  mEq/L), or alkalosis ( $>26$  mEq/L; Tables 9.10 and 9.11)?

Step 4: Match either the  $\text{PaCO}_2$  or  $\text{HCO}_3^-$  result with the pH result to determine the cause of the acid-base imbalance.

Step 5: Does either the  $\text{PaCO}_2$  or  $\text{HCO}_3^-$  go in the opposite direction of the pH? This result indicates compensation by that system.

Step 6: Review the  $\text{PaO}_2$  and  $\text{SaO}_2$  results. If they are below normal limits, then the patient is hypoxic.

**Safety Alert** It is important to interpret blood gases as part of the complete patient assessment, which includes pertinent details such as past medical history, presenting complaint, and current patient status. Abnormal values need to be addressed quickly with the assistance of the health-care team in order to establish a plan of care for the patient.

**Table 9.10 Example of Blood Gas Results—Uncompensated Respiratory Acidosis**

Blood Gas 1 Results	Interpretation
pH: 7.30	Acidosis
$\text{PaCO}_2$ : 55 mm Hg	Acidosis
$\text{HCO}_3^-$ : 25 mEq/L	Normal
$\text{PaO}_2$ : 85 mm Hg	Normal
$\text{SaO}_2$ : 96%	Normal

**Table 9.11 Example of Blood Gas Results—Uncompensated Metabolic Alkalosis**

Blood Gas 2 Results	Interpretation
pH: 7.48	Alkalosis
$\text{PaCO}_2$ : 41 mm Hg	Normal
$\text{HCO}_3^-$ : 28 mEq/L	Alkalosis
$\text{PaO}_2$ : 86 mm Hg	Normal
$\text{SaO}_2$ : 95%	Normal

**Connection Check 9.4**

Which acid-base imbalance should be suspected with these ABG results?

pH: 7.47

PaCO<sub>2</sub>: 31 mm Hg

HCO<sub>3</sub><sup>-</sup>: 24 mEq/L

- A. Respiratory acidosis
- B. Respiratory alkalosis
- C. Metabolic acidosis
- D. Metabolic alkalosis

**Connection Check 9.5**

When the body is in a state of alkalosis, what is the role of the renal buffers?

- A. ↑ Excretion of water
- B. ↓ Excretion of water
- C. ↑ Excretion of HCO<sub>3</sub><sup>-</sup>
- D. ↓ Excretion of HCO<sub>3</sub><sup>-</sup>

**CASE STUDY: EPISODE 2**

Cory presents to the emergency department with the following vital signs: afebrile, BP 100/62, respiratory rate (RR) 8, pH 7.30, PaO<sub>2</sub> 80 mm Hg, PaCO<sub>2</sub> 65 mm Hg, HCO<sub>3</sub><sup>-</sup> 24 mEq/L, blood alcohol level 0.24%. The clinical presentation upon arrival to the emergency department includes decreased responsiveness and respiratory distress. An emergent chest x-ray indicates a right-sided pneumothorax. Cory's treatment plan includes chest tube insertion for pneumothorax and artificial airway insertion for respiratory distress...

**ACID-BASE DISORDERS**

An individual's acid-base balance is essential to life. The two major categories of acid-base imbalances are acidosis and alkalosis. They are further classified according to respiratory and metabolic origin and degree of compensation. A thorough patient assessment, including ABG analysis, is vital for determining the type of imbalance and the treatment modality.

**Respiratory Acidosis**

Respiratory acidosis is the primary acid-base imbalance, resulting from altered ventilation leading to CO<sub>2</sub> retention. Characterized by a low pH and elevated CO<sub>2</sub> levels due to alveolar hypoventilation, respiratory acidosis may be acute or chronic, as in the case of COPD. The body attempts to

compensate by renal absorption of HCO<sub>3</sub><sup>-</sup>. Box 9.2 lists the causes of respiratory acidosis, which are associated with suppressed ventilation leading to CO<sub>2</sub> retention. Box 9.3 presents the clinical manifestations of respiratory acidosis.

**Arterial Blood Gas Results**

The ABG results for respiratory acidosis are pH less than 7.35 and PaCO<sub>2</sub> greater than 45 mm Hg. With metabolic compensation, then the HCO<sub>3</sub><sup>-</sup> is greater than 26 mEq/L.

**Treatment**

When the underlying cause is respiratory, the correction or improvement in ventilation is to lower the PaCO<sub>2</sub>. When the underlying cause is nonrespiratory, then correction or improvement of the underlying cause must occur.

**Possible Respiratory Treatments**

- Bronchodilators to open constricted airways
- Supplemental oxygen
- Medications to treat hyperkalemia
- Antibiotics to treat infection
- Chest physiotherapy to remove secretions from the lungs
- Removal of a foreign body from the airway, if indicated
- Chest tube insertion to increase lung expansion or remove drainage
- Intubation to allow mechanical ventilation

*test questions*

**Box 9.2 Causes of Respiratory Acidosis**

- Central nervous system depression (head trauma; oversedation, anesthesia, high spinal cord injury)
- Pneumothorax
- Hypoventilation
- Bronchial obstruction and atelectasis
- Severe pulmonary infections
- Heart failure with pulmonary edema (congestive heart failure)
- Massive pulmonary embolus
- Myasthenia gravis
- Multiple sclerosis

*test questions*

**Box 9.3 Clinical Manifestations of Respiratory Acidosis**

- Dyspnea
- Restlessness
- Headache
- Tachycardia
- Confusion
- Lethargy
- Dysrhythmias
- Respiratory distress
- Drowsiness
- Decreased responsiveness

### Possible Nonrespiratory Treatments

- Reversal of sedation to awaken the patient and increase the rate and depth of respirations
- Heart failure treatment such as diuretics to decrease fluid in the lungs

### Nursing Management

Before a nursing diagnosis or intervention can occur, the nurse must obtain a comprehensive patient history, identify health problems associated with respiratory acidosis, check for clinical manifestations of respiratory acidosis, obtain vital signs for a baseline comparison with future vital signs, and assess ABG values, particularly the pH and PaCO<sub>2</sub>.

### Nursing Diagnoses

- **Impaired gas exchange** related to alveolar hypoventilation from underlying disease process
- **Acute confusion** related to disturbance in acid-base regulation
- **Impaired oral mucous membrane** related to abnormal breathing pattern
- **Disturbed sleep pattern** related to frequent treatments and procedures
- **Ineffective family coping** related to stress reaction from family member's illness

### Nursing Interventions

Nursing interventions for patients with respiratory acidosis include maintaining the patient's airway; monitoring ABG levels; monitoring vital signs, especially respiratory rate and depth; administration of supplemental oxygen; assisting with intubation if necessary; monitoring potassium levels; administration of sedatives cautiously; and providing patient reassurance and teaching as needed.

### Complications

Respiratory acidosis results from altered ventilation leading to CO<sub>2</sub> retention. In response to prolonged increased CO<sub>2</sub> levels, paralysis and coma may result from cerebral vasodilation.

### Respiratory Alkalosis

Respiratory alkalosis is an acid-base imbalance caused by an increase in the rate of alveolar ventilation. Acute alveolar hyperventilation is frequently the result of anxiety and is commonly referred to as *hyperventilation syndrome*. Hyperventilation decreases serum CO<sub>2</sub> in the lungs and blood because CO<sub>2</sub> is eliminated by the increased rate of respirations. A decreased CO<sub>2</sub> concentration decreases the levels of carbonic acid and hydrogen ions circulating in the blood, therefore raising the arterial pH levels. The body tries to restore the pH to normal levels through renal compensation; in this process, renal excretion of bicarbonate is increased. Respiratory alkalosis may be acute, resulting from hyperventilation, or chronic, which can be difficult to identify because of the renal compensation. Patients in the early stage of pulmonary edema may present with a respiratory

alkalosis due to the increased respiratory rate secondary to anxiety and hyperventilation associated with attempts to increase oxygenation. Causes of respiratory alkalosis are listed in Box 9.4 and are associated with increased ventilation leading to excessive CO<sub>2</sub> excretion. Box 9.5 provides an overview of the clinical manifestations of respiratory alkalosis.

### Arterial Blood Gas Results

Arterial blood gas results for respiratory alkalosis are pH greater than 7.45 and PaCO<sub>2</sub> less than 35 mm Hg. With metabolic compensation, the HCO<sub>3</sub><sup>-</sup> is less than 22 mEq/L.

### Treatment

Several measures are indicated to correct the underlying cause:

- Discontinuation and possible removal of the causative agent (such as salicylates or other medications)
- Steps to reduce fever, including cooling measures and antibiotic therapy if the elevated temperature is secondary to an infectious process

## \* test questions

### Box 9.4 Causes of Respiratory Alkalosis

- Anxiety and nervousness
- Fear and pain
- Fever and gram-negative septicemia
- Hyperventilation
- Lung conditions such as pneumonia, pulmonary embolisms
- Thyrotoxicosis
- Central nervous system lesions
- Salicylate intoxication/overdose
- Hepatic failure
- Pregnancy
- Early pulmonary edema

## \* test questions

### Box 9.5 Clinical Manifestations of Respiratory Alkalosis

- Hyperventilation
- Light-headedness
- Confusion
- Decreased concentration
- Paresthesias
- Tetanic spasms in the extremities
- Cardiac dysrhythmias
- Palpitations
- Sweating
- Dry mouth
- Blurred vision

- Elimination of the source of sepsis by identifying the source
- Oxygen therapy to treat acute hypoxemia
- Sedative or anxiolytic therapy to treat anxiety
- Diuretics to treat pulmonary edema

Further measures taken to counteract hyperventilation include:

- Teaching the patient to breathe into a paper bag or cupped hands, which leads to “rebreathing” of exhaled carbon dioxide
- For intubated patients: adjusting mechanical ventilator settings as needed by decreasing the tidal volume (volume delivered with each mechanical breath) or rate (number of breaths per minutes)

### Nursing Management

Before a nursing diagnosis or intervention can be developed, the nurse must obtain a patient history of clinical problems, identify health problems associated with respiratory alkalosis, assess clinical manifestations of respiratory alkalosis, obtain vital signs for a baseline comparison with future vital signs, and assess ABG results, particularly the pH and PaCO<sub>2</sub>.

### Nursing Diagnoses

- **Ineffective breathing pattern** related to hyperventilation secondary to anxiety
- **Anxiety** related to difficult situation
- **Risk for falls** related to light-headedness, confusion, and blurred vision

### Nursing Interventions

Key nursing interventions for patients with respiratory alkalosis include assisting in achieving the goal of reducing the ventilation rate by encouraging slow, deep breathing; monitoring vital signs; providing emotional support and reassurance to the patient to reduce anxiety; assisting the patient with activities of daily living; and providing teaching as needed.

### Complications

Respiratory alkalosis results from an increase in the rate of alveolar ventilation. Hyperventilation decreases serum CO<sub>2</sub> in the lungs and blood as CO<sub>2</sub> is eliminated by the excess respirations. Complications of respiratory alkalosis include seizures related to decreased oxygen-carrying capacity to cerebral cells and chest pain from cardiac and noncardiac causes related to anxiety and hyperventilation.

### Metabolic Acidosis

Metabolic acidosis is an acid-base imbalance caused by an increased accumulation of metabolic acids that rise in proportion to a decrease in bicarbonate and result in decreased arterial pH. The decrease in serum bicarbonate is caused by one of the following mechanisms:

- Increase in the concentration of hydrogen ions in the form of nonvolatile acids, for example, ketoacidosis associated with diabetes mellitus or lactic acidosis

- Loss of alkali secondary to severe diarrhea or intestinal malabsorption
- Decreased acid excretion by the kidneys in acute or chronic renal failure

The decrease in arterial pH stimulates respirations. The body’s attempt to compensate occurs rapidly and may reduce the PaCO<sub>2</sub> levels by as much as 10 to 15 mm Hg. The most important mechanism for ridding the body of excess hydrogen ions (H<sup>+</sup>) is the increase in acid excretion by the kidneys. However, nonvolatile acids may accumulate more rapidly than they can be neutralized by the body’s buffers. Another way to decrease excess hydrogen ions is for a cellular exchange to occur. The intracellular potassium is pumped outside the cell in exchange for the excess extracellular hydrogen ions. This increases the serum potassium levels while the intracellular potassium levels decrease, resulting in hyperkalemia. In Box 9.6, the causes of metabolic acidosis are listed. Box 9.7 lists the clinical manifestations of metabolic acidosis.

**Safety Alert** In patients with metabolic acidosis related to hyperglycemia, potassium is moved outside the cell in exchange for hydrogen ions and may be excreted due to the osmotic diuresis associated with diabetic ketoacidosis. As the elevated blood glucose levels are normalized and acidosis resolves, potassium moves back into the cells, and the patient must be monitored for hypokalemia.

### Arterial Blood Gas Results

Arterial blood gas results for metabolic acidosis are pH less than 7.35 and HCO<sub>3</sub><sup>-</sup> less than 22 mEq/L. With respiratory compensation, the PaCO<sub>2</sub> is less than 35 mm Hg.

### Treatment

Metabolic acidosis treatment depends on the underlying cause. Sodium bicarbonate replacement administered intravenously neutralizes blood acidity in patients with a pH lower than 7.1. As needed to maintain fluid balance,

## Box 9.6 Causes of Metabolic Acidosis

### Accumulation of Acid

- Renal failure
- Ketoacidosis
- Anaerobic metabolism
- Starvation
- Salicylate intoxication

### Loss of Base

- Diarrhea
- Intestinal fistulas

## Box 9.7 Clinical Manifestations of Metabolic Acidosis

- Headache
- Confusion
- Restlessness
- Lethargy
- Weakness
- Stupor/coma
- Kussmaul respirations
- Nausea and vomiting
- Dysrhythmias
- Warm, flushed skin
- Seizures
- Twitching
- Peripheral vasodilation

parenteral fluid replacement may be used. Rapid-acting insulin may be needed for patients with diabetes mellitus in order to reverse diabetic ketoacidosis and drive potassium back into the cells. Antidiarrheals may be used to treat diarrhea-induced bicarbonate loss. Dialysis may be needed for patients with renal failure or for metabolic acidosis caused by a toxic reaction to a medication. Lastly, mechanical ventilation may be initiated to assist respiratory compensation.

### Nursing Management

Before a nursing diagnosis or intervention can occur, the nurse must obtain a patient history of clinical problems and identify health problems associated with metabolic acidosis, such as starvation, severe or chronic diarrhea, diabetic ketoacidosis, trauma and shock, and renal failure. Interventions include assessing the arterial bicarbonate, base excess, and serum CO<sub>2</sub> levels for metabolic acid-base imbalances, obtaining baseline vital signs for comparison with future vital signs, and checking laboratory results, especially blood glucose and serum electrolytes.

### Nursing Diagnoses

- **Decreased cardiac output** related to severe metabolic acidotic state
- **Deficient fluid volume** related to nausea, vomiting, and increased urine output
- **Imbalanced nutrition, less than body requirements**, related to the body's inability to use nutrition
- **Acute confusion** related to the disturbance in acid-base regulation
- **Impaired oral mucous membranes** related to the increase in insensible fluid loss secondary to hyperventilation
- **Disturbed sleep pattern** related to frequent treatments and procedures
- **Ineffective family coping** related to the stress reaction

### Nursing Interventions

Key nursing interventions for patients with metabolic acidosis are specific to the underlying cause and include

monitoring hemodynamic status through BP, pulse rate, respirations, and cardiac rhythm and assessing peripheral vascular status. Cautious administration of sodium bicarbonate may be indicated, along with providing patient reassurance and teaching as needed.

### Complications

Metabolic acidosis results from an increased accumulation of metabolic acids that rise in proportion to bicarbonate and leads to a decreased arterial pH. If the pH falls below 7.0, cardiac dysrhythmia can occur. This happens as a result of changes in cardiac conduction, which occur in direct response to a decrease in pH and because of the effects of increased hydrogen ion concentration on plasma and intracellular potassium levels. If metabolic acidosis is caused by chronic renal failure, complications may include renal osteodystrophy (bone disease) and renal encephalopathy.

### Metabolic Alkalosis

Metabolic alkalosis is an acid-base imbalance caused by an increased loss of acid. Most instances of this increased loss of acid are through the gastrointestinal tract, usually via vomiting or nasogastric suctioning, or through renal excretion. The loss in metabolic acid causes an increase in the arterial pH level, which in turn results in a reduction in the hydrogen ion concentration. The body's attempt to compensate occurs by creating a state of hypoventilation, which works to conserve PaCO<sub>2</sub> levels. Additionally, in order to increase serum hydrogen ion levels, serum potassium is pumped into the cell in exchange for the serum hydrogen ions. This decreases the serum potassium levels while the intracellular potassium levels increase, resulting in hypokalemia. In Box 9.8, the causes of metabolic alkalosis are listed. Box 9.9 lists the clinical manifestations of metabolic alkalosis.

### Arterial Blood Gas Results

Arterial blood gas results for metabolic alkalosis are pH greater than 7.45 and HCO<sub>3</sub><sup>-</sup> greater than 26 mEq/L. With respiratory compensation, the PaCO<sub>2</sub> is greater than 45 mm Hg.

### Treatment

Metabolic alkalosis treatment depends on the underlying cause. Discontinuation of potassium-wasting diuretics and nasogastric suctioning may be necessary. Patients may be administered an antiemetic to treat underlying nausea and vomiting. Lastly, in order to increase renal excretion of bicarbonate, medications such as acetazolamide are administered if the patient is not volume compromised or hypokalemic.

### Nursing Management

As with other acid-base imbalances, before nursing diagnosis or interventions can be proposed, the nurse must obtain a patient history and identify health problems associated with metabolic alkalosis, such as vomiting, gastric suction, and peptic ulcer disease. Additional interventions include assessing the arterial bicarbonate, base excess, and serum

## Box 9.8 Causes of Metabolic Alkalosis

### Accumulation of base

- Excess use of bicarbonate
- Lactate administration in dialysis
- Excess ingestion of antacids

### Loss of acids

- Vomiting
- Nasogastric suctioning
- Hypokalemia
- Hypochloremia
- Administration of diuretics
- Increased levels of aldosterone

## Box 9.9 Clinical Manifestations of Metabolic Alkalosis

- Muscle twitching and cramps
- Tetany
- Dizziness
- Lethargy
- Weakness
- Disorientation
- Convulsions
- Coma
- Nausea and vomiting
- Depressed respirations

CO<sub>2</sub> levels for metabolic acid-base imbalances, obtaining baseline vital signs for comparison with future vital signs, and checking laboratory results, especially blood glucose and serum electrolytes.

### Nursing Diagnoses

- **Decreased cardiac output** related to electrolyte imbalances from metabolic alkalosis induced by gastric suctioning or potassium-wasting diuretics
- **Acute confusion** related to the disturbance in acid-base regulation
- **Ineffective family coping** related to stress or the diagnosis

### Nursing Interventions

Key nursing interventions for patients with metabolic alkalosis are specific to the underlying cause but include monitoring hemodynamic status through respirations, pulse rate, and cardiac rhythm and assessing the patient's level of consciousness. Additional interventions include administering IV fluid (see Evidence-Based Practice) and electrolyte supplements as prescribed and providing patient reassurance and teaching as needed.

## Evidence-Based Practice

### 0.9% Saline Infusions

Patients in acute care settings who receive 0.9% saline infusions are at greater risk of developing a hyperchloremic acidosis. Fluid resuscitation with 0.9% saline dilutes serum bicarbonate through plasma volume replacement with nonbicarbonate fluids. This evidence-based literature review included studies that related to potential complications associated with the use of 0.9% saline solutions in comparison to the infusion of lactated Ringer's or Plasma-Lyte. On the basis of the findings of this study, fluid replacement is better accomplished with chloride-restricted PlasmaLyte because of decreased acid-base disturbances.

Barker, M. E. (2015). 0.9% saline induced hyperchloremic acidosis. *Journal of Trauma Nursing*, 22(2), 111–116.

### Complications

Metabolic alkalosis results from an increased loss of acid. The loss in metabolic acid causes an increase in the arterial pH level, which in turn results in a reduction of the hydrogen ion concentration. With a pH greater than 7.55, dysrhythmias and a coma may result from alterations in the depolarization of neuronal and cardiac muscle cells.

### Connection Check 9.6

A patient has been diagnosed with an intestinal obstruction. The nurse inserts a nasogastric tube and attaches the tube to low intermittent suction. For which acid-base imbalance is the patient at greatest risk?

- Respiratory acidosis
- Respiratory alkalosis
- Metabolic acidosis
- Metabolic alkalosis

### Connection Check 9.7

The patient's ABG results indicate worsening respiratory acidosis. He has rapid, shallow breaths and decreased bilateral breath sounds. Which intervention should be the nurse's first priority?

- Administer an antibiotic for suspected pneumonia.
- Administer diuretics for heart failure.
- Encourage the patient to breathe into a brown paper bag.
- Prepare the patient for intubation and mechanical ventilation.

## Making Connections

### CASE STUDY: WRAP-UP

Cory Nelson, 21 years old, presents via ambulance to the emergency department after a motor vehicle accident (MVA). When the car he was a passenger in struck a tree, Cory was wearing his seat belt. He sustained chest trauma due to the impact and has facial lacerations. The paramedic at the scene noted that Cory had alcohol present on his breath and slurred speech when questioned. Cory's vital signs in the emergency department are as follows:

Afebrile, BP 100/62 mm Hg, RR 8

Arterial blood gases are pH 7.30, PaO<sub>2</sub> 80 mm Hg, PaCO<sub>2</sub> 65 mm Hg, HCO<sub>3</sub><sup>-</sup> 24 mEq/L; and a blood alcohol level 0.24%

The patient's clinical presentation upon arrival to the emergency department includes a decreased level of consciousness, facial lacerations, and respiratory distress. An emergent chest x-ray reveals a right-sided pneumothorax. Cory undergoes oral intubation and is placed on a mechanical ventilator. A right-sided chest tube is inserted, and he is placed on continuous pain medication via infusion. An orogastric tube (OGT) is placed to provide gastric decompression as needed.

On day 2, the right-sided pneumothorax is resolving, and his respiratory status has stabilized. He is extubated and placed on oxygen 40% via face mask.

#### Case Study Questions

- The clinical team immediately creates a plan for the patient on the basis of Cory's ABG results and current patient assessment. Cory is being treated for which acid-base disorder?
  - Metabolic acidosis
  - Metabolic alkalosis
  - Respiratory acidosis
  - Respiratory alkalosis
- Cory's treatment plan includes chest tube insertion for pneumothorax and artificial airway insertion for respiratory distress. The clinical team also places immediate nursing orders for which of the following? (*Select all that apply.*)
  - OGT insertion
  - Electrocardiogram (ECG) monitoring
  - Fleet enema
  - Repeated ABGs
  - Physical therapy and occupational therapy consults
- Cory begins to regain consciousness and is extremely agitated. The clinical team wants to evaluate his neurological status before starting sedation to calm Cory. What nursing interventions should be used to calm Cory?
  - Restrain Cory's wrists.
  - Speak calmly with Cory when he is agitated.
  - Remove Cory's parents from the room.
  - Maintain a well-lit environment.

- What is the highest-priority nursing diagnosis during the emergency phase of Cory's hospital course?
  - Impaired oral mucous membrane related to abnormal breathing pattern
  - Disturbed sleep pattern related to frequent treatments and procedures
  - Ineffective family coping related to stress reaction
  - Impaired gas exchange related to trauma and agitation
- Cory successfully passes the neurological examination and is provided sedation. He is transferred to the ICU, where the new graduate nurse is having a difficult time managing Cory's nursing priorities. What are the top priorities that the new graduate nurse's preceptor emphasizes? (*Select all that apply.*)
  - Provide patient and family teaching.
  - Monitor vital signs.
  - Monitor ABG levels.
  - Monitor orogastric secretions.
  - Maintain patient's artificial airway.

## CHAPTER SUMMARY

Acid-base balance refers to the homeostasis of the hydrogen ion concentration in body fluids and is expressed as the body's pH level. The normal arterial blood pH range is 7.35 to 7.45. Acids are known as hydrogen ion donors and have a pH less than 7.35. Bases are known as hydrogen ion acceptors and have a pH greater than 7.45

An arterial blood gas (ABG) describes the set of values that permit the assessment of an individual's ability to maintain normal cell function. There are six parameters included in an ABG measurement: pH, PaCO<sub>2</sub>, HCO<sub>3</sub><sup>-</sup>, base excess, PaO<sub>2</sub>, and SaO<sub>2</sub>.

The two major categories of acid-base imbalances are acidosis and alkalosis. The categories are further classified according to respiratory and metabolic origin and levels of compensation. Nursing considerations related to patients with acid-base disorders are individualized and based on the imbalance origin and mode of compensation.

To maintain the pH of the extracellular fluid within the narrow range, the body has three regulating mechanisms: chemical buffers, respiratory buffers, and renal buffers. Compensation is the physiologic response to an acid-base imbalance in an attempt to normalize pH. If the imbalance is of respiratory origin, then the kidneys work to correct. If the imbalance is of renal origin, then the lungs work to correct. Arterial blood gases are further defined by their degree

of compensation and can be uncompensated, partially compensated, or fully compensated.

Respiratory acidosis is the primary acid-base imbalance resulting from altered ventilation leading to  $\text{CO}_2$  retention. Arterial blood gas results for respiratory acidosis are pH less than 7.35 and  $\text{PaCO}_2$  greater than 45 mm Hg. If compensated, then the  $\text{HCO}_3^-$  is greater than 26 mEq/L.

Respiratory alkalosis is an acid-base imbalance caused by an increase in the rate of alveolar ventilation. Arterial blood gas results for respiratory alkalosis are pH greater than 7.45 and  $\text{PaCO}_2$  less than 35 mm Hg. If compensated, then the  $\text{HCO}_3^-$  is less than 22 mEq/L.

Metabolic acidosis is an acid-base imbalance caused by an increased accumulation of metabolic acids that rise in proportion to bicarbonate and result in decreased arterial pH. Arterial blood gas results for metabolic acidosis are pH less than 7.35 and  $\text{HCO}_3^-$  less than 22 mEq/L. If compensated, then the  $\text{PaCO}_2$  is less than 35 mm Hg.

Metabolic alkalosis is an acid-base imbalance caused by an increased loss of acid. Most instances of this increased loss of acid are from the stomach or the kidneys. Arterial blood gas results for metabolic alkalosis are pH greater than 7.45 and  $\text{HCO}_3^-$  greater than 26 mEq/L. If compensated, then the  $\text{PaCO}_2$  is greater than 45 mm Hg.

# Chapter 10

## Overview of Infusion Therapies

*Gladdi Tomlinson*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Discussing reasons patients require infusion therapy
2. Describing the characteristics of common IV solutions
3. Comparing peripheral and central venous access, including indications, access devices, and potential complications
4. Describing the equipment used to provide infusion therapy
5. Describing the potential complications of infusion therapy and strategies to prevent these complications
6. Explaining the procedure for safely administering blood products
7. Describing the special precautions required to safely administer parenteral nutrition
8. Developing a teaching plan for a patient receiving infusion therapy

### CONCEPTS

- Assessment
- Fluid and Electrolyte Balance
- Medication
- Nutrition
- Skin Integrity

### ESSENTIAL TERMS

Air embolism  
Bolus  
Central venous access (CVA)  
Central venous access device (CVAD)  
Central venous catheter (CVC)  
Colloidal solutions  
Crystalloid solutions  
Electronic infusion device  
Euvolemic  
Extravasation  
Flushing  
Flushing and locking protocol  
Hemolytic transfusion reaction  
Implanted port  
Incompatibility  
Infiltration  
Intraosseous  
Intravenous access device (IVAD)  
Keep vein open (KVO)  
Locking  
Midline catheter  
Nonthrombotic  
Normovolemic  
Occlusion  
Osmolarity  
Peak and trough levels  
Peripheral venous access  
Peripherally inserted central catheter (PICC)  
pH  
Phlebitis  
Priming  
Vesicant

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Jason Blair is a 21-year-old male who was involved in a motor vehicle accident and arrives in the emergency department with abdominal and lower extremity injuries. Upon arrival, he is tachycardic and hypotensive. He has one peripheral IV in his left forearm that is infusing 0.9% normal saline at 200 mL/hr. The emergency department provider and general surgeon are evaluating his injuries. Jason is a well-conditioned professional hockey player in excellent health...

## INTRODUCTION

In today's healthcare environment, infusion therapy is delivered to patients across the continuum of care. Patients receive infusion therapy in hospitals, extended care facilities, outpatient clinics, infusion centers, and their own homes. Infusion therapy is undergoing rapid advancements as new evidence is constantly emerging to improve outcomes through improved techniques, equipment, and technologies. Research demonstrates that specialized "IV resource teams" result in better patient outcomes and reduced costs. However, generalist nurses in all practice settings are involved in the provision of infusion therapy and need to be knowledgeable in the most current evidence related to infusion therapy and competent in the care they provide to their patients.

The Infusion Nurses Society (INS) is a national organization that has established evidence-based practice standards of care to guide the delivery of infusion therapy. The standards were last revised in 2016 and are based on ranked evidence. A professional organization, the Infusion Nurses Certification Corporation, offers a national certification program that recognizes the expertise of nurses specializing in infusion therapy. The designation of Certified Registered Nurse of Infusion (CRNI®) is awarded after successfully passing a rigorous examination and completing the required hours of practice in infusion therapy.

Patients require infusion therapy for a variety of reasons, including fluid and electrolyte replacement, medication administration, blood product administration, and nutritional support. The duration of infusion therapy may be brief periods of hours or days to months or long-term therapy required for a lifetime.

Administration of IV fluids is initiated to both maintain and restore fluid and electrolyte balance when it is not possible to maintain this balance with the oral intake of fluids. To maintain fluid balance, adequate amounts of fluid need to be administered to account for sensible and insensible

fluid losses. Fluid and electrolyte replacement may also be required because of losses related to hemorrhage, surgery, burns, vomiting, or diarrhea. IV administration of medications is indicated when the oral or other routes are not available or appropriate. Certain medications are administered only by the IV route because of their pharmacological composition or because of the need to be given intravenously to attain higher blood levels or faster action. When the gastrointestinal tract is unable to absorb sufficient amounts of nutrients, the IV route can be utilized. Solutions containing protein, lipids, and high concentrations of dextrose can provide the calories and nutrition needed to sustain life.

Blood products can be administered only intravenously and include packed red blood cells (RBCs), platelets, plasma, albumin, and clotting factors. They may be needed in acute situations or to correct deficits related to chronic conditions and require special precautions to ensure patient safety; they are presented later in the chapter.

### Connection Check 10.1

The nurse recognizes that which patient may need infusion therapy? (Select all that apply.)

- A. Patient who sustained trauma presenting to the emergency department
- B. Patient with osteomyelitis receiving IV antibiotics at home
- C. High school teacher during an annual health appraisal
- D. Patient with cancer receiving parenteral chemotherapy
- E. Patient with multiple sclerosis in remission

## SOLUTIONS USED IN INFUSION THERAPY

Infusion therapy requires the specific IV fluid order by a licensed healthcare provider. The order needs to include the solution to be administered, any additives to the solution, and either the rate of infusion or the total dose or volume to be infused over a specific time frame.

The two major types of IV solutions are crystalloid solutions and colloidal solutions. **Crystalloid solutions** are composed of electrolytes dissolved in water and include dextrose solutions, sodium chloride solutions, balanced electrolyte solutions, and alkalizing and acidifying solutions. **Colloidal solutions** are composed of larger molecules, usually protein or starch, suspended in fluid and are not a true solution. Colloidal solutions are frequently referred to as *plasma volume expanders* because the larger molecules do not diffuse through cell membranes and draw fluid into the intravascular space. Colloidal solutions are used to maintain intravascular volume and prevent shock after major blood or fluid losses. Examples of colloidal solutions include albumin, dextran, and mannitol.

An important characteristic of IV solutions is **osmolarity**, a measure of the concentration of the solution that is expressed in terms of the number of particles (osmoles) per liter of solution. The concentration of the solution influences how water moves between the intracellular and extracellular compartments of the body. Normal blood and body solutions have a calculated osmolarity 270 to 300 mOsm/L. Solutions can be isotonic, hypotonic, or hypertonic (Table 10.1).

**Isotonic solutions** (Fig. 10.1A) have the same or nearly the same osmolarity as plasma and cause no movement of fluid into or out of cells. Isotonic solutions remain in the extracellular compartment in either the intravascular or interstitial compartments. The osmolarity of plasma varies from 270 to 300 mOsm/L, and solutions are considered to be isotonic if their osmolarity is between 250 and 375 mOsm/L. Isotonic solutions are administered to dehydrated patients with deficits in intravascular volume because they increase the amount of fluid circulating in the vascular system without causing movement of fluid in and out of cells.

**Hypotonic solutions** (Fig. 10.1B) have a lower solution concentration than plasma and cause fluid to move from the intravascular space into both the intracellular and interstitial spaces. Administration of hypotonic solutions hydrates cells but results in depletion of intravascular fluid volume. Hypotonic solutions are used in the management of hypernatremia, hyperosmolar conditions, hypertonic dehydration, and diabetic ketoacidosis after initial sodium chloride replacement. **Extreme caution** needs to be exercised when solutions that are not isotonic are administered because of resulting fluid shifts, and they should be administered only for brief periods.

**Hypertonic solutions** (Fig. 10.1C) have concentrations higher than plasma and cause fluid to move from the cells

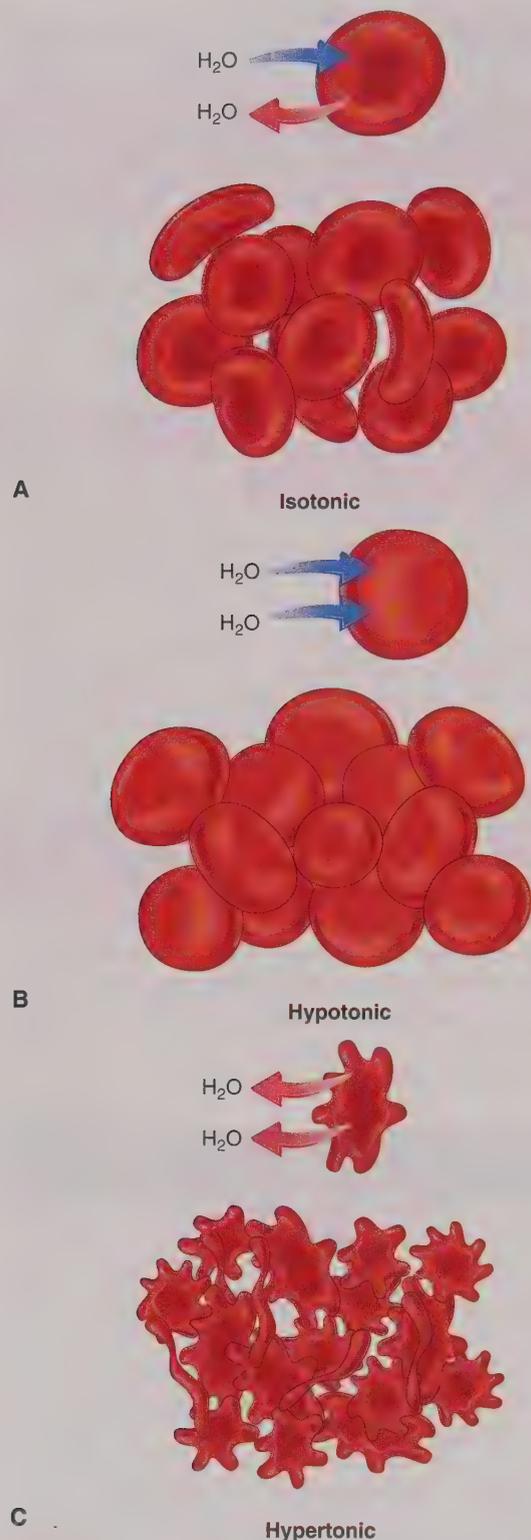

into the intravascular space. Because of the danger of circulatory overload, these solutions are given only in critical situations. Solutions with a concentration greater than 600 mOsm/L should be administered only via **central venous access (CVA)**, commonly referred to as a central line, where there is adequate blood flow to dilute the solution and prevent damage to the vein as the hypertonic solution infuses.

When administering any IV solution, the nurse needs to carefully monitor the fluid status of the patient regardless of the osmolarity of the solution being administered. This assessment includes respiratory status, vital signs, and skin turgor. Older adults and patients with compromised cardiovascular or renal function require even greater vigilance because of the risk of fluid overload.

The **pH** is a measure of the concentration of hydrogen ions in a solution and indicates the acidity or alkalinity of the solution. Most IV solutions are slightly acidic, which increases their stability and shelf life. Medications with a pH of less than 7 are acidic; those with a pH of greater than 7 are basic, or alkaline. Fluids or medications with a pH value of less than 5 or greater than 9 should be administered through a central line to avoid damage to the vein. (Acid-base disorders are discussed in more detail in Chapter 9.) The wrong diluent or incompatible solutions can alter the pH of a medication. Acidic medications are irritating to the walls of the vessels and can cause chemical **phlebitis**, which is irritation of the vein wall caused by the medication. Antibiotics are also a significant cause of phlebitis because of their low pH. Nurses need to be attentive to continually assessing peripheral IV sites where antibiotics are infusing to assess for signs of warmth and tenderness that may indicate phlebitis.

**Table 10.1 Osmolarity of Intravenous Solutions**

Isotonic	Hypotonic	Hypertonic
250–375 mOsm/L	Less than 250 mOsm/L	Greater than 375 mOsm/L

<ul style="list-style-type: none"> <li>● Fluid deficits</li> <li>● Dehydration</li> <li>● Fluid challenges</li> </ul>	<ul style="list-style-type: none"> <li>● Diabetic ketoacidosis</li> <li>● Hyperosmolar hyperglycemia</li> <li>● Hypertonic dehydration</li> </ul>	<ul style="list-style-type: none"> <li>● Severe dehydration</li> <li>● Severe electrolyte imbalance</li> <li>● Hypotonic dehydration</li> </ul>

**FIGURE 10.1** Effects of osmolality on fluid movement. **A**, Isotonic. The osmolality is the same in both the intracellular fluid (ICF) and extracellular fluid (ECF). There is typically no movement of fluid from cells when an isotonic solution is administered. If there is movement, it is equal between the two compartments due to the same osmolality. **B**, Hypotonic. With the administration of hypotonic solutions, fluid moves from the intravascular space into the intracellular space. **C**, Hypertonic. With the administration of hypertonic solutions, fluids move from the cells into the intravascular space.

The use of the wrong diluents can also alter the pH of a medication, and incompatible solutions can greatly affect the medication's pH. **Incompatibility** is an undesirable reaction occurring between two medications or a medication and its diluent. There are three main types of medication incompatibility. Physical incompatibility is the reaction that causes a visible change. This change may be in the form of color, cloudiness, haziness, turbidity, the formation of precipitate, and even the formation of gas. Precipitate formation is the most common physical incompatibility. Calcium in medication or solution increases the risk for precipitate. Ringer's solution is an example of a solution with calcium. The second type is chemical incompatibility, which correlates to the breakdown of the medication. This reaction will most likely not be visible. The most common reaction is the acid-alkaline reaction that results in an unstable pH of one of the medications. The third type of incompatibility is therapeutic incompatibility that causes an increased or decreased therapeutic response. The incompatibility may be undetected until the patient shows no clinical response to the medication. Therapeutic incompatibility may occur with the use of two antibiotics. For example, aminoglycosides may be inactivated when given with penicillins or cephalosporins. Therefore, they must be given in separate sites, 1 hour apart. Also, if the medication requires **peak and trough levels** (measurements of medication levels before and after administration), the levels may show no therapeutic response. Nurses must be vigilant about checking compatibility when giving IV medications, whether it is two medications together or the administration of an IV medication by direct IV or IV piggyback with a primary solution. Compatibility charts are readily available in most facilities, and many healthcare facilities utilize IBM Micromedex® as the standard for checking the compatibility of medications. The pharmacist is also an additional resource for information about medication incompatibility.

### Connection Check 10.2

The nurse anticipates which fluid movement when administering an isotonic IV fluid to a patient?

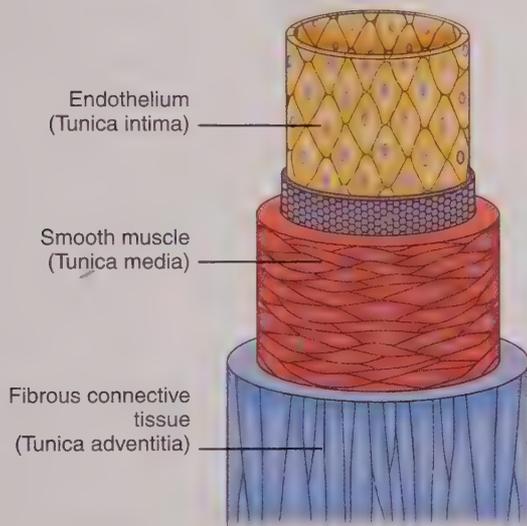

- Causes fluid to move from the cells into the intravascular space
- Causes fluid to move from the intravascular space into the intracellular space
- Causes no or equal movement of fluid into or out of cells
- Causes fluid to move from the intravascular space into the interstitial spaces

### VEINS USED IN INFUSION THERAPY

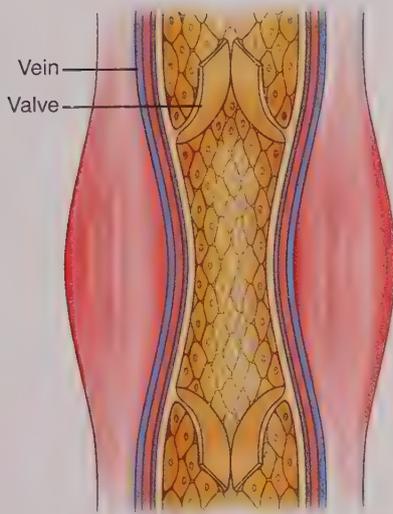

Veins are the low-pressure blood vessels that return deoxygenated blood to the heart. Vein walls consist of three layers: the tunica intima (innermost layer), tunica media

(middle layer), and tunica adventitia (outer layer) (Fig. 10.2A). The innermost layer consists of a single layer of endothelial cells lining the lumen of the vein. The middle layer contains smooth muscles that surround the vein, and the outer layer contains connective fibers that support the vein and nerve endings. Veins contain valves that aid the return of blood to the heart by preventing backflow of blood as veins are compressed by the surrounding skeletal muscles, thus facilitating blood return back to the central circulation.

The diameter of the veins and blood flow within the veins increase as the veins get closer to the heart. Larger veins with greater blood flow are appropriate when infusing larger volumes of fluid and when the osmolality of the solution is high or the pH is outside the normal range. The

B

**FIGURE 10.2** Layers of the vein. *A*, Vein walls consist of three layers: the tunica intima (innermost layer), tunica media (middle layer), and the tunica adventitia (outer layer). *B*, Valves in vein wall.

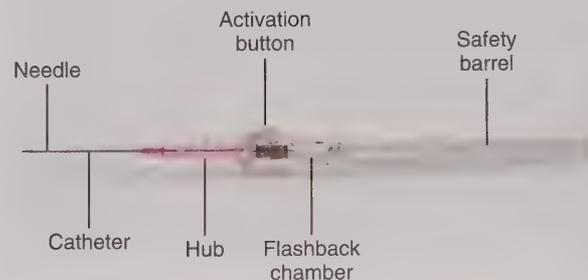

vein also needs to be large enough to accommodate the vascular access device selected while allowing for blood flow around the device. Nurses need to take into consideration patient condition, characteristics of the solution to be infused, volume and rate of the solution to be infused, and type of **intravenous access device (IVAD)** available when planning infusion therapy.

## TYPES OF INTRAVENOUS ACCESS DEVICES

Infusion therapy is divided into two general categories based on the location of the tip of the IVAD, peripheral or central. It is important to understand when peripheral infusion therapy is appropriate and when a CVA is preferred or required. The IVAD should be of the smallest gauge (size) and length with the fewest number of lumens and be the least invasive to provide the ordered infusion therapy.

### Peripheral Venous Access

**Peripheral venous access** describes when the tip of the IVAD terminates outside of the central vasculature in a peripheral vein. The most common type of peripheral IVAD is the short over-the-needle catheter (Fig. 10.3). The flexible catheter is introduced into the vein over a metal needle that is then removed and discarded. The catheters range in length from 1 to 7.5 cm and in size from 14 to 27 gauge. Standardized catheter hub colors are used to identify catheter gauge (Table 10.2). Therapies utilizing a short peripheral catheter should be expected to last less than a week, and indications include hydration and administration of pain medications and some antibiotics (Table 10.3). Another type of IVAD used for peripheral venous access, the steel-winged device (Fig. 10.4), is indicated only for short-term or single-dose therapy because the rigid steel needle is more likely to puncture the vein and lead to fluid or medication leaking out of the vein. This steel-winged device is often referred to as a butterfly because of the appearance of wings on each side of the needle.

**FIGURE 10.3** Over-the-needle peripheral catheter. The flexible catheter is introduced into the vein over a metal needle that is then removed and discarded. The Flashback chamber fills with blood when the vein is accessed, and the activation button progresses the catheter over the needle. The safety chamber protects the needle once the catheter is inserted to prevent inadvertent needle stick.

Gauge	Color
16	Gray
18	Green
20	Pink
22	Blue
24	Yellow

**Table 10.3 Peripheral Catheter Gauge Selections**

Catheter Gauge	Clinical Indications
14, 16, 18	Trauma, surgery, blood transfusion, need for rapid administration of large volumes
20	Continuous or intermittent infusions, blood transfusions
22	Continuous or intermittent infusions in small veins
24	Continuous or intermittent infusions in fragile veins

**FIGURE 10.4** Steel-winged infusion set.

Short-term peripheral IV access is established in the superficial veins of the upper extremity (Fig. 10.5; Box 10.1). It is recommended to start therapy in the most distal available and appropriate vein and move upward with subsequent insertions. Using more distal sites first preserves

**FIGURE 10.5** Veins of the upper extremities.

### Box 10.1 Obtaining Peripheral IV Access

1. Verify the order.
2. Explain the procedure to the patient.
3. Select the needed catheter and equipment on the basis of the prescribed therapy and the patient's age and condition.
4. Wash hands and put on gloves.
5. Apply the tourniquet proximal to the venipuncture site.
6. Select site for venipuncture.
7. Clean the site with an antiseptic agent and allow it to dry completely.
8. Perform venipuncture and obtain positive blood return.
9. Advance catheter into vein.
10. Release tourniquet.
11. Activate the safety release for the needle.
12. Attach primed administration set or extension set.
13. Apply sterile occlusive dressing.
14. Discard used equipment in appropriate containers.
15. Remove gloves and wash hands.
16. Assess patient's tolerance of the procedure and the security of the catheter.
17. Document per institutional policy.

sites less distal for future insertions. Veins selected for short-term infusion therapy should be soft (nonsclerotic), nontender, and not in an area where a previous infusion has infiltrated. Areas of the vein containing a valve should also be avoided. Veins in areas of flexion such as the wrist and antecubital fossa should be avoided if possible because it is more difficult to stabilize the IVAD in these areas. The movement of an IVAD that is not firmly secured can cause mechanical irritation of the vein. Recommended veins for peripheral infusion therapy include the metacarpal, cephalic, basilic, and median veins. Veins in the lower extremities are not recommended for infusion therapy in the adult patient because of the high risk for thrombophlebitis. Use of a vein in the arm on the side where a patient has had a mastectomy or has dialysis access is also contraindicated because venous return in the extremity may already be compromised.

Another type of peripheral infusion device is the **midline catheter**. Midline catheters are inserted in a peripheral vein in the upper extremities with tips that terminate distal to the shoulder in either the basilic, cephalic, or brachial vein. Midlines are appropriate for therapies expected to last between 1 and 4 weeks. The midline catheter is longer than the short peripheral catheter but is not a central catheter and should not be used to administer therapies when a central line is required, such as **vesicants** or other irritating solutions, parenteral nutrition solutions, or solutions with a pH of less than 5 or greater than 9 or osmolarity greater than 600 mOsm/L.

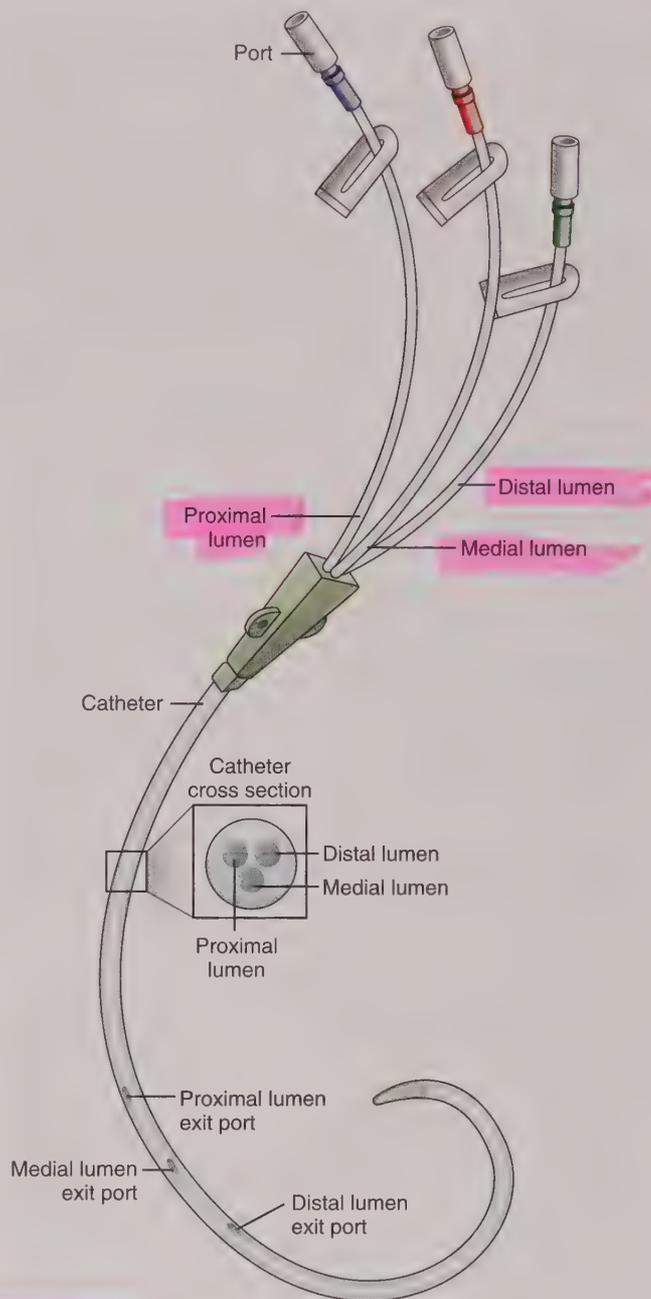

### Connection Check 10.3

A patient is admitted with osteomyelitis and is going to require 3 to 4 weeks of IV antibiotics. Which IVAD is most appropriate for this patient?

- 16-gauge central venous
- 18-gauge over-the-needle IVAD
- 20-gauge midline catheter
- 22-gauge steel-winged device

### Central Venous Access

Central venous access (CVA) describes when the tip of the IVAD terminates in the central vasculature at the level of the superior vena cava or the inferior vena cava. Central venous catheters are made of silicone or polyurethane and come in many sizes and can have single or multiple lumens. Multiple-lumen catheters (Fig. 10.6) provide separate fluid pathways that make it possible to deliver two or more solutions at the same time. Each lumen, or fluid pathway, is totally separate from the other lumens. The fluid infused in each of the lumens leaves the **central venous access device (CVAD)** and enters the central venous system at different points along the catheter. These lumens are referred to as proximal, medial, or distal lumens depending on the location of the end of the fluid path on the catheter. Because the

**FIGURE 10.6** Multiple-lumen central venous catheter. Multiple-lumen catheters provide separate fluid pathways to deliver two or more solutions at the same time. The lumens are referred to as proximal, medial, or distal lumens depending on the location of the end of the fluid path on the catheter, and the corresponding exit ports are noted on the distal end of the catheter.

lumens are separate, incompatible solutions can be infused using the different ports attached to each of the lumens. Each port of the catheter is attached to a separate lumen that provides a distinct fluid pathway within the catheter. Each lumen requires initial flushing, which fills the catheter with the ordered IV solution, and flushing is also used to maintain the patency of the individual lumens if fluids are not being continuously administered. Manufacturers offer devices coated or impregnated with anti-infective agents and devices that can withstand the

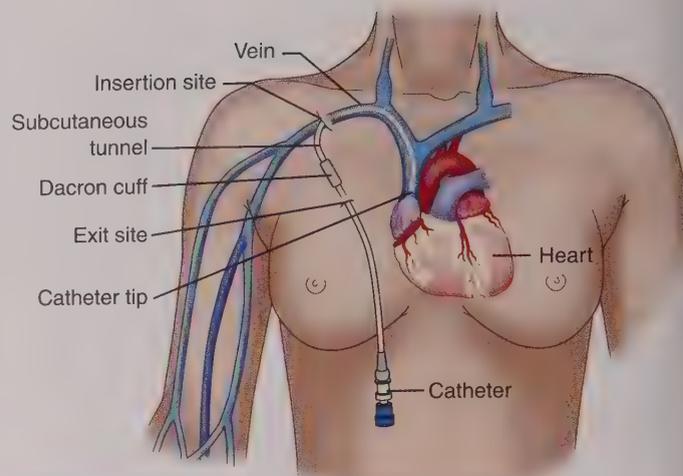

pressure created by the power injectors used in imaging studies.

Types of IVADs used to obtain central venous access include nontunneled percutaneous central catheters, tunneled catheters, **implanted ports**, and **peripherally inserted central catheters (PICCs)**. The tips of CVADs can be either open or closed. Closed CVADs contain a valve at the end of the catheter that prevents backflow of blood into the catheter when fluid is not being infused and minimizes the risk of the catheter clotting. Another important characteristic of the CVAD that nurses need to understand and communicate is the ability of the CVAD to tolerate the pressure created by the power injectors used during imaging studies.

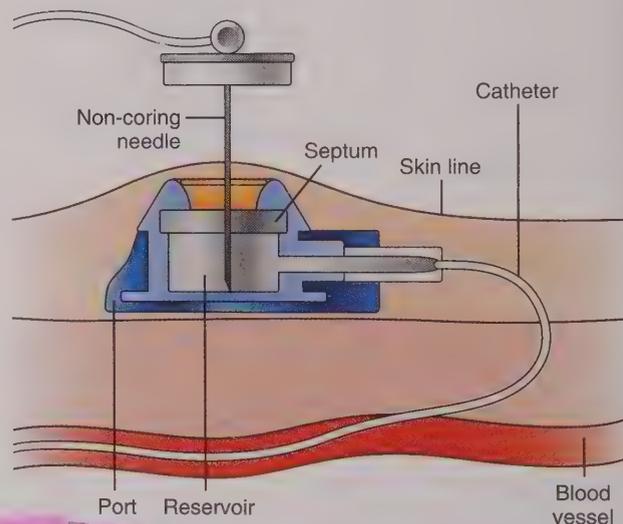

Factors that need to be taken into consideration when the selection of an appropriate CVAD is made include the therapy required by the patient, the projected length of therapy, the condition of the patient's veins, and the resources available to care for the device after insertion. These devices are placed by physicians or advance practice registered nurses. Nontunneled percutaneous central catheters are usually inserted in either the jugular or subclavian veins using venipuncture, and the tip of the catheter is advanced into the superior vena cava. The use of the femoral vein for nontunneled percutaneous catheters is used with caution because of the associated increased risk of infection. This type of CVAD is frequently used in emergency situations when peripheral access is not available. When the catheter is inserted in an emergency situation, it should stay in place no longer than 48 hours because of the risk of infection related to insertion in a less-than-optimal situation. Full barrier precautions (mask, gown, sterile gloves, and sterile drapes) are utilized for the insertion procedure. A chest radiograph is required prior to using the nontunneled percutaneous catheter to verify proper tip location and the absence of a pneumothorax that may have been inadvertently caused during insertion. Another disadvantage of this CVAD is easy dislodgement, and it is important to ensure the device is properly secured with an occlusive dressing.

Tunneled catheters (Fig. 10.7) exit the skin from a site distal from the site where they enter the vein and are tunneled through the subcutaneous tissue between the exit and insertion site. The tip of the catheter is advanced from the insertion site to the central vascular. The tunneled portion of the catheter contains a Dacron cuff that tissue adheres to after insertion. The cuff stabilizes the catheter and provides a barrier to organisms, minimizing infection. This type of CVAD can be permanent and appropriate for patients requiring long-term therapy. The exit site is usually located on the chest and allows the patient easy access, promoting self-care. Tunneled catheters are inserted in non-emergency situations in sterile environments such as an operating or procedure room.

Implanted ports (Mediports) are also used for long-term therapy and offer the added advantage of requiring minimal care when not in use. An implanted port consists of a small reservoir with a septum and an attached catheter (Fig. 10.8).

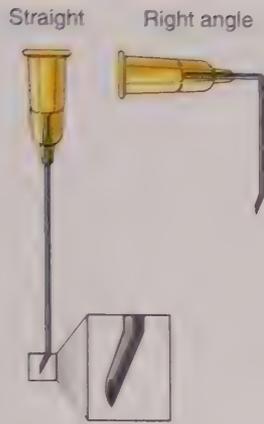

**FIGURE 10.7** Tunneled central venous catheter. Tunneled catheters exit the skin from a site distal from the site where they enter the vein and are tunneled through the subcutaneous tissue between the exit and insertion site. The tip of the catheter is located in the central vasculature. The tunneled portion of the catheter contains a Dacron cuff that tissue adheres to after insertion.

**FIGURE 10.8** Implanted port. The implanted port consists of a small reservoir with a septum and an attached catheter. The reservoir is placed under the skin. The catheter is inserted in the vein near the reservoir, and the tip is advanced into the central vasculature. The entire device is located internally.

The reservoir is placed under the skin. The preferred site is the upper chest wall because it allows the patient to more easily care for the implanted port. These implanted ports can also be placed in the upper extremity, abdomen, and back. The catheter is inserted in the vein near the reservoir, and the tip is advanced into the central vasculature. The entire device is located internally. In order to use the device, it needs to be accessed with a specially designed noncoring needle that is inserted using sterile technique through the skin and into the septum of the reservoir. Noncoring needles (Fig. 10.9) have a different bevel angle, allowing the septum of the port to be punctured multiple times without

**FIGURE 10.9** Straight and right-angle noncoring needles. Noncoring needles have a different bevel angle, allowing the septum of the port to be punctured multiple times without damage.

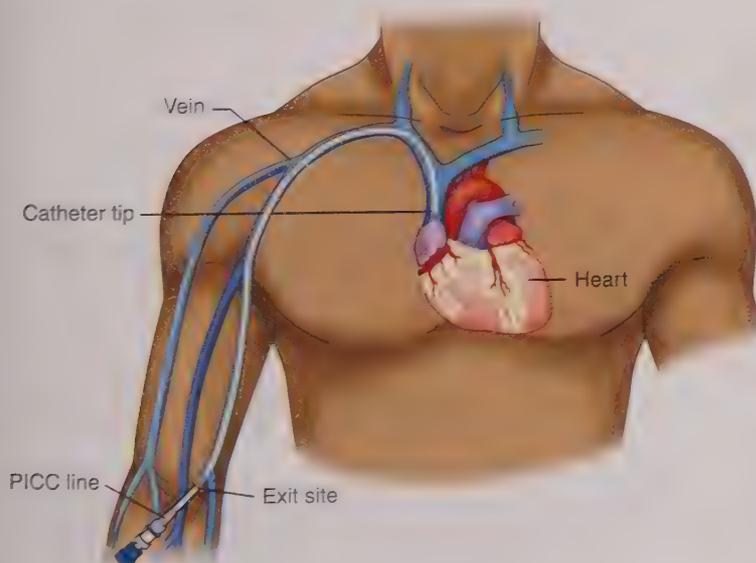

damage. Once the implanted port is accessed with the noncoring needle, it needs to either have a continuous infusion maintained or be flushed periodically according to institutional policy. Implanted ports can have one or multiple ports, and each port communicates with a separate lumen in the catheter and needs to be flushed separately. When not accessed, the ports interfere minimally with the patient's daily activities and require only infrequent flushing to maintain patency.

Peripherally inserted central catheters (PICCs) are CVADs that are inserted into a peripheral vein and advanced into the central vasculature (Fig. 10.10). Peripherally inserted central catheters are frequently placed by registered nurses trained and competent in their insertion at the bedside with the assistance of ultrasound guidance. These catheters also have the advantage of being more cost-effective and easy to place and are appropriate for therapies of moderate to long-term duration. As with all CVADs, verification of tip placement is required with a chest radiograph prior to use. Ultrasound guidance can be used to confirm the placement

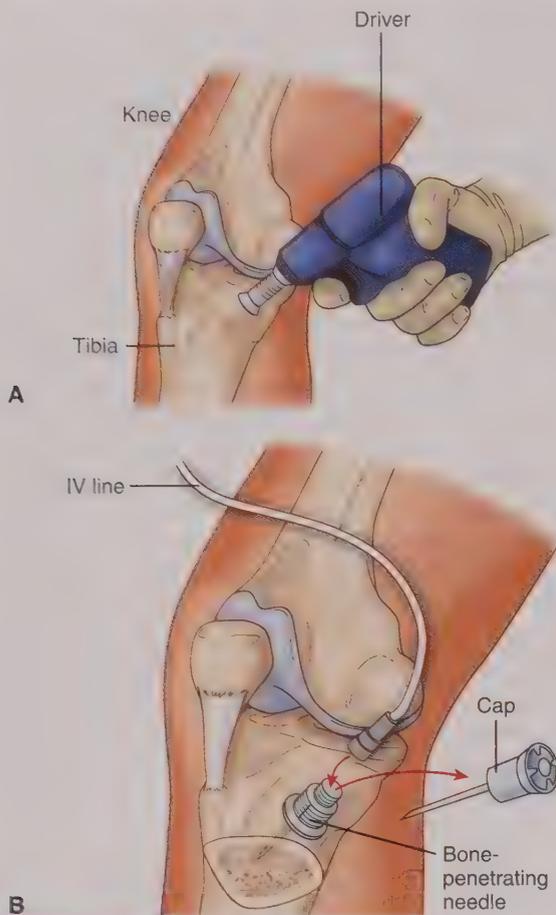

of PICCs. Recent studies show that the technique using electrocardiogram (ECG) guidance is more reliable and of lower cost compared with ultrasound guidance. The ECG-guided technique is accurate for the correct positioning in terms of catheter tip–carina distance and catheter tip–tracheobronchial angle.

The veins used for PICC insertion are usually the larger veins in the upper extremities. If infusion therapy using short peripheral therapy with repeated venipunctures has compromised these veins, PICC placement is much more difficult. Early placement of PICCs needs to be considered in patients who require therapies of longer than a few days to maximize the availability of veins that have not previously been accessed. The length of the fluid pathway in a PICC requires special attention to flushing to maintain patency because they need to be flushed before and after each use and periodically when not in use. Care needs to be taken when flushing a PICC so that excess pressure does not damage the thin walls of the catheter. Unless a PICC is specially designed to withstand higher pressures, only 10-mL or larger syringes, or flushing syringes especially designed to limit the amount of pressure they exert, should be used when flushing the PICC or administering medications through the PICC. If there is a possibility of the need for imaging studies requiring power injection, the power PICC is designed to withstand imaging contrast.

Access to the central venous system is also possible using the **intraosseous (IO)** (into bone marrow) route (Fig. 10.11). Using a handheld driver, the IO device is inserted into the vasculature of the bone marrow, allowing for infusion of fluids and medications. The insertion site is covered with a sterile occlusive dressing to decrease the risk of infection. Infusion rates of up to 1,800 mL per hour are possible, and the patient may require pain medications if experiencing discomfort and pressure during rapid infusions. The IO route is acceptable for any medication that requires a central venous route, and any medication

**FIGURE 10.10** Peripherally inserted central catheter. Peripherally inserted central catheters (PICCs) are central venous access devices (CVADs) that are inserted into a peripheral vein and advanced into the central vasculature.

**FIGURE 10.11** Obtaining intraosseous (IO) access. *A*, A handheld driver is used to access the bone marrow to place the IO device. *B*, The IO device is inserted into the vasculature of the bone marrow, allowing for infusion of fluids and medications.

or fluid that is administered by the IV route can be administered by this route.

Intraosseous access requires less skill than other types of venous access and can be accomplished in under 1 minute. It is especially useful in severely dehydrated patients and for prehospital vascular access. It is becoming more common for IO lines to be placed by emergency medical technicians prior to arrival to the hospital. Frequently used sites in the adult include the proximal humerus, proximal tibia, and distal tibia. The IO route provides rapid central venous access in emergency situations and is recommended as an alternative route in cardiopulmonary resuscitation by the American Heart Association.

## EQUIPMENT USED IN INFUSION THERAPY

Infusion systems consist of the containers and the tubing or administration sets that deliver solutions and medications to the IV access device. Needleless systems have been developed and are mandated by the Occupational Safety and Health Administration (OSHA) to reduce the number of

needle-stick injuries incurring when providing infusion therapy, and there are several types of needleless systems available to nurses. One type of needleless system makes use of a port that contains a valve that is accessed with a male Luer lock on the end of a syringe or administration set (Fig. 10.12). There are also Luer access valve systems available with a positive displacement feature that prevents blood from backflowing into the IV catheter after use. All needleless connectors are activated by pressure in the syringe Luer. This pressure facilitates the syringe Luer to enter an already-split septum to open or depress the septum/plunger. Needleless connectors are the microbial gatekeepers between blood and the unsterile outside of the system. The needleless system aims to prevent microorganisms on the system surface from gaining access into the bloodstream. Disinfection of the needleless system surface is of primary importance prior to use. Disinfection/alcohol caps can be used for continuous disinfectant contact. Even with these caps, the needleless system must be cleaned with an alcohol wipe. The Joint Commission recommends a 10- to 15-second scrub. Allow the disinfectant to dry prior to accessing the system.

Administration sets are either primary or secondary sets (Fig. 10.13). Primary sets are used to deliver the main

**FIGURE 10.12** Luer-activated injection cap. This is a needleless system that uses a port that contains a valve that is accessed with a male Luer lock on the end of a syringe or administration set.

**FIGURE 10.13** Primary administration set. Primary sets are used to deliver the main IV solution and consist of a spike that goes into the IV bag, a roller clamp that allows control of flow/infusion rate, ports for secondary access, and the end that connects to the IV catheter.

IV solution, and secondary sets are attached to the primary set to deliver additional solutions or intermittent medications into a y-site in the primary infusion set. These administration sets use gravity to deliver fluids into the vasculature. Administration sets allow for the control of delivery rates using a roller clamp. The infusion rate is determined by the drip factor of the infusion set. Macrodrop administration sets have drip factors of 10, 12, 15, or 20 drops/mL and are appropriate when delivering higher infusion rates. Microdrop administration sets have drip factors of 60 drops/mL and are appropriate when delivering rates of less than 100 mL/min. To determine the infusion rate:

$$\text{milliliters per minute} \times \text{drop factor} = \text{drops per minute}$$

There are situations when more accurate rate control is needed than can be provided by gravity administration set roller clamps, and one possible solution is the use of an **electronic infusion device** or pump. These infusion pumps can deliver solutions and medications with a greater degree of accuracy and can alert the nurse to situations when the infusion has slowed or stopped because of kinked tubing or increased resistance that can indicate that the IV catheter is clotted or has infiltrated into the subcutaneous tissue. Some electronic infusion devices use standard administration sets, whereas others require administration sets specifically designed for use in the device. Electronic infusion devices assist the nurse in providing accurate infusion therapy, but the nurse is still responsible for monitoring the delivery of the therapy.

One of the most important safety features offered by many electronic infusion devices is the ability to enforce parameters for safe administration of medications through the use of a medication library that sets high and low limits for medication administration. These electronic infusion devices are called “smart pumps” and have been shown to greatly improve the safety of IV medication administration because they prevent the setting of infusion rates outside established safe parameters. However, recent studies have found that more than half of infusions contain errors. These errors are not technology related but, instead, deviations in hospital policies. Seventy-seven percent of hospitals use smart pump technology, but adherence to clinical practice policies and procedures and competence in smart pump operation are crucial to the prevention of medication errors.

### Connection Check 10.4

In order to deliver 0.9% sodium chloride at 125 mL/hr, the nurse has selected an infusion set with a drop factor of 15 drops/mL. What is the correct drop rate required to deliver this volume?

- 15 drops/min
- 31 drops/min
- 60 drops/min
- 125 drops/min

## NURSING MANAGEMENT OF INFUSION THERAPY

### Monitoring and Preventing Complications

The fluid status of patients receiving IV fluids needs to be monitored to ensure that the intended outcome of therapy is being achieved; therapy should provide adequate amounts of fluid to maintain a **euvolemic** or **normovolemic** (having normal blood volume) state. Hypertonic and hypotonic fluids place the patient at the greatest risk for fluid imbalance and require more intense monitoring. Fluid status is monitored with physical assessment, periodic weights, and accurate measurement of intake and output. Laboratory values, particularly serum electrolytes, need to be monitored for further indications of fluid balance.

#### Phlebitis and Infiltration

Complications of peripheral infusion therapy include **phlebitis** and **infiltration**. Phlebitis, inflammation of the vein, is characterized by pain and erythema along the vein and is graded using a standardized scale according to signs, symptoms, and severity (Table 10.4). Peripheral sites that show signs of phlebitis should be removed and restarted in another location because **phlebitis** can progress to more serious conditions, including thrombus formation, cellulitis, and sepsis. The antecubital fossa site has been shown to have the lowest phlebitis rates, whereas hand veins have a high risk of phlebitis.

Causative factors of phlebitis are divided into three categories: chemical, mechanical, and bacterial. Chemical phlebitis is the result of the infusion of irritating solutions and medications that occurs when the peripheral vein does not allow for sufficient hemodilution of the IV fluid as it exits the catheter. Mechanical phlebitis is the result of the catheter irritating the vein wall and can be caused by introducing a catheter too large for the vein, inadequately securing the catheter, or movement of the catheter placed in an area of flexion such as the elbow or wrist. Bacterial phlebitis is the result of bacteria being introduced into the catheter

**Table 10.4** Infusion Nurses Society Phlebitis Scale

Grade	Clinical Criteria
0	No clinical symptoms
1	Erythema at access site with or without pain
2	Pain at access site with erythema and/or edema
3	Pain at access site with erythema, streak formation, and/or palpable cord
4	Pain at access site with erythema, streak formation, palpable venous cord greater than 1 inch in length, and/or purulent drainage

Data from Infusion Nurses Society. (2016). *Infusion therapy standards of practice*. Norwood, MA: Author.

because of improper site cleaning prior to venipuncture, failure to clean ports prior to accessing the administration set, or failure to perform adequate hand hygiene (see Evidence-Based Practice: Use of Aloe Vera to Prevent and Treat Infusion Phlebitis). The insertion sites of peripheral vascular access devices need to be assessed at regular intervals for phlebitis, as defined by institutional policies. It is important to continue to assess the site after the peripheral catheter has been removed because phlebitis can develop after the infusion has been completed.

## Evidence-Based Practice

### Use of Aloe Vera to Prevent and Treat Infusion Phlebitis

Because of the risk of phlebitis associated with IV fluid administration, a systematic review was conducted in 2014 to examine the effects of the application of aloe vera to prevent and treat phlebitis. Inclusion criteria included randomized and quasi-randomized controlled studies of participants receiving topical aloe vera or aloe vera–derived products applied to the insertion site. There was a total of 43 reviews, with 35 of these being randomized controlled studies that represented 7,465 participants. The trials compared the application of aloe vera alone or with another non–aloe vera treatment, such as wet compresses of 75% alcohol or 33%, 50%, or 75% magnesium sulfate, with no treatment. The findings suggest that the application of fresh aloe vera alone or in combination with other non–aloe vera treatment may be effective in preventing and treating phlebitis secondary to placement of IV access devices. The authors recommend cautious interpretation of these results secondary to some issues with low methodologic quality.

Zheng, G. H., Chen, J. F., Chu, J. F., & Mei, L. (2014). Aloe vera for prevention and treatment of infusion phlebitis. *Cochrane Database of Systematic Reviews*, 6, CD009162. doi:10.1002/14651858.CD009162.pub2

Infiltration occurs when a solution or medication is inadvertently infused into the tissue surrounding the vein and is a complication that can occur with any IVAD, peripheral or central. When the solution or medication that infiltrates is a vesicant (able to cause blisters), an **extravasation** (leakage of IV fluid into subcutaneous tissue) has occurred. Medications that are classified as vesicants include specific antineoplastic agents, antibiotics, and vasoactive medications. Nurses administering vesicants require additional education to ensure competency, and infusion should be routinely assessed for possible infiltration at intervals established by institutional policy. Clinical manifestations of

infiltration include blanched skin, skin cool to the touch, edema, unexpected pain or burning at the insertion site or along the path of the vein, and leaking of fluid from the insertion site. Assessment intervals need to take into consideration the patient's condition, type of device, type of therapy, and risk factors. In the case of an extravasation, the infusion needs to be stopped immediately, and corrective action needs to be taken to minimize damage to the tissue.

### Central Line Complications

Complications of central venous infusion therapy include infection, loss of patency, and air embolism. Strategies have been implemented in healthcare institutions to eliminate infections of **central venous catheters (CVCs)** because of their negative effects on patient outcomes and the high cost of treating central line–associated bloodstream infections. The use of maximal sterile barrier precautions, including mask, sterile gown and cap, sterile gloves, and large full-body drapes, while inserting a CVAD is now the standard of practice. Nurses play a key role in preventing these infections by following evidence-based best practices (see Safety Alert).

#### **Safety Alert** 2016 National Patient Safety Goal: Implement best practices or evidence-based guidelines to

prevent central line–associated bloodstream infections.

- Perform hand hygiene prior to line manipulation and dressing changes; use aseptic technique.
- Disinfect catheter hub and injection port when accessing.
- If assisting or supervising line insertion, maintain sterile technique, and speak up if sterile technique is broken; complete or collect line insertion checklist.
- Educate patient and/or family prior to insertion regarding prevention of central line infection.

Loss of patency, or **occlusion**, of a CVC can delay the delivery of lifesaving therapies and may also mean the patient is subject to the risk and discomfort of insertion of another CVC. Occlusions can be the result of a thrombotic process when blood or fibrin in or around the catheter interferes with flow. Thrombotic occlusions can result in slowed infusion rate and resistance to flushing or the complete inability to infuse or flush the catheter. Proper flushing before and after use of the catheter and at intervals when the catheter is not in use decreases the occurrence of thrombotic occlusions. There are injection caps specially designed to prevent thrombotic occlusions; these caps create a positive pressure that prevents blood from refluxing into the catheter when not in use.

Occlusion can also be **nonthrombotic** (not resulting from a clot) and can result from medication precipitation. Medication precipitation occurs when incompatible medications are administered together or without adequate

flushing between administrations of the incompatible medications. Nurses need to verify that medications being administered together by the IV route are compatible with the solution infusing and any other medications that may still be in the line or catheter.

An **air embolism** occurs when air is inadvertently introduced into the venous system. Air can be introduced if the catheter is damaged, during insertion and removal of CVCs, and if the connections in the IV delivery system (e.g., catheter hub, tubing, injection caps) are not tightly secured with Luer-locked connections. Nursing actions that can prevent air embolism include proper Trendelenburg positioning during CVC insertion (10–30 degrees), avoiding CVC insertion during inspiration, correcting hypovolemia prior to CVC insertion, ensuring all IV connections are intact and secure, and ensuring all lumens are capped and/or clamped. Additional actions include using Luer-locking connections, frequently checking the connections, and clamping catheters and injection sites when not in use. Other preventive measures include using infusion pumps, **priming** (flushing all the air out of the IV tubing with the ordered solution) all IV tubing prior to connecting to the CVC, expelling air out of all syringes prior to use, and inspecting all lines and connections. Ensure the central line dressing is intact, and use caution when repositioning the patient. The CVC should be removed only by personnel competent to perform this procedure, and removal should be performed with the patient in a supine position. Prior to removal, the patient should be instructed to perform a Valsalva's maneuver or exhale during the removal to prevent the introduction of air into the line. The catheter should be removed slowly, and a sterile occlusive dressing should be placed over the insertion site immediately and left in place for 24 hours.

### Connection Check 10.5

The nurse recognizes the presence of pain, redness, and streak formation at the site of a peripheral IV site as what grade of phlebitis?

- 1
- 2
- 3
- 4

### Maintaining Intravenous Access

In order to maintain the patency of both peripheral and central IVADs, proper flushing is required, and all IVADs need to be flushed prior to use to establish that they have been placed properly and are functioning correctly. Single-use vials or prefilled syringes of preservative-free 0.9% saline are the preferred methods of delivering flushes because they require less manipulation and are less likely to be contaminated. Whenever manipulating an IVAD, it is imperative to perform hand hygiene and to clean the injection ports prior to every

entry. The injection port needs to be cleaned with alcohol or chlorhexidine and allowed to dry completely; the nurse follows institutional protocols regarding which agent is used to clean the port. Catheters are flushed with a volume twice that of the catheter and any attached extension tubing (Box 10.2). The INS recommends a **flushing and locking protocol**.

- **“Flushing”** is the act of moving fluids, medications, blood, blood products, and nutrients out of a vascular access device into the bloodstream, ensuring delivery of these components and verifying device patency.
- **“Locking”** is the instillation of a solution into a vascular access device to maintain device patency.

The patency of CVADs requires a continuous infusion or periodic flushing. As with peripheral catheters, CVADs need to be flushed after the administration of a medication or blood product when changing from a continuous infusion to an intermittent “locked” device and also after the withdrawal of blood and when not in use. The frequency of periodic flushing is determined by the type of CVAD and institutional policies. The volume used to flush the CVAD needs to be at least twice the volume of the catheter to be sure all contents of the IVAD are cleared with the flush. Institutional policy determines which CVADs used intermittently are “locked” with saline or with a heparin solution. Studies have shown that the patency of some catheters can be maintained without heparin, which decreases the bleeding complications associated with this anticoagulant.

All IVADs, with the exception of well-healed tunneled catheters, are dressed with a sterile occlusive dressing to prevent bacterial contamination of the site. Transparent semipermeable dressings offer the advantage of allowing a clear view of the insertion site for assessment, but gauze dressing occluded with tape is acceptable. Dressings should be changed immediately if they are no longer occlusive or become moist. Peripheral IVADs do not require routine dressing changes or site care. The frequency of CVAD

### Box 10.2 Centers for Disease Control and Prevention (CDC) Protocol for Flushing Central Venous Lines

Positive-pressure technique (may not apply to neutral-displacement or positive-displacement needleless connectors):

- Flush the catheter, continue to hold the plunger of the syringe while closing the clamp on the catheter, and then disconnect the syringe.
- For catheters without a clamp, withdraw the syringe as the last 0.5 to 1 mL of fluid is flushed.

From Centers for Disease Control. (2011). *Guidelines for the prevention of intravascular catheter-related infections* [Updated 2017]. Retrieved from <https://www.cdc.gov/infectioncontrol/guidelines/bsi/recommendations.html>

dressing changes and site care is determined by institutional policy, type of CVAD, and type of dressing. Sterile gloves should be worn when changing a CVAD dressing to decrease the risk of infection.

A recent meta-analysis performed by the Cochrane Collaboration found no clear evidence for routine replacement of peripheral IV catheters. Rotating peripheral IV sites every 72 to 96 hours is unpleasant for the patient and expensive in terms of supplies and nursing time. The 2016 INS Infusion Nursing Standards of Care note that peripheral catheters should be replaced when clinically indicated, not at set intervals. Clinical indications for the removal of a peripheral catheter include whenever the patient reports discomfort or pain related to the infusion site and assessment findings indicating possible phlebitis, infiltration, or occlusion. IV tubing is changed according to institutional policy; there is no evidence that changing IV tubing more frequently than every 96 hours decreases the risk of infection (see Evidence-Based Practice: Peripheral IV Site Rotation Based on Assessment Findings).

### Evidence-Based Practice

#### Peripheral IV Site Rotation Based on Assessment Findings

There are variations in practice related to the length of time that peripheral IV catheters may remain in place prior to changing sites. In many healthcare settings, agency policies require that sites be changed at specific time intervals (usually 72–96 hours), despite the absence of complications such as phlebitis and infiltration. A descriptive study, based on Duffy's Quality Caring Model and conducted in a 500-bed community hospital, included a convenience sample of 71 patients with 89 IV catheters. At the time of the study, the policy at this facility required that IV catheter sites be changed every 96 hours, despite the absence of complications. The findings of this study demonstrated that IV catheters could remain in place past the 96-hour time frame with routine assessment of the site. Thirty sites maintained patency for 96 to 200 hours, five sites maintained patency at 201 to 300 hours, and four sites were patent when assessed over 300 hours after initial placement. These findings also are consistent with 2011 recommendations from the Infusion Nurses Society stating that IV catheter site changes should be based on assessment data, including site, length and type of IV therapy, patency, and stabilization.

Helton, J., Hines, A., & Best, J. (2011). Peripheral IV site rotation based on clinical assessment vs. length of time since insertion. *MEDSURG Nursing*, 25(1), 44–49.

Routine replacements or exchanges of CVADs are not necessary if the catheter is functioning and there is no evidence of complications. The continued need for a short-term central catheter (PICCs and nontunneled percutaneous central catheters) needs to be evaluated daily by the inter-professional team to determine if the catheter is required. Consideration needs to be made to possibly administering infusion therapies by a less invasive peripheral approach or by other routes, such as oral.

### CASE STUDY: EPISODE 2

Upon Jason's arrival in the emergency department, two large-bore (18-gauge) IV catheters are placed in his forearm, and the IV lines started in the field are discontinued. The nurse practitioner also inserts a nontunneled percutaneous central catheter. Blood samples are obtained for serum chemistries, complete blood count, and toxicology, and samples are also sent for type and crossmatch in the event Jason requires blood products. He is taken to the operating room for an emergency exploratory laparotomy, and in the post-anesthesia care unit (PACU), the nurse anesthetist places a triple-lumen CVC for the anticipated need for administration of blood products, IV fluids, and antibiotics. He is transferred to the surgical intensive care unit for postoperative management...

### Administration of Intravenous Medications

Terms used to describe the method used to administer medications or solutions include *continuous infusion*, *intermittent infusion*, *bolus* (a specific amount of fluid over a short time period) *infusion*, and *IV push* (direct IV administration). The order of a licensed independent practitioner needs to indicate which method is to be used. Continuous infusion refers to the ongoing administration of a solution and can be ordered as a specific rate per hour (e.g., 125 mL/hr) or a volume over a time period (1,000 mL over 8 hours). Clarification needs to be obtained for orders indicating a “keep open rate” or “keep vein open” (KVO) to obtain a more clearly defined rate unless a “keep open rate” is defined in institutional protocols. Interpretation of such orders can vary greatly, particularly depending on the age and weight of the patient, and can lead to possible fluid overload. Veins should never be kept open with solutions containing medications such as potassium because insufficient amounts will be delivered to be therapeutic.

Intermittent infusions can be given through the injection port on the administration set of the continuous infusion (“piggyback”) or infused into the injection port of the locked IVAD. Intermittent infusions concurrent with a continuous infusion need to be compatible with the continuous infusion. If not compatible, the continuous infusion needs

to be stopped while the intermittent infusion infuses and the tubing of the infusion set is cleared or flushed with a compatible solution, usually 0.9% normal saline. Prior to administration of an intermittent infusion through a locked IVAD, the IVAD device needs to be flushed to ensure proper functioning of the device and clearing of any potentially incompatible solution. When the intermittent infusion is completed, the IVAD then needs to be flushed again and relocked. When intermittent infusions are administered either into a continuous infusion or into a locked IVAD, the IV system needs to remain closed, and the tubing should not be disconnected to prevent the introduction of microorganisms into the IV system. Flushing and administration of intermittent infusions are done through an injection port that has been cleaned with alcohol or chlorhexidine, per institutional protocol, and allowed to completely dry.

Bolus infusions are concentrated medications and/or solutions given over a short period of time. This is the method used when administering a “fluid bolus” or “fluid challenge” to a patient who may have a low urine output because of decreased fluid volume status. Boluses are usually administered with small-volume solution containers (250 or 500 mL) in a manner similar to an intermittent infusion but over a shorter time period. Patients receiving bolus infusions need to be monitored closely to ensure they are tolerating the volume infused.

IV push, or direct IV, is the manual administration of a medication using a syringe. Special attention needs to be given to the correct concentration and rate of administration of medications given with this method. Some medications need to be diluted prior to administration to ensure a safe concentration and to more accurately control the rate of administration. IV push medications can be given into a locked IVAD or into an IVAD with a continuous infusion. Prior to administration, the IVAD and any tubing between the injection port and the IVAD needs to be flushed to ensure proper functioning of the device and clearing of any potentially incompatible solution or medications. Flushing and administration of the IV push are done through an injection port that has been cleaned with alcohol or chlorhexidine and allowed to completely dry. After the IV push medication has been administered, the IVAD needs to be flushed again. Keep in mind that the rate of this flush needs to be at the same rate that is acceptable for the medication administration because the medication that is in the tubing and IVAD will be flushed through and administered to the patient at the flush rate.

### Administration of Blood Products

Transfusion of blood components is a lifesaving therapy that includes risk and requires meticulous adherence to procedures and policies along with close monitoring of the patient. Modern practices for blood collection include multiple screening tests and volunteer donors, rendering the blood supply relatively free of the risk of transmissible diseases such as syphilis, hepatitis, and HIV. Transfusion of whole

blood is rare because it is more efficient to administer only the portion of the blood, or component, required by the patient (Table 10.5). Also, one unit of donated blood can be separated into individual components that can benefit multiple recipients. Components commonly infused include RBCs, fresh frozen plasma (FFP), platelets, granulocytes, clotting factors, and albumin.

Prior to releasing a blood component for administration to a patient, the blood bank or laboratory carefully matches the intended component to the sample of the patient’s blood to ensure that they are compatible using ABO, Rhesus (Rh), and human leukocyte antigen (HLA) testing. Antigens present on the surface of the RBC determine the ABO blood type of the patient. Antibodies to the ABO antigens are in the plasma, which means ABO antigens present on the transfused blood will be attacked by the antigens in the recipient’s blood if they do not have the same ABO antigens. This causes a **hemolytic transfusion reaction**. The Rh antigen is another antigen on the RBC that is either present (Rh-positive) or absent (Rh-negative). Recipients who are Rh-negative should receive only Rh-negative blood, but recipients who are Rh-positive can receive either Rh-positive or Rh-negative blood (Table 10.6). Patient identification and specimen labeling of blood samples collected from the patient need to be done with extreme care and usually require independent identification by two separate

**Table 10.5** Indications for Blood Component Transfusion

Blood Component	Indication
<b>Packed red blood cells</b> (volume 225–350 mL)	Symptomatic anemia Acute and chronic blood loss
<b>Plasma (fresh frozen plasma)</b> (volume 200–250 mL)	Deficiency of plasma coagulation factors Massive transfusion in trauma Need for emergency reversal of elevated prothrombin time and international normalized ratio (PT/INR) that indicates increased risk of bleeding Disseminated intravascular coagulation (DIC)
<b>Platelets</b> (volume 40–70 mL)	Bleeding due to thrombocytopenia or platelet abnormalities
<b>Granulocytes</b> (volume 200–300 mL)	Neutropenia with infection, unresponsive to appropriate antibiotics
<b>Albumin</b> (volume varies)	Volume expansion when crystalloid solutions are not adequate

**Table 10.6 ABO Compatibilities**

Blood Component	Type-Specific Compatibilities	
<b>Red blood cells (RBCs) and platelets</b>	Donor	Recipient
	O	O, A, B, AB
	A	A, AB
	B	B, AB
	AB	AB
<b>Fresh frozen plasma</b>	Donor	Recipient
	O	O
	A	A, O
	B	B, O
	AB	AB, B, A, O

healthcare providers. The HLA system relates to proteins located on the surface of white blood cells and other tissues. Important to immune function, HLAs form in response to exposure to foreign substances. In blood transfusions and organ transplants, the immune system recognizes these cells or tissues as foreign substances, activating the HLA system and leading to transfusion reactions and organ rejection.

Because blood components are “living transplants,” they need to be stored according to strict standards. Even though most blood components contain preservatives, they are stored in the laboratory until just prior to their transfusion. There are strict time limits placed on how long blood products can be outside of storage in the laboratory prior to administration and on the length of time over which they can be infused. Nurses must be knowledgeable of these timelines and follow the guidelines established by the institution where they practice. Compliance with these standards is monitored on the blood product administration forms required with the administration of each individual component. Each component or unit is accompanied by a unique form that provides information about the blood product.

Before the blood component is obtained from the laboratory, the patient’s informed consent and an order for the administration of the blood component need to be confirmed. The order should indicate the type of blood component to be administered, the number of units or volume of the blood component to be infused, the flow rate or duration of the infusion, and other parameters for infusion. Because there is a limited amount of time allowed for the component to be outside the controlled storage conditions of the laboratory, the nurse needs to confirm adequate IV access and that all supplies and equipment needed for the transfusion are available prior to the blood component being released from the laboratory for administration. Once the component is obtained from the laboratory, there needs to be verification performed by two

licensed staff members, which includes matching the blood product to the order and matching the patient to the blood product. The blood product should agree with the type of component prescribed, the volume or number of units to be transfused, and the patient’s full name and one other patient identifier. The ABO and Rh compatibility of the donor and recipient also needs to be confirmed prior to the initiation of the transfusion. The expiration date and the date and time the component was released from the laboratory need to be confirmed as acceptable.

**Safety Alert** The National Quality Forum has identified mismatched blood transfusions as an event that should never happen. Patient identification is the most important process in the safe administration of blood components. Fatal errors can occur because of mislabeled specimens or blood components and patient identification.

Immediately prior to starting the blood transfusion, a patient assessment needs to be completed, including baseline vital signs and respiratory status. The nurse needs to explain the procedure and confirm patient understanding, including clinical manifestations to immediately report. Blood transfusions can be an anxiety-producing situation, and adequate time for explanations and questions needs to be provided.

Close observation is required to detect any reaction the patient may have to the blood product (Table 10.7), especially during the first 15 minutes when reactions are most likely to occur. Assessments should continue at least every hour for the duration of the transfusion and should include respiratory status; vital sign status; and any complaints of discomfort, dyspnea, or itching.

The type of component ordered determines the method of administration and the type of equipment needed for the infusion. There are special filters and tubing for each type of blood component, but the only type of infusion solution used in flushing administration sets and IVADs, and in the administration of any of the blood components, is 0.9% sodium chloride. The rationale for this fluid is because it is isotonic and does not cause fluids to move into or out of the transfused RBCs. The gauge of the IVAD used for transfusion needs to be large enough to facilitate the required flow rates so that the blood is transfused within the prescribed time frame. An 18- to 20-gauge catheter is recommended for the infusion of packed RBCs in the adult population to prevent RBC lysis.

Packed RBCs consist of the cells that remain after the plasma portion of the whole blood is removed. Packed RBCs are the component that is used for most blood replacement therapy, including acute blood loss, and chronic symptomatic anemia that does not respond to pharmacological therapy. In certain situations, RBCs that have undergone

**Table 10.7** Types of Transfusion Reactions

Transfusion Reaction	Cause	Clinical Manifestations	Interventions if Suspected
<b>Acute hemolytic reaction</b>	Infusion of ABO-incompatible blood	Fever Chills Hypotension Flank pain Vascular collapse	Stop the transfusion immediately. Notify the provider. Maintain blood pressure.
<b>Febrile nonhemolytic reaction</b>	Antibody reaction to granulocytes or platelets in infused blood component	Temp increase of 1°C or 2°F Chills Headache Chest pain	Stop transfusion; notify provider. Monitor vital signs. Possible administration of antipyretics Restart transfusion slowly.
<b>Allergic reaction</b>	Sensitivity to donor's plasma proteins	Itching Hives Facial flushing Anxiety Dyspnea	Stop transfusion; notify provider. Monitor vital signs. Possible administration of antihistamines Restart transfusion slowly.
<b>Circulatory overload</b>	Administration rate higher than patient tolerance	Headache Dyspnea JVD Edema Increased BP	Stop transfusion; notify provider. Monitor vital signs. Elevate HOB. Possible administration of diuretics and oxygen Restart transfusion slowly.

BP, Blood pressure; HOB, head of bed; JVD, jugular venous distention.

special processing are ordered to meet special patient needs. These types of packed RBCs include irradiated and leukocyte-reduced RBCs. Irradiating RBCs inactivates donor lymphocytes and reduces allergic and febrile reactions in some patients. Leukocyte-reduced RBCs decrease febrile reactions in recipients with high levels of leukocyte antibodies.

A single unit of packed RBCs has a volume between 225 and 300 mL and is usually infused over 1 1/2 to 2 hours but no longer than 4 hours. The integrity of blood products infused over periods greater than 4 hours is compromised, and any remaining product not infused in the 4-hour period needs to be returned to the laboratory. Administration sets used to infuse packed RBCs are either a straight or y-type set with a 170- to 260-micron filter. Filters of this size allow for the movement of the RBCs through the filter but stop any small clots or other debris. The tubing is primed with 0.9% sodium chloride prior to use.

### Connection Check 10.6

A patient is ordered to receive a blood transfusion because of anemia. What is the recommended minimum gauge of the IV catheter to administer blood?

- 16
- 18
- 20
- 22

### Administration of Total Parenteral Nutrition

The use of the intravenous route to provide nutrition is indicated only when it is not possible to provide adequate nutrition using the oral or enteral routes. Intravenous total parenteral nutrition (TPN) is associated with increased risks

to the patient and greater costs. Parenteral nutrition solutions provide the major macronutrients (protein, carbohydrates, and lipids) along with required micronutrients (electrolytes, vitamins, and trace minerals) and water. The protein required by the body for growth, maintenance, and repair of tissues is provided in TPN in the form of amino acids in a combination that meets the body's needs. Carbohydrates used to generate energy for the body are supplied by dextrose in the TPN solution. Lipid emulsions may be included to provide an additional source of energy and serve as a source for essential fatty acids. Lipids can either be contained in the primary TPN solution or infused separately.

An interprofessional approach is required to design a TPN program that meets the needs of the individual patient, including the primary healthcare provider (physician, advanced practice registered nurse, physician's assistant), registered nurses, pharmacists, and dietitians. Total parenteral nutrition solutions are prepared in the pharmacy under special conditions to reduce the risk of bacterial contamination. Infusion of additional medications in the TPN solution is institution specific, and the risk of infection and medication incompatibilities needs to be carefully evaluated. Medications that are added in some institutions include insulin, heparin, and H<sub>2</sub>-receptor antagonists.

Because of the high concentrations of dextrose, TPN therapy is initiated gradually, and the patient's glucose and fluid tolerance are evaluated as the infusion rate is gradually increased until the targeted rate is reached. Blood glucose levels may be monitored every 6 hours, and an insulin scale is used to control blood glucose levels. Similarly, when the therapy is being discontinued, the rate of infusion should be gradually decreased as the patient adjusts to decreased amounts of concentrated IV dextrose and fluids.

When TPN is infused, special precautions are implemented to prevent complications. Because of the high osmolarity of TPN solutions, they should be infused into a CVAD with the tip placement confirmed in the vena cava. This allows for hemodilution of the TPN solution, decreasing the risk of phlebitis, thrombosis, and pain. The infusion system used to administer TPN should remain a closed and dedicated line and should not be used to administer other medications or access the CVAD for any reason. The administration set used to infuse TPN should be changed every 24 hours to decrease the risk of contamination and infection.

### Connection Check 10.7

The nurse recognizes the prevention of which complication as the primary rationale for initiating total parenteral nutrition at a slow rate?

- A. Infection
- B. Hyperglycemia
- C. Discomfort
- D. Air embolism

### Patient Teaching

One of the most important roles of the professional nurse in infusion therapy is patient and family education because they have the right to be involved in their care. In order to be actively involved and make decisions about the care they receive, patients need to be educated on the alterations in their health that require infusion therapy, the infusion therapies prescribed, and the expected outcomes and possible complications of the therapies.

Prior to the insertion of any IVAD, peripheral or central, the patient needs to be educated and learning verified regarding the rationale for the IVAD, alternatives to the selected device, and expectations during the insertion of the device, including the level of expected discomfort. Patients are also educated on the measures used to decrease discomfort and possible complications. The practice of aseptic techniques needs to be explained to the patients, and return demonstration by the patient, family member, or significant other of aseptic technique in caring for the IV access is included in the education.

Patients are informed of the type of IV solution and/or medications to be administered, including the reasons they are being administered, expected outcomes, and possible complications. During therapy, the patient's understanding of the importance of reporting any unexpected outcomes and signs of possible complications is assessed. Patients are taught measures to prevent possible complications, including reporting any discomfort or redness at the insertion site, temperature elevation, and whenever the IVAD dressing is no longer occlusive or is wet. Patients are encouraged to monitor hand washing and proper cleaning of ports in the IV delivery system prior to entry by all healthcare personnel.

### Connection Check 10.8

The nurse recognizes that education for patients receiving infusion therapy should include which information? (*Select all that apply.*)

- A. Precautions for preventing infection
- B. Signs and symptoms to report
- C. Manufacturer of the IVAD
- D. Purpose of infusion therapy
- E. Calculation of infusion rates

It is the professional nurse's responsibility to administer IV solutions and medications as prescribed and know the expected outcomes and possible side effects of the solutions and medications administered. Additionally, it is an expectation that the nurse is competent in the techniques used to provide infusion therapy and in monitoring the patient for responses to therapy and the development of any undesired outcomes or complications. The need for continuous infusion therapy and IV access is evaluated periodically, and discontinuation is considered as soon as therapy can be delivered by other, less invasive routes.

## Making Connections

### CASE STUDY: WRAP-UP

Four days postoperatively, Jason develops a peritoneal abscess requiring IV antibiotics and analgesics, blood products, and TPN. He remains in the surgical intensive care unit for 3 days and receives four more units of packed RBCs. On day 4, he is transferred to the surgical intermediate care unit, and 10 days after admission, he is transferred to a short-term acute rehabilitation facility until he can be discharged home.

#### Case Study Questions

- The nurse should be prepared to administer what IV solution to Jason as a result of the injuries he sustained in the motor vehicle accident?
  - 5% dextrose in lactated Ringer's
  - 5% dextrose in normal saline
  - 0.45% normal saline
  - 0.9% normal saline
- What is the rationale for the placement of a nontunneled percutaneous central catheter for Jason?
  - The catheter allows easy care of the catheter by Jason after discharge.
  - There is a lower risk of infection and other complications.
  - Jason prefers to not have an IV in his hand.
  - There is an urgent need for fluid and medication administration.
- The nurse recognizes that the multiple units of packed RBCs Jason received for blood loss after his motorcycle accident did not contain clotting factors and anticipates that which blood component may be required?
  - Fresh frozen plasma
  - Granulocytes
  - Platelets
  - Whole blood
- Into which port of his triple-lumen CVAD can the nurse infuse the next dose of antibiotics? (*Select all that apply.*)
  - Port with the parenteral nutrition infusion
  - Port with the packed RBCs infusing
  - Port where the patient-controlled analgesia is attached
  - Port that is saline locked
  - Port with 0.9% normal saline infusing

- On assessing Jason's central line, the nurse notes that the Luer lock on one of the lumens is not tight and recognizes that this places him at risk for which complication?
  - Air embolism
  - Clotting of the catheter
  - Infection
  - Fluid loss

## CHAPTER SUMMARY

Infusion therapy is an important part of the care provided to patients with a wide variety of conditions in many settings across the continuum of care. In order to provide safe and effective infusion therapy, nurses require specialized skills and knowledge of current evidence to guide their practice.

Infusion therapy is utilized to maintain fluid and electrolyte balances, administer medication and blood products, and provide nutritional support. In order to provide the safest care and prevent complications, nurses need to have knowledge of the anatomy and physiology of the vascular system, correct selection and care of various IV access devices, and the pharmacology of the medications and solutions administered intravenously. Nurses need to be alert to possible complications and perform interventions that minimize their occurrence and detect complications early when they do occur.

Intravascular devices selected to deliver infusion therapy should be the least invasive, with the smallest gauge and fewest number of lumens to provide the therapy prescribed. More invasive CVADs are indicated when larger volumes of fluid need to be delivered and for certain medications and solutions that require the greater hemodilution provided in the central vasculature. Specially designed CVADs are available to meet the needs of a variety of patients, including tunneled devices, ports, PICCs, and IO devices. CVADs are required for the administration of TPN due to the high osmolarity and glucose levels.

# Chapter 11

## Pain Management

*Sherrie Lessans*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Explaining the pathophysiological processes that underlie the pain process
2. Defining types of pain
3. Describing components that comprise a comprehensive pain assessment
4. Examining pain management strategies
5. Developing a comprehensive plan of nursing care for patients with pain
6. Incorporating both pharmacological and nonpharmacological evidence-based interventions into a plan of care for patients with pain
7. Developing patient educational strategies to promote self-care and improved patient outcomes

### CONCEPTS

- Assessment
- Comfort
- Communication
- Medication
- Safety

### ESSENTIAL TERMS

Acupressure  
Acute pain  
Addiction  
Adjuvant  
Allodynia  
Analgesia  
Anesthesia  
Biofeedback  
Breakthrough pain  
Chronic malignant pain  
Chronic pain  
Cutaneous pain  
Dependence  
Epigenetics  
Expectancy  
Gate control theory  
Guided imagery  
Hyperalgesia  
Hypnosis  
Meditation  
Music therapy  
Neuropathic pain  
Nocebo  
Nociceptive pain  
Nociceptors  
Opioid  
Pain  
Patient-controlled analgesia  
Persistent pain  
Placebo  
Plasticity  
Referred pain  
Rubefacients  
Somatic pain  
Tolerance  
Visceral pain

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Martha Jessup is a 68-year-old African American female, 2 days following coronary bypass surgery. She has a medical history significant for hypertension, diabetes, and chronic renal insufficiency. At change of shift, Mrs. Jessup reports 6/10 pain at the surgical site. She further reports spasms in her lower back and “burning” pain that “shoots” down her right leg. She states that “I hurt my back when I was teaching” and has not taken her “usual back pain medications” for more than 3 days. Mrs. Jessup is grimacing; rubbing her right leg; guarding her incision site with a pillow; and taking short, shallow breaths.

Mrs. Jessup is demonstrating a mixed type of pain: acute post-operative pain related to the cardiac surgery and nonmalignant persistent pain in her lower back. In completing a comprehensive pain assessment, the nurse considers how Mrs. Jessup’s age, gender, ethnicity, and prior pain experiences influence her pain experience. Her renal insufficiency with possible inherited genetic influences on pharmacokinetics and pharmacodynamics may influence how well she metabolizes her pain medications as well as her response to pain medications...

## INTRODUCTION

Pain is the most universal and the most personal of symptoms, an emotional and sensory experience shaped by biological, sociocultural, and psychological factors, including genetics, gender, health status, and life experience. No one person experiences pain like any other. The same person may experience pain in different ways, at different times, and under different circumstances, challenging both assessment and treatment. Although pain is the number one reason patients consult a healthcare provider in the United States, pain remains poorly understood, with mixed treatment success. For most patients in pain, a thorough assessment leads to the identification of the source of pain, a diagnosis, and successful treatment. For other patients, the source of their pain is difficult to determine, and a diagnosis is difficult to make. Treatments for many pain problems may bring little in the way of sustained relief or may create challenging side effects to manage.

Pain disrupts lives and represents a significant public health problem. Even with new medications and treatments, most people experience at least one episode of sustained and unrelieved pain in their lifetime. One in three patients presenting to an emergency department identifies pain as the chief complaint, with more than 60% of patients reporting

pain at primary care visits. For the hospitalized patient, pain accompanies surgical treatment, traumatic injury, childbirth, and invasive procedures. Often, the medications and treatments given to treat disorders such as cancer and cardiovascular disease cause pain and disability that linger beyond the treatment period. Pain interferes with sleep, activity, and nutrition patterns as well as relationships and social interactions. Pain contributes to a loss of independence and is frequently linked to the development of anxiety disorders and depression. One in every six adults in the United States reports chronic pain, a condition that is poorly managed or undertreated. Counting both the direct costs of provider visits and medications as well as the indirect costs of lost time from work or school and reduced productivity, the cost of pain is more than \$100 billion each year according to the National Center for Health Statistics.

Nearly 9 of 10 American households have one or more pain relief therapies in their homes, including over-the-counter (OTC) oral medications, analgesic heat rubs, and heating pads. More than 50% of these same households also have prescription pain medications, usually an opioid (opium-based medication used for pain), sharing the medicine cabinet with OTC medications. However, thousands of patients each year fail to satisfactorily manage pain, and the search for pain relief often finds providers who are not knowledgeable about pain management or are unwilling to treat pain that lasts for more than a short acute episode. Relatively few pain specialists are in practice, and they are often concentrated in city centers not easily accessible to rural populations. Health insurance may cover only a portion of the costs associated with comprehensive pain care.

At the end of 2000, President William J. Clinton declared the 10-year period beginning January 1, 2001, the Decade of Pain Control and Research. During this time, funding for pain research nearly doubled, leading to new insights into the biology of pain and a greater appreciation for the pathology that is chronic pain. The American Pain Society, the American Nurses Association, and The Joint Commission all released standards of care requiring that patients be educated about their right to appropriate assessment and pain management, with a special emphasis on pain management in older adults and patients at the end of life. Health professional organizations reaffirmed ethical obligations to relieve pain and alleviate suffering, supporting the growth of an evidence-based intervention science with new approaches to assessment, pain management, and improved quality of life for pain sufferers. This emphasis on improved pain management did lead to innovations in pain treatment, including new classes of medications. By mid-decade however, these advances contributed to only a marginally more complete understanding of the bio-psycho-social complexity that is chronic pain, a tripling of the number of patients addicted to opioids, and an opioid overdose problem that has reached epidemic proportions. Significant challenges continue with pain management, with many gaps in translating research findings into evidence-based pain management practice. Most significant is a fundamental shift in the

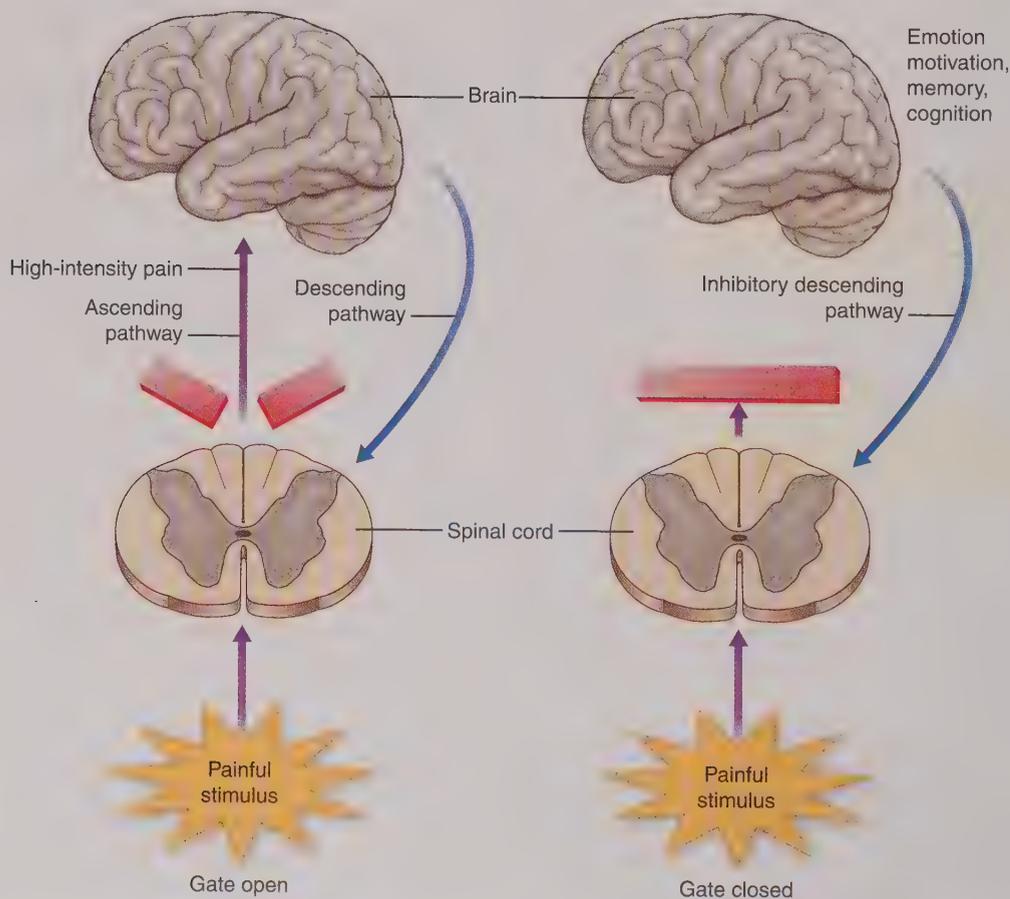

assessment and management of pain that is less focused on relieving all pain and more focused on improving comfort and functional engagement. This paradigm shift in pain care management will powerfully shape the next generation of health professionals.

## DEFINITIONS OF PAIN

For most of the 20th century, the prevailing view was that pain reflexively followed tissue injury, with peripheral nerves rapidly generating and transmitting electrochemical pain messages to the spinal cord and brain, leading to an equally rapid pain response. This peripheral nervous system–centric view failed to explain how or why pain persists for many patients or why chronic pain often appears so disconnected from tissue injury and so difficult to treat. Attention refocused on the dynamic role of the brain and spinal cord in pain messaging in 1965 with the introduction of the seminal **gate control theory**. The impact of this theoretical rethinking and redefinition of pain cannot be overstated. Pain is now understood to be more than the simple transmission of incoming messages to the central nervous system; descending pathways are also widely distributed throughout the brain and spinal cord, which serve to boost or inhibit pain messaging. Many of these specialized pain-messaging and pain-processing pathways are associated with diverse brain structures, including those

shaping motivation, memory, and cognition. It is the job of the spinal cord to integrate input from peripheral tissues with this central descending input by gating “open” or “closed” pain messages to form a neurophysiological response. Although the spinal cord is largely in charge of pain message processing, pain perception is centered in the conscious brain. Pain represents the creative transformation of nerve impulses by the brain into a meaningful and emotion-filled perceptual experience (Fig. 11.1).

With this broader understanding of pain, however, comes confusion about definitions and terminology. Are there physiological differences between acute and chronic pain? Does all pain cause suffering? Is pain relief the same as having no pain? How do health professionals develop a consistent pain language while acknowledging that pain is “whatever the experiencing person says it is”? Second only to gate control theory, this assertion by Margo McCaffery has had the most profound effect on the way healthcare providers assess and manage pain. Although clinicians have largely accepted that pain is subjective, the subjectivity of the pain experience compels the need to prove that pain is present and challenges clinicians when observed pain behaviors are not consistent with other pain experiences. Reliance on self-reports has left clinicians wondering how best to distinguish pain that may signal a medical emergency from more benign pain or whether treatment has provided relief. In 2017 at the most recent consensus conference on

**FIGURE 11.1** Pain perception (gate control theory). The spinal cord integrates painful stimuli from the periphery through descending input controlled by “open” or “closed” gates to form a neurophysiological response. The perception of pain is also influenced by the conscious brain that transforms these impulses into meaningful and emotion-filled experiences.

pain, experts reaffirmed the definition of pain as an unpleasant sensory and emotional experience associated with actual or potential tissue damage while acknowledging that much remains to be understood about the intersection of noxious conditions in the tissues and pain perception.

## Distinguishing Acute and Chronic Pain

Of all the different ways to classify pain, the most common may be a distinction based on pain duration (Table 11.1). **Acute pain** is sudden in onset and usually of short duration, presenting immediately following noxious stimuli and tissue damage and continuing for several hours to several weeks. The close association between tissue injury and sudden onset of pain suggests acute pain serves a biological purpose, alerting us to actual or potential tissue damage and prompting withdrawal or avoidance behaviors. The quick pulling back of the hand, for example, following touching of a hot surface protects the hand from burns. Pain-induced guarding of an abdominal incision reduces tension at the surgical site, minimizing further trauma. Patients frequently describe acute pain as sharp or intense and can generally pinpoint the pain to a well-defined and specific body location. Acute pain is generally responsive to common pain management treatments and predictably resolves as tissue heals. Examples of acute pain include the pain that accompanies trauma such as fractures or wounds and procedure pain. One of the most common examples of acute pain for nurses is postoperative pain following surgical disruption of superficial skin

and muscle. Because postoperative pain is common and predictable, it might be expected that it is well assessed and well managed. Evidence suggests, however, that nearly 70% of patients experience unrelieved pain at some point during their postoperative recovery. Patients themselves delay reporting postoperative pain, believing such pain is to be expected, whereas nurses frequently undermedicate, believing pain treatment may lead to respiratory depression and sleepiness, slowing recovery.

Pain that is present for more than 3 to 6 months, with or without an obvious link to tissue injury, is considered chronic pain. Chronic pain intensity can vary widely; patients describe pain that is aching, dull, stabbing, burning, and icy hot. Patients with chronic pain may also have difficulty localizing chronic pain with more precision than a general region of the body, such as the lower back or legs. Chronic pain is unpredictable in course and resistant to many common pain management approaches and, unlike acute pain, serves no apparent biological purpose. Examples of chronic pain include diabetic peripheral **neuropathic pain** (pain associated with damage or disease affecting the somatosensory nervous system), phantom limb pain following amputation, and fibromyalgia. Acute or chronic pain that responds to some therapeutic interventions but reoccurs when therapies reach the effective end of their dose is termed **persistent pain**. Examples of this type of pain include pain associated with wounds, arthritis, back pain, and some headaches. Although patients with persistent pain may have pain relief with medications, the application of heat, or the application of pressure at specific acupoints, these modalities have time-limited effectiveness, with pain returning as therapies “wear off.” Persistent pain can be particularly frustrating for patients and caregivers because pain solutions appear to work, but there is not sustained pain relief. **Breakthrough pain** is a term used by pain experts without consensus to describe short-term bursts of acute pain that present against a background level of controlled or managed pain. Breakthrough pain can be caused by patient movements, by underlying or escalating pathology, or by being at or near the end of a medication dose. Frequently, breakthrough pain appears for unknown reasons but may be remedied by medication, dose, or schedule modification.

Although chronic pain cannot always be linked to a specific tissue injury, some forms of chronic pain coexist with other health problems with enough frequency that a comorbid relationship between other pathologies and chronic pain must be considered. In **chronic malignant pain**, for example, rapidly dividing cells associated with cancer growth invade and distort bone and other tissues, causing quite severe pain. More than two-thirds of cancer patients report moderate to severe pain during their illness, especially as cancer progresses or becomes unresponsive to therapy. So interconnected are pain and cancer in the minds of cancer patients that fear of pain and fear of addiction are almost as debilitating as fear of cancer and its consequences, in spite of evidence that fewer than 5% of cancer patients become addicted to aggressive and largely effective opioid therapy.

**Table 11.1 Acute and Chronic Pain Characteristics**

Acute Pain	Chronic Pain
Short duration—hours to weeks	Long duration—months to years
Sudden and fairly immediate onset—linked to tissue injury or damage	Sustained or spontaneously acute—cannot always be linked to identified tissue injury or damage
Alerts and prompts withdrawal, avoidance, and protective behavioral responses	Disrupts normal activities, limiting ability to work, sleep, eat, and socially interact
Predictable in course—intensity improves as tissue heals	Unpredictable in course—intensity waxes and wanes over time
Responsive to common pain management strategies	Inconsistently responsive to both common and adjuvant pain management strategies
Examples include traumatic pain, myalgia following exercise, and postoperative pain.	Examples include migraine headaches, low-back pain, peripheral neuropathy, arthritis, and fibromyalgia.

Cancer is not the only chronic illness in which pain is a regular and constant presence. Most patients with chronic illness report moderate to severe pain, including patients with arthritis, sickle cell anemia, irritable bowel syndrome, fibromyalgia, and lupus erythematosus. Some patients with chronic illness in fact report pain as their primary symptom, including patients with migraine or cluster headaches, chronic oral-facial pain, and postamputation pain. Referred to as *nonmalignant* or *noncancer chronic pain*, this type of pain inconsistently responds to common pain treatments, including anti-inflammatory medications and opioids, and is least likely to be adequately managed, according to patients and pain experts.

### Connection Check 11.1

The nurse correlates which findings to the pathophysiology of chronic malignant pain?

- A. Recent trauma
- B. Rapidly dividing cells
- C. Direct damage to nerve fibers
- D. Persistent pain with no known etiology

### Distinguishing Nociceptive and Neuropathic Pain

A second useful way to classify pain is by the point of origin. Pain originating in different tissues has unique biological features that shape both the presentation of pain and its responsiveness to therapy. **Nociceptive pain** results from stimulation of peripheral nerve fibers by noxious stimuli or conditions in superficial skin and tissues as well as bones, joints, and muscles or in organs. Specialized receptors on peripheral nerves sense and respond to noxious mechanical stimuli, including pressure and pinprick, as well as to a range of potentially tissue-injuring cold and hot temperatures. Other specialized peripheral neuron receptors sense and respond to noxious chemical stimuli, including acidic or basic substances, as well as many locally released chemicals, including enzymes and growth factors. Nociceptive pain, when originating in superficial tissues, is termed **cutaneous pain**. Pain originating deeper in the joints, bones, and muscles is called **somatic pain**, whereas pain that has its origins in the organs is termed **visceral pain** (Table 11.2). Cutaneous pain tends to be sharp, with intensity varying from mild to severe. It is easily located to a well-defined area. Examples of cutaneous pain include superficial cuts and minor burns and the pain that accompanies some procedures, such as phlebotomy. Somatic pain tends to be dull, achy, and difficult to localize, although the intensity can also vary from mild to severe. Examples of somatic pain include pain associated with inflammatory diseases of the joints such as arthritis, overuse injuries involving the muscle following exercise, trauma, and degenerative diseases of the bone. Visceral pain can be sharp or dull but is relatively difficult to localize. It can begin in any of the large organs in the

thoracic or abdominal cavity, although the pain sensation is often present in a location some distance away from the source organ. This is known as **referred pain** and occurs when nerve fibers from normally high-sensory areas (superficial tissues) and input from normally low-sensory areas (visceral organs) all converge at a similar level of the spinal cord (Fig. 11.2). When visceral organs generate strong pain signals, the brain is not used to processing pain messages from these sites and interprets this input as coming from more superficial sites. Referred pain can be diagnostic for serious disorders and should be evaluated thoroughly.

The most challenging type of pain to assess and manage follows damage or injury to nervous system structures. This neuropathic pain presents with a mixture of both positive and negative symptoms. Patients report shooting, stinging, or “pins and needles” type of pain at the same time they describe areas where they lack feeling or sensation. *Peripherally generated neuropathic pain* presents in the peripheral tissues but may represent injury or dysfunction anywhere along the nerve pathway that supports that region of the body. Patients with phantom limb pain who, for example, have experienced a limb loss often continue to perceive pain, itching, and numbness in the absent limb. The loss of the limb involves a transection through the nerves supplying that limb. These damaged nerves continue to transmit nociceptive messages, often in hyperexcited bursts, that can permanently alter how the brain and spinal cord process incoming and descending pain messages. Even as the brain can visually recognize the loss of the limb, the perception of pain in the missing limb remains. Other examples of peripherally generated neuropathic pain syndromes include diabetic and alcohol-induced neuropathy, chemotherapy-induced neuropathy, and postherpetic neuralgia. *Centrally generated neuropathic pain* has its origins in injuries to the spinal cord and brain structures. Damage to the nerve roots that enter the spinal cord, the cord itself, or anywhere along ascending or descending central nociceptive pathways disrupts normal pain processing. Some parts of the pain-processing pathways can become hyperactive while others can lose function. New abnormal synaptic connections can form, contributing to sensations of pain that may be felt anywhere in the body. In some primary neurological conditions, such as stroke, Parkinson’s disease, or multiple sclerosis, damage to neurons, their supporting myelin, or the nourishing glial cells that surround the brain and spinal tissue also disrupt pain processing. One condition that has features associated with both peripherally generated and centrally generated neuropathic pain is fibromyalgia. Patients complain of pain and stiffness in the muscle and joints that are often accompanied by cognitive dysfunction, fatigue, disturbed sleep, depression, and anxiety. Evidence suggests these symptoms are associated with abnormalities in the brain regions responsible for these body functions as well as altered neuroendocrine functioning and may follow either prolonged stress or emotional trauma.

Neuropathic pain can last for months to years. The vagueness of complaints, frequently in the absence of diagnosable injury, leads patients on an often-frustrating search for solutions, with many health providers wondering

**Table 11.2 Cutaneous, Somatic, Visceral, and Neuropathic Pain Characteristics**

Type of Pain	Origin	Patient Descriptors	Duration	Other Features	Patient Examples
<b>Cutaneous</b>	Superficial skin and tissues  Easily localized	Tender, sharp, itchy	Short—hours to days	May be extra sensitive to touch in region around painful area; may have some numb areas next to very painful areas	Sunburn, minor cuts and scrapes, some types of procedural pain
<b>Somatic</b>	Deeper tissues, joints, and bones  Can be more difficult to localize area of pain	Dull achy; can be described as cramping, crushing, stabbing, sore, spasm	Can be short to very long	Often presents with reflex muscle contractions and muscle tenderness	Arthritis fractures, exercise- or flu-induced myalgias, some types of procedural pain
<b>Visceral</b>	Mostly hollow organs in the abdominal or thoracic cavities, including heart, bladder, stomach, intestinal tract  Difficult to localize area of pain; often referred to other body locations	Cramping, achy, dull, pressure, stabbing	Can be short or long; if long, can be intermittent or sustained	Often see autonomic nervous system effects, sweating, pallor, nausea, low heart rate and hypotension, syncope, restlessness	Myocardial pain, appendicitis, biliary and pancreatic obstructions, colitis
<b>Neuropathic</b>	Peripheral and central nervous system structures  Difficult to localize; often represents area served by a nerve structure and not necessarily location of nerve injury or damage	Numbness, tingling, shooting, burning, pins and needles, electric shock, stabbing	Long—months to years	Pain often worse at night or at rest; can occur spontaneously without any overt stimuli	Postherpetic neuralgia, phantom limb pain, diabetic neuropathy, chemotherapy-induced neuropathy, carpal tunnel or spinal root compression

about the truthfulness of patient reports. Some patients with neuropathic pain feel dismissed by their healthcare providers as having mental health concerns and not actual pain. New insights into the biology of pain processing are leading to the broader understanding that neuropathic pain is pathological pain; whether arising out of injury to central or peripheral nervous structures, neuropathic pain represents true dysfunction and disorder in the nervous system.

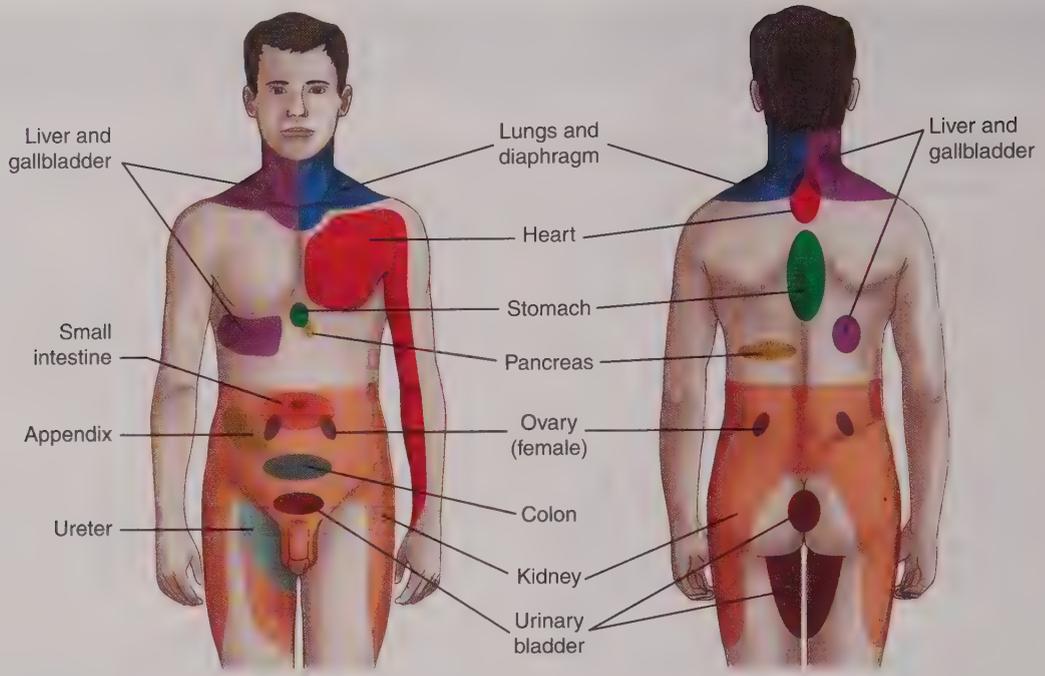

## PROCESSING PAIN MESSAGES

### The Processing of Pain Messages in Acute Pain

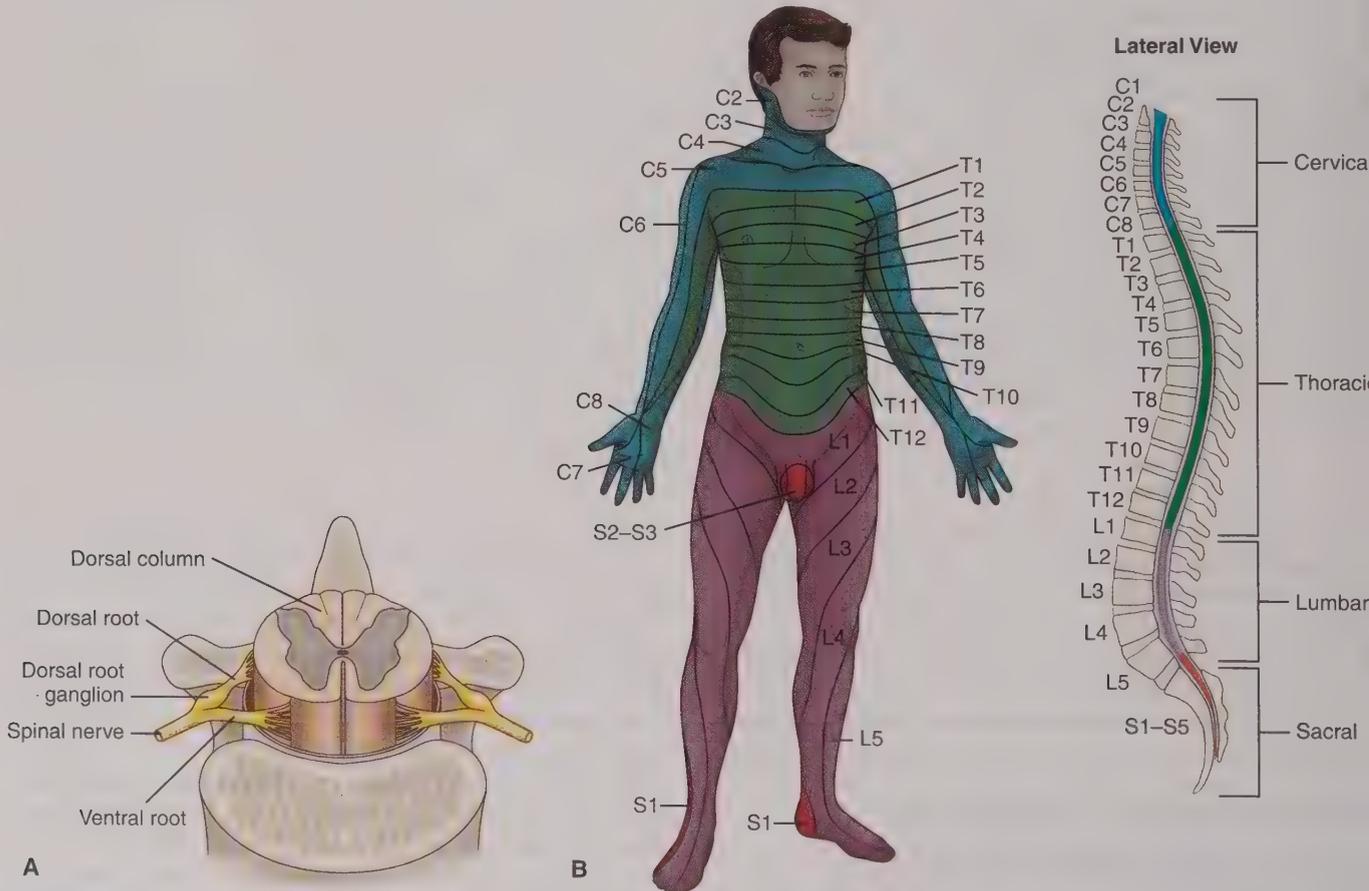

The peripheral nerves that innervate peripheral tissues have several unique features that allow them to sense and transmit information rapidly across great distances on their way

to the spinal cord and brain. Each nerve is composed of a bundle of single nerve fibers surrounded by connective tissue. Each nerve fiber is a long projecting axon for a single nerve cell or neuron leading to a cell body located near the entrance to the spinal cord. Some of these single projecting axons transmitting incoming sensory or afferent information, especially those innervating the distal extremities, can be several meters long. Along the dorsal side of the spinal cord, the cell bodies of these peripheral neurons are grouped in a nodular structure or ganglion called a *dorsal root ganglion* (DRG; Fig. 11.3A). Each DRG represents a large region of the body, and the chain of DRGs along the dorsal side of the spinal cord represents somatic regions, or dermatomes, on the body (Fig. 11.3B).

Dorsal root ganglion neurons are specialized at their terminal ends, all along their axons, and in their cell bodies to

**FIGURE 11.2** Common areas of referred pain. Referred pain occurs when nerve fibers from superficial tissues and visceral organs all converge to a similar level of the spinal cord. When visceral organs generate strong pain signals, the brain is not used to processing pain messages from these sites and interprets this input as coming from more superficial sites. Referred pain can be diagnostic for serious disorders and should be evaluated thoroughly.

**FIGURE 11.3** Dorsal root ganglion (DRG). *A*, Ganglion of nerve cell bodies entering the spinal cord. Cell bodies of peripheral neurons are grouped in a nodular structure or ganglion called a dorsal root ganglion. *B*, Dermatomes of the DRG ganglion chain along the body. Each DRG represents a large region of the body, and the chain of DRGs along the dorsal side of the spinal cord represents somatic regions, or dermatomes, on the body.

respond to different sensory stimuli. Some of these DRG neurons have large-diameter myelin-covered axons that are generally responsive to touch and proprioceptive input. Myelin is critical to nervous system functioning, serving as an insulating material that surrounds some nerve fibers to increase the speed at which electrical impulses move along the nerve fiber.

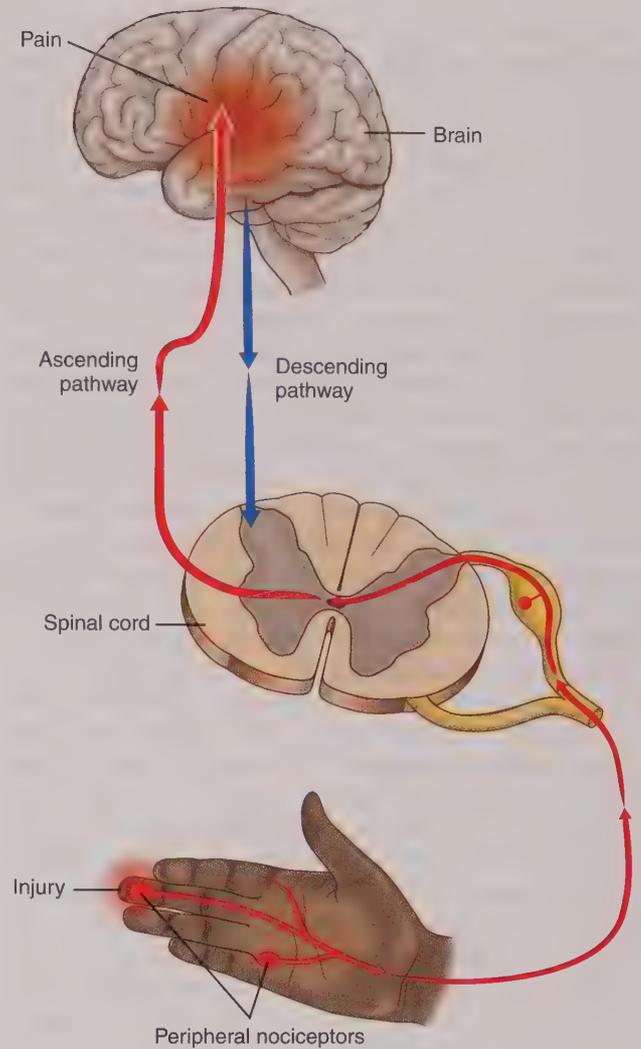

Some smaller-diameter DRG neurons have thinly myelinated axons, unmyelinated axons, or free nerve endings that respond to non-noxious temperatures as well as a wide range of noxious stimuli. Generally, nerve fibers with less myelin conduct sensory information more slowly than larger, fully myelinated fibers. Dorsal root ganglion neurons that selectively respond when stimuli become noxious or potentially injury inducing are called **nociceptors**. Some nociceptors are sensitive to tissue-injuring cold and hot temperatures, whereas other nociceptors are sensitive to mechanical pressure or pinprick. Still other nociceptors sense the presence of tissue-injuring chemical substances, including acids, bases, and specific injury-induced chemical substances released by the body.

Peripheral nociceptive neurons have the ability to convert a cellular response to noxious stimulation into an electrochemical message that is rapidly transmitted to the spinal cord along afferent (sensory) nerve pathways. Once in the spinal cord, peripheral sensory fibers make connections with other specialized pain-processing neurons that then relay pain messages to the brainstem, the forebrain, and finally the cerebral cortex (Fig. 11.4). This structural organization serves to filter, interpret, and influence ascending pain messaging to the brain. It is in the cerebral cortex where these electrochemical nociceptive messages are cognitively interpreted as pain. The pain response is coordinated through many of these same brain and spinal cord structures along descending pain-messaging pathways.

Acute pain is generally understood to be a product of this complex series of pain-processing steps. At every connection, or synapse, in the pain-processing system, there are important neurotransmitters that can either boost or inhibit the transmission of pain messages. In classic gate control theory, these neurotransmitters can either “open” or “close” the gate to the transmission of nociceptive information. Pain researchers have a better appreciation of how these neurochemicals either enhance or inhibit pain processing but are still at a loss to explain why patients experiencing similar injuries experience pain in very different ways. Patients may use a common language to describe their pain because of the specific pain pathways activated in specific types of injuries, but pain intensity varies widely from person to person.

### Dysfunctional Pain Processing Is the Hallmark of Chronic Pain

Evidence suggests that what happens at the beginning of an injury may well shape the pain experience long term. In the earliest stages of an injury, damaged cells release a wide

**FIGURE 11.4** Peripheral sensory fibers make connections with other specialized pain-processing neurons. The noxious stimulation is converted into an electrochemical message that is rapidly transmitted to the spinal cord. Once in the spinal cord, peripheral sensory fibers make connections with other specialized pain-processing neurons that then relay pain messages to the brainstem, the forebrain, and the cerebral cortex, where the nociceptive messages are cognitively interpreted as pain. The pain response is coordinated through many of these same brain and spinal cord structures along descending pain-messaging pathways.

range of chemicals, including histamine, bradykinin, and prostaglandins. Some of these locally released chemicals specifically activate local nociceptors to begin transmitting pain messages to the brain and spinal cord. Other locally released chemicals serve to stimulate the inflammatory response, attracting macrophages and other immune cells to begin the process of local tissue repair. Once attracted to the site of injury, activated immune cells in turn release pain-enhancing chemicals into the local injury environment. These pain-enhancing chemicals include cytokines and growth factors. The net result of this local inflammatory response is to increase the sensitivity of injured tissue to any further stimuli. This sensitization of peripheral tissues serves a protective function to try to minimize further tissue

damage. For example, patients do not normally find their clothes painful to wear, but following sunburn, patients find that wearing clothes is very painful. This **allodynia**, or painful response to normally innocuous stimuli, causes patients to limit stimulation to their injured tissue, allowing it to heal more quickly. These same patients are also likely to be **hyperalgesic**, with an exaggerated response to already painful stimuli. Sunburned patients, for example, rapidly withdraw from a hot surface to protect their already injured tissue from further injury.

Peripheral sensitization has the effect of increasing, prolonging, and amplifying the nociceptive messages that reach the spinal cord and brain, sensitizing these central nociceptive structures as well. Some sensitized spinal and brain nerve cells respond by releasing large amounts of pain-enhancing neurotransmitters, whereas other sensitized central nerve cells release large amounts of pain-inhibiting neurotransmitters. Sensitized nerve cells further respond to this increased neurotransmitter release by altering their synaptic relationships with adjacent nerve cells. Some synaptic connections quiet or die back, some new synapses appear, and some abnormal synaptic connections form, changing the balance of excitation and inhibition in pain processing. Some researchers describe the formation of these abnormal or pathological connections as a form of “cellular memory” that explains why pain may linger after all objective measures indicate tissues have healed.

This structural and functional reorganization of synapses is what allows nervous systems to respond to new experiences, including injury and disease; however, this synaptic flexibility feature, or **plasticity**, is also believed to be what contributes to the persistence and treatment resistance of many chronic pain conditions. There is still a great deal that is not known about how this synaptic reorganization occurs. Why, for example, do two people with similar injuries have different long-term pain experiences? One patient may have persistent pain that gradually resolves as the injury heals, whereas another patient goes on to develop debilitating chronic pain. Many chronic pain conditions have no clear-cut injury as a precipitating event, so it is not clear how or why chronic pain develops in such patients.

## FACTORS SHAPING THE PAIN EXPERIENCE

Some people seem to have a lower threshold for pain, whereas others appear to tolerate a great deal of pain in spite of common anatomy and physiology. Evidence suggests many factors shape the pain experience, including prior experience with pain, expectations of pain, and anxiety, as well as attention to and the situational meaning of that pain for that particular patient. A woman in labor, for example, may be able to endure quite a bit of pain knowing that at the end of this painful experience will be a new life. This same woman in labor, however, may find labor more painful in a subsequent delivery if she had a difficult delivery with a previous birth. The expectation of pain

during phlebotomy is often enough to make this procedure quite painful for one person but not painful to another who is distracted and does not expect the procedure. Patients are naturally apprehensive before surgery, but evidence suggests that patients with higher anxiety use more pain medications in the postoperative period. Patients who receive preoperative education about what to expect and reassurances about postoperative pain medication report less preoperative anxiety and use less postoperative pain medications. Patients who normally describe themselves as having a high **tolerance** for pain find their tolerance influenced by fatigue, nausea, and their ability to cope in the moment. Environmental factors, such as ambient temperature, humidity, light, and noise, and the presence of other people shape the pain experience.

## Sociocultural Determinants of Pain

One of the most powerful influences on the pain experience is the patient’s cultural experience. Social mores and customs shape families, the communities of residence, and the larger culture, just as the larger culture, communities, and families shape biology and behavior. People learn how to respond to pain in subtle and obvious ways. In some families, stoicism is valued, whereas in other families, it is acceptable to more demonstrably display pain. Depending on how health and illness are defined within a community, pain may mean different things. A patient’s cultural experience may lead to increased faith in Western medicine to diagnose and treat pain, whereas another patient’s experiences may reinforce non-Western approaches to managing pain. Limited access to healthcare resources may inspire creative and folk solutions to pain that continue even when access to healthcare is ensured.

Evidence suggests that pain assessment and pain management are likely to qualitatively improve pain diagnosis and pain relief when patients and caregivers share a common ethnicity or cultural perspectives. When the cultural background of the caregiver differs from that of the patient, caregivers are more likely to misread or misjudge the intensity and severity of pain. Language barriers between patient and healthcare providers serve to exacerbate cultural differences. Although educational programs for health professionals attempt to infuse cultural sensitivity into standards and practice, most cultural effectiveness is often and inconsistently gained through trial-and-error learning in actual practice. Nurses need to be aware that language and culture shape the pain experience and should incorporate culturally specific and validated assessment tools and population- or pain-specific dosing guidelines into the standards of care.

## The Influence of Gender and Genetics

Differences in pain sensitivities and the pain experience are both clinically and experimentally observed in humans. Inflammatory arthritis, irritable bowel syndrome, and neuropathic pain, for example, are among many pain conditions

more prevalent among women. Cluster headaches, as well as some muscle and visceral pain syndromes, are more prevalent among men (Table 11.3). Prominent meta-analyses of human pain studies found gender differences in the majority of selected studies, with evidence suggesting women have lower thresholds for pain, rate noxious stimuli as more painful, and have a lower tolerance for intense pain than do men. Gender differences in both clinical and experimental pain generally do not present until after the age of puberty, suggesting a prominent role for sex-linked hormones. Women generally report more pain sensitivity to acute pain during all phases of their menstruating adult lives than do postpubescent men, although these gender differences in pain sensitivity seem to lessen after female menopause. Differences between men and women may represent clearly distinct molecular and neurohormonal pain mechanisms. Gender differences, however, may also reflect the influence of a wide range of cognitive, affective, and sociocultural factors. Many pain researchers use the terms *sex* and *gender* interchangeably, whereas others make critical distinctions between the two terms. When distinctions are made, the term *sex* refers to purely biological differences, whereas the term *gender* encompasses the larger psycho-social-cultural context associated with being masculine or feminine. Modeled and learned behaviors, life history, and factors other than biological differences may influence both pain processing and the pain experience. Gender-role expectations, for example, may discourage men from reporting pain or even seeking regular medical care. On the other hand, women are more likely to have an ongoing relationship with a healthcare professional and may feel freer to report painful symptoms, even as evidence suggests that healthcare professionals may not recognize gender differences in pain presentation or may not take female pain complaints as seriously as complaints presented by males. In children as young as 5 or 6, masculine and feminine stereotypes appear to manifest, with boys more likely

to say they do not pay attention to pain, whereas girls are more comfortable discussing their pain. The incidence of reported pain is higher in people, regardless of gender, when a history of physical or sexual abuse is present. There is also evidence to suggest that women in pain utilize a broader range of coping skills than do men, including how they self-medicate, employ palliative behaviors, and use social supports.

In addition to reported gender differences in pain sensitivities, men and women are noted to respond differently to analgesics. Several studies of hospitalized postoperative patients using **patient-controlled analgesia** (PCA) found that men required more opioid dosing to achieve pain relief than did females. PCA technology delivers a constant low level of background opioid dose that is supplemented by patients choosing to bolus deliver additional opioids, within preset dosing programming. It is not clear whether this difference in therapeutic response represents only sex-influenced differences in opioid metabolism or is a manifestation of a larger gender influence on threshold and self-management strategies. Nonopioid analgesia use differs between genders as well, with men reporting more analgesic relief with ibuprofen (Motrin), one of many NSAID compounds. That women can be simultaneously more sensitive to pain and more responsive to most analgesics suggests a number of mechanistic questions about pain that remain underexplored.

Few pain disorders feature true inherited dominant or recessive genes, although there are rare sensory and autonomic neuropathies that pass generation to generation as well as some familial migraine disorders. Case-controlled association studies of unrelated individuals, however, identify thousands of possible genetic variations between individuals that can influence pain thresholds, tolerance, and response to analgesics. Some of these genetic variants might cause a protein to be malformed or to be produced in excess quantities or even result in a critical protein not being produced at all. For example, genes that regulate the production of several inflammatory cytokines, including interleukin-6, interleukin-1, and interleukin-10, vary extensively between people, suggesting differences in how an inflammatory response can shape the pain experience. Genes that play a role in how nerve cells form connections or synapses with adjacent nerve cells also vary widely between people, suggesting that how a nervous system sensitized by injury structurally and functionally restructures synapses may influence who may develop chronic pain. Genes also shape the pharmacodynamics and pharmacokinetics of medication, increasing the likelihood of toxic effects or altering the body's ability to resolve pain. Gene differences in medication metabolism, for example, can vary across genders, across ethnic groups, and within ethnic groups depending on geography. Genes responsible for some enzymes in medication metabolism pathways, for example, appear in less than 5% of Caucasians of Northern European descent and in less than 1% of people from southern Asia but in more than 25% of people of African descent. Understanding

**Table 11.3 Gender Differences in Prevalence of Human Pain Syndromes**

**Pain Syndromes More Prevalent in Females**

- Inflammatory arthritis
- Migraine headaches
- Irritable bowel syndrome
- Chronic orofacial pain
- Temporomandibular pain
- Neuropathic pain
- Interstitial cystitis

**Pain Syndromes More Prevalent in Males**

- Cluster headaches
- Back pain (slightly more prevalent)
- Visceral pain from nonreproductive organs including the heart and pancreas

how individual genetic differences contribute to pain processing, pain perception, and pain relief is a major research goal, with the promise of targeted or individually designed pain treatments.

## Epigenetics and Pain

Cells, particularly neurons, have evolved considerable ability to respond to both external and internal stressors. One critical evolutionary process involves how cells control access to DNA to shape a cellular response that is moment to moment and not dependent on any change in the basic nucleotide sequence of inherited DNA. **Epigenetics** refers to the cellular processes that allow access to the cell's DNA for transcription, regulation, and production of proteins critical to cell function. Compacting the nearly 2 meters of chromosomal DNA into the relatively small cell nucleus while allowing access for transcription and gene expression requires highly coordinated packaging processes that serve to temporally and functionally control access to DNA throughout the cell cycle. Histones are the chief compacting proteins within the nucleus, forming tight covalent bonds along the DNA backbone that essentially spool the DNA around the histone. The new histone–DNA spool, now called chromatin, organizes as repeating functional groupings of spooled DNA in a “bead on a string” formation, which can either open or restrict transcriptional access to the DNA as needed to shape a cell's response. It is this functionally relevant regulation of gene expression through dynamic remodeling and modification to chromatin that defines epigenetics. For example, the local changes around a cell that result from tissue injury release cellular contents such as histamine into the local tissue environment. This external stress to the cell alters signaling between and within cells that prompts chromatin to unspool a region of DNA, allowing transcription, replication, and the production of anti-inflammatory cytokines and glucocorticoids to respond to the local injury. This access to the DNA, however, is transient and often short-lived, with re-spooling of the DNA and tightening up of the chromatin access to DNA when no longer needed.

Chromatin remodeling processes result from the addition or removal of chemical groups, either to the histone molecule or the DNA molecule, within the chromatin complex. The addition of a methyl group, for example, is called methylation, and the addition of an acetyl group or phosphate group is called acetylation and phosphorylation, respectively. The orchestrated formation and disruption of chromatin that controls transcription also include ways to rapidly and dynamically demethylate and deacetylate protein structures, or remove phosphate groups, as well as recruit a wide range of other modifier proteins in the cell to shape a cellular response. These epigenetic processes have become increasingly important to the evolving science of pain management, representing new targets for pain medications and altering the way injury is managed from moment to moment.

Two of the most therapeutically intriguing insights arising from epigenetics research are suggestions that epigenetic mechanisms play a critical role in the transition from acute to chronic pain and that a wide range of environmental factors across the life span serve as epigenetic primers for individual pain and analgesic response. Evidence suggests that more than 1,000 genes in spinal cord neurons are epigenetically regulated within the first minutes to hours following a peripheral nerve injury. Often, these early modifications are followed by more sustained epigenetic processes shaping synaptic connectivity and are implicated in the formation of long-term pathological pain. Sustained DNA methylation, for example, has been linked to accelerated degeneration of vertebral disks in low-back pain in both animal models and human subjects. Sustained histone deacetylation has been identified as a factor driving long-lived neuropathic pain and decreased responsiveness to morphine analgesia. There is also compelling evidence that pain in the neonate, like that experienced by babies in the neonatal intensive care unit (NICU), epigenetically primes the nervous system, creating conditions that support the development of chronic pain later in life. New medications in development that target epigenetic processes include histone deacetylation inhibitors (HDAC inhibitors) that inhibit the removal of acetyl groups to stabilize DNA access and improve anti-inflammatory responses. Surgeons and anesthesiologists now recognize the pre-, intra-, and post-operative period as a very active period of epigenetic activity with the potential for shaping surgical outcomes. The promise in epigenetics lies in identifying the temporal ordering of chromatin remodeling changes linked to pathology, then therapeutically leveraging the transient and often reversible nature of epigenetic processes to interrupt or otherwise influence a health outcome.

## Pain and Older Adults

As the proportion of the population over 65 years of age grows, healthcare providers are challenged to assess and manage pain in an increasingly older population of patients. The pain assessment tools used in most healthcare settings were developed and tested with younger adults and may lack reliability and validity as pain measures in older adults. For example, evidence suggests that verbal descriptor scales and numerical rating scales become more difficult to use as patients age, with a higher frequency of incomplete or unscored responses. The evidence further suggests that older patients who are not acculturated to visual analog scales or numerical rating scales in their formal education or who may have mild to moderate cognitive problems demonstrate problems reporting their pain using tools that require a level of abstract reasoning. Some older patients with pain reluctantly report pain, feeling as if pain is to be expected and normal or out of fear that pain signals pathology, leading to a diagnostic process that itself may be painful.

The evidence is mixed on the prevalence of pain and pain patterns in older patients. Some studies report that migraine

headaches and low-back pain peak in middle age and decrease as patients age. Other studies report an increased incidence in all types of persistent pain, generalized musculoskeletal pain, and fibromyalgia in older patients. More than half of older patients report mild to moderate intermittent pain as they age, with the incidence of all types of pain more common in institutionalized elderly. Many of these studies date from the late 1980s and early 1990s, and relevant new research is needed to quantify pain experiences as patients age. There is no reason to expect that all types of pain will vary the same way as a function of age given that different pain mechanisms are responsible for different types of pain.

One type of pain in which differences between older and younger adults is most apparent is acute pain, especially acute pain associated with specific injuries or infections. Conditions that are painful in younger adults, such as urinary tract infections or duodenal ulcers, are likely to manifest as subtle behavioral changes in an older adult, including confusion, aggression, restlessness, or a loss of appetite.

The pathophysiological reason for this more subtle clinical presentation is not clear. It is theorized that age-related changes in these target organs or in pain-processing structures in the spinal cord and brain lead to an altered neurochemical response from sensitized nerve cells, changing the way nerve cells form synaptic connections. Instead of pain messages moving along established pain pathways, new synaptic connections are made that divert pain messages to other brain regions. Other types of visceral pain have an atypical presentation in older adults as well, with as many as 30% of adults reporting either no pain with myocardial infarction or referral patterns different from those of younger patients with myocardial pain. Similar atypical presentations are reported for older patients with pancreatitis and appendicitis. Older postoperative patients do, however, report more unrelieved pain, use analgesic agents longer than younger adults, and are more likely to have pain slow their surgical recovery. Inadequate pain control in older adults is associated with greater levels of postoperative confusion, depression of immune and respiratory systems, and increased mortality. Although evidence suggests that common pain treatments, including NSAIDs and opioids, are effective in managing pain in older adults, doses often need to be modified because of age-related changes in medication metabolism. Standard dosing may lead to more toxic side effects, whereas reduced dosages provide effective analgesia.

### Connection Check 11.2

The nurse recognizes that the incidence of pain is greatest in which patient population?

- Active teenagers
- Unemployed adults regardless of age
- Employed middle-aged and older adults
- Older patients who are institutionalized

## COMPREHENSIVE ASSESSMENT STRATEGIES FOR ACUTE AND CHRONIC PAIN

In early 1999, the Veterans Health Administration (VHA) began a system-wide initiative to improve pain management for the nearly 3.5 million veterans cared for nationwide. This VHA program, called “Pain as the 5th Vital Sign,” requires measurement and documentation of patients’ self-report of pain using a numeric rating scale for all clinical encounters. The American Pain Society soon championed this relatively straightforward way to improve pain management, believing the inclusion of pain assessment when assessing blood pressure, pulse, and respirations would give pain assessment clinical priority. This now familiar and widely accepted approach in most clinical settings asks patients to self-report their pain on a standardized 10-integer verbal or visual analog scale, with 0 representing no pain and 10 representing the worst possible pain. Visual scales are available for patients to use to assist in the communication of their pain score. Pain scores of 4 or higher require a clinician response, including a more comprehensive pain assessment and timely intervention. In the years since this initiative was launched, evidence suggests that the widespread use of numerical rating scales has improved awareness of the importance of pain assessment but has not always translated to improved pain management outcomes for patients. One of the big challenges in using a numeric rating scale is that this asks patients to measure their pain only on the single dimension of intensity and does not allow for a more nuanced self-report. A second challenge to using single-dimension tools such as numeric rating scales is that such tools are not designed to measure the mixed pain that most patients actually experience.

As this new decade in pain science is entered, there is a realization that this single-dimension pain scale has likely contributed to patients and caregivers believing the best pain score to have is 0. Pain specialists implicate the 0-to-10 pain-rating system as contributing to both the overprescribing of opioids and the larger opioid misuse epidemic. A new consensus is developing that measuring intensity is only one way to assess pain and analgesia response and that the most effective pain assessment approach is to assess across multiple dimensions of the pain experience.

### Measuring Pain Intensity

The most commonly used pain assessment tools provide valuable and useful information to clinicians about pain intensity. When serially administered over the course of hours to days, these tools reliably measure pain levels in a single patient, allowing staff to implement pain management strategies and measure treatment response. Examples of unidimensional assessment tools include numeric rating scales, verbal rating scales, and visual analog scales. Verbal rating scales ask patients to rate their pain by looking at a list of descriptive words ordered from least to most intense

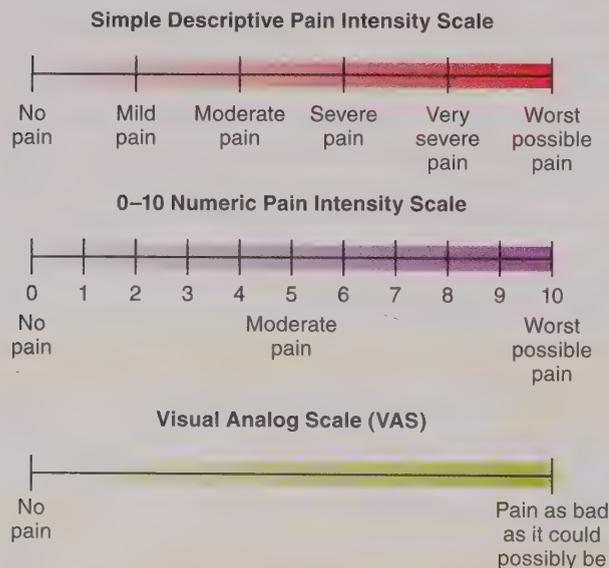

(no pain, mild, moderate, and severe). Patients then select the one word that best describes their pain, with the evaluator assigning a point value that corresponds to the descriptor (no pain = 0, severe = 3). Visual analog scales are structured with a 10-cm horizontal or vertical line with labeled endpoints. One end of the scale is marked “no pain,” and the other end is marked “worst pain ever” or uses a similar phrase to indicate intense pain. Patients place a mark on the line to indicate their level of current pain or indicate their pain by moving a sliding indicator, with the evaluator measuring the distance in centimeters from the low end of the scale as a numerical index of pain intensity. Often the patient is asked to evaluate the pain on not just one visual analog scale but several similarly constructed scales to assess different dimensions of pain besides intensity. Some of these other dimensions of pain include how disturbing or unpleasant the pain is, how close to the surface or how deep the pain is, and how disruptive the pain is to activities of daily living. These tools are reliable for measuring many types of acute pain, with evidence suggesting verbal rating scales are more effective with older people than the more common numeric rating scales (Fig. 11.5).

All of these unidimensional measures of pain are sensitive to measuring treatment response to both pharmacological and nonpharmacological interventions for many forms of acute pain, including burns, postoperative pain, and chronic noncancer pain. Although evidence suggests unidimensional scales may be less effective as measures of chronic pain or mixed acute and chronic pain, there is a clinical preference for numeric rating scales. Most clinicians find them easy to explain and relatively quick to administer; patients also find they are minimally intrusive and conceptually simple to understand. Visual analog scales can be more difficult to administer in many clinical settings, requiring preprinted forms and writing implements as well as

a patient whose vision and hearing are largely intact so that instructions are understood and followed. Patients with motor or physical impairments also have difficulty using visual analog scales. Some of these barriers to using visual analog scales were addressed with the introduction of the visual analog thermometer (Fig. 11.6).

Another useful approach to visual analog measures is to use cartoon faces expressing degrees of discomfort, unhappiness, and pain. Explanations are provided that direct the patient to choose the facial image that best describes how he or she is feeling, with each face associated with a specific score for quantification. Examples include the Wong-Baker FACES tool geared mostly to preverbal populations, such as children, and the FACES pain scale used with older adults with expressive aphasia. Such tools have not been found to be an effective assessment tool for patients with cognitive impairments or to bridge language and cultural differences. Patients from different ethnic backgrounds or who speak languages other than English may not understand or may not view the facial imagery in a qualitatively useful way for assessment.

Barriers to effective use of numerical rating scales, verbal rating scales, and visual analog scales include clinicians who doubt the accuracy of self-report. Some clinicians believe that including a subjective numerical assessment of pain at the same time objective data such as blood pressure and heart rate are collected overstates the qualitative usefulness of pain assessment information, especially because this measures only a single dimension of pain. Often these doubts about the accuracy of self-reports arise from the failure of unidimensional measures to support assessment and effective pain management in complex pain situations, such as in patients with chronic pain or addictions or at the end of life. Although pain intensity is an important aspect of the pain experience, it is not the only dimension of pain important to patients and therefore should not be the only dimension of pain important to clinicians.

**FIGURE 11.5** Pain scales. Pain scales allow patients to rate their pain, as well as responses to pain management modalities.

**FIGURE 11.6** Pain thermometer. The visual analog thermometer is used with patients with motor or physical impairments who may have difficulty using visual analog scales.

### Connection Check 11.3

The nurse chooses which pain scale to most effectively assess pain in an older patient with limited vision?

- A. FACES scale
- B. Numeric scale
- C. Verbal scale
- D. Visual scale

## The Focused Pain Assessment

### OPQRST-AAA

One critical aspect of pain assessment that is underemphasized in most healthcare settings relying on unidimensional measures of pain is the follow-up required to make effective use of this screening measure. Although these tools often advise intervention at pain levels 4 and above, these tools are not designed to recommend specific pain measures. Clinicians have a range of therapeutic options available to them and require more information to appropriately evaluate clinical manifestations and choose an intervention. OPQRST-AAA is a useful mnemonic to use to evaluate pain symptoms, with each letter representing an important area of assessment.

- **O: Onset of pain**  
When the pain first begins is critical to understanding whether the pain is more acute or chronic in nature. Ask patients to describe what they were doing when the pain first started and whether the pain onset was sudden, gradual, or ongoing. Follow-up questions include “What do you believe is causing this pain?”
- **P: Provocation**  
External factors such as movement and clinician examination can elicit a pain response. Ask the patient whether any specific factor, such as turning in bed, sitting, or walking, makes the pain worse.
- **Q: Quality of pain**  
Descriptive words or phrases, such as *sharp*, *dull*, *stabbing*, *burning*, or *crushing*, can give clinicians insight into the pain experience for patients. Open-ended questions such as “Can you describe your pain to me?” can be particularly effective at drawing out pain descriptors. In an urgent situation, leading questions such as “Is your pain sharp or stabbing?” can generate specific and immediate assessment information.
- **R: Region and radiation**  
The location of the pain and whether it radiates or moves to other body areas can be diagnostically significant, especially for deep somatic and visceral pain. Ask patients to point to areas on their body where they feel the pain. Sometimes it can be helpful to ask patients if they can trace the borders of their pain to help localize the extent of the pain.

- **S: Severity of pain**

The terms *severity* and *intensity* are often used interchangeably and generally mean the degree of discomfort associated with pain. Numerical rating scales are often used to gauge patient perception of pain intensity. Frequently, patients use this opportunity to compare this pain to a pain they experienced previously, as in “This is much worse than when I broke my arm” or “This is worse than childbirth.” Patients also describe their pain in terms of how it limits their activities, such as “I cannot sleep” or “I cannot sit for long periods.” These are important subjective comments that are worth noting in an assessment summary.

- **T: Time and duration**

As with onset of pain, the length of time a patient reports pain is diagnostically significant. Ask patients how long the pain condition they are experiencing has been going on and whether it has happened before. Follow-up questions include whether the pain condition has changed for the better or worse since they first had the pain.

- **AAA: Aggravating/Alleviating factors and Associated clinical manifestations**

Ask patients if there is anything they do that makes the pain better or worse. Sometimes focused questions will help them reflect, for example, “If you change your position, does this make the pain better?” or “Does sitting up help you feel better?” Follow-up questions include “Have you taken any medications that help you feel better?” or “Did you use a heating pad or put an ice pack on the area, and did it make it feel better or worse?” and “Do you have any other symptoms such as nausea, sweating, or odd sensations you can describe?”

A brief interview using the OPQRST-AAA mnemonic can be conducted in less than 5 minutes and can occur simultaneously with other assessment activities. The information gained through this structured questioning approach clarifies the nature of the pain experienced by the patient and informs the clinician’s review and selection of effective therapeutic interventions.

Other approaches to more comprehensive pain assessment include using assessment tools that ask the patient to evaluate pain on several dimensions, including the functional impact of pain. Examples of this more comprehensive tool include the McGill Pain Inventory and the Multidimensional Pain Inventory. The use of such structured tools to assess dimensions of pain beyond intensity with structured OPQRST-AAA interviewing techniques yields more complete pain assessments to guide diagnoses and treatment decisions.

### Physical Examination

There are many situations when a screening tool or serial measure, such as a numerical rating scale or the OPQRST-AAA mnemonic, yields insufficient information to support

the diagnosis and management of pain. For example, some patients may not be verbal enough to describe or measure their pain. Other patients present with complex pain conditions that are not easily measured using unidimensional scales or qualified solely through subjective answers to structured interview questions. Selected physical assessment techniques tailored to the pain complaint can support bedside diagnosis to help clinicians choose appropriate therapeutic interventions. The most useful of these techniques for bedside clinicians may be palpation and assessment of range of motion (ROM). Muscle groups in the area of the pain should be palpated, and both verbal and nonverbal response to this palpation should be recorded. Clinicians should also record responses to any assessments of joint flexion, extension, side bending, and extremity lifting to determine whether pain is experienced with movement or whether there are any functional limitations. Consultation with members of the health team may lead to more extensive bedside testing, including a tailored neurological examination consisting of cranial nerve assessments and sensory testing of sensitivity to light touch, pressure, and pinprick, as well as reflexes. A more extensive assessment of motor function may include tests for motor weakness, coordination, balance, and loss of endurance. Many acute care settings provide comprehensive pain teams composed of physicians, nurse specialists, physical therapists, pharmacists, and social workers. These comprehensive pain teams should be consulted early in the presence of complex pain for the best clinical outcomes.

### Connection Check 11.4

In assessing a patient's pain, the nurse asks the patient, "What makes the pain worse?" Which aspect of pain is the nurse determining?

- A. Onset and duration
- B. Intensity
- C. Quality
- D. Aggravating factors

## NURSING MANAGEMENT OF PAIN

### Patient and Nurse: The Therapeutic Partnership

Pain is so common to the patient experience that intervening to improve comfort and reduce suffering is central to the practice of nursing. When patients present with pain, it is frequently a nurse who first assesses the clinical presentation. It is also nurses who are often first to propose a remedy and to encourage self-management strategies. However, it is the critical role nurses play in understanding the larger context and impact of clinical manifestations, such as pain, that is at the core of what nurses are and what

nurses do. Although nurses, physicians, and other health team members work collaboratively to diagnose and treat health problems, it is nurses who are charged with recognizing the physiological and psychosocial responses to health problems that symptoms represent. Nurses are also charged with developing and implementing a comprehensive plan to address symptoms and the impact of those symptoms.

Effective interventions begin with comprehensive assessments of clinical manifestations of pain as well as functional health patterns. Specific tools or inventory forms are regularly used to collect initial or baseline data that establish physiological stability, the risk for physiological instability, and patient habits and routines. This data-collection step is critical to beginning to narrow down the range of risk for nursing diagnoses, identifying actual nursing diagnoses, and determining collaborative care problems with other disciplines. Although relatively few questions on most baseline assessment forms directly ask patients about their pain, in fact, most questions on comprehensive assessments are gathering pain-related information useful to planning effective interventions. Questions that ask patients how they perceive their health and well-being or that assess their knowledge of health practices add context to questions and answers about self-management of pain and adherence to prescribed treatment. Questions that determine usual patterns of food and fluid intake, as well as appetite and food preferences, add perspective to objective data gathered about weight lost or gained. In similar ways, questions that determine activity and exercise patterns, sleep-rest patterns, role and relationship patterns, and coping and stress tolerance patterns help nurses understand the larger impact of symptoms such as pain. This subjective portrait of a patient's health status is combined with physical assessment findings and other objective data to drive the identification of priority nursing diagnoses and a comprehensive plan of care.

### The Care-Planning Process for Managing Acute and Chronic Pain

The reasoning process that guides the nurse from data collection to nursing diagnoses begins with listing individual signs, symptoms, and health needs. Next, the nurse evaluates the significance of individual pieces of data, sorting them into significance clusters or diagnostic cues. These diagnostic cues help nurses formulate diagnostic hypotheses. Diagnostic hypotheses represent inferences or tentative explanations for specific pieces or clusters of data cues that require further investigation. To confirm a diagnostic hypothesis, nurses may need to validate the accuracy and reliability of key pieces of data, distinguish normal from abnormal findings, and recognize inconsistencies and possible information gaps. Nurses, for example, may need to recheck a blood pressure or follow up a patient interview with a corroborative family interview.

**CASE STUDY: EPISODE 2**

On the third postoperative day after Mrs. Jessup's coronary bypass surgery, at change of shift, the night nurse reports that Mrs. Jessup is sleeping poorly at intervals. She was medicated for surgical-site pain twice with oral opioids and once with ketorolac (Toradol) IV. She got up twice with the assistance of two caregivers to use the bathroom but otherwise indicated she "was not up to walking in the hall." She remains on oxygen at 3 L via nasal cannula, with oxygen saturations in the low to mid-90s. She has a poor cough effort, and she is able to achieve only 450 mL with her incentive spirometer. She continues to report lower back spasms and shooting, burning pain down her right leg that is not relieved with pain medications.

The nurse quickly reviews the admission database to determine her functional health patterns at baseline, identifying long-standing sleep complaints and diminished activity patterns at home. The nurse completes the morning assessment: Mrs. Jessup's blood pressure is elevated at 165/84, her pulse rate is 104 bpm, and her respiratory rate is 22 and shallow. Diminished breath sounds at the bases are noted on auscultation. Mrs. Jessup reports pain that is 4/10 in the area of her incision, along with back and leg pain that "comes and goes" between 2/10 and 9/10. She is lying in bed, grimacing, and rarely opens her eyes. Her answers to questions are terse, short responses...

### Nursing Diagnoses for Patients in Pain

The thinking language nurses use to organize and focus nursing care is the nursing process, organized around prioritized nursing diagnoses. A well-developed and well-constructed nursing diagnosis defines and shapes problem solving. When nurses identify a problem such as anxiety, insomnia, or delayed surgical recovery, they are choosing a diagnostic label that represents their reasoned conclusions arising out of data collection and data validation. This same process of reasoned evaluation of assessment data leads to the identification of related factors that have either caused or contributed to the identified health problem.

The value of diagnostic labels and the identification of related factors are often underappreciated. Not only do diagnostic labels focus nursing attention on prioritized care problems and define patient goals in the care-planning process, but the identification of related factors also guides critical interventions. It may seem self-evident that the grimacing postoperative patient reporting a variable 2/10 to 9/10 level in his or her pain should be diagnosed as being in acute pain, with the care goal being improved patient comfort. However, if this same patient is also breathing

shallowly, guarding with incisional pain, and presenting with a decreased oxygen saturation level even on supplemental oxygen, the diagnostic label of ineffective respiratory function represents a more completely reasoned evaluation of a comprehensive assessment. Rather than being the primary problem, in this circumstance the acute pain the patient is experiencing is part of the related factors that are shaping the larger diagnosis of ineffective respiratory function. The nursing plan of care would include management of pain in either diagnosis. However, the nursing goal for this patient is not necessarily to improve comfort; rather, it is to improve respiratory functioning and gas exchange. Nurses who too narrowly diagnose either acute or chronic pain for their patients in pain run the risk of missing priority care problems by failing to acknowledge the significant life and health impacts of pain, as well as the risk of not choosing an intervention appropriate to meeting the larger care priority. A re-focus on understanding how to optimize and improve system functioning also has the benefit of increasing reliance on a broader range of pain management options, lessening overuse of pharmacological remedies, and reframing patient expectancy on improving comfort and not total pain relief.

For patients in pain, the impact is far ranging. The activation of pain-processing networks in the brain and spinal cord engages hormonal responses and stimulates sympathetic and parasympathetic nervous system responses. It is not uncommon to see elevations of heart rate and blood pressure as a result of pain, which can exacerbate preexisting health conditions such as heart failure or kidney impairment. Pain may limit the ability of someone to work or engage in previously enjoyable social situations. Pain may limit partner intimacy and alter interpersonal relationships. Pain may cause patients to question their beliefs, their values, and their self-worth. Pain may disrupt sleep or affect a patient's appetite. Pain medications may alter elimination patterns or compromise the physiological integrity of vital organs such as the liver or kidney. In order to develop a comprehensive plan of care for the patient in pain, it is critical to once again review how clinical manifestations impact functional health patterns. Many site-based comprehensive assessment forms use some organizing framework to understand the impact that the clinical presentation has on the well-being of the patient and the patient's family unit. This wide-ranging impact is reflected in the diversity of diagnostic labels that can focus nursing diagnoses for patients who are in pain (Box 11.1).

Identifying which diagnostic label best defines the patient's priority nursing problems rests with the reasoned interpretation of data cues, including the patient's subjective report of problem urgency as well as clinician interpretation of physiological stability. So not only must the diagnostic label be appropriately identified for each patient, but a focused nursing diagnosis must also identify the correct etiology (or "related to factors" that are part of the diagnostic statement), or nurses run the risk of not

### Box 11.1 Nursing Diagnoses Relevant for Acute and Chronic Pain

- Acute pain; chronic pain
- Ineffective respiratory function
- Risk for aspiration
- Risk for injury: falls
- Ineffective management of therapeutic regimen
- Ineffective health maintenance
- Imbalanced nutrition greater or lesser than body requirements; deficit or excess fluid volume
- Constipation; risk for constipation
- Risk for impaired renal function
- Activity intolerance
- Impaired physical mobility
- Fatigue
- Insomnia; sleep deprivation; disturbed sleep pattern
- Anxiety; fear
- Acute confusion
- Disturbed body image
- Interrupted and dysfunctional family processes
- Impaired social interactions; social isolation
- Risk for loneliness
- Ineffective role performance
- Ineffective sexual patterns
- Compromised family coping; disabled family coping

intervening appropriately or wasting both nursing time and resources on ineffective interventions.

#### Measuring the Effectiveness of Care

Although data gathered through physical assessment, review of critical laboratory values, and structured questioning provide the evidence necessary to support the diagnostic labels that focus problem solving, this same evidence is used to measure both the success of nursing interventions and, ultimately, problem resolution. The nurse must provide both targeted pain medications and non-medication-based therapies designed to address the pain, such as thoughtful positioning and appropriately resourced assisted ambulation that promotes effective pulmonary hygiene. Organizing physical activity in the daytime combined with clustered nursing activities at night is an intervention designed to promote sleep and rest. When these care organizing strategies are combined with thoughtful use of massage and relaxation techniques, as well as pharmacologically appropriate medications to promote pain and sleep, nurses increase the likelihood that patients sleep more regularly and restfully. The success of nursing interventions and focused problem solving can be measured both by observational reports from night staff about the length of sleep periods overnight and by subjective reports from the patient about the quality of that sleep.

## PAIN MANAGEMENT OPTIONS

### Therapeutic Interventions to Promote Pain Relief

#### Pharmacological Treatment Options

The ready availability and general reliability of most pain medications mean that pharmacological treatments are among the first interventions used to bring pain relief. Since 2005, there has been tremendous growth in the variety of medications available, with strong evidence supporting the best pain practices. The nurse's role in intervening and advocating for effective pain management depends on understanding the broad range of treatment options.

#### Nonopioid Analgesics

Medications that reduce pain sensations without also inducing a loss of consciousness are called **analgesics**. The most common analgesics are nonnarcotic and nonopioid. This classification of pain medications includes three general categories of medications: salicylates (aspirin), acetaminophen (Tylenol), and NSAIDs. Medications such as ibuprofen or ketorolac exert their effect largely in the periphery, although some mechanisms of action have been identified in central nociceptive processing structures. Aspirin and NSAIDs are believed to reduce pain largely as a result of inhibiting local prostaglandin synthesis. Because prostaglandin is one of the chemicals released at the site of an acute injury that stimulates inflammation, the net effect of aspirin and NSAID administration is anti-inflammatory. Systemic effects of prostaglandin synthesis inhibition include a reduction in serotonin levels in the brain, lessening the effect of this critical pain-processing neurotransmitter. Acetaminophen has a similar analgesia effect as aspirin, although acetaminophen has few anti-inflammatory effects. Acetaminophen is believed to also activate one of the body's own natural pain-inhibiting neurochemical systems in the peripheral and central nervous systems, the cannabinoid system, to inhibit pain processing and minimize structural and functional reorganizing of central pain-processing synapses.

NSAIDs represent a broad category of anti-inflammatory medications. Originally developed to treat arthritis, they are also effective in treating a wide range of nonarthritic pain conditions. Because NSAIDs vary in both their potency and their elimination half-life (Table 11.4), different NSAIDs are recommended for specific pain complaints. Low-potency NSAIDs with a short elimination half-life, such as ibuprofen (Motrin, Advil), are particularly effective for patients with acute inflammatory pain, as well as visceral pain such as menstrual cramps. The rapid elimination of ibuprofen from the body means that it is safe to use for most patients, even those with severe liver or kidney impairments. NSAIDs with high potency and short elimination half-lives, including diclofenac (Voltaren) and ketorolac (Toradol), are effective in treating rheumatoid arthritis pain and acute gout. Because these NSAIDs also block the production of injury-induced proinflammatory molecules called *leukotrienes* in the upper

**Table 11.4 Potency and Elimination Half-Life for Commonly Prescribed NSAIDs**

<i>Half-Life</i>	<i>Potency</i>		
	<b>Low</b>	<b>Intermediate</b>	<b>High</b>
<b>Short</b>	ibuprofen (Motrin, Advil)		Diclofenac (Voltaren) Ketorolac (Toradol)
<b>Intermediate</b>		Diflunisal (Dolobid) naproxen (Aleve, Naprosyn)	
<b>Long</b>			Oxicams (meloxicam, piroxicam) Selective COX-2 inhibitors Celecoxib (Celebrex)

respiratory tree, they are particularly effective at treating postoperative pain following lung and thoracic surgery. Intermediate- to high-potency NSAIDs with longer elimination half-lives, including diflunisal (Dolobid), naproxen (Aleve), and the oxicams (meloxicam), have proven effective at treating migraine headaches, activity-induced muscle aches, and even cancer pain, but they must be used cautiously with patients with renal impairment. Because the body depends on local prostaglandin release to support small vessel vasodilation, especially in the kidneys, blocking prostaglandin release impairs the ability of the kidney to cope with low renal blood flow. This prostaglandin-blocking effect is magnified in kidneys with preexisting blood flow-sensitive impairment. Nonopioid analgesics are very effective when combined with opioids, potentiating the opioid effects. Oxycodone has been combined with aspirin (Percodan), acetaminophen (Tylox, Percocet), and ibuprofen (Combunox) to treat acute dental pain, orthopedic pain, and cancer pain. Hydrocodone has also been successfully combined with acetaminophen (Lortab, Vicodin) as well as ibuprofen (Vicoprofen) to treat both acute and chronic pain.

#### **Monitoring the Risks and Benefits of Nonopioid Analgesic Use**

The broad benefits associated with nonopioid use need to be balanced with the risks associated with these therapies, including the risks associated with the mechanism of action and with the mechanisms of metabolic clearance. Aspirin, in addition to effects on prostaglandin synthesis, inhibits platelet aggregation, thus its secondary use for cardiovascular prophylaxis in patients at high risk for myocardial infarction or cerebrovascular accident (stroke). The reduced ability for platelets to aggregate following aspirin intake increases the risk for bleeding from wounds, incisions, and even minor cuts or scrapes. Patients taking aspirin as well as other anti-inflammatory medications, including most NSAIDs, are also at increased risk for thrombocytopenia (low platelet count).

This side effect is not well understood, but the relationship between medication intake and the onset of reduced platelet counts suggests that thrombocytopenia may result from an immune response to these medications in patients with a heightened systemic inflammatory response following injury. A drop in platelet counts can occur fairly quickly and is likely to reoccur with subsequent use of the medication.

Cyclooxygenase (COX) is an enzyme critical in the synthesis of prostaglandin. Aspirin and most NSAIDs interfere with prostaglandin synthesis by COX inhibition. There are two major COX isoenzyme variations, COX-1 and COX-2. These COX isoenzymes have similar functions, but inhibition of different COX isoenzymes has a different physiological effect and presents different side-effect risks. Cyclooxygenase-1 isoenzymes are present in every cell type throughout the body. Their role in producing nearly constant levels of prostaglandins and related molecules helps maintain physiological homeostasis in many organs, including the lungs, kidneys, and stomach. Inhibition of COX-1 by NSAIDs is particularly harmful to the gastrointestinal tract, disrupting the protective lining of the stomach and increasing the risk for gastrointestinal ulcers and bleeding even at recommended dosages and with short-term use. Inhibition of prostaglandin synthesis can also compromise uterine wall integrity, and for this reason, NSAIDs are discouraged in the third trimester of pregnancy to minimize the risk for premature labor. Cyclooxygenase-2 isoenzymes are produced only by activated immune cells, including macrophages. The anti-inflammatory and antipyretic effects of aspirin and NSAIDs are believed to be largely associated with COX-2 inhibition. To address the risk associated with COX inhibition, several NSAID compounds have been developed that leave COX-1 enzyme function intact but selectively block COX-2. These compounds, including celecoxib (Celebrex), have limited benefit for managing acute pain because of their slow absorption and slow elimination, but they are effective at managing chronic osteoarthritis pain.

**Safety Alert** Longitudinal studies of the selective COX-2 inhibitors revealed an increased risk of thrombotic events, including myocardial infarction and stroke, leading to rofecoxib (Vioxx) being pulled from the market in 2004. Other selective COX-2 inhibitors remain in use, with their risk for thrombotic events not fully quantified.

As with most high-potency NSAIDs with long elimination half-lives, selective COX-2 inhibitors should be used cautiously in patients with renal impairment.

Acetaminophen also inhibits COX, with specific selectivity for COX-2, but has few if any anti-inflammatory effects. Acetaminophen is metabolized in the liver and excreted in the kidneys. When used at therapeutic dose limits of 1,000 mg per single dose and 3,000 mg in 24 hours, acetaminophen is generally safe for use in patients with healthy livers. Doses need to be adjusted for patients with liver impairments or not used at all. Extra precautions need to be taken to educate patients about taking OTC acetaminophen with any other OTC or prescription products. Patients may not be aware, for example, that OTC cold preparations and prescription pain medications, such as Tylox and Vicodin, also contain acetaminophen. The risk of accidental overdose leading to liver failure has been associated with cumulative acetaminophen doses of greater than 3,000 mg per day.

**Safety Alert** ● Be alert to combination medication preparations that contain acetaminophen, for example, Percocet, which includes acetaminophen and hydrocodone. Total acetaminophen doses should not exceed 3,000 mg in 24 hours because there is a risk for liver damage and failure.

- Patients should also be instructed to read medication labels closely and avoid any that contain acetaminophen if they are taking prescription narcotics that also contain acetaminophen.
- Recent studies link acetaminophen (Tylenol) taken during pregnancy to the development of attention deficit-hyperactivity disorders in children; because of the warnings and recommendations to limit the use of NSAIDs and acetaminophen during pregnancy, pregnant women should consult their providers for the best recommendations to manage pain and fever during pregnancy.

Significant drug–drug interactions are also noted in patients taking nonopioid analgesics and prescription medications (Table 11.5). Because many of the nonopioids, including aspirin, acetaminophen, and NSAIDs, are OTC, patients may self-treat minor aches and pains but not appreciate the interaction effects with other common prescription medications, including insulins, antihypertensive medications, and diuretics.

**Table 11.5 Drug–Drug Interactions With Common Over-the-Counter Nonopioid Analgesics**

Nonopioid Medication	Decrease Effect of	Increase Effect of + Toxicity Risk	Monitor
Aspirin (acetylsalicylic acid)	Proton pump inhibitors, antacids, H <sub>2</sub> -receptor blockers	Cyclosporine, tricyclic antidepressants, warfarin, calcium-channel blockers, oral contraceptives	Platelet counts Signs of bleeding
Ibuprofen (Advil/Motrin)	Thiazide diuretics	Digoxin, lithium, warfarin, cyclosporine, insulins	BUN, creatinine, AST, and ALT
Acetaminophen (Tylenol)		Increased hepatotoxicity with barbiturates, alcohol	AST, ALT, bilirubin, dark urine, BUN
Ketorolac (Toradol)	Thiazide diuretics	Lithium, cyclosporine Increased bleeding risk with anticoagulants and aspirin  Increased renal impairment with ACE inhibitors	BUN, AST, ALT, dark urine, tinnitus may indicate toxicity
Celecoxib (Celebrex)	ACE inhibitors	Lithium, anticoagulants	Platelet counts, BUN

ACE, Angiotensin-converting-enzyme; ALT, alanine aminotransferase; AST, aminotransferase; BUN, blood urea nitrogen.

## Connection Check 11.5

The nurse incorporates which content in the teaching plan for the patient receiving Coumadin?

- “It is important to take a stool softener to prevent constipation.”
- “Over-the-counter NSAIDs may increase the anticoagulation effect of Coumadin.”
- “This medication may cause drowsiness, so please do not take it before driving.”
- “You will need to monitor your blood glucose levels while on this medication.”

## Corticosteroids

Corticosteroids are naturally occurring steroid hormones produced in the adrenal cortex. These steroids are involved with the body’s stress response to illness and injury and play a role in the body’s immune response and inflammation. Synthetic steroid hormones, such as prednisone (Deltasone) and hydrocortisone (Cortef), are used as anti-inflammatory agents to treat arthritis, bone pain, and painful dermatitis as well as visceral pain conditions, including lupus erythematosus, sarcoidosis, and inflammatory bowel disease. They are also successfully used to treat acute inflammation and pain following nerve and spinal cord injuries and are used as **adjuvant** (increasing effectiveness of other medications) therapy for pain control in cancer patients. Corticosteroids work by blocking the synthesis of proinflammatory molecules, such as prostaglandin and leukotrienes. Corticosteroids can be delivered at low doses in topical creams, ointments, and drops. Higher doses can be given orally, inhaled, directly injected in targeted regions such as joints, or delivered intravenously. Secondary effects of steroid use include improved appetite and mood, which can also shape the pain experience. High-dose or sustained corticosteroid use is associated with several side effects, including hyperglycemia, weight gain, myopathies, and Cushing’s syndrome, as well as mental status changes, including delirium and psychosis. Dosage adjustments can minimize side effects; tapered discontinuation of corticosteroids is preferred over the sudden cessation of medication to prevent adrenal suppression and steroid withdrawal syndrome. Corticosteroids should not be used in combination with NSAIDs to minimize the risk of gastrointestinal bleeding.

## Local Anesthetics

Local anesthetic agents are pharmacological substances, either topically applied or injected into nerves and tissue, that eliminate sensation and pain without the loss of consciousness associated with general **anesthesia**. Local anesthetics are generally used in a defined location to accommodate minor surgery or to regionally target pain. Lidocaine (Xylocaine) is the most commonly used local anesthetic medication. Lidocaine alters the excitability of neurons by

blocking fast voltage-gated sodium ( $\text{Na}^+$ ) channels in the cell membranes responsible for propagating pain messages along nociceptive pathways. It acts quickly, usually within 10 minutes, and can last as long as 2 hours. Bupivacaine (Marcaine) is more potent and longer lasting than lidocaine and is used often as an injection for nerve blocks and as an epidural anesthetic. Bupivacaine also carries a greater risk for central nervous system and cardiac toxicity, so doses must be carefully adjusted. It can take as long as 20 minutes for bupivacaine to achieve anesthesia, but the effects can last as long as 8 hours when given as an epidural. Bupivacaine can also be injected into the tissues around a surgical wound intraoperatively, providing pain relief for as long as 20 hours.

Local anesthetics relax vascular muscle walls, bringing increased blood flow into the region. This increased blood flow can increase systemic medication absorption, which shortens effective anesthesia times. To maximize local anesthetic effectiveness, these anesthetic agents are often combined with short-acting vasoconstricting agents such as epinephrine. This allows the anesthetic agent to stay regionally active for a longer period of time and limits potential systemic toxicity from too-rapid absorption. Local vasoconstriction also reduces bleeding in the area of injection. Epinephrine-lidocaine combinations, however, are not recommended for small, confined, vascular-rich areas, such as the penis, fingers, or toes, where local vascular constriction can cause inadequate blood flow and tissue necrosis.

**Safety Alert** All medication labels should be read closely prior to administration. Vials containing lidocaine with epinephrine solutions look nearly identical to vials containing lidocaine without epinephrine, and using the wrong preparation can cause vascular injuries.

Local anesthetics are also diluted and compounded into sprays, pastes, and creams that can be applied to minor burns and abrasions. A commonly used mixture of local anesthetics (EMLA) is a combination ointment consisting of 2.5% lidocaine and 2.5% prilocaine and is applied to provide superficial dermal anesthesia for venipuncture, IV catheter insertion, and minor wound debridement. Applied 45 to 60 minutes before a procedure and covered with an occlusive dressing, EMLA provides up to 2 hours of local anesthesia once the occlusive dressing is removed. Dilute lidocaine anesthetic sprays and lozenges help soothe sore throats and aid in anesthetizing oral mucous membranes in preparation for tracheal or nasogastric intubation.

## Topical Rubefacients

**Rubefacients** are topically applied substances that cause local dilation of blood vessels and reddening of the skin, producing local sensations of coolness and warmth that

many people find soothing. Examples of rubefacients include rubbing alcohol, menthol-containing ointments and creams, salicylates (e.g., aspirin), and oil of wintergreen. Products such as Icy Hot and Bengay, which contain menthol, and aspirin-containing creams, such as Aspercreme and Myoflex, are used to treat low-back pain and general muscle aches associated with activity. Many homemade and folk recipes contain herbal rubefacients such as horseradish, nettle, garlic, cloves, rosemary oil, and turpentine. Rubefacients are believed to relieve pain by serving as a counterirritant. Rubefacients are often compounded to have a strong “medicinal” smell that is also believed to distract or offset the pain and are the most widely purchased OTC pain remedies after oral nonopioid analgesics. Rubefacients should not be used to treat painful dermatitis following radiation treatment because radiation damages epithelial cells and alters the permeability of the vascular bed, and the use of topical rubefacients can worsen radiation-induced dermatitis.

Capsaicin, the active ingredient in chili peppers, is frequently used in topical ointments and dermal patches to produce localized, soothing warm and hot sensations. Capsaicin is believed to activate specific temperature-sensitive receptors on peripheral neurons, causing a rapid propagation of warm and hot impulses to the spinal cord. At the level of the spinal cord, these heat impulses cause rapid release and emptying of stores of a pro-pain neurotransmitter called *substance P*. Until these neurotransmitter stores recover, which could be as long as 6 to 8 hours, these particular peripheral neurons cannot induce a pain response. In patient comparison studies, the evidence in support of capsaicin heat for providing effective pain relief is stronger than for the heat produced by other rubefacients. At low concentrations, capsaicin (Capzasin, Tiger Balm) is used to treat minor musculoskeletal aches and pains, including arthritis, backache, muscle strains, and sprains. At higher concentrations, capsaicin-containing ointments and patches have been used to treat the postherpetic neuralgia associated with shingles as well as other peripheral neuropathies. Gloves should be worn when applying capsaicin ointments and patches to avoid clinician exposure, and they should not be applied to open or broken skin. At higher doses, face masks, protective eyewear, and gloves are recommended for clinician safety. Capsaicin creams are not recommended immediately after hot baths or showers, nor are they recommended to be used with heating pads because the additional heat may allow for overabsorption of the medication.

## Opioids

Considered primary in the treatment and management of acute pain, opioids are among the oldest known substances used for the treatment of pain. It is increasingly recognized that opioids are much less effective in managing the pathologies underlying most chronic pain conditions, and their use in chronic pain should be carefully evaluated. Opioids work by binding to opioid receptors that are located primarily in the brain, in the spinal cord, and along peripheral nerves

and the gastrointestinal tract. These opioid receptors are classified as delta-, kappa-, and mu-type receptors (Table 11.6), with the physiological effect of opioids dependent upon the location, type, and binding affinity between medication and receptor. Some opioid receptors located in ascending pain-transmission pathways are activated by opioid medications and block the effects of pro-pain neurotransmitters, including substance P and glutamate. Other opioid receptors located in descending pain pathways are activated by opioid medications and enhance naturally occurring pain-inhibiting processes. It is the action of opioids on receptors in other brain regions, such as the hypothalamus and pituitary gland, that produces the autonomic effects seen with opioids, including pupil constriction, dry mouth, lowered body temperature, and reduced sensitivity to cold. Opioid activation of receptors in the brainstem mutes the activity of the sympathetic nervous system and causes relaxation, sedation, slowed breathing, and reductions in anxiety. Other effects of opioids on brain receptors activate the chemoreceptor trigger zone, which can induce nausea and vomiting.

Opioids are used in the treatment of severe to moderate pain and are often administered to postoperative patients (Box 11.2). Although most often administered via the oral route, opioids may be given via the IV, subcutaneous, intraspinal, transdermal, rectal, and epidural routes. Oral dosages may provide the most consistent therapeutic levels of these medications, but they must be administered at appropriate intervals. Patients may not receive adequate pain

**Table 11.6 Overview of Opioid Receptors and Physiological Effect of Opioid Binding**

Receptor	Location	Opioid-Binding Effect
<b>Delta</b>	Brain	Mild analgesia
	Peripheral sensory neurons	Antidepressant effects
		Stimulates respiration at low doses but slows respiration at high doses
<b>Kappa</b>	Brain	Analgesia
	Spinal cord	Sedation
	Peripheral sensory neurons	Miosis Dysphoria
<b>Mu</b>	Brain	Respiratory depression
	Spinal cord	Miosis
	Peripheral sensory neurons	Euphoria
	Intestinal tract	Reduced gastrointestinal motility

## Box 11.2 Dsuvia—New Opioid Approved by the FDA

In 2018 a new opioid, Dsuvia, was approved by the U.S. Food and Drug Administration (FDA). However, in light of the opioid epidemic in the United States, the approval was met with controversy and some criticism. Dsuvia is a formulation of sufentanil that is administered sublingually through a 30-mg disposable, prefilled single-dose applicator. Restricted to use only in settings that provide direct supervision by healthcare providers, such as hospitals, surgical centers, and emergency departments, this medication is 10 times more potent than fentanyl. Proponents of the new medication describe some of the unique features of the medication, including the ability to quickly administer an opioid to patients who are unable to swallow oral medication or when IV access is unavailable. One of the primary target populations for this new medication is patients in military settings, where Dsuvia meets a specific but limited unmet medical need in treating military members on the battlefield. This medication is not intended to be used as a first-line choice for pain relief in the general population, and it is only indicated under direct supervision in patients whose pain has not been controlled by more conventional pain approaches.

Gottlieb, S. (2018). *Statement from Commissioner Scott Gottlieb, M.D., on agency's approval of Dsuvia and the FDA's future consideration of new opioids* (U.S. Food and Drug Administration Statement). Retrieved from <https://www.fda.gov/NewsEvents/Newsroom/PressAnnouncements/ucm624968.htm>

relief because of a fear of side effects or fear of addiction, which is not the same as tolerance. Tolerance is characterized by the need for increasing doses of medication to get the same pain results. **Addiction** is characterized by a compulsive behavioral pattern to take a medication for both its physiological and psychic effects without regard for the negative consequences associated with continued medication ingestion. The growth in addiction, particularly to new synthetic opioid formulations, over the last 5 years has reached epidemic proportions. The numbers of patients addicted to opioids tripled in the years between 2003 and 2014, with the number of opioid overdose deaths annually now exceeding those dying from gun violence and motor vehicle deaths combined. Although there has been a national initiative to limit opioid-prescribing patterns, opioid overdose deaths are cited as a significant contributing factor to the recent drop in life expectancy, the first such drop in more than 50 years.

Patients receiving opioids are at risk for several side effects, particularly related to actions at the mu receptor sites, and prevention and management of these effects are central to any plan of care for patients receiving opioids. Respiratory depression is the most critical adverse side effect of opioids and requires close patient monitoring, especially after IV administration. Nausea and vomiting, frequent side effects, usually develop shortly after the first doses. In the

postoperative patient, assessment for nausea and vomiting is particularly important because it increases the risk of aspiration. Patients experiencing pain often have decreased physical activity and oral intake; these circumstances, along with the effects of opioids on the gastrointestinal system, increase constipation. Laxatives and stool softeners may be indicated to assist in the prevention or treatment of constipation. Other receptor-mediated adverse effects of opioids include urinary retention and pruritus. Opioids acting on opioid receptors in synaptically reorganized dysfunctional pain pathways can paradoxically increase pain in patients with chronic pain. This receptor response in patients who have taken opioids long term or who may also be addicted to opioids can confound the assessment and management of pain in this population, often leading to skepticism about pain severity and judgmental labeling of patients as “drug seeking.” Consultation with pain management experts can assist providers in safe and appropriate pain management in this challenging pain circumstance (see Evidence-Based Practice: Opioid Use in Pain Management).

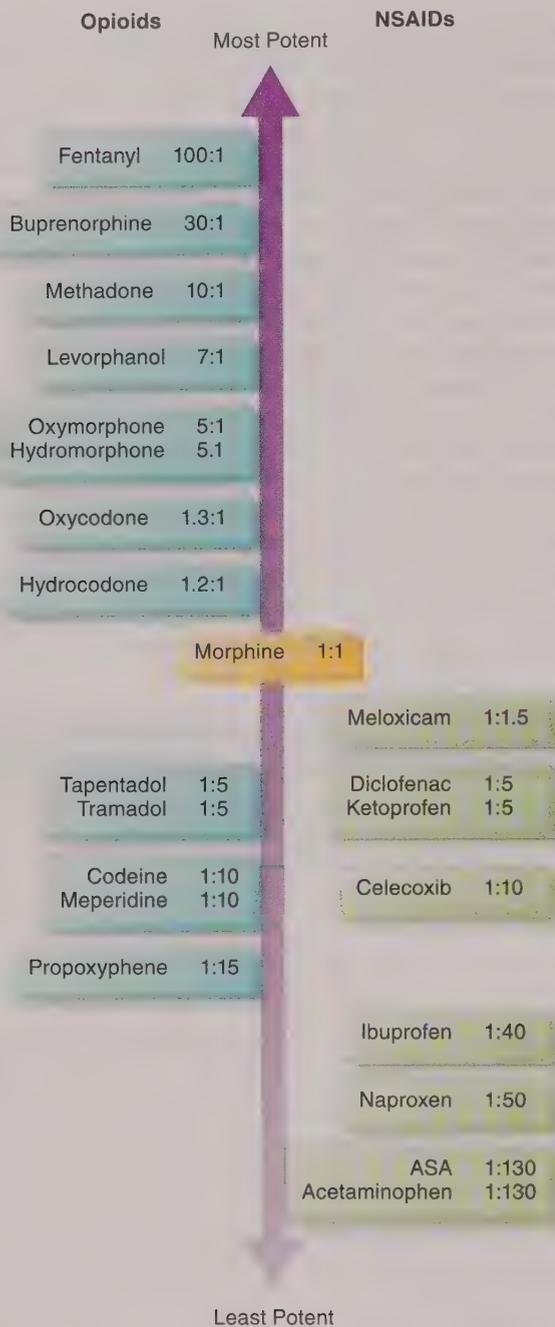

### Evidence-Based Practice

#### Opioid Use in Pain Management

- Opioids are effective for managing acute pain such as postoperative or trauma-associated pain, with few therapeutic benefits in chronic pain conditions.
- Opioids are more effective when combined with NSAIDs as most acute pain has an inflammatory component.
- Opioids are most effective when combined with teaching and self-management instruction that shapes a realistic expectancy of the pain experience and pain relief. The goal should NOT be relief of all pain but improvement of functional engagement.

Chou, R., Gordon, D. B., de Leon-Casasola, O. A., Rosenberg, J. M., Bickler, S., Brennan, T., ... Wu, C. L. (2016). Management of postoperative pain: A clinical practice guideline from the American Pain Society, the American Society of Regional Anesthesia and Pain Medicine, and the American Society of Anesthesiologists' Committee on Regional Anesthesia, Executive Committee, and Administrative Council. *Journal of Pain*, 17(2), 131–157.

Morphine (Roxanol) is considered the gold standard of opioids and is used in the treatment of acute pain. Oral morphine agents are available in both short-acting and controlled-release (MS Contin) forms. In the acute setting, particularly with severe pain, and in the postoperative setting, IV morphine is common. Hydromorphone (Dilaudid) is another opioid used in the treatment of severe pain and is five times more potent than morphine (Fig. 11.7). Available only in short-release forms, this medication is frequently used in the treatment of acute pain, particularly via the IV route.

**FIGURE 11.7** Not all opioids are created equal—understanding relative potency is a factor in pain management. New formulations are introduced all the time, and their potency should be considered in relation to the gold standard of morphine.

Newer synthetic opioids include different preparations of oxycodone, including the extended-release form branded as Oxycontin. This potent opioid, although marketed as having low addiction risk, is highly effective in relieving pain and is also highly addictive given its low cost and wide prescriptive availability. Until recently, this single agent was identified as being the most commonly abused opioid and responsible for a significant number of overdose deaths. Appropriately prescribed to manage short-term acute pain, this medication represents a significant treatment advantage

over other commonly prescribed opioids; however, tighter prescription controls have not necessarily reduced opioid overdose deaths. Patients who previously have been taking oxycontin and find themselves addicted but without a ready source of that medication have switched their opioid of choice to cheaper and often illegally obtained heroin and fentanyl. Opioid overdose deaths remain a significant public health concern.

### Connection Check 11.6

The nurse correlates respiratory depression and decreased gastrointestinal motility with the actions of which opioid receptor?

- A. Delta
- B. Kappa
- C. Mu
- D. Beta

### Atypical Analgesics

#### Adrenergic Agonists

Clonidine (Catapres) is a direct-acting alpha-2 adrenergic agonist used to treat high blood pressure. Its side effects of analgesia and sedation prompted clinical trials to evaluate clonidine for pain relief. Oral dosing of clonidine for pain management has limited benefit for the treatment of acute and chronic pain because doses sufficient to produce pain relief create excessive sedation. Intrathecal and epidural infusions of clonidine, however, have been used to treat cancer pain and neuropathic pain as well as chronic pain in patients who have become tolerant to opioids. Clonidine activates alpha-2 receptors at the level of the spinal cord to reduce cellular excitability and has been demonstrated to potentiate the action of local anesthetics and opioids. A related compound, tizanidine (Zanaflex), used to treat muscle spasticity, has proven effective at treating some forms of myofascial pain and peripheral neuropathy.

#### Tricyclic Antidepressants

Tricyclic antidepressants (TCAs) comprise a large class of medications that modulate the effects of serotonin and the related neurotransmitter norepinephrine in the central nervous system. First used to treat mood disorders and major depression in the 1960s, TCAs became more widely used to treat pain with the discovery of the critical role of serotonin and norepinephrine in modulating naturally occurring opioids in descending pain pathways. Tricyclic antidepressants largely affect the reuptake of serotonin or norepinephrine at the level of the individual synapse in the brain, with the net effect being an increase in the amount of neurotransmitter available, enhancement of neurotransmission, and changes in the level of naturally occurring opioids in the central nervous system. The most commonly prescribed TCAs, amitriptyline (Elavil), clomipramine

(Anafranil), desipramine (Norpramin), imipramine (Tofranil), and nortriptyline (Pamelor), have proven effective at managing neuralgias, fibromyalgia, and migraine headaches as well as the pain associated with irritable bowel syndrome, posttraumatic stress disorders, and neuropathies. Although doses for pain relief are generally lower than those prescribed to treat depression, the stabilization of mood that accompanies TCA use is generally viewed as a positive outcome for patients with pain who also report depression.

**Safety Alert** Because older adults are sensitive to anticholinergic side effects, nortriptyline (Pamelor) and desipramine (Norpramin) are preferred agents over amitriptyline (Elavil) in this population. Dosage titration should begin at 10 to 25 mg per day and gradually adjusted until the patient reports pain relief. Ensure adequate time for a TCA trial. It may take as long as 8 weeks or more at maximal tolerated doses to determine the true effectiveness of TCAs in older adults. Baseline and periodic electrocardiograms should be routinely performed to assess for cardiac side effects in older adults taking TCAs. The selective serotonin uptake inhibitor paroxetine (Paxil) should also be used cautiously in older adults because of anticholinergic side effects.

### Glutamate Receptor Antagonists and Gamma-Aminobutyric Acid Agonists

Glutamate is the principal excitatory neurotransmitter in the central nervous system. At the level of the spinal cord, glutamate interacts with several different receptors, including the *N*-ethyl-*D*-aspartic acid (NMDA) receptor. Calcium movement across NMDA receptors in spinal cord neurons is thought to influence how spinal neurons form synaptic connections with adjacent neurons, critically shaping “cellular memory” for pain. Blocking the activation of NMDA receptors is thought to limit the formation and permanency of abnormal synaptic connections. Ketamine (Ketalar) is the most commonly used medication to block glutamate activation of the NMDA receptor and has been successfully used to treat chronic pain resistant to most other analgesics. It is particularly useful at suppressing the central sensitization associated with surgical incisions and postherpetic neuralgia. Dose ranges for ketamine that produce analgesia are only slightly below dose ranges that produce pronounced hallucinations and ataxia; therefore, its use is largely restricted to anesthesia suites or emergency departments as part of pre-anesthesia induction or emergency sedation. Recent research has demonstrated that ketamine can be a life-saving therapy in depression that is nonresponsive to other antidepressant therapy. Although ketamine is an older and well-established analgesic, the overlap of brain regions shaping depression and chronic pain suggest that ketamine, and synthetic metabolites of

ketamine in the body, may hold new and exciting promise in treating chronic pain.

Dilute topical preparations of ketamine in combination with other anesthetics and anti-inflammatory agents have been used to treat nerve pain and painful dermatitis following radiation for cancer treatment. The most common topical preparation includes 10% ketamine, 10% of the NSAID ketoprofen, and 5% lidocaine. Other topical ketamine preparations combine ketamine with clonidine, TCAs including amitriptyline and tramadol, and the local anesthetic mepivacaine. Medications closely related to ketamine are being evaluated in clinical trials to treat chronic pain syndromes. Amantadine (Symadine), commonly used to treat viral syndromes and the symptoms of Parkinson’s disease, has demonstrated promising results in the treatment of neuropathic pain in cancer patients. Memantine (Namenda), used to treat the memory loss associated with Alzheimer’s disease, is also in clinical trials, with significant reductions reported in diabetic neuropathic pain.

When pain messages originating in the periphery reach the spinal cord, both excitatory and inhibitory neurotransmitters are released at synaptic connections. *Gamma-aminobutyric acid* (GABA) is the principal inhibitory neurotransmitter in the central nervous system. When GABA interacts with specific receptors in the pain-processing systems, it changes the electrical conductivity from neuron to neuron, inhibiting pain processing. When injury leads to more permanent restructuring of pain synapses and dysfunctional cellular memory, it is often because there are fewer functional pain inhibition connections. Synthetic medications can be used to mimic the action of GABA by activating GABA receptors more widely, increasing pain inhibition. The most commonly prescribed GABA receptor agonist is baclofen (Lioresal). It is generally used to treat spastic movement disorders associated with spinal cord injury, multiple sclerosis, and amyotrophic lateral sclerosis. It has proven effective for the treatment of pain following nerve crush injuries, spinal cord injuries, and complex peripheral neuropathies in which the underlying cause may be difficult to determine.

### Ion-Channel Blockers

Following the development of successful ion-channel-blocking agents, such as lidocaine, and the identification of other ion channels critical to pain processing, there has been great clinical interest in a broader ion-channel blockade to control pain. The anticonvulsant medications phenytoin (Dilantin), carbamazepine (Tegretol), and lamotrigine (Lamictal) are nonselective Na<sup>+</sup>-channel blockers effective at treating neuropathic pain and trigeminal neuralgia. They must be used cautiously in patients also taking oral anticoagulants, including warfarin (Coumadin), because these can increase the therapeutic effect of anticoagulants (increasing the risk of bleeding) or cause toxicity. Tricyclic antidepressants, in addition to their effects on serotonin reuptake, block Na<sup>+</sup> channels as a secondary mechanism of action, limiting the propagation of pain messages, which may also

help to explain their analgesic activity. Gabapentin (Neurontin) and pregabalin (Lyrica) are novel anticonvulsant medications with analgesic effects. Although gabapentin was initially synthesized to mimic the inhibitory neurotransmitter GABA, it is not believed to activate GABA receptors; instead, the analgesic mechanism of action is believed to be its binding to a subunit of ion channels that gate local calcium flow, limiting the propagation of pain messages. Both gabapentin and pregabalin, a more potent second-generation form of gabapentin, have proven effective at treating diabetic neuropathic pain and neuropathic pain following nerve injuries in the lower back. Other ion channels that influence calcium movement in pain-processing neurons and thus the propagation of pain messages have also been identified as potential analgesia targets. Blockers of L-type calcium channels, including nimodipine (Nimotop), verapamil (Calan), and diltiazem (Cardizem), allow for reduced doses of opioids when treating cancer patients, as well as a reduced need for postoperative analgesia following abdominal surgery (Table 11.7).

#### Decision Making for Effective Dose, Route, and Medication Choice

In spite of gains in pharmacology and a growing body of evidence to guide the best pain practices, too many patients wake each day in chronic pain, too many postoperative patients experience unrelieved pain that slows their recovery, and too many patients suffer at the end of life. Part of

the challenge in balancing the risks and benefits of intervention is acknowledging that significant variability exists among individual patients in analgesia response. The therapeutic goal is to choose medications that provide the best pain relief with the fewest adverse effects for the individual. There are many factors to consider when making a therapeutic medication choice, including (1) the type, intensity, and duration of a patient's pain; (2) the patient's age, gender, and general health; (3) the potential for pain relief and side effects based on mechanism of action and analgesia potency; (4) the potential for drug–drug interactions with current medications; and (5) the potential to improve or worsen comorbid health conditions.

Effective pain management depends on understanding how the body releases medications from their formulation and how medications enter the circulation and are distributed throughout the body's tissues, as well as how medications are metabolized and excreted from the body. Identical medications can produce different results depending on the route of administration. Inhaled steroids, for example, provide more targeted treatment in the bronchial tree with fewer systemic effects than if the same steroid is delivered orally or intravenously. Although oral medications are preferred by most patients because they are more convenient and do not involve sterile procedures or potentially painful injections, many medications cannot be formulated for therapeutically effective gastrointestinal absorption into the bloodstream. Although many oral medications do have

**Table 11.7 Dosing Guidelines for Common Atypical Analgesic Agents**

Anticonvulsants–Ion-Channel Agonists	Route	Dose Range (mg/day)	Schedule	Practice Recommendations
<i>Carbamazepine (Tegretol)</i>	PO	600–1,200	q6–8 hours	
<i>Clonazepam (Klonopin)</i>	PO	0.5–3.0	q8 hours	
<i>Phenytoin (Dilantin)</i>	PO	1,500–3,000	q8 hours	Two loading doses of 500 mg each PO or IV at 4- to 6-hour intervals can establish a blood level for better long-term pain relief.
<i>Gabapentin (Neurontin)</i>	PO	300–3,600	q8 hours	
Tricyclic Antidepressants	Route	Dose Range (mg/day)	Schedule	Practice Recommendations
<i>Amitriptyline (Elavil)</i>	PO	50–150	Bedtime	Was first line; now desipramine is preferred with fewer side effects and equianalgesia
<i>Desipramine (Norpramin)</i>	PO	50–150	Bedtime	Preferred for elderly
<i>Nortriptyline (Pamelor)</i>	PO	50–150	Bedtime	
<i>Doxepin (Sinequan)</i>	PO	50–150	Bedtime	Can combine with nortriptyline for improved analgesia
<i>Imipramine (Tofranil)</i>	PO	50–150	Bedtime	

PO, by mouth.

the benefit of being able to be compounded for sustained release, many dosing errors have been associated with improper crushing of sustained-released medications, both by patients at home and by clinicians who may not be aware of sustained-release formulations. Oral medications are also frequently compounded with dyes and pharmacologically inert substances that are allergenic for many people. Over-the-counter oral analgesics, for example, should be used cautiously in patients with a significant allergy history or a documented allergy to red and yellow dyes.

In addition to the mouth serving as a convenient entry to the gastrointestinal tract, the mouth is also an area of very vascular-rich tissue, allowing medication access through the mucosa. Some opioids, such as buprenorphine (Buprenex) or methadone (Methadose), can be formulated for sublingual doses, compounded into a lozenge, or packaged as a lollipop. The Actiq lollipop contains the opioid fentanyl and is particularly effective at treating breakthrough pain between scheduled doses of other medications.

The rectal route can also be an effective route of administration for many patients, although it is associated with the most variable absorption and peak-onset effects. The rectal route also can stimulate bowel evacuation in patients with low levels of bowel continence, with a subsequent loss of unabsorbed medication, minimizing effective dosing. The IV route of administration is reliable in emergency situations or when a rapid therapeutic effect is desired, but its use is often more limited to care settings and not as readily available for home use. Intravenous medications have the advantage, however, of being able to deliver both a bolus dose of medication or continuous infusions. Bolus dosing provides for a relatively rapid onset of pain relief, usually within 5 to 7 minutes, whereas continuous infusions allow for a steady level of medication that keeps plasma concentrations of the medication more constant. Continuous infusions may allow for lower cumulative levels of medication to be delivered, which has the potential to reduce medication side effects. In addition to IV delivery of medications, other infusion devices can deliver pain medication via subcutaneous tissues. Small 25- to 30-gauge needles can be placed into the subcutaneous tissues and connected to a small refillable medication reservoir. Some patients can also have implanted subcutaneous medication reservoirs with tunneled infusion systems under the skin to continuously deliver small doses of medications. These infusion sites need to be continually monitored for redness, swelling, signs of medication leakage, and the formation of dependent edema in the affected extremity. Pain relief can be variable with these delivery systems, and sites generally need to be rotated every 6 to 7 days to minimize infection and tissue trauma.

Transdermal patches comfortably provide both targeted and systemic pain relief, although there are relatively few pain medications currently formulated for transdermal administration. The most common pain medication delivered by transdermal patch is fentanyl (Duragesic), a powerful opioid. Patients and families do appreciate the ability to

self-medicate using this delivery system, with sustained medication delivery limiting the frequency of breakthrough pain; however, the risk of opioid-induced respiratory depression requires close monitoring of respiratory status. Transdermal patches may be applied to any clean, dry skin surface, although areas on the upper back and chest are recommended to minimize dislodging of the patch. It is important to remove old patches when new ones are applied so that patients are not overmedicated. New patches should be placed on rotating skin sites to minimize skin irritation. One important factor to consider with transdermal patches is that these sustained-release delivery devices can require up to 24 hours before effective pain relief is achieved, and often patients require a supplemental analgesic in the interim.

Intrathecal, epidural, or targeted injections into joints or nerve roots allow for regional analgesia with fewer systemic side effects but require specialist assessment and administration. Delivering medications directly into and around the spinal cord allows medications to act directly on specialized pain receptors and pain-processing networks of synapses to inhibit pain. The advantages of this targeted therapy include a generally longer duration of analgesia and at lower doses than can be achieved by other delivery methods. Often, targeted spinal analgesics combine an opioid with a local anesthetic to maximize pain relief by inhibiting several pain pathways. Side effects of targeted spinal analgesia and anesthesia include urinary retention and pruritus. Respiratory status must be closely monitored with targeted spinal opioid delivery and continued for several hours after discontinuation of therapy. Delayed respiratory depression has been noted, and patients should remain on continuous pulse oximeter monitoring for 8 to 12 hours after the medication has been discontinued. Frequent peripheral neurological and skin assessments should be performed with continuous targeted spinal analgesia, especially if opioids are combined with local anesthetic agents. Patients will have reduced sensation in the lower extremities and may not be able to readjust their position in response to pressure or other noxious stimulation. These patients should also have blood pressure monitored as well. Vascular tone can be affected by targeted spinal anesthesia, causing some pooling of blood in lower extremities, leading to lower systemic blood pressures and feelings of light-headedness. Epidural catheters are placed in the small space outside the dura mater of the spinal cord and are generally used for long-duration analgesia delivery, including pain relief in women in labor and some lower-extremity procedures. Implanted catheters connected to refillable reservoirs or pumps are used for days to months to provide long-lasting pain relief for patients with chronic pain. Intrathecal injections are usually single injections directly into the cerebrospinal fluid, bathing the spinal column with short-duration effects of 30 minutes to 8 hours.

Injections of corticosteroids and anesthetic agents directly into a muscle, joint, or nerve root are becoming increasingly common to treat such inflammatory complaints as osteoarthritis, bursitis, tendonitis, and rheumatoid arthritis.

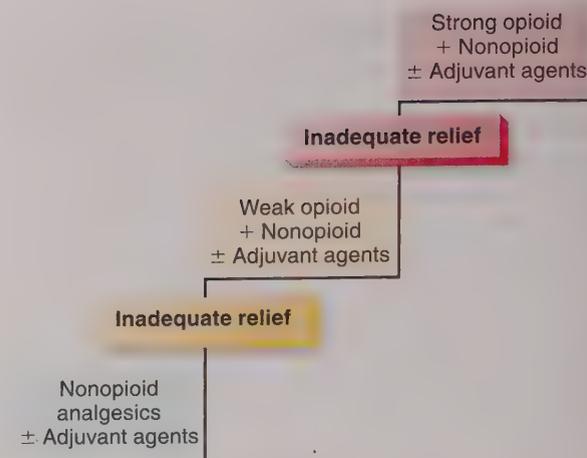

Injection of anti-inflammatory agents is being used as a less invasive treatment for carpal tunnel and other entrapment syndromes as well as chronic myofascial pain. It is contraindicated in immune-suppressed patients and in the presence of bleeding disorders, as well as active joint or systemic infections. Although some clinicians prefer to use single agents, such as long-acting methylprednisolone, most clinicians inject a cocktail of lidocaine and both intermediate- and long-acting steroids. These injections can be painful and often require the sterility of a procedure or operating suite as well as ultrasound guidance for proper injection placement. Pretreatment with a local anesthetic can minimize injection discomfort, followed by icing of the injection site for long-term comfort. Patients should be educated to expect that swelling and increased pain may occur. Injections into an already painful joint or muscle are likely to cause short-term hyperalgesia (increased sensitivity to pain) of 1 to 2 days' duration. Muscle and joint injections, however, can produce analgesia for several months, allowing physical therapy and stretching to improve muscle tone and joint flexibility for sustained pain control. Although trained clinician delivery of anti-inflammatory medications directly into the muscle is proving effective at providing pain control, the delivery of other medications via intramuscular injections is becoming less common. Intramuscular injections do provide fairly rapid pain relief; however, effectiveness varies widely from person to person, and this method poses considerable risk to patients. Even with the careful identification of anatomical landmarks and proper injection technique, intramuscular injections can injure muscle, nerves, and soft tissues. Patients also find intramuscular injections painful and may delay seeking pain relief to avoid injection-induced pain.

### Pain Management Guidelines

Principles established in 1987 by the World Health Organization (WHO) to guide pain management for cancer patients have been widely adapted to guide pain treatment for many different types of pain conditions. These principles suggest:

- Oral analgesics should be the first pharmacological treatment option used for most mild to moderate pain.
- Analgesics should be given at regular intervals rather than “on demand.”
- Analgesics should be administered according to pain intensity as evaluated on a reliable measure of pain intensity.
- The goal of pain management is *not* to produce an absence of pain but to improve functional quality of life.
- Dosing should be adapted to the individual.
- Analgesics should be administered with attention to the details of dose and response.
- Evaluation of therapeutic response is critical to long-term pain management success.

The WHO developed a treatment ladder to guide analgesia prescribing in support of these treatment principles (Fig. 11.8). This three-step ladder recommends beginning

<b>Step 1</b>	Mild Pain	<b>Simple analgesics</b> e.g., paracetamol, conventional NSAIDs, and COX-2 inhibitors with or without co-analgesics
<b>Step 2</b>	Moderate Pain	<b>Weak opioid</b> e.g., dihydrocodeine, dextropropoxyphene with or without adjuvant analgesics, e.g., gabapentin
<b>Step 3</b>	Severe Pain	<b>Strong opioid</b> e.g., morphine, fentanyl, with or without adjuvant analgesics, e.g., gabapentin. In clinical practice adjuvant analgesics may contribute to the relief of pain without being classical analgesics

**FIGURE 11.8** The World Health Organization three-step ladder. This three-step ladder begins with nonopioid analgesics (Step 1) and progresses to weak opioids (Step 2) and then stronger opioids (Step 3) as pain persists or becomes more severe.

with a nonopioid analgesic and progressing to weak opioids and then stronger opioids as pain persists or becomes more severe. Adjuvant therapies, including steroids, antidepressants, and anticonvulsant medications, can be added at any stage in the treatment ladder to maximize individual pain treatment success. The American Pain Society further endorses the use of nonopioid analgesics at each step in the pain treatment ladder even when opioids are prescribed, recognizing there are summative benefits of combining nonopioids and opioid analgesia agents that target both central and peripheral pain-processing pathways (Table 11.8).

### Equianalgesia

Medications with different potencies and different mechanisms of action can often be used interchangeably to achieve similar levels of pain relief in cases of patient sensitivity or when tolerance to medication effects or addiction is a concern. A 25-mcg-per-hour fentanyl patch will gradually release pain medication, providing pain relief for up to 3 days. This dose provides an equivalent level of analgesia as that delivered by 30 to 40 mg of morphine delivered orally every 4 hours over a 24-hour period. Reference conversion charts list doses for common medications that can provide equal amounts of analgesia. Using the information in Table 11.9,

**Table 11.8 Dose, Route, and Condition-Dependent Dosing for Common Nonopioid Analgesics**

Common Nonopioid Analgesic	Route and Condition-Dependent Maximum Dose	Onset and Duration
<b>Aspirin</b>	PO/rectal 1–2 g in 24 hr PO for arthritis 2–5 g in 24 hr	PO onset 15–30 min, peak 1–2 hr, duration 4–6 hr Rectal slow and variable onset, duration 4–6 hr
<b>Acetaminophen</b>	PO/rectal 1–4 g in 24 hr	PO onset 10–30 min, peak 1–2 hr, duration 4–6 hr Rectal slow and variable onset, duration 4–6 hr
<b>Ibuprofen</b>	PO 3.2 g in 24 hr	Onset 30 min, peak 1–2 hr, duration 6–8 hr
<b>Ketorolac</b>	PO/IM/IV 40 mg in 24 hr IM 30-mg single dose IV 15-mg single dose PO/IM/IV dosing limited to 5 days and dosed no less frequently than every 4 hr	PO onset 30–45 min, peak 2 hr, duration 4–6 hr IM onset 15–30 min, peak 1–2 hr, duration 4–6 hr IV onset 5–15 min, peak 1–2 hr, duration 4–6 hr Should begin IV or IM dosing and transition to PO dosing
<b>Celecoxib</b>	One single loading PO dose of 400 mg followed by divided bid dosing 200 mg in 24 hr PO for arthritis up to 400 mg in 24 hr	PO onset in 45 min, peak onset 6–8 hr, duration 12 hr

IM, Intramuscular; IV, intravenous; PO, by mouth.

**Table 11.9 Equianalgesic Dosing for Management of Acute or Chronic Pain\***

Medication	IM/SC/IV (mg)	PO/PR/SL (mg)	Hours of Pain Relief
<b>Morphine</b>	10	20–30	3–4
<b>Codeine</b>	120–130	200	3–4
<b>Oxycodone</b>	—	15–20	3–4
<b>Hydromorphone</b>	2	4	2–4
<b>Meperidine</b>	75–100	300	3–4
<b>Acetaminophen with codeine (Tylenol #3)</b>	—	Two tablets, each containing 300 of acetaminophen and codeine 30	3–4
<b>Acetaminophen with oxycodone (Percocet)</b>	—	Two tablets, each containing 325 of acetaminophen and oxycodone 2.5	3–6

IM, Intramuscular; PO, by mouth; PR, by rectum; SC, subcutaneous; SL, sublingual.

\*Dose conversion recommendations are for treating chronic pain, and lower doses may be required for acute pain.

a patient receiving 75 to 100 mg of meperidine (Demerol) IV, for example, could instead receive 20 to 30 mg of morphine by mouth or sublingually, with similar pain control results.

### Demand Dosing

Traditionally, pain medications have been administered by nurses either on an ordered frequency schedule or on an as-needed (prn) basis. This approach allows nurses to assess pain and to determine the most effective pain management treatment from a range of pain management options as well

as to monitor for and prevent treatment-induced side effects. In spite of considerable professional education about the science of pain management, studies indicate that nurses routinely underestimate the amount of pain experienced by patients and significantly undertreat pain in a demand-dosing pain management model. There have been several theories put forth as to why demand-dosing models lead to poorer pain management outcomes. It has been suggested that nurses implicitly substitute their judgment as to how much pain the patient is experiencing over that subjectively reported by the patient. When asked to describe the key

assessments and assumptions underlying their pain management decisions, nurses routinely report difficulties in validating subjective patient reports with objective clinical manifestations of pain. Although there are few well-studied or validated objective clinical manifestations of pain, when there are inconsistencies between a subjective report of patient pain and objective data, nurses tend to favor objective data. Nurses, for example, will question a patient self-report of pain of 10 on a scale of 1 to 10 when they bring pain medication to the bedside of a sleeping patient. This experience then tends to influence subsequent pain assessments such that nurses can become quite skeptical of patient self-reports if they do not conform to some preset image of what a patient in pain “should look like.” Undertreatment is significantly more of a clinical issue when prn pain medications are part of the treatment plan. Rather than being seen as a direction to medicate a patient as needed, it is often interpreted as administering a medication only on patient request. Nurses may administer pain medication at lower doses or at longer intervals than dosing guidelines suggest because of concerns about the development of respiratory depression or addiction.

Although evidence suggests that less than 1% of patients on long-term opioid treatment develop respiratory depression, **dependence**, and addiction, nurses report a belief that the risk of addiction is as high as 60%, with the risk of respiratory depression nearly as high. They also report a belief that addiction to narcotics can develop in as few as 5 to 6 doses, contrary to evidence that suggests that true narcotic addiction requires weeks to months of medication consumption. These beliefs are particularly influential in emergency settings, where there is less opportunity to know patients and learn patient patterns. Both emergency department nurses and physicians are quicker to describe patients as “drug seeking” than clinicians in other acute settings, especially if the patient is a member of an ethnic group, younger, or from social groups that clinician bias defines as having an increased risk for addiction.

Demand dosing can have negative effects on patient outcomes in other ways. Waiting until a patient requests medications often means that patients are in more intense pain before receiving an analgesic. They may receive some temporary sedation and pain control only to rise again to peak levels of pain before being treated once again. This leads to peaks and troughs in pain control rather than achieving a more steady state of pain relief. Demand dosing puts authority and control in the hands of providers rather than in the hands of patients. Not only does this lack of control over pain management increase patient anxiety about when their next dose will be or whether they will find pain relief, but this anxiety can also actually exacerbate the pain experienced by patients. Strategies for improving the clinical effectiveness of demand-dosing models are outlined in Evidence-Based Practice: Maximizing the Effectiveness of Demand-Dosing Pain Management Models.

## Evidence-Based Practice

### Maximizing the Effectiveness of Demand-Dosing Pain Management Models

- Scheduling prn pain medications at regular intervals around the clock rather than waiting for patients to request medication maintains more constant blood levels and improves patient comfort.
- Analgesics used in combination are more effective than the use of single agents alone.
- The use of adjuvant therapies is *not* intended to replace analgesics or to be used to reduce the dose of primary analgesics.
- Dosages should be adjusted upward within an acceptable range and titrated to patient comfort, with the goal of total pain relief not a reduced level of pain.
- Side effects such as constipation, nausea, and pruritus are treatable and should not cause nurses to limit side-effect-inducing medications.
- Recognize that clinician beliefs and attitudes affect both the assessment and treatment of pain; patients who challenge beliefs and assumptions about pain management need effective pain management, not clinician judgment and skepticism.

American Pain Society. (2008). *Principles of analgesic use in the treatment of acute pain and cancer pain* (6th ed.). Glenview, IL: Author.  
 Pasero, C., & McCaffery, M. (2001). The undertreatment of pain. *American Journal of Nursing*, 101(11), 62–65.

Philosophically, patient-controlled analgesia (PCA) puts patients “back in charge” of their own analgesia. In practice, one of the few places patients can exercise much control over their dosing and scheduling of medications is in the home, and even then, prescriptive limits on how much pain medication may be dispensed and undereducated patients contribute to ineffective self-analgesia for most patients. In acute care settings, PCA is generally used to refer to self-control of medication delivery for the small subset of patients receiving medications via IV or subcutaneous infusions. Pumps have been designed to be programmable and responsive to interactive patient commands to administer medications. Often, these pumps are used first to deliver a bolus dose of medication, usually an opioid, and to provide a continuous low dose or background dose of analgesia. Patients who are experiencing pain can self-medicate by pressing a control button that delivers a preset additional dose above the background dose. Programming determines the maximum amount of medication that may be patient-delivered in a prescribed time frame; if the patient attempts to self-medicate beyond these dose and time limits, the

patient is “locked out” of the system and cannot receive additional doses above the background dose.

The benefits of PCA are well documented. Patients report improved pain relief at lower doses of medication and with fewer side effects than with conventional approaches to pain management. Self-control over pain medication reduces anxiety about when a next dose might be delivered and about having to ask for medication. Patients are able to self-taper doses as their pain lessens and are generally able to discontinue pain medication earlier than with demand-dosing models of pain management. One of the challenges of PCA, however, is pain control during extended periods of daytime rest or night-time sleep. Basal levels of pain medications may be insufficient to provide sustained periods of pain control without waking to redose. Some pumps have more sophisticated programming algorithms that recognize patterns of self-medication and augment patient-delivered doses during periods of inactivity. Frequent patient assessments, which include patient education, ensure that the patient understands how to recognize when he or she needs additional doses and how to access the device.

### **Nonpharmacological Interventions**

Nurses have long recognized the critical role of the healing environment in pain management. Bed linens that are clean and smoothed at intervals help bedbound patients feel more comfortable. Pillows and positioning devices that are soft and provide ergonomic support can minimize tension on incisions or reduce muscle spasms associated with deeper pain. Ambient light and temperatures, as well as odors and even color choices in the care environment, can stabilize and elevate mood, which can help moderate pain perception. Often used in more targeted ways for pediatric care areas, colors such as greens, yellows, and blues in more muted and balanced tones have been demonstrated to be therapeutic for adults as well. Yellows and greens have been used in postanesthesia recovery areas, for example, to promote a positive sense of wellness and security in patients emerging from anesthesia. Deeper blue tones have been suggested to promote relaxation and well-being in patients with nervous system dysfunction, including those with chronic neuropathic pain and those experiencing depression. In a similar way, specific odors have been therapeutically used to promote relaxation and pain relief. The smell of vanilla, for example, delivered via a diffuser or when applied as an essential oil to the skin, has been demonstrated to reduce anxiety and promote relaxation. The aroma of green apples has been used to reduce the pain associated with migraine headaches and arthritic joint pain. Colors used alone or in combination with aromatherapy are suggested to influence pain states by engaging the limbic system and contributing to the descending modulation of pain.

Nurses, however, are challenged to provide a calming and healing environment in most modern healthcare settings, which can be noisy and frenetic, with interruptions around the clock. Higher nurse-to-patient ratios or complex task lists often limit extended contact with patients. Evidence

suggests, however, that successful care outcomes depend on how well nurses engage and meaningfully use the time they do spend with patients. The real value and power of nursing to affect care outcomes rest on the nurse’s ability to mobilize a true and authentic presence in patient interactions. Forming a therapeutic alliance with a patient requires nurses to develop this ability to be present, being attentive, involved, and fully engaged in the moment of care. Presence communicates acceptance, empathy, and concern. This skill takes practice and patience to develop. The use of nonpharmacological interventions to full effect requires that nurses understand the mechanism of action, review supportive evidence, hold collaborative discussions with prescribing providers, and use themselves skillfully as therapeutic tools to effect positive outcomes.

### **Positioning**

There is no one best position that promotes pain relief or comfort. Nursing efforts need to be focused on assisting a patient to find a position that the patient finds comfortable. Nurses can suggest side-lying positions or head elevations that may minimize stress on muscle groups or incisions. Nurses can also suggest upright sitting positions that encourage forward leaning. Such positions are often used to improve comfort for patients with dyspnea because they increase overall inspiratory muscle effort, allow for greater respiratory expansion, and decrease abdominal breathing as well as minimize the taking of guarded or shallow breaths. Many of these same respiratory issues affect patients in pain. Assuming respiratory-supportive positions can improve comfort for patients in pain. There are care guidelines that suggest position changes every 2 hours to promote skin integrity and minimize risks for skin breakdown. There are no similar guidelines, however, regarding the frequency of repositioning to aid in pain management. Nursing efforts again need to be focused on supporting patient choice in repositioning frequency. Evidence suggests that 45 minutes to 1 hour may be the comfort limit of most positioning strategies, although small adjustments in positions may allow for continued comfort between repositioning.

### **Heat and Cold Application**

The application of heat and cold is situationally recommended to reduce pain associated with underlying muscle, skeletal, or neurological pathology. Cold is better than heat, for example, at reducing low-back pain with spasticity associated with nerve injuries and degenerative joint disease. Most patients, however, prefer heat to manage lower-back pain discomfort in the absence of spasm, although neither cold nor heat brings sustained or permanent pain relief. Activity-induced muscle pain such as that experienced in sports injuries, including acute strains and sprains, can be reduced with an early application of cold combined with pressure such as that provided by an elastic bandage. Local cooling of skin and underlying neuromuscular tissues reduces blood flow into the area, slowing the development of inflammation and inflammatory pain. Cooling-induced

local vasoconstriction also limits bleeding into closed neuromuscular compartments around joints, slowing the development of painful tissue-deforming hematomas. Cooling also provides some local anesthesia effects by decreasing nerve conduction as well as increasing the threshold at which nociceptive receptors respond to several pain stimuli including pressure, pinprick, heat, and acidic conditions induced by local tissue injury. Cold has been used to provide a counterirritant effect, especially with dental pain. The application of cold combined with mentholated or alcohol spray has been used to increase the pain threshold for root canals and tooth extraction. This cold application works best when regionally applied to the skin web between the thumb and first finger on the same side of the body as the affected tooth, even as it is clearly some distance from the face and jaw region. This pain-relieving mechanism is not completely understood, but it is suggested that counterirritation activates sensory input into the spinal cord that engages natural inhibitory enkephalins and endorphins as well as influencing the descending modulation of naturally occurring opioids.

Both cold and heat have been used to provide relief from reflex muscle spasm associated with abdominal organ pain. Cold increases peristalsis and is preferred over heat application to the abdominal wall to address the pain associated with constipation, ileus, and mechanical bowel obstruction. Heat, on the other hand, reduces peristalsis and reduces acid production, helping to reduce the pain and discomfort associated with nausea, vomiting, and diarrhea. Heat has also been found to be superior to cold in reducing the reflex muscle spasms associated with menstrual cramps. Neither heat nor cold has been found effective in reducing the postoperative pain and discomfort associated with abdominal surgical approaches, although cold has been effective in reducing the postprocedural pain associated with gynecological surgery via vaginal approaches.

Heat can be delivered as wet or dry heat. Wet-heat technologies include paraffin wax and hydrotherapy baths, whereas dry-heat technologies include hot packs, heating pads, and radiant heat instruments such as heating lamps. Both wet- and dry-heat technologies allow for the sustained application of heat, with hydrotherapy having the additional benefits of allowing additional exercise or manipulation of painful joints with less resistance because of the buoyancy of being in the water. Hydrotherapy can also cleanse wounds less painfully because of the débriding action of whirlpool baths.

Cold can be delivered via ice packs, cold water baths, or commercially available cold-emitting chemical packs. Cloth layers are often placed between the skin and cold packs for patient comfort, but they can slow down cooling. The duration of cold application to achieve muscle cooling, relaxation of muscle spasm, and pain relief varies widely between patients and is somewhat dependent on the thickness of subcutaneous fat that insulates muscle. Even in a relatively slender patient with a thinner subcutaneous fat layer, effective cooling requires more than 10 continuous

minutes of application. Heavier patients with localized thicker fat layers may require as long as 20 to 30 continuous minutes of cold application for effective pain relief. Heat applications are generally shorter in duration to achieve effective pain relief, lasting 5 to 15 minutes, although some patients require longer continuous heat applications for improved comfort.

Patient comfort can guide length of application, as can regular assessment of skin integrity at the site of heat or cold application. Skin must continue to blanch when pressed to ensure that there is sufficient regional blood flow to continue the application of cold. Cold application should be discontinued if the patient experiences shivering. Skin that reddens and is accompanied by acute stinging sensations signals the end of both heat and cold application. Any sudden onset of pain suggests that safe temperature limits have been exceeded and the application of heat or cold must be removed. There remains a significant research gap as to how frequently to apply heat and cold to achieve therapeutic benefits. It is not known, for example, if heat and cold should be applied hourly or whether outcomes are improved if heat or cold is applied at 2-, 4-, or 8-hour intervals. It is also not known whether heat and cold work best with concurrent use of any specific pharmacological options or dosing regimen.

Although heat and cold applications can provide tremendous benefits for patients, there are clinical situations in which heat or cold is contraindicated or where they should be used with caution. Heat is contraindicated if deep visceral infections or inflammatory conditions are present or suspected, such as with acute appendicitis. Heat increases vasodilation and regional blood flow, increasing the likelihood of endotoxin absorption and systemic distribution. Heat should also be used cautiously in anesthetized areas or with patients with decreased levels of consciousness. In both situations, natural protective mechanisms that allow a patient to withdraw from noxious or potentially tissue-injurious stimulation are diminished. Heat and cold applications should be used with caution in patients with impaired local circulation. Such patients will have more limited benefits because the affected vascular bed can neither therapeutically constrict nor dilate predictably, nor can safe limits on the duration of cold or heat application be determined. Patients with peripheral vascular disease or diabetes therefore are not likely to benefit from heat or cold applications to the extremities. Local temperature elevations increase local metabolic demands, but a reduced vascular bed cannot adapt, and the risk for tissue injury and necrosis increases. Heat should also not be applied to areas of hematoma or frank bleeding because the increased vascular flow to the heated area will increase hematoma formation and bleeding. Areas of malignancies, both superficial and visceral, should not have applications of heat. Without the ability to precisely control local temperature, heat may stimulate tumor growth. Heat should be used cautiously in the scrotal area because it affects sperm production and sperm health. If the whole body is submerged in heated water greater than 100°F

(38°C), body temperature must be monitored at 15-minute intervals. Whole-body immersion in heated water can override homeostatic temperature-regulation mechanisms and drive body temperatures up very quickly.

Cold applications have fewer contraindications or precautions. Rarely, patients become hypersensitive to cold, with local histamine release and the development of cold urticaria. Occasionally, large applications of cold can cause cold-sensitive patients to experience systemic effects of histamine release, including facial flushing, swelling around the eyes, and laryngeal edema. Other cold-sensitive patients produce hemolysins, agglutins, or cryoglobulins in response to cold that can cause tissue blanching, vascular compromise, and necrosis. These patients include those with Raynaud's syndrome. Pretesting a small area on the thigh to cold application is recommended to assess cold sensitivity. The presence of urticaria in response to cold should lead to limits on cold application.

### Range of Motion and Exercise

Passive movement of a joint through its normal range of motion (ROM) is encouraged to prevent joint stiffness, promote motion, and prevent shortening of joint-supporting ligaments. Stiff or stiffening joints should be manually manipulated to the point of resistance but not pain. Patients can also be encouraged to actively move their joints through their normal ROM. More aggressive massage, targeted joint manipulation, progressive stretching, and vigorous exercise require specialized training and education for best outcomes. Evidence suggests that many inpatients, especially older adults, benefit from regular and targeted exercise or physical therapy. Even small increases in daily movement-focused exercise help improve balance, proprioception, gait, and muscle strength, shortening hospital lengths of stay and reducing readmissions associated with falls. Evidence further suggests that exercise improves mood as well as reduces symptoms of depression and anxiety, all of which shape the perception of pain. It is not completely understood why exercise has these wide-ranging effects. It is theorized that movement-focused exercise increases serotonin and norepinephrine levels throughout the central nervous system. These neurotransmitters activate the body's own opioid system, especially in descending pain pathways, with the net result being a reduction in pain. Studies are ongoing to evaluate the therapeutic benefits of movement-focused exercise on human neuropathic pain associated with traumatic nerve injuries, HIV and HIV treatment, and following chemotherapy. Nurses should work with other specialized disciplines to design and implement a comprehensive massage and exercise program that helps reduce pain and increase function.

### Massage, Relaxation, Acupressure, and Energy-Based Therapies

Pain, even short-term pain, can be disabling, limiting movement, mobility, and function. Techniques that restore movement and soothe pain include massage, joint manipulation,

and exercise. Massage involves the application of touch or force to muscles, tendons, and ligaments without changing the angle or position of joints. Specific massage techniques include effleurage or light stroking in a slow, repetitive, or rhythmic motion. Effleurage is particularly effective at reducing painful edema and can also be soothing when used to massage bony prominences or large body regions such as the back for bed-bound patients. Increasing applied pressure can influence deeper tissues and involves stroking in the direction of venous or lymph flow. Deeper stroking motions can improve blood flow, creating a sensation of warmth that many people find soothing. Muscle pain responds to kneading, where the skin and underlying tissues move with the hands. Kneading can be accomplished through a circular motion of the hands or moving the hands in a transverse fashion over the muscle.

A related technique uses pressure applied to specific body locations that correlate with specific healing areas or meridians in the body. These are the same locations that are used to place needles in acupuncture. Stimulation of these **acupressure points** produces both stress and pain relief. Similar to the specific application of cold to the skin web between the thumb and forefinger, firm pressure applied to this same area relieves same-side dental procedure pain, whereas firm pressure applied to the left lateral forehead can reduce discomfort associated with menstrual cramping. Tennis balls wrapped in socks can be used to stimulate several acupressure points along the lateral aspects of the spine. Patients can lie supine on and then move against the tennis balls to relieve the tension and discomfort associated with childbirth and low-back pain.

Many proponents of light and deep massage suggest that the benefits of massage go beyond the specific effects on muscle tension, lymph flow, and vascular beds. They argue that the laying on of hands and contact of skin to skin is uniquely healing. Physical proximity and physical interaction can be calming and reassuring when situationally and therapeutically used, communicating empathy and concern. Proponents of the healing power of touch further emphasize the essential energy or dynamic life force that is within each patient and each healer. It is working with and through this energy that shapes healing outcomes.

A number of noninvasive nonpharmacological interventions have been developed on the basis of this theoretical understanding, using physical proximity and touch to affect positive patient outcomes. These techniques include therapeutic touch, healing touch, and Reiki therapy. All of these therapies are based on the foundation that energy fields in the body need to be in harmony for there to be wellness. If energy fields are blocked or disturbed because of illness or pathology, this disharmony slows healing or leads to more illness. Those who use energy-based therapies consciously use their physical proximity with direct touch or near touch to influence the human energy field. What distinguishes these techniques from the more general use of touch in nursing practice is the training and mentored skill required to be a successful practitioner. Strong anecdotal evidence

suggests that patients with specific pain conditions, including carpal tunnel, postoperative pain, and trauma, report significant pain relief following these energy-based therapies. When therapeutic touch, healing touch, and Reiki have been subjected to rigorous experimental studies using double-blind and placebo controls, pain relief is more mixed. Evidence suggests that energy-based therapies work best when combined with more traditional pharmacological interventions, allowing patients greater comfort and less anxiety at reduced analgesia doses than when pharmacological interventions are used alone.

Relaxation is defined as a deep level of rest that represents an integrated psychological and physiological response characterized by a decrease in sympathetic nervous system activation, decreased metabolic activity, and self-reported feelings of well-being. There is little consensus on what constitutes a relaxation intervention. Some clinicians use music, for example, to promote a relaxing, healing environment. Other clinicians suggest music has benefits on pain outcomes independent of relaxation and should not be considered strictly a relaxation intervention. Still other clinicians encourage specific breathing techniques or sequenced “tensing-relaxing” exercises of the extremity muscles to induce a state of relaxation.

In deep-breathing interventions, patients are asked to take a deep breath while simultaneously clenching their fists or staring at a focusing object. After a moment of breath holding, patients are instructed to slowly release their breath while relaxing their bodies to the point of being limp. In rhythmic breathing, patients are instructed to coordinate their breathing with more equal inhalation and exhalation cycles. Timing devices such as metronomes or patterned music can help establish rhythms. Deep breathing and rhythmic breathing techniques are commonly used with women in labor and in some procedure areas. Proponents of relaxation techniques suggest a range of theories as to why relaxation reduces pain. Advocates suggest that relaxation reduces muscle tension and spasm. Some suggest that having a patient focus on his or her breathing or “tensing-relaxing” specific muscle groups diverts attention in pain perception. Patient ability to relax varies, and it is important to remember that relaxation cannot be forced. It may be less effective during short hospital stays because it may take up to 3 weeks of practice using a selected relaxation technique before patients report positive results. One positive aspect of relaxation techniques is that patients report reduced levels of pain for as long as 6 to 8 hours even after relatively short relaxation sessions (10 to 15 minutes once a day).

In well-controlled studies using several different relaxation techniques, relaxation is usually combined with biofeedback. **Biofeedback** is the presentation of a sensory stimulus to a patient, usually visual or auditory, that changes in proportion to a self-reported or “fed-back” biological response. Examples of fed-back biological responses include electromyography (EMG) waveforms of muscle activity, skin temperature, electroencephalogram (EEG) waveforms

of neurological activity, skin resistance, pulse rate, and blood pressure. Proponents suggest biofeedback enables the patient to objectively measure individual relaxation progress. Evidence suggests that biofeedback in conjunction with relaxation reduces the severity and frequency of muscle contraction or “tension” headaches, migraine headaches, and low-back pain. Unfortunately, poorly designed or underpowered studies outnumber more rigorous controlled studies, making it difficult to quantify the benefits of any particular relaxation technique.

### Distraction Therapies

Any activity that cognitively refocuses attention to stimuli other than pain can serve as a therapeutic distraction. The most effective distractions are those that are interesting to and appropriate for the patient situation, as well as those that engage the widest range of senses. Large wall murals of nature scenes, for example, coupled with headphone-delivered nature sounds have been used to distract patients undergoing bronchoscopy and dental procedures, as well as during childbirth. Other techniques that can be used to cognitively refocus or distract patients in pain include many initiated by the patient, such as watching television, reading, doing puzzles or crafts, listening to music, and making phone calls or otherwise engaging in conversation. Nurses also use these same techniques to therapeutically distract patients. **Music therapy**, for example, is very versatile. Patients passively listen to music that they find enjoyable or relaxing; some patients use music to support meditation or use music to help them form distracting mental images. Some patients sing to distract, whereas others use music as a creative diversion for their pain by writing or performing music. Music is used to specifically manage the pain associated with headaches and childbirth and the pain associated with both cancer and cancer treatment. Humor is also used to distract patients in pain, whether it is watching a funny video of a favorite comedy routine, watching cartoons for children, or reading a funny story. Well-controlled studies of experimental pain demonstrate that humor increases the threshold and tolerance for both cold and pressure pain. Humor has a similar effect on pain threshold as on relaxation, so it is suggested that humor, or more critically, laughing, may be more of a relaxation technique than a distraction technique.

**Guided imagery** is a technique that therapeutically uses the patient’s imagination to create mental pictures or situations that are soothing, relaxing, or pain relieving. Some practitioners describe guided imagery as helping patients to daydream in a very deliberative way, whereas others describe guided imagery as a form of self-hypnosis. Generally, patients being guided through the imagining process begin by closing their eyes and focusing on an image. This image is anything the patient finds useful, such as imagining a ball of healing energy or imagining their pain as electrical wires that can be cut. Other patients find that reliving a pleasant memory or imagining a visit to a favorite place distracts their attention from pain. **Meditation** is a related

distraction technique in which patients focus their attention on a healing place or person. This healing place or person may have a religious or spiritual significance to the patient, and specific breathing or chanting phrases are used to achieve an altered state of peaceful contentment. Although some patients use meditation techniques to specifically divert attention away from painful or unpleasant situations, other patients practice meditation daily as a way of providing more consistent healing energy and a sense of peace in their lives, increasing the effectiveness of other pain management interventions. Evidence suggests that most distraction techniques work best for helping patients through an uncomfortable procedure or helping bridge the interval between receiving pain medication and when pain medicine takes full effect. Although distraction techniques are thought to be less effective for treating chronic or complex pain syndromes, some patients report sustained relief over several hours or as long as the techniques are in use. However, pain returns near or at previous levels when distraction techniques are no longer being used. Some patients also report feeling more tired and irritable after distraction sessions longer than 45 minutes to 1 hour.

**Hypnosis** is described as a special guided state of consciousness in which the focus of attention is therapeutically narrowed and the patient is believed to be more responsive to hypnotic suggestions. Proponents suggest that any patient can be placed in a state of altered or hypnotic consciousness, whereas others suggest that relatively few patients respond to hypnotic techniques, including specific relaxation exercises, the use of guided visualization imagery, and the shaping of expectations through hypnotic suggestion. There is considerable evidence from positron emission tomography that hypnosis may inhibit thalamicsomatosensory cortex pain pathways that are believed to be involved in the cognitive perception of pain. Hypnosis is used to treat the pain associated with burns and burn treatment, cancer, dental care, childbirth, and headache and following thoracic and abdominal surgery. Many of these nonpharmacological pain management techniques fall under the umbrella of complementary and alternative medicine (CAM), and the reader is referred to Chapter 12 for a broader discussion of CAM therapies.

## Prayer

Prayer means different things to different people, and even patients who do not describe themselves as very religious often find a sense of peace and spiritual connection to all that is around them through the process of prayer. Patients may pray for improved health or a cure, or they may pray for the strength to endure suffering and limitations. For many patients, prayer is a way to feel less vulnerable, fearful, and isolated or to take back some of the control they feel they may have lost because of pain and illness. In many religions, prayer is used to establish a necessary connection with a higher power so that healing can happen. In this same way, patients pray for their caregivers to use their knowledge, skills, and technology for healing. For other

patients, prayer and faith are not engaged with the expectation of a cure, but they do help to create positive energy to support healing. Prayer also has been used to relax the body, helping to create a more positive healing environment. Some religions use intercessory prayer, the prayer of strangers from a distance, to help channel healing energy toward someone who is ill in addition to private prayer.

Just as the importance of spirituality, prayer, and religion varies from patient to patient, health providers themselves have different spiritual and religious beliefs and differ among themselves as to how important spiritual beliefs are to healing. The intersection of religion and healthcare can be uncomfortable for healthcare professionals. Nurses are taught about different religions and cultures, with an emphasis on the importance of respecting beliefs and cultural traditions. However, nurses often find themselves in awkward patient care situations because they are unsure of how their own beliefs may support or conflict with those of their patients. Nurses may also find it challenging to support a patient's beliefs that are contradicted by provable science. Nurses or physicians may be asked to pray with patients or be asked if prayer can make a difference. Reflecting techniques can be helpful, with offers to provide support in any way patients find useful. Institutional resources such as chaplaincy services or outreach to spiritual contacts in the patient's home community can also help patients find prayer resources.

## Invasive Treatment Options

### *Transcutaneous Electrical Nerve Stimulation*

Transcutaneous electrical nerve stimulation (TENS) is an older nonpharmacological intervention used to treat postoperative pain, osteoarthritis, and chronic musculoskeletal pain. Transcutaneous electrical nerve stimulation is used under provider direction and by specially trained practitioners. Although the exact mechanism of action of TENS is not clearly understood, it is thought to interfere or compete with pain transmission or to stimulate nonpain receptors in the same location of the pain. Transcutaneous electrical nerve stimulation units (Fig. 11.9) are battery operated and have electrodes that are placed directly on the skin to produce tingling and vibratory sensations to decrease pain. Research continues to determine the exact mechanism of action of this therapy, as well as to determine the effectiveness of high- or low-intensity stimulation.

### *Deep Brain Stimulation*

Used in the treatment of intractable pain for more than 50 years, deep brain stimulation (DBS) is often effective in selectively chosen patients. This nonpharmacological treatment for pain requires provider oversight, including the surgical implantation of brain pacemakers that send electrical impulses to specific parts of the brain. Consisting of three components, the DBS system includes an implanted pulse generator, the lead, and the extension, which are surgically placed. The lead is placed under local anesthesia through a hole that is drilled in the skull. The lead connects

**FIGURE 11.9** Transcutaneous electrical nerve stimulation (TENS) unit. The TENS unit is thought to work by interfering or competing with pain transmission or stimulating nonpain receptors in the same location as the pain. The units are battery operated, and electrodes are placed directly on the skin to produce tingling and vibratory sensations to decrease pain.

to the pulse generator by the extension that runs down the side of the head and neck, where it is placed subcutaneously below the clavicle. The patient must be awake during the procedure to test the electrical impulses for therapeutic effects. Deep brain stimulation is also used in the treatment of tremors in patients with Parkinson's disease.

### Managing Pain and Pain Relief Expectancy

One of the more significant insights gained over the last decade in assessing and managing pain, including lessons learned through the overprescribing of opioids, is that clinicians have communicated to patients in ways both subtle and explicit that the goal of pain management is the relief of all pain. When patients rate their pain on a scale of 0 to 10, with 0 as the state of being in no pain and 10 being the worst pain they have experienced, the message patients receive is that a pain score of 0 is a desirable state to be attained. This **expectancy** of no pain often has antecedents in a preoperative visit where surgeons indicate that there will be some pain but that it can be relieved by pain medication, with encouragement to take pain medication as prescribed for their maximal comfort. Additionally, the no-pain message is reinforced by policies and procedures that include pain assessment with each vital sign assessment and follow up after medication is delivered to determine pain relief effectiveness. Mass-marketing messaging and advertising for pain medications also emphasize that pain is something to be extinguished as opposed to being managed as a part of life and work.

Recent research has identified the powerful role that reality-informed expectations of pain levels on analgesia can have in managing the pain experience. A profound change in pain management philosophy is the shift from an approach focused on the relief of all pain to an approach in which pain

is expected and in which the therapeutic goal of pain management is improved comfort. Much of this philosophical shift can be traced to a more complete understanding of both the **placebo** and **nocebo** effects. Aside from its use as a control in clinical trials, the placebo effect has often been narrowly and historically defined as the substitution of an inert substance for one that is pharmacologically active, with therapeutic effectiveness derived from convincing patients that they received the pharmacologically active agent. Any positive therapeutic benefit that was achieved was often taken as mistaken evidence that the underlying condition was not real. A more evidence-supported understanding defines the placebo effect as the positive cognitive modulation of behaviors and outcomes related to therapeutic treatment, with the nocebo effect referring to the negative modulation of behaviors and outcomes.

As early as the 1970s, evidence from studies in both animal and human subjects supported the role that opioid receptors play in the placebo effect. It was demonstrated that conditioning or training a subject to associate an external cue or tone with the delivery of analgesia and then the replacement of the analgesic with a saline solution paired with the same external cue would produce analgesia. That this analgesic effect could be blocked by pretreatment with an opioid-receptor blocker, like naloxone, implies that the saline, although not a pharmacological analgesic, was not inert. In this cueing-conditioning context, saline functioned as an analgesic based on how this substance worked with engaged brain regions to produce analgesia. More recent research has expanded the understanding of the involvement of more extensive brain regions in the placebo and nocebo effects, with broader receptor engagement throughout the brain.

There are many examples in clinical care where the placebo and nocebo effects shape an outcome, but the explicit connection between clinician cueing behavior and analgesic outcome has not been universally embraced as a therapeutic intervention. It is common, for example, to explain to patients that they will “feel a pinch” prior to phlebotomy, or to frame the resetting of a dislocated shoulder as a very painful, if temporary pain. In this way, clinicians communicate an expectancy of pain that has a link to a real-world experience. Pain expectancy, however, can also be shaped by forces outside the clinician. A patient, for example, who watches another patient have a smooth and relatively pain-free phlebotomy will be cued to expect a relatively low-pain phlebotomy experience, especially when reinforced through clinician cueing. Conversely, patients who enter the labor suite cued by family members and friends to expect labor to be painful may be less amenable to clinician cueing.

There is great potential in taking a more intentioned and collaborative approach to shaping pain expectancy and clinician cueing. Care providers across the continuum of care need to be consistent with shaping expectancy for pain experiences, including building new pain communication skill sets, with the goal being the communication of a

more reality-based description of expected pain levels and a realistic outcome for analgesia interventions aimed at improving comfort and reducing but not eliminating pain.

## MANAGING PAIN IN SPECIAL POPULATIONS

### Managing Pain in Older Adults

Pain is such a common experience for older adults that it is often viewed and even dismissed as inevitable by both patients and caregivers alike (see Evidence-Based Practice: Educating Patients for Self-Management of Acute and Chronic Pain). Fear of addiction and oversedation and a misunderstanding of the mixed-pain conditions that most older adults experience lead to significant underdiagnosis, undertreatment, and needless suffering. Even experienced clinicians mistakenly assume older adults are more tolerant of or less sensitive to pain and that opioids should be the treatment of last resort. Ineffective pain management, however, is more likely to contribute to depression, anxiety, impaired mobility, social isolation, falls, sleep disturbances, reduced food and fluid intake, and malnutrition in older adults than in younger adults. This is often exacerbated by the costs of medications and insurer regulations that require high co-pays or limit prescriber treatment options. Older adult patients, however, are eight times as likely as the general adult population to live with a painful chronic health problem. Inflammatory conditions such as osteoarthritis affect up to 80% of older adults. Musculoskeletal pain commonly accompanies age-related changes in bone density, disk compression, and posture. Circulatory problems lead to fatigue, muscle cramps, aching vascular pain in the lower extremities, and sores that are slow to heal. Medication side effects and dental problems are also significant sources of orofacial pain.

### Evidence-Based Practice

#### Educating Patients for Self-Management of Acute and Chronic Pain

- Patients need a realistic view of the type and intensity of pain they can anticipate with specific procedures or after traumatic injuries to better self-manage pain.
- Give patients multiple pain relief options to choose from and written guidelines on when each may be used to maximal effectiveness.
- Use more than single-dimension pain scales to help patients better qualify the impact of their pain; then help them define specific goals. Beyond reducing the level of pain, patients may find that improving the quality of their sleep is how they want to measure the success of their self-management.

- Provide written instructions on how to safely dose primary and adjuvant medications.
- Instruct patients on how to use nonpharmacological therapeutic options, including the application of heat/cold, relaxation techniques, and physical exercise.
- Provide patients with the Web addresses of reliable pain management information and resources; caution patients to evaluate “sure-fire” pain cures with a skeptical eye.
- Refer patients who are unable to achieve pain relief through self-management to reputable pain specialists who can recommend more aggressive therapeutic approaches.

American Pain Society. (2008). *Principles of analgesic use in the treatment of acute pain and cancer pain* (6th ed.). Glenview, IL: Author. Boyers, D., McNamee, P., Clark, A., Jones, D., Martin, D., Schofield, P., & Smith, B. (2013). Cost effectiveness of self-management methods for the treatment of chronic pain in an aging adult population: A systematic review of the literature. *Clinical Journal of Pain*, 29(4), 366–375.

There is a wide range of treatment options for managing pain in older adults, and often, utilizing multiple approaches leads to the best outcomes. Combining nonsteroidal anti-inflammatory medications and heat application to arthritic joints with a focused stretching and exercise regimen improves functional mobility, pain, and social engagement. Relaxation training combined with deep massage and antispasmodic medications is effective at relieving lower back pain. Acupuncture, guided imagery, and music therapy have proved beneficial for older patients with severe orofacial pain. Although many of the same treatment options available to the wider populations of patients in pain can be used with older adults, adjustments in either dose or treatment intensity are often required to accommodate age-related changes in pharmacokinetics, pharmacodynamics, and general physiology. Doses of many medications, including NSAIDs, opioids, and steroids, need to be lowered or the frequency of administration adjusted to accommodate reduced kidney and liver function. Many older patients have comorbid health conditions and take other medications. The risk of potentially dangerous drug–drug interactions significantly increases with the addition of even one new medication, with NSAIDs particularly likely to interfere with common medications such as anticoagulants, thiazide diuretics, and both angiotensin-converting enzyme (ACE) inhibitors and calcium-channel blockers. An aging vascular system is less responsive to changes in temperature, and so applications of heat and cold, as well as therapeutic positioning, need to be shorter and very closely supervised to avoid the potential for injury.

Clinicians need to be vigilant to the development of adverse effects. Constipation, for example, is a more common

response to opioids in older adults than in the general adult population but can be prevented or reduced in severity through adjustments in diet and exercise. Respiratory depression occurs at the same frequency in older adults as in the general population of adults; however, it may present at lower doses and last longer because of changes in the metabolism of medication. Confusion and delirium are much more common reactions to opioids in older adults than even respiratory depression, and keeping patients safe from injury and falls is critical.

### Managing Pain in Adults With Cognitive or Communication Impairments

Although less than 20% of older Americans live in institutional settings such as assisted living or nursing homes, more than half of those who are in eldercare settings have cognitive impairments and dementia, challenging both assessment and treatment. This population more regularly interacts with nursing assistants and technicians who lack access to more effective assessment tools and adequate training to assess pain, leading to misconceptions that patients with dementia or patients with low cognitive skills do not experience pain. The blunted affect and nonexpressive facial expressions of many cognitively impaired patients lead caregivers to assume that the patient is not experiencing pain, especially if there is no clinical presentation that exhibits “typical” acute pain behaviors, such as groaning, grimacing, or muscle guarding. Given the prevalence of persistent and chronic pain in institutionalized older adults and the increasing presence of cognitively impaired patients in the general hospital population, there is no reason to assume that there is less pain in adults with cognitive impairment. Neurophysiological testing confirms that most cognitively impaired patients, including those with Alzheimer’s, have an intact somatosensory cortex and can receive and process painful stimuli, although they may have difficulty understanding, interpreting, and communicating pain.

Assessing pain in the cognitively impaired adult requires a systematic approach and thorough documentation of assessment techniques and assessment results. Because attention and clarity of thought can vary by time of day and can be affected by medications, surroundings, and care routines, pain assessment should begin with an attempt at self-report. Tests of cognition such as the Mini-Mental State Examination, the Abbreviated Mental Test Score, or the St. Louis Mental Assessment can predict the ability to self-report. Patients who are verbal but cognitively impaired can reliably use more concrete visual analog scales to identify their pain, although they may have difficulty remembering previous self-reports and so may not be able to quantify whether they are feeling “better” or more comfortable following treatment.

If patients are not able to provide a verbal report, caregivers should systematically search for a potential cause for pain, beginning with a review of diagnoses, health issues, and procedure exposure. Cognitively impaired patients with

wounds, arthritis, and cancer are as likely to have pain as cognitively intact elders, so the presence of pain should be assumed and treated accordingly. Similarly, cognitively impaired patients undergoing chemotherapy, rehabilitation activities, or diagnostic procedures should also be assumed to be in pain and appropriately proactively treated. If there are no known painful conditions or diagnostic activities, other physiologically distressful situations should be assessed and treated appropriately. For example, bed-bound patients should be repositioned, and all skin sites vulnerable to breakdown should be assessed. Ambulatory patients should have the fit of clothing assessed; belts or shoes that are too tight or the presence of clothing tags can cause unintentional distress. All patients should be toileted as part of the assessment process to be sure that undiagnosed continence issues or constipation are not causing pain or distress. A physical examination should survey each body area, moving each joint through passive and active ROM, with observations of differences in affect, mood, or nonverbal body signaling of discomfort. Special assessment attention should be focused on the most common sites of pain in older adults: the knee, hip, hands, and lower back. Hands-on assessments of joints and body regions are also likely to identify redness, heat, or other signs of inflammation or infection.

Observations of patient behavior, noting changes from baseline or routinely exhibited behaviors, can reliably indicate distress and pain in cognitively impaired patients, especially in settings where patients are regularly observed by the same caregivers or family members. Behavioral observations can be less reliable in hospitalized settings, where patients find themselves out of the structure of their normal routines, surrounded by unfamiliar noises and caregivers. Several dementias, including mid-stage Alzheimer’s, are associated with “wandering” or “compelled walking” behaviors that hospital personnel worry will lead to falls or elopement. Physical or chemical restraints can exacerbate distress or mask pain, and clinicians must balance the need for patient safety with humane behavioral approaches to managing cognitive pathophysiology. Each cognitively impaired patient’s behavioral responses to distress and pain are unique. Some patients may refuse food or withdraw from care and caregivers. Other patients may become belligerent, swear, or be physically violent. There is no set of behaviors that can reliably reflect pain intensity. These can be some of the most challenging patients for whom bedside hospital clinicians provide care.

Assessment skills that work with more cognitively intact patients are not reliably effective with cognitively impaired patients. Altered physiological parameters such as elevated blood pressure, heart rate, or respiratory patterns also do not reliably reflect pain in the presence of chronic or persistent pain; nervous systems have largely attenuated to painful input and do not fluctuate as predictably with pain. Patients with altered interaction patterns do not reliably respond to caring, nurturing caregiver behaviors. Nurses who are used to acknowledgments of their caring activities can be put off when cognitively impaired patients do not “give something

back.” It can be easy to become desensitized to the “yelling,” plaintive calls for help, or quiet withdrawal of cognitively impaired patients and communicate to other caregivers this desensitization in reports with comments such as “He is a biter” or “She always yells like that.”

Establishing a behavioral baseline is critical to pain assessment. Often, family members or caregivers from their regular care environment can provide behavioral details that provide this baseline to guide subsequent assessments. A comprehensive baseline should include behavioral patterns at rest and with activity. Behaviors that are more commonly associated with discomfort include guarding or bracing. Patients may be observed rubbing or massaging a body part. Some patients display escalating repetitive motions, such as clenching and unclenching a fist, tapping their hands or feet, or rocking. Facial expressions may change, with an increase in frowning, grimacing, brow furrowing, or clenching of teeth. Some patients may cry, yell, or become verbally abusive. Documentation of behavioral patterns helps subsequent clinicians understand the relationship between behavioral patterns and discomfort and be better prepared to intervene.

There are several instruments in development for use in both acute and long-term care. Most of these tools are measures of behavioral change suggesting pain or discomfort, but significantly, they do not measure pain intensity. The most widely used tools include the Pain Assessment in Advanced Dementia Scale, which summarizes behaviors into five pain indicators, and the Checklist of Nonverbal Pain Indicators, which sorts behaviors into six pain indicators (see Evidence-Based Practice: Assessing Pain in Cognitively Impaired Adults).

## Evidence-Based Practice

### Assessing Pain in Older Adults With Cognitive Impairments

Although pain assessment in older adults is sometimes challenging, individuals with moderate to severe dementia often self-report pain. This study evaluated self-reported, nurse-reported, and observational pain tools in a convenience sample of 156 older adults admitted to an acute geriatric ward. Observational pain was assessed through the Pain Assessment in Advanced Dementia (PAINAD) tool, and cognition and mood were evaluated with the Mini-Mental State Examination (MMSE) and the Geriatric Depression Scale (GDS015). Findings included statistically significant correlations between self-reported pain and the GDS-15 but not between self-reported pain and the MMSE. There was moderate agreement between self-reported pain and the PAINAD and fair agreement between self-reported pain and nurse-reported pain. The results of this study support the

use of self-reported pain assessment data first in adults with cognitive impairment, with the use of an observational assessment tool when the individual is unable to self-report pain.

Ngu, S. S. C., Tan, M. P., Subramanian, P., Rahman, R. A., Kamaruzzaman, S., Chin, A., & Poi, P. J. H. (2015). Pain assessment using self-reported, nurse-reported, and observational pain assessment tools among older adults with cognitive impairment. *Pain Management in Nursing*, 16(4), 595–601.

If painful conditions are present or behavioral changes indicate that distress or pain is likely, nonpharmacological interventions and an analgesic trial are recommended. Nonopioid analgesics including NSAIDs should be considered first-line therapy, administered on a standing schedule rather than a prn schedule. Nonverbal or cognitively impaired patients may not be able to request pain medications. Psychotropic medications should be avoided if possible because they may blunt the behavioral evidence of pain without providing pain relief or may sedate the patient, making serial monitoring of behavior more challenging. Opioids can be safely administered to older and cognitively impaired patients but may require starting at lowered doses and titrating carefully to monitor for risks and side effects. Short-acting opioids are preferred if the patient’s previous exposure to opioids is unknown because shorter half-lives allow for safer titration to manage pain. Hydromorphone and fentanyl are the preferred opioids in older adults with kidney or liver impairment, whereas meperidine should be avoided because of the adverse effects associated with a toxic metabolite, normeperidine. Similarly, propoxyphene (Darvon) has been associated with neuroexcitatory side effects, including dizziness and ataxia, in older patients. Carefully assess and document the behavioral response to interventions. Changes in behavior consistent with less discomfort and the reestablishment of baseline behaviors should be positive indicators that pain was present and that some measure of pain relief has been established.

Other therapies proven effective for managing pain in cognitively impaired adults include a tailored plan of physical activity and cognitive-behavioral therapy (CBT). Too often, cognitively impaired patients are restricted to their rooms or to their beds to ensure their safety, when safe outcomes are more likely if patients are out of their rooms and able to participate in regular physical activity. A physical therapist should be consulted to help design an activity schedule that exercises the full range of joints and promotes muscle strength and balance. Critical to the success of any activity plan of care is the incorporation of exercise into the daily routine. When administered by trained clinicians, CBT can help cognitively impaired patients replace ineffective behaviors with new behaviors that help focus their understanding of their situation and

provide clinicians with new behavioral problem-solving strategies. Although this approach is more effective in outpatient or long-term settings, nurses in inpatient settings should avail themselves of nurse consultants who specialize in geriatric or cognitive impairments for care recommendations.

## Making Connections

### CASE STUDY: WRAP-UP

The assessment of Mrs. Jessup reveals that gas exchange and airway clearance are compromised, as is her quality of sleep. Her mobility is also compromised by persistent low-back pain following a preexisting back injury. Nursing diagnoses that focus the care Mrs. Jessup receives include:

1. **Ineffective respiratory function** related to positional guarding and shallow respiratory pattern secondary to surgically induced tissue trauma and reflex muscle spasm across thorax as evidenced by oxygen saturation values 92% to 94% on 3 L via nasal cannula, incentive spirometry volume at 450 mL, diminished breath sounds at the bases bilaterally to auscultation, and radiology reports of atelectasis in bases
2. **Disturbed sleep patterns** related to pain secondary to surgical incisions and lower-back injury exacerbated by frequent care interruptions associated with the hospital stay and medication side effects of diuretic use as evidenced by self-report of poor-quality sleep, nurse report of shortened sleep intervals of 1 to 2 hours overnight, and nurse report of total sleep hours less than 4 hours overnight
3. **Impaired mobility** related to chronic lower back pain secondary to preexisting traumatic injury exacerbated by neuropathic sensory dysfunction in feet and lower extremities as evidenced by observed inability to self-position to seated position with legs dangling; self-report of inability to bear weight on both feet simultaneously because of leg pain and weakness; and can ambulate no farther than 3 feet, requiring the assistance of two caregivers

Mrs. Jessup continues to rehabilitate from her coronary bypass surgery and is discharged to an inpatient rehabilitation facility that can address both her cardiac and chronic back pain issues. The plan is for her to be in the inpatient facility for 5 to 7 days and then be discharged to home. The goals are to increase her comfort and maximize her independence in activities of daily living.

### Case Study Questions

1. What clinical manifestations can the nurse use to indicate the level of Mrs. Jessup's pain on a.m. assessment? (*Select all that apply.*)
  - A. A subjective report of 6/10 pain level; shallow, guarded breathing; short, terse responses to questions
  - B. Mrs. Jessup's report of poor overnight sleep and decreased supported ambulation
  - C. Facial grimacing and observed rubbing of lower back and legs by patient
  - D. Decrease in blood pressure
  - E. Increased urinary frequency
2. The nurse correlates Ms. Jessup's clinical presentation with which type of pain?
  - A. Acute pain
  - B. Chronic pain
  - C. Mixed acute and chronic pain
  - D. Malignant chronic pain
3. Which pain management approach is best for Mrs. Jessup?
  - A. NSAIDs and opioid medications, cold application to the back, supported ambulation, and distraction
  - B. Aspirin and opioid medications, heat application to the chest and back, bedrest, and Reiki therapy
  - C. Opioid medication, prayer, and music therapy
  - D. TCA, TENS, and guided imagery
4. What is the best physiological explanation of why Mrs. Jessup may be experiencing chronic back pain?
  - A. The injury she has in her back has just never healed.
  - B. Non-nociceptive pain messaging has overtaken nociceptive pain messaging.
  - C. Hyperexcited neurons at the time of injury created new pathological synaptic connections that persist.
  - D. Chronic inflammation has reduced the effectiveness of descending inhibitory pathways.
5. What is the rationale for using ketorolac as the preferred NSAID to treat Mrs. Jessup?
  - A. It is both high potency and has a long half-life for less breakthrough pain.
  - B. It targets both prostaglandins and leukotrienes.
  - C. It does not cause respiratory depression or constipation.
  - D. It can be given every hour as needed to manage pain.

## CHAPTER SUMMARY

Pain is a very individualized experience, and people with the same injuries or disease processes may exhibit very different clinical manifestations of pain. For many patients,

the source of their pain can be readily identified, diagnosed, and treated. For other patients, the pathology underlying their pain is difficult to diagnose and to treat. Many factors shape the pain experience, including a patient's prior experience with pain as well as expectations for painful procedures and conditions. Other sociocultural and biological influences also shape the pain experience, including gender, genetics, ethnicity, and age. Females and males generally experience pain in different ways, with some pain conditions more prevalent in one as compared to another, whereas older patients generally present with more complex, mixed pain.

Acute pain serves a biological purpose, alerting to noxious and potentially tissue-injuring conditions and prompting tissue-protecting withdrawal and guarding behaviors. Chronic pain serves no similar biological function, representing true pathology and dysfunction in pain-processing structures. Painful sensations largely begin in peripheral tissues innervated by a fine network of nerves that transmit electrochemical messages to the spinal cord and brain. Some of these nerves carry proprioceptive and touch sensations. Specialized nerves that sense and transmit pain messages are called nociceptors. Some nociceptors respond to painful heat or cold, prick, or pressure, whereas others respond to noxious acidic and basic conditions in the tissues. With tissue injury comes a local release of pain-promoting substances, including prostaglandin and histamine. These substances sensitize peripheral tissues, amplifying the pain messages being sent to the central nervous system. Once in the spinal cord, incoming pain messages are processed and transmitted up the spinal cord and through serial regions of the brain, where pain is consciously perceived in the cerebral cortex. Descending pathways move through many of these same brain structures, returning to the spinal cord. It is in the spinal cord where incoming pain messages from the periphery are integrated with descending modulating pain messages to produce a neurophysiological pain response.

The peripheral sensitization that follows injury can lead to hyperexcited and sustained painful input into the spinal cord, sensitizing central neurons in the spinal cord and brain as well. Sensitized central neurons respond by producing more pro- and anti-nociceptive neurotransmitters. This hyperexcited nervous system alters nerve-to-nerve contact at the level of individual synapses. Some synapses die back while others newly form, altering the balance of excitation and inhibition in pain processing. This reorganization of synapses or plasticity at the level of the spinal cord is generally normal and adaptive in injury and illness. For some patients, however, this reorganization of synapses leads to dysfunctional synaptic connections forming, creating a long-lasting rerouting of pain messages, essentially a "cellular memory" for pain that can linger long after injuries heal and that can be very difficult to treat. Pain often accompanies many chronic illnesses such as arthritis and cancer. The most challenging pain conditions to manage follow

injury to nociceptive structures, including the peripheral nerves, spinal cord, and brain.

Comprehensive pain assessments are essential to the nursing care of patients experiencing pain. There are many valid and reliable tools that have been developed to assess pain; these include relatively easy-to-administer numeric, verbal, and visual scales where patients can indicate pain intensity as well as their response to therapeutic interventions. For some populations with low verbal or abstract reasoning skills, such as children or cognitively impaired adults, cartoonlike scales display increasingly grimacing faces to represent different levels of pain intensity. Such tools can be helpful in measuring acute pain serially for one patient, although they can be less useful when measuring chronic pain or the mixed pain that most patients actually experience. In complex pain situations, it is often helpful to combine several scales to measure more than one dimension of pain, including how deep the pain is and how pain functionally disrupts lives. Pain assessments are culturally sensitive, and the use of any tools in pain assessment should be subject to rigorous review for use with special populations.

Nurses have the responsibility of recognizing the impact of clinical manifestations of pain on functioning and well-being. They are uniquely positioned in the healthcare system at the front lines of patient care to implement a tailored plan of care. Treatment options include a wide range of pharmacological and nonpharmacological interventions. For most patients in acute pain, NSAIDs or acetaminophen (Tylenol) is an effective first-line medication. These are easily accessible as over-the-counter (OTC) remedies and can be supplemented with OTC topical rubs, heating pads, or ice. Opioids are stronger medications available through provider prescription and are well suited to manage the pain associated with acute pain following traumatic injury, surgery, or dental pain. Opioids are also effective at managing the progressive chronic malignant pain that often accompanies cancer. The WHO advocates a stepwise approach to pain management that pairs nonsteroidal anti-inflammatory medications with progressively more potent narcotic medications as pain becomes more severe. Nurses should work collaboratively with the interdisciplinary team to integrate new classes of targeted pain medications, including sodium and calcium channel blockers as well as medications that act to alter neurotransmitter levels in the brain.

Nonpharmacological interventions include the selective use of heat and cold, positioning for comfort, and massage therapy. A team approach to pain management may include targeted physical therapy as well as a full range of CAM methods, including the skilled use of therapeutic touch or Reiki therapy, relaxation, hypnosis, acupressure, and aromatherapy. Special populations of patients challenge assessment and pain management, especially patients who are cognitively impaired. Family members and caregivers can aid in establishing a baseline and often provide context for atypical pain behaviors. A comprehensive use of stepwise

NSAID and opioids combined with CAM methods can reduce pain and improve quality of life for those with cognitive impairments or at the end of life. Effective pain management balances pain relief and functional improvement with the management of therapeutic side effects. Nurses need to monitor laboratory values, including kidney and

liver function, and be alert to potentiated or reduced effectiveness of other medications because of drug–drug interactions. Although nurses do need to be alert to oversedation and the development of tolerance with some opioid medications, nurses also need to advocate for opioid use with patients and providers alike.

## Complementary and Alternative Care Initiatives

*Susan Sartorius-Mergenthaler*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Defining complementary and alternative medicine
2. Differentiating the classifications of complementary and alternative medicine
3. Discussing the nursing implications of complementary and alternative medicine

### CONCEPTS

- Assessment
- Comfort
- Healthcare System
- Medication
- Nursing
- Nursing Role
- Promoting Health

### Finding Connections

#### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Ms. E. Ellicott is a 52-year-old woman with a new diagnosis of hypertension. Her medical history is unremarkable except for occasional migraines. She states that her 82-year-old mother recently had a stroke and is recuperating at an inpatient rehabilitation center. Ms. Ellicott is an only child, and her mother lives 3 hours away. She is married and has two children, a 16-year-old girl and a 12-year-old boy. She is currently employed as a district attorney. Her husband owns a software company. Assessment: vital signs (VSs): temperature (T): 99.5°F (37.5°C), heart rate (HR): 80, respiratory rate (RR): 20, blood pressure (BP): 150/98. She is currently not taking medications. She states to the nurse that she is feeling overwhelmed with the new diagnosis of hypertension and the fact that her mother recently had a stroke...

Conventional medicine  
Holistic care  
Integrative medicine  
National Center for Complementary and Integrative Health (NCCIH)  
Western medicine

### INTRODUCTION

**Conventional medicine**, also known as **Western medicine**, is the dominant healthcare system in the United States, Canada, and most of Europe. Conventional medicine is a well-established, organized system that is rooted in scientifically proven theories. It is practiced by licensed providers, nurses, physical therapists and occupational therapists, social workers, and other allied healthcare professionals. **Complementary and alternative medicine (CAM)** is a collection of old-world traditions and healthcare practices that have been handed down through the generations. The therapies and products that are recognized as CAM are rooted in ancient wisdom traditions, folklore, and religious and spiritual practices. These traditional practices and doctrines are based on theoretical foundations and are performed by licensed and specially trained practitioners. The CAM model for delivery of care has three guiding principles, all described in Box 12.1.

The goals of CAM include the promotion of wellness, the prevention of illness, a reduction in treatment side effects, improvement of the immune system, and enhancement of quality of life. Although these goals of care are not unlike those of conventional medicine, CAM

## Box 12.1 Guiding Principles of Complementary and Alternative Medicine

1. Recipient/Practitioner Partnership
  - Established relationship—builds trust, instills hope
  - Healing takes place in the context of the relationship
  - Treatment design is intrinsic to the holistic care model
2. Wellness Model of Care
  - Emphasizes healthy lifestyle—proactive approach to being well
  - Encourages self-awareness related to changes in the body and interconnectedness with lifestyle choices
  - Uses broad concepts for the promotion of health and wellness for the treatment of disease
3. Energy Paradigm
  - Health is defined as harmonious and balanced.
  - Healing is defined in the context of the whole person—mind, body, and spirit.
  - The basic theory involves a Life Force or Vital Force called *qi* that permeates and bonds all living things.
  - All living things have a universal spirit and wholeness.

healthcare practices are considered outside the sphere of conventional scientific methodologies, hence the terms *alternative* and *unconventional* as an approach to medical treatments. The term *complementary* refers to practices, treatments, or modalities that are stand-alone therapies or therapies that can be paired with conventional medicine to modify, restore, or renew balance; ease symptoms; or improve quality of life.

In 1992, the National Institutes of Health established the Office of Alternative Medicine (OAM) in response to the public's unforeseen and increasing interest in CAM. In 2014, the OAM name was changed to the **National Center for Complementary and Integrative Health (NCCIH)**. The NCCIH has identified pain, anxiety, depression, and headache as being among the top 10 reasons why adults seek CAM as an alternative and complement to managing healthcare needs.

Today, the NCCIH advocates for CAM through scientific, evidence-based research projects and provides a clearinghouse for safe and reliable information related to CAM. The NCCIH makes available academic research opportunities for investigators and offers a variety of educational formats for both healthcare providers and patients. The blending of conventional medicine and CAM is the nucleus of integrative medicine. As the term implies, **integrative medicine** joins together the best of Western medicine and the most effective CAM modalities. Philosophically, the foundation of integrative medicine is that of **holistic care**, treating the individual as a whole person—physically, mentally, and spiritually—to promote optimum health and well-being.

## Connection Check 12.1

The defining characteristics of CAM include which of the following? (*Select all that apply.*)

- A. Rooted in scientifically proven theories
- B. Rooted in ancient wisdom traditions
- C. A collection of old-world traditions
- D. A collection of old-world healthcare practices
- E. Works in isolation from conventional medicine

## CLASSIFICATION OF CAM

The NCCIH classifies CAM according to specific techniques, methods, and applications. The five categories of CAM are:

1. Whole medical systems/alternative medicine systems
2. Mind/body therapies
3. Manipulative and body-based therapies
4. Energy healing therapies
5. Dietary supplements and botanical/herbal medicine

## Whole Medical Systems/Alternative Medical Systems

Whole medical systems/alternative medical systems are time-honored ancient arts and practices with comprehensive methods of care that are used to nurture and promote the healing process. They are complete systems of theory and practice that are rooted in healing traditions. Treatments are personalized according to the physical, emotional, spiritual, religious, nutritional, and environmental needs of the patient. They are helpful in the management of emotional and psychological disorders such as chronic fatigue; stress, anxiety, and depression; symptoms related to menopause; and sleeping problems or insomnia. They are also helpful in the management of pain caused by arthritis, osteoarthritis, fibromyalgia, chronic back pain, carpal tunnel syndrome, migraines, sports injuries, and neuropathy. Examples include Ayurvedic medicine, traditional Chinese medicine, naturopathy, and Native American medicine.

### Ayurvedic Medicine

Ayurvedic medicine is a 5,000-year-old integrated, natural medical system that originated in India. It uses a combination of herbs, yoga, massage, and diet to restore balance and wellness. The belief behind this treatment method is that there is an interconnection between the mind and the body. This distinctive connection, when encouraged, will facilitate, maintain, and restore health and well-being. It includes physical, mental, and spiritual practices to maintain inner harmony. The individual is evaluated on the basis of his or her unique, well-defined energy patterns, called *doshas*. According to the pattern of the *doshas*, various modalities are incorporated into a complex change in lifestyle.

## Traditional Chinese Medicine

Traditional Chinese medicine has been practiced for more than 5,000 years. This medical system (also referred to as **acupuncture**) is the oldest and most continuously practiced medicine in the world. The goal of treatment is to sustain the balance, or flow, of *qi*. *Qi* is defined as the universal Life Force or personal life force and is considered the connecting “energy” that influences all living and nonliving things. The flow of *qi* is facilitated by the acupuncturist’s point placement of small needles, which are inserted just under the surface of the skin (Fig. 12.1). Each point represents a specific area and normalizes energetic function to stimulate the body’s innate power to heal. The modern theory of acupuncture describes certain electrical properties stimulated by the needles, altering neurotransmitters in the body and resulting in changes associated with natural physiological chemicals.

### Safety Acupuncture Alert

Caution is advised for patients who are receiving chemotherapy and/or taking anticoagulants. Patients are at an increased risk for infection or bleeding under the following conditions:

- Neutropenia ( $\leq 1,500/\text{mm}^3$ )
- Thrombocytopenia ( $\leq 50,000/\text{mm}^3$ )
- Elevated liver functions
- Anticoagulation therapy

Avoid inserting acupuncture needles in or around:

- Radiation site areas
- Burns
- Direct tumor sites
- Fractures
- Varicose veins
- Areas of lymphedema

## Naturopathy

Naturopathy is a 100-year-old practice that integrates natural therapeutics such as acupuncture, hydrotherapy, manipulative therapy, homeopathy, and botanicals. The focus of care is on supporting health, not combating illness. Naturopathic providers integrate care according to the individual needs of the patient.

## Native American Medicine

Native American medicine is a collection of indigenous customs, beliefs, and practices. It is believed that humans, community, and nature are interconnected and that healing must be restored to a state of wholeness to achieve optimal spiritual balance, well-being, and harmony. Native American healing traditions include shamanism, which represents a spiritual practice between the physical and spiritual worlds;

**FIGURE 12.1** Auricular acupuncture. Considered microsystems of the body, the ears are used to treat conditions that are present anywhere in the body.

herbal medicine, defined by common practices such as the use of tinctures, salves, and teas; and ceremonial healing practices such as chanting, dancing, and singing to ask for spiritual help and guidance.

## CASE STUDY: EPISODE 2

Ms. Ellicott is unsure what to do about her stress, which is related to her new diagnosis of hypertension and her worry for her mom after her stroke. She is so busy with her job and family that she is not sure which way to turn. Looking into acupuncture was recommended by a friend, but she is unsure if she is comfortable with that option. She is unfamiliar with CAM and is unaware of the many different modalities. After opening a discussion with the nurse, she finds she is interested in pursuing some form of alternative medicine as a way of relieving her stress...

## Mind/Body Therapies

During the past 30 years, there has been scientific advancement in the field of neuroscience exploring the mind–body connection. It has been discovered that during mind/body treatment techniques, the limbic system and frontal cortex areas of the brain can have significant changes in patterns and functions. Research has shown that mental imagery can produce biochemical, immunological, and physiological

changes in the body that have positive effects on health. Meditation, for example, can regulate the fight-or-flight response by slowing the heart, improving blood flow, and increasing the activity of the digestive tract. Many of the mind/body practices can be done in groups led by a facilitator or as a stand-alone practice. Many practices may also incorporate music, chanting, speaking, and reciting, such as prayer/spirituality, yoga, imagery, tai chi, and zero balancing (ZB). Mind/body therapies promote relaxation and are helpful in the management of emotional disorders such as stress, fatigue, and depression; physical conditions such as acute and chronic pain, elevated blood pressure, nausea and vomiting, and menopausal and menstrual symptoms; and nonverbal states by facilitating communication.

### Meditation

Meditation is a self-directed technique used to quiet the mind and relax the body toward peace and calmness. This is achieved by closing the eyes and creating a sound or chanting. Methods include:

- Mindfulness meditation, or the practice of focusing on the present moment (Box 12.2)
- Transcendental meditation, or the repetition of a word or sound that has special meaning
- Breath meditation, which focuses on the process of inhaling and exhaling

### Box 12.2 Mindfulness

Mindfulness is a practice of focusing active, open attention on the present moment.

A common technique to help engage in mindfulness is to focus on one's breathing, not controlling it but being aware of the natural breathing process. Another technique is focusing on areas of the body or body movements such as walking. While practicing mindfulness, it is not unusual for the mind to wander. When that happens, it is acknowledged in a nonjudgmental, accepting way, and then thoughts are returned to the present and whatever is the focus of the session. The practice of mindfulness can help ease feelings of tension and anxiety. It has been used to treat depression, insomnia, and pain, to name a few. A few practice tips include:

- Find a comfortable, safe place to sit or walk if the movement of the legs and feet is the focus.
- Set time limits when new to the practice (e.g., 5 or 10 minutes).
- Notice your breathing, body, or walking, again focusing on whatever is the emphasis of the session.
- Notice and be nonjudgmental when the mind wanders.
- Come back to the focus of the session.

Mindfulness does not require special equipment, and it can be practiced anywhere if it is safe to do so. If at work and having a stressful day, take a few minutes to be mindful to help ease the tension. Mindfulness can help build resilience in dealing with the everyday, common pressures in the workaday world.

### Prayer/Spirituality

Prayer/spirituality is a commonly used practice that provides comfort for those who are ill or in distress and serves as a healing modality to promote empathy, love, and caring. Often used in religious and spiritually based communities, prayer may be done individually or in groups.

### Yoga

Yoga is an example of a mind/body practice that incorporates breathing techniques, body movements, forms of exercise, diverse postures, meditation, and chanting. It is used to create a union of the mind, body, and spirit and to increase a sense of awareness and inner peace. Yoga is often used as a technique to quiet the mind and ease thought patterns.

### Imagery/Guided Imagery

Another example is imagery, or guided imagery, which is used to promote relaxation and transform attitudes and behaviors. Music, chanting, and speaking are often included to enhance the meditative state.

### Tai Chi

Tai chi is an ancient form of Chinese exercise that is considered a martial art; tai chi uses movement to balance the Life Force, or *qi*. It consists of low-impact body movements and breathing techniques that flow into each movement. The gentle, low-impact movements are helpful in reducing stress and alleviating the pain associated with osteoarthritis.

### Zero Balancing

The final example in this classification is ZB. Zero balancing uses skilled touch to address the relationship between the energy and structures of the body. Zero balancing focuses primarily on specific skeletal joints that conduct and balance forces of gravity, posture, and movement. When the deepest and most dense tissues are addressed, the energy fields of the body and soft tissue clear or become unblocked, thereby contributing to an increase in vitality and better postural alignment. As with other mind/body therapies, ZB leaves the individual with feelings of calmness and inner peace.

**Safety Alert** Consult a provider for physical limitations or mobility restrictions before initiating any mind/body therapies if the following conditions are present:

- Joint/back problems
- Recent surgery or back injury
- Uncontrolled hypertension
- Glaucoma (some forms of physical activity may increase eye pressure)
- Pregnancy

## Manipulative and Body-Based Therapies

Manipulative and body-based therapies represent the largest, continuously organized complementary care profession. These methods have been used and respected for more than 1,000 years. At one time, a provider's hands were considered his or her greatest assets; Hippocrates discussed the benefits of touch and massage with his students. In the 1800s, Florence Nightingale valued massage as an essential nursing skill, and the first schools of nursing included massage therapy as a foundational skill in the nursing curriculum.

In the manipulative and body-based therapy classification system, practitioners are trained in various body manipulations and techniques, such as massaging or kneading of the body's soft tissues, muscles, tendons, and ligaments to realign the skeletal and lymphatic systems. There are more than 50 practices identified in this classification system, and all require specific training, certification, or state licensure for practice. Two examples of manipulative and body-based practices that are recognized around the world and require advanced degrees are chiropractic medicine and osteopathic medicine.

Manipulative and body-based techniques also incorporate strategies and techniques from mind/body medicine and energy medicine to enhance the overall effectiveness of treatment. In general, the most common use of body-based treatments is for musculoskeletal problems, which include back pain, neck pain, and arthritis. General benefits of manipulative and body-based therapies include enhancing the immune system; facilitating mental clarity and decreasing mental stress; relief of insomnia, asthma symptoms, and muscle tension; relief of nausea associated with chemotherapy; managing blood pressure and heart rate; and reduction of the pain caused by headaches, back and joint disorders, cancer, and surgery.

## Massage Therapy

*Massage therapy* is defined as using one's hands to apply pressure and motion on the skin and underlying muscle of the recipient for the purposes of physical and psychological relaxation. Today, there are more than 30 types of massage therapy techniques, each requiring specific training and having a purpose that is uniquely its own. A few examples include Swedish massage, shiatsu, craniosacral massage, sports massage, and deep connective tissue massage.

## Chiropractic Medicine

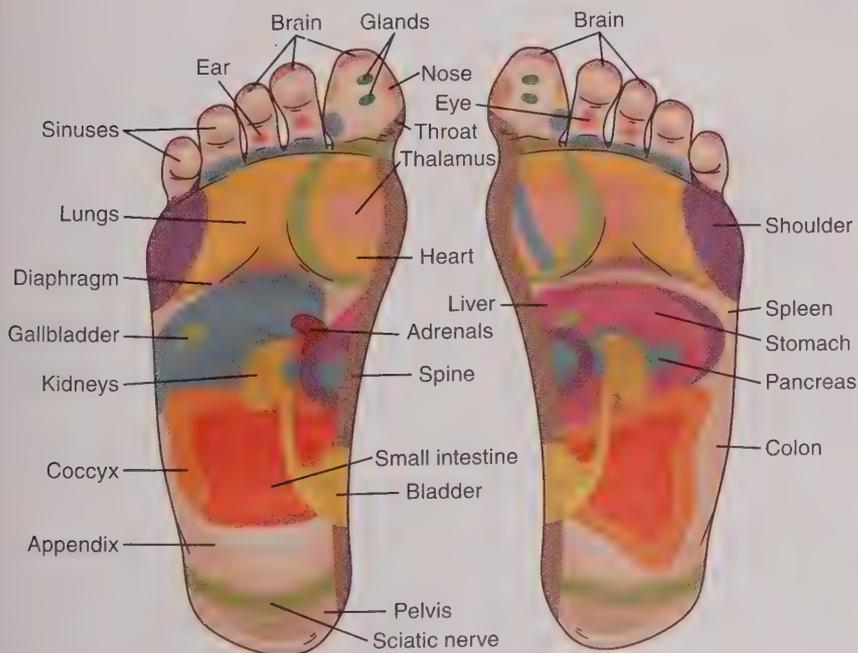

**Chiropractic medicine** uses the hands to manipulate the spine and body to restore spinal movement and overall body function. The general theory is that various forms of palpation and specific structural manipulation techniques can repair a dysfunctional relationship between the physical body and the nervous system and restore health. Research continues to sort out the effects of movement and manipulation and the relationship between the nervous system and improved physical functioning.

## Osteopathic Medicine

Osteopathic medicine has been a continuous healing method since the late 1800s. It is the process of using one's hands to manipulate and palpate soft tissues, muscles, and bones, moving them in specific ways to bring the body back into optimal function and to restore health.

## Reflexology

A unique form of body manipulation is reflexology. Within this specific discipline, it is believed that the body is divided into zones that are located in precise areas along the soles of the feet, the hands, and the ears (Fig. 12.2). Practitioners use various forms of pressure, touch, and manipulative

**FIGURE 12.2** Reflexology. Reflex points on the soles of the feet that, when skillfully massaged, can relieve tension and treat illness.

techniques directed toward the zone or zones that need to effect physical change.

### Safety Massage and body manipulation

#### Alert

Avoid massage under the following conditions or in the following areas:

- Radiation sites
- Burns
- Direct tumor sites
- Fractures
- Varicose veins
- Open wounds
- Areas with lymphedema
- Contraindicated in patients taking Coumadin (warfarin), Lovenox (enoxaparin injection), and heparin (heparin) products because of increased bleeding risk
- Caution during pregnancy—requires certification in pregnancy massage techniques

## Energy Healing Therapy

Energy healing therapy is an ancient form of treatment. Energy healing therapy enables or reestablishes the balance or flow of energy, allowing the body to be restored to optimum health. *Energy* is a general term used to explain or describe the body's essence, or inner force. In this form of healing, the practitioner places his or her hands nearby or gently on the individual receiving the treatment to guide the flow of energy. In the 1970s, Dolores Krieger, a registered nurse (RN), introduced therapeutic touch (TT) as part of the nursing curriculum at New York University.

There is little scientific evidence to support the subtle effects of energy healing on the body. However, research has shown its effectiveness in decreasing anxiety and altering the perception of pain. Anecdotal evidence suggests that energy healing is beneficial for such imbalances as stress, high blood pressure, asthma, and pain. It can also promote relaxation and a sense of well-being. Energy healing is often used in combination with other forms of CAM, including whole medical systems and manipulative and body-based therapies.

### Therapeutic Touch/Healing Touch

Therapeutic touch (TT), or healing touch, is a contemporary interpretation of several ancient healing practices. It is a consciously directed process of energy exchange during which the practitioner uses the hands to focus and to facilitate the healing process in someone who is ill.

### Reiki

Much like TT, Reiki—an ancient Japanese method—disseminates energy along the centers and pathways of the body as a means of manipulating the energy fields to restore health and well-being.

## Qi Gong

Breathing and movement add variety to the energy healing method known as *qi gong*, a 3,000-year-old Chinese healing modality. Often practiced in groups and with a skilled healer-facilitator, qi gong uses specific, gentle body movements with particular breathing techniques. This synergistic action allows the restoration of balance.

**Safety Alert** As with mind/body therapies, consult a provider for physical limitations or mobility

restrictions before initiating any energy healing therapy if the following conditions are present:

- Joint/back problems
- Recent surgery or back injury
- Uncontrolled hypertension
- Glaucoma (some forms of physical activity may increase eye pressure)
- Pregnancy

## Dietary Supplements, Herbal Medicine, and Botanicals

### Dietary Supplements

Dietary supplements are the most common alternative modality in use today and are used to support the immune system, improve memory, aid digestion, decrease nausea, alleviate cold symptoms, reduce stress, reduce menopausal symptoms, decrease arthritic pain, support heart health, and enhance the condition of the skin and hair. Mineral, vitamin, hormone, and diet-based therapies are also included in this category. The World Health Organization has estimated that 80% of the world's population uses some form of dietary supplement. In 1994, the U.S. Congress passed the Dietary Supplement Health and Education Act to ensure the safety of dietary supplements and to ensure that manufacturers are responsible for their products and appropriate label information.

### Herbal Medicine and Botanicals

Herbal medicine and botanicals are products that originate from natural plant sources such as flowers, seeds, stems, and fruits. There are more than 1,000 herbal medicine compounds, each having a unique quality, consistency, and healing property. Whether they are added to food, used as a tea or tincture, or applied to the skin for healing, herbs are the foundation of many CAM systems and are being made use of in many households in the world. Herbal medicines are included in the healthcare regimen for alternative-based systems such as Ayurvedic medicine, homeopathy, naturopathy, and Native American healing. They are also integrated into conventional medicine practices to support pharmacological approaches and augment symptom management.

Specifically, botanicals are used for their scent, flavoring, and healing properties. The term *natural* is often applied to this classification system. As nurses, we must be aware that although something may be a product from natural substances, it is not without potential risks. It is most important to consult an herbalist, naturopath, provider, or pharmacist before taking or applying an herbal or botanical product. Also, before combining herbal products and pharmaceutical products, check with the provider for potential risks of incompatibility and side effects that could cause harm. Benefits of herbal medicine include the management of gastrointestinal problems such as nausea, vomiting, constipation, and diarrhea. It can also help manage cough and congestion as well as pain, poor appetite, and insomnia.

**Safety Alert** Consult with a provider, pharmacist, or herbalist before taking, mixing, or combining herbs, botanicals, and vitamins with medications. Serious interactions and complications can occur when using these supplements in combination with pharmaceuticals. Read the label and instructions. Interactions or complications include:

- Allergy to plant content, causing:
  - Systemic effects
  - Local skin irritation
  - Asthma/respiratory distress
- Increased risk of bleeding
- Liver toxicity
- Decreased effectiveness of anesthesia

## Connection Check 12.2

The classifications of CAM include which of the following? (Select all that apply.)

- A. Hypertension prevention
- B. Guided imagery
- C. Recreational therapy
- D. Massage therapy
- E. Dietary supplementation

## NURSING IMPLICATIONS: ASSESSMENT, EDUCATION, AND RESEARCH

As CAM continues to grow in popularity, it is vital that nurses be knowledgeable about the usefulness, safety, and appropriateness of CAM in order to guide patients through the labyrinth of Western medicine and complementary healthcare choices.

The NCCIH has identified dietary supplements and manipulative and body-based therapies, as well as yoga and mind/body therapies, as the most common CAM modalities

used by adults (Box 12.3). Additionally, 40% of adults use CAM for various illnesses and symptom relief, such as for pain relief, anxiety and depression, and insomnia. Most often, adults choose CAM for its natural characteristics and the quality of care that they receive. Individuals are seeking a value-driven partnership and rapport related to overall healthcare needs, and CAM supports that need as defined by the guiding principles of partnership, wellness, and energy models. A thorough assessment of the patient's attitudes related to CAM is an important first step in establishing a baseline holistic health assessment and building rapport with the patient and the family. Possessing an accepting and respectful communication style will enhance the effectiveness of the assessment and help build a trusting partnership.

Understanding the goals of care and how the patient will benefit from CAM is another component needed in building a foundation for competent, safe nursing care. Patients have constant access to CAM information via the Internet and popular press and through word of mouth. It is the responsibility of the nurse to ensure that patients have an understanding of the principles of CAM, the reasons for choosing CAM, and how the integration of therapies into their plan of care may benefit them. Providing and assisting individuals with finding accurate and reliable Web sites, well-written reading materials, and documented evidence-based research will help them and their family members make well-informed choices. Other information that is vital for patients is how to choose a CAM practitioner. Before treatment, patients may wish to interview CAM practitioners and review their qualifications and credentials. Box 12.4 is a guide to assist patients in finding a qualified and skilled CAM practitioner. Providing the patient with this list of provider questions will help to ensure that he or she receives treatment from a qualified therapist.

The use and acceptance of CAM in the conventional medical community are diverse and multifaceted. Some of the challenges of supporting an integrative healthcare approach are a shortage of qualified CAM practitioners; the

## Box 12.3 Most Common Complementary and Alternative Medicine Modalities Used by Adults

1. Natural products
2. Deep breathing
3. Meditation
4. Chiropractic/osteopathy
5. Massage therapy
6. Yoga
7. Diet-based therapies
8. Progressive relaxation
9. Guided imagery
10. Homeopathic therapy

## Box 12.4 Questions to Ask When Seeking a Complementary and Alternative Medicine Provider

1. What benefits can I expect from this therapy?
2. How will this therapy benefit my current condition?
3. Are there any risks associated with this therapy?
4. Should I expect any side effects from this therapy?
5. Will the therapy interfere with any of my daily activities?
6. How many sessions, and how often, will be needed for my condition?
7. How often will my progress or plan of treatment be assessed?
8. Will I need to buy any equipment or supplies?
9. Do you have any scientific articles or references about this particular treatment?
10. Can I use this therapy along with my conventional treatment plan and medications?
11. Could the therapy interact with conventional treatments?
12. Are there any conditions for which this treatment should not be used?
13. What type of education is required for this therapy?
14. Are you licensed for this type of therapy?
15. How long have you been in practice?
16. What are the costs for this form of therapy? Do you take insurance?

lack of knowledge related to CAM, which may deter open communication by conventional medicine healthcare providers; insufficient funding to support an integrated program; the lack of insurance reimbursement; and the need for more research to demonstrate and substantiate the effectiveness of treatment. Barriers to conducting research include limited funding, the lack of research infrastructure and standardization processes to interpret systemic reviews, and a limited number of patients to support trials. Most important is that the care is very nonstandard and personalized, so it is hard to evaluate on a large scale. Despite these challenges, CAM therapies are being sought out and used by the public with increasing frequency. This is an opportunity for nurses to consider evidence-based research projects related to CAM therapies to validate their clinical efficacy and ensure patient safety.

### Connection Check 12.3

As a nurse who understands the guiding principles of CAM, your first step in guiding the patient is:

- A. Referring the patient to a massage therapist to help manage stress
- B. Explaining that the patient's *qi* is out of balance
- C. Asking questions related to the presenting symptoms, work, and family to start building trust and rapport with the patient
- D. Giving information related to a specific symptom the patient has reported to build a partnership with him or her

## Making Connections

### CASE STUDY: WRAP-UP

In a discussion with her nurse, Ms. Ellicott begins to explore CAM therapies in detail. In addition to acupuncture, there are other options to be considered. Manipulation and body-based therapies such as massage may be helpful. Mind/body therapies such as meditation or tai chi also seem promising. Ms. Ellicott and her nurse agree that a healthy diet that includes appropriate dietary supplements is a necessary foundation for any therapies considered.

#### Case Study Questions

1. Which of the following symptoms of Ms. Ellicott are listed among the NCCIH's top 10 reasons that adults seek CAM therapies? (*Select all that apply.*)
  - A. Migraine headaches
  - B. Depression
  - C. Hypertension
  - D. Anxiety
  - E. Stress
2. Ms. Ellicott states to you that she is interested in CAM. You explain to her that the goals of CAM are: (*Select all that apply.*)
  - A. To improve quality of life
  - B. To repair and restore *qi*, the Life Force
  - C. To promote wellness
  - D. To treat hypertension
  - E. To eliminate stress
3. Ms. Ellicott has decided that she would like to learn more about massage therapy, acupuncture, and guided imagery. She states, however, that she has concerns about the safety and efficacy of the treatments. Which of the following resources should you refer her to so that she can learn more about CAM?
  - A. National Center for Complementary and Integrative Health (NCCIH)
  - B. White House Commission on Complementary and Alternative Medicine
  - C. Center for Integrated Medicine
  - D. American Association of Acupuncture and Oriental Medicine
  - E. All of the above
4. Ms. Ellicott is expressing concerns about being touched. You explain to her that there are CAM therapies that have a meditative and restful quality and do not involve touch. As the nurse, which of the following therapies do you suggest?
  - A. Homeopathy
  - B. Reflexology
  - C. Yoga or prayer
  - D. Massage therapy

5. Ms. Ellicott's provider is considering starting a hypertensive medication along with an anti-anxiety agent. Ms. Ellicott states that she has heard of herbal remedies that can help with depression and lower blood pressure. She states that she would like to take something more natural. As the nurse, your best response is:
- To discuss the use of herbal remedies with the provider
  - To agree with Ms. Ellicott that because she is newly diagnosed with hypertension, trying an herb first is a good idea
  - To explain to Ms. Ellicott that even though an herb is natural, there are contraindications when combining herbs with pharmaceutical medications
  - To suggest further discussion with the provider along with a review of resources and collaboration with a pharmacist, naturopath, or herbalist

## CHAPTER SUMMARY

The popularity of and growth in the field of CAM are expanding into hospital units, outpatient centers, and private provider offices, which are more commonly considered venues for conventional medicine. The National Health Interview Survey estimated that CAM is a multibillion-dollar industry and that those seeking CAM are paying more than a quarter billion dollars out of pocket annually for services. Although CAM systems are centuries old, CAM is a relatively new concept in the United States and other developed countries where conventional medicine is the dominant source for healthcare. The need for education is paramount,

as are opportunities for CAM research to substantiate the effectiveness and best practices related to CAM therapies. Currently, 57 academic medical centers in the United States are part of the Consortium of Academic Health Centers for Integrative Medicine, whose mission is to advance the principles and practices of integrative medicine.

The NCCIH classifies CAM into five categories: old-world traditions, mind/body therapies, manipulative and body-based therapies, energy therapy, and dietary supplements and botanical/herbal medicine. Of these therapies, various forms of manipulative and body-based therapies, yoga, meditation, and breathing therapy are most commonly used by adults for symptoms such as pain, headache, anxiety, and depression. The goals of CAM include promotion of wellness, prevention of illness, reduction of treatment side effects, improvement of the immune system, and enhancement of quality of life—often reasons why 40% of adults seek CAM as an alternative for maintaining a healthy lifestyle. With 40% of the population using CAM, it is essential to include CAM in nursing education not only at the university level but also in hospital and outpatient settings so that the benefits and safety risks associated with CAM modalities are well understood. Along with advocating for educational opportunities, another fundamental need is for evidence-based research projects to ensure safe and competent care.

Bridging between the practices of Western medicine and CAM is a fundamental nursing role; being attuned to the guiding principles of CAM gives way to understanding the wisdom of integrative medicine, that is, treating an individual as a whole person—physically, mentally, and spiritually—to promote optimum health and well-being. Nurses are the channels for building collaborative partnerships so that all care, for all individuals, will be safe and best practices for individualized care will be considered.

# Chapter 13

## Overview of Cancer Care

*Brenda Shelton*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Discussing the epidemiology of cancer
2. Explaining the pathophysiology of cancer cells
3. Describing vital diagnostic and preventive measures for the oncology patient
4. Identifying treatment options for oncology patients
5. Analyzing nursing care for the oncology patient
6. Developing teaching and support strategies for the oncology patient and family

### CONCEPTS

- Assessment
- Cellular Regulation
- Fluid and Electrolyte Balance
- Infection
- Promoting Health

### ESSENTIAL TERMS

Adjuvant therapy  
Anaplasia  
Anchorage dependence  
Antineoplastic  
Apoptosis  
B symptoms/constitutional symptoms  
Brachytherapy  
Cancer  
Carcinogen  
Carcinogenesis  
Carcinogenic  
Chemoprevention  
Chemotherapy  
Contact inhibition  
Dysplasia  
Hematological malignancies  
Malignant  
Metastasis  
Metastatic tumor  
Neoadjuvant therapy  
Neoplasia  
Oncogene  
Palliation  
Primary tumor  
Radiation therapy  
Remission  
Secondary tumor  
Solid-tumor malignancies  
Vesicants

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Margaret Jones is a 49-year-old woman who has presented to her primary care provider with a new lump in her right upper, outer breast that was noted during showering. She reports no associated symptoms such as nipple discharge or breast pain. Mrs. Jones is premenopausal, stating she has noted no changes in her menstrual cycle. When the nursing medical history screening form is completed, the following are noted:

- Normal functional status, working as a schoolteacher
- Absence of smoking or substantial alcohol intake
- Family history of ovarian cancer in mother; maternal aunt dying of unknown abdominal cancer
- Past medical history of fibrocystic breasts, hypertension for 5 years, and moderate obesity

Physical examination shows:

- A palpable and immovable mass approximately 2 cm in size deep in the breast and near the axilla
- No other adenopathy is appreciable.
- Her abdominal organs are palpated as regular in size...

## INTRODUCTION

**Cancer** is a constellation of diseases involving a **malignant** (unregulated) transformation of cells within a specific body system. Although there are many different types of cancers, all cancers are characterized by uncontrolled growth of malignant cells that compromises the integrity and function of normal, healthy cells. Cancer affects males and females of all ages, infants to adults. Its clinical presentation can vary from severe and acute clinical findings to a more chronic and indolent, or slowly developing, disease. Clinical features vary on the basis of cancer type, staging, and specific molecular characteristics.

## EPIDEMIOLOGY

Cancer is the second leading cause of death worldwide, and rates are expected to increase over time. Globally, the most common types of cancer are lung, breast, colorectal, prostate, skin, and stomach cancer. However, cancer incidence (rate of new cases), prevalence (number of total cases), and mortality vary on the basis of gender, national socioeconomic indicators, and carcinogen exposure. Globally, women are more likely to develop breast, cervical, or colorectal cancer; men are more likely to develop lung, prostate, or colorectal cancer. Socioeconomic indicators are correlated with different cancer epidemiological patterns. In countries where life expectancy is

beyond 70 years of age because of robust economic and healthcare systems, such as the United States, cancer is more common. This is because individuals are more likely to live longer in these countries, and older adults are simply more likely to develop cancer. It is well known that the competence of immune surveillance mechanisms weakens with aging, increasing the risk of missed mutations and the development of malignancy. Cancer is generally regarded as a disease of advanced age and is linked to mutations that occur over time. In developing countries where life expectancy is lower secondary to poor healthcare infrastructure and economic challenges, the risk of developing cancer is lower compared with the risk of contracting other diseases such as infectious disease. People simply do not live long enough to have high rates of cancer. Unfortunately, although there are fewer cases of cancer in developing countries, mortality is higher than in developed nations secondary to a healthcare infrastructure that is unable to effectively identify cancer early or provide treatment, accounting for 70% of worldwide deaths due to cancer. Cancer-causing infections such as hepatitis and human papillomavirus (HPV) are the attributable etiology for cancer in 25% of cases in developing countries. Finally, **carcinogen** (cancer trigger) exposure varies across nations for different reasons, leading to different cancer disease patterns. For example, rates of thyroid cancer and leukemia are higher in Ukraine than in other countries. This is believed to be associated with Ukrainian population exposure to **carcinogenic** levels of radiation after the 1986 explosion of the Chernobyl nuclear reactor. Food contaminants such as aflatoxins and water contaminants such as arsenic also contribute to cancers in specific populations.

## Prevalence in the United States

Cancer is the second most common illness and cause of death in the United States. There were 1,735,350 cases projected for the United States in 2018. There is a high incidence of cancer in infants, children, and young adults, but it is primarily a disease more prevalent in elders. This is presumably because of increased rates of cell mutation with older age. Seventy-eight percent of all cancers are diagnosed in adults aged 55 years or older. Despite a general concept that cancer is typically a life-threatening disease, the majority of patients with cancer survive more than 5 years after diagnosis. The most current 5-year overall cancer survival rate based on data collected between 1975 and 2014 is estimated to be greater than 68%, up from 50% in the 1970s.

The most common cancers in adults in the United States in order of greatest incidence are prostate, breast, and lung. In men, prostate cancer is the most common, followed by lung and colorectal. In women, breast cancer is the most common, followed by lung and colorectal cancer. In children, leukemia is the most common, followed by brain tumors. Cancers that are detected at an early stage or with a slow proliferation rate are associated with longer survival. Prevalent cancers, such as breast and prostate cancers, are

associated with excellent 5- to 10-year survival, but lung and colon cancers have a less promising prognosis unless detected when still surgically excisable. Cancers of highest risk are listed in Table 13.1.

### Connection Check 13.1

Cancer is the \_\_\_\_\_ most common cause of death in the United States.

- A. first
- B. second
- C. third
- D. fourth

### Risk Factors for Cancer

The most common risk factor for cancer is exposure to a carcinogen. Carcinogens are internal or external exposures that predispose individuals to DNA destruction, resulting in cellular mutation that may ultimately lead to malignant transformation of cells. Examples of some well-documented carcinogens are ionizing radiation, benzene, HPV, sun exposure, and tobacco. Carcinogen exposure alone is unlikely to trigger cancer. **Carcinogenesis**, the initiation and promotion of cancer, involves a series of other molecular changes that occur after exposure to carcinogens. For this reason, not all individuals with known risk factors or known exposure to a carcinogen develop the disease. Environmental, hormonal, and lifestyle factors; infectious disease; medications; immune status; and nutritional factors are all believed to influence the development of cancer.

In addition to carcinogens, there are other modifiable and nonmodifiable risk factors for cancer. **Nonmodifiable cancer risk factors**, or factors that the individual cannot alter to decrease the risk for cancer, include age and genetic predisposition. Advanced age increases the risk of cancer. This is believed to be related to greater exposure to carcinogens over time as well as changes in immune function. Another nonmodifiable risk factor is genetic predisposition.

**Table 13.1 Cancer Statistics: Five Most Common Cancers by Gender**

Males	Females
Prostate	Breast
Lung and bronchus	Lung and bronchus
Colon and rectum	Colon and rectum
Urinary bladder	Corpus and uterus
Melanoma of the skin	Thyroid

Data from Siegel, R. L., Miller, K. D., & Jemal, A. (2018). Cancer statistics, 2018. *CA: A Cancer Journal for Clinicians*, 68(1), 7–30. doi:10.3322/caac.21442

Approximately 5% to 10% of cancers are related to known genetic syndromes. Genetic counseling is a useful tool for identifying and screening individuals who have a family history of cancer or a known genetic syndrome associated with cancer. A generally recognized modifiable risk factor for cancer is lifestyle. Specifically, a sedentary lifestyle and poor diet and/or smoking put an individual at increased risk for cancer. Cancer associations with specific diseases, such as the relationship between colon cancer and inflammatory bowel disease or hepatic cancer resulting from hepatitis C infection, are modifiable but only as much as the management of the triggering disease. Regardless of whether a risk factor is modifiable or not, risk factors are believed to be cumulative, with multiple risks connoting additive cancer risk. Risk modification leading to primary prevention is possible in some circumstances, but when not preventable, frequent screening to detect cancer (secondary prevention) at its earliest stage is recommended.

## PATHOPHYSIOLOGY

### Carcinogenesis

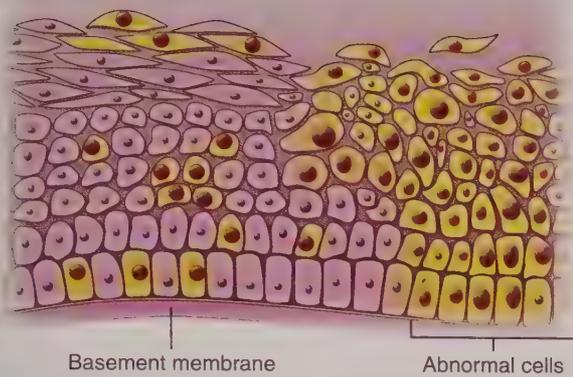

Cancer initiation typically begins with carcinogen exposure, which subsequently triggers single- or multiple-gene mutations. An individual likely experiences multiple carcinogen exposures and genetic mutations over time; however, the immune system protects the individual by recognizing the mutation and initiating cell death. In carcinogenesis, the mutated cells are not detected by the immune system and are therefore able to proliferate and progress into cancer. The specific gene or multiple gene associations with different types of cancer is a growing field of study, and many cancers have identified mutations that can be abrogated with newer targeted antineoplastic therapies.

### Cancer Characteristics

Cancer is characterized by two hallmark characteristics: uncontrolled cell growth and altered cell differentiation.

#### Uncontrolled Cell Growth

Normal cells grow in a structured pattern, and stimulation for cell growth is tightly controlled so that the number of cells produced by the body is roughly equivalent to the number of cells lost through cell death or shedding. Cancer cell growth and proliferation are unregulated by typical mechanisms. Normal cells are regulated by **contact inhibition** and stop growing and reproducing when they come into contact with other cells. Cancer cells lack contact inhibition. A regular cell cycle that ends with programmed cell death, **apoptosis**, is common with normal cells, but cancer cells do not undergo apoptosis. Normal cells typically need to anchor to either neighboring cells or basement cells so that they can plug into a nutrient-rich extracellular matrix to remain viable, but cancer cells do not have this type of **anchorage dependence** and can grow and flourish in atypical patterns and environments. This uncontrolled growth may result in **dysplasia** (Fig. 13.1),

**FIGURE 13.1** Mild dysplasia of cancer cells. Yellow cells indicate abnormal cells.

or deranged cell growth, in which cells vary in size, shape, and organization. In healthy tissue, dysplasia may be a risk for cancer, but it is not synonymous with cancer; it simply describes a cell-growth pattern but is often thought to be a precursor to malignant cell transformation. Another term often used to describe cell-growth patterns in cancer is **neoplasia**, which means uncontrolled cell proliferation. Like the term *dysplasia*, neoplasia is not synonymous with cancer because there are benign neoplasms; however, the term *neoplasia* describes a new cell-growth pattern that is characteristic of cancer. In summary, cancer cells are malignant neoplasms that grow uncontrollably and invade surrounding tissues and vessels. They have the capacity to destroy normal tissue, steal nutrition, create their own blood vessels, and survive even under anoxic or acidotic conditions.

### Altered Cell Differentiation

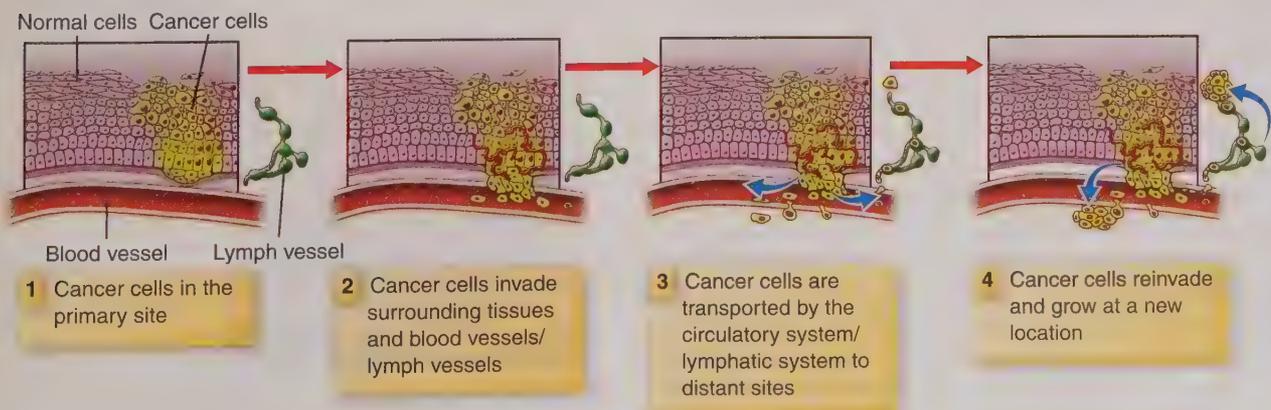

Healthy, fully developed cells are well differentiated and have specific structural and functional characteristics. A malignant cell derives from a parent cell, such as a breast tissue cell, but no longer performs the expected functions of the parent cell, and the structure may be different as well. When a cell loses expected structure and function, it is called **anaplasia**. As cancer proliferation progresses, the cancer cell loses similarity to the parent cell. There is

a range in pathological presentation: Cancer cells may be well differentiated and look similar to the parent cell, undifferentiated and look nothing like the parent cell, or somewhere in between these extremes. Poorly differentiated cells are more difficult to treat. These cancers are often associated with more refractory and aggressive tumors, even if from the same tissue origin. The extent of differentiation is an important element in grading malignant neoplasms. Tumor grading is a mechanism to classify or describe tumors and is often used to plan treatment.

### Metastasis

Cancer cells replicate and expand locally into masses of cells known as malignant tumors. The propensity for tumors to spread is called **metastasis** (Fig. 13.2). Cancer cells spread by cell-to-cell transfer, through the lymphatic system, or through the blood (hematogenous). Cell-to-cell transfer is characterized by direct invasion into adjacent cells. Lymphatic spread occurs when the tumor cells migrate into the lymphatic system using lymph channels that serve the organ where the cancer originated. Once in a lymph node, the cancer cell may be destroyed, grow into a mass, remain dormant, or spread to more distant lymph nodes and potentially into the vasculature. Hematological spread, or spread through the blood system, typically occurs when the cancer cell migrates into the venous system that drains the organ where the cancer originated.

Many cancers metastasize in a predictable pattern. For example, prostate cancer is notable for a tendency to spread by cell-to-cell transfer, so advanced disease is most likely to present with metastasis to nearby tissues, such as the rectum, pelvic floor, lower spine, or hip. Colorectal cancer commonly metastasizes hematogenously, and because the blood supply in closest proximity to the colon is the portal circulation, the liver is a common site of metastasis. When a tumor metastasizes, it often remains molecularly similar to the tumor of origin. That is to say, prostate cancer that has metastasized to the rectum has the same cellular and molecular qualities as prostate cancer; the prostate cancer cell has simply relocated

**FIGURE 13.2** The stages of cancer metastasis.

to the rectum to create a prostate cancer tumor in the rectum. In other words, a rectal tumor originating from cancer of the rectum is different from a rectal tumor originating from cancer of the prostate. In the latter case, the tumor in the prostate is the **primary tumor**, and the tumor in the rectum is the **secondary tumor**, or **metastatic tumor**. Despite these similarities to the site of origin, metastatic lesions may also be molecularly unique and resistant to therapies that are effective for tumors in their primary site of origin.

### Connection Check 13.2

What is the difference between the cells of a benign tumor and the cells of a malignant tumor?

- The cells of benign tumors are typically aplastic.
- The cells of malignant tumors are apoptotic.
- The cells of malignant tumors lack contact inhibition.
- The cells of benign tumors are characterized by uncontrolled cell growth.

## TYPES OF CANCER

Cancers are generally divided into two main categories: solid tumors and hematological malignancies. **Solid-tumor malignancies** arise from specific body organs and grow into masses that invade and erode normal body tissue as they expand in size. An example of a solid-tumor malignancy is lung cancer. **Hematological malignancies** arise from cells of the hematopoietic cell line or from secondary immune organs such as the lymph nodes or spleen. The hematopoietic stem cell gives rise to all myeloid and lymphoid cells in the body, which later develop into cells of the blood system and immune system. A hematological malignancy can therefore affect any of the blood cells in the hematopoietic cell line, including red blood cells, white blood cells, and platelets. The three major subcategories of hematological malignancies are leukemia, cancers involving blood cells; lymphoma, cancers involving the lymphatic system; and multiple myeloma, cancers involving plasma cells and immunoglobulins.

Cancers are further classified according to the organ of origin or system of origin. This classification generally determines naming conventions, particularly for solid-tumor malignancies. To illustrate, a malignant tumor arising from tissue in the lung is called *lung cancer*. Naming conventions for hematological malignancies generally follow the same rules. For example, leukemia refers to a subclass of hematological malignancies in which the leukocytes involved in bone marrow development are affected. However, in both solid-tumor and hematological malignancies, there is a spectrum of disease presentation within each general class that is determined by specific molecular characteristics, genetic mutations, and clinical findings. Understanding the broad classification as well as the unique

presentation of a particular disease is critical for treatment planning.

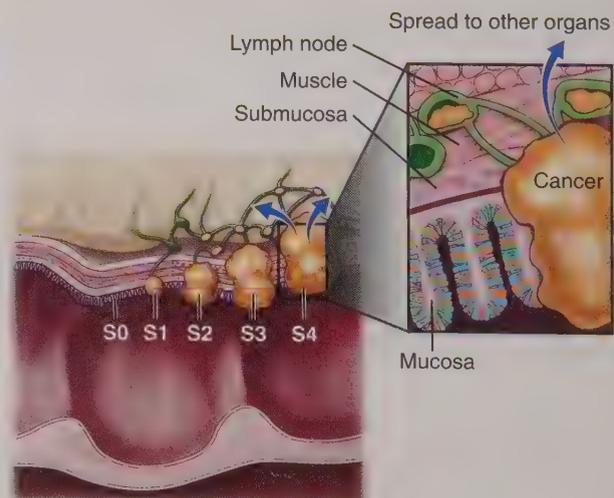

## STAGING

Once a cancer type has been diagnosed, the cancer is then further classified by stage. Staging is a classification system that considers the size of the tumor, burden of the disease, and extent of disease spread (Fig. 13.3). The stage of disease is used to plan patient assessment, clinical management, and treatment strategies. The basic components of solid malignancy staging are tumor size (T), number of lymph nodes involved (N), and presence of metastases (M). This TNM staging has differing combinations of tumor size or lymph nodes involved for each different kind of cancer. The American Joint Committee on Cancer (AJCC) has a book devoted to defining all staging systems. Cancer is generally staged along a continuum of one (I) through four (IV). A small tumor without obvious spread outside the organ is termed stage I, invasion of deeper tissues or involvement of local lymph nodes is stage II, large or locally invasive tumors are stage III, and cancers that have metastasized are considered stage IV. Some malignancies also include tumor-specific markers or molecular features in their staging system. All hematological malignancies are cancer stage IV at diagnosis because the disease is not well contained or localized because the hallmark clinical feature is that it is present in the hematological system at diagnosis.

## CLINICAL PRESENTATION

Patients with cancer often initially present with three general types of symptoms:

- CAUTION symptoms
- Constitutional symptoms
- Malignancy-specific signs and symptoms

**FIGURE 13.3** Staging of cancer. In S4, cancer cells have invaded surrounding tissue and spread to other organs.

**CAUTION** is an acronym used to describe common “warning signs” for cancer. Please see Box 13.1 for a full description. Often, patients experience a **CAUTION** symptom, and that serves as the impetus for visiting a doctor and therefore is a part of the initial clinical presentation. **CAUTION** symptoms occurring for more than 2 weeks warrant evaluation by a medical provider.

Cancer may also present with a constellation of vague symptoms, including fatigue, significant unexplained weight loss, fever of unknown etiology, and night sweats described

as **constitutional symptoms**. This term is a formal classification in B-cell lymphoma. In B-cell lymphoma, constitutional symptoms are described as **B symptoms**, but fatigue is not an element of this formal classification system. B symptoms are considered an important prognostic indicator in B-cell lymphoma.

Finally, patients may present with symptoms characteristic of a specific malignancy; therefore, clinical presentation varies on the basis of the disease. These symptoms are related to the location of the primary cancer, the location of metastatic disease, metabolic changes associated with the malignancy, and the specific pathology of the disease. Symptoms and complications of solid tumors are often related to tumor-mass compression or erosion into normal anatomical structures. For example, individuals with primary brain cancer may present with pain secondary to tumor compression of nerves in the skull or signs of increased intracranial pressure from tumors that are occupying space within the cranium and minimizing room for functioning neurons, blood flow, and cerebrospinal fluid flow. This causes pain as well as other central nervous system changes. Please see Table 13.2 for key clinical features of specific cancers.

### Box 13.1 CAUTION or Warning Signs of Cancer

- C** Change in bowel or bladder habits
- A** A sore that does not heal
- U** Unusual bleeding or discharge
- T** Thickening or lump in the breast or any other part of the body
- I** Indigestion or difficulty swallowing
- O** Obvious change in a wart or mole
- N** Nagging cough or hoarseness

**Table 13.2 Common Cancers With Risk Factors and Defining Features**

Cancer	Risk Factors	Clinical Signs and Symptoms	Common Sites of Metastases (in order of frequency)
<b>Bladder cancer</b>	Tobacco	Hematuria	Regional lymph nodes
	Cigarette smoking	Abdominal discomfort	Bone
		Distended abdomen	Lung
		Low-back pain	Skin
			Liver
<b>Brain tumor</b>	Alcohol, excessive	Headaches	Spinal cord
		Personality changes	
		Somnolence or hyperactivity	
		Memory deficits	
		Visual disturbances	
		Focal motor deficits	
<b>Breast cancer</b>	Endocrine disruptors: early menses, late menarche, nulliparity, late first child	Breast mass	Bone
		Axillary node enlargement	Lung
	Genetic propensity ( <i>BRCA1</i> , <i>BRCA2</i> , <i>p53</i> )	Asynchrony of breasts	Lymph nodes
		Nipple discharge	Liver
Obesity, high-fat diet		Brain

**Table 13.2 Common Cancers With Risk Factors and Defining Features—cont'd**

<b>Cancer</b>	<b>Risk Factors</b>	<b>Clinical Signs and Symptoms</b>	<b>Common Sites of Metastases (in order of frequency)</b>
<b>Cervical cancer</b>	Multiple sexual partners, early sexual contact	Vaginal bleeding, especially postcoital	Endometrium
	Human papillomavirus	Vaginal discomfort	Vagina
	Tobacco	Malodorous vaginal discharge	Extrapelvic wall
	Oral contraceptives used over a long period of time	Tumorous lesions on cervix Pain with sexual intercourse	Vulva
<b>Colon cancer</b>	Alcohol, excessive	Altered bowel habit—may be constipation or diarrhea; thin, ribbonlike stools	Liver
	Beer consumption (rectal cancer only)	Blood in stool—overt or occult	Lung
	Intestinal polyps, polyposis	Abdominal fullness/distention	Muscle
	Obesity, high-fat diet	Anorexia	
	Chronic bowel disease—Crohn's or ulcerative colitis	Weight loss Unexplained anemia	
<b>Esophageal cancer</b>	Alcohol, excessive	Dysphagia	Liver
	Cigarette smoking	Indigestion/reflux Chest discomfort	Lung Bones
<b>Gastric cancer</b>	Alcohol, excessive	Indigestion	Lymph nodes
	Gastric ulcers	Loss of appetite	Esophagus
	Asbestos	Abdominal discomfort	Periumbilical soft tissue
	Cigarette smoking <i>Helicobacter pylori</i> infection	Postprandial fullness Nausea/vomiting	Liver
<b>Head and neck cancer</b>	Alcohol, excessive	Oral lesions or bleeding	Varies with each specific tumor region (e.g., soft tissue, oropharyngeal, nasopharyngeal)
	Tobacco	Facial/oral/neck masses	
	Wood dust	Pain in neck/jaw	
	Human papillomavirus infection	Lymph node enlargement of face/neck	Lymph nodes Lung
<b>Hepatic cancer</b>	Alcohol, excessive	Abdominal discomfort	Omentum/peritoneum
	Budd–Chiari syndrome	Nausea/vomiting	Pleura
	Hepatitis A/B/C	Easy bruising Jaundice	

**Table 13.2 Common Cancers With Risk Factors and Defining Features—cont'd**

<b>Cancer</b>	<b>Risk Factors</b>	<b>Clinical Signs and Symptoms</b>	<b>Common Sites of Metastases (in order of frequency)</b>
<b>Kidney cancer</b>	Pesticides Solvent exposures Tobacco	Flank pain Hematuria Weight loss	Lymph nodes Lung Liver Bone Adrenal gland Brain Opposite kidney Subcutaneous skin nodules
<b>Leukemia</b>	Alkylating agents Genetic mutations Radiation exposure	Fatigue Anemia Chronic infection Bruising, petechiae, gum bleeding	Diffuse at diagnosis
<b>Lung cancer, non-small cell and small cell</b>	Asbestos Coal, soot, tar Pollution Tobacco Wood dust	Chronic cough Hemoptysis Dyspnea Chest discomfort Weight loss Paraneoplastic syndromes	Brain Bone Adrenal gland Contralateral lung
<b>Lymphoma, Hodgkin's and non-Hodgkin's</b>	Immunosuppression, chronic (e.g., long-term corticosteroids or after solid-organ transplant) Radiation Viruses—Epstein-Barr, HIV	Lymphadenopathy Palpable masses, subcutaneous tissue	Generally considered diffuse at diagnosis, but staging does allow for limited lower stage disease with limited lymph node groups involved
<b>Melanoma</b>	Sun exposure Ionizing radiation Family tendency	Skin lesions—varied color, irregular shape, raised or crusty texture Lesions that are new or growing Lesions on palms of hands, soles of feet	Lymph nodes Subcutaneous tissue Lung Brain Liver Bones
<b>Multiple myeloma</b>	Older age African American	Fatigue Dark, infrequent urine Bone pain	Not exactly metastatic, but bone and kidney infiltrations are signs of advanced disease

<b>Cancer</b>	<b>Risk Factors</b>	<b>Clinical Signs and Symptoms</b>	<b>Common Sites of Metastases (in order of frequency)</b>
<b>Ovarian cancer</b>	Genetic— <i>BRCA1</i> , <i>BRCA2</i>	Abdominal fullness, bloating	Peritoneum, omentum
	Endocrine disrupters—nulliparity, no breastfeeding, long-term oral contraceptive use	Fatigue	Pleura
<b>Pancreatic cancer</b>	Genetic— <i>BRCA2</i>	Nausea, vomiting	Liver
	Tobacco	Early satiety	Peritoneum
	Diabetes	Vague abdominal discomfort	Lungs
	Hereditary or chronic pancreatitis	Anemia	Bones
	Hepatitis A/B/C	Jaundice	
	Stomach ulcers		
	Obesity		
<b>Prostate cancer</b>	Age	Pelvic/rectal pain	Bones
	Family history	Dysuria	Lymph nodes
	Pesticides	Nocturia	Rectum
		Erectile dysfunction	Bladder
<b>Sarcoma</b>	Arsenic	Dependent upon location of mass—soft tissue masses or evidence of organ dysfunction that shows masses on radiological tests	Almost anywhere—extension of mass or recurrence at original site is common
	Dioxins		
	Herbicides		
	Radiation, ionizing		
<b>Skin cancers</b>	Radiation, ionizing	Dark, irregularly shaped skin lesions	Rare, soft tissues
	UV/sun exposure		
<b>Testicular cancer</b>	Undescended testicles	Painless lump in scrotum	Lymph nodes
	History of HIV	Dull ache or heavy sensation in pelvis, anus, or scrotum	Lung
	Age (20–34)		Liver
			Bones
	Brain		
<b>Thyroid cancer</b>	Radiation, ionizing	Enlarged thyroid—diffuse and irregular	Lymph nodes
		Dysphagia	Lung
			Bone
<b>Uterine (endometrial) cancer</b>	Early menarche, late menopause	Abnormal menstrual cycles	Lymph nodes
	Estrogen replacement therapy	Vaginal bleeding, especially between cycles	Vagina
	Polycystic ovary disease	Lower abdominal pain/cramping	Abdominal peritoneal cavity, omentum
	Infertility		
	Tamoxifen		
	Diabetes mellitus		
	Obesity		

## Oncological Emergencies

Oncological emergencies are acute clinical complications that may occur in the presence of malignancy. They require urgent treatment to prevent long-term physiological deficits. Oncological emergencies may be secondary to the processes of tumor growth and invasion of body organs, metabolic changes from malignant cells, or a result of treatment. They are generally categorized as structural, metabolic, and hematological, but organ dysfunction may also be present. Probabilities of oncological emergencies vary with cancer type. The nurse should become familiar with oncological emergencies associated with specific cancers and when each emergency is more likely to be expected

across the disease and treatment trajectory. This allows the nurse to anticipate the diagnosis and proactively manage symptoms. **Management of oncological emergencies** should be based on evidence-based practice as well as the patient's condition, prognosis, and preferences. If a patient is at the beginning of treatment and has the potential for recovery, the oncological emergency should be aggressively managed. On the other hand, if the emergence of an oncological emergency is an ominous sign of progressive disease, then the patient and the team may opt for a less aggressive, palliative approach to management. A summary of common oncological emergencies, important clinical features, and nursing implications is provided in Table 13.3.

**Table 13.3 Selected Oncological Emergencies**

Oncological Emergency	Pathophysiology	Clinical Presentation	Clinical Management	Nursing Implications
<b>Bowel obstruction:</b> most commonly found in tumors involving the bowel such as colon cancer and pancreatic cancer and abdominal masses such as ovarian, hepatic, and prostate cancers	Masses in bowel lumen obstruct normal flow of enteral contents, GI fluids, and wastes. External compression causes bowel obstruction. Obstructions can be partial or complete and involve the small or large bowel. The greatest danger of obstruction is rupture or perforation.	Obstruction causes reverse peristalsis with vomiting and abdominal distention. Bowel sounds are increased prior to the obstruction and diminished or absent after the obstruction. Stools may be thin or ribbonlike, or constipation with intermittent diarrhea may be present.	Best treated with surgery when resectable.  Medical management: NPO/parenteral nutrition, peristaltic stimulants unless complete obstruction, when stimulants may cause intestinal rupture.	Detailed GI assessment: appetite; bowel movements; constipation; diarrhea; thin, ribbonlike stools; bowel sounds; presence of nausea, vomiting, distention, pain.
<b>Hypercalcemia:</b> most commonly found in cancers that metastasize to bone, such as breast, lung, and renal cancers, but can be related to paraneoplastic hormone production in lung and pancreatic cancers	Produced by bone demineralization (resorption) with release of calcium into systemic circulation. Bone invasion with tumor can activate osteoclasts; tumors may create their own parathormone-like substance, or renal dysfunction can contribute to this process.	Common symptoms include delirium symptoms, somnolence, muscle weakness, polyuria, bradycardia, nausea, and constipation. Symptoms vary depending on the calcium level and how quickly the hypercalcemia developed.	Hydration with normal saline dilutes calcium and enhances excretion of calcium. Bisphosphonates (e.g., pamidronate, zoledronate) are used as treatment or prevention of hypercalcemia in patients with bone metastases.  Monoclonal antibody directed at the RANK ligand (denosumab) lowers calcium.  Less-often-used agents that are still available in specific situations include calcitonin, corticosteroids, Mithracin, and strontium-90.	Monitoring of calcium, phosphorous, and renal function.  Assessment for symptoms of hypercalcemia, such as:  ● Delirium, somnolence, muscle weakness, fatigue, polyuria, bradycardia, nausea, constipation  ● Provide hydration and medication as ordered.

Continued

**Table 13.3 Selected Oncological Emergencies—cont'd**

Oncological Emergency	Pathophysiology	Clinical Presentation	Clinical Management	Nursing Implications
<b>Leukostasis:</b> most commonly found in acute myelocytic leukemia with high white blood cell counts	Excessive immature white blood cells (most commonly myelocytes) cause capillary sludging, thrombosis, and rupture of vessels.	Congestion and dysfunction due to cell migration, inflammatory response, and hemorrhage within the organ; most commonly affect the kidney, lung, and brain	Emergency chemotherapy  Leukopheresis  Supportive interventions	Monitor white blood cell count.  Assess for signs of occluded microcirculation, such as blurred vision, headache, transient ischemic attacks, cerebrovascular accidents, dyspnea, poor peripheral perfusion, and oliguria.  Assess for signs of bleeding.
<b>Pericardial effusions/tamponade:</b> most commonly found in cancers of the chest such as lung and breast cancers and also lymphoma; can also be found in any cancer that has metastasized to the chest	Small amounts of pericardial fluid (approximately 15–30 mL) exist in the pericardial space to allow for heart distention with blood filling the ventricles. When there is excess fluid accumulation in this space, it causes positive pressure in this space and impedes venous return of blood. This reduced blood inflow leads to impaired cardiac output.	Dyspnea is the most common although nonspecific symptom with which patients initially present. Acute signs of poor perfusion occur in most patients with pericardial effusion of noncardiac origin, but because it often progresses slowly in cases of neoplastic effusion, signs of progressive right heart failure may be more likely.	Immediate evacuation of excess fluid by needle or catheter pericardiocentesis or surgical placement of a pericardial window or shunt is recommended. Until expert clinicians can perform one of these procedures, large amounts of fluids are administered to increase the venous pressure above the pericardial pressure, permitting inflow of blood.	Assess vital signs, signs of dyspnea, poor perfusion, and signs of heart failure, such as respiratory distress, fatigue, and edema.  Prepare for pericardiocentesis; administer IV fluids as ordered.
<b>Pleural effusions:</b> most commonly found when there are tumors in the chest, such as breast and lung tumors; also can be present in patients with leukemia, lymphoma, ovarian cancer, pancreatic cancer, and prostate cancer	Approximately 50–150 mL of fluid is normally in the pleural space to provide lubrication for lung expansion, but when excess fluid is in the space, it impedes breathing, increasing the work of breathing and compressing alveoli.	Dyspnea is the most common symptom. Increased work of breathing with use of accessory muscles, unequal chest excursion, and diminished breath sounds occur because of increased fluid in the pleural space. Resulting hypoxemia can cause confusion, anxiety, and agitation.	Intermittent therapeutic thoracenteses are commonly used until frequency is greater than weekly. Catheter drainage of pleural fluid (traditional chest tube or long-term silastic pleural catheter) used for palliation of symptoms unless a surgical talc pleurodesis can be performed. Bedside catheter pleurodesis with bleomycin, doxycycline, and talc may still be used when other therapies are unavailable.	Assess for dyspnea, shortness of breath, breath sounds, chest excursion equality, and signs of hypoxemia.  Assess how frequently symptoms are appearing or progressively worsening.

**Table 13.3 Selected Oncological Emergencies—cont'd**

Oncological Emergency	Pathophysiology	Clinical Presentation	Clinical Management	Nursing Implications
<b>Spinal cord compression:</b> most commonly found when there are tumors near the spinal cord	Infectious or tumorous masses compress or invade the epidural space or its blood supply, leading to lack of communication from that level of the spine downward.	Symptoms are present in the dermatome affected. Pain and other sensory symptoms (numbness, tingling) precede motor weakness. Autonomic dysfunction is late.	Treatment based on etiology. Radiation therapy most common and produces rapid relief of symptoms if tumors are radiosensitive. If the cord is completely compressed, laminectomy (posterior approach preferred) can restore cord function.  Rapid-onset corticosteroids provide immediate reduction of inflammation and symptoms.  Vertebroplasty or kyphoplasty allows injection of cement between vertebrae for treatment of compression fractures.	Assess for back pain, weakness, numbness and tingling, unsteady gait, and loss of ability to distinguish hot and cold.  Depending on level of compression, assess for constipation or incontinence.
<b>Superior vena cava syndrome:</b> most commonly found in chest tumors, lung cancer, and lymphoma	Tumor or tumor-involved lymph node compression of the soft-walled superior vena cava, causing reduced return of blood flow to the heart and venous congestion	Dyspnea is the most common clinical symptom, although venous congestion and edema of the upper body are common. Visual disturbances, headache, and altered mental status occur with cerebral edema. Prominent jugular veins, brachial veins, and chest vessels	Immediate chemotherapy or radiation, depending on the sensitivity of the tumor to specific therapy.  Corticosteroids are administered to reduce inflammation.  If a thrombus is present, systemic or catheter-directed thrombolytics are given.  If vessel rupture is of concern, a superior vena cava stent with or without a graft may be performed.	Early assessment for dyspnea; edema of neck, face, and eyes (most severe in the morning); and prominent upper body vasculature.  Later assess for signs of poor perfusion and decreased cardiac output, such as confusion, cyanosis, hypotension, and tachycardia.
<b>Syndrome of inappropriate antidiuretic hormone (SIADH):</b> most commonly found in patients who have primary or metastatic brain or lung cancer	Excess antidiuretic hormone (ADH) causes fluid volume retention and vasoconstriction; ADH receptors in the brain and lungs are stimulated and trigger ADH release. Some	Most clinical effects relate to the severity of hyponatremia, such as mental status changes or seizures. Fluid volume overload with effusions or edema and	Initial treatment is fluid restriction that causes increased sodium concentration and increased urine osmolarity. If ineffective, hypertonic saline may be administered, but sodium correction	Assess for signs of fluid overload, such as hypertension and hyponatremia, confusion, seizures, and coma.  Restrict fluids and administer medication as ordered.

*Continued*

**Table 13.3 Selected Oncological Emergencies—cont'd**

Oncological Emergency	Pathophysiology	Clinical Presentation	Clinical Management	Nursing Implications
	tumors create their own ADH-like substance, producing the same effects.	dilutional reduced electrolytes and hematocrit are also common. Hypertension occurs even with mild SIADH but is more severe with fluid overload.	may not exceed 0.5 mEq/hr. For chronic SIADH, treatment may be lithium carbonate or demeclocycline.	
<b>Tracheobronchial obstruction:</b> most commonly found in patients who have lymphoma and lung cancer or centrally located metastatic lung lesions	Tumor-related obstruction or invasion of the major air-exchanging airways	Dyspnea with stridor is the most common finding. Wheezing may be present if the bronchi are involved. In severe and late-stage obstruction, breath sounds are absent, and chest excursion is reduced.  Patients are more hypoxic than hypercarbic.	Immediate therapy with supportive interventions, such as bronchodilators or corticosteroids, provides immediate relief of symptoms to permit time for assessment for airway stent, laser therapy, cryotherapy, endobronchial brachytherapy, or photodynamic therapy. Definitive antineoplastic treatment is initiated simultaneously.	Assess for signs of respiratory distress, stridor, wheezing, and hypoxemia.
<b>Tumor lysis syndrome (TLS):</b> most commonly found in patients with rapidly proliferative tumors such as leukemia and lymphoma or therapy-sensitive tumors that respond quickly to treatment	Rapid cell lysis either with rapidly proliferative disease or after antineoplastic treatment. Lysing cells that cannot be cleared accumulate and cause electrolyte imbalance or renal dysfunction.	Primary clinical findings reflect the degree of electrolyte imbalance and renal dysfunction. Most patients are highly symptomatic with hypocalcemia and hyperkalemia. Acidosis may also produce unique features such as heart block and tachypnea. Hyperphosphatemia can cause renal dysfunction and worsening clinical symptoms.	Large-volume IV fluid administration with diuretics is immediately started to enhance excretion of electrolytes.  Hyperuricemia is treated with rasburicase if the uric acid is already elevated, and allopurinol is given to prevent hyperuricemia for the patients at high risk for TLS.  Electrolyte abnormalities are managed supportively.  Patients are given Amphojel or other phosphate binders.  If renal failure occurs, an initial hemodialysis treatment followed by continuous renal replacement therapy (CRRT) is recommended.	Assess for signs of hypocalcemia, such as paresthesias and numbness of the fingertips and perioral area, neuromuscular irritability, and severe signs such as laryngeal contraction. Assess for signs of renal dysfunction: elevated blood urea nitrogen (BUN), creatinine, decreased urine output.  Assess for ECG changes such as heart block or peaked T waves indicative of dangerous hyperkalemia, and assess for hypotension.

Other complications of cancer are common but are not classified as oncological emergencies. The presence of malignancy alters the microenvironment of the body, causing changes in hormonal balance, metabolic pathways, and cellular nutrition. Some of the complications of malignancy that are not clearly explainable but present in higher proportions of patients with cancer than those without it include anorexia/cachexia syndrome, hypercoagulation, effusions, fluid or electrolyte imbalances, glucose metabolism abnormalities, and clinical depression. Proactive prevention of deep vein thrombosis for patients with adenocarcinoma, large abdominal masses, or when clotting has been problematic is implemented in both inpatients and for patients being treated in the outpatient setting. Monitoring for these other complications and providing prompt interventions can minimize their associated negative outcomes.

### Connection Check 13.3

The nurse understands that an important laboratory assessment parameter for a patient with cancer that has metastasized to bone is which of the following?

- A. White blood cell count
- B. Calcium level
- C. Glucose level
- D. Sodium/potassium level

## PREVENTION

Cancer prevention initiatives fall into three levels: primary, secondary, and tertiary. Primary prevention is focused on identifying and modifying risk factors for cancer to reduce the probability that an individual will develop cancer. Secondary prevention is focused on early screening and detection of cancer in an effort to identify and control the disease early. Tertiary prevention is focused on reducing the complications of disease and improving the quality of life once an individual has been diagnosed with cancer. It is important to note that some cancers are not preventable because some risk factors are not easily modified or the risk factors and disease process are not well understood at this time. In these cases, general cancer prevention techniques and screening are recommended.

### Primary Prevention

Primary prevention initiatives include:

- Risk factor modification
- Immunization
- Chemoprevention

#### Risk Factor Modification

There is increasing evidence that individuals can reduce their lifetime risk of developing certain types of cancers by avoiding known carcinogens. Primary cancer prevention initiatives

are generally targeted at helping individuals identify their own cancer risk behaviors and modify their behavior in order to avoid exposure to carcinogens. An example of one such initiative is the multilevel approach to reducing tobacco use in the United States. There are system-level initiatives attempting to control national regulations and policy, as well as individual provider–patient initiatives to promote smoking cessation. Cancers linked to tobacco include cancers of the bladder, breast, lung, and pancreas. It has been shown that even after considerable exposure to tobacco, quitting smoking and remaining tobacco-free for 10 years can decrease the risk for lung cancer by 30% to 50%. A list of general cancer prevention guidelines is included in Box 13.2.

#### Immunization

Some cancers are believed to be triggered by viral exposure. An example of such a cancer is cervical cancer, believed to be triggered by HPV exposure. Exposure to HPV has also been linked to head and neck cancers of the oral, nasal, and pharyngeal regions. Other examples include hepatitis C, which is believed to trigger liver cancer, and Epstein–Barr virus (EBV), which has been associated with certain lymphomas. This does not mean that all individuals exposed to a potentially carcinogenic virus will develop viral disease and subsequently cancer, but the individual's lifetime cancer risk increases. Immunization against these viruses is recommended for susceptible individuals.

#### Chemoprevention

**Chemoprevention** is the administration of medications to reduce the risk of specific cancers in high-risk patients. Chemoprevention is a primary prevention strategy for some survivors of early-stage hormonal cancers such as breast and prostate cancers. High-risk patients who have been evaluated to be sensitive to chemoprevention are prescribed hormone stimulants or ablation agents that create hormonal environments that impede recurrence of the malignant cell

### Box 13.2 Cancer Prevention Measures

- Avoid exposure to known carcinogens such as tobacco.
- Wear sunscreen every day.
- Prevent and/or treat infectious diseases known to be related to cancer: hepatitis B and C, human papillomavirus (HPV), HIV, *Helicobacter pylori* (*H. pylori*).
- ☒ Maintain a healthy weight.
- ☒ Engage in regular moderate to vigorous physical activity.
- ☒ Eat a healthy, plant-based diet.
- ☒ Limit consumption of alcoholic beverages: no more than one drink a day for women and no more than two drinks per day for men.
- Recognize family risks, consider assessment or prophylactic interventions for genetic mutations, or alter screening practices.

clone. There are only a few chemoprevention agents available on the U.S. market, and providers must carefully evaluate the risks and benefits of therapy prior to the initiation of a chemoprophylaxis regimen. In addition to pharmaceutical chemopreventive agents, researchers are currently exploring the use of nutraceuticals, food and food products that may have medicinal properties, such as vitamins such as C and E and antioxidants, for cancer prevention. However, there is no conclusive evidence from high-quality clinical trials that supports the use of any nutraceuticals for chemoprevention at this time. In fact, some initial clinical trial results suggest that certain nutraceuticals may increase the risk of the development of specific cancers in certain populations.

## Secondary Prevention

Secondary prevention is essentially cancer screening for early detection and management of the disease. Clinical outcomes are better for individuals diagnosed and treated

for cancer earlier in the disease process compared with individuals diagnosed later in disease development. Ideally, individuals with cancer-related risk factors should have access to noninvasive screening tests that can identify cancer in its earliest stages, when it can be treated effectively with minimal risk of recurrence. Screening tests should be highly sensitive (able to detect in a low-risk population with few false negatives) and specific (able to accurately detect with few false positives). In order for a cancer screening test to provide the greatest benefit with the least harm, it must be cost-effective and easy to perform and have minimal adverse effects. Unfortunately, there are few cancer screening tests that meet these criteria. A summary of current cancer screening guidelines is included in Table 13.4.

For cancers that have no available standard screening test, clinician assessment is critical. Clinicians must become familiar with the individual patient's risk profile to determine high-risk cancers. Assessments may then be focused on organs or systems that present the highest cancer risk.

**Table 13.4 Screening Guidelines**

Type of Cancer	Screening Guidelines	Special Considerations for Health Disparities
<b>General cancer checkup</b>	Men and women aged 20 and older: <ul style="list-style-type: none"> <li>● Discuss individual cancer risk factors and screening needs with your primary care provider during annual physical checkup.</li> <li>● Share family history of cancer—particularly first-degree relatives—with provider.</li> </ul>	
<b>Breast cancer</b>	Women aged 40 and older: <ul style="list-style-type: none"> <li>● Annual mammogram until age 55 years, then may switch to mammograms every 2 years</li> <li>● Annual clinical breast examination</li> </ul> Women aged 20 to 39: <ul style="list-style-type: none"> <li>● Clinical breast examination every 3 years</li> </ul>	Caucasian women aged 40 and older have a higher risk of breast cancer than African American women aged 40 and older.  African American women have higher breast cancer-associated mortality.  Women from racial minority groups are: <ul style="list-style-type: none"> <li>● More likely to be diagnosed with later stage and/or higher-grade cancer</li> <li>● At higher risk for breast cancer-related mortality</li> <li>● Less likely to have insurance</li> </ul> Women with less than a high school education and of lower socioeconomic status are less likely to get mammograms.  Medical assistance/financial assistance for screening is available through state-run Medicaid programs.
<b>Cervical cancer</b>	Women aged 21 to 29: <ul style="list-style-type: none"> <li>● Screening every 3 years with regular Pap test</li> </ul> Women aged 30 to 65: <ul style="list-style-type: none"> <li>● Pap test plus HPV test every 5 years or</li> <li>● Pap tests every 3 years and HPV test every 5 years</li> </ul>	Ethnic minorities and women of disadvantaged socioeconomic status are less likely to participate in screening.

**Table 13.4 Screening Guidelines—cont'd**

Type of Cancer	Screening Guidelines	Special Considerations for Health Disparities
<b>Colon cancer</b>	<p>Men and women aged 45 and older (screening may be stopped over age 85):</p> <ul style="list-style-type: none"> <li>● Stool assessment for low-risk individuals <i>or</i></li> <li>● Flexible sigmoidoscopy every 5 years <i>or</i></li> <li>● Colonoscopy every 10 years <i>or</i></li> <li>● Double-contrast barium enema every 5 years <i>or</i></li> <li>● CT colonography every 5 years</li> </ul>	<p>Incidence and mortality in African Americans are higher than in Caucasians; some suggest this is related to differences in socioeconomic status.</p> <p>In the United States, incidence and mortality among Asian/Pacific Islanders, American Indians/Alaskan Natives, and Hispanics/Latinos are lower than among Caucasians.</p> <p>Mortality of colon cancer is inversely associated with education.</p> <p>Globally, incidence and mortality are higher in the Western Hemisphere (United States, Canada, Europe) than the rest of the world.</p> <p>Individuals with lower socioeconomic status and/or no health insurance are less likely to participate in screening across all racial and ethnic groups.</p>
<b>Prostate cancer</b>	<p>Men aged 50 and older or men aged 45 and older with risk factors:</p> <ul style="list-style-type: none"> <li>● Talk to your primary provider about the risks, benefits, and frequency of screening using:</li> <li>● PSA level (blood test)</li> <li>● Digital rectal examination</li> </ul>	<p>African Americans have highest incidence of prostate cancer among all racial groups in the United States.</p> <p>African Americans have higher mortality (two times) than Caucasians.</p> <p>Prostate cancer is common in the Western Hemisphere but rare in Asia and South America.</p>
<b>Lung cancer</b>	<p>No evidence-based consensus guidelines for the general population at this time</p> <ul style="list-style-type: none"> <li>● American Cancer Society and National Comprehensive Cancer Network (NCCN) recommends yearly helical low-dose CT screening for high-risk patients (current smokers or those having quit within the past 15 years and have a 30-pack-year smoking history).</li> </ul>	<p>Incidence and mortality are higher in African American men than in Caucasian, Hispanic, and Native American/Alaskan Native men.</p> <p>Incidence and mortality in African American women and Caucasian women are similar; both are higher than in other races.</p> <p>Of individuals who smoke, African Americans and Native Hawaiians are at higher risk of developing lung cancer than are Caucasian Americans, Japanese Americans, or Latinos.</p>
<b>Melanoma</b>	<p>No evidence-based guidelines for the general population at this time</p> <ul style="list-style-type: none"> <li>● American Cancer Society (ACS) recommends individuals monitor skin and skin changes (perform self-examination) annually to identify any concerning skin changes.</li> </ul>	
<b>Non-Hodgkin's lymphoma</b> <b>Pancreatic cancer</b> <b>Multiple myeloma</b>	<p>No evidence-based guidelines for the general population at this time</p>	

CT, Computed tomography; HPV, human papillomavirus; PSA, prostate-specific antigen.

Source: American Cancer Society. (2019). *Cancer screening guidelines*. Retrieved from <https://www.cancer.org/healthy/find-cancer-early/cancer-screening-guidelines.html>

For example, if a patient has a significant family history of multiple myeloma, there is no consensus-driven standardized screening tool. The clinician may individualize the annual health examination to include a focused assessment for multiple myeloma, which may include urine analysis for Bence Jones protein—a characteristic sign of multiple myeloma. Although clinician-based, cancer-focused assessments vary across clinicians and may be imprecise secondary to limited guidance in the form of evidence-based practice, it is best to include cancer screening in primary care rather than not include it at all.

Evaluation of the family history for genetic cancer syndromes is an essential component of an optimal secondary cancer prevention program. The most well-known genetic cancer syndromes are related to *BRCA1*, *BRCA2*, *p53* (Li-Fraumeni syndrome), familial adenomatous polyposis, and retinoblastoma. The key assessment for familial cancer syndromes is the identification of two first- or second-generation relatives with one of the marker cancers. A family tree identifying specifics of the cancer and age at diagnosis can provide clues of familial cancers. Serum blood tests can detect the presence of the altered gene in an individual but may be imperfect in detecting the risk to future generations. Testing of family members experiencing cancer is the best method to determine if the cancer is potentially genetic in origin. A frequent misperception is that the genetic mutations place individuals at risk for a single cancer, but many of these known genetic syndromes confer a risk for several different cancers. For example, the *BRCA1* gene is associated with a higher risk for breast and ovarian cancer; however, the *BRCA2* gene is also known to convey increased risk for pancreatic or bile duct, prostate, or melanoma skin cancers and possible risk for bone, laryngeal/pharyngeal, esophageal, and gastric cancers.

### Tertiary Prevention

Tertiary prevention focuses on reducing morbidity and mortality once a disease has been diagnosed. The treatment and management of the side effects of cancer or its treatment, which are discussed in subsequent sections, may be considered tertiary prevention.

## CASE STUDY: EPISODE 2

After the history and physical examination are completed, Margaret is scheduled for a mammogram. The mammogram reveals a suspicious mass, so a biopsy is scheduled for the next week. A fine-needle aspiration biopsy reveals abnormal cells. Because of these findings, Ms. Jones's provider recommends that she see an oncologist for evaluation. An appointment is scheduled for the next week...

## DIAGNOSING CANCER

The initial assessment for possible cancer is usually triggered when a patient presents to a provider with one of the seven CAUTION signs, constitutional symptoms, or other unexpected symptoms of unknown etiology. There are diagnostic tests designed to identify the specific cancer cells that uniquely define them as different from normal cells (cancer vs. nonmalignant tumors), tests that define the precise molecular makeup of the tumor (tumor markers, molecular or genetic profiling), and tests used to stage the disease (identify tumor size, lymph nodes involved, and spread). Tests from all three categories may be used to subsequently monitor the presence or absence of malignancy or the response to antineoplastic treatment. Nurses play a key role in translating essential information for patients, such as the intention of the diagnostic test, patient preparation and postprocedure care, what to expect during the test, and the anticipated time for results. Patients may require clarification when the same diagnostic tests are used for more than one purpose.

### Diagnostic Evaluation

Diagnostic evaluation for cancer is dependent on the suspected cancer subtype, possible disease location, and expected extensiveness of the disease. It may include laboratory tests, radiological tests, ultrasound, invasive techniques, or combinations of these methods. Most initial diagnostic tests are performed to confirm the presence of masses associated with cancer. Radiological tests are most helpful for the detection of unusual masses, although ultrasound or even physical examination may also be valuable. Confirmation of malignant tissue requires a biopsy with cytopathological diagnosis, which is a diagnosis of disease based on the evaluation of cell pathology from cells obtained at biopsy.

### Laboratory Tests

Laboratory diagnostic tests provide useful conjunctive information to validate some malignancies. Some laboratory tests can be performed on blood and serum, whereas others require a tissue sample. An example of a laboratory test is the prostate-specific antigen (PSA) test, obtained via a venous blood sample, used to validate the presence of prostate cancer. A high PSA level is associated with prostate cancer, although its presence is actually indicative of inflammation, and will reduce as the tumor shrinks in response to therapy. The PSA test has a high sensitivity (ability to accurately find cancer in patients who actually have cancer—true positive) but a low specificity (accurately identifying patients who do not have cancer—the test yields false positives), which means PSA elevations may not be cancer related. The PSA level is only one piece of information that can be considered in a definitive diagnosis of prostate cancer.

Laboratory diagnostic tests can also be used to track responses to therapy. These test results may be important for patients to adjust self-care. For instance, when patients are

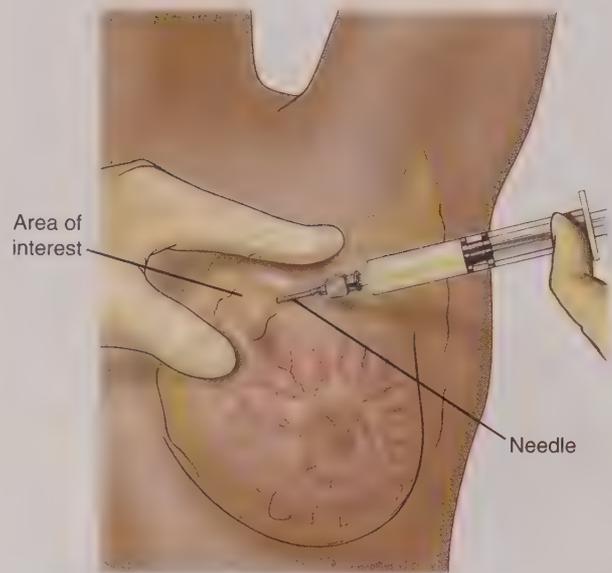

aware of their blood counts during chemotherapy, they are more able to understand when they are at risk for bleeding or infection and adjust their activities of daily living. Tumor markers may be assessed at initial diagnosis but also followed intermittently throughout and after treatment as one indicator of disease response.

### Imaging

Imaging studies use radiographical, sonographical, or other technology to create images of the body for clinical evaluation. They are often used to assess the structure or function of body organs or systems. They are effective in identifying tissue masses, one of the most common presenting signs of cancer. Imaging studies allow for the detection of these tissue masses that are undetectable on physical examination. They are also used to detect metastasis, or tumor spread to other tissues. A computed tomography (CT) scan is indicated for general assessment of mass locations and involvement of vessels or body organs. In metabolically active tumors, positron emission tomography (PET) scans are preferred. Positron emission tomography scans typically involve the injection of radioactive material that, when imaged, appears to accumulate in areas of increased metabolic activity (“hot spots”) that correspond to areas of disease. Magnetic resonance imaging (MRI) is preferred for evaluating changes in brain, joint, and breast tissues. Some of the imaging technologies use contrast, or the administration of dyes or radiosensitive markers, to enhance imaging details. Contrast is also helpful in identifying the involvement of blood and lymphatic vessels. Radiological imaging tests are useful in the diagnosis and assessment of solid tumor masses but may not be as useful for the diagnosis of hematological malignancies that are diffuse and do not present with masses (malignant lymphoma is the exception).

### Biopsy

Biopsy is the primary method of obtaining samples required to determine the presence of malignancy. It is a surgical method of obtaining a tissue sample for evaluation, most commonly used in solid-tumor evaluation. Biopsies can be incisional (into the mass) or excisional (cut out the total mass and a margin around it). When an incisional biopsy, also known as a core biopsy, is performed, there is a danger of tracking malignant cells through the surrounding normal tissue. Excisional biopsy is preferred over incisional, and the standard margin of normal tissue to be removed (how much healthy tissue to remove around the suspected tumor) is dependent on the suspected malignancy. An alternative, less traumatic method of obtaining a tissue sample is via fine-needle aspiration (FNA) biopsy (Fig. 13.4). This method can be used when cells of interest are located close to the skin and can be extracted via a needle. This method yields fewer cells than traditional biopsy methods, but histological analysis is improved because cell structure is maintained. The limitation of FNA tissue sampling is that it may not be possible to conduct a thorough analysis of the tissue (DNA, molecular features, typing,

**FIGURE 13.4** Fine-needle aspiration (FNA) breast biopsy.

etc.). Hematological malignancies are evaluated via bone marrow aspiration and biopsy, with cytopathological molecular testing for subtle cell differences.

### Endoscopic Procedures

Endoscopic procedures, such as endoscopy and bronchoscopy, are performed with a rigid or flexible tube, light, and lens and allow visualization of hollow, tubelike structures in the body (e.g., the gastrointestinal tract) and may be necessary in order to access tissue for biopsy. An example is the use of bronchoscopy in the work-up for lung cancer. Bronchoscopy allows for visualization of the airways while also providing access to hard-to-reach tissue for sampling (Fig. 13.5).

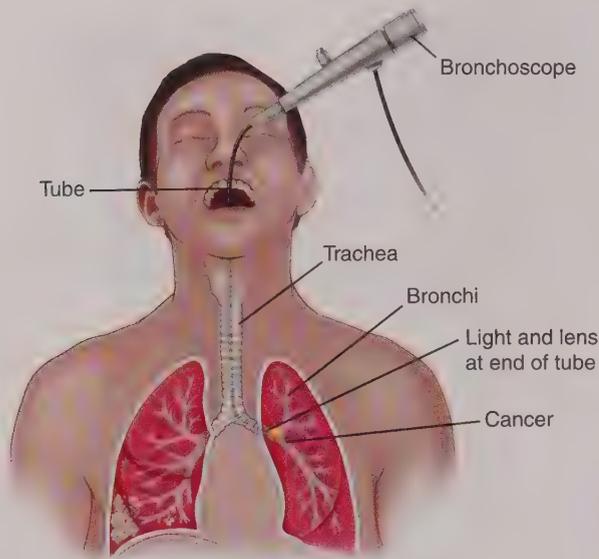

### Connection Check 13.4

What is the most specific method of diagnosing a malignancy?

- Serum laboratory tests
- MRI
- CT scan
- Biopsy

### TREATMENT

The treatment of cancer varies according to the cell type and stage of disease and occasionally the markers that predict response to specific therapies. In addition, cancer treatment varies with the goal of care: cure, remission, maintenance/prevention of progression to extend life, or palliation. Whenever possible, the goal of cancer treatment is to cure the disease and maintain disease-free survival. Some resources define a disease cure as 5 years of disease-free survival; however, the interpretation of survivorship

**FIGURE 13.5** Bronchoscopy, a diagnostic procedure to look for evidence of cancer in the tracheobronchial tree.

and long-term disease-free status has been greatly debated. Many believe survivorship is a continuum that begins at the time of diagnosis and that disease-free survival is a more appropriate defining point than cure. Examples of cancers believed to be curable are early-stage, resectable cancers of the breast, cervix, colon, kidney, oropharynx, skin, testicles, and uterus.

If cancer is not curable, the goal may be simply to reduce tumor burden or prevent progression. Sometimes this may be referred to as **remission**, which is a disease-free state in which it is unclear if the disease has been eradicated or if this disease-free state will remain stable. Remission is often the goal of care in hematological malignancies. Long-term remissions based on suppression of the **oncogene** (the gene that has the potential to cause cancer) that produces cancers such as hairy cell leukemia and chronic myelogenous leukemia have reached a level of response that is relatively new to the oncology specialty. These patients remain disease-free as long as they consistently take their medications targeting the faulty cellular pathway, in much the same way as patients with hormonal disorders such as hypothyroidism can be free of clinical disease while maintained on hormonal replacement therapy. The hope is that scientific discovery leads to the identification of more targeted therapies that expand the number of patients who can experience this type of disease response. Although some diseases may have long periods of remission, such as many lymphomas, they are not considered curable because they will ultimately relapse.

Another goal of therapy may be to increase years of life—for example, to increase the projected life span from 2 years with untreated disease to 5 years with treatment. And finally, if the cancer is not curable or the harm from any treatment modality greatly exceeds the benefit, the primary goal may be **palliation**, the alleviation of the burdensome symptoms of cancer. Palliation is increasingly a

consideration in all cancer treatments but typically not the primary consideration if a long-term disease-free status is possible. Patient-centered care reinforces that goals of treatment are mutually agreed on by patients, their significant others, and the healthcare team. Providing patient education regarding the language and meaning of these oncological treatment goals may be necessary to create a meaningful collaboration.

## Treatment Modalities

Cancer treatment includes three broad modalities: surgical procedures, radiation therapies, and medical treatments. Treatment may be single therapy or may be multimodality. If a cancer treatment requires a multimodality approach, the definitive treatment is referred to as the primary therapy. A therapy that is used to shrink the tumor prior to definitive removal or destruction is called **neoadjuvant therapy**. Neoadjuvant strategies are used with many large solid tumors that are not resectable at diagnosis but may be after the initial treatment to shrink the size of the mass has been completed. **Adjuvant therapy** is defined as a treatment that is used in a patient who is currently disease-free or in remission but at high risk for relapse because of remaining microscopic malignant cells that will regrow at a later time. Evidence for the effectiveness of adjuvant treatment is currently limited to a handful of cancers, which includes breast, colon, head/neck, lung, and melanoma cancers. Ongoing trials using adjuvant therapy are in process for many other solid tumors, such as bladder, esophageal, pancreatic, renal, and testicular cancers and sarcoma. Patients with these cancers in moderate stages of disease who receive adjuvant therapy have a significantly increased disease-free survival rate. An example of a case in which all these terms may be relevant is a woman diagnosed with breast cancer who requires multimodality treatment: surgical, medical, and radiation interventions. The primary therapy is surgical because the main interest is to surgically remove the malignant tumor. Her oncology team determines she also needs neoadjuvant **chemotherapy** (medical therapy) to reduce the size of the tumor prior to surgery and adjuvant radiation therapy after surgery to decrease the risk of disease recurrence.

## Surgical Treatment

Surgical resection of a tumor is the preferred cancer treatment modality because it offers the greatest probability of producing a cancer-free state. It is also the primary treatment modality for patients with solid-tumor malignancies. The primary goal of surgical oncology is total excision of malignant tumors and the local area of potential metastasis immediately surrounding the tumor. Surgical oncology also includes debulking of tumor masses (partially removing a tumor that cannot be completely excised). Redirection of vital functions after tumor removal and reconstructive procedures are also components of surgical oncology. Redirection

and reconstructive procedures are necessary because surgical procedures for cancer usually involve the removal of the tumor as well as a margin of normal surrounding tissue, which may affect organs that perform vital functions. Surgery may often involve the reconstruction of normal blood vessels and nerves or the construction of drains. Removal of large masses may require the construction of diversions and ostomies, which are surgical openings to allow for the elimination of body waste. An example of a more extensive surgical procedure is the case of a patient with colon cancer who requires the removal of a section of the colon. If possible, the surgeon tries to connect the remaining pieces of the colon back together. If this is not possible, the patient will be unable to pass stool through an intact colon, requiring the creation of an opening (ostomy) through which the patient is able to pass stool. Another example of a more extensive surgical procedure is a mastectomy, or removal of a breast to remove a breast cancer tumor. Although this surgery does not necessarily impact vital body function, it does significantly impact the nervous and lymphatic systems. It also affects patient body image and quality of life. Because of these issues, a mastectomy is sometimes followed with reconstructive surgery. Advances in surgical oncology are allowing for surgical processes that are less invasive and that increasingly preserve vital organ structure and function. The impact of our enhanced knowledge of tumor biology has also provided greater opportunity to apply neoadjuvant therapy with successful later resection. This has led to higher numbers of patients with stage III locally advanced cancers realizing long-term remissions and cures.

Nursing considerations for the surgical oncology patient are similar to care for the general surgical patient. The patient may be at greater risk for infection and have increased morbidity compared with the noncancer patient, but this morbidity profile is secondary to the presence of remaining cancer and comorbidities. Nursing implications include a thorough understanding of the patient's goals of care, overall treatment plan, anticipated physical deficits, barriers to or facilitators of postoperative recovery, and self-care or education needs. It is not uncommon for patients with cancer to come to surgery with unique clinical problems that should be incorporated into the plan of care. Patients with cancer often have pain and are taking long-term medications for pain before surgery, requiring a modified postsurgical pain management plan. Patients may also have deconditioning, recent weight loss or malnutrition, altered skin integrity, and variable organ function. Rehabilitation and consultation with physical and occupational therapists are often required for optimal return to activities of daily living while adjusting to changes in body function. Anesthetic clearance may be impaired because of renal or hepatic dysfunction, and chronic infections may necessitate atypical antibiotic regimens. Nurses should thoroughly familiarize themselves with the recent medical history and consider the patient's physical and psychological status in planning care and education related to cancer surgery.

### Connection Check 13.5

The nurse understands that the patient receiving chemotherapy prior to definitive surgical excision is receiving which type of treatment?

- A. Secondary treatment
- B. Adjuvant therapy
- C. Neoadjuvant therapy
- D. Primary treatment

### Radiation Therapy

**Radiation therapy** is the localized delivery of ionizing radiation to intentionally destroy DNA structures within malignant cells and induce cell death. A radiation therapy treatment plan is designed with the goal of maximizing tumor exposure to radiation while minimizing injury to normal cells. Radiation therapy can be delivered externally via an external beam, internally via placement in a cavity or reservoir in the body (**brachytherapy**), or systemically via injection of a radioactive substance. These methods use different radioactive sources, chosen in part by the sensitivity of the defined tumors being treated. For external-beam radiation therapy, the radiation treatment plan is designed to deliver a planned total dose and is divided into "fractions." Fractions are the doses delivered in a single treatment. The normal fractionation cycle is a daily dose for 5 days followed by 2 days' rest. This cycle is repeated for 5 to 18 cycles. Radiation doses may be further divided into more than once per day, termed *hyperfractionation*, for the purposes of enhancing delivery to rapidly dividing tumor cells or to minimize some adverse effects. On occasions of severe tumor-related organ dysfunction or compression of major body organs (e.g., spinal cord compression, super vena cava syndrome, tracheobronchial obstruction), the daily dose may be higher for the initial 3 to 6 days in order to rapidly reduce the tumor size and its effects. The total radiation dose is determined by the amount of radiation needed to destroy the type and size of tumor. Available specialized techniques for the delivery of direct-beam radiation include intensity-modulated radiation therapy, conformal (three-dimensional) radiation therapy, invasive direct-beam therapy (e.g., intraoperative radiation or intrabronchial radiation), proton-beam therapy, and stereotactic radiation therapy. Stereotactic radiosurgery is a one-time treatment to a small, well-defined target in the body or brain. Cyberknife is the most common technique used. These techniques are designed to reduce injury to normal tissue while optimizing the radiation delivery to the tumor.

Brachytherapy, or internal delivery of low-dose or high-dose radiation, is an alternative method of delivering radiation therapy. Radioactive isotopes are placed in "seeds," which are then administered to the patient. These seeds may be infused via a catheter or surgically implanted. Low-dose brachytherapy allows for the continuous delivery of radiation in the body for as long as the source of active radiation remains in the body. This can be for a period of a few days or, in some cases, permanent. Low-dose brachytherapy is

used in gynecological, prostate, head and neck, and brain cancers. High-dose radiation, such as radioactive isotopes, must be managed more closely than low-dose therapy. Radioactive isotopes are introduced into the body and allowed to dwell for a certain period and then removed in one treatment session. The patient may need multiple high-dose treatment sessions, but high-dose radiation therapy does not dwell within the patient unmonitored or for extended periods of time as may be the case for low-dose brachytherapy (Fig. 13.6).

Systemic radiation therapy typically involves the vascular administration of a radioactive substance. Radioactive iodine, for example, is sometimes used to treat thyroid cancer. The thyroid naturally attracts iodine, so the isotope concentrates in a local area after systemic delivery. Systemic radiation therapy may be administered with targeted therapy, such as a monoclonal antibody (see next section), to help the active isotope find the desired target. The monoclonal antibody targets a specific tissue or organ, and the radioactive isotope goes along for the ride. This technique is commonly used in the treatment of lymphoma that expresses a specific receptor so that the monoclonal antibody is able to carry radiation directly to the tumor.

Nursing considerations for the care of the patient receiving radiation therapy are related to symptom management and self-care. Because radiotherapy is delivered to a localized area, the adverse effects are usually a direct reflection of the body area treated. Common signs of local injury peak in the second to third week of treatment. Acute inflammatory effects are followed by fibrotic changes indicative of tissue injury. Inflammatory adverse effects and organ dysfunction

are possible outcomes. General patient education regarding skin care and management of treatment markings are provided to all patients.

### Complications

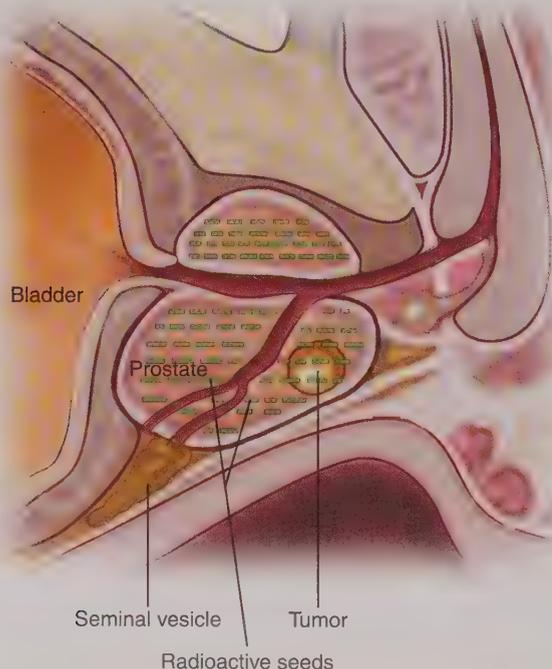

Patients are evaluated before treatment and regularly throughout the radiation course for symptoms of inflammation, irritation, and altered mucosal integrity in the area receiving radiation. For some patients, this may be as minor as erythema of the skin, but assessment of radiation injury to internal structures such as the trachea may present as more subtle symptoms such as chest discomfort or cough. Fibrosis is a late effect of radiation, causing internal adhesions; fibrotic skin changes, and strictures (e.g., vaginal). Interventions may be routinely employed to reduce these effects (e.g., vaginal dilator) or implemented on an as-needed basis (e.g., feeding tubes for patients receiving neck or throat radiation).

Fatigue is a common adverse effect of both cancer and its treatment but is particularly prevalent in patients receiving radiation therapy. This symptom is thought to be related to the cumulative effect of cell damage and hence escalates throughout treatment, peaking at 3 to 6 weeks. It is important to provide patient education and support for activities of daily living such as transportation and self-care, realizing the prevalence and distress this symptom presents for patients. Evidence-based interventions include pacing of activities and mild to moderate exercise. Early patient education and reassurance can reduce the risk of misperceptions by patients and families or the fear that fatigue signals advancement of the cancer.

To minimize harmful exposure to radiation, the oncology nurse must be mindful of donning all appropriate personal protective equipment and following the self-care standards of the institution. This is particularly true for the nurse who handles potentially radioactive waste from patients receiving brachytherapy that may be eliminated in body fluids. Providing the same education to family members also prevents unintentional radiation exposure to individuals other than the patient.

### Antineoplastic Medications

**Antineoplastic** medications are a broad class of chemicals and drugs used to treat cancer. Antineoplastic therapies are loosely divided into four different categories: (1) chemotherapy, (2) immunologic therapies, (3) targeted agents, and (4) hormonal agents. This type of therapy is indicated in patients with more advanced disease, diseases of the blood or bone marrow, or cancers that are not amenable to single-modality surgical or radiation therapy. Antineoplastic therapy is often administered systemically (IV), making it appropriate for more widespread advanced cancers. This route of administration is effective but also leads to a systemic side-effect profile. Some therapies act more specifically on tumor cell targets or receptors, whereas others are effective because they destroy *all* rapidly dividing cells, including most cancer cells. “Normal” rapidly dividing cells

**FIGURE 13.6** Brachytherapy, radiation therapy delivered internally via placement in a cavity or reservoir in the body.

that are destroyed along with the cancer cells include hair, skin, intestinal tissues, and blood-forming cells. Additionally, a potential complication of the IV route is extravasation, or the infiltration of the medication out of the vessel and into the surrounding tissue. Many antineoplastic medications are **vesicants**, medications that can cause extensive damage to the tissue on direct contact. Great care must be taken by the nurse when administering these medications to avoid and prevent leakage of the medication into the tissue.

The selection of antineoplastic or targeted and immunologic agents is individualized according to the specific cancer type, molecular features, and location of the disease. Most antineoplastic medication therapies involve a combination of medications from different classes or categories that are able to destroy tumor cells at various phases of development. This ensures more effective destruction of the entire tumor cell population and balances the adverse effects common in a single class of medication. Each medication class has an adverse-effect profile that correlates to its mechanism of action, and common effects are seen with most medications within the class, termed “class effects.” Chemotherapy regimens have been established through clinical trials evaluating the efficacy of single agents and then combined in specific doses and patterns of administration. They are often delivered every few weeks, with the plan to destroy a percentage of the tumor cells with each subsequent cycle until maximum control or cure is accomplished. The total dose of chemotherapy is carefully calculated according to the tumor type, growth rate, and total volume of the tumor mass. Any chemotherapy delays or dose reductions can compromise the potential for maximum response. Other considerations include the patient’s baseline health status and comorbid conditions, the synergy of combination therapies, the adverse-effect profile, the social or financial circumstances of the patient, and previous therapies. Patients receiving antineoplastic medications require extensive education and support to understand the

treatment plan, monitoring, adverse-effect management, and self-care. Nurses often provide this education across several sessions and supplement verbal information with written reinforcement, multimedia information, and support networks. Given the complexity, physical symptoms, and possible associated anxiety, the involvement of the patient’s family members is essential. Table 13.5 describes adverse effects associated with antineoplastic medications.

### Stem Cell and Bone Marrow Transplants

Hematopoietic stem cell transplantation (HSCT) and bone marrow transplantation (BMT) are treatment methods for some cancers and hematological disorders. Hematopoietic stem cell transplantation/BMT involves two major steps: the administration of high-dose antineoplastic therapy (sometimes in combination with radiation therapy) followed by the infusion of hematopoietic stem cells (HSCT) or whole bone marrow (BMT). This method allows for the administration of high doses of antineoplastic/radiation therapy that would normally not be tolerated because high-dose chemotherapy and radiotherapy permanently damage bone marrow. The stem cell/bone marrow transplant essentially “rescues” the patient. If the stem cells are donated from another individual, the added benefit may be immunologic. The donated stem cells may work to fight the cancer in what is called a “graft-versus-tumor” effect. This therapy is normally administered to patients with nonmalignant hematological and immunologic disorders and hematological malignancies. The use of transplants for the treatment of refractory solid-tumor malignancies is not considered routine at this time. Variations within this therapy include variable levels of bone marrow destruction (fully myeloablative or nonmyeloablative); stem cells harvested from the periphery or bone marrow; and differing levels of genetic match (haploidentical or identical) and self (autologous; Fig. 13.7), related (allogeneic), or unrelated (matched unrelated) donors. Complications of HSCT/BMT may be related to the

**Table 13.5 Common Adverse Effects Associated With Antineoplastic Medications and Nursing Implications**

#### Common Adverse Effects

Alopecia—It is variable, but loss of hair typically begins soon after therapy begins. Again, variable, but hair begins to grow back several weeks after completion of therapy. Interestingly, when growing back, hair typically comes back different from pretherapy: curly, thicker, or a different color.

Myelosuppression (bone marrow suppression)

#### Nursing Implications

Loss of hair may cause a self-image disturbance, especially in women. They should be encouraged to investigate wigs or other head coverings to use during therapy. Patients should be reminded to cover their heads while outside to protect against sun damage.

Inform patients that a complete blood count will be assessed frequently during therapy.

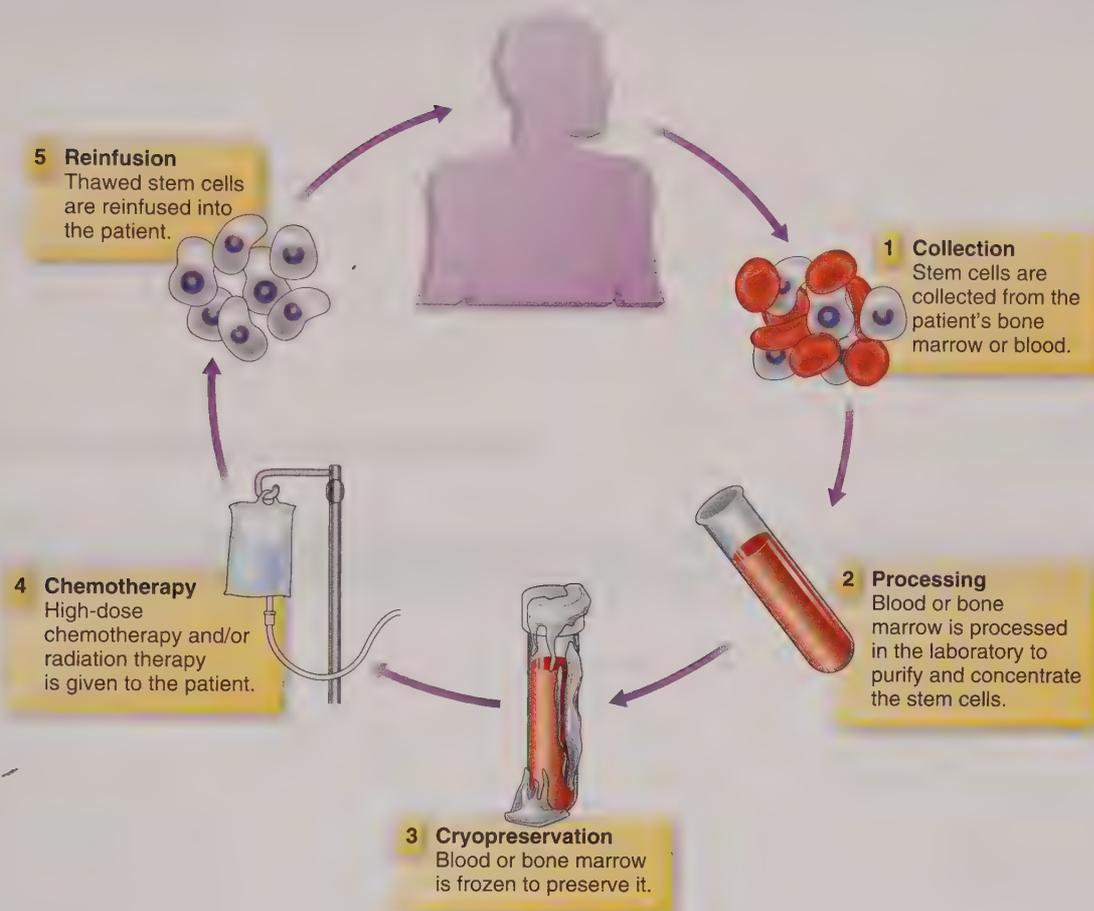

Instruct patients to call the provider immediately if a fever presents. Patients with myelosuppression and fever may be managed aggressively to prevent severe sepsis or shock.

*Continued*

**Table 13.5 Common Adverse Effects Associated With Antineoplastic Medications and Nursing Implications**

Common Adverse Effects	Nursing Implications
Nausea/vomiting	Administer prophylactic antiemetic therapy as ordered. Assess fluid and nutritional status frequently.
Hemorrhagic cystitis	Administer IV hydration before and after chemotherapy as ordered; prophylactic bladder protectant medication mesna (chemoprotectant medication to help prevent bladder toxicities) may be used.
Oral mucositis—inflammation and ulceration of the mucosal lining of the mouth, causing pain and difficulty with eating	Encourage frequent oral rinsing (every 2–4 hours) with toothbrushing to reduce severity of mucositis; encourage the use of 2% viscous lidocaine mouth rinse if ordered to help control pain. Oral saliva substitute may be recommended for comfort or to reduce severity of symptoms.
Hypersensitivity	Administer premedication for hypersensitivity as ordered. Emergency equipment should be readily available.
Infertility	Encourage patient to consider sperm or egg banking prior to therapy if desired.
Diarrhea	Administer antimotility agents for diarrhea as ordered. Assess fluid and nutritional status frequently.
Skin toxicities (palmar-plantar erythema)	Encourage the use of emollients to reduce skin toxicities. Teach patient to report severity of skin toxicities because it may require therapy break.
Cardiotoxicity	Teach patient that cardiac function will be monitored with echocardiograms or multi-gated acquisition scans (MUGAs). Many medications are held if decreased ejection fraction is found. Serum troponin levels may be drawn during curative therapy with doxorubicin to identify patients who may receive prophylactic treatment with cardioprotectant agents. Maintain fluid and electrolyte balance to reduce the risk of dysrhythmias.
Hepatic (liver) toxicity	Inform patient that hepatic function tests will be assessed regularly during therapy.
Pulmonary fibrosis	Inform patient that pulmonary function tests will be assessed periodically.
Clotting abnormalities—thromboses and/or bleeding	Some antineoplastic medications are never given within 6–8 weeks of major surgery because of bleeding risk. Prophylactic anticoagulation is common to prevent thromboses. The nurse and/or patient should frequently assess for bleeding. Teach patient about bleeding precautions; avoid falls or trauma, so no aggressive sports; avoid sharps such as razors, scissors, nail clippers; use stool softeners to avoid straining.
Peripheral neuropathy—weakness, numbness, and pain in hands or feet	Teach patient fall precautions; remove scatter rugs from home; remove any trip hazards such as electrical cords; use nonslip mats in your bathtub or shower.
Capillary permeability syndrome	Administer fluid replacement for hypovolemia as ordered. Weight assessment and management may be used to avoid fluid overload.
Menopausal symptoms	Teach patients possible effects regarding menopausal symptoms—hot flashes, insomnia, fatigue.

## The Autologous Transplant Process

**FIGURE 13.7** An autologous bone marrow transplant.

chemotherapy/radiotherapy or linked to the transplant of foreign marrow.

## NURSING MANAGEMENT

Nursing care of patients with cancer crosses all subspecialties of medical-surgical nursing and ambulatory primary care because the disease can affect any organ system and can be managed in a variety of clinical settings. Patient problems are based on the type of cancer, sites of metastases, stage of disease, comorbidities, and therapy plan. Nurses providing care to patients with cancer should have specialized training in the management of the specific antineoplastic therapy being delivered and the special needs of patients experiencing cancer.

Common medical-surgical problems may be managed differently in the patient with cancer on the basis of this specialized knowledge. For example, oncology patients may receive pain medications for both acute and chronic pain, yet the symptoms of constipation that may occur with opiates must also be considered as a symptom of tumor-related bowel obstruction. See *Geriatric/Gerontological Considerations* for care needs specific to the geriatric population. A list of common nursing diagnoses for the cancer patient with evidence-based care recommendations is provided in Table 13.6.

## Geriatric/Gerontological Considerations

Older adults may have many comorbidities that require complex therapy or may already have some organ dysfunction, and their clinical presentation of disease sometimes differs from that of younger adults. Older individuals may also have unique reimbursement and treatment challenges, warranting a thorough socioeconomic evaluation for barriers to successful completion of the treatment plan. In order to provide safe care to older adults, nurses must be mindful of:

- Polypharmacy (multiple medications)—conduct medication reconciliation with patients; be mindful of potential medication interactions.
- Organ dysfunction—assess kidney and liver function in the physical assessment and via laboratory monitoring; be conscientious of the need for medication dose alterations, such as renal dosing, to minimize harm.
- Clinical presentation of infection—may not present with traditional signs and symptoms of infection, such as

- fever or pain; onset of acute confusion may be secondary to an infectious process.
- Increased risk for injury from falls—control the environment to minimize risk from falls, and conduct frequent rounding (toileting, etc.) to assist with activities of daily living (ADLs), particularly if the patient is at risk for bleeding.
- Decreased ability to tolerate intensive oncology treatment regimens—assess for side effects that are more likely and potentially more severe in the elderly patient secondary to decreased ability to maintain hydration, thermoregulation, and elimination of toxic material; manage side effects proactively.

- Caregiver support and available home care resources—patients may have personal limitations and lack established caregiver support to meet their clinical and daily function needs.
- Interactions between comorbidities and cancer therapies—most older individuals have an average of three to five comorbid health conditions, and many of these are affected by the adverse effects of therapy. Coordinated management of the oncological plan and comorbidities may require increased vigilance and modification of the primary care plan or oncological therapy.

**Table 13.6 Evidence-Based Practice for Cancer Care**

Problem or Potential Problem	Secondary to	As Evidenced by	Management
<b>Neurological</b>			
Change in mental status	Medications (e.g., corticosteroids, voriconazole)	Patient disoriented to person, place, time, and/or situation	Use a delirium assessment tool routinely.
	Infectious disease	Waxing and waning of symptoms	Assess for associated symptoms.
	Electrolyte imbalance (calcium)	May be hypervigilant or more somnolent	Identify and correct underlying organic cause if possible (remove offending medication).
	Delirium (multifactorial)		Manage patient environment to reduce risk of harm. Reorient patient.
Cognitive impairment	Medication and hormonal therapy	Subjective self-report or clinician assessment of decreased attention; decreased concentration, executive function, information-processing skill; slowed psychomotor function, learning, and/or memory  (+) Change on Mini-Mental State Examination (+) Attentional Function Index (+) Cognitive Failures Questionnaire	Assess for cognitive changes.
	Disease		Evaluate for underlying organic disease and treat if possible.
	Delirium		Limited strong evidence-based recommendations exist for managing cognitive impairment; try supportive care and coping strategies based on symptoms.
<b>Respiratory</b>			
Ineffective breathing pattern	Pulmonary toxicity from chemotherapeutic agents (e.g., Bleomycin; targeted therapies)	Breathing rate outside expected normal range of 12–20 breaths/minute  Uneven breathing rhythm  (+) Dyspnea on a numeric rating scale or dyspnea index	Assess respiratory system, including oxygen saturation.  Identify and correct underlying organic cause if possible.  Pharmacotherapy for dyspnea: morphine  Oxygen
	Radiation therapy		

**Table 13.6 Evidence-Based Practice for Cancer Care—cont'd**

<b>Problem or Potential Problem</b>	<b>Secondary to</b>	<b>As Evidenced by</b>	<b>Management</b>
	Decreased lung capacity (pneumectomy, lobectomy)		Pharmacology: benzodiazepines for dyspnea-induced anxiety
	Infection		Increase ambient airflow directed at the face (a fan).
	Sedation		Promote relaxation and stress reduction.
Impaired gas exchange	Anemia	Oxygen saturation less than 90%	Assess respiratory system, including oxygen saturation.
	Pulmonary tumor	Impaired chest excursion	ABG for assessment
	Radiation	Abnormal breath sounds assessment	Identify and correct underlying organic cause if possible.
	Pulmonary embolism	Evidence of decreased perfusion	Symptomatic support
	Acute lung injury from treatment (chemotherapy, blood transfusion reaction)		Oxygen therapy
	Pneumonia		Noninvasive ventilator support
	Pleural effusions		
	Fluid overload		
<b>GI</b>			
Anorexia	Disease-induced anorexia	Patient self-report	Assess GI system and nutritional and hydration status.
	Treatment-induced anorexia	(+) Patient-Generated Subjective Global Assessment (PG-SGA)	Pharmacotherapy: corticosteroids, progestins (megestrol acetate)
	Nausea and vomiting	Body mass index (BMI) less than baseline	Dietary counseling/diet diary
	Food intolerances	Decreased PO intake	Monitor eating patterns, content, nutrient intake.
	Psychological distress	Cachexia	Evaluate need for/potential value of appetite stimulants.
	Infection	Laboratory changes: decreased albumin or prealbumin	
Ineffective elimination pattern: diarrhea	Medication therapy (e.g., chemotherapy)	Increase of stools per day over baseline	Measure and document the frequency, volume, and character of stool output.
	Radiation therapy	(+) Diarrhea Assessment Scale	Assess for dehydration and electrolyte imbalances.
	Infection	(+) Per National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events: diarrhea	Rule out infectious disease origin.
	Abnormal bowel integrity (e.g., bowel resections, ileostomy)	Establish baseline stool characteristics for comparison.	Consider dietary modifications.
	Graft-versus-host disease (GVHD) after hematopoietic stem cell transplant		Pharmacotherapy: PO loperamide, PO opiates, or IM/SQ octreotide

Continued

**Table 13.6 Evidence-Based Practice for Cancer Care—cont'd**

<b>Problem or Potential Problem</b>	<b>Secondary to</b>	<b>As Evidenced by</b>	<b>Management</b>
Ineffective elimination pattern: constipation	Medication therapy (e.g., opioids)	Decrease in stools per day; hard stools that are difficult to pass	<p>Measure and document the frequency, volume, and character of stool output.</p> <p>Pharmacotherapy: stool softeners and peristaltic stimulants; polyethylene glycol</p> <p>Establish fluid intake goals.</p> <p>Enhance normal routines and optimal mobility.</p> <p>Pharmacotherapy: prophylactic bowel regimen for patients on opioids or switch to less constipating opioids</p>
	Altered nutritional profile	Subjective complaints of constipation (+) Constipation Assessment Scale	
	Altered fluid intake	Abdominal distention	
	Altered mobility	Abdominal/back pain	
	Altered daily routines	Sensation of fullness	
Chemotherapy-induced nausea and vomiting (N/V)	Chemotherapy	Subjective complaints of nausea	<p>Assess and document cause of nausea and vomiting.</p> <p>Assess and document frequency, volume, and character of emesis.</p> <p>Benzodiazepine (lorazepam) for anticipatory N/V or combinations of 5-HT<sub>3</sub>, NK1 receptor antagonist, corticosteroids, benzodiazepine for acute and delayed nausea/vomiting</p> <p>Acupressure</p>
		Emesis	
		(+) Index of Nausea, Vomiting, and Retching (+) Per NCI Common Terminology Criteria for Adverse Events: nausea and vomiting	
Impaired oral mucous membrane (mucositis and stomatitis), xerostomia (dry mouth)	Disease	Subjective reports of oral discomfort and/or pain	<p>Patient education on oral hygiene</p> <p>Oral care should include a soft toothbrush that is replaced regularly and frequent mouth rinsing.</p> <p>Cryotherapy for patients receiving rapid infusions of 5-FU or melphalan</p> <p>Pharmacotherapy: palifermin</p>
	Chemotherapy	Redness, swelling of oral mucosae	
	Hematopoietic stem cell therapy	Sores or ulcerations on oral mucosae	
	Oral infection	Dry mouth by self-report	
	Malnutrition		
<b>Skin</b> Radiodermatitis	Radiation therapy	Rash on or near area exposed to radiation therapy characterized by mild to severe erythema, pruritus, desquamation (dry or moist), dryness, and/or pain	Encourage skin hygiene with mild, pH-neutral soaps.
	Intensity-modulated radiation therapy has decreased risk for radiodermatitis compared with conventional radiation therapy.	Rash that may occur shortly after treatment to months after treatment	

**Table 13.6 Evidence-Based Practice for Cancer Care—cont'd**

Problem or Potential Problem	Secondary to	As Evidenced by	Management
Rash and skin reactions other than radiodermatitis	Chemotherapy and targeted therapies GVHD related to hematopoietic stem cell transplant Infection Other medications	Rash or other dermatitis syndromes Hand-foot syndrome Nail changes	Pharmacology: prevent with calendula or hyaluronic acid cream  Limited evidence-based recommendations for treatment  Interventions as with radiodermatitis  Prepare patients for evaluations of potential treatable etiologies such as infections and GVHD and potential cultures or biopsies.
<b>Other</b> Risk for bleeding	Thrombocytopenia (platelets less than 50,000)	Occult heme-positive excrement Visible bleeding from soft tissue and mucous membranes Bruising, ecchymoses	Monitor complete blood count (CBC).  Assess for signs of bleeding.  Maintain platelet threshold of at least 10,000–20,000 per mL to reduce risk of spontaneous bleeding; consider higher thresholds prior to procedures or when receiving anticoagulant therapy.  Platelet transfusion for patients below minimum platelet threshold.  Manage environment and patient needs to reduce risk of injury and falls.
Risk for infection	Neutropenia (white blood cell [WBC] count less than 1,500/mm <sup>3</sup> ) Impaired skin integrity Mucositis Immune suppressive therapy	Fever Constitutional symptoms Purulent exudate Organ-specific symptoms of infective secretions/excretions (e.g., cough and abnormal breath sounds with pneumonia)	Monitor CBC.  Assess for signs of infection, particularly temperature greater than or equal to 38°C (100.4°F).  Hand hygiene using soap and water  Strict adherence to standard precautions for general population and isolation precautions as needed  Do not allow visitors with symptoms of respiratory infection.

**Table 13.6 Evidence-Based Practice for Cancer Care—cont'd**

<b>Problem or Potential Problem</b>	<b>Secondary to</b>	<b>As Evidenced by</b>	<b>Management</b>
Anxiety	Fears about disease Concerns about treatment Concerns about symptoms Medication adverse effects	Patient self-report (+) NCCN distress-thermometer	Pharmacology: influenza vaccine, prophylactic antibiotics, antivirals, and antifungals for patients at risk for severe neutropenia  Psychoeducational interventions: educate about disease, treatment, symptom management, and self-care.  Psychosocial interventions: cognitive-behavioral therapy, individual or group counseling, support group  Pharmacotherapy: benzodiazepines  Massage therapy
Fatigue	Disease Treatment Infection Specific complications (e.g., anemia)	Patient self-report (+) Brief Fatigue Inventory (+) Oncology Nursing Society Fatigue Scale	Screen for organic causes that can be corrected (e.g., anemia, depression, sleep disturbances).  Encourage exercise several times per week.  Patient education on energy conservation and activity management  Optimize sleep quality (good sleep hygiene).  Relaxation training  Massage and healing touch
Acute pain	Disease Treatment (surgery) Infection Other medical-surgical conditions	Patient self-report Reports pain on a numeric rating scale or a visual analog scale (+) Brief Pain Inventory	Assess pain.  Pharmacotherapy for nociceptive pain: acetaminophen, NSAIDs, opioids, fentanyl, methadone, corticosteroids  Pharmacotherapy for neuropathic pain: antidepressants, gabapentin, pregabalin, topical lidocaine, opioids, tramadol
Chronic pain	Tumor infiltration Postchemotherapy pain syndrome Postradiation syndrome Peripheral neuropathy Phantom limb syndrome	Patient self-report Reports pain on a numeric scale or visual analog scale	Assess pain. See pharmacotherapy for acute pain.

### Connection Check 13.6

Which statement by the patient indicates that teaching about chemotherapy was effective?

- "I know everyone loses their hair with chemo."
- "I know it is important that I monitor my temperature."
- "I know I should eat whatever I want so that I don't lose weight while on chemo."
- "I understand that I can skip a chemo treatment if I don't feel well."

## Making Connections

### CASE STUDY: WRAP-UP

Mrs. Jones is diagnosed with stage III breast cancer. Her treatment plan includes chemotherapy followed by a mastectomy. The chemotherapy is done in an effort to decrease the size of the tumor prior to mastectomy. She is scheduled for a class that will provide information on chemotherapy: administration and side effects. After her mastectomy, she will be started on oral hormonal therapy and will start radiation therapy.

#### Case Study Questions

- Mrs. Jones has stage III breast cancer. What does this mean?
  - The tumor has spread to lymph nodes and other organs.
  - The tumor is small and localized and has not invaded other organs.
  - The tumor is large, locally advanced, and possibly in local lymph nodes.
  - The tumor is large and has spread to the lymph and hematological systems but not to other solid organs.
- Mrs. Jones's oral hormonal therapy is considered what type of treatment?
  - Chemotherapy
  - Adjuvant therapy
  - Neoadjuvant therapy
  - Primary treatment
- The nurse is preparing to provide patient education to Mrs. Jones, who is about to start her first cycle of chemotherapy. In addition to self-management strategies and supplemental medications for persistent acute effects, the nurse will educate her on the importance of immediately calling her provider if she experiences what symptom?
  - Hair loss
  - Dry skin
  - Fever
  - Nausea
- The nurse is about to start Mrs. Jones on her first dose of the taxane chemotherapy. This will be Mrs. Jones's first infusion of paclitaxel, a plant alkaloid which is a vesicant and can cause hypersensitivity reactions. What should be done as a part of the nurse's preparation for medication infusion? (*Select all that apply.*)
  - Premedicate Mrs. Jones with vitamin K.
  - Make sure emergency equipment (oxygen, medication) is working and easily accessible.
  - Review Mrs. Jones's medical record to make sure she has had an electrocardiogram completed within the last 24 hours.
  - Check Mrs. Jones's IV access by flushing the line and checking for good blood return.
  - Check Mrs. Jones's blood glucose level.
- Mrs. Jones is now presenting post-mastectomy for external-beam radiation therapy to her left breast and left chest wall. The nurse caring for Mrs. Jones pays particular attention to which of the following systems during the head-to-toe assessment? (*Select all that apply.*)
  - Renal system
  - Integumentary system
  - Musculoskeletal system
  - Cardiac system
  - Respiratory system

## CHAPTER SUMMARY

Cancer is a constellation of diseases involving a malignant transformation of cells within a specific body system. Cancer cells are characterized by uncontrolled cell growth and altered differentiation. Risk factors for cancer include exposure to a carcinogen (most common), age, and genetic predisposition. Advanced age increases the risk for cancer. Other factors include a sedentary lifestyle and poor diet. Risk factors are believed to be cumulative, with multiple risks connoting additive cancer risk.

Two broad classes of cancer are solid and hematological. Cancers are further classified according to the organ

of origin or system of origin. Cancer is then further “staged” by evaluating the size of the tumor, the burden of the disease, and the extent of disease spread. The stage of disease is used to plan management and treatment strategies. Cancer presentation varies on the basis of tumor location and disease stage.

Diagnostic evaluation includes laboratory tests, imaging studies, biopsy, and endoscopic procedures. Three primary modes of cancer treatment are surgical, radiation, and medical antineoplastic therapy. Each treatment modality has unique side effects that must be managed to minimize morbidity and mortality.

# Chapter 14

## Overview of Shock and Sepsis

*Nancy Sullivan*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Discussing the pathophysiology of shock
2. Identifying hypovolemic, cardiogenic, obstructive, and distributive shock
3. Describing the stages of shock
4. Describing the assessment of and monitoring techniques indicated for shock
5. Correlating clinical manifestations to pathophysiological processes of
  - a. Hypovolemic shock
  - b. Cardiogenic shock
  - c. Obstructive shock
  - d. Distributive shock
    - Neurogenic shock
    - Anaphylactic shock
    - Septic shock
6. Describing the medical management of selected shock states
7. Analyzing the nursing management of shock states
8. Discussing the complications associated with shock, including
  - a. Disseminated intravascular coagulopathy
  - b. Multiple-organ-dysfunction syndrome

### CONCEPTS

- Assessment
- Fluid and Electrolyte Balance
- Infection
- Medication
- Oxygenation
- Perfusion
- pH Regulation

### ESSENTIAL TERMS

Afterload  
Anaphylactic shock  
Anaphylaxis  
Cardiac output (CO)  
Cardiogenic shock  
Central venous oxygen saturation (ScvO<sub>2</sub>)  
Compensatory stage  
Contractility  
Disseminated intravascular coagulopathy (DIC)  
Distributive shock  
Ejection fraction  
Hemodynamic parameters  
Hypovolemic shock  
Initial stage  
Lactate  
Mixed venous oxygen saturation (SvO<sub>2</sub>)  
Multiple-organ-dysfunction syndrome (MODS)  
Neurogenic shock  
Obstructive shock  
Oxygen consumption (VO<sub>2</sub>)  
Oxygen debt  
Oxygen delivery (DO<sub>2</sub>)  
Preload  
Progressive stage  
Refractory stage  
Sepsis  
Septic shock  
Systemic inflammatory response syndrome (SIRS)  
Venous oxygen saturation

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Mike Adams, a 42-year-old Caucasian male, is admitted to the emergency department from home with a complaint of shortness of breath. He has a history of hypertension and well-controlled diabetes. Upon presentation to the emergency department, his vital signs are as follows: temperature, 101.9°F (38.83°C); pulse, 120 bpm; respirations, 20; blood pressure, 90/54 mm Hg; and SpO<sub>2</sub>, 91%. His chest radiograph reveals pneumonia. He is alert and oriented, but he complains of dizziness when changing positions. His weight is confirmed at 80 kg/176 lb.

The following orders are written for the patient:

Place two large-bore IV lines and infuse a 2.5-L (30-mL/kg) bolus of 0.9% normal saline and then begin 125 mL/hr.

Obtain complete blood cell count, serum electrolyte level, lactate level, and blood cultures.

Provide oxygen at 2 L/min via nasal cannula.

Begin administration of cefotaxime 2 g IV every 8 hours after blood cultures are drawn...

## OVERVIEW OF SHOCK

The tissues of the body require a continuous supply of oxygen in order to maintain cellular functioning. Shock is a life-threatening syndrome that occurs when the circulatory system is unable to supply adequate amounts of oxygen to the tissues to meet basic metabolic requirements. This creates a state of tissue hypoxia, which is an imbalance of cellular oxygen supply and demand. Without immediate treatment to reverse this imbalance, organ system failure and death may result. Important concepts to understand when evaluating shock include cardiac output, oxygen delivery, oxygen consumption, and oxygen debt.

### Cardiac Output

**Cardiac output (CO)** is the amount of blood ejected by the heart every minute. It is a function of stroke volume and heart rate (HR). The heart rate is simply the number of ventricular contractions per minute or heartbeats per minute. It can be affected by many variables. Stimulus from the autonomic nervous system or hormones from the adrenal medulla can adjust the HR up or down. Changes in blood pressure sensed by baroreceptors can also affect the HR.

Stroke volume is the amount of blood ejected with each ventricular contraction. It is influenced by three variables: preload, afterload, and contractility. **Preload** is the amount

of blood in the ventricles at the end of diastole. It is a reflection of a patient's fluid volume status. The values obtained to measure preload are sometimes referred to as *filling pressures*. An increase in preload may result in an increase in cardiac output. Conversely, a decrease in preload may decrease cardiac output. **Afterload** refers to the resistance to flow that the ventricle must overcome to eject its contents. Increasing afterload may make it harder for the heart to eject blood into the systemic circulation. **Contractility** refers to the force of the mechanical contraction. Poor contractility decreases stroke volume, thus decreasing cardiac output. These concepts related to cardiac output are discussed in depth in Chapter 28.

**Oxygen delivery (DO<sub>2</sub>)** is the amount of oxygen delivered to the tissues. It is assessed through the evaluation of cardiac output and arterial oxygen content. Arterial oxygen content is a combination of hemoglobin levels, the percentage of hemoglobin saturated with oxygen, and the amount of oxygen dissolved in the plasma (the partial pressure of oxygen in arterial blood [PaO<sub>2</sub>]). **Oxygen consumption (VO<sub>2</sub>)** reflects the amount of oxygen extracted from the blood at the tissue level. It can be measured through evaluation of a blood sample, a **venous oxygen saturation**. The venous oxygen saturation level reflects the amount of oxygenated blood returned to the right heart. Oxygen consumption is typically stable at the tissue level. Normal SvO<sub>2</sub> values are between 60% and 75%. When that value falls below normal, it means the tissues are extracting more oxygen than normal. That results from a decreased DO<sub>2</sub>, which may be a decrease in oxygen content, hemoglobin, or cardiac output. It may also reflect an inability to increase delivery in response to stressors such as pain or fever. **Oxygen debt** is the difference between normal VO<sub>2</sub> and VO<sub>2</sub> during the low-DO<sub>2</sub> state. The longer there is an imbalance between cellular oxygen supply and demand, the larger the oxygen debt becomes. This resulting oxygen debt must be repaid in order to maintain cellular function.

### Connection Check 14.1

The nurse understands that which of these increase as the delivery of oxygen to the tissues falls below the tissues' requirements? (Select all that apply.)

- A. VO<sub>2</sub>
- B. Oxygen debt
- C. SvO<sub>2</sub>
- D. PaO<sub>2</sub>
- E. Preload

## Classifications of Shock

### Hypovolemic Shock

**Hypovolemic shock** results when there is a rapid fluid loss resulting in inadequate circulating volume. Most commonly, hypovolemic shock is secondary to blood loss from

penetrating or blunt trauma or severe gastrointestinal (GI) bleeds. Examples of penetrating trauma include gunshot wounds and knife injuries. Blunt trauma examples include blood loss into the abdomen due to damage to the liver, trauma to the thoracic cavity resulting in a ruptured aorta, or long bone or femur fractures. Excessive fluid loss may be caused by severe vomiting or diarrhea. Extensive burns can also cause severe loss of fluids, resulting in hypovolemic shock.

### Cardiogenic Shock

**Cardiogenic shock** is characterized as inadequate pumping ability of the heart muscle, most typically the result of an acute myocardial infarction (AMI). Independent of fluid volume status, the inadequate pumping of the heart results in decreased cardiac output and poor perfusion at the tissue level.

### Distributive Shock

**Distributive shock** is the result of disease states such as sepsis, anaphylaxis, or neurogenic shock that cause poor vascular tone and vasodilation, resulting in increased vascular capacity and venous pooling. In this form of shock, a state of relative hypovolemia exists due to vasodilation without a concurrent increase in volume. Venous pooling results, causing a decreased venous return to the right heart.

### Obstructive Shock

**Obstructive shock** is caused by a mechanical barrier to ventricular filling or ventricular emptying (increased afterload), causing decreased cardiac output. Examples of disorders resulting in impaired filling include cardiac tamponade and tension pneumothorax. An example of a disorder resulting in increased afterload is severe valvular disease.

See Table 14.1 for an overview of the classifications of shock.

## Connection Check 14.2

The nurse understands that which patient is at risk of developing hypovolemic shock?

- A patient with severe valvular disease
- A patient receiving spinal anesthesia
- A patient with severe diarrhea
- A patient with a large pneumothorax

## Stages of Shock

There are four distinct stages of shock: initial, compensatory, progressive, and refractory. Each stage is characterized by specific clinical manifestations, the initiation of compensatory mechanisms, and progressive indications of worsening hypoperfusion. Without effective treatment, shock progresses through the stages. The earlier the identification and treatment of shock take place, the better is the possible outcome.

**Table 14.1 Classifications of Shock**

Classification	Potential Cause
<b>Hypovolemic shock</b>	<ul style="list-style-type: none"> <li>External blood loss due to trauma, gastrointestinal bleeds, surgery</li> <li>Internal bleeding due to fractures, dissecting aneurysms, hemothorax, retroperitoneal bleed</li> <li>Fluid loss secondary to severe vomiting, diarrhea, excessive urination or burns</li> <li>Third-space/transcellular fluid loss (pleural, peritoneal, joint spaces)</li> </ul>
<b>Cardiogenic shock</b>	<ul style="list-style-type: none"> <li>Myocardial infarction</li> <li>Severe valvular dysfunction</li> <li>Severe heart failure</li> </ul>
<b>Distributive shock</b>	<ul style="list-style-type: none"> <li>Sepsis</li> <li>Anaphylaxis</li> <li>Brain injury, spinal injury, or spinal anesthesia</li> </ul>
<b>Obstructive shock</b>	<ul style="list-style-type: none"> <li>Tension pneumothorax</li> <li>Cardiac tamponade</li> <li>Severe valvular disease</li> </ul>

### Initial Stage

The **initial stage** of shock is marked by hypoxia due to decreased  $DO_2$  to the cells. Clinical manifestations are subtle or subclinical, but cellular damage may be occurring. Invasive hemodynamic monitoring would note decreased cardiac output. Without identification and treatment at this stage, shock will progress to the next level.

### Compensatory Stage

The **compensatory stage** is characterized by the initiation of compensatory mechanisms in an effort to maintain adequate volume, cardiac output, and blood flow to the tissues. These mechanisms include neural, endocrine, and chemical compensations.

### Neural Compensation

Neural compensation is characterized by the detection of hypotension by baroreceptors in the carotid sinus and aortic arch that results in the stimulation of the sympathetic nervous system and the release of the catecholamines epinephrine and norepinephrine from the adrenal medulla. Heart rate and contractility increase, improving cardiac output. Also in response to this catecholamine release, systemic vasoconstriction occurs, resulting in increased blood pressure and redistribution of blood flow from nonessential organ systems, such as the kidneys, GI tract, and skin, to vital organs, such as the heart and brain.

## Endocrine Compensation

Endocrine compensation or hormonal mechanisms that exert control over blood pressure include angiotensin II, epinephrine and norepinephrine, aldosterone, and antidiuretic hormone (ADH). Angiotensin II, created in response to low BP, is an end product of a series of events. After a drop in blood pressure, the kidneys respond by releasing the enzyme renin. Renin reacts with angiotensinogen to create angiotensin I. Angiotensin I is then converted in the lungs to angiotensin II via angiotensin-converting enzyme. Angiotensin II is a potent vasoconstrictor that increases blood pressure. Angiotensin II also acts on the adrenals to release aldosterone. The release of aldosterone promotes sodium and water reabsorption in the kidneys, which increases the circulating fluid volume. This is called the *renin-angiotensin-aldosterone system (RAAS)*. Aldosterone release is also stimulated by the release of adrenocorticotropic hormone in response to low blood pressure from the anterior pituitary, which then stimulates the adrenal cortex to release aldosterone. Also in an effort to increase the circulating volume, antidiuretic hormone is released by the posterior pituitary in response to decreased blood volume. It acts on the kidney to conserve water. Other compensatory mechanisms include the release of the catecholamines epinephrine and norepinephrine from the adrenal medulla, causing vasoconstriction as part of the fight-or-flight mechanism in the sympathetic nervous system. There is also a compensatory mechanism to increase glucose levels for energy. Circulating glucose levels are increased through the release of glucocorticoids from the adrenal cortex in response to decreased blood pressure.

## Chemical Compensation

Chemical compensation is produced through the reaction of chemoreceptors in the aorta and carotid arteries that are stimulated by low oxygen levels. Low oxygen levels occur as a result of decreased blood flow through the alveoli. Tachypnea, or hyperventilation, occurs in an effort to increase circulating oxygen levels. The respiratory alkalosis that results causes a constriction of the carotid arteries. Although tachypnea is effective at improving oxygen levels, cerebral hypoxia and ischemia may result.

## Progressive Stage

The **progressive stage** is marked by the failure of compensatory mechanisms to maintain adequate blood pressure and circulating fluid volumes. There is extensive shunting of blood to vital organs, which results in decreased blood flow to the periphery. Without effective treatment, profound hypoperfusion occurs, resulting in worsening metabolic acidosis, electrolyte imbalances due to the failure of the sodium-potassium pump, and respiratory acidosis.

## Refractory Stage

The **refractory stage** is marked by prolonged inadequate blood supply to the cells, resulting in cell death and multi-system organ failure. There is a loss of aerobic metabolism,

and only extremely inefficient anaerobic metabolism is available. Shock is irreversible at this stage.

Table 14.2 outlines the stages of shock and the clinical manifestations associated with each stage.

## Connection Check 14.3

The nurse monitors for which clinical manifestations in the patient in compensatory shock?

- A. Low but normal blood pressure, oliguria
- B. Cold extremities, hyperglycemia
- C. Weak pulses, hypoventilation
- D. Hypotension, tachycardia

## ASSESSMENT AND MONITORING OF SHOCK

The assessment and monitoring of shock are multifaceted. The first challenge is to quickly determine the presence and extent of shock. In some circumstances, such as obvious extensive external bleeding, a massive myocardial infarction, or rapid changes after spinal cord injury, shock may be evident quickly. Other times, it may be less obvious, such as bleeding that results in an internal sequestration or collection of blood that may occur with a femur fracture or retroperitoneal hemorrhage (i.e., blood accumulation in the abdominal cavity behind the peritoneum). Astute assessment and prompt response are essential to halt the progression of shock to the more advanced stages.

The second challenge is monitoring the progression of shock and resuscitation through physical assessment, hemodynamic monitoring, and laboratory analysis. Conventional parameters such as restoration of normal blood pressure are not adequate to gauge the extent of shock or the success of resuscitation strategies. The initiation of compensatory mechanisms in the second stage of shock may temporarily restore homeostasis without fully repaying the oxygen debt, allowing continuing hypoperfusion at the tissue level. Physical assessment parameters to assess perfusion at the tissue level, such as level of consciousness, urine output, respiratory status, pulse quality, skin color and/or mottling, and temperature, are important to monitor. Hemodynamic monitoring and laboratory analyses of endpoints, such as lactate, base deficit, venous oxygen saturation, and blood gas analysis, are also essential parameters to consider when evaluating the extent of shock and success of resuscitation.

## Physical Assessment

### Central Nervous System

Changes in central nervous system perfusion may be the initial indication of inadequate  $DO_2$  to the tissues. As noted earlier, in addition to low  $DO_2$ , the respiratory alkalosis that results from tachypnea causes vasoconstriction of the

**Table 14.2 Stages of Shock**

Stage of Shock	System Response	Clinical Manifestations
<b>Initial</b>	<ul style="list-style-type: none"> <li>● Decreased oxygen delivery to the tissues</li> </ul>	<ul style="list-style-type: none"> <li>● Subtle or no clinical manifestations</li> </ul>

carotid arteries, resulting in decreased cerebral blood flow. Restlessness, confusion, and irritability are several beginning indicators of poor cerebral perfusion. Without treatment, continued poor perfusion may progress to lethargy and coma.

### Cardiovascular System

The cardiovascular system provides several parameters effective in the assessment of the presence or resolution of shock. Blood pressure is a valuable indicator of fluid status and cardiac output. A decreased blood pressure level can be indicative of a problem. In shock, blood pressure decreases because of inadequate venous return to the heart, vasodilation, or decreased contractility of the heart muscle. It is important to remember that a return to the baseline blood pressure level does not mean the resolution of the problem, but prolonged hypotension does indicate the continued presence of shock. A common finding indicative of the compensatory stage of shock is a narrow pulse pressure,

which results from compensatory vasoconstriction causing an increase in diastolic pressure with only a slight increase in systolic pressure.

Tachycardia is a typical finding due to stimulation of the sympathetic nervous system as a way to increase cardiac output. If shock is not resolved but is allowed to progress to later stages, the HR may slow. Skin color, temperature, quality of pulses, and capillary refill indicate perfusion in the extremities. Because of shunting of the blood to vital organs, the skin and periphery become cool, pale, mottled, or cyanotic, with thready pulses and sluggish capillary refill.

### Respiratory System

The respiratory system also provides insight as to the presence and progression of shock. Early stages of shock are characterized by increased respirations done in an effort to increase oxygenation and decrease carbon dioxide (CO<sub>2</sub>) levels due to the metabolic acidosis. Oxygenation can be

measured through pulse oximetry, but poor peripheral circulation may cause inaccurate readings. Arterial blood gases (ABGs) may be necessary for more accurate assessment.

### Renal System

The renal system provides a clear indication of poor perfusion if urine output decreases. **Oliguria is a common finding in early shock because of decreased perfusion of the renal tubules, which stimulates the initiation of the renin-angiotensin-aldosterone system.** If unresolved, later stages of shock will present with anuria, increased creatinine level, and other signs of acute renal failure.

### Gastrointestinal System

The GI system indicates poor perfusion through sluggish, **hypoactive bowel sounds that reflect a slowing of intestinal activity.** Nausea and vomiting may also be present. The GI system is particularly vulnerable to poor perfusion and ischemia. Cell damage in the GI tract allows translocation of intestinal bacteria to the systemic circulation, increasing the risk of sepsis. Some have suggested that hypoperfusion in the GI system may initiate a systemic inflammatory response, which, if not resolved, may be the precursor to multiple organ dysfunction syndrome (MODS).

### Hemodynamic Monitoring

Monitoring of blood pressure, cardiac output, and the variables that affect cardiac output provides valuable insights into the presence, stages, or resolution of shock. Invasive hemodynamic monitoring is done through an arterial line and a central venous catheter or pulmonary artery (PA) catheter.

### Arterial Line

A critically ill patient in shock benefits from the placement of an arterial line. Blood pressure is continually displayed, and it provides easy access to blood for analysis, especially ABG samples. As mentioned previously, oxygenation is sometimes better measured through ABGs because of peripheral shunting and inaccurate pulse oximetry readings.

### Pulmonary Artery Catheter

A pulmonary artery (PA) catheter is a flexible, balloon-tipped catheter that is guided through the right side of the heart and into the pulmonary artery. Pulmonary artery catheter monitoring allows the nurse to obtain detailed information about cardiac output and the variables that affect it: preload, also referred to as filling pressures; afterload; and contractility.

Although variable, the typical PA catheter has four lumens—proximal, distal, thermistor, and inflation—each of which leads to a specific port (Fig. 14.1). The proximal port, located approximately 30 cm from the tip of the catheter, typically resting just in the right atrium, is used to monitor right atrial pressure, a reflection of right heart preload, and *right ventricular end-diastolic volume*. It is also the port used to inject the solution to obtain a thermodilution cardiac output.

The distal lumen port is located at the tip of the PA catheter and rests within the pulmonary artery. Through this port, the nurse can monitor systolic, diastolic, and mean PA pressures and the pulmonary artery wedge pressure, also referred to as pulmonary artery occlusive pressure (PAOP). The PAOP is obtained when the balloon located at the

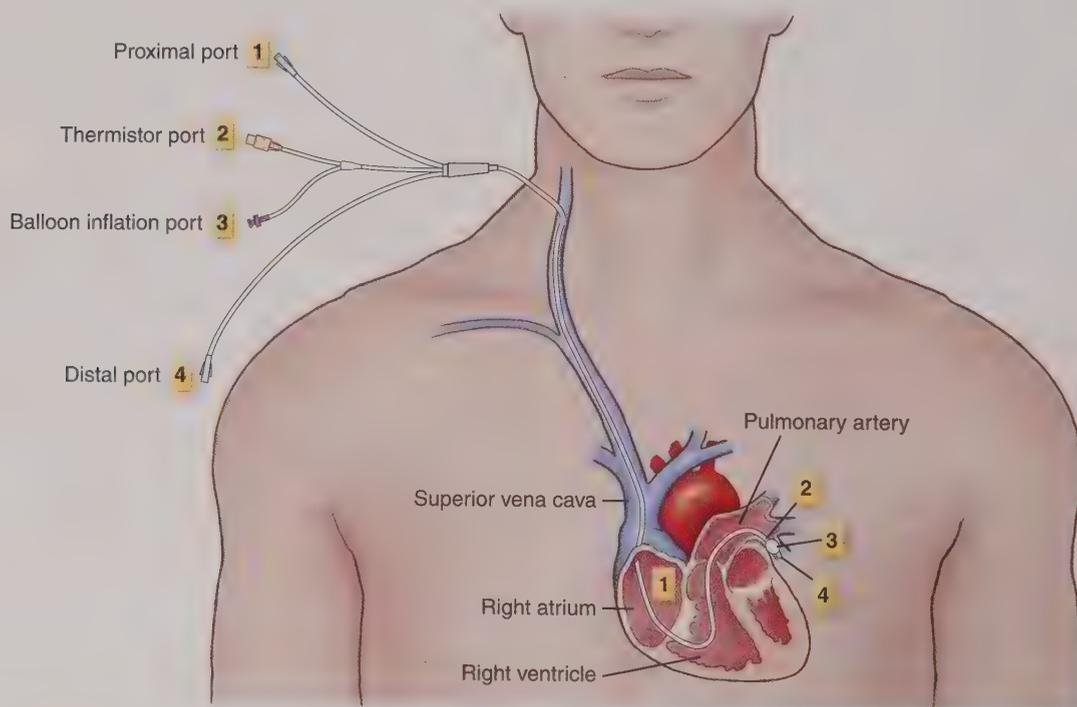

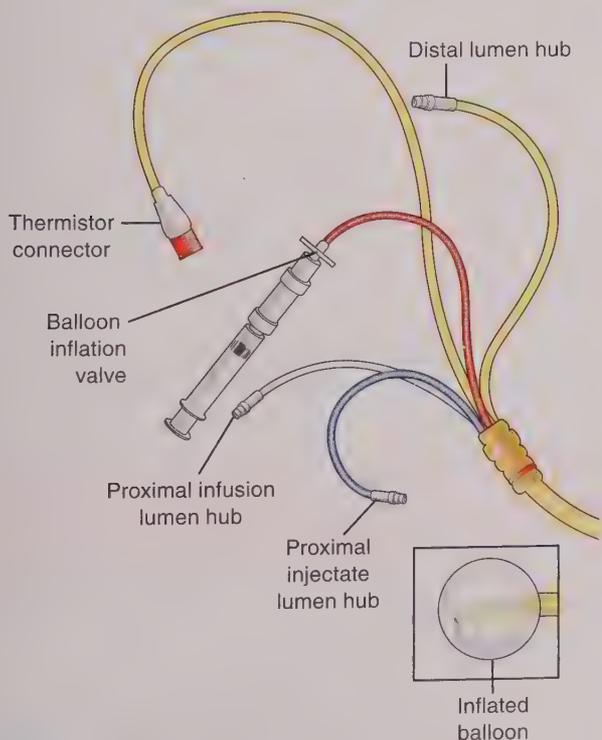

FIGURE 14.1 Pulmonary artery catheter.

end of the inflation lumen is inflated with 1.5 mL of air (Fig. 14.2). The balloon floats into a wedge position in the PA, which occludes that branch of the PA, obscuring data from the right heart. In this position, the values obtained reflect pressures proximal to the balloon or left heart pressures. Specifically, the PAOP reflects left heart preload or the amount of blood in the left ventricle at the end of diastole, also referred to as *left ventricular end-diastolic pressure*. The distal lumen port can also be used for drawing a venous oxygen saturation sample, specifically, a **mixed venous oxygen saturation (SvO<sub>2</sub>)** sample. The SvO<sub>2</sub> obtained through a PA line provides a “mixed” sample of blood returned from both the superior and inferior vena cava, thus providing information on oxygen extraction throughout the entire body.

Cardiac output can be directly obtained through a PA catheter. There is a temperature sensor, or thermistor port, built into the tip of the PA catheter. It continuously measures the ambient blood temperature around it. To obtain a cardiac output, a small bolus of cooler saline is briskly injected into the PA catheter through the proximal port. As a result of the injection of cooler fluid, the temperature of the blood flowing by the sensor changes. The time it takes for the cold injectate to pass the sensor is measured in liters of blood pumped per minute. This is called the “thermodilution” method of obtaining cardiac output. Normal cardiac output is 4 to 6 L/min. Typically, cardiac output is indexed, meaning it is calculated on the basis of the patient’s body surface area. A normal cardiac index is 2.5 to 4 L/min.

**FIGURE 14.2** Pulmonary artery catheter with inflated balloon.

Other hemodynamic variables obtained through a PA catheter include afterload and contractility. Afterload, also known as *systemic vascular resistance*, is a calculated value obtained using mean arterial and mean right atrial pressure divided by cardiac output. Pulmonary vascular resistance, the afterload of the right heart, is obtained by substituting PA pressures into that calculation. Contractility is another value calculated through measurements obtained via the PA catheter. It is inferred by evaluating the right and left ventricular stroke work indexes, or calculations of work done by the heart with each contraction. As discussed, invasive hemodynamic monitoring with a PA catheter allows a more in-depth look at volume status and DO<sub>2</sub> but provides only a partial assessment of recovery.

The use of the PA catheter has not demonstrated a consistent benefit in the overall mortality of shock patients, so the decision to use this diagnostic monitoring tool should be based on individual case-based need by practitioners skilled in insertion and interpretation of the data. There are several less invasive tools for hemodynamic monitoring to help guide resuscitation in critically ill patients. One example presently in use is pulse contour analysis. This analysis estimates stroke volume through analysis of the systolic phase of the arterial waveform. Cardiac output is estimated through the calculation of HR × SV. There are several pulse contour systems; some require just an arterial line, some require the addition of a central line. They have limitations such as attempting to evaluate CO in a patient with an irregular heart rhythm. They continue to be evaluated for accuracy.

See Table 14.3 for a comparison of hemodynamic parameters in different types of shock and in early and late sepsis.

### Central Venous Catheter

Central venous monitoring utilizes a long catheter threaded through the superior vena cava with the distal port resting in the superior vena cava immediately above the junction with the right atrium. This allows central venous pressure (CVP) monitoring. This value indicates a mean CVP, which,

<b>Anaphylactic shock</b>	<ul style="list-style-type: none"> <li>● Decreased cardiac output</li> <li>● Decreased CVP and PAOP</li> <li>● Decreased SVR</li> <li>● Decreased venous oxygen saturation (SvO<sub>2</sub> or ScvO<sub>2</sub>)</li> <li>● Hypotension and tachycardia</li> </ul>
<b>Neurogenic shock</b>	<ul style="list-style-type: none"> <li>● Decreased cardiac output</li> <li>● Decreased CVP and PAOP</li> <li>● Decreased SVR</li> <li>● Decreased venous oxygen saturation (SvO<sub>2</sub> or ScvO<sub>2</sub>)</li> <li>● Hypotension and bradycardia</li> </ul>
<b>Early septic shock</b>	<ul style="list-style-type: none"> <li>● Increased cardiac output</li> <li>● Decreased CVP and PAOP</li> <li>● Decreased SVR</li> <li>● Increased venous oxygen saturation (SvO<sub>2</sub> or ScvO<sub>2</sub>)</li> <li>● Normal or decreased blood pressure, tachycardia, and hyperthermia</li> </ul>
<b>Late septic shock</b>	<ul style="list-style-type: none"> <li>● Decreased cardiac output</li> <li>● Variable CVP and PAOP</li> <li>● Variable SVR</li> <li>● Decreased venous oxygen saturation (SvO<sub>2</sub> or ScvO<sub>2</sub>)</li> <li>● Hypotension, tachycardia, and hypothermia</li> </ul>

similar to the RAP, is used as an estimate of volume returning to the right heart or right heart preload, or the *right ventricular end-diastolic volume*. The CVP and RAP are typically the same or very similar unless there is a pressure differential between the SVC and the right atrium, and the terms are sometimes used interchangeably. For consistency purposes, this book will refer to the measure of right heart preload as CVP. A decreased CVP reading may be indicative of a low-volume state, such as hypovolemic shock or peripheral vasodilatation that occurs as a result of distributive shock. An elevated CVP may indicate increased volume that may occur with cardiogenic shock.

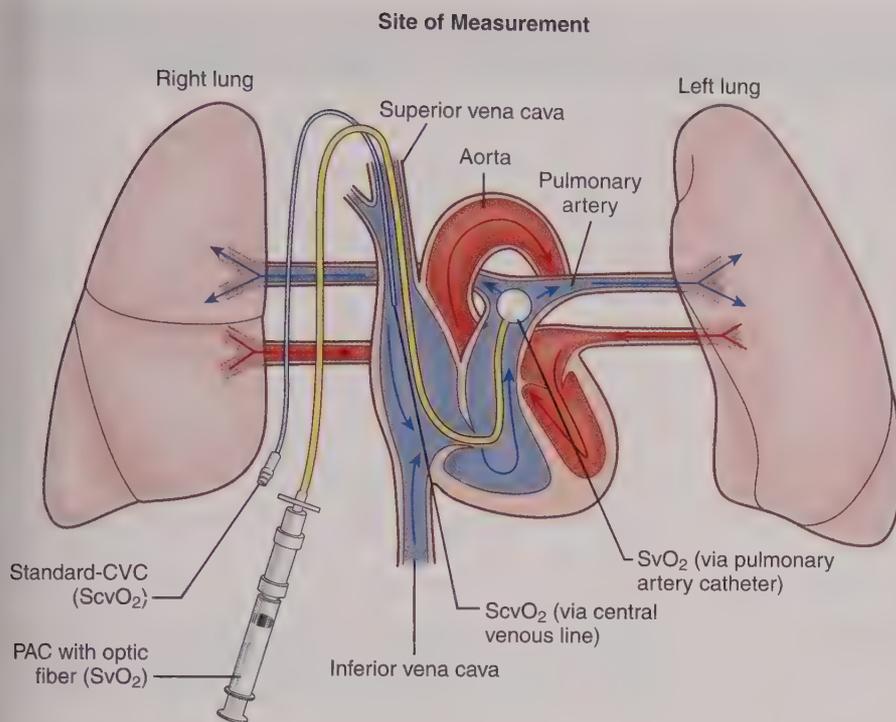

This line may also be used as a port to draw another type of venous oxygen saturation, specifically, a **central venous oxygen saturation (ScvO<sub>2</sub>)**, if a PA line is not in place. Unlike the sample drawn through the PA line, the ScvO<sub>2</sub> provides information primarily on oxygen extraction in the brain and upper body (Fig. 14.3). Although ScvO<sub>2</sub> is not reflective of whole-body VO<sub>2</sub>, good correlation has been found between SvO<sub>2</sub> and ScvO<sub>2</sub> for monitoring and treatment purposes.

### Laboratory Analysis

Evaluation of laboratory studies provides valuable information regarding the presence, severity, or resolution of shock. Several very important indicators include ABG analysis, SvO<sub>2</sub> or ScvO<sub>2</sub>, base deficit, and lactate level. Arterial blood gas analysis provides information on oxygenation, ventilation, and the presence of acidosis or alkalosis (metabolic or respiratory), which provides insight into the adequacy of treatment. Results will vary on the basis of early or late shock. As already stated, hyperventilation in early shock produces a respiratory alkalosis. In later stages of shock, a metabolic acidosis will be present. The presence of hypoxemia, or decreased PaO<sub>2</sub>, indicates the development of respiratory complications such as acute respiratory distress syndrome (ARDS). Evaluation of VO<sub>2</sub> via SvO<sub>2</sub> or ScvO<sub>2</sub> is also an extremely valuable parameter to consider when evaluating the sufficiency of DO<sub>2</sub> or oxygen debt. As stated earlier, when that value falls below normal, it means the tissues are extracting more oxygen than normal. That results from a decreased DO<sub>2</sub> and provides information on oxygen debt.

An elevated lactate level indicates increased anaerobic metabolism due to tissue hypoperfusion. It can be used as an overall assessment of the state of shock and as an evaluation of the resuscitative effort. Base deficit, a value obtained with an ABG analysis, also provides an indication of the level of acidosis. It is defined as the amount of base required to achieve a pH of 7.4. A higher level of base required to achieve a normal pH (a negative base deficit) is consistent with acidosis. Base deficit is a sensitive indicator of the level of severity and potential for complications of shock.

Hemoglobin and hematocrit, part of the equation of arterial oxygen content, provide information about oxygen-carrying capacity and are valuable for determining the

**FIGURE 14.3** Measurement sites for ScvO<sub>2</sub> and SvO<sub>2</sub>.

effectiveness of DO<sub>2</sub>. Electrolytes, renal studies, liver studies, and glucose level are all valuable indicators of the state of shock. Unfortunately, by the time they are elevated, shock has progressed to later stages.

Table 14.4 lists laboratory tests that can aid in the evaluation of shock.

### Connection Check 14.4

The nurse understands that which of the following are the best parameters for evaluating the severity of the shock state? (Select all that apply.)

- A. SvO<sub>2</sub>
- B. Lactate level
- C. Base excess
- D. Glucose level
- E. PaO<sub>2</sub>

## HYPOVOLEMIC SHOCK

### Epidemiology

*Hypovolemic shock* is defined as inadequate intravascular volume producing decreased cardiac output that results when there is a severe loss of blood or fluids due to acute injury or illness. An acute bleed may be the result of penetrating or blunt trauma or massive GI bleeding. Rapid fluid loss may be due to severe vomiting and diarrhea, excessive urination, or loss of fluids due to burns. The most common cause of hypovolemia is blood loss. Incidence or prevalence data are unavailable because the data are reported for the causative mechanism rather than for the resultant hypovolemic shock.

### Pathophysiology

Acute loss of circulating fluid volume results in decreased venous return to the right heart and decreased stroke volume and cardiac output, resulting in decreased perfusion at the tissue level. This decreased intravascular volume results in the initiation of several compensatory mechanisms. The initial response is the stimulation of the sympathetic nervous system, which increases the HR in an attempt to increase cardiac output. The sympathetic nervous system also stimulates the release of epinephrine and norepinephrine from the adrenal medulla, improving contractility and inducing systemic vasoconstriction. Blood pressure and cardiac output are increased. Blood flow is redirected from nonessential organs to vital organs such as the heart and brain.

The endocrine system, through the RASS and the release of antidiuretic hormone from the posterior pituitary, increases sodium and water reabsorption in the renal tubules, effectively increasing venous return to the right heart. The end product of the renin–angiotensin–aldosterone system, angiotensin II, also produces potent systemic vasoconstriction that increases blood pressure and venous return.

### Clinical Manifestations

Clinical manifestations vary depending on the stage of shock. Initially, the patient may be in a compensated state and have no outward symptoms. Without intervention, clinical manifestations appear because of the stimulation of compensatory mechanisms. In the early stages, blood pressure may remain within normal limits, but the HR is typically increased. The patient may present as restless or confused. Urine output decreases because of

**Table 14.4 Laboratory Tests Valuable in the Evaluation of Shock**

Laboratory Test	Abnormal Value	Implication
<i>pH</i>	Less than 7.35 or greater than 7.45	Early shock pH is elevated, reflecting respiratory alkalosis; late shock pH is decreased, reflecting metabolic acidosis.
<i>Partial pressure of carbon dioxide in arterial blood (PaCO<sub>2</sub>)</i>	Less than 35 mm Hg or greater than 45 mm Hg	Early shock PaCO <sub>2</sub> is decreased because of hyperventilation.
<i>Partial pressure of oxygen in arterial blood (PaO<sub>2</sub>)</i>	Less than 80 mm Hg	Decreased PaO <sub>2</sub> indicates the development of complications such as acute respiratory distress syndrome.
<i>HCO<sub>3</sub></i>	Less than 22 mEq/L	Decreased in late shock because of metabolic acidosis
<i>Base deficit</i>	Less than -2 mEq/L	Sustained negative levels reflect the severity of shock.
<i>Mixed venous oxygen saturation (SvO<sub>2</sub>)</i>	Less than 60%	Decreased SvO <sub>2</sub> indicates increased oxygen extraction at the tissue level, indicating decreased oxygen delivery.
<i>Lactate</i>	Greater than 2 mg/dL	Increased values indicate the presence of anaerobic metabolism.
<i>Hemoglobin</i>	Less than 11.7 g/dL	Decreased levels indicate blood loss and decreased oxygen-carrying capacity.
<i>Hematocrit</i>	Less than 38%	Decreased values indicate blood loss.
<i>Glucose</i>	Less than 70 mg/dL or greater than 105 mg/dL	In the absence of diabetes, increased values indicate the initiation of fight-or-flight compensatory mechanisms.
<i>Blood urea nitrogen</i>	Greater than 21 mg/dL	Increased values indicate renal hypoperfusion.
<i>Creatinine</i>	Greater than 1.2 mg/dL	Increased values indicate acute renal failure.
<i>Aspartate aminotransferase</i>	Greater than 20 units/L	Increased values indicate hepatic injury.
<i>Lactic dehydrogenase</i>	Greater than 102 units/L	Increased values indicate hepatic injury.

the reabsorption of sodium and water. The skin becomes pale, cool, and clammy. Pulses are weak, with sluggish capillary refill. Hyperventilation is present, producing a respiratory alkalosis. Decreased or hypoactive bowel sounds are present because of the shunting of blood to vital organs. Hyperglycemia is evident because of the initiation of the fight-or-flight response in the initial compensatory phase.

Later stages of shock produce more pronounced clinical manifestations, such as lethargy; hypotension; metabolic and respiratory acidoses; anuria; cold, cyanotic skin with weak or absent pulses; and dysrhythmias. Without effective intervention, the patient enters the refractory stage of shock. Coma, severe hypotension, ischemic and necrotic cold extremities, renal failure, and hepatic failure follow.

Hemodynamic parameters that present in hypovolemic shock are a decreased central venous pressure and decreased PA occlusive pressure, which reflect decreased volume. Decreased venous oxygenation saturation, SvO<sub>2</sub> or ScvO<sub>2</sub>, is present as a result of decreased cardiac output. An increased systemic vascular resistance reflects the initiation of compensatory mechanisms (see Table 14.3).

## Management

### Medical Management

Resuscitation priorities in hypovolemic shock include maximizing oxygenation, initiating fluid resuscitation, and identifying and treating the underlying cause. Maximizing oxygenation is essential in the treatment of the patient in shock. Assessing and stabilizing the patient's airway is the immediate first priority. High-flow oxygen via a 100% non-rebreather mask may be utilized if the patient is able to adequately maintain and protect his or her airway. Frequently spontaneous respiratory effort is inadequate requiring the need for intubation and positive-pressure mechanical ventilation. Positive-pressure mechanical ventilation should be used with caution because the associated increased intrathoracic pressures decrease cardiac output further, exacerbating poor DO<sub>2</sub> to the tissues.

Rapid fluid resuscitation is the mainstay of treatment for hypovolemic shock. The type of fluid used varies depending on the cause of hypovolemia. Nonhemorrhagic shock is typically treated with isotonic crystalloid fluids such as normal saline solution or lactated Ringer's solution. Fluid resuscitation strategies for trauma patients suffering large

volumes of blood loss call for a balanced response that includes the minimization of crystalloids, 1:1:1 blood product replacement ratios with packed red blood cells (PRBCs), fresh frozen plasma (FFP) and platelets, and permissive hypotension. Whatever the cause of hypovolemia, it is important to continue resuscitation until the oxygen debt accumulated has been repaid. This is indicated by clinical signs such as stabilization of blood pressure, strong peripheral pulses, warm extremities, adequate urine output, no signs of a decreased level of consciousness, and lowering of lactate and base deficit to within normal limits. The patient with prolonged or unresponsive hypovolemia may need monitoring with a central venous monitor to evaluate filling pressures and cardiac output.

See Evidence-Based Practice: Fluid Resuscitation for a discussion of fluid resuscitation strategies in hemorrhagic shock.

## Evidence-Based Practice

### Fluid Resuscitation

Previous fluid replacement strategies in severe trauma began with the rapid infusion of crystalloid solutions, but increased morbidity and mortality are well documented with the use of excessive crystalloids. Resuscitation with normal saline solution, although initially producing an increase in blood pressure, ultimately results in a shift of fluid from the intravascular space into the interstitial and intracellular spaces. The most notable complication of this is adult respiratory distress syndrome. Crystalloid infusion also worsens coagulopathy through dilution and alters pH, resulting in acidosis, and excessive infusion of cold solution contributes to hypothermia, all of which result in the trauma triad of death: acidosis, hypothermia, and coagulopathy.

Recent research suggests a balanced resuscitation strategy for severe hemorrhagic shock: minimization of crystalloids, 1:1:1 blood product ratios for infusions, and permissive hypotension. Based on the significant experiential evidence in the military population, an approach utilizing equal amounts of packed red blood cells with fresh frozen plasma and platelets along with limited resuscitation with crystalloids may have a positive impact on overall survival. Additionally, maintaining a mean arterial pressure (MAP) of 50 rather than 65 or greater results in less bleeding and reduces the risk of dislodging a clot that may have formed to stop bleeding.

Cantle, P. M., & Cotton, B. A. (2017). Balanced resuscitation in trauma management. *Surgical Clinics*, 97(5), 999–1014.

Identifying and controlling further loss of blood or fluid is an obvious priority in this patient. If bleeding or fluid loss is not immediately apparent, diagnostic studies may be necessary to determine the cause of shock. An ultrasound and a focused assessment with sonography for trauma (FAST) may be necessary to determine if blunt trauma has caused thoracic or abdominal bleeding. Although obvious deformity may be evident, radiographs or computed tomography (CT) scans may be necessary to determine the presence of long bone or pelvic fractures, which can cause sequestration of large amounts of blood. Definitive treatment may include surgery to locate and control the source of bleeding, stabilization of fractures, and medications to control vomiting and diarrhea.

### Nursing Management

#### Assessment and Analysis

The clinical manifestations of hypovolemic shock are related to the decrease in cardiac output and impaired blood flow to all vital organs. The manifestations vary depending on the stage of shock. Without adequate treatment, the results are hypotension; tachycardia with weak pulses; tachypnea; cold, cyanotic, and mottled skin; decreased or absent urine output; severely decreased level of consciousness; and severely decreased or absent bowel sounds. Continuing decompensation results in multiple organ system failures, as evidenced by increased renal studies such as blood urea nitrogen (BUN) and creatinine and increased liver function tests. The refractory stage is evidenced by coma, severe hypotension, bradycardia, and acute respiratory failure due to profound cellular hypoxia.

**Hemodynamic parameters** also vary according to the stage of shock. If a PA catheter is in place, decreased cardiac output will be noted beginning in the initial stage of shock. The compensatory stage is notable for an increase in systemic vascular resistance due to the sympathetic nervous system response. Central venous pressure and PAOP are decreased. Although initial compensation maintains a normal blood pressure, hypotension eventually results.

#### Nursing Diagnoses

- **Altered tissue perfusion** related to inadequate cardiac output
- **Inadequate oxygenation** related to poor gas exchange

#### Nursing Interventions

##### ■ Assessments

- **Neurological status**  
*A decreased level of consciousness occurs as a result of decreased cardiac output and carotid vasoconstriction that occurs as a result of hyperventilation and respiratory alkalosis.*
- **Vital signs**  
*Blood pressure may remain normal initially because of the stimulation of compensatory mechanisms. Tachycardia will be present as one of the compensatory mechanisms. Hypotension and bradycardia signal the end of effective compensation.*

- Hemodynamic readings  
*Decreased cardiac output occurs as a result of decreased filling pressures, as evidenced by decreased CVP and decreased PAOP. Increased systemic vascular resistance is evident as the sympathetic nervous system is stimulated, resulting in vasoconstriction to increase blood pressure and cardiac output.*
- Urine output  
*Decreased urine output occurs as a result of decreased cardiac output and stimulation of compensatory mechanisms that increase reabsorption of sodium and water.*
- Skin color and temperature  
*Cold and clammy skin may be a sign of decreasing peripheral perfusion and progressing shock.*

#### Laboratory Tests

- ABGs  
*Initial ABGs may reflect a respiratory alkalosis due to hyperventilation. Later stages of shock reveal a metabolic acidosis due to anaerobic metabolism.*
- Venous oxygen saturation; SvO<sub>2</sub>/ScvO<sub>2</sub>  
*Decreased oxygen saturation is an indicator of inadequate oxygen delivery.*
- Hemoglobin and hematocrit  
*Hemoglobin and hematocrit values may be decreased if the cause of hypovolemic shock is bleeding.*
- Metabolic profile  
*Renal failure and liver failure, as evidenced by increased BUN and creatinine levels and liver function test results, may become evident as a result of decreased organ perfusion.*
- Lactate/base deficit  
*Increased lactate level and negative base deficit are evidence of poor perfusion at the cellular level. Decreasing lactate level is an endpoint demonstrating adequate resuscitation.*

#### Actions

- Apply a 100% nonrebreather mask.  
*Maximizing oxygenation is the number one priority.*
- Anticipate and prepare for intubation.  
*Intubation and mechanical ventilation may be required to improve oxygenation.*
- Insert large-bore IV lines for fluid administration.  
*Large-bore IV lines facilitate the rapid infusion of fluid necessary to reverse hypovolemic shock.*
- Administer fluid replacement as prescribed:
  - Normal saline
  - Lactated Ringer's solution
  - Blood products*Fluid replacement is the foundation of treatment in hypovolemic shock.*

#### Teaching

- Instruct patient and family on the cause of hypovolemia.  
*Depending on the cause of hypovolemia, patient and family understanding may help prevent a repeat occurrence.*

- Allow family members visitation during hospital treatment; provide frequent updates on condition and treatment.  
*Family visitation and information can help to decrease a patient's and family's anxiety.*

#### Evaluating Care Outcomes

Rapid intervention with adequate oxygenation and fluid resuscitation may result in the restoration of hemodynamic stability. A well managed patient will be awake and alert with a stable blood pressure and have adequate urine output, warm extremities, strong peripheral pulses, and a normalizing lactate with the loss of fluid under control.

**Safety Alert** Permissive hypotension during resuscitation is a strategy that is recommended to reduce

postresuscitation mortality and morbidity. One study compared patients who were resuscitated to a mean arterial pressure of 50 mm Hg with patients resuscitated to a mean arterial pressure of 65 mm Hg. The results were positive. Patients in the group with low mean arterial pressure required less fluid and blood administration and had decreased coagulopathy after treatment. It is thought that an increase in blood pressure may dislodge a newly formed clot, thus increasing the possibility of bleeding. Lower mean arterial pressures may decrease this risk.

Meticulous care must be taken to monitor the patient's hemodynamic status, including CVP, PAOP, blood pressure, SvO<sub>2</sub>, and other endpoints of resuscitation, such as level of consciousness and urine output, to ensure the mean arterial pressure is adequate.

#### Connection Check 14.5

The nurse understands that which hemodynamic parameters are consistent with hypovolemic shock?

- Decreased cardiac output, decreased systemic vascular resistance, decreased CVP
- Decreased cardiac output, increased systemic vascular resistance, decreased CVP
- Decreased cardiac output, increased systemic vascular resistance, increased CVP
- Decreased cardiac output, decreased systemic vascular resistance, increased CVP

## CARDIOGENIC SHOCK

### Epidemiology

The prevalence of cardiogenic shock ranges from 5% to 10% in patients with AMI. The incidence is higher in men than in women because of the increased prevalence of

coronary artery disease in males. The incidence of cardiogenic shock following AMI is higher in women. Cardiogenic shock has a mortality rate of approximately 50%, but the rate is higher in patients older than 75 and lower in younger patients.

Risk factors for cardiogenic shock include any disorder that results in the acute deterioration of myocardial mechanical contraction. Most commonly, cardiogenic shock results when more than 40% of the myocardium is damaged because of AMI. Other risk factors include end-stage congestive heart failure, cardiomyopathy, hypertension, diabetes, multiple-vessel coronary artery disease, and acute vascular disease.

## Pathophysiology

*Cardiogenic shock* is defined as a state of hypoperfusion at the tissue level resulting from severe impairment of ventricular contraction in the presence of adequate vascular volume. As a result of damaged myocardium, there is a marked reduction in contractility, which reduces the **ejection fraction** (the percentage of blood ejected from the ventricle with each contraction) and **cardiac output**. The result is increased left and right ventricular filling pressures but decreased cardiac output. Venous oxygen saturation decreases with increased oxygen extraction at the tissue level because of low cardiac output. The ultimate result is univentricular or biventricular failure, profound hypotension, and pulmonary edema.

The decreased cardiac output leads to stimulation of compensatory mechanisms. In the case of cardiogenic shock, the sympathetic stimulation that increases HR and contractility also increases myocardial workload and myocardial oxygen demand, worsening the ischemia. Systemic vasoconstriction also increases the workload on an already-stressed heart by increasing afterload. Fluid retention induced by the renin-angiotensin-aldosterone system increases filling pressures, which ultimately contributes to the development of pulmonary edema and hypoxemia. The end result is a vicious cycle of increased cardiac workload and increased myocardial

oxygen demand combined with poor perfusion of myocardial tissue (Fig. 14.4). This worsens myocardial ischemia, which, if left untreated or unsuccessfully managed, ends in death.

## Clinical Manifestations

Patients in cardiogenic shock frequently present with clinical symptoms similar to those of AMI, such as chest pain, diaphoresis, nausea, and vomiting. The decreased cardiac output, hypotension, and resulting compensatory mechanisms cause a decreased level of consciousness; decreased urine output; poor pulses; pale, cool skin; and decreased bowel sounds. Shortness of breath, crackles on auscultation, and decreased saturation of arterial blood with oxygen ( $SpO_2$ ) are evident as a result of **pulmonary edema**. Decreased cardiac output greatly impairs tissue perfusion, leading to anaerobic metabolism that produces lactic acid, as evidenced by increased lactate levels. Arterial blood gases reveal a metabolic acidosis.

As shock progresses, clinical manifestations become more pronounced. Profound hypotension and bradycardia develop. Organ systems begin to fail. Laboratory analysis reveals increases in creatinine and liver enzymes, demonstrating renal and liver failure. Coma; cyanotic, mottled skin; absent bowel sounds; and anuria are present.

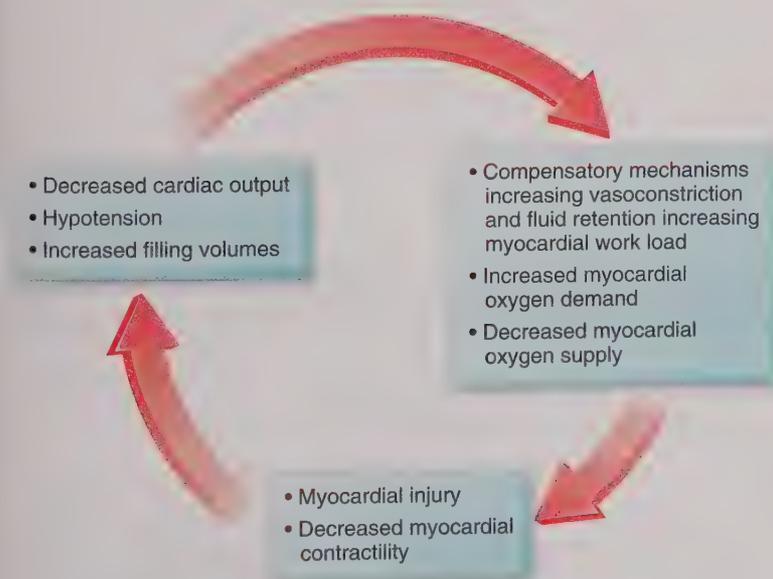

Hemodynamic parameters obtained through a PA catheter include increased CVP and PAOP. Systemic vascular resistance is high, and cardiac output is very low. Venous oxygen saturation is decreased.

## Management

### Medical Management

#### Laboratory and Diagnostic Tests

Laboratory and diagnostic tests related to cardiogenic shock include a 12-lead electrocardiogram (ECG), cardiac enzymes, and a chest radiograph. The initial diagnostic test

**FIGURE 14.4** Vicious cycle of cardiogenic shock.

should be the 12-lead ECG, conducted to rule out or rule in myocardial infarction as the cause of shock. Cardiac enzymes will also help confirm the presence or absence of AMI. The chest radiograph is obtained to rule out other causes of hypotension and shock, such as tension pneumothorax or cardiac tamponade. A chest radiograph will also confirm the presence of pulmonary edema.

### Treatment Priorities

Treatment priorities include stabilizing oxygenation and initiating drug therapy to increase blood pressure and cardiac output. Consideration of emergency revascularization, an attempt to restore blood flow through percutaneous coronary intervention, may be indicated. Intra-aortic balloon pump (IABP) therapy to increase myocardial oxygen supply and decrease myocardial oxygen demand may also be considered. If these treatments are not successful, a ventricular assist device (VAD) may be necessary.

### Stabilizing Oxygenation

Providing 100% oxygen through a nonrebreather mask is a minimal first step to stabilize oxygenation. Intubation and mechanical ventilation are frequently necessary to support ventilation and maximize oxygenation. This may help decrease myocardial workload, increase myocardial oxygen supply, and preserve myocardial tissue.

### Medications

Medications that support blood pressure through vasoconstriction (vasopressors), such as dopamine and norepinephrine, should be started to sustain blood pressure and help maintain adequate mean arterial pressure. Although there is no difference in mortality in most shock states with the use of dopamine or norepinephrine, there is some evidence that norepinephrine has a lower mortality rate in cardiogenic shock. Care should be taken when using vasopressors to increase blood pressure because they will also increase systemic vascular resistance, increasing myocardial workload. Inotropic support, medications such as dobutamine that increase myocardial contractility, should also be initiated to improve cardiac output. Nitroglycerin may be very carefully added in an attempt to decrease preload and afterload. It decreases preload through venous dilation and decreases afterload through arterial dilation. It will also decrease blood pressure, so it should be used with extreme caution. Nitroprusside may also be used with extreme caution to decrease afterload. Diuretics may also be used with caution in an attempt to decrease filling volumes. Morphine sulfate may also be administered. It is useful for several reasons. First, it helps relieve pain due to a myocardial infarction. Second, morphine is a vasodilator that decreases venous return and preload. Fentanyl may also be used for pain relief. See Table 14.5 for a list of medications commonly used in the

**Table 14.5 Medications Commonly Used to Treat Shock States**

Medication	Indication	Action
<b>Dobutamine</b>	Low cardiac output	Stimulates $\beta_1$ receptors; increases cardiac contractility and heart rate (HR)
<b>Dopamine</b>	Low cardiac output, hypotension, oliguria	Dose-dependent action: <ul style="list-style-type: none"> <li>● A dose of 1–3 mcg/kg/min stimulates dopaminergic receptors on arteries in the heart, kidneys, brain, and abdomen, resulting in vasodilation; this will produce an increase in urine output (benefit of this diuresis is unclear).</li> <li>● A dose of 3–10 mcg/kg/min stimulates <math>\beta_1</math>, increasing contractility and HR.</li> <li>● A dose greater than 10 mcg/kg/min stimulates <math>\beta_1</math>, resulting in vasoconstriction and increasing blood pressure.</li> </ul>
<b>Epinephrine</b>	Low cardiac output, hypotension	Dose-dependent action: <ul style="list-style-type: none"> <li>● Lower doses (0.01–0.05 mcg/kg/min) primarily stimulate <math>\beta_1</math>, increasing contractility and HR.</li> <li>● Higher doses stimulate <math>\alpha_1</math>, resulting in vasoconstriction and increasing blood pressure.</li> </ul>
<b>Norepinephrine</b>	Hypotension, low cardiac output	Primarily stimulation of $\alpha_1$ , resulting in vasoconstriction and increasing blood pressure; some stimulation of $\beta_1$ to increase contractility and HR
<b>Nitroglycerin</b>	Preload and/or afterload reduction	Vasodilation through direct smooth muscle relaxation; dose-dependent action: <ul style="list-style-type: none"> <li>● Lower doses (less than 40 mcg/min) produce venous dilation, decreasing preload.</li> <li>● Higher doses produce arterial dilation, decreasing afterload and blood pressure.</li> </ul>
<b>Nitroprusside</b>	Preload and/or afterload reduction	Arterial vasodilation through direct smooth muscle relaxation, decreasing afterload and blood pressure
<b>Phenylephrine</b>	Hypotension	Stimulates $\alpha_1$ , resulting in vasoconstriction and increasing blood pressure
<b>Vasopressin</b>	Hypotension	Arterial vasoconstriction through smooth muscle contraction, increasing blood pressure

treatment of shock and Table 14.6 for information about adrenergic receptors affected by vasopressors.

Because many classes of medications are used in the treatment of cardiogenic shock, an arterial line is essential for continuous monitoring of blood pressure. Although not clearly beneficial in other forms of shock, a PA line has been shown to be helpful in the complex management of a patient in cardiogenic shock. The evaluation of cardiac output, preload, afterload, systemic vascular resistance, and SvO<sub>2</sub> is essential in order to gauge the response to treatment.

### Emergency Revascularization

Early revascularization through percutaneous coronary intervention has been shown to increase short-term and long-term survival in most patients in cardiogenic shock. Percutaneous coronary intervention involves balloon angioplasty, or the insertion of a catheter through an artery up into the involved coronary artery and inflation of a balloon to break up the plaque causing the obstruction of flow. Typically, a stent is placed to maintain the patency of the vessel.

### Intra-Aortic Balloon Pump Therapy

Intra-aortic balloon pump therapy may be considered when drug therapy does not improve cardiac output. The primary goal of IABP therapy is to increase myocardial oxygen supply and decrease myocardial oxygen demand. The IABP catheter is inserted into the aorta, usually via the femoral artery. Upon placement, the tip of the catheter should lie just below the aortic arch, about 2 cm from the left subclavian artery. There is a balloon at the tip of the catheter. It is timed to inflate at the start of diastole and deflate just before systole. When the balloon inflates, blood is displaced toward the coronary arteries and also into the systemic circulation, improving coronary and systemic perfusion. Deflating the balloon decreases afterload, thus decreasing the workload of the left ventricle (Fig. 14.5).

### Ventricular Assist Device

A ventricular assist device (VAD) may be necessary if other treatments have not been successful. A VAD is a surgically inserted mechanical pump that assists the pumping of the left ventricle and decreases the workload of the heart. The pump works by displacing blood from the left ventricle into a receptor within the pump. The pump then works to eject blood into the aorta.

## Nursing Management

### Assessment and Analysis

The clinical manifestations of cardiogenic shock are related to a decrease in cardiac output and impaired tissue perfusion. They are similar to the presenting symptoms of AMI—chest pain, nausea, and diaphoresis—but also include hypotension, tachycardia, and tachypnea. Crackles on auscultation, shortness of breath (SOB), and decreased oxygenation may be present if the patient is in pulmonary edema. Systemically, the patient has a decreased level of consciousness and weak pulses with cold, cyanotic, and mottled skin. Urine output and bowel sounds are decreased or absent. Without successful intervention, profound hypotension, bradycardia, and hypoxia result.

### Nursing Diagnosis

- **Altered tissue perfusion** related to inadequate cardiac output

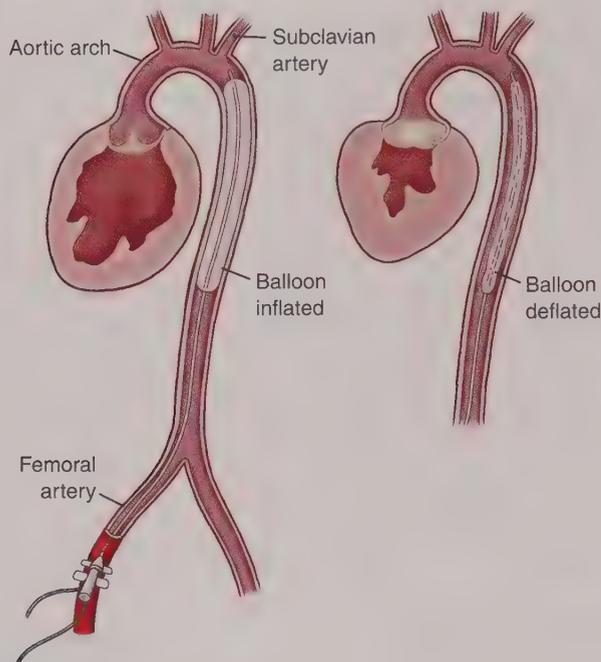

### Nursing Interventions

#### ■ Assessments

- Neurological status  
*Decreased level of consciousness occurs as a result of decreased cardiac output and carotid vasoconstriction that occurs as a result of hyperventilation and respiratory alkalosis.*
- Vital signs  
*Hypotension and tachycardia are present because of decreased cardiac output. Respiratory rate increases in an effort to increase tissue oxygenation and remove CO<sub>2</sub> to compensate for metabolic acidosis. Oxygenation may be decreased due to the presence of pulmonary edema*
- Hemodynamic parameters  
*Both right and left preloads are increased because of the impaired pumping ability of the heart, but cardiac output is low. As a result of compensation for low cardiac output, vasoconstriction occurs, increasing systemic vascular resistance.*
- Breath sounds  
*Crackles may be heard on auscultation due to the presence of pulmonary edema.*
- Urine output  
*Decreased urine output occurs as a result of decreased cardiac output and stimulation of compensatory mechanisms that increase reabsorption of sodium and water.*
- Skin color and temperature  
*Cold and clammy skin may be a sign of progressing shock.*

**Table 14.6 Adrenergic Receptors**

Adrenergic Receptor	Locations	Response When Stimulated
$\alpha_1$	Veins, arteries, arterioles	Vasoconstriction
$\alpha_2$	Gastrointestinal tract	Decreased tone, secretions, and motility
$\beta_1$	Heart	Increased cardiac contractility and HR
$\beta_2$	Coronary arteries, bronchial smooth muscle, skeletal muscle vessels	Dilation of the coronary arteries and skeletal muscle vessels, relaxation of bronchial smooth muscle

**FIGURE 14.5** Intra-aortic balloon pump (IABP).

### Laboratory Tests

- ABGs  
*Initial ABGs may reflect a respiratory alkalosis due to tachypnea. Later stages of shock reveal a metabolic acidosis due to anaerobic metabolism.*
- Venous oxygen saturation  
*Decreased SvO<sub>2</sub>/ScvO<sub>2</sub> is an indicator of inadequate DO<sub>2</sub>.*
- Metabolic profile  
*Renal failure and liver failure as evidenced by increased BUN and creatinine levels and liver function test results may become evident because of decreased organ perfusion.*
- Lactate/base deficit  
*Increased lactate level and negative base deficit are evidence of poor perfusion at the cellular level. Decreasing lactate levels are an endpoint demonstrating adequate resuscitation.*

### Actions

- Apply a 100% nonrebreather oxygen mask.  
*Maximizing oxygenation is essential.*
- Prepare for intubation and mechanical ventilation.  
*Intubation and mechanical ventilation are frequently necessary with patients in cardiogenic shock in an effort to decrease VO<sub>2</sub> and increase oxygen availability.*
- Administer medications as ordered:
  - Vasoactive medications such as norepinephrine or dopamine  
*Vasoactive medications produce vasoconstriction, increasing blood pressure.*
  - Inotropic medications such as dobutamine  
*Inotropic medications increase contractility and cardiac output.*
  - Diuretics  
*Diuretics may be very cautiously utilized to decrease vascular volume if filling pressures are extremely elevated.*

- Morphine sulfate

*Morphine will relieve pain, which can help to decrease myocardial VO<sub>2</sub>. It will also decrease venous return through vasodilation.*

- Administer fluids as prescribed.  
*Fluids may be utilized cautiously to increase cardiac output if filling pressures are low and there are no signs of pulmonary edema.*
- Restrict activity.  
*Restricting activity will decrease cardiac workload and VO<sub>2</sub>.*

### Teaching

- Instruct patient and family about the importance of rest periods.  
*Increased activity or stress levels cause increased myocardial VO<sub>2</sub> and can worsen the progression of shock.*
- Teach patient and family about the causes of cardiogenic shock and myocardial infarction.  
*Early recognition and treatment of myocardial infarction will help avoid a complication of cardiogenic shock.*

### Evaluating Care Outcomes

Rapid recognition of the presence of cardiogenic shock is essential in effective treatment. Swift intervention with inotropic and vasoactive support helps maintain adequate cardiac output and blood pressure to ensure sufficient oxygen supply to the tissues. Careful monitoring of clinical manifestations and hemodynamic status helps evaluate therapeutic interventions. Successful treatment is demonstrated by a satisfactory blood pressure level and cardiac output and adequate tissue perfusion. Cardiogenic shock is discussed in detail in Chapter 32.

### Connection Check 14.6

The nurse correlates which of the following hemodynamic parameters to the patient with cardiogenic shock?

- Decreased afterload
- Increased contractility
- Increased cardiac output
- Increased right atrial pressure

## OBSTRUCTIVE SHOCK

### Epidemiology

As with hypovolemic shock, incidence and prevalence data are typically unavailable because the data are reported for the causative mechanism rather than the resultant obstructive shock.

Risk factors for obstructive shock include extracardiac disorders that impair ventricular filling or emptying. Impaired emptying is also referred to as *increased right or left afterload*. An example of a disorder resulting in increased right afterload is acute pulmonary embolism (PE). Examples of disorders resulting in impaired filling include cardiac

tamponade and tension pneumothorax. These disorders are discussed in detail in Chapter 27.

## Pathophysiology

Obstructive shock is caused by a mechanical barrier to ventricular filling or ventricular emptying (increased afterload) causing decreased cardiac output. As in cardiogenic shock, symptoms are independent of fluid volume status. The mechanical obstruction to the pumping action of the heart results in decreased cardiac output and poor perfusion at the tissue level. The specific pathophysiology varies depending on the cause of shock. For instance, a PE, typically the result of the mobilization of clot material to the lungs from a deep vein thrombosis (DVT), may result in obstructive shock. This results in extreme increases in right heart afterload due to an obstruction of blood flow into the lungs because of a clot or embolus in the PA. Alveoli are ventilated but not perfused, producing an extreme ventilation-perfusion mismatch.

Obstructive shock caused by cardiac tamponade is the result of excessive pressure on the heart muscle that occurs as fluid fills the pericardial sac. This may be the result of trauma to the cardiac muscle that results in bleeding and blood in the pericardial sac or a large, uncontrolled pericardial effusion. As the fluid accumulates around the heart, less blood enters the ventricles with each successive diastole, impairing ventricular filling.

## Clinical Manifestations

As with other forms of shock, clinical manifestations are the result of decreased cardiac output and impaired peripheral perfusion: a decreased level of consciousness; decreased urine output; poor pulses; pale and cool skin; and decreased bowel sounds. Chest pain, nausea and vomiting, and shortness of breath are also common findings. Muffled heart sounds may be apparent with cardiac tamponade. Signs of right heart failure, such as jugular vein distention, may be noted with increased right heart afterload or impaired filling.

Hemodynamic parameters obtained through a PA catheter indicate variable CVP and PAOP depending on the problem, impaired filling or impaired emptying. Systemic vascular resistance is high, and cardiac output is very low. Venous oxygen saturation is decreased.

## Management

### Medical Management

As with other forms of shock, providing oxygen through a 100% nonrebreather mask is a minimal first step to stabilize oxygenation. Intubation and mechanical ventilation are frequently necessary to support ventilation and maximize oxygenation. Improving or enhancing oxygenation may help decrease myocardial workload, increase myocardial oxygen supply, and help preserve myocardial tissue. Vasoactive

medications may be utilized to help maintain blood pressure in the short term, but early definitive treatment of the cause of obstructive shock is necessary for survival.

If the cause of shock is impaired filling due to cardiac tamponade, the blood or fluid in the pericardial sac must be removed or drained as quickly as possible. This is a medical emergency. If the fluid is not promptly removed, death may ensue quickly. Removing the fluid or blood can be done through a procedure called pericardiocentesis. This procedure uses a large-bore needle inserted into the pericardial sac, guided by ultrasonography or echocardiography when possible, to remove the fluid. A pericardial window, a procedure to remove part of the pericardium to relieve pressure, may also be performed. After removal of the blood or fluid, it is essential to identify and treat the source of the problem. If the cause is left unknown and untreated, the cardiac tamponade may reoccur.

If the cause of shock is impaired ventricular emptying due to PE, the definitive treatment is to remove the clot through the use of thrombolytic therapy. Thrombolytics are medications capable of dissolving a clot. They are infused via a catheter directly into the clot. An alternative approach to minimize the dosage of thrombolytics is the combination of low-dose thrombolytics and targeted ultrasonic waves delivered through a catheter directly into the clot to aid in dissolution. If thrombolytics are contraindicated or unsuccessful, suction thrombectomy may be indicated. Suction thrombectomy is performed by inserting a catheter and guiding it toward the clot. The clot is essentially sucked through the catheter. Another option is a mechanical device at the tip of the catheter, such as a rotating head, that may be used to break up the clot. Infrequently, surgery (a pulmonary embolectomy) is required to remove the clot if other methods are unsuccessful. Depending on the cause of the PE, long-term anticoagulation therapy may be indicated to decrease the likelihood of a recurrent event.

## Nursing Management

### Assessment and Analysis

As in other forms of shock, the clinical manifestations of obstructive shock are related to a decrease in cardiac output and impaired tissue perfusion. Hypotension, tachycardia, and tachypnea are present. The patient has a decreased level of consciousness and weak pulses, with cold, cyanotic, and mottled skin. In addition, the patient may present with muffled heart sounds due to the presence of excessive fluid in the pericardial sac or signs of right heart failure due to elevated right heart afterload. As shock progresses, urine output and bowel sounds may become decreased or absent; typically, without definitive treatment of the cause, death occurs rapidly.

### Nursing Interventions

#### ■ Assessments

#### ● Neurological status

*Decreased level of consciousness occurs as a result of decreased cardiac output and carotid vasoconstriction that occurs as a result of hyperventilation and respiratory alkalosis.*

*Anxiety and restlessness may occur initially but will rapidly progress toward a further decreased level of consciousness without treatment.*

- Vital signs  
*Hypotension and tachycardia are present because of decreased cardiac output. Respiratory rate increases in an effort to increase tissue oxygenation and remove CO<sub>2</sub> to compensate for metabolic acidosis.*
- Hemodynamic parameters  
*Filling pressures are variable depending on the cause—elevated with impaired emptying; decreased with impaired filling. Both right and left afterloads may be increased as a result of mechanical resistance to ventricular emptying. Increased oxygen consumption is evidenced through a decreased venous oxygen saturation. Cardiac output is low.*
- Urine output  
*Decreased urine output occurs as a result of decreased cardiac output and stimulation of compensatory mechanisms that increase reabsorption of sodium and water.*
- Skin color and temperature  
*Cold and clammy skin is present as a result of poor peripheral perfusion.*

#### Laboratory Tests

- ABGs  
*Initial ABGs may reflect a respiratory alkalosis due to hyperventilation.*
- Venous oxygenation  
*Decreased SvO<sub>2</sub>/ScvO<sub>2</sub> is an indicator of inadequate oxygen delivery.*

#### Actions

- Apply a 100% nonrebreather oxygen mask.  
*Maximizing oxygenation is essential.*
- Prepare for intubation and mechanical ventilation.  
*Intubation and mechanical ventilation are frequently necessary with patients in obstructive shock in an effort to decrease VO<sub>2</sub> and increase oxygen availability.*
- Administer medications as ordered:
  - Vasoactive medications such as norepinephrine and dopamine  
*Vasoactive medications produce vasoconstriction, increasing blood pressure and allowing the patient to stabilize until definitive treatment is implemented.*
  - Anticoagulation via heparin administration if the cause of obstructive shock is PE  
*Anticoagulation is used to decrease the formation of new clots and prevent the existing clot from increasing in size while the body is naturally dissolving it.*
  - Thrombolytic therapy if the cause of obstructive shock is PE  
*Thrombolytics are given to dissolve the clot.*
- Prepare for definitive treatment of the cause, for example:
  - If cardiac tamponade:
    - Pericardiocentesis  
*Pericardiocentesis is a procedure to drain fluid or blood from the pericardial sac, relieving pressure and allowing the ventricles to fill normally.*

- Anticipate/prepare for emergency transport to the operating room for a pericardial window procedure  
*A pericardial window procedure will ease the pressure on the heart muscle, allowing the ventricles to fill.*
- If PE:
  - Suction thrombectomy  
*Suction thrombectomy is done to remove the obstruction to ventricular emptying.*

#### Teaching

- Teach the patient and family about the causes of PE: avoid prolonged periods of inactivity, walk every hour, and drink plenty of fluids.  
*Mobilization helps reduce the likelihood of PE formation by decreasing the formation of a DVT, typically the initial source of the PE. Dehydration may increase the tendency to clot.*
- Anticoagulation teaching:
  - Use electric razors, use soft toothbrushes, and avoid contact sports.  
*Avoid potential causes of bleeding.*
  - If on Coumadin:
    - Regular follow-up laboratory testing—international normalized ratio  
*Determine effective dosing of anticoagulants.*
    - Limit foods high in vitamin K, such as green leafy vegetables.  
*These foods interfere with the efficacy of anticoagulants.*

#### Evaluating Care Outcomes

Rapid recognition of the presence of obstructive shock is essential in effective treatment. Swift intervention with inotropic and vasoactive support helps maintain blood pressure, but definitive treatment of the cause is required to promote survival. Careful monitoring of clinical manifestations and hemodynamic status help evaluate therapeutic interventions. Successful treatment is demonstrated by satisfactory blood pressure and cardiac output and adequate tissue perfusion.

#### DISTRIBUTIVE SHOCK

Distributive shock is the result of disease states that cause poor vascular tone and vasodilation, resulting in increased vascular capacity and venous pooling. Even though blood volume is adequate, a state of relative hypovolemia exists because of decreased venous return to the right heart. Sepsis is the most common cause of widespread vasodilation and distributive shock. Anaphylaxis, another cause of distributive shock, is caused by the release of histamine, which results in vasodilation, decreased venous return, and hypotension. The least common form of distributive shock is neurogenic shock, which is due to a loss of vasomotor tone. There is a loss of stimulation from the sympathetic nervous system, resulting in the vessel walls relaxing and dilating. Venous return is decreased, and the patient is hypotensive, with a decreased cardiac output. Neurogenic shock can be caused by an injury to the brain, general or spinal anesthesia, or spinal cord injury.

Neurogenic shock (discussed in detail in Chapter 39) and anaphylaxis are discussed briefly here first. The major focus of this section is sepsis, which is discussed last.

## Neurogenic Shock

### Epidemiology and Pathophysiology

**Neurogenic shock** is caused by disruption of the sympathetic nervous system, typically as a result of spinal cord injury, regional spinal anesthesia, or an injury to the brain. The incidence of neurogenic shock is approximately 20% in patients with a cervical spinal cord injury. It is very uncommon in patients with lower spinal cord injuries. The sympathetic nervous system disruption causes several problems. First, vascular tone is significantly decreased, hampering vasoconstriction and leaving vessels relaxed and dilated. Vascular volume is increased in the peripheral vessels, but venous return to the right heart is decreased, resulting in decreased cardiac output. This is termed *relative hypovolemia*. This problem is made worse by the heart's inability to compensate through tachycardia. Also, unopposed parasympathetic activity may result in profound bradycardia. As with other types of shock, the decreased cardiac output of neurogenic shock causes systemic hypoperfusion, resulting in anaerobic metabolism and metabolic acidosis. These patients are especially susceptible to orthostatic hypotension.

### Clinical Manifestations

Clinical manifestations include warm, dry skin and a flushed appearance due to systemic vasodilation. Hemodynamic parameters include decreased cardiac output, decreased right and left filling volumes, and decreased systemic vascular resistance.

## Management

### Medical Management

#### Treatment Priorities

The treatment focus is on providing cardiovascular support while attempting to resolve the primary cause of shock. Cardiovascular support is done through cautious fluid resuscitation and the use of vasoactive IV medications such as dopamine, epinephrine, norepinephrine, or phenylephrine (see Tables 14.5 and 14.6). If necessary, bradycardia is treated with atropine. Repeated episodes of bradycardia may require transcutaneous or transvenous pacing. Ventilatory support through intubation and mechanical ventilation may be required.

### Nursing Management

#### Assessment and Analysis

The clinical manifestations of neurogenic shock are slightly different from the manifestations of other forms of shock. Similar to other forms of distributive shock, the patient has decreased cardiac output as a result of decreased vascular tone and reduced venous return; however, because of the disruption in the sympathetic nervous system, the patient may be bradycardic rather than tachycardic. The patient may appear pink and flushed as a result of vascular vasodilation.

### Nursing Diagnosis

- **Altered tissue perfusion** related to decreased cardiac output

### Nursing Interventions

#### ■ Assessments

- Vital signs  
*Hypotension may be present due to decreased venous return to the right heart secondary to systemic vasodilation. Bradycardia may be present because of the disruption of sympathetic nervous system activity.*
- Hemodynamic parameters  
*Cardiac output, CVP, and PAOP are low related to decreased venous return to the right heart secondary to systemic vasodilation. Systemic vascular resistance is low secondary to systemic vasodilation.*
- Respiratory rate and SpO<sub>2</sub>  
*Respiratory rate may be low because of the injury causing neurogenic shock, such as cervical spinal cord injury, which may depress the respiratory rate and thus decrease oxygenation.*

#### ■ Actions

- Administer IV fluid as ordered.  
*Cautious fluid resuscitation is provided to increase vascular volume to match the increase in the size of the vascular space due to the massive dilation.*
- Administer IV medications as ordered:
  - Vasoactive drips  
*Administration of vasoactive drips aids in increasing vasomotor tone and systemic vascular resistance.*
  - Atropine  
*Atropine is used for the treatment of bradycardia to block the action of the vagus nerve in the parasympathetic nervous system, increasing the HR.*
- Prepare for transcutaneous pacing or transvenous pacing.  
*Pacing may be necessary to treat recurrent episodes of bradycardia.*
- Raise the head of the patient's bed slowly.  
*Because of loss of systemic vasomotor tone, patients in neurogenic shock are particularly vulnerable to orthostatic hypotension.*
- Apply venous thromboembolism prophylaxis, such as sequential compression devices or medication such as heparin.  
*Patients in neurogenic shock are at high risk for venous thromboembolism, particularly in cases where the etiology of neurogenic shock is spinal cord injury.*

#### ■ Teaching

- If the cause of neurogenic shock is spinal cord injury, teaching related to the anticipated impact on the patient's immediate and future healthcare issues is vital. Psychosocial support from social workers, clergy, or a professional requested by the family is also essential in the care of the patient.  
*A spinal cord injury has profound long-term healthcare and life implications. An understanding of treatment and outcomes is essential to maximize recovery.*

### Connection Check 14.7

The nurse understands that which of the following are clinical manifestations of neurogenic shock? (Select all that apply.)

- A. Tachycardia
- B. Vasoconstriction
- C. Tachypnea
- D. Decreased CVP
- E. Bradycardia

#### Evaluating Care Outcomes

As with other forms of shock, prompt recognition and treatment of neurogenic shock are essential. Adding to the urgency is the patient's inability to compensate for the decreased cardiac output with tachycardia because of the disruption of the sympathetic nervous system. Pacing to maintain a normal HR may be required while the patient is treated and stabilized. A stabilized blood pressure, HR within normal limits, and adequate cardiac output are signs of a successful intervention.

### Anaphylactic Shock

#### Epidemiology and Pathophysiology

Anaphylaxis, or **anaphylactic shock**, is a severe and life-threatening systemic hypersensitivity reaction. It is caused by an allergic reaction leading to a release of histamine and resulting in widespread venous dilation, increased capillary permeability, and smooth muscle contraction. The incidence of anaphylactic shock has been approximated at 30 to 950 per 100,000 people per year. Common triggers include food, such as seafood, and medications, such as antibiotics.

Common characteristics consist of sudden onset and rapid progression of symptoms that include airway compromise and circulatory collapse. Airway compromise is caused by airway muscle contraction and throat and/or tongue swelling. Circulatory collapse is caused by widespread vasodilation and capillary leak, resulting in decreased venous return and decreased cardiac output.

#### Clinical Manifestations

Clinical manifestations of airway compromise include shortness of breath, tachypnea, wheezing, stridor, cyanosis, and confusion due to hypoxia. Untreated, this will lead to respiratory arrest. Clinical manifestations of circulatory problems are tachycardia; hypotension; cool, pale, clammy skin; weak pulses; and edema. As in neurogenic shock, these patients are particularly vulnerable to orthostatic hypotension.

Also common are sudden onset and rapid progression of skin or mucosal changes. These changes include flushing, urticaria (an itchy, red, raised rash; Fig. 14.6), and angioedema, which is similar to the swelling of urticaria, only deeper. It is edema of the subcutaneous or submucosal

FIGURE 14.6 Urticaria.

tissues, usually occurring around the eyes and mouth. Hemodynamic changes include hypotension, tachycardia, decreased cardiac output, decreased filling pressures, and decreased systemic vascular resistance.

#### Management

##### Medical Management

##### Treatment Priorities

Treatment priorities include immediately removing the trigger if possible. If the trigger is the administration of antibiotics or blood, the infusion should be stopped immediately. If the trigger is a bee sting, the stinger should be removed. Sometimes the trigger is unknown or has been ingested, so removal is not possible. Maneuvers to induce vomiting are not recommended. Definitive treatment should not be delayed because cardiac arrest and death can ensue within minutes if treatment is delayed.

Treatment with intramuscular (IM) epinephrine is the immediate first treatment priority. Intramuscular is the preferred route of administration because it provides a consistent, rapid rise in therapeutic concentration and lowers the risk of cardiovascular complications that can be seen with IV administration. This dosing can be repeated two or three times. Most patients will respond, but if not, IV epinephrine may be administered. Epinephrine promotes bronchodilation, relieving respiratory distress, and vasoconstriction to aid in restoring blood pressure. Intravenous vasopressin has been found to be an effective alternative in refractory anaphylactic shock (see Table 14.5). The second priority is assessing the airway, maximizing oxygenation through the initiation of oxygen via a 100% nonrebreather, and preparing for intubation if the airway is compromised. Circulatory support via administration of IV fluid is essential. Other medications utilized to treat anaphylaxis include antihistamines, corticosteroids, and inhaled bronchodilators.

## Nursing Management

### Assessment and Analysis

Anaphylactic shock is characterized by a sudden and severe hypersensitivity reaction causing a release of histamine that results in smooth muscle contraction, widespread vasodilation, increased capillary permeability, and decreased venous return. This results in respiratory distress, circulatory collapse, and skin reactions. Airway compromise is manifested by wheezing, stridor, and shortness of breath. Skin reactions include itching, a raised red rash, and severe swelling, specifically around the eyes. Hemodynamically, the patient is hypotensive and tachycardic, with decreased filling pressures and decreased cardiac output.

### Nursing Diagnoses

- **Impaired gas exchange** related to airway compromise
- **Impaired tissue perfusion** related to decreased cardiac output

### Nursing Interventions

#### ■ Assessments

- Vital signs/hemodynamic parameters  
*Hypotension and decreased filling pressures are present because of widespread vasodilation, resulting in decreased venous return and cardiac output. Tachycardia results as a compensatory mechanism. Systemic vascular resistance remains low because of the vasodilation.*
- Respiratory  
*Shortness of breath, wheezing, and decreased oxygenation may be present because of airway smooth muscle contraction and edema of the throat and/or tongue.*
- Skin/peripheral perfusion  
*Urticaria and angioedema are indicators of an allergic reaction. Pale, cool, clammy skin is an indicator of poor peripheral perfusion related to decreased cardiac output.*

#### ■ Actions

- Remove trigger immediately.  
*If possible, remove the trigger. If not possible, do not delay definitive treatment; the hallmark of anaphylaxis is sudden onset and rapid progression of symptoms.*
- Administer IM epinephrine as ordered.  
*Epinephrine promotes bronchodilation and vasoconstriction, helping to relieve respiratory distress and restore or maintain blood pressure.*
- Apply oxygen via a 100% nonrebreather mask or prepare for intubation.  
*Maximizing oxygenation is important in maintaining adequate delivery of oxygen to the tissues.*
- Insert an IV line and administer IV fluid as ordered.  
*Fluid shifts may occur with the increased vascular permeability. Infusion of IV fluids helps to increase and maintain vascular volume.*
- Administer adjunctive medications as ordered:
  - Antihistamines  
*Antihistamines may help counter histamine-mediated vasodilation and bronchoconstriction.*

- Corticosteroids  
*The anti-inflammatory action of steroids may help shorten the anaphylactic reaction.*
- Inhaled bronchodilators  
*Bronchodilators help relieve bronchoconstriction, relieving respiratory distress.*

#### ■ Teaching

- Teaching related to the cause of anaphylaxis  
*Understanding the cause of the anaphylactic response is essential in avoiding a repeat occurrence.*
- Administration of epinephrine via an EpiPen  
*Typically, allergic reactions occur in the home or away from the hospital. Patients or family members must know how to use the EpiPen as a first-line treatment in an allergic reaction to avoid anaphylactic shock if possible.*

#### Evaluating Care Outcomes

As with other forms of shock, prompt recognition and treatment of anaphylactic shock are essential. Without a rapid response, airway compromise and circulatory collapse can quickly lead to death. Successful treatment is demonstrated by stable hemodynamics; the resolution of airway compromise, as evidenced by a resolution of wheezing and shortness of breath; and the resolution of skin reactions, itching, and swelling.

## CASE STUDY: EPISODE 2

Mike's condition deteriorates. He is admitted to the emergency department with a complaint of shortness of breath. His chest radiograph reveals pneumonia. Initially, he was alert and oriented, but he has since become confused and lethargic. He is admitted to the intensive care unit. Upon admission, his blood pressure is noted to be 80/50 mm Hg, with an HR of 130 bpm. His blood glucose level is 220 mg/dL. He is flushed, with bounding pulses and a temperature of 102.6°F (39.2°C).

Oxygen is maintained via a 100% nonrebreather mask. His SpO<sub>2</sub> is borderline at 90%. The staff anticipates intubation. Two liters of normal saline is given wide open. A Foley catheter is inserted to closely monitor urine output, and IV antibiotics are continued...

## Sepsis/Septic Shock

### Epidemiology

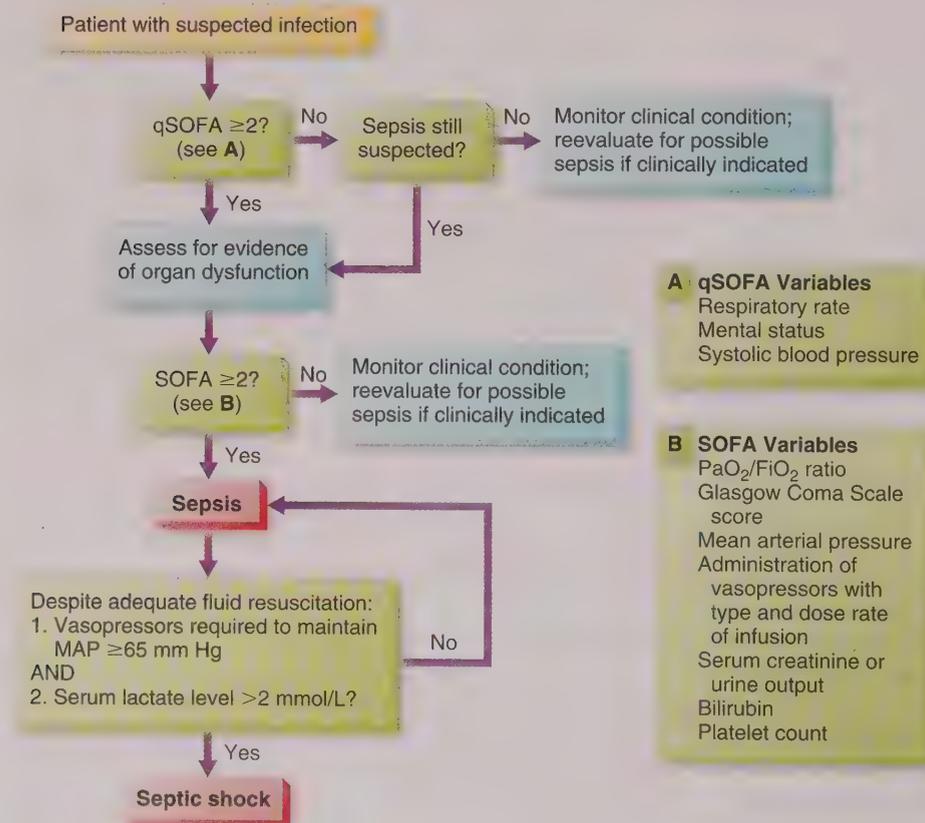

Accurately determining the incidence of sepsis is variable depending on sources and methods, but one international retrospective study indicated an incidence of 437 per 100,000 person-years between 1995 and 2015. Infection with gram-positive organisms is more commonly associated with the progression of sepsis, but infection with gram-negative

organisms is still substantial. Fungal infections are increasing but are still fewer than bacterial infections. Mortality statistics vary also and range from 10% to 52% depending on disease severity, with older intensive care patients reporting the highest mortality. Most sources report that the incidence of sepsis is increasing. This may be attributed to innovations and changes in healthcare and our aging population. The use of invasive procedures and monitoring devices is much more common. This increases the patient's risk of infection. The use of chemotherapy and immunosuppressive medications is increasing, making patients more vulnerable to infection. A huge factor is the increase in antimicrobial resistance to antibiotics. Although the incidence is increasing, mortality is decreasing, which is thought to be due to increased sophistication in treatment.

There are ongoing efforts to more accurately define sepsis and septic shock. The Third International Consensus Definitions for Sepsis and Septic Shock (Sepsis 3) define **sepsis** as a life-threatening organ dysfunction caused by a deregulated host response to infection. **Septic shock** occurs when circulatory and metabolic abnormalities are profound, greatly increasing mortality. In the worst case, further complications such as **disseminated intravascular coagulopathy (DIC)**, a hematological disorder associated with enhanced coagulation, and secondary **multiple organ dysfunction syndrome (MODS)** may result. Figure 14.7 illustrates the defining characteristics and assessment criteria for sepsis.

**Pathophysiology**

The invasion of a pathogen initiates a series of complex responses by the host's immune system. The initial, immediate response is the activation of the innate immune response. This response is nonspecific to any antigen. It involves the mobilization of macrophages and neutrophils to the area; the activation of pro-inflammatory cytokines or signaling molecules; the activation of complement proteins, proteins that immobilize and break down pathogens; and the activation of the coagulation system. Activated coagulation produces a fibrin mesh to help localize the invading organism and activates bradykinin, which dilates vessels and increases capillary permeability. Local blood vessels dilate, increasing circulation to the involved area, which allows an influx of immune cells, causing local redness, warmth, and edema. This is done in an effort to kill the invading organism and keep the response localized. Sepsis occurs when the inflammatory response is no longer localized. The response becomes amplified and uncontrolled. The normal deactivation process, which decreases the production of pro-inflammatory cytokines and produces anti-inflammatory cytokines, is impaired. The excessive release of proinflammatory cytokines results in damage to the endothelial cells lining the blood vessels, producing vasodilation, decreased vasomotor tone, and increased capillary permeability. Ultimately, sepsis and septic shock result when proinflammatory cytokines overpower anti-inflammatory cytokines, resulting in overwhelming and excessive systemic inflammation, massive peripheral vasodilation, and increased

**FIGURE 14.7** Algorithm to guide the identification of sepsis and septic shock.

capillary permeability. Other forces that contribute to widespread inflammation are substances produced by the invading organisms. Endotoxins released by gram-negative bacteria and exotoxins produced by gram-positive bacteria add to the pro-inflammatory effect.

A part of the excessive inflammation is activated and enhanced coagulation, resulting in widespread fibrin deposition and excessive clotting throughout the vascular system. It also results in decreased fibrinolysis (breakdown of clots). This occurs due to the decreased levels of activated protein C and antithrombin III seen in septic patients. The primary role of protein C is to modulate the production of thrombin and promote fibrinolysis. Antithrombin III deactivates thrombin. The role of thrombin in the coagulation cascade is to modulate the conversion of fibrinogen to fibrin clots. Decreased levels of both protein C and antithrombin III lead to enhanced formation of thrombin, resulting in clot formation and impaired fibrinolysis, which ultimately results in impaired blood flow due to microvascular clots and organ dysfunction.

### Clinical Manifestations

The clinical manifestations of septic shock reflect the poor vascular tone and vasodilation that result in increased vascular capacity and blood pooling in the venous system. There is adequate blood volume, but a state of relative hypovolemia exists because of decreased venous return to the right heart. Septic shock is typically divided into early and late stages. Early stages of septic shock, sometimes termed *hyperdynamic* or *warm* sepsis, reflect the initial inflammatory response. The patient is tachycardic, with bounding pulses and warm, flushed skin, and is febrile. Blood pressure may be normal as a result of initial compensatory responses. Initial signs of decreased organ perfusion may be present, such as confusion and decreased urine output. Hemodynamic parameters indicate increased cardiac output that occurs as long as there is adequate fluid resuscitation. Filling pressures, CVP and PAOP, remain low. Systemic vascular resistance is low because of profound systemic vasodilation. Venous oxygen levels are temporarily increased due to the increase in cardiac output.

Late stages of septic shock, also referred to as *hypodynamic* or *cold* shock, are characterized by cool, pale skin; weak and thready pulses; and hypothermia. Tachycardia persists, but blood pressure remains low. Further signs of end-organ hypoperfusion, such as lethargy or coma and anuria, may be present. Hemodynamic parameters indicate decreased cardiac output with variable filling pressures depending on fluid resuscitation. Systemic vascular resistance may remain low but may increase as vasoconstriction occurs with compensation and drug therapy. Venous oxygen levels decrease, reflecting overall inadequate  $DO_2$  to the tissues. Ultimately, venous oxygen levels may increase because of the maldistribution of blood flow in the microcirculation, resulting in decreased oxygen extraction at the tissue level.

See Table 14.3 for a comparison of hemodynamic parameters in different types of shock and in early and late sepsis.

## Management

### Diagnosis

Identification of infection is done through the evaluation of general non-specific indicators of infection such as fever, increased white blood cell count, changes in blood pressure, respiratory rate, and heart rate. There may also be signs of specific infections such as lung consolidation, frequent or painful urination, or peritonitis. Laboratory testing includes complete blood cell counts, metabolic profiles, urine testing, and cultures. Imaging procedures such as general radiographs, CT scans, or magnetic resonance images help identify and locate areas of abnormalities.

Assessment of the presence of sepsis is guided by the use of the Sequential Organ Failure Assessment (SOFA), with a higher score associated with higher mortality. Patient evaluation begins with a quick SOFA (qSOFA), which evaluates for an increased respiratory rate, decreased BP, and altered mentation. If indicated, evaluation continues with the SOFA. The SOFA rates patient deterioration through decreasing  $PaO_2/FiO_2$  ratios, hypotension with or without vasopressor support, increased coagulopathies, decreased liver and renal function, and a decline in neurological status.

### Medical Management

The European Society of Intensive Care Medicine, the Society of Critical Care Medicine, and the International Sepsis Forum initiated the Surviving Sepsis campaign in 2004. The goal of the campaign was to standardize care and reduce the high mortality associated with sepsis through the use of evidence-based practice. The guidelines were updated in 2018.

First-line therapy is prevention—hand washing, meticulous aseptic technique for invasive procedures, and elimination of invasive therapies when possible. Aggressive mouth care, including brushing the teeth with chlorhexidine products, in ventilated patients may help prevent ventilator-associated pneumonia.

### Bundle of Care

#### Hour 1

The Surviving Sepsis campaign developed a bundle of care to help standardize the very complex treatment needed by patients in severe sepsis. They may vary hospital by hospital, but the basic elements should be adhered to in order to optimize treatment. The bundle includes activities that need to be completed within 1 hour after identifying sepsis. This recommendation is made with the understanding that treatment may not be completed in 1 hour, however, it clearly identifies that treatment should begin immediately (Table 14.7). The Surviving Sepsis Web site (<http://www.survivingsepsis.org>) is routinely updated and is an excellent source of information regarding treatment options.

#### Blood Work

Obtaining a serum lactate and two sets of blood cultures should be done immediately. Other recommended laboratory work includes: a complete blood count with differential,

**Table 14.7 Surviving Sepsis Campaign Bundle of Care**

Time Frame	Actions
<b>Within 1 hour</b>	<ul style="list-style-type: none"> <li>● Measure lactate levels. Reassess if initial lactate is <math>&gt;2</math> mmol/L.</li> <li>● Obtain blood cultures (prior to administering antibiotics).</li> <li>● Administer broad-spectrum antibiotic.</li> <li>● Administer 30 mL/kg of crystalloid if patient hypotensive or lactate level at least 4 mg/dL.</li> <li>● Administer vasopressors if blood pressure is unresponsive during or after fluid resuscitation; maintain mean arterial pressure (MAP) at 65 mm Hg or above.</li> </ul>

Adapted from Society of Critical Care Medicine. (n.d.). *Surviving Sepsis campaign*. Retrieved from <http://www.survivingsepsis.org>

coagulation studies, chemistries, liver function tests, and arterial blood gasses, as well as the culturing of any other potential sources of infection.

### Antibiotics

Evidence suggests that prompt identification and treatment of the offending microorganism with antibiotics can decrease mortality in sepsis. It is recommended that antibiotics be administered within 1 hour of arrival at the hospital. Cultures should be done before antibiotics are administered to ensure appropriate antibiotic coverage.

### Fluid Resuscitation

Fluid resuscitation is essential to restore hemodynamic stability, maximize  $DO_2$ , and begin repaying oxygen debt. A crystalloid solution such as normal saline or lactated Ringer's is commonly used to improve and maintain filling pressures. Evidence suggests that aggressive resuscitation in early sepsis has been shown to decrease mortality. Fluid resuscitation should be tapered as the patient demonstrates improvement. If fluid resuscitation is not successful at restoring blood pressure during or after administration, initiation of vasopressors to maintain a mean arterial pressure greater than 65 mm Hg may become necessary (see Table 14.5). The Surviving Sepsis campaign suggests the use of norepinephrine as the first-line vasopressor.

### Corticosteroid Therapy

Adrenal insufficiency is sometimes a feature of sepsis, but the use of steroids in treatment is not routinely recommended. Studies have been inconclusive as to the benefits of low-dose steroids in septic shock. They have not been shown to decrease mortality in sepsis. The Surviving Sepsis guidelines recommend low-dose steroids only if the patient has not been responsive to fluid and vasopressor therapy.

### Ongoing Monitoring

Frequent assessment of vital signs, peripheral perfusion, mental status, cultures, and laboratory analyses, including white blood cell count and differential and lactate, are essential. Hemodynamic parameters such as CVP or PAOP and  $SvO_2$  or  $ScvO_2$  help monitor responsiveness to therapy, but the use of a PA catheter, and thus PAOP and  $SvO_2$ , is

not recommended because the PA catheter has not been shown to have an improved impact on outcomes. Instead, monitoring of responsiveness to therapy can be done through evaluation of CVP and  $ScvO_2$  in combination with dynamic measures such as monitoring cardiac output through echocardiology after a passive leg raise (PLR) maneuver. An increase in cardiac output demonstrates a good response to fluid resuscitation.

## Connection Check 14.8

An older adult patient was admitted to the hospital 1 hour ago with a urinary tract infection, fever, tachycardia, hypotension, and confusion. The nurse anticipates which of the following interventions?

- Assess fluid status; insert arterial line; insert central venous line.
- Initiate a vasoactive drip; obtain lactate level and blood cultures.
- Obtain blood and urine culture; initiate broad-spectrum antibiotics; fluid resuscitation.
- Assess fluid status; obtain lactate level; insert central venous catheter.

### Complications

#### Disseminated Intravascular Coagulopathy

Disseminated intravascular coagulopathy (DIC) is a hematological disorder most commonly caused by sepsis. It occurs because of enhanced coagulation that results from the release of procoagulant factors as part of the inflammatory response associated with sepsis. Disseminated intravascular coagulopathy is typically described in two phases: a clotting, or thrombotic, phase and a bleeding phase, but in some cases they may occur simultaneously. The initial thrombotic stage may last hours or several days. Once initiated, large amounts of thrombin are produced in response to decreased levels of protein C and antithrombin III, resulting in the excessive production

of fibrin clots and consumption of clotting factors. As a result of the excessive coagulation, clots lodge in the microvasculature, causing ischemia and necrosis (Fig. 14.8). Patients present with cyanosis and ischemia in the fingers and toes and the tip of the nose. Organ ischemia may also be present. Patients are at risk for thrombophlebitis, PE, and stroke.

The second stage starts with the initiation of fibrinolysis. Although impaired in sepsis, the process of fibrinolysis occurs in an attempt to break down and remove the clots. The breakdown of the clot results in increased circulating fibrin degradation products, which are powerful anticoagulants. They impair the activity of thrombin, resulting in a decreased ability to form a fibrin clot. The combination of lack of available clotting factors and the anticoagulant properties of the fibrin degradation products results in excessive bleeding due to the inability to form clots. Diagnosis is based on the clinical picture in combination with laboratory results: decreased levels of fibrinogen, increased fibrin degradation products, increased D-dimer levels (an indicator of clot breakdown), decreased platelets, prolonged prothrombin and activated partial thromboplastin times, and decreased antithrombin III levels.

Management of DIC involves the vigorous treatment of the underlying disorder as well as treating other disorders caused by the excessive clotting and bleeding, such as hypotension, hypoxemia and respiratory distress, and the metabolic acidosis associated with poor tissue perfusion. Additional supportive treatment consists of volume replacement with crystalloids such as normal saline, blood replacement, and replacement of clotting factors with fresh frozen plasma and platelets. Identifying and correcting the cause are essential. The use of anticoagulation is not routinely recommended.

### Multiple Organ Dysfunction Syndrome

Multiple organ dysfunction syndrome (MODS) is another complication that occurs as a result of the excessive inflammation associated with severe injury or sepsis. The cause of MODS is multifaceted. Several factors lead to

**FIGURE 14.8** Disseminated intravascular coagulopathy.

decreased  $DO_2$  to the organ systems, causing impaired tissue perfusion:

- Evidence suggests that apoptosis, or programmed cell death that occurs in all cells, is accelerated in sepsis.
- Widespread damage to the vascular endothelium, which occurs as a result of inflammation and causes the increased capillary permeability and vasodilation of sepsis, continues as a result of the excessive production of inflammatory mediators.
- The microvascular dysfunction that causes maldistribution of blood flow in the capillary beds continues, resulting in uneven flow to different organ systems.
- Enhanced coagulation leads to clots in the microcirculation, mechanically obstructing flow.

Additional factors include the following:

- The accelerated production of glucose as initial compensation eventually becomes harmful. This hypermetabolism causes increased cellular oxygen demand.
- The direct toxicity of mitochondrial cells that occurs with excessive inflammation affects the ability to use oxygen even when present.

Eventually, poor  $DO_2$  coupled with increased oxygen demand and poor oxygen utilization results in profoundly impaired cellular functioning, metabolic acidosis, and organ failure.

The initial organ system to become symptomatic is typically the lungs, with the development of acute respiratory distress syndrome (ARDS). Sequential failure frequently includes the renal system, the hepatic system, and then the GI system. The mortality rate for ARDS averages 40%. Mortality increases as organ systems fail. Three or more systems are associated with an 80% to 90% mortality rate. There can be a 100% mortality rate if the cardiovascular and neurological systems are involved.

The focus of medical management of MODS is supportive in the form of controlling infection, maximizing oxygenation, and restoring and maintaining intravascular volume. Antibiotics are given as appropriate. Fluid is administered to maintain intravascular volume. Blood products are administered as necessary to maintain adequate hemoglobin levels. Mechanical ventilation is usually necessary to protect the airway and support oxygenation.

### Connection Check 14.9

The nurse understands that which of the following indicates the initial phase of DIC?

- Bleeding from all puncture sites
- Cold, mottled extremities
- Increased antithrombin III levels
- Increased fibrin degradation products

## Nursing Management

### Assessment and Analysis

Unlike other forms of shock, the early clinical manifestations of septic shock are related to the initial increase in cardiac output that occurs due to the tachycardia and decreased SVR associated with sepsis. The patient presents as warm and flushed, with bounding pulses. Later manifestations reflect the prolonged poor tissue perfusion. Hypotension, tachycardia, and hyperventilation are present. Systemically, the patient has a decreased level of consciousness and weak pulses, with cold, cyanotic, and mottled skin. Urine output and bowel sounds are decreased or absent. Without successful intervention, the clinical manifestations of enhanced coagulation, such as necrotic tissue in the extremities, begin to appear. In later stages, excessive bleeding from any puncture wounds, IV sites, or wounds begins.

### Nursing Diagnosis

- **Altered tissue perfusion** related to inadequate cardiac output

### Nursing Interventions

#### ■ Assessments

- **Neurological status**  
*Decreased level of consciousness occurs as a result of decreased cardiac output and hyperventilation causing a decrease in cerebral blood flow.*
- **Vital signs**  
*Hypotension is present because of vasodilation, producing relative hypovolemia and decreased venous return. Tachycardia will be present as one of the compensatory mechanisms. Initially, the patient will be febrile as an adaptive response. In later stages, the patient will be hypothermic, potentially signaling the body's inability to continue the adaptive response.*
- **Hemodynamic readings**  
*Initially, cardiac output is increased; however, as sepsis progresses, cardiac output decreases as a result of continued decreases in filling pressures, such as CVP and pulmonary artery occlusion pressures. Initially, systemic vascular resistance is decreased as a result of widespread vasodilation. Later, it may increase due to compensation and vasopressor therapy.*
- **Urine output**  
*Decreased urine output occurs as a result of decreased cardiac output and the initiation of compensatory mechanisms.*
- **Skin color and temperature**  
*Initially, the patient's skin is flushed and warm because of increased cardiac output. Later, the skin becomes cold and clammy, signaling the progression of shock. Tissue necrosis in the extremities may indicate the enhanced coagulation of DIC.*
- **Bleeding**  
*Excessive bleeding from wounds and puncture sites may be present because of consumption of clotting factors in DIC.*

#### Laboratory Tests

- **ABGs**  
*Initial ABGs may reflect a respiratory alkalosis due to hyperventilation. Hypercapnia and hypoxia are present as*

*respiratory failure worsens. Later stages of shock reveal a metabolic acidosis due to anaerobic metabolism.*

- **Venous oxygen saturation**  
*Decreased SvO<sub>2</sub> and ScvO<sub>2</sub> are typically indicators of inadequate oxygen delivery. In later sepsis, values may be elevated because of maldistribution of blood flow and are not indicative of recovery.*
- **Metabolic profile**  
*Renal failure and liver failure, as evidenced by increased BUN and creatinine levels and liver function test results, may become evident as a result of decreased organ perfusion.*
- **Lactate/base deficit**  
*Increased lactate level and negative base deficit are evidence of poor perfusion at the cellular level. Normalizing levels are an endpoint demonstrating adequate resuscitation. Sustained abnormal levels are indicators of increased risk of mortality.*
- **Clotting studies**  
*Decreased levels of fibrinogen, increased fibrin degradation products, increased D-dimer levels (an indicator of clot breakdown), decreased platelets, prolonged prothrombin and activated partial thromboplastin times, and decreased antithrombin III levels indicate the progression to DIC.*

#### ■ Actions

- **Meticulous hand washing and aseptic technique with all procedures**  
*Hand washing and aseptic techniques are basic interventions to help prevent and control infection.*
- **Administer oxygen as ordered.**  
*Maximizing oxygenation is essential.*
- **Anticipate and prepare for intubation.**  
*Intubation and mechanical ventilation may be required to improve oxygenation or if respiratory failure ensues.*
- **Obtain lactate level.**  
*Lactate levels are an indicator of adequacy of perfusion; increased levels signal the presence of anaerobic metabolism.*
- **Obtain two blood cultures from two different sites, obtain urine, sputum, and wound cultures.**  
*Cultures are obtained to identify the offending organism.*
- **Administer antibiotics as ordered after cultures are obtained.**  
*Antibiotics are the first-line treatment in an attempt to control the infection.*
- **Administer fluid replacement as ordered.**  
*Aggressive fluid replacement is the initial treatment to restore filling volumes and blood pressure in septic shock.*
- **Administer vasoactive drips such as norepinephrine as ordered.**  
*Vasoactive drips may be necessary to restore vascular tone if fluid replacement therapy is not effective at increasing blood pressure and cardiac output.*
- **Provide mouth care every 4 hours and when needed.**  
*Oral care is effective at reducing the occurrence of ventilator-associated pneumonia.*
- **Supportive care: nutrition, turning, DVT prophylaxis, range of motion exercises, mobilize as tolerated.**  
*These actions provide a supportive healing environment while active treatment of the underlying problem is provided.*

### Teaching

- Instruct the patient and family on the cause of sepsis and the importance of meticulous hand washing.  
*Patient and family understanding of factors important in preventing, minimizing, and controlling infection are essential in the treatment.*
- Allow family member visitation during hospital treatment.  
*Family visitation can help decrease a patient's and family's anxiety.*

### Evaluating Care Outcomes

Rapid recognition of the presence of sepsis is essential in preventing progression along the continuum. Swift intervention with antibiotics and fluids is essential in maintaining cardiac output. Vasoactive support may be necessary if fluid replacement is not effective at maintaining blood pressure. Hemodynamic monitoring and frequent laboratory assessments are necessary to monitor the effectiveness of treatment. Supportive care, such as mouth care, frequent turning, nutrition, and DVT prophylaxis, is essential to prevent complications. Timely, aggressive medical care combined with meticulous monitoring and supportive care help ensure recovery. Successful treatment is demonstrated by a satisfactory blood pressure level and cardiac output and adequate tissue perfusion.

## Making Connections

### CASE STUDY: WRAP-UP

Mike's condition worsens. After admission to the intensive care unit and administration of several liters of normal saline, his blood pressure continues to deteriorate. He becomes increasingly lethargic and tachypneic, with a respiratory alkalosis. His urine output is noted to be decreasing, and laboratory values indicate the beginning of acute renal failure.

His deteriorating respiratory rate status requires intubation and mechanical ventilation. A central line is inserted to monitor CVP and ScvO<sub>2</sub>. Aggressive fluid replacement is continued, and norepinephrine is started at 1.0 mcg/kg per minute. Antibiotics are continued.

After several days of frequent monitoring and meticulous care involving fluids and antibiotics, Mike begins to improve. His CVP normalizes, and his blood pressure finally begins to stabilize. The norepinephrine is decreased and then discontinued. His ScvO<sub>2</sub> returns to normal. After several days, Mike's respiratory status improves, and weaning parameters demonstrate that he is ready for extubation. His urine output improves, and his BUN and creatinine values return to normal.

### Case Study Questions

1. Mike's nurse monitors him for which clinical manifestations in the early stages of septic shock?
  - A. Decreased cardiac output
  - B. Increased systemic vascular resistance
  - C. Increased PA wedge pressure
  - D. Increased cardiac output
2. It is a priority for Mike's nurse to follow up with the provider about which order?
  - A. Start antibiotics.
  - B. Prepare a norepinephrine drip.
  - C. Take hourly vital signs.
  - D. Send one set of blood cultures.
3. Mike's nurse incorporates which nursing diagnosis into the plan of care?
  - A. Decreased cardiac output related to impaired contractility
  - B. Decreased cardiac output related to increased afterload
  - C. Impaired tissue perfusion related to vasodilation
  - D. Impaired tissue perfusion related to loss of sympathetic tone
4. Mike's nurse evaluates which parameter as an indication of adequacy of treatment?
  - A. CVP
  - B. PAOP
  - C. SpO<sub>2</sub>
  - D. SvO<sub>2</sub>
5. Mike's nurse understands that which laboratory results indicate his condition is improving? (*Select all that apply.*)
  - A. Increasing lactate level
  - B. Decreasing base excess level
  - C. Increasing ScvO<sub>2</sub> level
  - D. Decreasing lactate level
  - E. Increasing BUN and creatinine

## CHAPTER SUMMARY

Shock is a syndrome that results from inadequate delivery of oxygen (DO<sub>2</sub>) and nutrients to the tissues, resulting in poor tissue perfusion and impaired cellular metabolism. Without immediate treatment, organ system failure and death may result. Delivery of oxygen is assessed through the evaluation of cardiac output and arterial oxygen content. When DO<sub>2</sub> falls below the tissue requirements, also called *oxygen consumption* (VO<sub>2</sub>), an oxygen debt results. Oxygen consumption can be indirectly measured through the evaluation of venous oxygen saturation, which reflects the amount of oxygenated blood returned to the right heart. Normal values are between 60% and 75%. When that value

falls below normal, it signals that an oxygen debt is occurring because of a decrease in oxygen content, hemoglobin, or cardiac output. The longer the imbalance between oxygen supply and demand, the larger the debt becomes.

There are four distinct stages of shock:

- The initial stage is subtle or subclinical, but cellular damage may be occurring.
- The compensatory stage is characterized by the initiation of neural, endocrine, and chemical compensatory mechanisms to maintain adequate volumes and cardiac output.
- The progressive stage is marked by the failure of compensatory mechanisms.
- The refractory stage is marked by prolonged inadequate blood supply to the cells, resulting in irreversible multi-system organ failure.

The assessment and monitoring of shock involve the assessment of physical parameters such as level of consciousness, urine output, respiratory status, pulse quality, and skin color and temperature. It also requires invasive hemodynamic monitoring done through arterial lines or central venous or PA catheters. Laboratory analyses of end-points such as lactate, blood gas analysis including base deficit, and SvO<sub>2</sub> are essential parameters to consider when evaluating the extent of shock and success of resuscitation.

*Hypovolemic shock* is defined as an acute loss of circulating fluid volume that results in a decreased venous return to the right heart, decreased stroke volume and cardiac output, and ultimately, decreased perfusion at the tissue level. Identifying and controlling further loss of blood or fluid is an obvious priority in this patient. Fluid replacement with normal saline or lactated Ringer's solution is the mainstay of initial resuscitation. Blood product replacement is necessary in the case of acute blood loss.

*Cardiogenic shock* is defined as a severe impairment of ventricular contraction in the presence of adequate vascular volume, resulting in decreased cardiac output. Treatment priorities include stabilizing oxygenation and drug therapy to

increase blood pressure and cardiac output. Also considered is emergency revascularization, intra-aortic balloon pump therapy, or when other treatment fails, ventricular assist devices.

*Distributive shock* is the result of disease states that cause poor vascular tone and vasodilation, resulting in increased vascular capacity and venous pooling. This can be caused by sepsis, anaphylaxis, or neurogenic shock. Treatment priorities in anaphylactic shock include removing the trigger when possible, initiating drug therapy with IM epinephrine, and providing ventilatory support when necessary. Treatment priorities for neurogenic shock include cardiovascular support through fluid resuscitation and drug therapy and ventilatory support when necessary.

Sepsis and septic shock are two clinical conditions on a continuum that starts with infection and ends with septic shock and multiple organ dysfunction syndrome (MODS). Characteristically, the invasion of the host with a microorganism is the first step in the continuum, resulting in an inflammatory response. Identification of the offending microorganism and prompt treatment with antibiotics have been shown to decrease mortality in sepsis. Fluid resuscitation is essential to restore fluid deficits and maximize oxygen delivery. The initiation of vasopressors may become necessary if fluid resuscitation is not successful at restoring blood pressure.

Disseminated intravascular coagulopathy (DIC) and MODS are complications of shock and sepsis. Disseminated intravascular coagulopathy occurs because of the enhanced coagulation that results from the release of pro-coagulant factors as part of the inflammatory response associated with sepsis. Multiple organ dysfunction syndrome occurs as a result of the excessive inflammation associated with severe injury or sepsis. Factors such as widespread damage to the vascular endothelium cause increased capillary permeability, vasodilation, and microvascular dysfunction that result in maldistribution of blood flow in the capillary beds and enhanced coagulation, leading to clots in the microcirculation that mechanically obstruct flow to the organs.

## Managing the Surgical Experience

# Chapter 15

## Priorities for the Preoperative Patient

*Deborah Ennis*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Discussing the essentials of the surgical experience
2. Explaining the priority assessments for the surgical patient
3. Identifying the vital preoperative preparation for the patient
4. Analyzing the nursing role in the preoperative process
5. Developing teaching and support strategies for the surgical patient and his or her family

### CONCEPTS

- Assessment
- Fluid and Electrolyte Balance
- Legal
- Medication
- Nursing Roles
- Perioperative
- Safety

### ESSENTIAL TERMS

Ablative surgery  
Advance directive  
Ambulatory (outpatient) surgery  
Cosmetic surgery  
Elective surgery  
Emergency surgery  
Exploratory (diagnostic) surgery  
Informed consent  
Intraoperative  
Last oral intake  
Minimally invasive surgery  
NPO (nothing by mouth)  
Palliative surgery  
Post-anesthesia care unit (PACU)  
Postoperative  
Preoperative  
Preoperative checklist  
Reconstructive surgery  
Robotic surgery  
Telesurgery  
Time-out  
Urgent surgery

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Maria Gonzalez is admitted to your facility for preparations for her total abdominal hysterectomy. She is 40 y.o. with two children aged 4 and 6 years. She has a history of fibroid tumors and deep vein thrombosis (DVT) with her most recent pregnancy. During your initial assessment, Maria informs you of her allergies to penicillin and latex. She has smoked 10 cigarettes a day for the past 20 years. Vital signs are noted as follows:

- Blood pressure (BP): 140/88 mm Hg
- Heart rate (HR): 80 bpm
- Respirations: 20/min
- Temperature: 98.7°F (37°C)
- Pain score: 0 out of 10...

## INTRODUCTION

There are many different purposes and types of surgical procedures. Some common terms associated with the surgical process are:

- **Emergency surgery**—surgery that must be done immediately to save a patient's life, limb, or ability to function
- **Urgent surgery**—surgery that must be done within 24 to 48 hours to prevent permanent injury to the patient or death
- **Elective surgery**—surgery that may be necessary but can be planned around the patient's and surgeon's schedule
- **Ambulatory (outpatient) surgery**—surgery usually performed in 1 day, with the patient being admitted to the ambulatory surgical center (ASC) in the morning and discharged after acceptable recovery criteria have been met
- **Exploratory (diagnostic) surgery**—surgery performed to obtain a diagnosis and possible resolution
- **Ablative surgery**—surgery to remove tissue from an organ or area of the body
- **Palliative surgery**—surgery performed to decrease pain or symptoms in patients suffering from incurable illnesses
- **Reconstructive surgery**—surgery to restore function or a defect in an area of the body
- **Cosmetic surgery**—surgery to change or revise an area or structure of the body
- **Minimally invasive surgery**—surgery performed through very small openings in the skin, using

instruments through with the surgeon can visualize the area such as a laparoscope

- **Telesurgery or robotic surgery**—surgery performed from a location other than the surgical suite, by use of robotic equipment

The operative experience is broken up into three phases: **preoperative, intraoperative, and postoperative**. Although each of these phases possesses unique nursing needs, the preoperative phase is a patient's first impression of the surgical setting. The preoperative phase commences when the decision for surgery is made and ends when the patient is transferred to the surgical suite. During this time, the preoperative nurse takes on a multitude of roles, including educator, advocator, and admittance nurse. It is crucial for the nurse to identify any potential needs the patient may have while in his or her care. The nurse's main priority is to complete a **preoperative checklist (Fig. 15.1)**. Each facility's unique checklist ensures that the necessary documentation, admission assessment, physical preparation, and educational needs have been completed prior to the patient entering the surgical suite. This includes but is not limited to:

- A full medical history (including prescription, over-the-counter, herbal, and other alternative therapies)
- Assessment of the patient's health status
- Collection of information and paperwork necessary for intraoperative and postoperative care
- Completion of preoperative orders (IV antibiotics, thromboembolic-deterrent [TED] hose, etc.)
- Patient education regarding the entire surgical process
- Verifying the patient and a witness signed the informed consent
- The initial time-out—"pause for cause"—when the patient verifies:
  - All information on the identification band as correct
  - The name of the surgeon
  - The procedure that will be completed by the surgeon
  - The correct side of the body on which the surgery will occur if this is a unilateral procedure

These interventions not only identify potential issues prior to surgery but also ensure that all procedures are performed in a timely and safe manner.

## INFORMED CONSENT

**Informed consent** is when a patient autonomously and cognitively grants permission to a provider to perform a surgical procedure after considering all alternatives, benefits, and risks of the procedure. Although obtaining consent is *not* the role of the nurse but that of the provider, it is the nurse's responsibility to ensure that the patient has all the

information needed to make an informed decision about the procedure being offered.<sup>1</sup> Working with the patient to identify and correct educational deficits not only makes the patient more comfortable about consenting to the surgical experience but also ensures the safest and most successful outcome. An informed patient is more likely to follow

instructions preoperatively for preparation and postoperatively for recovery. It is important for the preoperative nurse to understand that every patient has the right to refuse a surgical intervention even when death is a risk of refusal of treatment. In the eyes of the law, treatment without consent is not allowed even at the risk of death.

## Components of an Informed Consent

Surgical consent forms are similar in most institutions. Some may be preprinted; others must be completed to describe each procedure. Whichever form or forms are used, the required components are universal (Fig. 15.2).

Components of consents include:

- Consent for the procedure itself, which should include the following information:
  - Name of surgery, type of surgery, and reason for the surgery
  - Name of the surgeon to perform the surgery
  - Reason that intervention will benefit the patient

- All alternative options to surgery
- Potential outcomes if surgery is not performed
- Consent for anesthesia
- Consent to administer blood products

### Anesthesia

Anesthesia consent is an additional consent the patient must sign. At this time, the anesthesiologist informs the patient of the type of anesthesia, the medications to be used, and the risks associated with the type of anesthesia planned. The anesthesiologist or nurse anesthetist may also describe how the medication is administered, such as epidural anesthesia or regional block. The role of the preoperative nurse remains

**DO NOT COMPLETE THE SECTION BELOW UNTIL THE FINAL TIME-OUT IS CONDUCTED**

**Time-Out Verification**

This documents that a final verification (time-out) was performed prior to starting the procedure. Documentation of time-out may be completed elsewhere in the patient's medical record (e.g., procedure/progress note, procedure flowsheet, checklist, ORMIS). I verify that the treatment team (for OR, minimum of provider, anesthesiologist/CRNA, circulating RN) participated in the time-out using active communication and that we verified the following:

- Correct patient identity
- Agreement on procedure to be done (as stated on the informed consent)
- Correct side and site procedure

the same, one of patient advocate, ensuring that the patient understands the information being presented.

**Blood Products**

Consent to administer blood products may be a component of the general surgical consent or a separate form. The surgeon describes what situations will warrant the need for blood products and requests consent from the patient for their use. The nurse must be aware of cultural and religious

obligations that prevent the patient from consenting to receive blood products. For example, because of religious beliefs, patients who are Jehovah's Witnesses will not consent to the use of blood products. In that case, the surgeon documents that the patient has refused blood products in the patient's chart. The preoperative nurse is responsible for identifying the patient as "no blood products" with a bracelet and sign on the patient's chart. Facilities have blood refusal forms that a patient is asked to sign if this situation

presents. Providers can give blood without consent only in an emergency situation where the patient lacks the capacity to consent.

### Inability to Consent

Special considerations occur when the patient is not able to consent for care. These situations include patients who are cognitively impaired or who are cognitively aware but unable to physically sign, a deaf patient or one who speaks another language, minors, or emergency situations. In situations where the patient is impaired, a medical power of attorney may be established for consent purposes. Patients who cannot physically sign but are able to make their own care decisions may sign with an “x.” This consent needs to be witnessed by two people instead of just one as normally required. If the patient speaks another language or is deaf, a hospital interpreter may be used. For purposes of consent, this is desirable over a family member. The hospital interpreter is familiar with the medical terms being used. Also, the use of an anonymous interpreter avoids any bias that may occur with a family member during translation. Surgical consent for minors may be signed by the legal guardian of the child. However, if the child is old enough to understand the care, the procedure should still be explained.

In emergency situations, a verbal consent is acceptable. Written consent should be obtained in a timely manner following the surgery. If the patient is incapable of giving consent, two providers document the need for surgery. This is acceptable only if the patient’s medical power of attorney or next of kin is unreachable or the surgery is emergent and the patient has no support present. Other situations require special permits done well before the procedure. An example of this is sterilization procedures. The patient must sign a unique consent 6 weeks prior to the surgery.

### Advance Directives

The Patient Self-Determination Act of 1991 grants all patients the right to determine and direct their care in times of medical emergency; the right to create an **advance directive**. An advance directive defines a patient’s wishes should he or she be deemed incompetent to express his or her wishes in a medical emergency. Facilities are required by law to provide the means and guidance to complete an advance directive if desired prior to surgery. Within the advance directive, the patient may name a durable medical power of attorney, usually a spouse or adult child, who is designated to make all medical decisions should the patient become incompetent. The advance directive also allows the patient to express desires related to organ donation and end-of-life issues.

As part of the advance directive, a living will defines care in the case of cardiac or respiratory failure or when the likelihood of recovery to a quality level of functioning is deemed unlikely. Patients may elect to have all necessary measures taken or may elect to stop life-sustaining

procedures in the event of a cardiac arrest. The phrases “do not intubate,” DNI, or “do not resuscitate,” DNR, are recorded in the patient’s chart. The patient also has the opportunity to express wishes in regard to feeding tubes or long-term ventilator-assisted breathing. The patient may select any combination of treatments he or she feels best matches his or her values and beliefs. It is imperative that if a patient has advance directives and/or a living will at the time of surgery, the nurse notes that on the chart and places a copy of these documents on the chart if the patient has brought them to the hospital.

### Obtaining Informed Consent

#### Surgeon

The surgeon is solely responsible for obtaining consent in the presence of the patient and one witness. Family members or support persons may be present at this time. Informed consent for a scheduled procedure must be obtained prior to the administration of pain medications and sedatives or the induction of anesthesia because these medications may alter the patient’s ability to make an informed decision. In addition to obtaining informed consent, the surgeon uses this uninterrupted time to ensure that all of the patient’s and family member’s questions are answered.

#### Preoperative Nurse

Many patients admit to not reading the entire consent before signing (Box 15.1). The role of the preoperative nurse is to clarify information and ensure patient understanding. Nurses correct common misconceptions and ease concerns of the patient, family members, or support persons.

In addition to reviewing the consent form and validating patient understanding, nurses often serve as the witness to the consent. The nurse is witnessing the physical signature, not the information provided. It is essential that the witness be with the patient as the consent is being signed. The nurse or other witness should never sign the consent form if the patient has not signed in his or her presence. As part of preoperative procedures, the nurse is also responsible for documenting that a signed consent has been placed in the patient’s chart.

### Box 15.1 Why Patients Do Not Read the Full Consent

The most common reasons patient do not read the form are:

- It is too long.
- There is too much information.
- It is too intimidating.
- It is typed in small print.
- The terms used are too medical or legal.

## TIME-OUTS/PAUSE FOR CAUSE

Surgical errors and wrong-site procedures are a documented occurrence and have been identified by hospital accreditation organizations as an area for improvement. A **time-out** is a formal process of identification performed by the patient and the healthcare team to identify the correct patient, correct procedure, and correct surgical site. The preoperative nurse is a part of the time-out process.

The time-out, or “pause for cause,” starts when the patient enters the surgical facility. On admission, the patient receives a wristband (Fig. 15.3) containing his or her identifying information.

After reviewing the wristband, the patient confirms that all the information is correct; it is essential that the wristband note accurate information before the patient is moved into the surgical suite. The first responsibility of the preoperative nurse is to review the information on the wristband with the patient and have the patient name the procedure and site. This time-out is performed again by the circulating nurse upon transfer to the surgical suite and once more immediately preceding incision by the entire team (Fig. 15.4). The surgeon marks the surgical site with his or her signature using a permanent marker. Some surgeons may require that, if possible, the patient marks the site him- or herself.

### Components of a Time-Out

Although the process may vary in different facilities, the components of a time-out are consistent. The patient is asked to state his or her full name as printed on the identification bracelet and at least one other identifier, which is typically the patient’s date of birth, although there are other acceptable identifiers (see Safety Alert). The patient is next asked to state the correct site and the procedure he or she is receiving. The surgeon then marks the correct site. As stated earlier, the process of identifying the patient, procedure, and site is completed again by the team immediately

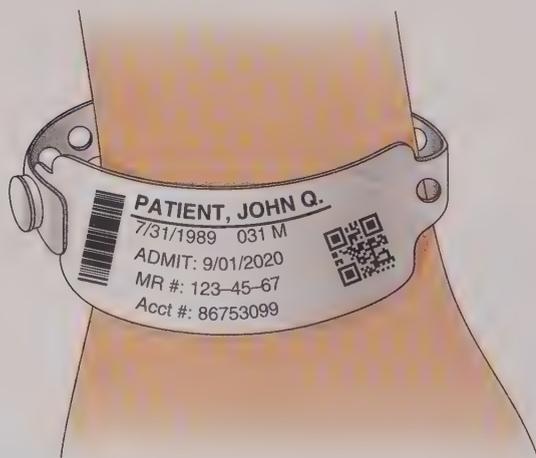

FIGURE 15.3 Patient armband.

prior to incision. Performing a time-out immediately prior to incision makes an irreversible mistake less likely.

### Safety Alert Acceptable Patient Identifiers

- Name
- Date of birth
- Social Security number
- Photo printed on band
- Address
- Telephone number

### Connection Check 15.1

You are preparing a patient for surgery and have asked her to verify her information on her patient identification band. She tells you that the birth date is incorrect on her identification band. The most appropriate action by the nurse at this time is which of the following?

- A. Cross out the birth date and put the correct one in its place with the nurse’s initials.
- B. Ask the family members to validate the patient’s birth date.
- C. Call the surgeon’s office to validate the birth date.
- D. Ask the admissions office to please send a corrected identification band.

## PATIENT ASSESSMENT

The surgical patient requires a detailed medical history and assessment to ensure a safe and successful surgery. The preoperative nurse is responsible for obtaining and documenting this history on admission. If a patient has already been admitted to an inpatient unit and has a history on record, the information should be reviewed and documented on the preoperative record. This allows the preoperative nurse and surgeon to identify any patient learning and medical needs that are unique to his or her surgical experience.

### Patient History

Completed patient medical, social, and surgical histories are the key to a successful surgical experience. These questions may be asked during a preoperative work-up or upon admission to the surgical facility. As the nurse prepares the patient for surgery, he or she asks a series of detailed questions. Some of the questions may be very personal and, at times, uncomfortable for the patient to answer. The nurse should remind the patient that this information is important in providing a safe outcome. It is also important to assure the patient that no judgment will be made on his or her responses and that the information will be used only for medical purposes. Box 15.2 lists the components of a complete patient history.

## Box 15.2 Components of a Complete Preoperative History

- Age (see Geriatric/Gerontological Considerations)
- Allergies and sensitivities to latex
- Current medications, including over-the-counter medications, vitamins, and herbal supplements
- Medical history and treatment plans
- Surgical history
- Previous anesthesia and responses to anesthesia
- Last oral intake
- Any medical implants or devices
- Any piercings
- Dental implants
- Nutrition deficiencies
- Family history
- Social history, including smoking and drug and alcohol habits
- History of mental illness or abuse
- Support system and living conditions
- Advance directives

## Geriatric/Gerontological Considerations

### Age and Preoperative History

The patient's age is important for a multitude of reasons; specifically, the elderly patient (65 or older) may have many issues that can interfere with a positive surgical outcome.

This patient must be assessed carefully for the following issues:

- **Polypharmacy**—the use of multiple medications, from multiple providers, purchased at multiple pharmacies. This can lead to medication interactions, which can also affect medications given during the perioperative period.
- **Cardiac status**—verify the presence of a preoperative electrocardiogram (ECG); place on the cardiac monitor and establish a baseline cardiac rhythm.
- **Respiratory status**—determine whether the patient is having any breathing difficulties. Establish a baseline

oxygen saturation on room air if the patient is not on oxygen at home or on the patient's normal administered oxygen level.

- Cognitive and sensory function—determine whether the patient is capable of giving consent for the procedure; does the patient understand the risks and outcomes of the surgery? Will the patient be able to follow postoperative teaching? Does the patient require postoperative hospitalization because he or she has no caregivers or is unable to care for him- or herself after surgery?
- Muscular function—determine whether the patient is at risk for falls, especially after anesthesia and pain medications.
- Skin assessment—the elderly very often have decreased adipose tissue, which can lead to an increased risk of hypothermia during surgery. They very often also have a change in the epidermis, which can lead to a risk of shearing injury to the skin and delayed healing.
- Nutritional status—due to the NPO status, this patient must be assessed carefully for dehydration before surgery.
- Laboratory studies—determine whether decreased renal/hepatic function is noted in the preoperative laboratory studies. Are all laboratory studies within normal range? The elderly patient typically has a decreased number of kidney nephrons and a decrease in the size of the liver, both which can affect how medications are metabolized.
- Chronic conditions—document all chronic conditions for which the patient is being treated.
- Support—it is important to ensure that the elderly patient has a strong support system and identify who will be responsible for helping the patient with any care needs he or she has when returning home.

### Medical History

As the nurse asks questions pertaining to the patient's medical history, he or she should be taking special note of any conditions that will pose a risk during the surgical experience. For example, a patient with a history of DVT should be receiving coagulation studies prior to surgery. A patient with a cardiac condition may have an untoward response to anesthesia or may experience harmful hemodynamic changes during the surgical procedure and may require enhanced cardiac monitoring with a cardiologist's input before surgery. Chronic pulmonary conditions such as asthma, emphysema, and chronic bronchitis may complicate the removal of ventilatory support postoperatively and should be monitored with pulse oximetry and arterial blood gas (ABG) testing. These patients

may require extended intubation, and admission to the intensive care unit (ICU) postoperatively should be anticipated. The presence of chronic illness such as diabetes or immune deficiencies places the patient at risk for poor wound healing postoperatively and indicates the need for increased blood glucose monitoring. Lastly, any implants, such as replacement joints and dental work, may interfere with positioning during surgery or intubation. If a patient has a pacemaker, because of possible electromagnetic interference from the use of an electrocautery device to control bleeding during the surgery, it may be necessary for the patient's pacemaker to be disabled during surgery. A representative of the pacemaker company may need to be present before and after surgery to manage the pacemaker.

### Surgical and Anesthesia History

A patient's surgical and anesthesia history is a very important part of the patient's history. Previous surgery may have left scar tissue, internal adhesions, or medical implants that need to be considered. The nurse should inquire about types of surgery, the year the surgery was performed, the indication for surgery, any poor incision healing, and what type of anesthesia was used for each procedure. Any negative responses to anesthesia or wound healing must be taken into consideration while planning the patient's care.

### Allergies

All patient allergies must be documented to ensure patient safety. Allergies to medications, food, medical dyes, latex, medical adhesive, and environmental conditions must be documented along with the patient's physical response to exposure to these products. An alert bracelet is placed on the patient, and the surgical team is made aware. Allergies to antibiotics determine what pre- and postoperative prophylaxis medications are used. If a patient is allergic to antiseptic solutions such as Betadine or chlorhexidine, an alternative skin preparation must be selected. Latex allergies are a serious concern. Each facility must have adequate latex-free equipment available for these cases. In some outpatient settings, patients with latex allergies are scheduled as first cases of the day to ensure that the surgical suite is free of latex contamination. Many hospitals are choosing to create latex-free environments for all surgical suites for this reason.

### Medications

Current medications are an extremely important part of the preoperative history (Table 15.1). The use of antihypertensives, anticoagulants, and antiarrhythmics, to name a few, can have a tremendous impact on the care provided in the operating room (OR). Herbal remedies and over-the-counter medications also may have potential interactions with medications used during the procedure and postoperatively or may increase the risk of bleeding.

### Last Oral Intake

Last oral intake is an essential assessment parameter prior to anesthesia. The guidelines may be modified for different populations, but typically, all patients requiring

**Table 15.1** Current Medications and Possible Implications

Medication Class	Potential Implications	Nursing Interventions	Rationale
<b>Antiarrhythmic:</b> <ul style="list-style-type: none"> <li>● Amiodarone</li> <li>● Sotalol</li> <li>● Ibutilide</li> <li>● Dofetilide</li> <li>● Dronedarone</li> </ul>	<p>Affect tolerance of anesthesia and potentiate neuromuscular blockers; depress cardiac function, output, and pulse</p>	<p>Obtain baseline electrocardiogram, vital signs.</p> <p>Monitor vital signs during the procedure.</p> <p>Communicate all medications to anesthesia team.</p>	<p>Continuous monitoring provides early detection of deviations.</p>
<b>Antihypertensives</b> <ul style="list-style-type: none"> <li>● Captopril</li> <li>● Clonidine HCl</li> <li>● Metoprolol</li> <li>● Atenolol</li> <li>● Losartan</li> <li>● Olmesartan</li> <li>● Telmisartan</li> <li>● Valsartan</li> </ul>	<p>Alter response to muscle relaxants and opioids</p> <p>May cause hypotensive crisis during and after the procedure</p>	<p>Monitor blood pressures.</p> <p>Communicate all medications to anesthesia team.</p>	<p>Hypotensive crisis can be prevented through monitoring and early detection.</p>
<b>Corticosteroids</b> <ul style="list-style-type: none"> <li>● Dexamethasone</li> <li>● Hydrocortisone</li> <li>● Prednisone</li> </ul>	<p>Surgery increases need for higher doses in patients who use steroids for replacement therapy.</p> <p>May increase healing time because of blockage of collagen formation</p> <p>Increase risk of hemorrhage and may mask signs of infection</p>	<p>Assess for hyperglycemia, infection, bleeding, and wound healing.</p> <p>Splint incisions to promote healing.</p> <p>Continue therapy during the procedure.</p>	<p>Continuing therapy avoids withdrawal and adrenal crisis.</p>
<b>Anticoagulants</b> <ul style="list-style-type: none"> <li>● Warfarin</li> <li>● Heparin</li> <li>● Aspirin</li> </ul>	<p>Increase risk of hemorrhage</p>	<p>Obtain baseline coagulation studies.</p> <p>Taper medication at least 48 hours prior to the procedure.</p> <p>Have vitamin K and protamine sulfate available as antidotes if excessive bleeding occurs during the procedure.</p>	<p>Obtaining coagulation studies at intervals during care can detect trends and potentially prevent hemorrhage.</p> <p>Vitamin K is the antidote for Coumadin; protamine sulfate is the antidote for heparin.</p>
<b>Nonsteroidal Anti-Inflammatory Drugs (NSAIDs)</b> <ul style="list-style-type: none"> <li>● Ibuprofen,</li> <li>aspirin,</li> <li>naproxen</li> </ul>	<p>May prolong bleeding time and may cause intraoperative or postoperative bleeding</p>	<p>Inform physicians if the medication has not been withheld before surgery.</p>	<p>Bleeding risk must be assessed by the physicians.</p>
<b>Anticonvulsants</b> <ul style="list-style-type: none"> <li>● Phenobarbital,</li> <li>phenytoin</li> </ul>	<p>These medications may alter the metabolism of anesthesia.</p>	<p>Must be alert for the potential of seizures because they can cause injury during a procedure.</p> <p>Maintain medication schedule</p> <p>Have suction and oral airway available.</p>	<p>Maintaining medication prevents seizures and injury.</p>

Continued

**Table 15.1 Current Medications and Possible Implications—cont'd**

Medication Class	Potential Implications	Nursing Interventions	Rationale
<b>Insulin</b>	<p>The patient will have a decreased need for insulin during the preoperative period due to decreased oral intake.</p> <p>Increased need postoperatively due to the stress of the surgery increasing glucose release</p> <p>Needs may fluctuate postoperatively because of decreased oral intake.</p>	Closely monitor blood glucose levels pre-/intra-/postoperatively.	Essential to monitor glucose levels so that treatment can be quickly administered with abnormal glucose levels

surgical intervention should have had nothing to eat or drink (NPO) for at least 8 hours prior to the procedure. A patient who has eaten within 8 hours is at risk of aspiration, the introduction of food particles into the lungs through emesis. The preoperative nurse is responsible for documenting the last oral intake. Patients who have special needs, such as those with diabetes mellitus, may have altered NPO orders before surgery. Exceptions are sometimes made that allow patients to take essential medications with sips of water prior to the procedure. According to recent guidelines for elective procedures, the patient may be advised to be NPO 6 to 8 hours for solid foods and 2 hours for clear fluids (see Evidence-Based Practice).

## Evidence-Based Practice

### Preoperative NPO Status

General anesthesia depresses many of the body's protective reflexes, including the gag reflex that prevents stomach contents from entering the lungs. Preoperative fasting decreases stomach acid and volume to help prevent aspiration. In the past, it was accepted practice to instruct the patient to be NPO after midnight the night prior to his or her procedure. After review in 2012 and updates in 2017, the recommendation has changed to NPO for 8 hours for solid foods and 2 hours for clear fluids. These recommendations may vary based on pre-morbid conditions such as diabetes and age.

Practice guidelines for preoperative fasting and the use of pharmacologic agents to reduce the risk of pulmonary aspiration: Application to healthy patients undergoing elective procedures: An updated report by the American Society of Anesthesiologists Task Force on Preoperative Fasting and the Use of Pharmacologic Agents to Reduce the Risk of Pulmonary Aspiration. (2017). *Anesthesiology*, 126(3), 376–393.

There are different preoperative NPO parameters for children and infants:

- No solid food is allowed for 8 hours before surgery.
- Infant formula can be given up to 6 hours before surgery.
- Breast milk can be given up to 4 hours before surgery.
- Clear liquids can be given up to 2 hours before surgery.

### Alcohol, Smoking, and Drug Use

Alcohol, smoking, and drug use are sometimes uncomfortable but important questions to ask of all patients. Smoking puts patients at risk for respiratory depression during the procedure and DVT during postoperative care. Because of changes in the pulmonary system, intubation and ventilation may also be compromised. Smoking may also increase the healing time for surgical wounds. Alcohol and drug use may compromise the patient's response to anesthesia. Additionally, postoperative pain management is complicated with recreational drug use, and such use must be taken into consideration when making discharge plans.

### Special Considerations

When a patient history is obtained, some questions require privacy because of their sensitive nature. All psychosocial questions, such as questions about abuse at home and gynecological and mental illness, must be asked with no other family or support persons present. Any conflicting medical information from the patient's chart and the patient's responses should also be addressed at this time.

## Connection Check 15.2

The nurse should report which of the following findings from a patient's history as increasing the risk for DVTs postoperatively? (Select all that apply.)

- History of smoking
- Age
- History of DVTs with previous pregnancy
- Borderline hypertension
- Allergies

## Physical Assessment

The physical assessment of the surgical patient is another component of the preoperative admission work-up. Assessment parameters include:

- Height and weight
- Vital signs
- Systems assessment

### Height and Weight

Height and weight help the anesthesia provider determine fluid needs and medication dosages for anesthesia or antibiotics during the procedure. A patient with a high body mass index (BMI) may also require a larger operating table and recovery bed. Most operating tables have extensions that can meet increased weight requirements. In addition, the OR team may adjust diligence equipment used to transfer the patient.

### Vital Signs

Vital signs are obtained by the nurse during the initial assessment. This includes blood pressure, respirations, pulse, temperature, and pulse oximetry. If available, the nurse should compare the admission vital signs with any previously recorded vital signs to note trends or major changes. If the initial set varies significantly from the patient's normal, a second set of vital signs may be taken 10 to 15 minutes later because many patients may be nervous, which may alter their vital signs. The presence of fever may be an indication of infection. That may necessitate a postponement of the surgical procedure. If the patient is held in the preoperative room for longer than 2 hours, a second set of vital signs may be required before transfer to the surgical suite.

Assessment of vital signs must include the fifth vital sign, pain. The patient is asked to rate pain in one of several ways. Examples of pain scales include:

- A scale of 0 to 10, with 10 being the worst pain the patient has ever experienced
- A series of faces ranging from a smile to a frown for pediatric patients

Another required admission question is the documentation of the patient's acceptable pain score. Each patient handles pain differently, and therefore a subjective pain scale is interpreted differently. This score is used by the post-anesthesia nurse and surgeon as a guide for adequate pain management.

## Systems Assessment

During the initial assessment, the nurse performs a head-to-toe physical assessment of the preoperative patient. Key elements for the preoperative assessment are presented in the following subsections.

### Cardiovascular Assessment

In addition to pulse and blood pressure, the nurse further assesses the patient's cardiovascular health. Peripheral pulses, color, skin turgor, capillary refill, temperature, and

edema are important parameters to assess. The nurse also auscultates the heart for rhythm, rate, and murmurs.

### Respiratory Assessment

The nurse assesses the patient's breathing for rate, depth, rhythm, and adventitious breath sounds such as crackles, rhonchi, or wheezing. Pulse oximetry is used to assess the patient's oxygen saturation on room air. In addition, the nurse should report any clubbing in the fingers, which could indicate long-term oxygen deprivation. The nurse must also ensure that the patient has a clear airway. The patient is asked to stick out his or her tongue, breathe with the head tilted up and with the chin down, and swallow. This ensures that an airway and any intubation may be safely maintained during the procedure. The anesthesiologist assesses the patient as well during his or her consultation.

### Neurological Assessment

Prior to the induction of anesthesia, it is important for the nurse to obtain a baseline neurological evaluation. Assessment of general cognition and the ability to understand commands is important prior to the induction of general anesthesia. The nurse also assesses the movement, strength, and sensation of the extremities. This is especially important in a patient who will receive some type of regional block for the procedure. The presence of preoperative delirium or confusion may delay or postpone the procedure or necessitate admission to the hospital postoperatively.

### Liver/Renal Assessment

It is important to note potential renal or liver disease in the surgical patient. The effects of anesthesia and other medications used before, during, and after an operation may be altered if the patient has decreased hepatic or renal clearance. A complete metabolic panel helps the team to identify any signs of dysfunction.

### Integumentary Assessment

A general assessment of the patient includes assessing appearance, such as skin integrity and hygiene. Patients with poor skin turgor or fragile skin may heal more slowly than a healthy individual. Also, the team may want to be careful as to the type of dressings that are used to protect the skin from further damage beyond the incision. For example, in an older patient or a patient with fragile skin, the nurse may want to use a leg strap instead of an adhesive to secure a urinary catheter. If hygiene is an issue, the nurse may need to give extra instruction on wound care in an effort to decrease the risk for infection.

### Gastrointestinal Assessment

It is important for the nurse to note typical bowel habits of the patient, especially if the patient will be admitted to the hospital after surgery. The nurse should also document the presence of normal bowel sounds and any areas of tenderness on the abdomen.

### Genitourinary Assessment

The nurse should document any devices noted for urinary elimination, such as an indwelling urinary catheter. The nurse should have the patient void before entering the operating suite and note any unusual odor or color of the urine. The patient may wish to discuss any concerns about urination postoperatively; some patients worry about being able to get into the bathroom without assistance. The nurse should also document any perineal abnormalities on the chart.

### Connection Check 15.3

Which of the following patients presents the greatest risk for a negative response to anesthesia?

- A. A 40-y.o. male with high blood pressure
- B. A 20-y.o. female with no prior surgical history
- C. A 29-y.o. female with a history of stage II acute renal failure
- D. An 85-y.o. male who drinks one glass of scotch every night

### CASE STUDY: EPISODE 2

While Maria is interviewed, she expresses concern for her stay at the hospital and her upcoming procedure. Maria states that other than the birth of her children, this is the first time she has been in a hospital, and this is her first surgical procedure. She expresses anxiety over “being put under” and worries about how she will take care of her children after discharge...

## PATIENT PREPARATION FOR THE SURGICAL EXPERIENCE

### Laboratory Assessment

Preoperative laboratory work is essential in determining the patient’s readiness for surgery. This can be done at an appointment prior to surgery or the morning of surgery. If done on the day of surgery, labs will be drawn as the nurse places an IV line to be used for venous access during surgery.

A type and screen to determine blood type and the presence of antibodies is drawn. This sample is used to cross-match blood in the event the patient needs blood during the surgical procedure. Often, facilities have the patient wear a blood identification bracelet with unique numbers that match the drawn sample for the purpose of easy and safe identification.

A complete metabolic panel provides baseline information on renal and liver functions, including liver enzymes,

albumin, electrolytes, blood urea nitrogen, and creatinine. This information helps in the selection of medications and dosages for the surgical procedure. Coagulation studies show how quickly the patient’s blood clots after injury, determining any bleeding abnormalities. The CBC, or complete blood count, measures hemoglobin/hematocrit (blood volume and oxygen-carrying capability) and the white blood cell count for indications of infection. Any deviation from the facility’s defined ranges should be reported to the surgeon or anesthesiologist, as appropriate, to be corrected to avoid complications. For example, a low platelet count or hemoglobin/hematocrit will be further decreased by surgery. The surgeon may ask for blood to be typed and cross-matched prior to the procedure, or the provider may ask for platelet administration before surgery. Clotting abnormalities may also require the administration of fresh frozen plasma before the procedure can begin.

Lastly, urine is measured for the presence of glucose, blood, protein, and specific gravity and the presence of ketones. These measures help determine the presence of infection or the hydration status of the patient. Women of childbearing age may be tested immediately prior to surgery for pregnancy.

### Radiological Assessment

Radiological imaging is sometimes required prior to surgery. Common preoperative images are magnetic resonance imaging (MRI), computerized axial tomography (CAT scans), ultrasonography, or x-ray imaging. Imaging studies may also be required immediately before and during the surgery to monitor progress. An electrocardiogram (ECG) may also be performed prior to or on admission to the surgical facility, and cardiac monitoring may be ongoing.

### Patient Teaching

It is important at this time to complete any necessary patient teaching. Patient teaching helps decrease anxiety, which has been shown to improve patient outcomes. Anxiety has been shown to increase postoperative pain medication requirements, necessitating more pain medication. This can affect the postoperative recovery by decreasing activity and mobility, which puts the patient at risk for complications such as DVT, pneumonia, and constipation. Anxiety also plays a role in increasing the risk of infection by decreasing the immune system response. Most facilities have a patient teaching record where teaching is documented.

The patient’s family should be included in the preoperative teaching. At this time, the nurse should take the opportunity to have a discussion with the patient and his or her family support regarding what to expect during the patient’s surgical and postoperative experience. For example, the nurse should discuss how long the procedure will be, how long the patient will be in the post-anesthesia care unit (PACU), and how soon

the family will receive an update on the patient's status and be able to see the patient. Discharge care may be covered at this time because the patient may be fatigued or drowsy after the procedure. The nurse can address any family concerns at that time as well. Lastly, the nurse should ensure that the family is guided to the appropriate waiting area where the staff will be able to locate them for updates. See Box 15.3 for a checklist of preoperative learning needs.

## Physical Preparations

### Intravenous Line (IV Line)

An IV line is inserted during the preoperative admission, typically for the purpose of the administration of anesthesia and fluids during the surgery. An 18-gauge catheter is preferred because this size is required for the administration of all blood products. Factors to consider when placing the IV line include the location of the procedure and if multiple sites are required. The IV should be labeled with gauge, time and date of placement, and the nurse's initials. The nurse may also administer any preoperative antibiotics at this time.

### Bowel and Bladder Preparation

Patients receiving abdominal, intestinal, gynecological, or rectal surgery may be asked to perform a bowel preparation. This may be done by use of an enema or gentle laxatives that the patient self-administers at home the night before the procedure. The nurse should confirm and document that this preparation has been performed.

Patients scheduled for abdominal, gynecological, or long procedures may also require the insertion of an indwelling catheter to drain urine. This will keep the bladder empty during a procedure, preventing injury to the bladder. It also allows the surgical team to monitor output in the operating room and PACU.

## Connection Check 15.4

During the initial assessment and admission questions, the nurse asks Maria for the time of her last oral intake. The patient replies, "I had dinner last night at 8 p.m., but I took a few sips of water this morning with my vitamins. The nurse's best response is which of the following?"

- Explain to the patient that just a sip of water should not be a problem for anesthesia but that the vitamins may be a problem. That information will be passed on to the anesthesiologist.
- Tell the patient that the sip of water is not an issue because it was only a sip.
- Inform the patient that her surgery will not be performed today because the risk is too high for a negative outcome.
- Inform the patient that taking her vitamins before surgery was a good plan.

## Box 15.3 Checklist of Preoperative Learning Needs

- Reason for procedure
- Nature of procedure
- Members of the surgical team
- Length of the procedure
- Location of the procedure
- Components and use of the pain scale
- Anesthesia plan
- Postoperative pain management plan
- Location of the incisions
- Presence of postoperative drains and dressings
- Surgical site preparation
- Ambulation guidelines after surgery
- Coughing and deep breathing exercises expectations
- Splinting incisional area when coughing to decrease the pain
- Family instructions—the patient should not be alone for the first 24 to 48 hours.

### Skin Preparation

Prior to surgery, skin preparation is done to help prevent infection at the surgical site. Patients may be instructed to shower and wash with Betadine or hexachlorophene soap prior to admission. A surgical shave may be necessary depending on the patient's skin type and the location of the incision. If a shave is appropriate, the nurse uses a sterile electric clipper. A razor is not recommended because of the risk of infection caused by small nicks in the skin that may occur with a razor. Shaving may be done in the OR after the induction of anesthesia. In addition, the nurse should confirm that all body piercings have been removed and that nails are clear of polish.

### Medications

Preoperative medications may be required. Patients with preoperative anxiety may be prescribed a benzodiazepine such as midazolam HCl, diazepam, or lorazepam. Antiemetics such as metoclopramide HCl or ondansetron HCl may be used preoperatively if a patient has a history of nausea and vomiting due to anesthesia.

### Transfer

Preparing the patient for transfer to the OR suite is the final responsibility of the preoperative nurse. Before transport, the nurse should make sure that all consents have been signed; the history and assessment have been completed and documented, including vital signs; learning needs have been met; skin and bowel preparation are complete; and preoperative medication has been administered. The intraoperative nurse may accompany the patient to the surgical suite, or the anesthesia team may be responsible for this transport depending on the surgical suite's policies. Once transferred, the patient is now considered to be receiving intraoperative care.

### **Safety Alert** **Transfer of Patient to Surgical Suite**

The preoperative nurse must ensure that the following have been completed before transfer to intraoperative care:

- Patient identification
- Physical preparations
- Confirmation of NPO status
- Documentation of complete medical history and admission vital signs and laboratory work
- Allergy bracelet visible
- Documentation of initial time-out
- Copies of all appropriate documentation are in patient's file
- Patient education with verbalized return of information
- Family and patient questions answered

### Connection Check 15.5

Maria's surgeon has asked that thromboembolic-deterrent (TED) stockings be placed on the patient before surgery as well as sequential compression devices on both legs to the knees. Maria asks the nurse what these devices will do for her. Which response by the nurse is most appropriate?

- A. "They work together to make sure that you do not have a decrease in arterial blood flow in your legs during the surgery."
- B. "They complement each other to prevent blood from backing up in your legs and causing a deep vein thrombosis due to your immobility during the surgery."
- C. "They prevent deep tissue clotting during the surgery."
- D. "The two devices do the same thing, but one is better during the surgery, and the other is better postoperatively."

## NURSING MANAGEMENT

### Nursing Diagnoses

- **Fear and anxiety** related to loss of control and the unknown
- **Knowledge deficit:** treatment procedure

### Nursing Interventions

#### ■ Assessments

- Vital signs/oxygen saturation  
*Initial vital signs provide a base to determine the patient's condition during and after the procedure. Increased or*

*decreased heart rate, increased or decreased blood pressure, increased temperature, and decreased oxygen saturation may necessitate a postponement of the procedure, if elective.*

- Physical examination/laboratory analysis  
*Evaluation of the physical exam and laboratory values determines readiness for the procedure, indicates necessary adjustments to be made prior to the procedure, and provides a baseline for comparison in the OR and postoperatively.*
- Last oral intake  
*NPO prior to the procedure is essential to guard against aspiration during intubation and extubation due to decreased gag reflexes.*
- Confirm appropriate skin prep and bowel prep have been completed.  
*Prepping the skin with a special soap prior to surgery helps reduce the risk of infection; a bowel prep prior to some abdominal, gynecological, or rectal surgeries is necessary to clear the bowel, which prevents the risk of peritoneal contamination if the bowel is compromised during surgery.*

#### ■ Actions

- Ensure removal of jewelry and prosthetics.  
*An electrocautery unit is used during operative procedures to decrease bleeding. Electricity may travel to any metal on the body, causing a burn. There is also a risk during positioning that the patient's ring may get caught in a piece of equipment, causing injury to the finger.*
- Inform anesthesia and surgical personnel of the presence of any implants.  
*A patient with a pacemaker may need to have the pacemaker disabled; the pacemaker company or a representative of the hospital needs to assume responsibility for this action. Personnel must also be aware of items such as central intravenous lines or Mediports, typically used for long-term medication therapy.*
- Time-out  
*Establishing the right patient, procedure, and site is essential to avoid operative errors.*
- IV insertion  
*An IV is necessary for fluid and medication administration.*

#### ■ Teaching

- What to expect of the OR experience  
*An understanding of what to expect of the OR experience helps control anxiety and increase patient comfort.*
- How to prevent postoperative complications  
*Knowledge of postoperative teaching, such as coughing, deep breathing, early ambulation, and leg and ankle exercises, significantly reduces the risk of postoperative complications.*

### Connection Check 15.6

When planning discharge education for a 65-y.o. male who is having a hip replacement, it is appropriate for the nurse to consider which of the following? (*Select all that apply.*)

- A. The patient's resources at home for completing activities of daily living
- B. The number of stairs in the patient's home
- C. Transportation to follow-up appointments
- D. Pre-existing medical conditions
- E. The number of bathrooms in the home

## Making Connections

### CASE STUDY: WRAP-UP

Maria's nurse completes the preoperative preparation. An IV line is inserted, and normal saline is started. The anesthesia provider is reminded of Maria's allergies to penicillin and latex and her smoking history. Once completed, the nurse spends time with Maria, attempting to allay her fears by explaining what to expect in the OR and when she wakes up. They review potential plans for childcare postoperatively.

#### Case Study Questions

1. Maria expresses her anxiety about the procedure and anesthesia to her nurse. Which is the most appropriate response?
  - A. Tell her, "It's okay; we do this every day."
  - B. Assure her that her fears are normal and encourage her to use her consultation time with the surgeon and anesthesiologist to address her concerns.
  - C. Share a story about your friend who had similar fears prior to her surgery.
  - D. Document her concerns in the chart so that the PACU nurse will expect her to be anxious during recovery.
2. Maria is allergic to latex. What is the appropriate action to prevent an allergic reaction in the patient who is having surgery?
  - A. Terminally clean the OR before her case and remove all latex products.
  - B. Maria should be the first case of the day, and only non-latex items should be used.
  - C. All surgical suites are latex-free, so this is not a concern.
  - D. Anesthesia should be prepared to intubate and treat her if a reaction occurs because there is no way to ensure a latex-free environment.

3. Because of Maria's smoking history, the nurse understands she is at great risk for which of the following? (*Select all that apply.*)
  - A. Increased postoperative pain
  - B. Difficulty with anesthesia
  - C. Respiratory depression during the procedure
  - D. Increased healing time after the procedure
  - E. Deep vein thrombosis after the procedure
4. The nurse recognizes teaching has been effective by which of the following statements?
  - A. "My neighbor was able to eat right up to the time of her procedure."
  - B. "I know there is nothing you can do about nausea after the procedure."
  - C. "So that IV line will stay in throughout the procedure?"
  - D. "I know I will need blood during this procedure."
5. What is the priority responsibility of Maria's nurse before the procedure?
  - A. Explaining the procedure and having Maria sign the consent form
  - B. Reviewing the risks of anesthesia
  - C. Marking the surgical site with the patient
  - D. Ensuring completion of the preoperative assessment

## CHAPTER SUMMARY

The preoperative phase of the surgical experience begins when the decision for surgery is made and ends when the patient is transferred to the surgical suite. During this time, the preoperative nurse takes on a multitude of roles, including educator, advocator, and admittance nurse.

Priority assessments include patient history and medications (prescribed and over the counter [OTC]), physical assessment, allergies, alcohol and drug use, and advance directives. The nurse must assess the elderly for specific concerns that may affect their surgical experience. It is essential to get a baseline for comparison in the intraoperative and postoperative periods, specifically with vital signs, cardiac rhythm, and oxygen saturation. Also, the assessment may identify a patient who requires additional monitoring to avoid complications associated with the procedure or anesthesia. Patient preparation includes education about the operative experience, IV insertion, labs, postoperative teaching, and family support. The patient should be aware of the potential for IV lines or drains that may be present postoperatively.

The nurse is involved in all aspects of preoperative care: patient education, time-outs, and confirmation of informed consent and family support. Education must include the many facets of the surgical experience, including postoperative care that will be vital to preventing complications, specifically coughing, deep breathing, and early mobility

after surgery. The nurse must also be sure the patient is clear about postoperative medications and the regime for taking these medications. Teaching is a vital aspect of the preoperative nurse's care, to ensure that the transition to the operative suite and subsequent post-anesthesia care unit (PACU) is seamless and without adverse outcomes.

## Priorities for the Intraoperative Patient

*Jamie Maher*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Identifying the roles and responsibilities of operating room (OR) team members
2. Explaining priority assessments and procedures in the OR
3. Discussing types of anesthesia utilized in the OR
4. Analyzing the importance of airway management in the OR
5. Examining risks and complications for the surgical patient
6. Developing support strategies for the surgical patient and his or her family

### CONCEPTS

- Assessment
- Communication
- Infection
- Medication
- Perioperative
- Safety

### ESSENTIAL TERMS

Airway management  
Anesthesia  
Anesthesia provider  
Appendectomy  
Asepsis  
Elective surgery  
Emergency surgery  
Exploratory laparotomy  
Fowler's position  
General anesthesia  
Hemostasis  
Inpatient surgical settings  
Intraoperative phase  
Jackknife position  
Laryngospasm  
Lateral  
Lithotomy  
Local anesthesia  
Malignant hyperthermia (MH)  
Mayo stand  
Monitored anesthesia care (MAC)  
Nonsterile team members  
Outpatient surgical centers  
Perioperative registered nurse  
Positioning devices  
Post-anesthesia care unit (PACU)  
Postoperative phase  
Preoperative assessment  
Preoperative phase

Sterile technique  
Supine  
Surgeon  
Surgical pause  
Surgical scrub  
Time-out  
Trendelenburg position  
Urgent surgery

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Your assigned operating room (OR) patient is Ms. Doe, a 71-year-old widow who has a history of chronic bronchitis and eczema and no known medication or food allergies. She has been brought to the emergency department (ED) by ambulance after complaining of severe abdominal pains for 2 days. She states that she has had bouts of diarrhea and vomiting for the last 2 hours, with increasing right lower quadrant pain. She verbalizes to the nurse in the ED, "I am so weak I can hardly speak..."

## OVERVIEW OF THE SURGICAL EXPERIENCE

### Surgical Settings

Surgical technology is changing every day. As new equipment is developed and evidence-based practice is integrated into surgical protocols, the setting of surgery also changes. Surgical procedures are not only performed in the traditional inpatient hospital setting but also in **outpatient surgical centers** that offer the same amenities.

**Inpatient surgical settings** perform surgical procedures that require admittance to a hospital unit postoperatively. Inpatient procedures are often very invasive and long. Patients require close monitoring and recovery for more than 24 hours after completion. Examples include procedures such as cardiac surgeries, which may require intensive care unit (ICU) care postoperatively with continuous monitoring. Joint replacements may require complex pain management. Inpatient surgery may also be indicated if admittance to the hospital after the procedure for rehabilitation is required.

**Ambulatory or outpatient surgery** is performed without admittance to a hospital unit before or after the procedure. The surgery center may be freestanding or located in a hospital. Also known as "same-day surgery," outpatient surgery is often less invasive, shorter in operating time, and requires less than 24 hours of monitored recovery time. Patients are often admitted 2 hours prior to surgery and discharged directly to their homes. Candidates for outpatient procedures typically have no other comorbidities, such as substantial medical histories. They do not need additional recovery care beyond post-anesthesia. Successful recovery at home requires the patient to be receptive to teaching prior to discharge from the surgical center and to have a caregiver who will be present with the patient at all times for at least 24 hours. Advances in surgical science have greatly increased

the number of procedures that are done on an outpatient basis. Outpatient surgical examples include some ear, nose, and throat (ENT) procedures and oral and orthopedic surgeries. More complex procedures such as mastectomies can also be performed in an outpatient setting. Ambulatory surgery centers follow the same safety and clinical guidelines as an inpatient setting. These include the presence of an anesthesiologist, a sterile operating environment, and a **post-anesthesia care unit (PACU)**. Before a patient is discharged from the outpatient settings, goals are met regarding pain control and recovery education.

Freestanding outpatient surgery is a rapidly expanding option for many patients. Freestanding surgical centers tend to be located in a more convenient setting, away from the intimidating hospital setting. They allow more flexibility in scheduling for the patient. Family members are only separated from the patient during the actual procedure and are able to participate in the postoperative care and education. Freestanding surgical centers are less expensive than inpatient settings and often provide more face-to-face time with the nurse during the patient's stay.

Outpatient operative nursing poses unique challenges. The nurse needs to quickly identify and prioritize the patient's learning needs because there is a shorter recovery time and therefore less time to complete postoperative education. Also, some education may need to be completed during the preoperative time when the patient is more alert rather than sleepy after undergoing anesthesia.

### Surgical Categories

Types of surgery can be divided into six subcategories. Diagnostic surgeries, such as biopsies, exploratory procedures, and laparotomies/arthroscopies, are performed to determine sources of disorders. Curative surgeries repair or remove causes of disorders. Restorative surgeries are those that repair disorders, such as a total hip replacement. They improve patient function by reconstructing mechanical parts of the body. Palliative procedures are for comfort and help relieve pain or symptoms of a disease process. Cosmetic surgeries restore or improve personal appearance, and lastly, transplant surgery is done to replace nonfunctioning or poorly functioning organs to improve or sustain life. Examples of this include kidney or heart transplants. Often the name of the surgery describes the nature of the procedure (Table 16.1).

Surgical procedures may be further classified as *elective*, *urgent*, or *emergency*.

- **Elective surgery** is surgery that the patient chooses to have. It is performed for his or her well-being but is not absolutely necessary. Most elective surgeries are scheduled at the patient's convenience, and many are performed in the outpatient setting. These often include plastic surgeries, oral surgeries, and orthopedic surgeries.
- **Urgent surgery**, although necessary, may be scheduled rather than done immediately. Examples include

**Table 16.1 Suffixes for Surgical Procedures**

Suffix	Meaning	Examples
<b>-centesis</b>	Puncture	Amniocentesis, thoracentesis
<b>-ectomy</b>	Removal	Cholecystectomy, hysterectomy
<b>-lysis</b>	Destruction	Electrolysis
<b>-oscopy</b>	View with scope	Arthroscopy, endoscopy
<b>-ostomy</b>	Create an opening	Colostomy, ileostomy
<b>-otomy</b>	Incision	Episiotomy, tracheotomy
<b>-plasty</b>	To reshape or repair	Abdominoplasty, mammoplasty

hysterectomies, laminectomies, and hip or knee replacements.

- **Emergency surgery** is unscheduled and is done immediately to save a patient's life or limb. The need for this type of surgery is always unanticipated. Gunshot wounds, stabbings, and auto accidents often require emergency surgery.

Procedures can have a minor or major degree of risk. Minor procedures such as oral surgeries and dilations and curettage (D&C) are often performed under **local anesthesia**, hold less surgical risk for the patient's well-being, and require minimal post-anesthesia recovery. Major procedures are longer, more complex, and have a higher degree of risk. They are performed under general anesthesia and require overnight stays in the hospital, sometimes in the ICU setting. Cardiac procedures, neurological procedures, or thoracic procedures typically fall into this category.

Finally, surgical procedures are defined as simple or radical in extent. A simple procedure means that the surgeon is working within a small defined affected area. A radical procedure involves not only the small defined affected area but also the surrounding tissue. For example, a surgeon may only need to perform a simple tumor removal. Alternatively, a radical procedure involves removing the tumor and the surrounding tissues. A gynecologist may perform a simple hysterectomy where only the uterus is removed or may remove the fallopian tubes and ovaries in what is known as a radical total hysterectomy.

## OVERVIEW OF THE SURGICAL TEAM MEMBERS

Each day, several million individuals worldwide face a surgical procedure of some kind. Surgical patients must depend on the knowledge and skills of surgical team members

who work in the OR. As in other healthcare settings, an efficiently functioning team in the surgical environment is of extreme importance to the patient. Respect for others' expertise, the ability to work harmoniously, and the art of communicating effectively are necessary ingredients for a well-functioning OR team.

The surgical procedure dictates the number and type of members on the surgical team. Normally, this team includes a surgeon; an anesthesia provider; a **perioperative registered nurse** (RN who works in the OR); and perhaps a variety of unlicensed assistive personnel, such as surgical technologists, OR associates, and critical care technicians. Team members are categorized as sterile, individuals who perform a surgical scrub and don a gown and gloves to work inside the **sterile field** (the identified surgical area considered free from microorganisms), and/or nonsterile, individuals who function outside the identified sterile field.

### Sterile Team Members

**Sterile team members** are those who work within the sterile field and have the responsibility of maintaining **asepsis** (controlling the sterile field to avoid contamination by microorganisms) throughout the surgical procedure. The sterile field includes the OR table and the area closely surrounding it, an equipment stand called the **Mayo stand** that is conveniently positioned close to the patient, and the instrument table. The team members scrub their hands and arms with special disinfecting soaps and wear surgical gowns, caps, eyewear, gloves, and sturdy footwear (with or without optional shoe covers). Sterile team members include:

- The surgeon
- Surgical assistants
- The scrub nurse or surgical technologist

### Surgeon

The **surgeon** is considered the leader of the surgical team and has the ultimate responsibility for performing the surgery in an effective and safe manner. Depending on the complexity of the surgical procedure, the surgeon may have one or more providers assisting. These providers may be interns or hospital residents who are participating in the surgery as part of their advanced training. There may also be other surgeons who are specialists in a particular field and part of the interprofessional team caring for the patient.

### Surgical Assistants

Surgical assistants are practitioners with specialized training that allows them to assist with surgical procedures. These roles include physician assistants (PAs), surgical first assistants (SFAs), nurse practitioners (NPs), and RN first assistants (RNFAAs).

The PAs primary role is to assist licensed providers. In addition to helping in the OR, the PA provides both preoperative and postoperative care for patients, freeing the

surgeon to perform the more specialized care appropriate to his or her training and expertise. The PA's duties may include ensuring the acquisition of patient diagnostic films, records, laboratory studies, and history and physical examinations (also known as an H&P) and reporting any issues or concerns to the appropriate parties.

The SFA is typically a certified surgical technologist with additional specialized education or training. Under the surgeon's direction, the SFA provides aid in exposing of the surgical site, **hemostasis** (controlling blood flow and stopping or preventing hemorrhage), and other technical intraoperative functions as directed by the provider.

The RNFA or NP is an RN who has gone through extensive education beyond the traditional nursing preparation. The actual scope of the RNFA's/NP's practice in the perioperative environment is dependent on specific state regulations. In most instances, similar to the PA, the RNFA/NP functions interdependently with the surgeon during the procedure to assist in performing the operation.

### **Scrub Nurse, Surgical Technologist, and Operating Room Technician**

The scrub nurse, surgical technologist, or operating room (OR) technician is also known as the **scrub**. This individual works directly with the surgeon within the sterile field by passing instruments, sponges, and other items needed during the surgical procedure. Before an operation, scrubs help prepare the OR by setting up surgical instruments and equipment, sterile drapes, and sterile solutions. They assemble both sterile and nonsterile equipment, checking to ensure that it is working properly. The scrub is also responsible for helping the surgical team don sterile gowns and gloves in preparation for the surgical procedure. Scrubs help count sponges, needles, instruments, and other miscellaneous supplies and help prepare, care for, and dispose of specimens taken for laboratory study. Depending on the institution's policies, scrubs may hold retractors, cut sutures, and assist with the application of surgical dressings. After an operation, scrubs assist with readying the room for the next procedure by restocking and cleaning.

### **Nonsterile Team Members**

**Nonsterile team members** perform their duties outside the sterile field. These team members include but are not limited to:

- The anesthesia provider
- The circulating RN
- Unlicensed assistive personnel
- The OR director/coordinator/manager

### **Anesthesia Provider**

The **anesthesia provider** is responsible for maintaining and sustaining the physiological status of the patient throughout the surgical process. This person may be an anesthesiologist or certified registered nurse anesthetist (CRNA). An anesthesiologist is a physician. CRNAs are advanced practice

RNs trained to administer anesthetics. They can work independently or in collaboration with an anesthesiologist.

The anesthesia provider must be constantly aware of the surgeon's actions, doing everything possible to ensure the safety of the patient and reduce the stress of the operation. Specific responsibilities include providing smooth induction of the patient's **anesthesia** (temporary induced loss of sensation or awareness) in order to prevent pain; maintaining satisfactory degrees of relaxation of the patient; providing continuous monitoring of the patient's life functions, including oxygen exchange, circulatory functions, systemic circulation, and vital signs; and advising the surgeon of impending complications and independently intervening as necessary.

The anesthesia provider has contact with the patient during all phases of the surgical process: preoperative, intraoperative, and postoperative. During the **preoperative phase**, the anesthesia provider meets with the patient and conducts a preoperative interview. At this time, the patient's medical history and medications are reviewed, facilitating the development of a plan for managing these conditions during surgery. The upcoming surgery and options for anesthesia are also discussed.

During the **intraoperative phase**, the anesthesia provider administers anesthetic agents and carefully monitors the patient's vital signs, including heart rate and rhythm, blood pressure, and respiratory status. As the surgical procedure progresses, adjustments in anesthesia agents may be made to compensate for changes in the patient's physical condition. At the completion of surgery, the recovery phase begins. If a general anesthetic has been used, the anesthesia provider gradually stops the anesthesia administration to allow for the metabolism of the medications, thereby allowing the patient to regain consciousness.

The **postoperative phase** begins when the patient is transported from the operative suite to a PACU or ICU. If to the ICU, responsibility for patient care is assumed by the ICU medical team after a thorough hand-off from the surgical team. If to a PACU, the anesthesia care provider maintains the oversight of patient management. This includes but is not limited to airway management; pain, nausea, and vomiting management; and monitoring of physiological outliers, such as changes in vital signs. When PACU discharge criteria are met, the anesthesia provider approves the movement of the patient to the predetermined post-surgical destination (i.e., home, floor bed, or unit bed).

### **Circulating Registered Nurse**

The circulating registered nurse (RN) observes the surgical procedure from a broad perspective, assisting the team in creating and maintaining a safe and comfortable environment for the surgical patient. The scope of the nurse's responsibilities includes:

- Initial assessment of the patient in the preoperative area. During this time, an essential role of the perioperative nurse is to establish a therapeutic relationship with the patient, attempting to calm fears and establish trust.

- Initial assessment upon admission to the OR
- Assisting the anesthesia provider with positioning, monitor placement, line placement, and patient monitoring
- Assisting the surgeon and scrub nurse/technologist with donning of sterile gowns, gloves, and other protective gear
- Anticipating the need for equipment, instruments, and medications
- Assisting the scrub nurse or technician by opening packages of sterile supplies necessary for the procedure
- Ensuring samples are appropriately labeled and sent to the laboratory for analysis
- Counting the number of sponges, needles, instruments, and other miscellaneous supplies used during the operation to prevent accidental retention or loss of an item in the surgical wound
- Documenting information pertinent to the surgery and the surgical patient

### Unlicensed Assistive Personnel

Unlicensed assistive personnel are accountable to and work under the supervision of perioperative RNs. Their duties include patient transport to the OR and helping with the positioning and securing of patients on the operating table in preparation for their procedures. They may also be assigned other tasks, such as delivery of specimens to the laboratory, blood pickup, and equipment retrieval and housekeeping duties.

### Operating Room Director/Coordinator/Manager

The OR director/coordinator/manager is responsible for oversight of the business aspect of the OR. This individual is accountable for budgets, staffing, and other areas critical in ensuring the efficient running of the OR.

### Connection Check 16.1

Which of the following is the identified leader of the surgical team?

- The circulating registered nurse
- The anesthesia provider
- The scrub nurse
- The surgeon

## PRIORITY ASSESSMENTS AND PROCEDURES

There are several priority assessments and procedures that are essential in ensuring a safe operative experience for the patient. These include:

- The preoperative assessment
- The surgical pause
- The surgical scrub
- The donning of surgical attire

## Preoperative Assessment

The **preoperative assessment** is done by the perioperative nurses, typically in the preoperative area, and must accomplish, at a minimum, four goals:

1. Determine the patient's level of knowledge related to the planned surgery, potential complications, and interventions, such as insertion of an indwelling catheter, and provide education as appropriate. This time also allows the patient to voice specific concerns or questions regarding the procedure.
2. Confirm that informed consent for the proposed surgical procedure has been obtained. Informed consent discussions are intended to explain the proposed procedure in terms the patient can understand and is able to articulate.
3. Determine the patient's level of anxiety in order to support his or her management of preoperative fears and postoperative concerns. This is done by openly discussing the causes of anxiety, such as fear of death or disability, fear of pain, fear of poor prognosis, and fear of rejection if a transplant is the planned procedure.
4. Obtain relevant information about the patient, which may include:
  - Verification of the patient's name and date of birth, such as verifying that the medical record numbers match the patient's name band and paperwork
  - Verification of NPO status prior to surgery
  - Determination of medications taken in the morning prior to surgery
  - Assessment of skin color, temperature, and integrity (i.e., tattoos, bruises)
  - Verification of health history, including current medications
  - Verification of allergy status and specific allergic reactions the patient experiences, such as a rash or itching
  - Verification of placement of any metal implants, especially automatic implanted cardioverter defibrillators and pacemakers
  - Assessment of family support

## Surgical Pause

The **surgical pause**, or **time-out**, is done prior to the start of the procedure to verify correct patient, correct procedure, correct surgeon, correct position, correct equipment, and correct imaging studies (radiography, etc.). The presence of implants, such as a pacemaker, is confirmed. If antibiotics were indicated, their administration is verified. If the surgical site involves laterality, the correct site is verified and clearly marked with the operating surgeon's initials.

This universal protocol developed by The Joint Commission also includes the introduction of all team members in the room; thus, it involves active communication among all members of the interprofessional team (see Evidence-Based Practice). It is consistently initiated by a designated

member of the team and is conducted in a “fail-safe” mode, which means the surgical procedure does not commence until every question or concern has been resolved.

## Evidence-Based Practice

### Guideline Implementation: Team Communication

*Communication* is best defined as the meaningful exchange of information between individuals or groups. The need for effective communication in the perioperative setting is well recognized and vital to safe surgical practice. Studies aimed at exploring failures in communication and information transfer across the surgical care pathway indicate that poor communication contributes to an unsafe operating room culture and affects patient safety and employee engagement, decision making, efficiency, morale, and retention. More specifically, The Joint Commission cites communication failure as the leading root cause for medication errors, delays in treatment, and wrong-site surgeries as well as the second most frequently cited root cause for operative and postoperative events. The new Association of periOperative Registered Nurses (AORN) “Guideline for Team Communication” provides guidelines for using standardized processes to improve team communication. Key points include handovers between phases of care, pre-, intra-, and postoperative; a brief discussion on the surgical plan; a time-out or pause to verify the correct patient, procedure, site, and side; and a debriefing after the procedure to discuss what was done and what was learned or could be done better in the future.

Link, T. (2018). Guideline implementation: Team communication. *AORN Journal*, 108(2), 165-177.

## Surgical Scrub

The **surgical scrub** is another key element of patient care in the OR that is done to prevent surgical site infections.

Although the human hand represents a vital tool in the care of a patient, it also may act as a portal and transmitter of infection. The warm, moist conditions inside surgical gloves are an ideal environment for the rapid growth of microorganisms. To minimize the risk of infection to the patient, it is essential that OR personnel who will be directly involved in invasive surgical procedures follow appropriate hand-hygiene and hand-scrub procedures.

A systematic approach to this procedure is an efficient way to ensure proper technique is completed. The traditional surgical scrub starts with washing the hands thoroughly. This is followed by washing with a disposable scrub sponge from a clean area (the hand) to a less clean

area (the arm). Scrubbing with a long-acting, powerful antimicrobial sponge for at least 3 to 5 minutes allows adequate time to remove, inhibit, or kill as many microorganisms as possible and protect against infection if gloves develop holes, tears, or nicks during the operative procedure (Fig. 16.1). An alternative hand rub using a waterless alcohol-based preparation may be used, especially if surgical staff members are allergic to available antiseptic scrub solutions. Prior to performing the scrub, all jewelry must be removed. Nails should be clean and short. Nail acrylics and gels are not allowed.

## Surgical Attire

Wearing of appropriate surgical attire is another important step in reducing the risk of postoperative infections. There are several levels of surgical attire. The first level is worn by everyone working in the OR. This apparel is popularly referred to as *scrubs* because it is usually worn in a scrubbed or sterile environment. Scrubs are the shirts and pants or dresses worn as uniforms by surgeons, nurses, and other support staff in the OR. The next level of attire, which is typically referred to as *surgical attire*, consists of the sterile gown and gloves worn by staff working directly within the sterile field. This attire includes gloves, caps, masks, gowns, protective eyewear, and sturdy footwear (Fig. 16.2; Box 16.1).

## Connection Check 16.2

The OR nurse is completing a perioperative assessment for a patient who is scheduled for exploratory surgery. Which of the following interventions must be completed prior to this patient going into the OR? (*Select all that apply.*)

- Verify operative consent has been signed.
- Ensure allergy and ID bands are in place.
- Remove the patient’s personal clothing.
- Determine evidence of advance directive.
- Validate completed patient history and physical examination.
- Determine NPO status (last food/fluid consumed).

## ANESTHESIA

The term *anesthesia* is derived from the ancient Greek word *an-aisthesis*, meaning “lack of or no sensation.” Without anesthesia, most surgical procedures performed today would not be possible. The goals of anesthesia are amnesia, analgesia, depression of reflexes, muscle relaxation, and manipulation of physiological systems and functions. These are accomplished through the use of balanced anesthesia, which consists of one to several agents, each with a different action. The agents used depend on the patient, the procedure, and the anesthesia provider’s preference.

FIGURE 16.1 The surgical scrub.

FIGURE 16.2 Surgical attire.

Prior to surgery, each patient is given a preoperative physical examination and evaluation by the anesthesia team. On the basis of that evaluation, the patient is assigned a physical (P) status from the scale developed by American Society of Anesthesiologists (ASA) providers to assess and assign a perioperative risk, which helps in determining the anesthesia to be administered. This may also be called the *ASA status* using the same numbering system (Box 16.2).

### Types of Anesthesia

There are four major types of anesthesia. They are general, regional, and local anesthetics and monitored anesthesia care (MAC).

### Box 16.1 Surgical Attire

- **Caps and masks** are made from paper and should never be reused because there is no way to properly clean them.
- **Gloves** protect the hands from infectious materials and protect patients from microorganisms on staff members' hands. The use of gloves is *not* a substitute for proper hand-washing techniques.
- **Masks** are worn to help contain moisture droplets expelled as staff members speak, cough, or sneeze. A mask is also a protective barrier against accidental splashes of blood or other contaminated body fluids. Masks should be changed between each patient contact.
- **Eyewear** protects staff in the event of an accidental splash of blood or other body fluid. Eyewear must always be worn when there is a potential for splash exposure.
- **Surgical gowns** are worn to reduce the transmission of microorganisms from the skin and clothing of members of the surgical team to the patient. They are made of fluid-resistant materials to also protect the surgical team against blood and other fluid exposures.
- **Sturdy footwear** is worn to protect the feet from injury by sharps or heavy items that may accidentally fall on them. Shoe covers are unnecessary if clean, sturdy shoes are available for use only in the surgical area.

### Box 16.2 American Society of Anesthesiologists' Classification System

1. A normal healthy patient
2. A patient with mild systemic disease
3. A patient with severe systemic disease
4. A patient with severe systemic disease that is a constant threat to life
5. A moribund patient who is not expected to survive without the operation
6. A patient who is declared brain-dead and whose organs are being removed for donor purposes

### General Anesthesia

**General anesthesia** is what the layperson calls "being put to sleep." Under general anesthesia, a patient is in a reversible unconscious state. General anesthesia provides all of the goals stated previously, including manipulation of physiological systems and functions. It is achieved using a variety of methodologies, either alone or together. These include inhalation of volatile agents (gases), IV agents, and muscle relaxants. The patient receiving a general anesthetic that includes the administration of a muscle relaxant requires ventilatory support in the form of an endotracheal tube (ETT). General anesthetics can also be administered without the use of muscle relaxants. In such instances the airway is frequently supported with supraglottic airways,

such as a laryngeal mask airway (LMA), oral airway, or nasal airway. Airway management is discussed later in this chapter.

### Volatile Agents

Volatile (inhalation or gas) anesthetic agents used in the United States include isoflurane, sevoflurane, desflurane, and nitrous oxide. The potency of the gases is identified as the minimum alveolar concentration needed to achieve the desired effect (the lower the minimum alveolar concentration, the more potent the gas). For example, sevoflurane has a minimum alveolar concentration of 2, whereas nitrous oxide has a minimum alveolar concentration of 105. Although these gases have been used for more than 100 years, their exact mechanism of action is not yet clearly understood. Some studies indicate that the synaptic transmission of nerve impulses is reversibly inhibited in areas of the central nervous system.

### Intravenous Agents

Current IV anesthetics include:

- Barbiturates
- Benzodiazepines
- Opioids
- Propofol
- Ketamine
- Sedative-hypnotics

Barbiturates are central nervous system depressants. Examples include thiopental sodium, sodium methohexital, thiamylal, and Nembutal. They are excellent anesthetics and amnestics with a short onset and duration of action.

Benzodiazepines increase receptor availability for the inhibitory neurotransmitter gamma-aminobutyric acid. Examples include midazolam, diazepam, and lorazepam. They have a longer time to onset but have a longer duration than barbiturates. They are excellent amnestics but provide no analgesia.

Opioids bind to G-protein receptors as ligands or signaling molecules, producing analgesia. They also decrease the perception of pain. Examples include morphine, fentanyl, hydromorphone (Dilaudid), sufentanil, and remifentanil. They are excellent analgesics, but adverse effects include respiratory depression.

Propofol, sometimes referred to as “milk of anesthesia” because of its white color, is a hypnotic agent. It has a fast onset of action. The effects wear off quickly when the medication is discontinued. The patient is awake more quickly than with other sedatives. It is a good amnestic but provides no analgesia. For this reason, it is typically used in conjunction with analgesics.

Ketamine is a phencyclidine hydrochloride (PCP) derivative. It causes a dissociative state, which means the patient appears to be “dissociated” from the external environment but not necessarily asleep. Patients may experience hallucinations, so it is generally used in conjunction

with amnestics for sedation. It is an excellent analgesic and sedative.

Etomidate, a sedative-hypnotic, causes the least detrimental cardiovascular changes of all nonopioid induction medications. It may be used as an alternative to ketamine for induction in hypovolemic patients.

Dexmedetomidine (Precedex) is an anxiolytic, analgesic, and sedative. Unlike fentanyl and midazolam, it provides semi-arousable sedation without respiratory depression.

### Muscle Relaxants

Muscle relaxants are categorized as depolarizing or nondepolarizing agents. Depolarizing agents, such as succinylcholine, act by occupying the acetylcholine-binding sites at the neuromuscular junction. The membrane becomes depolarized; thus, no impulses can be transmitted, and paralysis ensues. The depolarizing action causes muscle fasciculation (twitching) prior to relaxation. Succinylcholine has a fast onset (30–40 seconds), quickly producing paralysis. Adverse effects include hyperkalemia, cardiac dysrhythmias, masseter spasm, and malignant hyperthermia (MH). Depolarizing agents cannot be reversed; they are metabolized and must “wear off.” Ventilatory support is not withdrawn until the medication effects are no longer apparent.

Nondepolarizing agents, such as pancuronium, vecuronium, cisatracurium, and rocuronium, work by competing with native acetylcholine for binding at the neuromuscular junction without causing depolarization. When these medications are administered, progressive paralysis results as a chemical response. The reaction starts in the smaller muscles of the eyelids and face, then moves to the larger muscle groups, including the tongue, neck, and shoulder, and finally to the respiratory muscles: the intercostals, larynx, and diaphragm. The onset of action is longer, minutes compared to seconds. Nondepolarizing agents do not cause muscle fasciculation. Different agents have differing lengths of onset, duration, and hemodynamic effects. All nondepolarizing muscle relaxants can be reversed, which must be done before ventilatory support and airway protection are withdrawn. Some reversal agents are called *cholinergic agents*. They increase the amount of acetylcholine at the neuromuscular junction and reverse the relaxation. Examples include neostigmine, pyridostigmine edrophonium, and sugammadex. Because of cholinergic side effects such as bradycardia and increased secretions, anticholinergic medications are usually given concurrently. Examples of these are atropine and glycopyrrrolates. See Table 16.2 for a list of anesthetic medications and Table 16.3 for the sequencing of anesthesia.

### Complications of General Anesthesia

Untoward effects or complications of general anesthesia include:

- Hypoxia
- Respiratory and cardiovascular dysfunction

**Table 16.2 Commonly Used Anesthetics**

Medication	Use	Advantages	Disadvantages	Comments
<b>IV Anesthetics</b>				
<b>Thiopental sodium (Pentothal)</b>	Induction of anesthesia	Induction; short-acting barbiturate	May cause laryngospasm; large doses may cause apnea and cardiovascular depression	Can be administered rectally as well as intravenously
<b>Sodium methohexital (Brevital)</b>	Induction of anesthesia	Ultra short-acting barbiturate	May cause hiccups	Can be administered rectally as well as intravenously
<b>Diazepam (Valium, Dizac)</b>	Amnestic, hypnotic preoperative medication	Good sedation	Prolonged duration of effects	Residual effects for 20–90 hr
<b>Midazolam (Versed)</b>	Hypnotic, anxiolytic sedation; adjunct to induction	Excellent amnestic; water soluble (no pain with IV injection); short acting	Slower induction than thiopental	Often used for monitored anesthesia care and regional anesthesia or insertion of invasive monitors
<b>Propofol (Diprivan)</b>	Induction and maintenance of anesthesia; sedation with regional anesthesia or monitored anesthesia care	Rapid onset; rapid awakening after infusion discontinued	May have pain on injection	Short elimination half-life (34–64 min)
<b>Ketamine (Ketalar)</b>	Induction and occasionally maintenance of anesthesia (IV or intramuscular)	Short acting; patient maintains airway; good for small children and patients with burns or trauma	In large doses, may cause hallucinations and respiratory depression	Needs darkened, quiet room for recovery to prevent hallucinations
<b>Etomidate (Amidate)</b>	Induction of anesthesia	Least cardiovascular changes	May have pain on injection	
<b>Dexmedetomidine (Precedex)</b>	Anxiolytic, analgesic, and sedative	Provides semi-arousable sedation without respiratory depression	May cause bradycardia and hypotension	
<b>Opioid Analgesics</b>				
<b>Morphine sulfate</b>	Premedication; perioperative pain	Inexpensive; excellent analgesia; duration of 4–5 hr; euphoria; good cardiovascular stability	Nausea and vomiting; may be sedating in high doses	Used intrathecally and epidurally for postoperative pain
<b>Fentanyl (Sublimaze)</b>	Surgical analgesia; epidural infusion for postoperative analgesia	Good cardiovascular stability; duration of action 0.5 hr	May be sedating in high doses	Most commonly used opioid
<b>Remifentanyl (Ultiva)</b>	Infused for surgical analgesia; small boluses given for brief, intense pain	Easily titratable; short duration; good cardiovascular stability	Expensive; requires mixing	

Continued

**Table 16.2 Commonly Used Anesthetics—cont'd**

Medication	Use	Advantages	Disadvantages	Comments
<b>Sufentanil</b> ( <i>Sufenta</i> )	Surgical analgesia	Short duration of 0.5 hr; prolonged analgesia; good cardiovascular stability	Prolonged respiratory depression	
<b>Depolarizing Muscle Relaxants</b>				
<b>Succinylcholine</b> ( <i>Anectine</i> , <i>Quelicin</i> )	Airway intubation; short cases	Rapid onset (30–40 sec); short duration	May cause fasciculations, postoperative myalgia; a trigger for malignant hyperthermia	Prolonged muscle relaxation with certain antibiotics
<b>Nondepolarizing Muscle Relaxants</b>				
<b>Cisatracurium</b> ( <i>Nimbex</i> )	Intubation of the airway; maintenance of relaxation	No significant cardiovascular or cumulative effects	No histamine release	Good for renal failure patients
<b>Rocuronium</b> ( <i>Zemuron</i> )	Intubation of the airway; maintenance of relaxation	Rapid onset (dose dependent)	Vagolytic that may increase heart rate	
<b>Vecuronium</b> ( <i>Norcuron</i> )	Intubation of the airway; maintenance of relaxation	No significant cardiovascular or cumulative effects	Requires mixing	Mostly eliminated in bile
<b>Pancuronium</b> ( <i>Pavulon</i> )	Maintenance of relaxation	Onset 2–3 minutes after administration	May cause tachycardia and increased heart rate	Mostly renal elimination
<b>Cholinergic Agent</b>				
<b>Neostigmine</b> ( <i>Prostigmin</i> )	Reverses effects of nondepolarizing neuromuscular blocking agents	Prevents acetylcholine breakdown by inhibiting acetylcholinesterase		Given with either atropine or glycopyrrolate
<b>Anticholinergics</b>				
<b>Atropine</b>	Blocks the effects of acetylcholine; reverses muscle relaxants; treats sinus bradycardia	Increases heart rate; suppresses salivation and bronchial and gastric secretions	Depresses sweating; may cause dry mouth, flushing, dizziness	Selective at muscarinic receptor in smooth and cardiac muscles and exocrine glands
<b>Glycopyrrolate</b> ( <i>Robinul</i> )	Similar to atropine	Slightly increases heart rate; does not cross blood–brain barrier	Prolonged duration of effects	Lower incidence of dysrhythmias than with atropine
<b>Sugammadex</b>	Reverse nondepolarizing neuromuscular blocking agents	Fewer adverse effects than older reversal agents; does not inhibit acetylcholinesterase, so no cholinergic effects	Significantly interferes with oral contraceptives for 2 weeks after receiving it (inform women of childbearing age if used); may cause bradycardia	Approved December 2015. Rocuronium and Vecuronium are the most reliably reversed muscle relaxants with this agent

**Table 16.3 Sequence of General Anesthesia**

Stages	Actions
<b>Induction</b>	<ul style="list-style-type: none"> <li>● Gain IV access and place monitors (blood pressure cuff, electrocardiogram leads, pulse oximeter); preoxygenate with oxygen via face mask.</li> <li>● Infusion of narcotics and/or muscle relaxants</li> <li>● Induction with sodium pentothal (propofol, ketamine, or etomidate)</li> <li>● Adequate sedation (indicated when patient becomes apneic and eyelid reflex disappears)</li> </ul>
<b>Intubation</b>	<ul style="list-style-type: none"> <li>● Place and secure airway.</li> </ul>
<b>Maintenance</b>	<ul style="list-style-type: none"> <li>● Maintain patient using balanced anesthesia.</li> </ul>
<b>Emergence</b>	<ul style="list-style-type: none"> <li>● Suction patient to decrease the chance of laryngospasm and aspiration.</li> <li>● Reverse residual muscle relaxant.</li> <li>● Provide oxygen to wash out inhalation agents.</li> <li>● Remove airway when patient is breathing on his or her own and follows commands.</li> </ul>
<b>Recovery</b>	<ul style="list-style-type: none"> <li>● Patient transported to post-anesthesia care unit (recovery room) or intensive care unit; vital signs monitored and oxygenation continued until patient is stable</li> </ul>

- Hypotension
- Hypertension
- Fluid and electrolyte imbalances
- Residual muscle paralysis
- Neurological problems such as dementia, prolonged awakening, paresthesias
- Malignant hyperthermia

**Malignant hyperthermia (MH)** is a hypermetabolic state that can be caused by exposure to a triggering agent, such as a volatile gas anesthetic (except nitrous oxide) and/or succinylcholine. The triggering agent causes sustained muscular contractions related to an increase in intracellular calcium ion concentration. The sustained contractions result in signs of hypermetabolism. These include acidosis, tachycardia, hypercarbia, glycolysis, hypoxemia, and hyperthermia. The reaction usually begins to occur soon after the exposure, but it has been known to be delayed until the patient is in the recovery area.

The most specific sign of MH is skeletal muscle rigidity. However, the first sign noted by the anesthesia or nursing staff is an unexplained tachycardia. For the anesthesia provider, hypercarbia is the most sensitive indicator of potential MH. Myoglobinuria is another early sign. The patient's urine turns from dark amber to brown. Hyperthermia, the classic sign of MH, is usually a late sign.

**Safety Alert** Malignant hyperthermia is a medical emergency. Without quick and appropriate treatment, the patient will die. It is treated with dantrolene, a muscle relaxant that depresses the coupling mechanism in

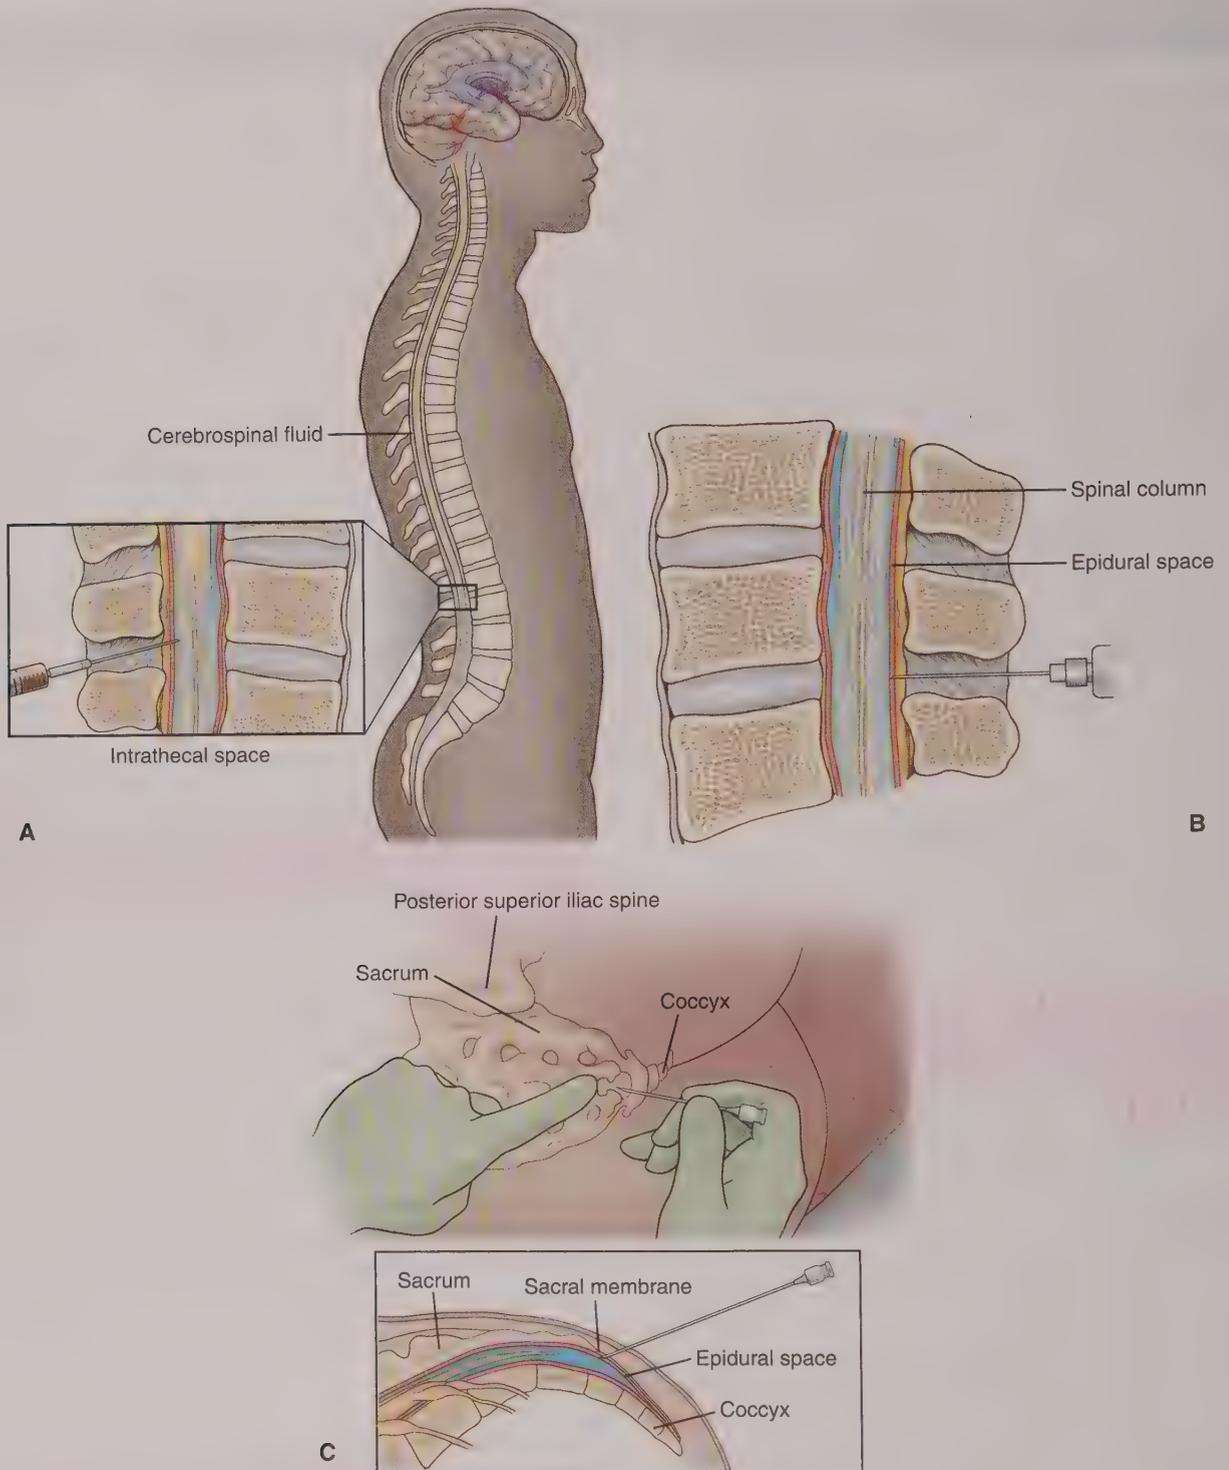

skeletal muscles. Important nursing interventions include administering dantrolene and cooling the patient. This can be done by removing blankets and drapes, IV infusion of cold normal saline, ice bags around the body, and cold nasogastric lavage. If MH occurs during the intraoperative period, cold body cavity lavage can be done. When MH is diagnosed early and treated promptly, the mortality rate for the condition should be near zero. The incidence of MH in children is 1 in 30,000, and in adults, it is 1 in 100,000. About 1 in 2,000 may harbor the genetic change that makes an individual susceptible to MH. It can be found in all ethnic groups.

All patients should be asked preoperatively if they or any family members have had problems with anesthesia. Patients should be cautioned to wear an alert bracelet that indicates they are susceptible to MH when exposed to anesthesia.

### Regional Anesthesia

**Regional anesthesia** is a local anesthetic used to block or anesthetize a nerve or nerve fibers. Types of regional anesthesia or blocks include spinal, epidural, caudal, and nerve blocks.

Spinal medication is injected into the spinal canal or intrathecal space surrounding the spinal cord, typically in the lower back or lumbar region (Fig. 16.3A). The injection lasts for several hours. It may also be given as continuous **spinal anesthesia** via a catheter. It is important to keep the head of the patient's bed flat after spinal anesthesia to avoid a headache.

**FIGURE 16.3** A, Intrathecal anesthesia injected into the spinal canal or intrathecal space surrounding the spinal cord. B, Epidural anesthesia injected into the epidural space. C, Caudal anesthesia injected into the epidural space through the caudal canal in the sacrum.

Epidural medication is injected into the epidural space into the lumbar region or thoracic region (Fig. 16.3B). A catheter is inserted for periodic or continuous injection. Spinal headache is avoided because the intrathecal space is not entered. Caudal is a form of epidural anesthetic where

the medication is injected into the epidural space through the caudal canal in the sacrum (Fig. 16.3C).

A nerve block, anesthetizing of a nerve in an extremity, is done to allow surgery in a specific area (e.g., performing a block on the axillary nerve to allow surgery in the arm).

Untoward effects of epidural or spinal anesthesia may include the following:

- A rapid decrease in blood pressure due to vasodilation of the sympathetic nerves that control vasomotor tone, causing peripheral pooling and decreasing venous return. A vasopressor may be used to counteract this effect.
- Spinal headache is a risk with intrathecal anesthesia because of potential leakage of cerebrospinal fluid. It usually resolves in 1 to 3 days.
- Respiratory paralysis is a risk with a high intrathecal injection.
- Seizure is a risk if medication is injected intravascularly.
- Finally, nerve damage and epidural hematoma/abscess occur rarely.

### Local Anesthetics

Local anesthetics cause a reversible conduction blockade of nerve impulses when they are placed in proximity to nerve membranes. The anesthetic diffuses into the nerves and inhibits the propagation of signals for pain and muscle contractions. Pain fibers are affected first, then sensory fibers and motor fibers. High concentrations inhibit all qualities of sensation as well as muscle control. Lower concentrations selectively inhibit pain sensation, with minimal effect on muscle power. Adverse reactions are due to overdose, rapid absorption, and hypersensitivity. Reactions vary from mild (hives, itching, and rash) to severe (acute anaphylactic reaction). Examples include amides and esters, which are defined by their chemical composition.

#### Amides

- Lidocaine has a rapid onset and a short to intermediate duration of 60 to 120 minutes. The maximum dose is 4.5 mg/kg (30 mL in an average 70-kg adult). It has excellent spreading ability and is the main local anesthetic.
- Bupivacaine has a slow onset and a long duration of 4 to 8 hours. The maximum dose is 2 mg/kg (50 mL in an average 70-kg adult). It provides excellent postoperative analgesia.

Both medications may be mixed with epinephrine for its vasoconstrictive effects to help control bleeding at the procedure site. It also prolongs the action of the medications.

#### Esters

- Cocaine has a slow onset and medium duration. It is used in nasal surgery more for its vasoconstrictive effects than as an analgesic. It can cause hypertension and tachycardia as a result of increased catecholamine release.

### Monitored Anesthesia Care

Monitored anesthesia care (MAC) provides anesthesia without unconsciousness. The patient has a decreased level of consciousness but maintains a patent airway and responds

appropriately to verbal commands and physical stimulation. Objectives for the patient receiving MAC are:

- Maintenance of consciousness
- Elevation of pain threshold
- Enhanced cooperation
- Some degree of amnesia
- Minimal variation in vital signs
- Quick and safe return to activities of daily living

MAC couples sedation/analgesia with local anesthetics. The usual medications utilized are benzodiazepines such as diazepam and midazolam and narcotics such as fentanyl and meperidine. During the administration of both local anesthesia and MAC, signs are posted outside the OR alerting staff that the patient is awake. It is important that OR staff are mindful of conversations in the room and keep them to the minimum needed to communicate needs or to comfort the patient.

### Connection Check 16.3

Which of the following is an example of a local anesthetic?

- Diazepam
- Lidocaine
- Pavulon
- Morphine

### AIRWAY MANAGEMENT

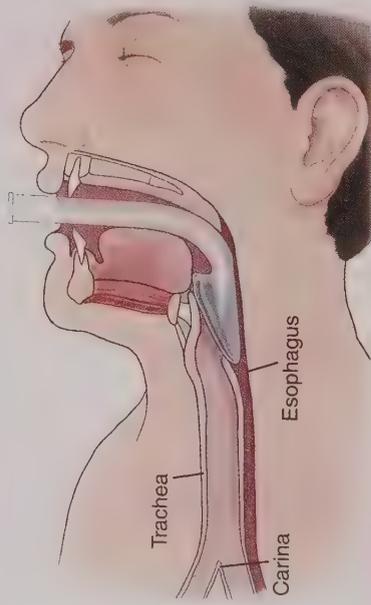

Airway management is the process of protecting and ensuring adequate oxygenation and ventilation during an operative procedure. This is not only an essential component of care for patients receiving general anesthesia but also an important consideration with any kind of anesthesia that can potentially compromise the airway. Airway compromise can be caused by relaxation of the soft tissues of the oropharynx. This relaxed effect may create an occlusion of the trachea or trigger a **laryngospasm**, where the larynx constricts and cannot easily be re-expanded. The airway may also be compromised in patients who present with anatomical abnormalities such as a small mouth, short neck, inability to open the mouth fully, obesity, or facial or cervical injuries. See Table 16.4 for the different methods of managing airway patency in the OR.

Airway complications include:

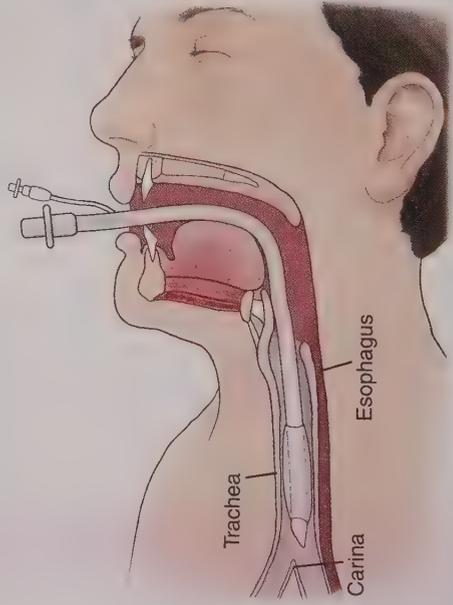

- **Laryngospasm:** A reflexive and prolonged closure of the vocal folds in response to a trigger. It is most common during anesthesia induction/intubation or extubation. It is caused by stimulation of the airway by airway devices, secretions, or gastric contents.
- **Bronchial intubation:** This occurs when an ETT is passed below the carina into one of the mainstem bronchi, resulting in hyperinflation of the intubated lung and collapse (deflation) of the opposite lung.

**Table 16.4** Types of Airway Devices

Name	Application	Indication	Comments
<p><i>Face mask</i></p>	<p>Placed externally, covering patient's nose and mouth</p>	<p>To maintain the patient with spontaneous breathing</p>	<p>Use is dependent on factors such as the type and duration of the procedure and the patency of the airway.</p>
<p><i>Laryngeal mask airway</i></p>	<p>Inserted into the pharynx above the glottis, forming a low-pressure seal that allows positive pressure into the airway without entering the trachea (Fig. 16.4)</p>	<p>Used for patients undergoing anesthesia for brief and superficial surgeries</p>	<p>Less irritating than the standard endotracheal tube (ETT) and does not require muscle relaxants or laryngoscopy for placement</p>
<p><i>ETT</i></p>	<p>A tube inserted into the trachea just above the carina; may have a cuff that is inflated just enough to occlude the airway, preventing aspiration (Fig. 16.5)</p>	<p>Best method for managing the airway Protects the airway, and the patient is able to breathe by spontaneous respirations with assistance as needed. Muscle relaxants can be given, and mechanical ventilation can be initiated.</p>	<p>Depending on the procedure and the patient's anatomy and physical condition, there are assorted variations of ETTs that can be used.</p>

**FIGURE 16.4** Laryngeal mask airway for airway protection during anesthesia.

**FIGURE 16.5** Endotracheal tube for airway protection during anesthesia.

- **Tracheal and esophageal perforation:** This may occur during intubation if excessive force is applied or as a complication of the use of a stylet or other stiff intubation-assisting device.
- **Aspiration:** The patient regurgitates, and stomach contents or other secretions go into the lungs, resulting in pneumonia or airway obstruction.

### Connection Check 16.4

Which of the following is an airway used to support airway management? (Select all that apply.)

- A. MAC
- B. MH
- C. LMA
- D. ETT
- E. PCP

### CASE STUDY: EPISODE 2

Review of Ms. Doe's laboratory and diagnostic studies reveals the following: white blood cell leukocytosis, 12,500/mm<sup>3</sup>; neutrophil count, 80%; and abdominal radiograph revealing hardened fecal material in the appendix. Findings from her physical examination include moderate abdominal distention and rebound pain on abdominal palpation. The attending surgeon schedules Ms. Doe for an emergency **exploratory laparotomy** (diagnostic surgery that allows providers to examine the abdominal organs) with possible **appendectomy** (removal of her appendix). Ms. Doe is transported emergently to the OR holding area from the ED. She was accompanied by her eldest daughter (the patient-identified spokesperson), who has since been escorted to the family lounge to await further information from the surgeon. As Ms. Doe arrives in the holding area of the OR, you observe that she is demonstrating nonverbal expressions of pain and is outwardly combative because she has previously expressed that she feels she will die on the operating table...

## POSITIONING THE PATIENT IN THE OPERATING ROOM

Patient positioning for surgical procedures is done to provide for optimal anatomical exposure and patient safety. There are a variety of **positioning devices** utilized to ensure safe alignment of anatomical structures while contributing to surgical outcomes. The use of these devices may place the patient at risk for temporary or permanent injury. The challenge in positioning is to provide the exposure the surgeon needs in order to perform the procedure and allow for access

to IV lines and monitoring equipment while also ensuring a safe, comfortable position for the patient.

Patient positioning is a collaborative activity involving all surgical team members. The surgeon determines the position that is appropriate for a specific procedure, and after consultation with the surgical team, the patient is placed in the appropriate position. The RN documents all positioning aids used and the team members assisting with patient positioning. The RN ensures that the patient is treated in a dignified manner throughout the positioning activity. The patient's dignity and right to privacy cannot be overlooked before, during, and after positioning activities.

### Common Intraoperative Positions

There are four standard positions commonly used for surgical procedures. These positions are often modified according to the surgeon's preferences and surgical approaches and the patient's physiological requirements (Fig. 16.6). These positions are:

- Supine (Trendelenburg, reverse Trendelenburg, and Fowler's are modifications)
- Prone (jackknife is a modification)
- Lateral
- Lithotomy

#### Supine

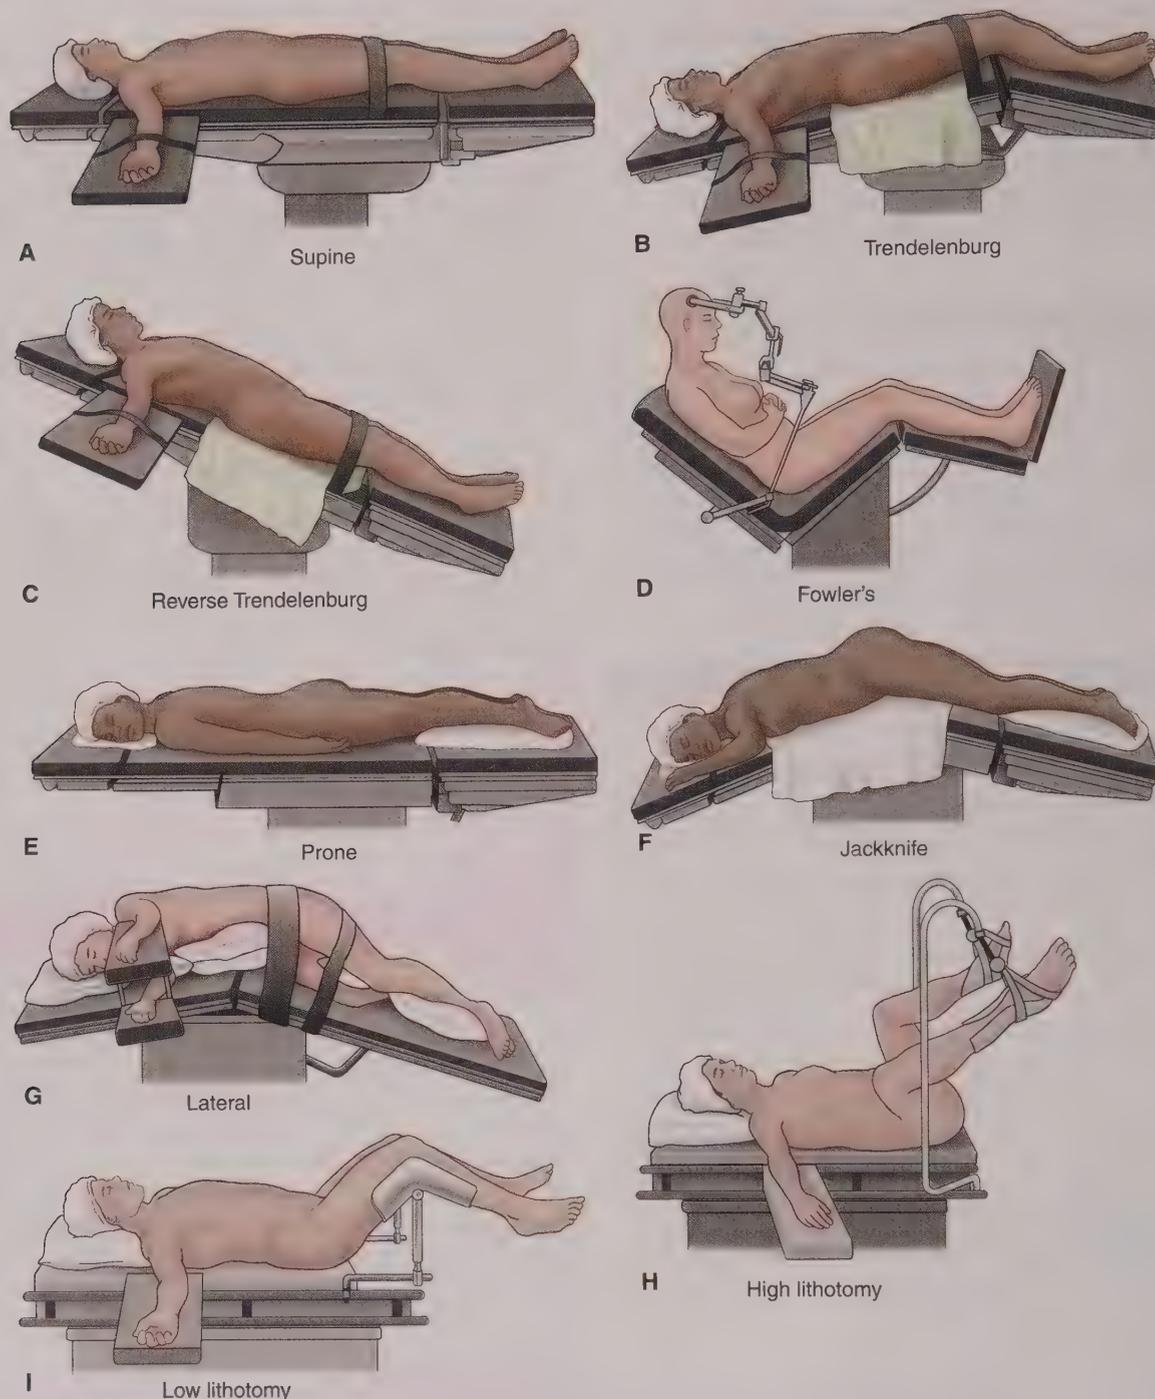

The **supine** position (Fig. 16.6A) is the most frequently used patient position and is the most natural position for the body at rest. This position is used for procedures on the anterior surface of the body, including abdominal, abdominothoracic, vascular, orthopedic, head/neck, and ophthalmic operations. The patient is placed on his or her back with the legs extended and uncrossed and the arms on arm boards or at the sides with the palms down. Proper arm placement with extension at less than a 90-degree angle is necessary to avoid brachial plexus stretching and compression. The arms must not be positioned lower than the spinal column, and the spinal column should be in a straight line, with the legs parallel to the OR bed. The patient's head is in line with the spine, and the face is upward. The hips are parallel with the spine.

#### Trendelenburg

In the **Trendelenburg position** (Fig. 16.6B), the patient is placed in the supine position, and the OR bed is modified to a head-down tilt of 35 to 45 degrees. This position is used for procedures in the lower abdomen or pelvis when it is desirable to move the abdominal viscera away from the pelvic area for better exposure. Although exposure is increased, lung volume is decreased, and the pressure of the organs against the diaphragm mechanically compresses the heart.

#### Reverse Trendelenburg

In the **reverse Trendelenburg position** (Fig. 16.6C), the entire OR bed is tilted so that the patient's head is higher than his or her feet. This position is used for procedures on the head and neck to facilitate exposure, aid breathing, and

**FIGURE 16.6** Common intraoperative positions: A, Supine position. B, Trendelenburg position. C, Reverse Trendelenburg position. D, Fowler's, or sitting, position. E, Prone position. F, Jackknife position. G, Lateral position. H, High lithotomy position. I, Low lithotomy position.

decrease blood supply to the operative area. A padded footboard is used to prevent the patient from sliding toward the foot of the bed.

#### Fowler's

For the **Fowler's position** (Fig. 16.6D), also called the sitting, lawn-chair, or beach-chair position, the patient is first placed in the supine position. The foot of the OR bed is lowered slightly, flexing the patient's knees. The body section is raised to 35 to 45 degrees, thereby becoming the

backrest. The entire OR bed is tilted slightly, with the head end downward to prevent the patient from sliding. The patient's feet rest on a padded footboard. For cranial procedures, the head is supported in a headrest. This position can be used for shoulder or breast reconstruction procedures.

#### Prone

In the **prone** position (Fig. 16.6E), also known as the ventral recumbent or ventral decubitus position, the patient is placed facedown, resting on his or her abdomen and chest.

Chest rolls under the clavicles to the iliac crests raise the weight of the body from the abdomen and thorax. The arms may be supported along the sides of the body. The head is turned to one side, resting on a padded donut to prevent pressure on the ears, eyes, and face. Female breasts should be moved laterally to reduce pressure on them, and male genitalia must be positioned to be free from pressure.

### Jackknife

The **jackknife position**, or Kraske position (Fig. 16.6F), is a modification of the prone position in which the patient is placed in the prone position on the OR bed and then inverted in a V position. The hips are over the center break of the OR bed between the body and leg sections. This position is used for gluteal and anorectal procedures.

### Lateral

The **lateral** (lateral decubitus) position (Fig. 16.6G) is used primarily for thoracic, renal, and orthopedic (hip) procedures. The patient is placed in the supine position for anesthetizing and then turned to the unaffected side.

### Lithotomy

In the **lithotomy** position, the patient is in the supine position, with the legs raised and abducted to expose the perineal region. The legs and feet are placed in stirrups that support the lower extremities. The lithotomy position is used for vaginal, obstetrical, urological, and rectal procedures and for radical resections of the groin, the vulva, and the rectal areas. There are two variations of the lithotomy position.

### High Lithotomy

The high lithotomy position (Fig. 16.6H) is frequently used for procedures that require a vaginal or perineal approach.

### Low Lithotomy

The low lithotomy position (Fig. 16.6I) is used in vaginal procedures and routinely for most laparoscopic surgeries. See Table 16.5 for risks and interventions related to surgical positions.

**Table 16.5 Risks and Interventions for Surgical Positions**

Position	Risks	Interventions
<b>Supine</b>	Pressure points: occiput, scapulae, thoracic vertebrae, olecranon process, sacrum, coccyx, knees, and heels Pressure to peripheral vessels and nerves, primarily brachial plexus and ulnar nerves Venous pooling of blood in the legs	Pressure-reducing operating room (OR) mattress with additional padding as needed Arm boards level with OR mattress, less than 90-degree extensions and palms up; ankles uncrossed Application of sequential compression devices
<b>Trendelenburg</b>	In addition to supine risks: Diminished lung capacity Shift in venous pooling toward heels Sliding and shearing	Close respiratory monitoring Slow, smooth postural transitions to diminish cardiovascular effects Flex knees slightly; limit time in position.
<b>Reverse Trendelenburg</b>	In addition to supine risks: Deep vein thrombosis (DVT) in lower extremities Sliding and shearing	Antiembolic or sequential compression stockings Padded footboard
<b>Fowler's</b>	Pressure to scapulae, sacrum, coccyx, ischium, back of knees, and heels Air embolism if venous sinus is opened Shearing DVT in lower extremities Venous pooling that shifts toward lower body	Pressure-reducing OR mattress with additional padding as needed Doppler probe over chest wall; insertion of central venous catheter Momentary tilting of torso slightly away from the OR bed to allow skin to realign with skeletal structures Sequential compression stockings Slow, smooth postural transitions to diminish cardiovascular effects

Continued

**Table 16.5 Risks and Interventions for Surgical Positions—cont'd**

<b>Position</b>	<b>Risks</b>	<b>Interventions</b>
<b>Prone</b>	<p>Pressure to cheeks, eyes, ears, breasts, genitalia, patellae, and toes</p> <p>Falls and dislodgment of airway, monitoring cords, and IV lines</p> <p>Diminished lung capacity</p> <p>Injury to shoulders, arms, and upper extremity nerves</p>	<p>Use a pressure-reducing OR mattress with additional padding as needed; check ears, cheeks, eyes, and genitalia for pressure; tape eyes closed.</p> <p>Lock both beds; use a minimum of four people for turning patient; secure airway and all cords and lines.</p> <p>Chest rolls and close respiratory monitoring</p> <p>Arms on arm boards are flexed and pronated, with upper arms at less than 90-degree angle to the OR bed; pads placed above and below elbows to free ulnar nerve.</p>
<b>Jackknife</b>	<p>In addition to prone risks:</p> <p>DVT in lower extremities</p>	<p>Check distal pulses before, during, and after positioning; if position maintained for extended time, use antiembolic or sequential compression stockings.</p>
<b>Lateral</b>	<p>Pressure to structures on dependent side: ear, shoulder, ribs, hip, greater femoral head, knee, and ankle</p> <p>Risk of tilting and falling during procedure</p> <p>Brachial plexus injury</p> <p>Venous pooling that shifts toward dependent side</p> <p>Diminished capacity of dependent lung</p> <p>DVT in lower extremities</p>	<p>Use a pressure-reducing OR mattress with additional padding as needed; check that earlobes are not folded over; place pillow between knees and under ankles; be sure neck is in alignment.</p> <p>Flex dependent leg for support; may require additional straps or wide tape to secure patient.</p> <p>Place padded roll under lower armpit.</p> <p>Slow, smooth postural transitions to diminish cardiovascular effects</p> <p>Ventilator support includes positive end-expiratory pressure; anesthesia team inserts double-lumen ETT to ventilate dependent lung if a thoracotomy is performed.</p> <p>Check distal pulses before, during, and after positioning; use antiembolic or sequential compression stockings.</p>
<b>Lithotomy</b>	<p>Hip dislocations, fractures, and muscle and nerve injuries</p> <p>Pressure injuries to feet, ankles, and knees</p> <p>Back strain</p> <p>Diminished lung capacity</p> <p>Venous pooling that shifts toward head</p> <p>DVT in lower extremities</p> <p>Crushed fingers</p>	<p>Securely fasten stirrups to OR bed; avoid hyperabduction of hips and leaning against inner thighs.</p> <p>Use stirrups that disperse support and pressure over wide areas; check distal pulses before and after positioning.</p> <p>The buttocks should not hang off the edge of the torso section of the bed.</p> <p>Close respiratory monitoring</p> <p>Slow, smooth postural transitions to diminish cardiovascular effects</p> <p>Antiembolic or sequential compression stockings if patient in position for more than 2 hours</p> <p>Ensure fingers are away from the break in the OR bed when leg section is elevated.</p>

**Safety Alert** Fourteen basic safety rules apply to all patients:

1. The side rails of the transport stretcher/bed are always up while the patient is on the vehicle.
2. At a minimum, two people are needed to assist the patient from the stretcher to the OR table.
3. The OR bed and stretcher are locked while the patient is being transferred.
4. Both side rails of the stretcher are down during transfer.
5. The safety strap is applied across the patient's thighs once he or she is on the OR table.
6. Body parts should not extend over the table.
7. The patient's legs should never be crossed.
8. Body parts should not come in contact with metal or an unpadded surface.
9. Always consult with the anesthesiologist before touching or moving an anesthetized patient.
10. Move the anesthetized patient slowly and gently.
11. Always check the pressure points and cauterizing pad if a patient is moved during the procedure.
12. Document baseline skin condition, position, and positioning devices/equipment.
13. Perioperative personnel should use proper body mechanics when transporting, moving, lifting, or positioning patients.
14. Positioning equipment should be used in a safe manner and according to the manufacturer's written instructions.

## Positioning Devices

The choice of a particular positioning device for a surgical procedure depends on many variables. Patient variables such as height, weight, age, and physiological condition and the position required for the procedure influence which devices are used. The surgeon's preference affects the selection of a positioning device as well. Routine positioning devices used for most surgical procedures include but are not limited to the following: OR bed, headrest, arm boards, arm restraints, padding for bony prominences, blankets, pillows, safety straps, sandbags, bean bags, towels and sheets, foam pads, and gel-type devices.

## Positioning Complications

Preoperative assessment of the patient is crucial in providing information about the patient's individual risk factors that may influence the selection of **positioning devices** and any alterations to a proposed position. Patients at high risk for complications due to positioning include:

- Geriatric patients, whose thin skin layer and impaired circulation make them susceptible to skin breakdown due to pressure and moisture

- Pediatric patients (immature systems)
- Extremely thin patients who may be malnourished, anemic, or hypovolemic
- Obese patients with an overabundance of fat tissue
- Paralyzed patients
- Diabetic patients who are already prone to skin breakdown
- Patients with prosthetic or arthritic joints
- Patients with edema and circulatory limitations
- Patients with medical conditions such as cancer that can alter cardiac, respiratory, or immune reserves
- Patients with infections
- Patients who have existing or previous trauma

Improper positioning may contribute to the development of a **pressure injury**. Also referred to as a decubitus ulcer, pressure injury is localized damage to the skin and/or underlying tissue, generally over a bony prominence. Pressure due to prolonged contact causes constriction of the blood vessels feeding the area and consequent damage to the skin and possibly underlying areas. High-risk situations include but are not limited to:

- Long surgical procedures
- Vascular surgery in which blood perfusion may be already compromised
- Demineralizing bone conditions (e.g., malignant metastasis or osteoporosis)
- Excessive sustained pressure on body parts due to surgical procedures or retraction

## Connection Check 16.5

The nurse caring for a patient in the supine position on the OR table incorporates which nursing diagnosis into the plan of care?

- A. Risk for fluid volume deficit
- B. Risk for knowledge deficit
- C. Risk for aspiration
- D. Risk for potential alteration in skin integrity

## NURSING MANAGEMENT

### Nursing Diagnoses

- **Risk for impaired tissue and skin integrity**
- **Risk for infection**
- **Risk for injury** related to the surgical environment
- **Risk for knowledge deficit**
- **Risk for potential unplanned hypothermia** related to ambient room temperature and/or exposed body cavities
- **Risk for potential thrombus** related to prolonged immobility

## Nursing Interventions

### ■ Assessments

- Ensure OR consent has been signed.  
*Signed consent indicates the patient has had all risks, benefits, and alternatives to the procedure explained and is required before surgery can begin.*
- Ensure the patient is correctly positioned and the appropriate patient positioning devices are used.  
*Avoid unnecessary pressure points, thus skin breakdown or injury.*
- Monitor staff in the use of a proper scrub and donning of OR attire, and validate that OR room and equipment have been thoroughly cleaned.  
*Maintain sterility in the OR to prevent infection.*
- Ensure readiness of the OR suite.  
*Ensure a smooth procedure without unnecessary delays and or/complications.*
  - Check that all necessary equipment/supplies are available.  
*Having all equipment/supplies at the ready helps ensure a smooth procedure without unnecessary delays.*
  - Ensure irrigation fluid and instruments are at the appropriate temperature.  
*Fluid or instruments at inappropriate temperatures can cause skin irritation, breakdown, or burns or unwanted changes in patient temperature*
  - Confirm flashed instruments are cool.  
*Insufficiently cooled instruments can cause skin or tissue burns.*

### ■ Actions

- Perform time-out.  
*Time-out is a safety factor essential in preventing “preventable errors.”*
- Perform equipment safety check.  
*Properly functioning equipment can prevent patient injury.*
- Utilize **sterile technique** (avoiding the chances of exogenous items coming in contact with the catheter) while inserting a Foley catheter and setting up the sterile field.  
*Proper sterile technique prevents patient infection.*
- Assist the anesthesia care provider during intubation by applying cricoid pressure as indicated.  
*Cricoid pressure can help prevent patient aspiration.*
- Properly ground the patient as indicated.  
*Proper grounding can prevent the patient from electrical injury and burns.*
- Keep the patient safety belt in place while the patient is on the OR bed.  
*Patient falls can be avoided through the proper use of a safety belt and side rails.*
- Apply support hose and sequential compression devices (SCDs) as indicated.  
*Deep vein thrombus can be prevented by the use of support hose and SCDs.*

- Keep the patient warm with blankets, and use warm irrigation.  
*Hypothermia can be avoided by using blankets and warm irrigation.*
- Maintain a sterile field.  
*Maintain sterility in the OR to prevent infection.*
- Accurately record the number of sponges and sharps used on the count board.  
*Accurate counting prevents retained foreign bodies.*
- Accurately measure irrigation fluids and communicate the amount to the anesthesia care providers.  
*Accounting for blood and fluid loss helps avoid a fluid deficit.*
- Keep OR doors closed during the procedure.  
*Maintain sterility in the OR to prevent infection.*
- Keep hallways clear of extra equipment.  
*An unobstructed path is necessary to ensure quick access to the patient in an emergency.*

### ■ Teaching

- Explain to the patient your actions and what to expect when entering the OR.  
*Decrease and manage the patient’s fear of the operative experience.*
- Keep the family updated during the procedure (at the time when surgery begins and then every 2 hours).  
*Decrease and manage the family’s fear of the operative experience.*

## Connection Check 16.6

The nurse understands that which actions are essential when providing support to the intraoperative patient and family during the OR experience? (Select all that apply.)

- Introduce the patient and family to the surgical team members.
- Give family members updates every 2 hours as possible during the procedure.
- Explain what to expect from the operative experience.
- Alert the family to mealtimes.
- Explain that once the procedure is complete, the surgeon will discuss surgery outcomes.

## Making Connections

### CASE STUDY: WRAP-UP

The nurse caring for Ms. Doe alerts both the surgeon and anesthesiologist that she appears to be in pain and is combative. Her pre-operative check is completed quickly, and she is provided with IV pain medication and a benzodiazepine for her anxiety. Her daughter is brought to her bedside to provide support while she waits to enter the OR. Soon after, Ms. Doe is transported into the

OR and transferred to the OR bed. Her daughter is escorted to the waiting area and is told she will be updated on a regular basis. After proper positioning and safety checks are completed, the time-out is performed and surgery is started. Ms. Doe has her appendix removed without complication.

### Case Study Questions

- If Ms. Doe indicates there is a family history of problems with anesthesia, it is important to discuss this with the anesthesia provider in order to avoid the use of which MH-triggering agent?
  - Nitrous oxide
  - Morphine
  - Succinylcholine
  - Ketamine
- The nurse understands that surgical attire is worn for what purpose? (*Select all that apply.*)
  - Prevent transmission of microorganisms between the patient and the team
  - Promote cleanliness in the OR suite
  - Prevent the spill of blood and body fluids to the surgical team's apparel
  - Promote confidentiality of patient and staff identity
  - Facilitate the surgical team working together collaboratively
- Prior to the start of Ms. Doe's surgical procedure, all members of the surgical team participate in a time-out. Which of the following are components of the time-out? (*Select all that apply.*)
  - Correct procedure
  - Correct site
  - Correct equipment
  - Laterality
  - Correct OR
- While Ms. Doe is in the OR, what considerations will be taken to ensure her safety and positive outcome? (*Select all that apply.*)
  - Time-out
  - Maintenance of sterile technique
  - Continuous patient monitoring
  - Instrument count/sponge count
  - Breaks for personnel
- Potential adverse effects of the supine position for Ms. Doe's surgery include which of the following? (*Select all that apply.*)
  - Skin breakdown in the heels and elbows
  - Venous pooling in the legs
  - Ulnar nerve injury
  - Retinal detachment
  - Cerebral edema

## CHAPTER SUMMARY

Surgical procedures are classified as elective, which indicates they can be scheduled at the patient and surgeon's convenience; urgent, which means they should be performed within 48 hours; and emergent, which means the procedure needs to be performed immediately to prevent loss of life or bodily function. There are six types of surgery: palliative (to relieve symptoms or improve life quality), restorative (to restore bodily function), curative (removing disease through surgery), diagnostic (or exploratory—to diagnose disease), cosmetic (to improve or change the look of a patient), and transplant (to replace a poorly or nonfunctioning organ).

The surgical team includes the surgeon; an anesthesia provider; a perioperative RN; and a variety of unlicensed assistive personnel, such as surgical technologists and OR associates and/or critical care technicians. Team members who have a key function in a surgical procedure are usually categorized according to their roles and responsibilities in preparing for the operation—nonsterile team members and sterile team members. The surgeon is the identified team leader.

As the patient's advocate, the perioperative nurse has a vital responsibility to ensure patient safety during all surgical procedures. Procedures the OR nurse may perform to accomplish these goals include patient assessment, time-out or "surgical pause," planning, interventions during surgery, and postoperative evaluation. An essential component of safety is hand washing whenever necessary during the operative procedure.

An important part of the perioperative nurse's role is to quickly develop a therapeutic and trusting relationship with the patient and family to help with decreasing fear and managing anxiety regarding the operative experience. Ensuring that the patient is introduced to the anesthesia provider and talks with the surgeon is vital. Making sure the patient knows what to expect from the procedure helps decrease fear. Regular updates, ideally every 2 hours, should be given to the family during the procedure.

Anesthesia is the process of allowing the patient to be pain-free and comfortable during surgery. It also provides optimal operating conditions for the surgeon. There are four major types of anesthesia: general, regional, monitored anesthesia care (MAC), and local. An example of local anesthesia is lidocaine.

Malignant hyperthermia is a rare but potentially fatal complication of anesthesia, typically due to a genetic disorder making the patient more susceptible. When these patients are exposed to any of the volatile gases except nitrous oxide or succinylcholine, they exhibit signs of hypermetabolism. Left undetected and/or untreated, circulatory collapse and possibly death can occur in a short amount of time.

Airway management is the process of protecting the airway and ensuring adequate oxygenation and ventilation during the operative procedure. Oxygen delivery devices include the face mask, LMA, and ETT.

Patient positioning for surgical procedures requires the collaboration of the entire surgical team to provide for

optimum anatomical exposure and patient safety. A variety of positioning devices may be used depending on the position necessary to perform the surgery. Positions include supine, Trendelenburg, reverse Trendelenburg, prone, lateral, and lithotomy. Skin breakdown is a risk when positioning the patient for surgery.

## Priorities for the Postoperative Patient

Maren Reinholdt

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Discussing the significance of the postoperative period
2. Explaining the priority assessments for the post-surgical patient
3. Developing support strategies for the surgical patient's family in the immediate postoperative period
4. Applying the vital postoperative interventions for the patient in the immediate postoperative period
5. Evaluating postoperative interventions on the inpatient unit

### CONCEPTS

- Assessment

### Finding Connections

#### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Howard Wells is a 70-year-old African American man. He is widowed and lives with his daughter, a nurse. Mr. Wells's daughter brought him to the hospital today for surgery. Mr. Wells has colon cancer and is scheduled to have a partial colectomy in the operating room. His additional significant medical history includes coronary artery disease and myocardial infarction 3 years ago; he is in chronic atrial fibrillation, has obstructive sleep apnea, and has type 2 diabetes. His regular medications include metoprolol, Coumadin, and omeprazole. Mr. Wells is scheduled to have general anesthesia and is to be admitted to the hospital for a few days after surgery. Mr. Wells's daughter will wait in the family waiting room during the procedure. She is eager to visit him in the post-anesthesia care unit...

### ESSENTIAL TERMS

Anesthesia  
Hand-off  
Patient-controlled analgesia (PCA)  
Phase I  
Phase II  
Phase III  
Post-anesthesia care unit (PACU)  
Sedation

### INTRODUCTION

The postoperative period begins immediately after surgery and continues until the first follow-up postoperative physician visit. During this time, it is vital that the patient be closely monitored to ensure recovery and avoid serious complications that may occur related to the surgical experience. Postoperative care is delivered on a continuum. It begins in the post-anesthesia care unit immediately after surgery and continues either in a hospital setting or at home. The focus of this chapter is the specialized care delivered in the post-anesthesia care unit and important nursing assessments and interventions delivered on the general inpatient surgical unit.

### THE POST-ANESTHESIA CARE UNIT

The **post-anesthesia care unit (PACU)** is the special critical care unit where patients are transferred immediately following **sedation or anesthesia** for surgical, diagnostic, or therapeutic procedures. Because of anesthesia, there is a temporary decrease in or loss of consciousness and loss of motor and reflexive control of respiration. The transition from anesthesia

to recovery carries risks for potentially life-threatening complications as well as discomforts such as nausea and vomiting and pain. During this transition, patients need assistance to maintain a safe internal physiological balance.

The goal of care in the PACU is to safely allow the patient who has had anesthesia/sedation to awaken and resume normal bodily functions while controlling/minimizing pain and preventing complications of surgery and anesthesia. The PACU is generally located adjacent to the operating room (OR) or procedure area to decrease the time needed for transportation immediately following procedures and to ensure proximity to anesthesia providers if needed. The role of the nurse in the PACU is to frequently assess and monitor the patient's recovery from anesthesia and support and manage pain relief, maintaining and assessing the patient carefully. In addition, the nurse is responsible for educating the patient and family about the care following the PACU (next level of care), whether it be in the patient's home or in an acute care unit in the hospital.

Coordination of care with the staff and providers in the OR and the preoperative area as well as the availability of preoperative records defining all aspects of the patient's history are essential for the PACU nurse to adequately and completely assess the patient's condition, understand the potential risks or complications, and individualize care for each patient and family.

### Post-Anesthesia Care Unit Phases of Care

The American Society of PeriAnesthesia Nurses has defined three levels of PACU care: phase I, phase II, and phase III. **Phase I** involves the nursing care provided in the immediate post-anesthesia period. This phase is generally in the PACU or intensive care unit (ICU). There is intensive, close monitoring of all vital signs with continuous electrocardiogram monitoring. There is a focus on cardiac, respiratory, and neurological functions, surgical-site monitoring, and pain and temperature control. The goals of care in this phase are to stabilize the patient's vital signs, allow the patient to awaken from anesthesia, and achieve adequate pain control. After meeting specific criteria, the patient is transferred to phase II care or to an inpatient unit. The specific discharge criteria vary by institution but generally include:

- An awake patient with a stable airway
- Adequate oxygen saturation
- Stable vital signs

In **phase II**, the monitoring is less intensive because the patient has met the criteria allowing transfer from phase I. The focus of nursing care is on preparing the patient to be discharged to an extended-care environment or home. Again, the patient needs to meet specific criteria for discharge home (Box 17.1).

**Phase III**, or extended observation of post-anesthesia care, focuses on providing ongoing care for those patients remaining in the postoperative care area after discharge criteria have been met. Extended observation starts after phase II

### Box 17.1 Home Discharge Criteria

- The patient is awake and alert.
- Vital signs have returned to preoperative values.
- Tolerating liquids without nausea or vomiting
- Pain relief and comfort are provided with oral pain medications and nonpharmacological measures (e.g., positioning, pillow, cold and heat therapy).
- The patient is stable and able to walk safely.
- The patient is able to void (urinate) before discharge—voiding prior to discharge is typically required when urinary retention is a risk of the surgical procedure or the patient has a history of urine retention. The patient may go home without voiding if there is no risk per provider order.
- There are no signs of bleeding from the surgical site.
- Skin is intact, and the surgical wound is clean and dry.
- There are no adverse reactions or complications from surgery and nonsurgical procedures related to the surgery (e.g., radiology procedure).
- The patient demonstrates understanding of teaching, including medications and activities. It is critical that an interpreter is available if the patient does not speak or understand the English language.

critical elements have been met, but additional care is needed because a transfer bed is not ready or transportation home is unavailable. When this occurs, the nurse continues to monitor and provide care to this patient. A delay in discharge home when anticipated after a same-day surgery is most often caused by uncontrolled postoperative nausea and vomiting or pain, delays in the surgery schedule and OR availability, and social factors, such as a responsible adult not being present to take the patient home. The goal is to prepare the patient for transfer to an inpatient unit when a transfer bed is made ready or self-care and discharge home.

### Connection Check 17.1

The nurse understands PACUs are designed for which of the following?

- A. Managing the transition from anesthesia to long-term care
- B. Managing the transition from anesthesia through phase III of recovery
- C. Managing the transition from anesthesia through phase II of recovery
- D. Managing the transition from anesthesia through rehabilitation

### Post-Anesthesia Care Unit Settings

Post-anesthesia care is provided in a variety of settings. They include but are not limited to:

- Inpatient PACU
- ICU

- Outpatient PACU
- Procedure areas

### Inpatient Post-Anesthesia Care Unit

The inpatient PACU is typically one big room, but recent PACUs are being designed with individual rooms for patient privacy. Patients are managed by anesthesia and nursing staff. Inpatient PACUs care for patients recovering from major or minor surgical procedures on a continuum from low to high risk of complications. Examples of surgical procedures requiring recovery in an inpatient PACU include radical retropubic prostatectomy, lung lobectomy, ileostomy reversal, nephrectomy, exploratory laparotomy, and open reduction and internal fixation of fractures.

The staffing varies according to the acuity level of the patients. The nurse–patient ratio can be 1:1 or 1:2. The extended-stay patients, patients meeting transfer or discharge criteria but requiring extended monitoring, may be in 1:3 ratios. The length of stay is generally short, 1 to 2 hours, except for the extended-stay patients, so patient flow is fast, with high volumes.

### Intensive Care Unit

Postoperative care in the ICU is indicated for critically ill patients who require extensive and complex monitoring because of the high risk of complications. These patients are transferred directly to the ICU immediately following the operative procedure. They are managed by the ICU team and nursing staff. Examples of patients who undergo recovery in the ICU setting include patients undergoing transplant surgery, craniotomy, and coronary artery bypass procedures and trauma patients undergoing multiple procedures.

### Outpatient Post-Anesthesia Care Unit

Outpatient post-anesthesia care is provided for patients going home after the procedure. The post-anesthesia care is delivered in the same outpatient setting where the procedure is performed. These settings include an outpatient area in the hospital setting, freestanding ambulatory surgery centers, providers' offices, urgent-care centers, and rural health clinics.

Examples of procedures done on an outpatient basis include orthopedic arthroscopic procedures and cholecystectomies. Outpatient procedures can also include more complex procedures such as mastectomy. Other procedures commonly performed in surgery centers or provider offices include diagnostic procedures, dental procedures, some plastic surgery, and ophthalmological procedures.

### Procedure Areas

Patients undergoing procedures in a "procedure area" such as endoscopy or cardiac vascular interventional laboratories require postoperative monitoring and care in the procedural area if IV sedation or anesthesia is required for the procedure before return to the inpatient setting or being discharged home.

## Connection Check 17.2

The nurse understands that a patient undergoing right upper lobe lobectomy requiring general anesthesia will receive recovery care in which of the following settings?

- Outpatient PACU
- Procedure area PACU
- Surgical center PACU
- Inpatient PACU

## PATIENT CARE IN THE POST-ANESTHESIA CARE UNIT

Patients are all individuals and react differently to the different types of medications, treatments, surgery, procedures, or anesthesia. Therefore, postoperative nursing management should be individualized and should include:

- Assessment and monitoring of the patient's response to surgery and anesthesia
- Timely interventions to resolve the problems, concerns, and needs of patients (physical, psychological, emotional, spiritual)
- Evaluation of these interventions, including effects or adverse effects of medications (e.g., opioids)
- Reassessment of the patient's condition
- Evaluation of achievement of discharge criteria

### Priority Assessments

The patient is brought into the PACU immediately following surgery accompanied by the anesthesia provider who provided care for the patient during the surgical procedure, a member of the surgical team, and an OR nurse. Good OR–PACU coordination is necessary to ensure a good transition of care. In addition to all of the priority needs, good communication is necessary during the initial transfer from the OR table to the correct stretcher or bed before transfer to the PACU; some patients may require a special bed to best meet their recovery needs.

On admission to the PACU, the patient is simultaneously connected to cardiac and other monitoring devices while an immediate assessment is performed. Critical areas of assessment on admission to the PACU include the following:

- Airway patency
- Respiratory status, including oxygen saturation (and capnography, if indicated) and auscultation of lung sounds
- Vital signs:
  - Blood pressure
  - Pulse: apical and peripheral
  - Cardiac monitor rhythm
  - Hemodynamic pressure readings if indicated
  - Temperature
- Neurological function, including level of consciousness, motor function, and sensation
- Temperature and color of skin

- Pain level/comfort level
- Condition of dressings; assessing for bleeding or drainage
- Condition of visible incisions
- Presence and patency of IV catheters, drains, and other catheters
- Hydration status and fluid therapy

### Diagnostic Tests

Laboratory tests done postoperatively assess for bleeding, fluid loss, electrolyte imbalance, renal function, and clotting abnormalities. Table 17.1 outlines common laboratory tests done postoperatively. Depending on the patient and comorbidities, some of these tests are done in the initial recovery stage, such as a glucose test if it is a patient

with diabetes, but most are done the next day, on postoperative day 1 (POD 1), as routine screening for postoperative complications.

Other studies done postoperatively may include:

- Chest radiograph
- Electrocardiogram (ECG)

A chest radiograph is done postoperatively if any complications from surgery due to central line placement, intubation, or anesthesia are suspected. An ECG is always done as a preoperative assessment. It is ordered postoperatively if any ECG changes were identified during surgery or after. Measurement of the ST segment among post-anesthesia patients will detect perioperative acute myocardial ischemia, and cardiac rhythm analysis may detect postoperative atrial fibrillation.

**Table 17.1 Common Laboratory Tests in the PACU**

Category	Significance
Prothrombin time/activated partial thromboplastin time (PT/aPTT); international normalized ratio (INR)/platelet count	<p>These tests are done to evaluate clotting abnormalities. This is significant because of the possibility of bleeding postoperatively. It is also important to monitor if patients were on anticoagulants preoperatively.</p> <p>Normal values:</p> <p>PT: 10–13 seconds</p> <p>aPTT: 25–35 seconds</p> <p>INR: 0.9–1.1</p>
Renal function: blood urea nitrogen (BUN), creatinine	<p>Renal function may be decreased because of dehydration from blood or fluid loss. Consider age and renal disease.</p> <p>Normal values:</p> <p>BUN: 8–21 mg/dL</p> <p>Creatinine: 0.5–1.2 mg/dL</p>
Glucose	<p>Decreased glucose levels should be ruled out in cases of decreases in level of consciousness or inability to arouse postoperatively.</p> <p>Normal value:</p> <p>Glucose: 65–99 mg/dL fasting blood glucose level</p>
Electrolytes: serum potassium (K), serum sodium (Na)	<p>Values may be abnormal because of fluid loss, blood loss, or overhydration.</p> <p>Normal values:</p> <p>Potassium: 3.5–5.0 mEq/L</p> <p>Sodium: 135–145 mEq/L</p>
White blood cell (WBC) count	<p>An increase in the WBC count may indicate infection.</p> <p>Normal value:</p> <p>WBC count: 4.5–11.1 <math>10^3/\text{mm}^3</math></p>
Hematocrit/hemoglobin	<p>Low values may indicate excessive blood loss.</p> <p>Normal values:</p> <p>Hematocrit: females, 36%–48%; males, 42%–52%</p> <p>Hemoglobin: females: 11.7–15.5 g/dL; males, 14–17.3 g/dL</p>

### Connection Check 17.3

The nurse understands that the immediate postoperative assessment upon admission to the PACU includes which of the following? (*Select all that apply.*)

- A. Medical history
- B. Full system review
- C. Neurological assessment
- D. Blood pressure
- E. Surgical-site drainage

### Pain Management

Pain management is an essential component of patient management in the PACU and beyond. In the preoperative area, the nurse assesses and documents the patient's physical and emotional status and discusses pain management following surgery. It is important that the nurse understands each patient's perception of pain, teaches him or her about postoperative pain management expectations, and engages the patient and family in developing a postoperative pain management plan. Important discussion and education points include:

- The importance of pain control and treating pain before it becomes severe
- The importance of reporting pain; terminology; pain scale that will be used in the PACU; patient's terminology regarding pain location and intensity
- Goals of treatment for pain, understanding that on a scale of 0 to 10, a goal of zero pain is often not realistic
- Pharmacological and nonpharmacological options available to manage pain in the PACU
- Fears about pain medication, such as addiction
- Chronic, current, or past use of opioids
- Nonpharmacological methods that the patient currently uses to reduce anxiety and improve comfort (e.g., music, deep breathing, prayer)
- Whether having family at the bedside is helpful or if the patient prefers to be alone

### Pain Management Strategies

Although postoperative pain is expected in all patients, behavioral responses to pain vary widely from patient to patient. During the immediate postoperative period, anesthetic effects may mask or prevent the patient from reporting pain. The PACU nurse should use an appropriate method of pain assessment for the patient, such as a numerical scale, the Wong-Baker FACES scale, or a behavioral scale. The PACU nurse must know that there are physiological signs that indicate pain even if the patient is unable or unwilling to describe what he or she is feeling. These include restlessness; sweating; dilation of pupils; increase in respiration, blood pressure, and heart rate; and piloerection. Additionally,

the patient may be frowning, opening his or her eyes widely, making facial grimaces, clenching the teeth, or moaning—all indications of pain. It is recommended that the nurse assume that pain is present, with or without overt symptoms, and provide treatment based on the knowledge that surgery is painful (see Evidence-Based Practice: Postoperative Pain Management Strategies).

### Evidence-Based Practice

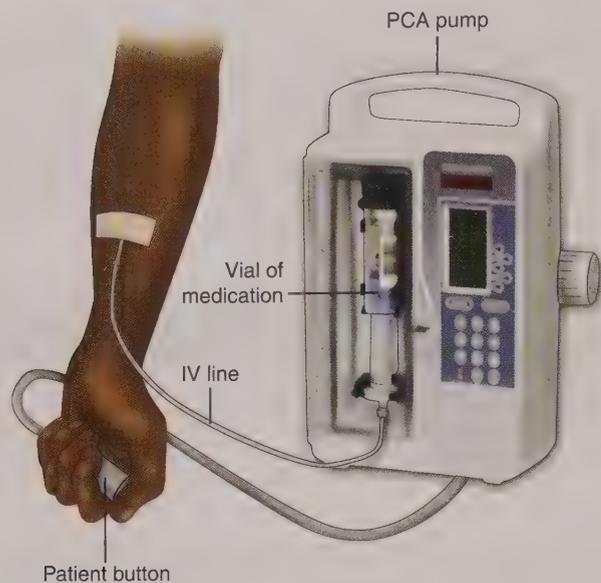

#### Postoperative Pain Management Strategies

In 2016, the American Pain Society, in conjunction with other professional organizations, published a clinical practice guideline on treating postoperative pain. The report states that although most patients experience pain postoperatively, less than half of the patients say that their pain is adequately controlled. The clinical practice guideline comprises 32 recommendations made by an expert panel after a systematic review of the evidence. The recommendations include preoperative evaluation for current opioid use and education about pain control expectations, tailoring of pain control plans to the individual patient and surgery, and the use of different pharmacological and nonpharmacological modalities (e.g., combining analgesics like ketamine, lidocaine, gabapentin, and pregabalin with opioids and the use of transcutaneous electrical nerve stimulation). The panel also recommends that clinicians provide education to all patients and primary caregivers on how to taper off pain medications.

Chou, R., Gordon, C. B., de Leon-Casasola, O. A., Rosenberg, J. M., Bickler, S., Brennan, T., ...Wu, C. L. (2016). Guidelines on the management of postoperative pain. *Journal of Pain*, 17(2), 131–157. doi:10.1016/j.pain.2015.12.008

The best results in postoperative pain management involve multimodal pharmacological therapy or synchronous administration of NSAIDs, acetaminophen, opioids, and local anesthetics. In addition to pain medication, studies demonstrate that a variety of nonpharmacological methods decrease pain (and the need for medication) postoperatively, such as music therapy, massage, prayer, and meditation; however, few PACUs offer these options to all patients as a part of their pain management programs.

Many postoperative patients are given a **patient-controlled analgesia (PCA)** pump for the delivery of opioid medications (Fig. 17.1). A PCA pump is an infusion of a prescribed amount of analgesia through an IV route when the patient pushes a button. This requires the patient to be able to understand and communicate effectively with the

**FIGURE 17.1** Patient-controlled analgesia (PCA) pump. The patient pushes a button when pain medication is required, resulting in the delivery of a preset dose of pain medication through the IV line.

nurse and might not be appropriate therapy if cognitive or communication problems exist. Assessment of the patient in the preoperative area prior to initiating PCA is essential to the safe implementation of this type of pain control. Also important is education that only the patient (not family members, the nurse, or other healthcare providers) should push the button to deliver a dose of the pain medication.

### Management of Postoperative Nausea and Vomiting (PONV)

Postoperative nausea and vomiting (PONV) is often more anticipated and feared by patients than postoperative pain. In the immediate postoperative period, PONV can cause dehydration, electrolyte imbalance, wound dehiscence, and aspiration. Postoperative nausea and vomiting has been associated with an increased length of stay, a decreased ability to perform activities of daily living and return to school/work after discharge, and emergency department visits and hospital readmissions. Risk factors for PONV include being a young, nonsmoking female and having a history of PONV or motion sickness. Certain types of surgeries are more likely to cause PONV, such as cholecystectomies and laparoscopic, intra-abdominal, gynecological, and neurological surgeries. General anesthesia causes more PONV than regional anesthesia. The longer the patient is under general anesthesia, the more likely the patient is to experience PONV. High doses of the neuromuscular blockade reversing agent neostigmine also increase the likelihood of PONV.

In order to treat PONV, postoperative opioid use should be minimized, and hydration should be optimized. It is suggested that nausea be measured on a numerical scale, much

like pain, or a descriptor scale (mild, moderate, severe) so that providers can decide which antiemetic approach to use. This method of rating nausea gives nurses the ability to determine the effectiveness of different pharmacological agents. Multimodal pain management strategies should be taken to avoid relying on opioids alone, which increase PONV. Prophylactic treatment by using a combination of antiemetic medications in high-risk patients before surgery can help reduce PONV.

### Connection Check 17.4

Which statement is true about the complicated nature of managing pain medication in the immediate post-anesthesia patient?

- All patients respond to pain in the same way but have different medications ordered.
- All patients respond to pain in different ways, potentially requiring different medications.
- The synergy of all multimodal pain management is unpredictable.
- Nonpharmacological methods of pain control do not work in the PACU setting.

### CASE STUDY: EPISODE 2

Mr. Wells is transferred from the OR to the PACU. He is drowsy but responds to his name. He has on an oxygen mask, and a nasogastric tube is in place. He has a urinary catheter and is on the cardiac monitor, which shows atrial fibrillation with a rate of 85 beats per minute (bpm) and a respiratory rate of 12. His oxygen saturation is 97%. His breath sounds are clear and equal bilaterally. He has a dry abdominal dressing and two drains draining a small amount of sanguineous liquid. On his legs, he has intermittent pneumatic compression boots that are connected to the small pump on the bed. In addition to IV fluid that is running, Mr. Wells has a PCA pump, and he received IV doses of fentanyl and morphine before leaving the OR. He responds to his name and shakes his head “no” when asked if he has any pain. He says the pain is 1 on a scale of 0 to 10...

### Potential Complications

Immediately following surgery and anesthesia, all patients are at risk for respiratory depression from anesthesia and pain medication and bleeding from the surgical procedure itself, requiring careful and frequent nursing assessment. In addition to these major complications, Table 17.2 includes

additional serious complications that require either prevention or treatment in the PACU (see Geriatric/Gerontological Considerations).

## Geriatric/Gerontological Considerations

The normal physiological decline associated with aging (see Chapter 6) can be exacerbated by the effects of stress of surgery, anesthesia, and immobility. Older adults are at higher risk for postoperative complications, delayed recovery, and an increased length of stay. The postoperative nurse should anticipate the following:

- **Respiratory:** decreased rib-cage expansion, increasing the risk for atelectasis; hypoxia; hypercarbia; increased work of breathing
- **Cardiac:** reduced cardiac output; hypotension, which can develop quickly; higher risk for postoperative atrial fibrillation; greater risk for orthostatic hypotension related to dehydration
- **Renal:** greater risk for postoperative volume overload and electrolyte imbalances; greater risk of medication toxicity—requires careful evaluation of dosage of medications excreted by the kidney
- **Skin:** more susceptible to friction, sheer, pressure, and moisture
- **Delirium:** higher risk postoperatively. Free from tethering devices as soon as possible, avoid physical restraint, use nonpharmacological interventions (e.g., reorientation, fall risk precautions, involve family in care), and consider administering antipsychotics.
- **Immobility/decreased mobility:** increased risk of deep vein thrombosis (DVT), pneumonia, pressure injuries, respiratory failure, delirium, orthostatic hypotension, and fatigue
- **Nutrition:** the older adult is more likely to have inadequate nutrients for wound healing and strength.

## NURSING MANAGEMENT

### Nursing Interventions

#### Assessment

- **Neurological:** level of consciousness/motor and sensation  
*Anesthesia produces a decreased level of consciousness or a reversible loss of consciousness. A continued decrease in level of consciousness, restlessness, agitation, and confusion may*

*indicate inadequate reversal of anesthesia or complications of anesthesia or could also be a result of hypoxia. Motor and sensation abilities must also be monitored to assess for the reversal of any nerve blocks administered during surgery for patient safety.*

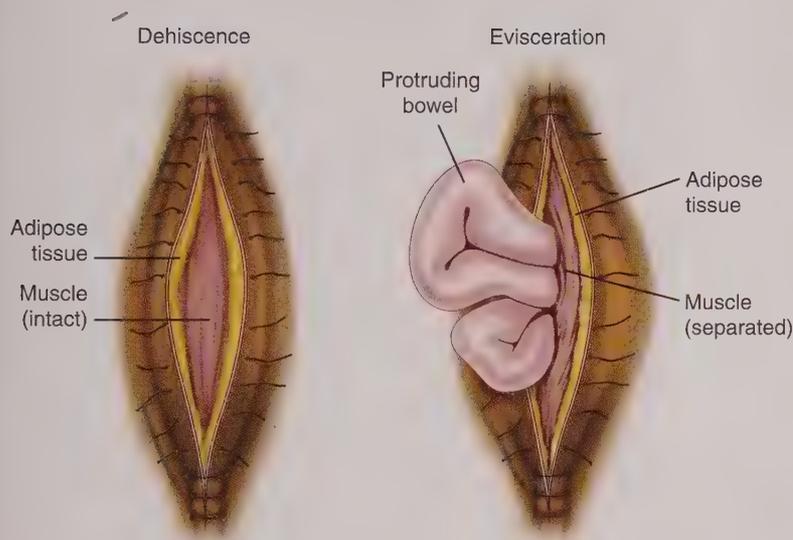

- **Vital signs**  
*Any deviation from the normal range of values for blood pressure, heart rate, oxygenation saturation, respiratory rate, or temperature could indicate a postoperative complication.*  
*Excessive blood or fluid loss may cause hypotension and tachycardia.*  
*Excess catecholamine production from the physical and emotional stress of surgery may cause hypertension and tachycardia.*  
*Increased or decreased respiratory rate, use of accessory muscles, and decreased oxygen saturation may indicate inadequate reversal of or recovery from anesthesia.*  
*Increased temperature may be an indication of malignant hyperthermia, which can be triggered by anesthesia; hypothermia, not unusual postoperatively because of cool OR temperatures, prolonged skin exposure, and anesthesia that interferes with normal temperature control, may require warming measures.*
- **Peripheral pulses/skin temperature/skin color**  
*Weak peripheral pulses, cool skin temperature, and/or pale skin color could signify inadequate perfusion resulting from blood loss and decreased cardiac output.*
- **Urine output**  
*Decreased urine output, less than 30 mL/hr, may indicate dehydration due to fluid or blood loss or urinary retention.*
- **Pain**  
*Pain is an expected outcome of a surgical procedure but should be managed appropriately. Regular assessment of pain is necessary for the evaluation of pain management. Uncontrolled pain may be an indication of a complication.*
- **Skin/surgical incisions/wounds**  
*Extended time in intraoperative positioning may cause excessive pressure and skin breakdown. Excessive blood or drainage on wound dressings may indicate inadequate wound closure or bleeding and requires follow-up by the provider.*
- **Actions**
  - Connect to continuous cardiac monitor immediately upon admission to the PACU.  
*Changes in vital signs or dysrhythmias may indicate complications associated with anesthesia or the operative procedure.*
  - Start admission assessment immediately upon admission to the PACU.  
*It is essential to get a baseline to understand the patient's presenting status.*
  - Document vital signs.  
*Vital signs are often documented every 15 minutes to allow prompt response to changes as necessary.*

**Table 17.2 Potential Complications in the PACU**

<b>System</b>	<b>Complication</b>	<b>Intervention</b>
<b>Neurological</b>	<ul style="list-style-type: none"> <li>● Drowsy and hard to arouse</li> <li>● Restless</li> <li>● Not following commands</li> <li>● Confusion</li> </ul>	<ul style="list-style-type: none"> <li>● Check glucose level.</li> <li>● Hold pain medication.</li> <li>● Consider naloxone (Narcan).</li> <li>● Restrain as ordered.</li> <li>● Reorient/provide explanation/reassurance.</li> <li>● Have family present as possible.</li> <li>● Evaluate oxygenation; evaluate for alcohol withdrawal.</li> </ul>
<b>Respiratory</b>	<ul style="list-style-type: none"> <li>● Airway obstruction/stridor</li> <li>● Inadequate oxygenation</li> <li>● Ineffective ventilation</li> <li>● Aspiration</li> </ul>	<ul style="list-style-type: none"> <li>● Check airway and O<sub>2</sub> saturation.</li> <li>● Check breath sounds (auscultate).</li> <li>● Supplement oxygen as per provider's orders.</li> <li>● Consider ventilatory support.</li> <li>● Chest radiograph</li> </ul>
<b>Cardiovascular</b>	<ul style="list-style-type: none"> <li>● Hypotension</li> <li>● Tachycardia</li> <li>● Bleeding</li> <li>● Venous thromboembolism (VTE)/pulmonary embolism (PE)</li> <li>● Dysrhythmias</li> <li>● Myocardial infarction</li> <li>● Fluid imbalance; dehydration/retention</li> </ul>	<ul style="list-style-type: none"> <li>● Monitor vital signs.</li> <li>● Fluid and blood replacement as ordered.</li> <li>● For prevention of VTE: compression stockings, intermittent pneumatic compression boots</li> <li>● For treatment of VTE: anticoagulation</li> <li>● Monitor intake and output.</li> <li>● Monitor electrolytes.</li> </ul>

<b>Skin integrity</b>	<ul style="list-style-type: none"> <li>● Skin breakdown or redness at pressure sites</li> <li>● Abnormal wound drainage; yellow/cloudy, bloody, foul-smelling</li> <li>● Severe wound complications such as dehiscence (wound rupture along surgical suture) or evisceration (extrusion of viscera outside the body through the surgical incision; Fig. 17.2)</li> </ul>	<ul style="list-style-type: none"> <li>● Relieve pressure as possible through positioning and support with blankets and pillows.</li> <li>● Check amount of drainage, color, and frequency of dressing change; reinforce dressing and report to provider.</li> <li>● Dehiscence/evisceration requires immediate notification and intervention by the surgeon; maintain low Fowler's position, minimize movement, and cover wound with sterile saline dressing.</li> </ul>

**Table 17.2 Potential Complications in the PACU—cont'd**

System	Complication	Intervention
<b>Pain</b> (see Chapter 11 for more information on pain control)	<ul style="list-style-type: none"> <li>Persistent pain may lead to deconditioning and respiratory compromise, such as atelectasis, through decreased mobility; hormonal response, such as excess catecholamine production resulting in hypertension and tachycardia; and neuropsychiatric effects, such as insomnia.</li> </ul>	<ul style="list-style-type: none"> <li>Mild pain—nonopioid (e.g., acetaminophen, NSAIDs)</li> <li>Moderate to severe pain—multimodal therapy: nonopioids, mu opioid agonists (e.g., morphine, hydromorphone, fentanyl), and adjuvants (e.g., anticonvulsants, local anesthesia, antidepressants)</li> <li>Other pain modalities provided by the providers and supported by the nurses: preemptive analgesia (given preoperatively by anesthesia) and rescue analgesia (given postoperatively to supplement pain medication)</li> <li>Other considerations: multimodal therapy (opioid and nonopioid analgesia to avoid unwanted sedation, regional blocks by anesthesia providers, and systemic or epidural patient-controlled anesthesia (PCA). Systemic PCA (IV) is used more often than epidural PCA for surgery below the waist or specific area that needs an analgesia block (e.g., thoracic block).</li> <li>Comfort measures: physical/psychological (e.g., positioning, heat and cold therapies, sensory aids), sociocultural (e.g., family, caregiver, interpreter), psychospiritual (e.g., chaplain, religious objects), and environmental (e.g., reasonably quiet room, privacy)</li> </ul>

**FIGURE 17.2** Surgical wound-healing complications include wound dehiscence; wound rupture along the surgical suture line; and wound evisceration, the extrusion of viscera outside the body through the surgical incision.

- Participation in hand-off from the OR  
*Good communication is essential for a smooth transition of care between the OR and PACU to ensure the patient's needs are met and complications are avoided as much as possible (Box 17.2).*
- Continuous monitoring of patient's status  
*The initial PACU assessment is compared with the preoperative assessment. The assessment is monitored continuously to track the patient's recovery or to identify problems.*
- Medicate as ordered for pain and nausea.  
*Nausea centers may be triggered by anesthesia; pain is a result of tissue trauma from surgery.*

- Hand-off to inpatient unit if necessary (Box 17.3)  
*A clear, concise hand-off to the inpatient unit is essential for safe patient care.*

#### ■ Teaching

- Family care (Box 17.4)
  - Inform family when the patient arrives in the PACU, and make contact every hour.
  - Communicate plan of care (i.e., time of transfer to bed or discharge home).
  - Allow visiting per hospital guidelines.

### Box 17.2 Hand-Off of Care—OR to PACU

Transferring patient care, especially immediately after surgery, requires effective multidisciplinary communication. Without effective hand-off communication, there is an added risk of error due to lack of information and/or misinformation.

Following the admission assessment confirming the patient's stability, the PACU nurse participates in the **hand-off** communication with the three OR team members who have accompanied the patient in transfer (anesthesia, surgical team member, and OR nurse). This hand-off communication includes:

- Patient identification using two identifiers
- Significant medical history
  - Details about the surgical procedure/significant events that occurred in the OR
  - Significant laboratory results
  - Anesthesia and reversal agents administered intraoperatively
- Medications administered intraoperatively, including last dose of pain medication
- Fluid intake and estimated blood loss
- Placement of IV lines and drains
- Important home medications
- Discussion of actual and/or potential clinical issues (e.g., pain, changes in vital signs)
- Nonclinical information, such as family or placement issues
- Overall plan of care
- Team members' names and contact information

Both providers and the OR nurse give their own report. Prior to handing off care to the PACU nurse, the surgical provider and PACU nurse should discuss orders that have been written, the plan for pain management, and any potential complications that can be anticipated.

OR, Operating room; PACU, post-anesthesia care unit.

- **If the patient is being discharged, provide discharge instructions with family members present. *Communicating and maintaining contact with a family member, as well as allowing visitation, is essential to help relieve anxiety and stress. Because of the effects of anesthesia, the patient may not remember discharge instructions. Having a family member present is essential.***

### Connection Check 17.5

Upon patient admission to the PACU, the nurse understands that the priority intervention is which of the following?

- A. Administer antiemetics.
- B. Administer pain medication.
- C. Connect patient to the monitor.
- D. Start IV fluid.

### Box 17.3 Hand-Off of Care—PACU to Inpatient Unit

The clear and concise hand-off of care from the PACU nurse to the inpatient unit nurse is crucial to a smooth and safe transition of care. Important components to include are:

- Surgical procedure
- Perioperative treatment course, including medications and fluids received intraoperatively
- Surgical complications, if any
- Past medical history
- Current vital signs
- Current assessment status
- Surgical incision and drain information
- Medications received for pain and/or nausea
- Plan for pain management
- Time for the receiving nurse to ask any clarifying questions to adequately prepare for accepting the patient into the nurse's care.

PACU, Post-anesthesia care unit.

### Box 17.4 Family Visitation

Following the comprehensive admission assessment by the PACU nurse, a family member/loved one may be invited to have a brief visit with the patient in the PACU. It is believed that family visits can decrease anxiety for both the patient and loved one, improve family satisfaction, and encourage family support. Prior to the visit, the nurse ensures that the patient is awake and that pain is well controlled, sets expectations regarding the intended length of the visit, and explains the environment to the family member. During the visit, the PACU nurse should be available to answer questions about the procedure and the next level of care, such as being transferred to the inpatient surgical unit. Patients and family members are typically eager to know about transfer timing and expectations of care on the receiving unit. If the patient is being discharged to home, patient teaching prior to discharge should always be done with a family member present.

Many family members feel it is their right to be able to visit in the PACU; however, the nurse is empowered to terminate the visit depending on the patient, visitor, and unit circumstances. Protecting the safety, privacy, and confidentiality of all patients (and other family members) in the unit is a priority.

PACU, Post-anesthesia care unit.

### PATIENT CARE ON THE INPATIENT UNIT

After receiving the hand-off from the PACU nurse, the inpatient nurse must review the new orders written by the provider on the postoperative inpatient unit to prepare to care for the patient in this new setting. Orders will contain

information about vital sign parameters; activity and diet (see Evidence-Based Practice: Diet After Surgery); medications for postoperative pain, nausea, and vomiting; thromboembolism prophylaxis; postoperative imaging and laboratory studies; any special precautions related to the surgery; and the continuation of the patient's routine, preoperative medications. The nurse and staff of the inpatient unit can then begin setting up the room with the supplies necessary to support the patient.

Once the patient has arrived, taking vital signs and completing a thorough assessment should begin immediately to establish a baseline. This baseline can be compared to pre-surgical status and can be used to evaluate the patient's postoperative progress. Patients who are transferred to an inpatient unit are susceptible to many complications, so it is imperative that assessments identify any changes that need intervention.

## Evidence-Based Practice

### Diet After Surgery

Diet orders after surgery depend greatly on the type of surgery performed. The traditional idea of a patient progressing from ice chips or a clear liquid diet up to a regular diet is not supported by current evidence. For example, those who have had neurosurgery may not be able to eat until an evaluation of their swallowing ability has occurred because of possible cranial nerve disruption resulting in swallowing impairment. Patients who have had gastrointestinal surgery may have volume intolerance because of a risk for a leak at anastomosis sites in the postoperative period. Otolaryngology patients may not be able to eat a regular diet because they cannot chew or are at an increased risk for infection if foods pocket in surgical sites in the oral cavity. Some patients complain of very sore throats following intubation and benefit from choosing softer foods. Early feeding after surgery is generally safe, speeds recovery, shortens length of stay, and is more in line with patient preferences. Interestingly, some studies suggest gum chewing to recover bowel function more quickly when treating an ileus.

- Boarin, M., Villa, G., Di Monte, V., Abbadesse, F., & Manara, D. F. (2017). The use of chewing gum for postoperative ileus prevention in patients undergoing radical cystectomy. *International Journal of Urology Nursing*, 11(3), 129–135. doi:10.1111/ijun.12141

## Potential Postoperative Complications

### Respiratory System

Some potential complications in the respiratory system include atelectasis, pneumonia, and pulmonary embolus, all potentially resulting in inadequate gas exchange, hypoxemia, and hypoxia. All are related to hypoventilation, venous stasis, and an ineffective cough secondary to immobility and pain. Immobility can cause an accumulation of mucus in the lungs, resulting in atelectasis and pneumonia. Immobility can also result in venous stasis and clot formation or deep vein thrombosis (DVT) formation, which can ultimately result in a pulmonary embolus. Pain can cause hypoventilation, which results in poor gas exchange and a weakened cough, further compromising the removal of secretions and oxygenation.

### Cardiovascular System

The body's natural stress response to the surgical procedure may result in fluid and electrolyte complications. Acute stress and surgical fluid losses lead to a sympathetic response of tachycardia and vasoconstriction. There is increased secretion of adrenocorticotropic hormone (ACTH), stimulating the adrenals to release cortisol, hydrocortisone, and aldosterone. The pituitary is stimulated to release antidiuretic hormone (ADH), and the renin-angiotensin-aldosterone system (RAAS) is stimulated. All result in fluid retention, sodium retention, and urinary loss of potassium. This may result in fluid overload and hypokalemia. Hypokalemia affects cardiac contractility and may lead to lethal dysrhythmias. Conversely, fluid losses secondary to untreated or poorly treated preoperative dehydration, surgical fluid losses, bleeding, wound drainage, and/or vomiting may result in decreased cardiac output and poor tissue perfusion.

### Neurological System

There are several severe neurological complications related to surgery and, more specifically, anesthesia. Delirium, defined as inattention and disorganized thinking, is a common complication affecting up to 70% of patients over 60 years of age. It is associated with persistent cognitive decline, prolonged ICU and hospital length of stay, and increased mortality. Treatment is mostly based on recognition of populations at risk and prevention. Preventative measures include decreasing the irritation of invasive lines, tubes, and drains that increase agitation as quickly as possible. Antipsychotic medications, such as low-dose haloperidol (Haldol), may be used as a treatment, along with reorientation and reassurance. Another complication common in the older patient is postoperative cognitive decline (POCD), which can be subtle and temporary or may last for weeks or months, causing delays in return to normal functioning such as work.

For both delirium and POCD, measures such as maintaining stable hemodynamic parameters, normal bowel and bladder functioning, early mobility, and frequent reorientation are helpful in preventing or limiting cognitive issues

### Gastrointestinal System

Postoperative ileus (POI), a slowing of gastric and bowel motility, is a complication largely associated with gastrointestinal (GI) surgery when there is manipulation of the bowel. It can also occur with other procedures due to anesthesia, immobility, opioid pain medication, and previous abdominal surgery. Patients present with nausea and abdominal pain. Interventions include insertion of a nasogastric tube to decompress the stomach to ease nausea and prevent vomiting and aspiration. Patients are kept nothing by mouth, NPO, until bowel motility returns.

### Urinary System

Urinary retention can occur due to complications from anesthesia, opioids, and immobility. Anesthesia depresses the nervous system, which can affect the nervous system's control of micturition. This can result in a decreased sensation of a full bladder and urinary retention. Opioids may interfere with the patient's ability to fully empty the bladder. Immobility and bedrest impact the ability to fully relax the perineal structures to allow voiding and complete emptying of the bladder.

### Integumentary System

A surgical procedure typically involves an incision through the skin and tissues, disrupting the first barrier to infection, the skin. Surgical-site infection is a risk in the perioperative period more commonly seen in older, immunosuppressed, or malnourished patients and those with longer hospital length of stays. The surgical site will appear red, warm, and edematous, with purulent drainage, and the patient will complain of increased pain—the cardinal signs of inflammation. In the worst-case scenario, the wound may dehiscence; the sutures or staples fail, and the wound opens up. The wound must be cleaned and drained. Sterile saline dressings must be maintained until the wound is healthy enough to be reapproximated or resutured. Adequate nutrition is imperative for wound healing.

## NURSING MANAGEMENT

Although postoperative needs are specific to the patient and surgical procedure, there are assessments and interventions that are common to all surgical patients. Case-specific needs are covered in the chapters where specific surgical procedures are discussed. This chapter focuses on common post-surgical needs. These patient assessments and interventions are crucial for safe patient care.

### ■ Assessment

#### ● Respiratory status

*Low oxygen saturation and/or increased respiratory rate and work of breathing could signify a pulmonary embolism (PE), atelectasis, aspiration, or pneumonia. Adventitious lung sounds such as rhonchi or diminished or absent sounds could also reveal atelectasis, aspiration, or pneumonia. Rales may indicate fluid overload.*

- Vital signs—blood pressure (BP), heart rate (HR), and temperature: Monitor for trends in values. *Deviations from normal vital signs could signify complications. The most common postoperative complication is hypotension and tachycardia due to blood or fluid loss. Hypertension and tachycardia may occur due to the stress response to surgery and pain. Increases in temperature may indicate infection due to pulmonary issues or surgical-site infection.*
- Peripheral perfusion *Cool, pale skin with weak pulses and delayed capillary refill may indicate decreased volume and cardiac output.*
- Neurological *Decreases in level of consciousness, confusion, agitation, or disorientation may indicate the onset of delirium or POCD. It may also be due to excessive pain medication or respiratory dysfunction. Irregularities in pupillary size and reaction or Glasgow Coma Scale (GCS) score may be due to increased intracranial pressure.*
- GI *Bowel sounds, flatus, and bowel movements reflect the return of GI motility. Postoperative nausea and vomiting may be associated with anesthesia. Absent or hypoactive bowel sounds, nausea, and vomiting may indicate paralytic ileus.*
- Genitourinary (GU) *Increased urine output in the initial postoperative period may be due to excessive IV fluids given intraoperatively. Decreased urination can result from dehydration or the release of anti-diuretic hormone (ADH) and initiation of the RAAS due to stress and surgical fluid losses. Monitor for urinary retention that may be caused by complications from anesthesia, opioids, and immobility. Cloudy urine, tea- or cola-colored urine, and urine with a foul odor are signs of urinary tract infection.*
- Skin/drains *Assess surgical incisions and dressings for proximity of closed edges, presence and quality of drainage, and intactness of surrounding skin. Red, warm, edematous tissue with purulent drainage, along with complaints of increased pain, indicates infection. Assess for the presence and staging of any skin breakdown or pressure injuries that may be associated with prolonged positioning in the OR or immobility postoperatively.*
- Drains *Assess for excess, bloody, or cloudy drainage. Excessive or bloody drainage may indicate surgical-site bleeding. Cloudy drainage may indicate infection. Absent drainage may indicate a clogged drain.*
- Pain *Pain should be monitored and treated. Poorly controlled pain may indicate surgical complications or the need for alternate pain control treatment.*
- Fluid and electrolyte balance; monitoring of glucose levels *Fluid retention may occur due to activation of the RAAS and release of ADH in response to stress and dehydration.*

*Hypokalemia, a risk factor for lethal dysrhythmias, and hypernatremias may occur with the activation of the RAAS. Hyperglycemia may occur related to the stress of the surgical experience and is a risk factor for infection because high blood glucose fuels bacterial growth.*

### ■ Actions

- **Respiratory care**  
*Encourage patient to cough and breathe deeply to facilitate full lung expansion and airway clearance (see Evidence-Based Practice: Incentive Spirometry).*
- **Fluid management**  
*Maintain IV fluids as ordered to maintain intravascular volume. Start PO fluid as ordered with the return of bowel sounds. Maintain as tolerated/no nausea.*
- **Mobility: change position frequently; encourage ambulation as soon as possible.**  
*Mobility encourages lung expansion, requires muscle use to prevent atrophy, aids in DVT prevention, helps relieve constipation, aids in pain and fatigue relief, improves mood, reduces anxiety, increases comfort, instills a greater quality of life and independence, and is a factor in decreased length of stay.*
- **DVT/venous thromboembolism (VTE) prophylaxis**  
*DVTs, when they occur, commonly occur in the posterior calf, with noticeable redness, swelling, heat, and pain. A combination of administering anticoagulants as ordered, encouraging activity, and using compression devices is the most effective means of prevention.*
- **Diet management**  
*Provide diet as ordered. Nutrition is essential for healing. The progression and type of diet are unique to each type of surgical procedure but, in general, PO fluids and diet are started when bowel sounds return and are maintained as tolerated by the patient.*
- **Surgical site and wound management**  
*Change dressing as ordered, utilizing proper hand hygiene before and after care and correct use of clean and sterile gloves to prevent surgical-site infections. Provide complete documentation of wound assessment and care.*
- **Pressure-injury prevention**  
*Prolonged pressure deprives tissues of oxygen and nutrients, causing ulceration. Pressure injuries are most often found over bony prominences. To prevent pressure-injury development, patients should be encouraged to mobilize and adjust their position frequently. Those who are not able to do so should be assisted to turn and reposition every 2 hours. Encourage proper nutrition to promote skin integrity and wound healing.*
- **Fall prevention**  
*Encourage patients to call for assistance. Most falls happen when patients are trying to do something unassisted and/or without supervision, such as transferring from the chair to the bed or ambulating to the bathroom. Use bed alarms as necessary. Preoperative falls put patients at higher risk for postoperative falls.*

- **Managing constipation: administer stool softeners and laxatives as ordered.**  
*Constipation in the postoperative patient is a common occurrence due to the effects of anesthesia or other medications (particularly opioids), immobility, or improper hydration. Encourage the patient to ambulate, drink plenty of fluids, and eat a nutritious diet high in fiber. Medications other than or in conjunction with opioids to treat pain should be explored. Stool softeners add water into the bowel; laxatives improve bowel mobility to aid in defecation.*
- **Remove the Foley catheter as ordered.**  
*Removal of the indwelling Foley catheter helps prevent catheter-associated urinary tract infections (CAUTIs) and reduces the risk of falls by removing a tripping hazard.*

### ■ Teaching

- **Unit education**  
*Educate the patient on unit routines (e.g., frequency of vital signs and assessments, visitation hours, staff members on the unit), and orient the patient to his or her room (how to work the call bell, how to order food).*
- **Safety**  
*Topics include standard or isolation precautions, patient identification methods, fall precautions, activity or diet restrictions, and bleeding risk precautions.*
- **Discharge education (Box 17.5)**  
*Education is essential to ensure that the patient safely transitions to home and avoids readmission to the hospital. Teaching should be done in the presence of a family member or significant other who will help the patient upon returning home.*

## Evidence-Based Practice

### Incentive Spirometry

Incentive spirometers are designed to give the patient visual feedback for deep breathing and lung expansion. The use of incentive spirometry has traditionally been a part of postoperative care, but the American Association of Respiratory Therapists no longer recommends routine, prophylactic use in postoperative patients. The guidelines state that “the use of Airway Clearance Therapy in the setting of atelectasis without retained airway secretions does not seem to be effective.” The guidelines suggest early ambulation instead to expand the lungs and promote airway clearance.

Armstrong, C. O. (2017). Post-op incentive spirometry: Why, when, & how. *Nursing*, 47(6), 54–57. doi:10.1097/01.NURSE.0000516223.16649.02

## Box 17.5 Home Discharge Instructions

- Signs and symptoms that need to be reported to the provider immediately
- When and how to take any prescriptions
- Signs and symptoms of infection
- Care of incision and dressings, bathing restrictions
- Activities allowed and prohibited (e.g., driving, exercising, sex, swimming, and weight restrictions)
- Dietary restrictions
- When and where to return for follow-up
- When to return to work/school

\*More topics may be necessary to include based on the individual patient needs and the type of surgery performed (e.g., smoking cessation, signs and symptoms of hormonal imbalances, spinal precautions, signs and symptoms of a cerebrospinal fluid leak, or sternal precautions).

## Making Connections

### CASE STUDY: WRAP-UP

Mr. Wells's daughter has come in to visit at his bedside. She is happy that his surgery is over but is very worried about his post-surgical pain. The PACU nurse discusses the PCA pump with her and explains that her father has been resting comfortably and using the pump when needed. His vital signs are stable, and urine output has been good. Because Mr. Wells had bowel surgery, his nasogastric tube has been connected to low continuous suction as ordered by the surgeon. The nurse assesses his abdomen and hears no bowel sounds, but the incision is clean and dry. Soon Mr. Wells meets discharge criteria and is transferred to his inpatient bed.

#### Case Study Questions

1. The PACU nurse understands that the first priority for Mr. Wells upon admission to the PACU is which of the following?
  - A. Informing the family of his status
  - B. Checking vital signs and neurological status
  - C. Providing pain medication
  - D. Assessing the nasogastric tube
2. Initially upon admission, Mr. Wells remains sleepy and hard to arouse. The PACU nurse anticipates an order for which laboratory test?
  - A. Glucose level
  - B. Arterial blood gas
  - C. Lactate level
  - D. Liver function test

3. Shortly later, Mr. Wells becomes restless, and his heart rate goes up to 100 bpm. As the nurse assesses him, the priority assessment should include which interventions? (*Select all that apply.*)
  - A. Check his dressing and drains for bleeding.
  - B. Check his breathing and oxygen saturation.
  - C. Check his pain and comfort level.
  - D. Check to see if he has to have a bowel movement.
  - E. Check his blood pressure and fluid volume status.
4. Before administering pain medication to Mr. Wells, the nurse's assessments include which of the following? (*Select all that apply.*)
  - A. Sedation level
  - B. Self-report of pain
  - C. Vital signs
  - D. Bowel sounds
  - E. Urine output
5. The PACU nurse supports Mr. Wells's family by doing which of the following? (*Select all that apply.*)
  - A. Informing family when the patient arrives in the PACU
  - B. Allowing visitation immediately prior to transfer to his inpatient room
  - C. Allowing visitation as safety and privacy allow
  - D. Providing frequent updates
  - E. Providing a visitation policy that allows visitation after discharge from the PACU

## CHAPTER SUMMARY

The transition from anesthesia to recovery carries risks for potentially life-threatening complications. One of the most critical risk factors is that there is a temporary decrease in or loss of consciousness and loss of motor and reflexive control of respiration after anesthesia in the OR, so intense monitoring of respiratory status must occur. Also, the postoperative transition period is the time when many patients experience discomforts such as nausea, vomiting, and pain. During the transition from the OR, patients need assistance to maintain a safe internal physiological balance. Post-anesthesia care units (PACUs) specialize in managing both the potential life-threatening complications and the inevitable discomforts related to recovery from a surgical procedure.

Post-anesthesia care is provided in a variety of settings. They include but are not limited to the inpatient hospital PACU, intensive care unit (ICU), outpatient PACU, and procedure areas such as endoscopy. Examples of surgical

procedures for which patients recover in an inpatient PACU include lung lobectomy, nephrectomy, exploratory laparotomy, and open reduction and internal fixation of fractures. Recovery from complex procedures with a high risk for complication, such as open-heart procedures, craniotomy, and transplantations, is done in an ICU setting. Patients who receive recovery care in an outpatient setting are able to go home the same day as the procedure, as are patients who receive recovery care in a procedure area.

Effective post-anesthesia care nursing requires knowledge of preoperative status, completion of an immediate postoperative assessment, and evaluation of pertinent laboratory and diagnostic studies. Priority assessments include vital signs and temperature; respiratory adequacy; postoperative cardiac status, including peripheral circulation; postoperative neurological status; IV patency; motor abilities and return of sensory and motor control in areas affected by local or regional anesthetics; and skin integrity. Priority interventions include connecting the patient to the monitor,

completing the assessment, pain management, and management of nausea and vomiting. The post-anesthesia care nurse should inform the family of the patient's arrival into the PACU setting and allow visiting as soon as the assessment has been completed and the patient has been stabilized. Supporting the patient's family members and involving them in the discharge instructions is essential to recovery in the hospital or at home.

Patients who are transferred to an inpatient unit for continued monitoring and recovery from surgery are susceptible to many of the same complications as patients in the PACU, such as deep vein thrombosis (DVT) or pulmonary embolism (PE), wound infection, atelectasis, or pneumonia, or problems with gastrointestinal motility. The longer length of stay expands on the assessments and interventions done in the PACU, many of which are standard, but many are patient and surgery specific. Standard postoperative care includes assessment, monitoring, facilitating mobility, wound care, and very importantly, patient and family education.

## Promoting Health in Patients With Immune Disorders

### Chapter 18

## Assessment of Immune Function

*Diane Vail Skojec*

#### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Identifying key anatomical components of the immune system
2. Discussing the function of the immune system
3. Describing the procedure for completing a history and physical assessment of a patient with impaired immune function
4. Correlating relevant diagnostic examinations to immune function
5. Explaining nursing considerations for diagnostic studies relevant to immune function
6. Discussing changes in immune function associated with aging

#### CONCEPTS

- Assessment
- Infection
- Immunity
- Inflammation

#### ESSENTIAL TERMS

Adaptive (acquired) immunity  
Antibodies  
Antigen-antibody response  
Antigen-presenting cells (APCs)  
B lymphocyte (B cell)  
Basophil  
Cell-mediated immune response  
Complement  
Cytokines  
Cytotoxic T cell  
Dendritic cell  
Eosinophil  
Helper T cell  
Humoral immune response  
Immunoglobulin  
Inflammation  
Inflammatory response  
Innate (natural) immunity  
Leukocyte  
Lymphocyte  
Macrophage  
Major histocompatibility complex (MHC)  
Mast cell  
Monocyte  
Natural killer (NK) cell  
Neutrophil  
Phagocytosis  
Plasma cell  
Suppressor T cell  
T lymphocyte (T cell)

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Grace Hall is a 60-year-old female who presents to an urgent care clinic with a 4-day history of low-grade fever, malaise, headache, and an itching and painful sensation on the right side of her chest. She states that she has stopped exercising due to the discomfort and finds tight clothing to be irritating. Her maximum oral temperature has been 100.4°F (38°C). Ms. Hall denies weakness, dizziness, confusion, difficulty swallowing or breathing, cough, nausea, vomiting, diarrhea, and weight loss. She also denies exposure to ill individuals or recent travel...

## INTRODUCTION

**Immunity** refers to the body's ability to resist infection and disease. Innate and adaptive immune responses provide three lines of defense against unwanted antigens (Fig. 18.1). **Innate (natural) immunity** provides the first and second lines. The first line consists of physical, biochemical, and mechanical barriers that offer surface protection to prevent

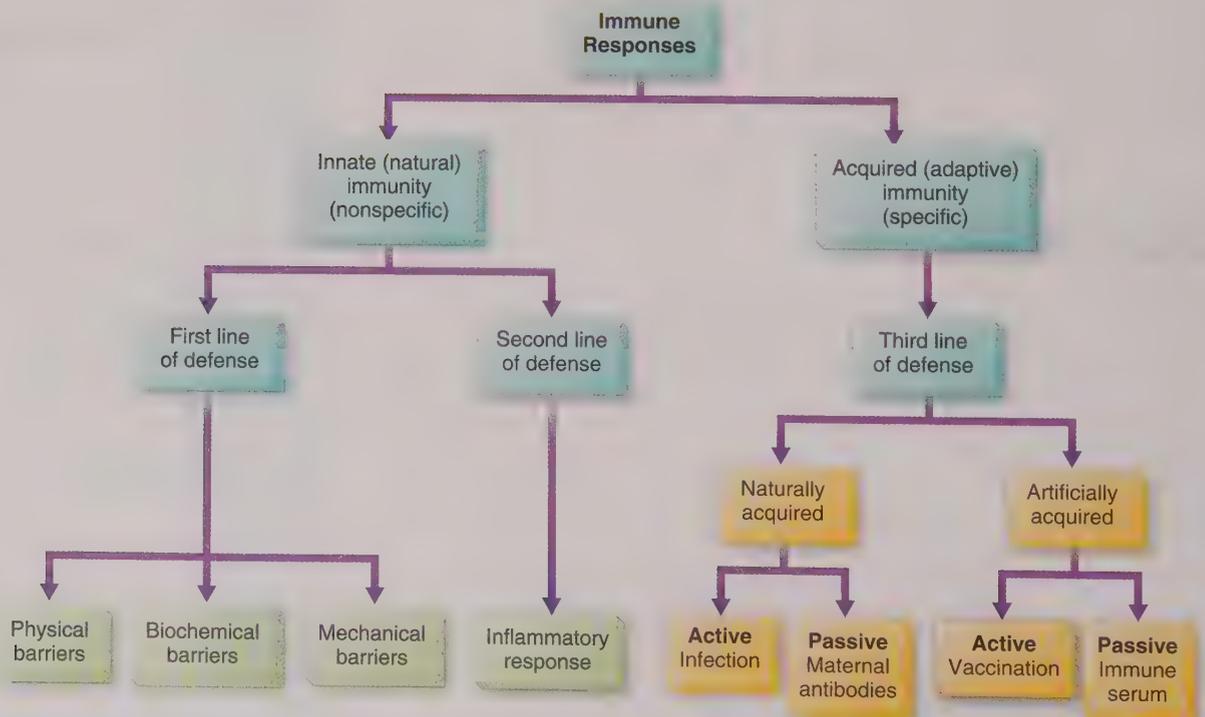

the invasion of microbes. When those barriers are breached, the second line of defense, the **inflammatory response**, is initiated to prevent and/or limit infection, clean out the debris of dead cells, and initiate tissue healing. The first and second lines are nonspecific, responding the same way for any invasion. The third line, **adaptive (acquired) immunity**, occurs by natural exposure; infection, transfer of maternal antibodies, or artificial exposure; vaccination; or infusion of immune serum globulin. This type of immunity is specific and protects by way of cellular-mediated and humoral-mediated mechanisms.

When competent, the immune system wards off the penetration of foreign microbes and the proliferation of abnormal or malignant cells. When the system is incompetent, the failure can lead to allergies, infection, cancer, and autoimmune and immunodeficiency disorders. Age, medications, nutrition, genetics, physical or emotional stress, and illness can all impact immunity and how the immune system functions.

## OVERVIEW OF ANATOMY AND PHYSIOLOGY

### Anatomy of the Immune System

Components of the immune system include the lymphatic system, primary and secondary lymphoid organs, and the cells and proteins involved in the immune response. The lymphatic system consists of lymphatic vessels and collecting ducts. Primary lymphoid, or central, organs include the thymus and bone marrow. Secondary lymphoid,

**FIGURE 18.1** The immune response: innate (natural) immunity and acquired (adaptive) immunity.

or peripheral, organs include the spleen, lymph nodes, tonsils, adenoids, and Peyer's patches (Fig. 18.2). The cells and proteins include leukocytes (white blood cells [WBCs]), T and B lymphocytes (T cells and B cells), cells involved in the inflammatory response, antibodies, signaling proteins (cytokines), and other protein systems (complement system) that support the immune response. See Table 18.1 for an overview of the cells involved in the immune response.

### Lymph Nodes and the Lymphatic System

Fluid continually filters out of the blood and into the interstitial space, the majority of which is reabsorbed back into the bloodstream. The lymphatic system is a network of vessels that transports excess interstitial fluid that has not been reabsorbed (lymph fluid) back to the bloodstream, helping to maintain fluid balance. This system contains thousands of lymph nodes strategically located superficially and deep within the tissues near the lymphatic vessels (Figs. 18.3, 18.4, and 18.5). The nodes are small glandular structures that house macrophages, **lymphocytes**, and **monocytes** that actively filter and phagocytize microorganisms and other invading particles from circulating lymphatic fluid. The lymph fluid moves through the lymphatic vessels, eventually emptying into the lymphatic ducts, the right lymphatic or thoracic duct, and returning to the general circulation through the subclavian veins. This filtering

process prevents unwanted substances from reentering the bloodstream.

### Thymus

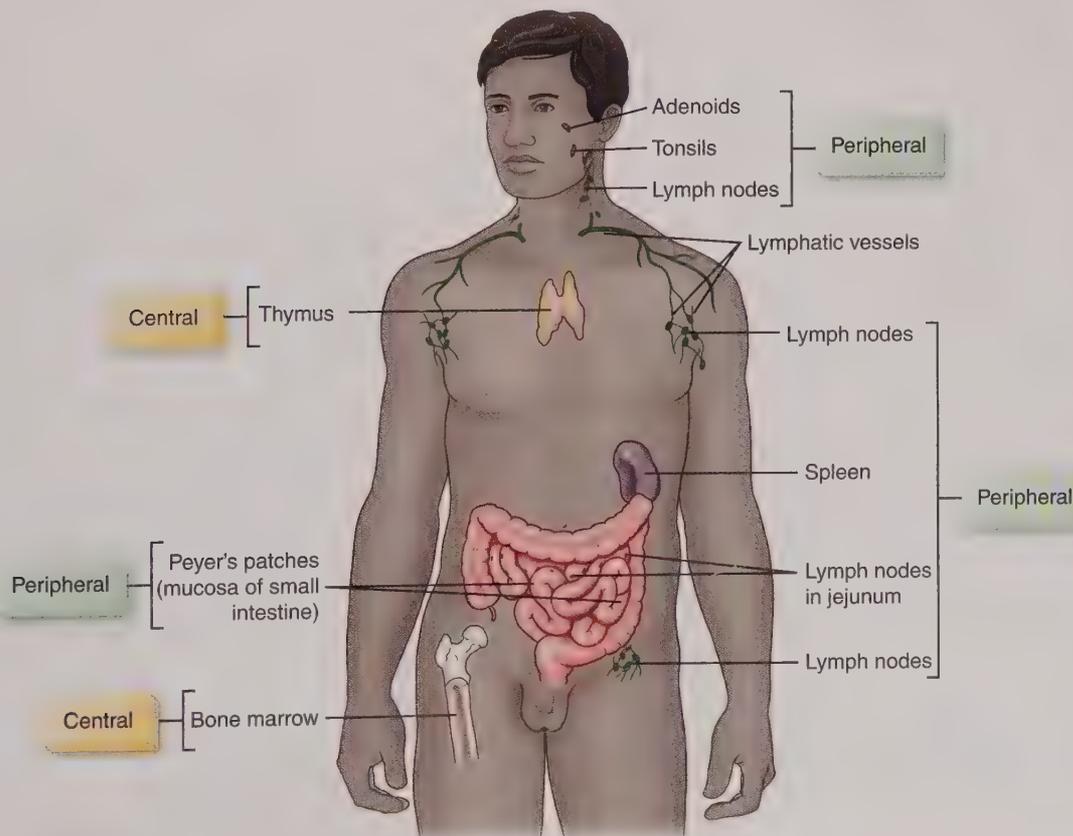

The thymus is a soft organ located within the chest cavity near the heart. It is large in children and decreases in size into adulthood. It is the central lymphoid organ that produces thymosin (a hormone that stimulates T-cell production) and is where T-cell development takes place.

### Bone Marrow

Within the cavities of bone resides bone marrow, or myeloid tissue, consisting of red (active) marrow and yellow (inactive) marrow. This is where B- and T-lymphocyte formation and differentiation of B cells and T cells occur. B cells stay within the bone marrow to mature. T cells migrate to the thymus to mature and become active as regulatory T cells (suppressor T cells) or effector T cells (helper T cells and cytotoxic T cells; Fig. 18.6).

### Spleen

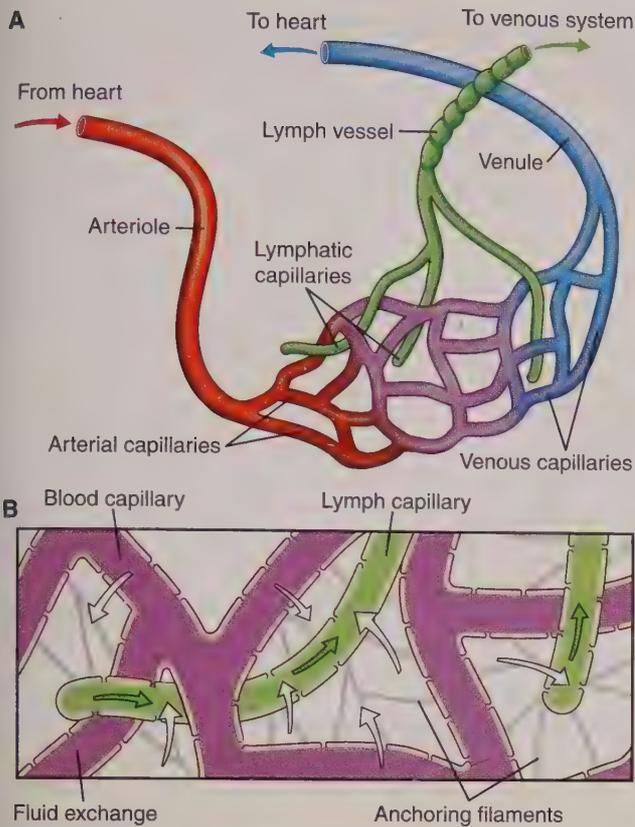

Approximately the size of a fist, the spleen is located in the left upper quadrant of the abdominal cavity. As a part of the lymphatic system, it serves as a blood filter. It is divided into compartments that contain red and white splenic pulp. The red pulp serves as the filtering site for old or damaged red blood cells. It can also store blood. The white pulp of

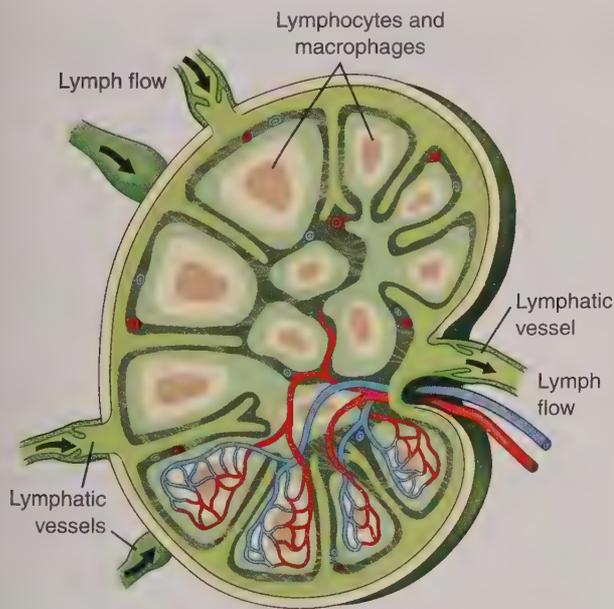

**FIGURE 18.2** Central and peripheral organs of the immune system.

**Table 18.1** Cells of the Immune System

Name	Site Produced/Found	Function
<b>Leukocytes</b> (white blood cells)	Formed in bone marrow and lymph tissue Found in the blood, lymphatic system, spleen, and body tissues	Innate and adaptive immune function
<b>Neutrophils</b>	Found in bone marrow, blood, and tissues	Innate immune response/inflammation Phagocytosis
<b>Basophils</b>	Found in circulation	Innate immune response/inflammation Release histamine, heparin when stimulated Associated with allergic reactions
<b>Eosinophils</b>	Found in tissue	Phagocytosis in parasitic infections, allergens Associated with allergic reactions
<b>Monocytes</b>	Found in circulation When they migrate to tissue, they differentiate into macrophages or dendritic cells.	Innate and adaptive immune response In the circulation: present pathogens to T cells to aid in recognition and destruction
<b>Lymphocytes</b>	Found in bone marrow, thymus, spleen, lymph nodes, and circulation	Coordinate adaptive immune responses
<b>B cells</b>	Formed and mature in the bone marrow	Adaptive/humoral immune response Responsible for antibody-mediated response: on activation, convert to plasma cells and produce antibodies or immunoglobins
<b>T cells</b>	Formed in bone marrow; mature in the thymus	Adaptive/cellular-mediated response
<b>Cytotoxic T cells</b> (CD8 cells)		Bind to and destroy invading viruses and cancer cells
<b>Helper T cells</b> (CD4 cells)		Humoral and cellular immune response Secrete signaling proteins (cytokines) to activate B cells, cytotoxic T cells, and natural killer (NK) cells (described below) Facilitate phagocytosis by activating macrophages
<b>Suppressor T cells</b>		Down-regulate immune response/prevent overactivity and autoimmune disease
<b>Natural killer cells</b>		Target and kill cancer and virus-infected cells
<b>Macrophages</b>	Differentiated from monocytes Found in tissue	Innate and adaptive immune response Phagocytize and ingest engulfed microorganisms Present processed antigens to helper T cells Secrete signaling proteins (cytokines) to activate helper T cells and inflammation
<b>Dendritic cells</b>	Differentiated from monocytes Found in tissue	Phagocytosis Present processed antigens to other immune cells
<b>Mast cells</b>	Differentiated from bone marrow cells Found in tissue	Innate immune response/inflammation Release histamine, heparin when stimulated Associated with allergic reactions Similar to basophils

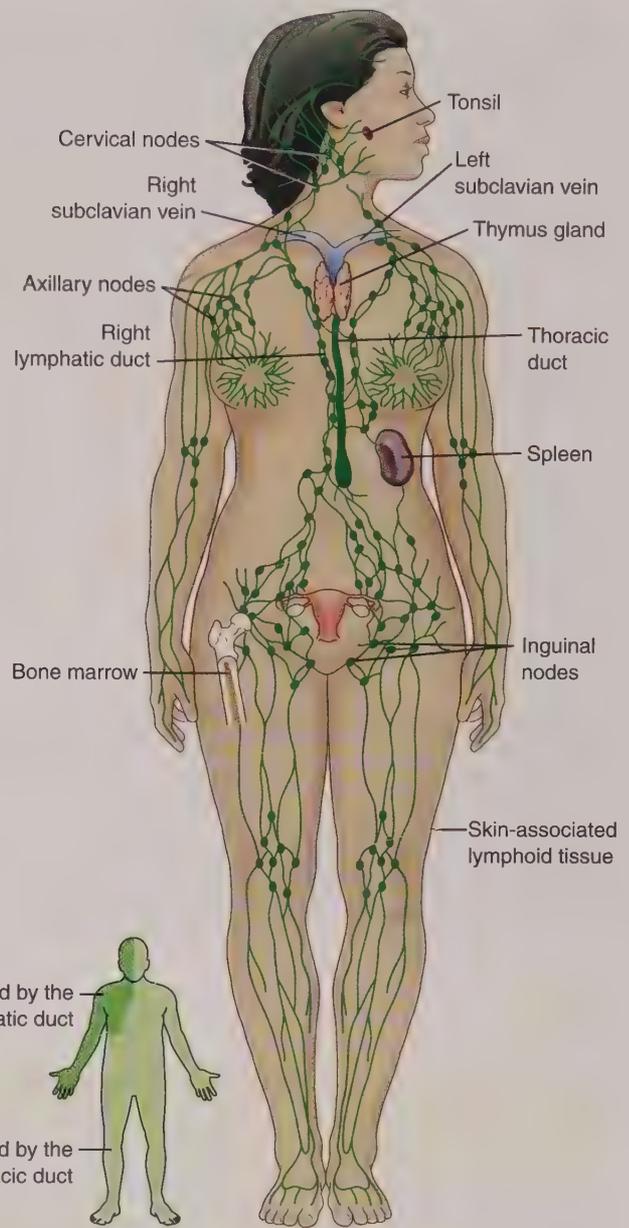

**FIGURE 18.3** Lymphatic capillary circulation. *A*, Representation of the interaction of lymphatic capillaries with the arterial and venous vascular system. *B*, Representation of the interaction of the vascular system and lymphatic system microcirculation.

**FIGURE 18.4** Lymph node.

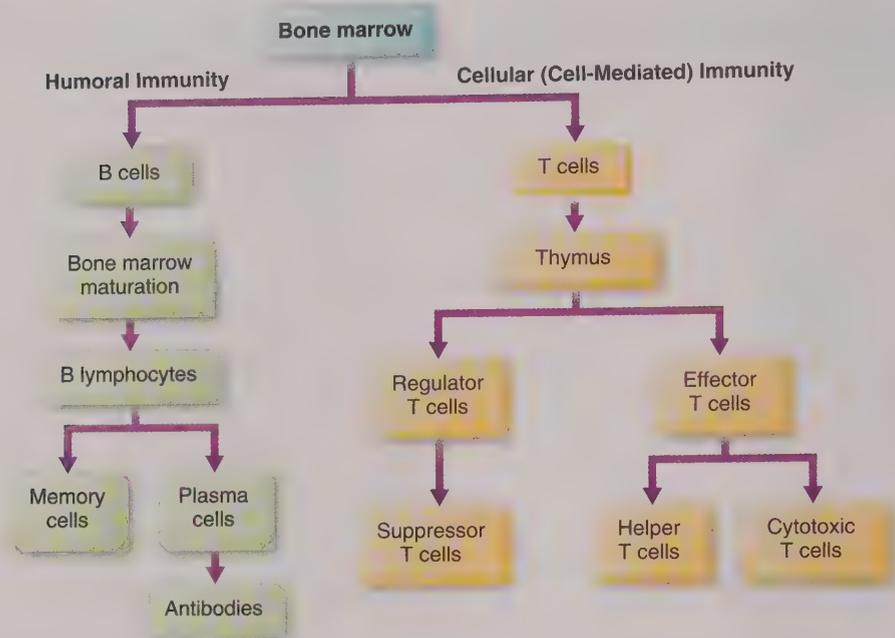

lymphoid tissue houses lymphocytes and macrophages, filtering unwanted debris like a lymph node. Although it is a redundant organ in the immune system, if it is removed due to accident or disease, the patient may become immunocompromised, with high-risk patients requiring lifetime antibiotics.

**FIGURE 18.5** The nodes and vessels of the lymphatic system.

**Tonsils, Adenoids, and Peyer’s Patches**

Additional lymphoid tissues, such as the tonsils, the adenoids, and Peyer’s patches, are located in close proximity to mucosal surfaces within the body and provide another means of protection against invading microorganisms. The tonsils are located between the palatine arches on either side of the pharynx. They function as traps to protect against bacteria and viruses that are inhaled. Located at the nasopharyngeal border, the adenoids also defend against inhaled bacteria and viruses. Peyer’s patches are lymphoid follicles located on the mucosa of the small intestine. They are known as intestinal immune sensors and defend against pathogens that gain entry to the intestinal tract. See Figures 18.2 and 18.5 for an overview of the structures of the immune system.

**FIGURE 18.6** Process of differentiation of T-cell and B-cell lymphocytes.

### Connection Check 18.1

Central lymphoid organs include which of the following?

- Spleen and tonsils
- Bone marrow and lymph nodes
- Thymus and Peyer's patches
- Thymus and bone marrow

### Cells

#### Leukocytes

White blood cells, or **leukocytes**, are formed in the bone marrow and lymph tissue; mature in the thymus or bone marrow; and are found in the blood, lymphatic system, spleen, and other body tissues. Leukocytes are mobile units traveling through the bloodstream to defend the body against infection. There are five types of leukocytes: neutrophils, monocytes, eosinophils, basophils, and lymphocytes (B and T cells). They are further classified as granulocytes or agranulocytes depending on their function.

Granulocytes have granules in the cytoplasm and release histamines and other substances to defend the body against foreign materials by increasing capillary permeability through vasodilatory effects and mediating the inflammatory response. Neutrophils, basophils, and eosinophils are all phagocytic (cells that engulf bacteria and debris) granulocytes. **Neutrophils** are phagocytes of early inflammation that destroy bacteria. **Basophils** release heparin as an anticoagulant and histamine during the early inflammatory response. **Eosinophils** are phagocytes that destroy allergens and combat parasitic infections.

Agranulocytes (without granules in the cytoplasm) include monocytes and lymphocytes. In the bloodstream, monocytes are a part of the adaptive immune response, presenting pathogens to T cells for destruction. In the tissue,

they develop into macrophages and are a part of the tissue macrophage system. **Macrophages** are phagocytes and initiators of the inflammatory response that digest and destroy, or phagocytize, microorganisms and other debris. They also activate helper T cells by secreting signaling proteins, called cytokines, and presenting processed antigens for destruction by the T cell.

### Connection Check 18.2

Which of the following cells are classified as granulocytes?

(Select all that apply.)

- Basophils
- Monocytes
- Neutrophils
- Eosinophils
- Lymphocytes

#### Lymphocytes

Lymphocytes are active in both **humoral** and **cell-mediated immune responses**. They are formed in the bone marrow and are found in the lymph nodes, spleen, and thymus and enter the bloodstream through the lymphatic system.

#### B Lymphocytes

**B lymphocytes (B cells)** are the cells involved in humoral immune responses. They are a subset of lymphocytes that mature in the bone marrow and produce **antibodies**, or **immunoglobulins**. Antibodies bind with specific antigens, marking them for destruction by other components of the immune system, or directly neutralize the antigen by inhibiting an essential function necessary for its survival. Once B cells are exposed to a specific antigen for the first

time, they proliferate and differentiate into **plasma cells** and memory cells. Plasma cells secrete antibodies after the first exposure to the antigen. Memory cells, restimulated by the same antigen, mount a specific **antigen–antibody response**, sometimes long after the initial exposure. B cells can function independently but typically require the help of T lymphocytes.

### Immunoglobulins

The immunoglobulins (Igs), or antibodies, that B cells produce include the following five classes: IgA, IgD, IgE, IgG, and IgM. Immunoglobulin A is found in exocrine-gland secretions such as breast milk and tears. Immunoglobulin D plays a role in B-cell activation, and IgE is associated with allergic reactions and parasitic infections. Immunoglobulin G is effective against bacteria, viruses, and other toxins, and lastly, IgM is the initial antibody produced after an infection (Table 18.2).

### T Lymphocytes

**T lymphocytes (T cells)** are participants in cellular-mediated immune responses. T-cell activation occurs when macrophages present the T cell with a phagocytized antigen. Their main functions include the elimination of cells infected by pathogens, continued activation of the inflammatory response against persistent infections, and regulation of innate and adaptive immune responses. T cells include **cytotoxic T cells**, **suppressor T cells**, and **helper T cells**. Cytotoxic T cells respond to foreign cells, including tumors,

non-self cells, and virus-laden cells. Helper T cells are important cells in both adaptive and innate immunity. They augment the effectiveness of the innate immune response by activating macrophages. They augment both humoral and cellular immunity through the activation of B cells to produce antibodies. They also activate cytotoxic T cells and natural killer cells. Suppressor T cells are activated by helper T cells when the immune response is no longer needed. **Natural killer (NK) cells**, another form of T cell, targets virus-infected and tumor cells. As individuals age, the number of NK cells increases. This increase helps to control infections in the elderly and is important for successful aging.

### Dendritic and Mast Cells

**Dendritic cells** are a type of macrophage that reside in lymphoid tissue and are the most potent of the **antigen-presenting cells (APCs)**. APCs capture and engulf antigens, producing a molecule, the major histocompatibility complex (MHC), that identifies the antigen to aid in T-cell and B-cell recognition and response. The MHC process is discussed later in this chapter. When APCs attack an antigen, such as bacteria or a virus, they secrete signaling proteins (cytokines) that stimulate both the innate and adaptive immune response. **Mast cells** are heavily granulated and are found in the skin and lining of the respiratory and gastrointestinal tracts. Similar to basophils, they release heparin and histamine during the early inflammatory response. Mast-cell degranulation is responsible for many allergic reactions, including anaphylaxis, a severe systemic allergic reaction that is rapid in onset and can be fatal.

### Proteins

#### Cytokines

**Cytokines**, which include interleukins (ILs), interferon (IFN), and tumor necrosis factor alpha (TNF $\alpha$ ) are small proteins that act to regulate immune responses. They are produced in response to specific antigens by cells of the acquired immune system. They have systemic and local signaling effects that enable them to signal cells of the immune system. The production of ILs occurs predominantly by macrophages and lymphocytes in response to the initiation of the inflammatory response. They are responsible for the general enhancement or suppression of inflammation and the stimulation of leukocyte production and maturation. Interferons are proteins that protect against viral infections and tumor growth. They do not destroy a virus directly; rather, they prevent the virus from infecting the surrounding healthy cells and interfere with its ability to replicate. Tumor necrosis factor alpha, produced primarily by macrophages, enhances inflammation and is involved in the regulation and production of immune cells. Interleukins and IFNs rely on TNF $\alpha$  to mount an effective inflammatory response.

### Complement System

**Complement**, a complex system of proteins, provides cell-killing effects for both innate and acquired immunity. Initiation of the complement can activate every component

**Table 18.2 Immunoglobulins**

Immunoglobulin	Function
<b>IgA</b>	Dominant Ig found in secretory-gland secretions such as breast milk, sweat, saliva, mucus, and tears
<b>IgD</b>	Located primarily on the surface of developing B lymphocytes Plays a role in B-cell activation
<b>IgE</b>	The least concentrated Ig that acts as a mediator of many common allergic responses Also acts as a defender against parasitic infections
<b>IgG</b>	Most abundant of the immunoglobulins. Transported across the placenta and effective against bacteria, viruses, and other toxins.
<b>IgM</b>	Largest of the Igs First antibody produced during the primary response to an antigen Expressed by competent B cells

Ig, Immunoglobulin.

of the inflammatory response as well as “complement” the antibacterial function of antibodies. Complement proteins are synthesized primarily in the liver and circulate in the bloodstream in an inactive form until activated by bacteria, viruses, fungi, tumor cells, antigen–antibody complexes, or endotoxins. The complement system is activated through classic, lectin, and alternative pathways. The classic pathway is activated by antibodies of the acquired immune system bound to their specific antigens to form an antigen–antibody complex. The lectin pathway is activated through exposure to bacteria rather than antibodies. The alternative pathway is activated by polysaccharides in gram-negative bacterial and fungal cell walls.

## Physiology of the Immune Function

### Innate Immune Response

Innate immunity provides protective barriers and an inflammatory response that is immediate, nonspecific, and without memory as first and second lines of defense against threats that are foreign. An important first step in the immune response is to differentiate whether an invader is self (a self-antigen on the host’s cells) or non-self (a foreign antigen). If recognized as non-self (i.e., from antigens such as a pathogen, pollen, or foreign tissue or blood product), an attack is mounted to stop and destroy the invading microorganism or toxin. To aid in the identification of self versus non-self, and to identify antigens to allow for a specific adaptive immune response, a group of proteins, the **major histocompatibility complex (MHC)**, codes for the antigens on APC cell surfaces to aid in recognition by the immune cells. That coding occurs when an APC cell, most commonly a dendritic cell, encounters an antigen, consumes it, and “presents” it on its surface to allow recognition by the immune cells. In humans, this process is called the *human leukocyte antigen (HLA)* system.

### Physical, Mechanical, and Biochemical Barriers

The first line of defense relies on anatomical and biochemical barriers for protection. These all work in concert to mount a passive defense against pathogens. The epithelial cells of the skin, mucous membranes, and protective linings of the organs provide protection through the mechanisms of sloughing, coughing, sneezing, vomiting, and urination. Working with the physical and mechanical barriers, biochemical surface and glandular secretions such as tears, saliva, perspiration, and earwax provide additional means of protection.

### Inflammatory Response

The second line is the inflammatory response that occurs due to tissue damage, such as a break in the skin, that introduces microorganisms. Inflammation may also be initiated through noninfectious processes, such as trauma or exposure to noxious compounds. The goal of **inflammation**

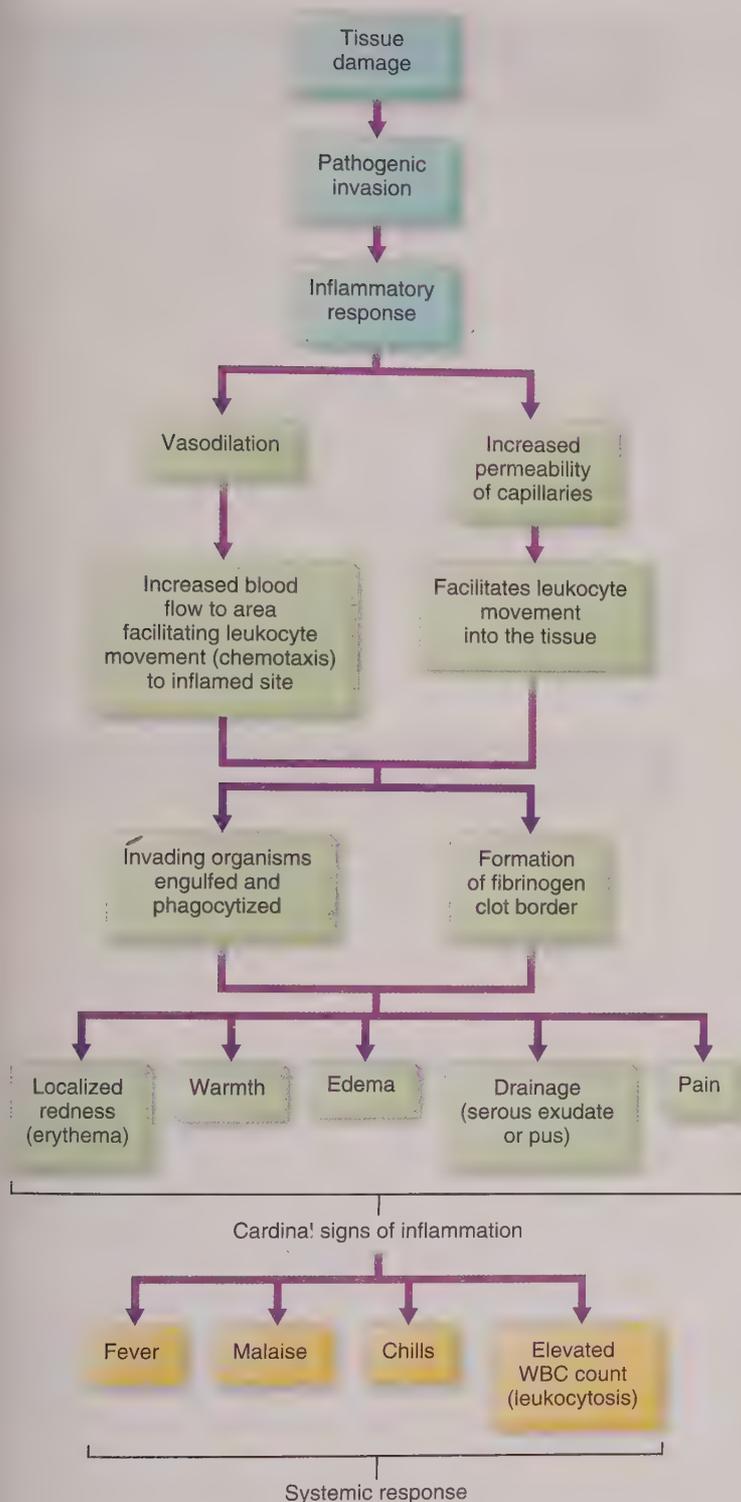

is to prevent and/or limit infection and further damage to the involved area, remove debris, and prepare the area of injury for healing. Cellular mediators involved in the inflammatory response include those in the circulation (neutrophils, eosinophils, basophils, platelets, monocytes, and lymphocytes) and those in tissue (macrophage and mast cells). The proteins involved include complement, clotting factors, kinins (inflammatory mediators generated after tissue injury), and cytokines.

Initiation of the inflammatory response includes vasodilation and increased permeability of the capillaries stimulated by histamine released by mast cells, kinins, and other inflammatory mediators, such as prostaglandins and leukotrienes. Vasodilation increases blood flow to the inflamed area, facilitating leukocyte movement (chemotaxis) to the affected site. Increases in permeability allow the leukocytes to move into the tissues. Once in the tissue, invading organisms are engulfed and phagocytized. In order to limit infection and further damage, an area of margination or a border is created through the formation of fibrinogen clots around the area. The action of the inflammatory cells creates excess fluid and debris that are then removed by lymphatic vessels. Moving through the lymphatics, offending antigens identified through this process come in contact with lymphocytes residing in the lymph nodes, initiating the adaptive immune response with the production of antibodies. Lastly, a promotion of fibrous scarring to facilitate tissue repair and healing is seen. Clinical evidence that can be observed as a result of this response includes the cardinal signs of inflammation: redness and heat due to the increased blood flow and increased metabolic activity, edema due to the accumulation of fluid in the affected area, and pain due to the injury and swelling. Drainage, serous exudate or pus (a combination of dead immune cells and digested bacteria), may also be seen. Systemically, fever, chills, malaise, and an elevated WBC count (leukocytosis) may also occur as a result of the inflammatory response (Fig. 18.7).

### Adaptive Immune Response

The adaptive immune response to foreign antigens consists of cellular and humoral responses. The cellular response is mediated by the T lymphocytes, and the humoral response is mediated by the B lymphocytes. For an immune response to be initiated, the foreign antigen must be recognized as non-self upon presentation by APCs via the MHC molecule on its surface. Each T or B cell recognizes only one antigen, but together as a group, they can recognize a host of foreign antigens (Fig. 18.8).

Acquired after birth, the adaptive immune response develops through active or passive immunity. In active immunity, antibodies or T cells are produced either after natural exposure to an antigen during illness or infection or after immunization. Passive immunity happens when preformed antibodies or T lymphocytes are transferred from one individual to another. For example, a newborn

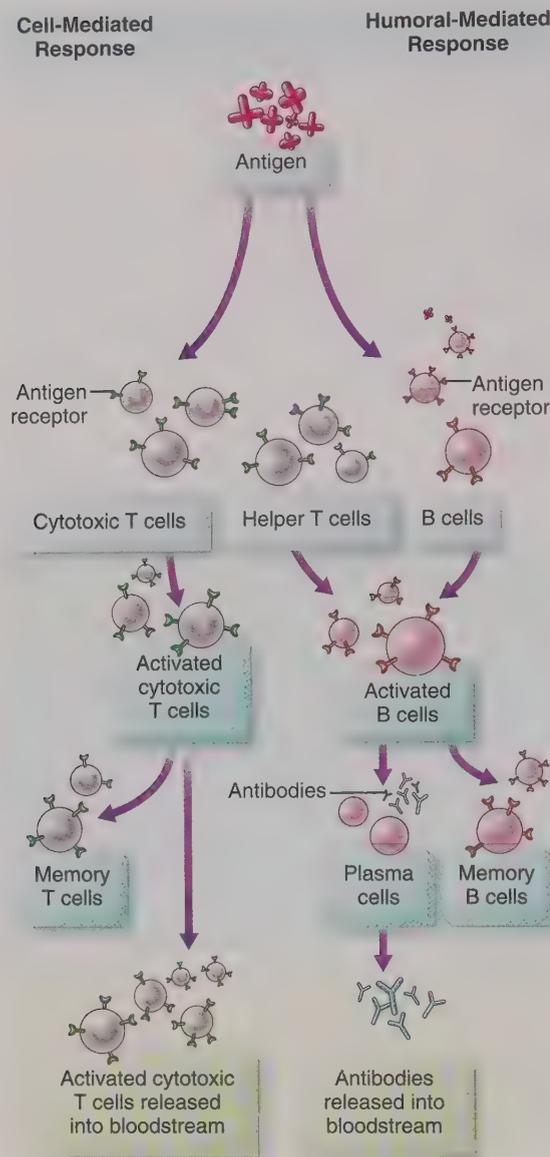

**FIGURE 18.7** Acute inflammatory responses.

acquires immunity from his or her mother through the placenta, or an individual can acquire immunity through transfusion of antibody-laden blood products. Different from the immediate and nonspecific innate response, the adaptive immune response is delayed and very specific. It also has memory, which confers long-term protection (Table 18.3). Adaptive immunity works in tandem with innate immunity and relies on antigen-specific receptors on

T and B cells to mount a response against exposure to a threat or disease (see Fig. 18.8).

### Cellular-Mediated Response

After formation in the bone marrow, undifferentiated T cells move to the thymus and develop specific surface antigen receptors in the process of maturation. *Naive* effector T cells (helper and cytotoxic T cells) leave the thymus and move to

**FIGURE 18.8** Adaptive immune response.

lymphatic tissue throughout the body, ready for activation. This activation, followed by subsequent proliferation, occurs when there is binding of an antigen to a T-cell receptor following recognition through the MHC after presentation by the APCs. This allows direct destruction of foreign or abnormal cells and activation of other cells such as macrophages. This function is carried out by cytotoxic T cells. Activated T helper cells release signaling cytokines to other activated cells, B cells and cytotoxic T cells. This facilitates the process of proliferation and direct binding of the helper T cells to the B cells, which facilitates B-cell division to plasma cells and memory cells. T memory cells are also produced during this process to stimulate secondary cell-mediated immune responses. These memory cells have the ability to respond rapidly to additional exposures to the same antigen (see Geriatric/Gerontological Considerations).

**Table 18.3** Humoral-Mediated and Cellular-Mediated Adaptive Immunity

	<b>Humoral-Mediated Immunity</b>	<b>Cellular-Mediated Immunity</b>
<b>Type of response</b>	Antibody mediated	Cellular mediated
<b>Cell type</b>	B lymphocytes (B cells)	T lymphocytes (T cells)
<b>Defense modality</b>	Circulating antibodies	Cell-to-cell contact
<b>Mechanism of defense</b>	Defends against extracellular microorganisms: bacteria, viruses	Defends against intracellular microorganisms: viruses, fungi, bacteria, tumor and transplant antigens

## Geriatric/Gerontological Considerations

### Changes in the Aging Immune Response

The aged are noted to have a decline in T-cell function and antibody production when exposed to specific antigen challenges. They also tend to have an increase in circulating antibody levels, leading to autoimmune disorders.

### Humoral-Mediated Response

After maturation in the bone marrow, B cells circulate through the lymphatic system as *naïve* B cells with specific membrane-bound antibodies attached to their surface. When they encounter an antigen that “matches” their antibody, they become activated and divide into plasma and memory cells. This process is commonly assisted by the helper T cell. Plasma cells are the effector cells, secreting antibodies to bind to the antigen. They have a short life span. Memory cells have the same membrane-bound antibody as the parent B cell. They remember and respond to the same antigen if there is repeated exposure. They have a longer life span.

Antibodies defend against foreign substances in several ways. They can react between two antigens, causing them to clump, which is termed *agglutination*. Agglutination facilitates **phagocytosis** and enables the body to clear itself of the invading organism. Opsonization, a process in which the antigen-antibody binding is coated with a pasty substance, also facilitates phagocytosis and assists in the clearing of the invading organism.

**CASE STUDY: EPISODE 2**

The nurse practitioner at the clinic obtains a comprehensive health history and performs a physical examination on Ms. Hall. Her vital signs show her to have a low-grade fever, with a temperature of 100.2°F (37.8°C), a heart rate of 88 bpm, and a blood pressure reading of 128/82 mm Hg. Her examination is significant for an erythematous maculopapular rash with several vesicles on the right upper chest...

**ASSESSMENT OF THE IMMUNE SYSTEM**

Obtaining a comprehensive history and performing a thorough physical examination will assist the nurse in assessing a patient's immune function. Laboratory and other diagnostic tests are also helpful in the assessment of immune function.

**History**

Pertinent information to obtain from the patient or significant other includes the patient's age, current medications, allergies, and the current problem he or she is experiencing. Medications that have immune system side effects include antibiotics, anti-inflammatory and immunosuppressive agents, antimetabolites, antineoplastic agents, and thyroid-suppressive therapy. The medical and surgical history is also important to obtain in addition to the family and social history because some immunological problems are genetic or chemically induced. Also included should be nutritional status, infection history, prior immunizations, chronic illnesses, autoimmune disorders, and cancers.

Nutritional status is important to assess because suboptimal nutrition can negatively impact the immune system. Adequate vitamins and minerals are vital for the maturation of immune cells and their function. A fatty acid imbalance can have suppressive effects. Illness leading to inadequate oral intake may negatively alter nutritional status and the body's ability to fight off infection and disease. Childhood and adult immunizations should be assessed to make sure adequate protection is present. Tuberculin test administration and results and recent exposure to infections, including sexually transmitted diseases, are also important to assess. Box 18.1 details a comprehensive patient history. Table 18.4 details risk factors for immune system malfunction.

**Physical Examination**

Physical assessment includes the taking of vital signs; an inspection of the skin and mucous membranes; palpation of lymph nodes; and an examination of the neurological,

**Box 18.1 Comprehensive Patient History****Current Problem**

- Constitutional: fevers, chills, night sweats, weight loss, fatigue, malaise, rashes
- Dizziness; changes in mental status, memory, gait
- Shortness of breath, cough, wheezing
- Chest pain, palpitations, presyncope, syncope
- Loss of appetite, nausea, vomiting, diarrhea, abdominal pain
- Bleeding: site, characteristic, associated symptoms
- Enlarged nodes: site, characteristic, associated symptoms, predisposing factors
- Joint pain, stiffness, swelling, muscle weakness, myalgias, arthralgias
- Extremity swelling: unilateral/bilateral, characteristic, predisposing factors, associated symptoms, treatment
- Medications: chemotherapy, immunosuppression, antibiotics/antivirals, interferon, leukotriene antagonists
- Allergies and severity of reactions
- Physical activity and tolerance

**Past Medical and Surgical History**

- Childhood illnesses
- Medications: chemotherapy, antibiotics, immunosuppression, steroids
- Malignancy
- Recurrent infections
- Surgery or trauma (splenectomy)
- Chronic illnesses with or without risk factors
- Blood transfusions
- Tuberculosis (TB) or other infectious history

**Immunization History**

- Immunizations based on current Centers for Disease Control and Prevention (CDC) immunization guidelines

**Family History**

- Malignancy
- Anemia
- Recent infections
- TB history
- Immune disorders
- Hemophilia

**Social History**

- Lifestyle factors
- Smoking status
- Alcohol intake
- Illicit drug use
- Recent foreign travel
- Employment history
- Environmental exposure history

**Table 18.4 Immune System Infection Risk Factors**

Problem	Impact
<b>Hepatic disease</b>	Decreased neutrophil count
	Decreased phagocyte action
	Diminished immunoglobulin production
<b>Malnutrition</b>	Decrease in white blood cell count
	Diminished neutrophil activity
<b>Pulmonary disease</b>	Decreased neutrophil activity
<b>Radiation therapy</b>	Decreased white blood cell production
	Damage to first-line barrier defenses
<b>Renal disease</b>	Decreased neutrophil action
	Decreased immunoglobulin activity
<b>Splenectomy</b>	Loss of recognition and encapsulation of bacteria
<b>Surgery</b>	Disruption of normal flora
	Disruption of barrier defenses
	Reduced neutrophil action
<b>Trauma</b>	Disruption of barrier defenses
	Contamination from soil, water, objects

respiratory, cardiovascular, gastrointestinal, genitourinary, and musculoskeletal systems. In a patient with immune dysfunction, the normal inflammatory responses may be blunted, and subtle changes may be present.

### Inspection

The nurse should perform a thorough assessment, inspecting each area of the patient's body for evidence of an immune disorder. Look for hypothermia or hyperthermia, enlarged lymph nodes, or edema. Also important to inspect are changes in skin color and skin integrity, rashes, dermatitis-type lesions, hematomas, petechiae, or purpura. Changes in level of consciousness, cognition, gait, and vision and hearing are important to note. Also important are changes in the respiratory system, such as tachypnea, air hunger, retractions, coughing, and nasal flaring. Collect and examine the urine for sediment, odor, and blood. Stool samples should be assessed for blood, smell, and the presence of diarrhea.

### Auscultation

Listen to the lungs for adventitious (abnormal) breath sounds such as crackles, wheezing, rubs, or rhonchi. Also note if there is any decrease in or absence of breath sounds. Listen to heart sounds; note if tachycardia, rubs, or irregularity of heart rhythm is present. Check for bowel sounds and note if they are hyperactive, hypoactive, or absent.

### Palpation and Percussion

Palpate the skin to check the temperature and whether clamminess is present. Also examine the lymph nodes for evidence of enlargement or tenderness. With light palpation, move the skin over the areas where nodes may be palpable. Nodes are not easily palpable in a healthy adult. If nodes are noted to be enlarged, tender, or fixed in position, this is cause for concern. Explore the adjacent area and regions that are drained by the enlarged node for signs of infection or malignancy. Cancerous nodes are not usually as tender as those from an infection or inflammatory process.

To assess the abdomen, perform light and deep palpations with percussion to assess for hepatosplenomegaly (enlargement of the liver or spleen), palpable masses, and the presence of abdominal fluid or abdominal pain. The liver and spleen may be enlarged because of infections, primary or metastatic cancer, or diseases of the blood or lymph system. Joints should be examined for mobility, pain, swelling, warmth, and erythema.

### DIAGNOSTIC STUDIES

Diagnostic studies, including blood tests, skin tests, bone marrow aspiration and biopsy, and radiological imaging, may be necessary to evaluate the state of an individual's immune competence. Immune deficiencies that may occur can be primary (due to aberrant development of immune cells or tissues) or secondary (due to outside interference of the normal immune system) in nature. The disorders that follow may be due to infection, autoimmunity, hypersensitivity, or gammopathies (caused by abnormal protein produced by plasma cells). AIDS, which is caused by HIV, is an example of a secondary immune deficiency caused by a viral infection. Autoimmunity refers to the body's attack against tissue that is self, causing organ or tissue dysfunction. Hypersensitivity occurs when an exaggerated response to an antigen is present, and gammopathies are caused by an overproduction of Igs from the plasma cell.

Tests to evaluate immune disorders are obtained to identify antibody deficiencies, T-lymphocyte and neutrophil defects, and complement abnormalities. Specific tests to evaluate problems are based on the assessment and are related to the suspected deficiency or disorder. For example, if the patient has a history of chronic bacterial infections, a complete blood count (CBC) with differential to evaluate individual leukocyte counts may be ordered. If the patient is fighting an infection, a CBC to evaluate the WBC count and inflammatory markers such as C-reactive protein may be drawn to evaluate responsiveness to a prescribed antibiotic. If neutropenia (low neutrophil count) with a low absolute neutrophil count (ANC) is present, reverse isolation may be necessary to protect the patient from infections. Immune system deficiencies and disorders are more thoroughly discussed in additional chapters of this textbook.

The patient undergoing an immunological workup requires adequate preparation, education, and counseling regarding the studies that are ordered. Teaching will allow the patient to be prepared for the procedure. Ideally, the

patient should repeat what he or she has been taught to evaluate comprehension of the material and should be encouraged to ask questions if clarification is needed. Patients may feel anxious or frightened about the pain and discomfort they might experience while undergoing

testing. They may also experience anxiety and distress over a diagnosis based on test results. The nurse and health-care team should be ready to provide information and support. A summary of diagnostic studies can be found in Table 18.5.

**Table 18.5 Diagnostic Tests for Immune Function**

Function Evaluated	Diagnostic Test	Test Interpretation	Nursing Considerations
<b>Leukocytes</b>	Complete blood count with differential	Measures total leukocytes, with a breakdown of leukocyte types and percentage present  Increases in leukocytes with an increase in immature neutrophils, also known as band neutrophils, indicates infection or inflammation; referred to as a left shift	For all testing, provide patient teaching on what to expect, what the test is, and why it is being done.
	Leukocyte (white blood cell) total	Normal values: 4.5–11.1 $10^3/\text{mm}^3$	
	Differential:	Normal values: Number (%)	
	● Neutrophils	6,300 (40–70)	
	● Lymphocytes	4,100 (20–40)	
	● Monocytes	1,800 (2–8)	
● Eosinophils	250 (1–3)		
● Basophils	60 (less than 1)		
● Absolute neutrophil count (ANC)	ANC calculates number of neutrophils available for fighting bacterial infections		
● Absolute lymphocyte count (ALC)	ALC calculates number of lymphocytes available to fight viral and opportunistic infections		
<b>Inflammation</b>	Erythrocyte sedimentation rate	Screening for presence of inflammatory process	
	C-reactive protein	Detected if inflammatory process or tissue destruction is present	
<b>Humoral immunity</b>	Antibody production:		
	● Total immunoglobulin (Ig) levels: IgA, IgG, and IgM	Presence of antibody-producing B cells	
	● Levels of antibodies against vaccines	Ability to produce IgM, IgG antibodies	
	B-cell numbers:		
● Lymphocytes with surface Ig	Presence of circulating B cells		
● Flow cytometry			
<b>Cellular immunity</b>	Delayed hypersensitivity skin test:		
	● Skin test to measure reaction to exposed antigens	Presence of antigen-responsive T cells	

Continued

**Table 18.5 Diagnostic Tests for Immune Function—cont'd**

Function Evaluated	Diagnostic Test	Test Interpretation	Nursing Considerations
	T-cell numbers: <ul style="list-style-type: none"> <li>● Numbers of T cells reacting to sheep erythrocytes or CD3 or CD11 antigen</li> </ul>	Presence of circulating T cells	
	T-cell proliferation: <ul style="list-style-type: none"> <li>● Proliferation response to mitogens (substances that stimulate mitosis)</li> <li>● Proliferation response to antigens</li> </ul>	Ability of T cells to divide with nonspecific stimulation  Ability of antigen-reactive T cells to respond to antigens	
<b>Leukocyte and lymphocyte evaluation</b>	Bone marrow evaluation: <ul style="list-style-type: none"> <li>● Bone marrow aspiration</li> <li>● Bone marrow biopsy</li> </ul>	Status of blood-forming tissue  Presence of hematological malignancies or primary bone marrow disorders	Prepare the patient for procedural specifics, including positioning and technique, pain or discomfort, and risk of bleeding or infection.
<b>Hypersensitivity</b>	Tissue allergy panel	Ability to mount an antibody response to an injected antigen	Prepare the patient for possible discomfort at injection site and positive wheal reaction.
<b>Phagocytic cell function</b>	Nitroblue tetrazolium test	Status of phagocytic cell function to evaluate for chronic granulomatous disease	
<b>Complement</b>	Complement component: <ul style="list-style-type: none"> <li>● Complement CH50</li> <li>● Complement C3 level</li> <li>● Complement C4 level</li> <li>● Complement fixation ratio</li> </ul>	Decreased if secondary deficiencies or autoimmune disorders  Decrease can increase risk for pulmonary infections  Decrease present with immune complex disease  Immunofluorescence to detect antigen-antibody reactions	
<b>Specific antigen-antibody panels</b>	Hepatitis A or B, cytomegalovirus, or respiratory syncytial virus	Immunofluorescence to detect antibodies or core antigens to specific viral antigens	
<b>Organs and structures</b>	Radiologic imaging: <p>computed tomography scan, magnetic resonance imaging, ultrasound,</p> <p>positron emission tomography (PET) scan</p>	Imaging to detect presence of lymphadenopathy, tumor formation, or metastatic disease	If contrast necessary, confirm absence of iodine allergy or previous contrast intolerance.  Patient may be NPO for a period of time prior to the scheduled test.  If patient claustrophobic, sedation may be necessary.  For PET scan, blood sugar must be under 200 mg/dL.

### Connection Check 18.3

Which statement by a patient undergoing a bone marrow biopsy indicates a need for additional teaching?

- “My lymph nodes are enlarged because of my immune system disorder.”
- “I might need something to calm my nerves before having this biopsy.”
- “Odds are that I will die from this procedure.”
- “My biopsy results may show that I have a problem with my immune system.”

### Connection Check 18.4

Which of the following diagnostic tests are drawn to assess cellular immunity? (Select all that apply.)

- Total Ig levels
- Specific antibody response
- Total lymphocyte count
- Helper T-cell functions
- Complete blood count

## AGE-RELATED CHANGES

Immune competence may decrease as the immune system changes and weakens with age. Aging has been noted to negatively affect both the innate and adaptive immune responses. *Immunosenescence* refers to those changes that occur with aging and their consequences—increased infection risk, increased risk of malignancy, and increased autoimmune disorders. Pneumonia and influenza are seen at much higher rates and are included in the top 10 causes of death for individuals aged 65 years and older. Atrophy of the thymus gland enhances with age, increasing the risk of viral infections. A greater incidence of shingles (herpes zoster virus) is seen in the older population; therefore, the shingles vaccine (Shingrix or Zostavax) is recommended for those 50 years of age and older.

Innate and adaptive immune responses actively provide defense against tumor cells. These responses decline with aging, creating an increased incidence of cancers. Older adults are also noted to have a decline in T-cell production and function and in antibody production when exposed to specific antigen challenges. They also tend to have an increase in the production of autoantibodies, leading to autoimmune disorders. Autoimmune disorders such as polymyalgia rheumatica, rheumatoid arthritis, and systemic lupus erythematosus are examples of problems due to increased autoantibody production.

A decrease in B-cell production and function and antigen-specific Ig activity may also be seen, creating a diminished immune memory and delayed hypersensitivity reactions. Malnutrition, which is associated with immune system defects, is sometimes seen in the older individual as a result of chewing and swallowing problems, blunted taste sensations, and chronic conditions that interfere with the absorption of

food and nutrients. Additionally, economic factors, medication side effects, depressive moods, and decreased social interaction may all negatively impact oral intake and nutritional status in the aging population negatively impacting the immune response. Figure 18.9 and Table 18.6 detail age-related changes in the immune system.

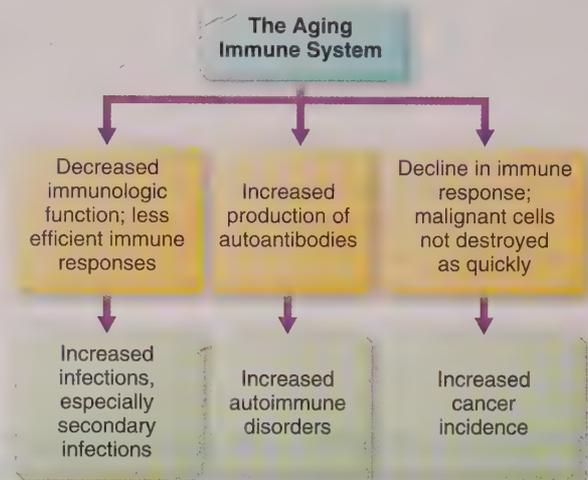

FIGURE 18.9 Age-related changes in the immune system.

Table 18.6 Age-Related Changes in the Immune System

#### Innate Immune Response Changes

##### Hematopoietic cells

- Decreased number in bone marrow
- Decreased proliferation ability

##### Macrophages

- Decreased precursors in bone marrow
- Decreased phagocytic capacity

##### Neutrophils

- Decreased phagocytic capacity

##### Natural killer cells

- Decreased number and percentage

##### Dendritic cells

- Increased number of myeloid dendritic cells

#### Adaptive Immune Response Changes

##### Thymic precursors

- Decreased thymic size
- Decreased number of thymic precursors

##### T lymphocytes

- Decreased number of immature T cells
- Decreased T-cell diversity

- Decreased proliferation ability

- Decreased signaling ability
- Decreased regulatory T-cell function

##### B lymphocytes

- Decreased precursors in bone marrow

- Decreased peripheral B cells
- Decreased antibody response
- Increased autoreactive antibodies in the circulation

### Connection Check 18.5

The nurse associates which of the following findings with immunosenescence in a 68-year old woman? (*Select all that apply.*)

- A. Pneumonia
- B. Shingles
- C. Cervical dysplasia
- D. Cancer
- E. Leukemia

**Safety Alert** Nutritional status is a critical component of immunocompetence. Cellular immunity, phagocyte activity, and complement ability are greatly impacted by protein deficiencies. Because of this, patients who suffer from malnutrition are more susceptible to infections.

## Making Connections

### CASE STUDY: WRAP-UP

Based on Ms. Hall's history of presenting symptoms and physical examination, she was diagnosed with herpes zoster (shingles). Herpes zoster is a reactivation of the chickenpox or varicella-zoster virus (VZV) that can result in post-herpetic neuralgia.

The nurse practitioner instructs Ms. Hall to increase her fluid intake and avoid exposure to individuals who may be immunosuppressed. She is instructed to immediately report if she develops increasing fever or pain. She will follow up every 1 to 2 weeks until resolution of her symptoms.

#### Case Study Questions

1. The nurse caring for a patient with herpes zoster incorporates which nursing diagnosis into the plan of care?
  - A. Risk for bleeding
  - B. Persistent fatigue
  - C. Pain
  - D. Inadequate nutrition
2. The nurse monitors for which advancing clinical manifestations in a patient diagnosed with shingles? (*Select all that apply.*)
  - A. Worsening pain
  - B. High fever
  - C. Malaise
  - D. Nausea
  - E. Headache

3. A nurse providing care for a patient with shingles understands that the illness is caused by reactivation of which of the following viruses?
  - A. Cytomegalovirus
  - B. Epstein-Barr virus (EBV)
  - C. Varicella-zoster virus (VZV)
  - D. Human immunodeficiency virus (HIV)
4. The nurse includes which information in the teaching plan about the management of shingles?
  - A. Limit fluid intake
  - B. Encourage bed rest
  - C. Post-herpetic neuralgia can develop
  - D. Take antibiotics as directed
5. Which statement by Ms. Hall indicates that teaching has been effective?
  - A. "I'm so glad I can continue my exercise schedule."
  - B. "I need to stay away from my aunt who had a kidney transplant."
  - C. "So I should contact you if I have more blisters appear?"
  - D. "I don't drink a lot of fluids, so it shouldn't be hard for me to limit my fluid intake."

## CHAPTER SUMMARY

The immune system is a network that remains in a continual mode of surveillance and on constant alert to defend the body against infection and disease. Lymphoid organs work in collaboration with specialized immunity and immune responses to afford this protection. Innate and adaptive immunity involve first-, second-, and third-line defenses that include physical and chemical barriers and inflammatory, cell-mediated, and antibody-mediated responses. Multiple bodily structures, including the circulatory, respiratory, and gastrointestinal systems, are involved in these protective mechanisms and work in concert to protect the host against infection and invasion by microorganisms.

Components of the immune system include the lymphatic system, the primary and secondary lymphoid organs, and the cells and proteins involved in the immune response. The lymphatic system defends the body against the invasion of microorganisms and consists of lymphatic vessels, lymph fluid, and collecting ducts. Primary lymphoid, or central, organs include the thymus and bone marrow. Secondary lymphoid, or peripheral, organs include the spleen, lymph nodes, tonsils, adenoids, and Peyer's patches.

Innate immunity provides the first two lines of defense. The first line is through anatomical, biochemical,

genetic, or physiological barriers that include the skin and mucous membranes. Inflammatory responses provide the second line of defense with the assistance of IFN, complement, and phagocytosis. This response is rapid, nonspecific, and void of memory cells. Neutrophils are phagocytes and early responders to inflammation. Monocytes and macrophages respond later and stay longer to clean up debris at the site of inflammation. Eosinophils defend against parasitic infiltration, whereas NK cells eliminate viruses and cancer cells. Cytokines, including INF, IL, and TNF, are regulators of the inflammatory response. Local manifestations of inflammation include redness, heat, swelling, and pain.

The third line of defense is through adaptive immunity, which is acquired through natural or artificial exposure to

an infection, antigen, or vaccine. This type of immunity protects through cell-mediated and antibody-mediated mechanisms by providing a specific antigen–antibody response with B- and T-cell activation. It can be active or passive immunity depending on whether the immune response originated in the host or in a donor.

When immune competence is present, the immune system prevents the penetration of foreign microbes or antigens and the proliferation of abnormal or malignant cells. Conversely, immune incompetence can lead to allergies, infection, cancer, and autoimmune and immunodeficiency disorders. Age, medications, nutrition, genetics, physical or emotional stress, and illness can all impact immunity and immune responses, thereby influencing the overall function of the immune system.

# Chapter 19

## Coordinating Care for Patients With Immune Disorders

*Diane J. Morey*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Describing the epidemiology of immune dysfunction
2. Describing pathophysiological processes of immune dysfunction
3. Correlating clinical manifestations to pathophysiological processes of
  - a. B-cell deficiencies
  - b. T-cell deficiencies
  - c. Secondary immune deficiencies—therapy based
  - d. Excessive immune response
4. Describing the diagnostic results used to confirm the diagnoses of selected immune dysfunctions
5. Discussing the medical management of:
  - a. B-cell deficiencies
  - b. T-cell deficiencies
  - c. Secondary immune deficiencies—therapy based
  - d. Excessive immune response
6. Describing complications associated with selected immune dysfunctions
7. Developing a comprehensive plan of nursing care for patients with immune dysfunction
8. Designing a teaching plan for a patient with immune dysfunction

### CONCEPTS

- Assessment
- Immunity
- Infection
- Inflammation
- Medication

### ESSENTIAL TERMS

Allergen  
Anaphylaxis  
Angioedema  
Antibody  
Antigen  
Atopic  
Autoimmunity  
Autosomal dominant  
B-cell deficiencies  
B lymphocytes  
Complement  
Cytotoxic  
Histamine  
Hypersensitivity reactions  
Immunoglobulin E (IgE)  
Immunoglobulin G (IgG)  
Immunoglobulin M (IgM)  
Immunosuppression  
IV immune globulin (IVIG)  
Primary immune dysfunction  
Secondary immune dysfunction  
T-cell deficiencies  
Thymus gland  
T lymphocytes  
X-linked recessive

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Samuel Smith is a 50-year-old male patient who presents in the emergency department with a temperature of 101°F (38.3°C), a productive cough, fatigue, and difficulty breathing. He has a history of seasonal allergic rhinitis and mild asthma but no other significant health history. He does not report any known medication allergies. Initial orders include:

- Chest radiography
- Complete blood count
- Complete metabolic profile
- Pulse oximetry
- Sputum for culture and sensitivity...

## INTRODUCTION

The immune system provides defense against microorganisms through first-line barriers to infection and the inflammatory and immune response. Additionally, it prevents the proliferation of cancer cells and initiates the healing of damaged tissue. Immune disorders may be due either to a deficiency or to overactivity and may involve one or more components of the immune system. Deficiency can result in disease processes; overactivation results in reactions that include **anaphylaxis** and autoimmune disorders.

## OVERVIEW OF PRIMARY AND SECONDARY IMMUNE DYSFUNCTION

**Primary immune dysfunction** occurs in persons born with an immune system that is deficient or is limited in its ability to function. In this case, there is an intrinsic (inborn), congenital, or genetic cause. Most are inherited diseases, but some are the result of the interaction of predisposing genetic factors and environmental factors. These primary immunodeficiencies result from defects in **T lymphocytes**, B lymphocytes, natural killer cells, phagocytic cells, or the complement system. The majority are diagnosed in childhood. Table 19.1 lists warning signs that a primary immune dysfunction is present.

**Secondary immune dysfunction**, or acquired immune deficiency, occurs when there is damage caused by an extrinsic or external environmental factor or agent. This arises secondary to some other disease process or exposure to medications or chemicals. Examples of secondary immune dysfunction include immune deficiency caused by HIV disease, irradiation, chemotherapy, malnutrition, or burns.

**Table 19.1** Warning Signs of Primary Immune Deficiency

### Frequent Infections, Unusual Infections, or Unusual Complications of Usual Infections Are the Most Frequent Presentation of Immune Deficiency

- Eight or more new infections within 1 year
- Two or more serious sinus infections within 1 year
- Two or more months on antibiotics with little or no effect
- Two or more pneumonias within 1 year
- Failure of an infant to gain weight or grow normally
- Recurrent deep skin or organ abscesses
- Persistent thrush in the mouth or elsewhere on skin after age 1
- Need for IV antibiotics to clear infections
- Two or more deep-seated infections
- A family history of immune deficiency

Secondary immune dysfunction comprises the majority of deficiencies presented in the clinical setting.

## PRIMARY IMMUNE DYSFUNCTION: B-CELL DEFICIENCIES

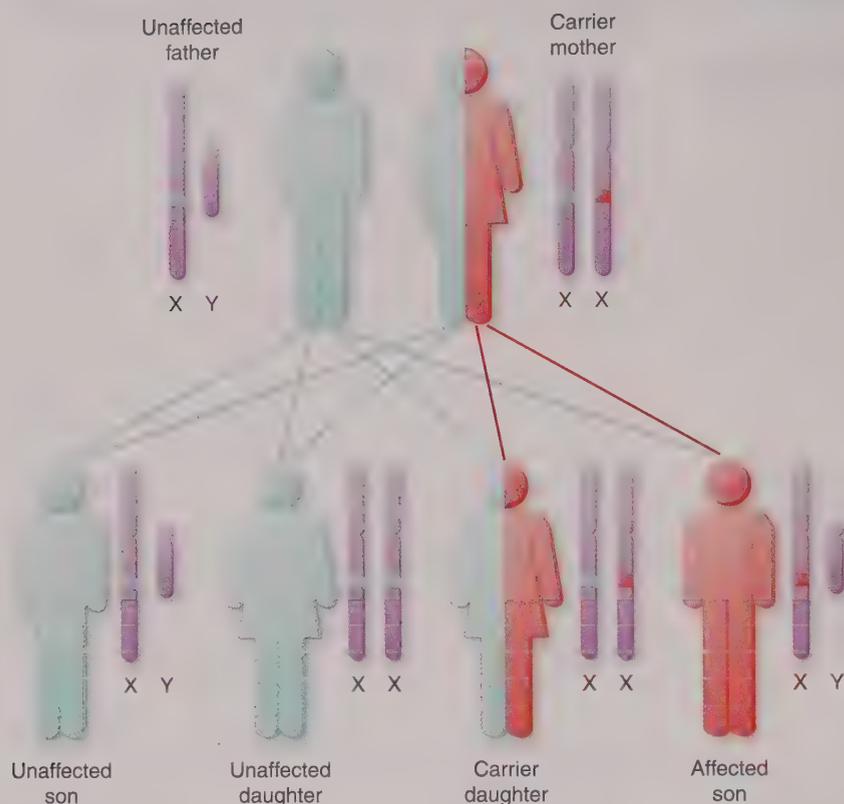

One classification of primary immune dysfunction involves **B-cell deficiencies**. B cells are involved in producing a humoral immune response, which is the **antibody** response. An antibody, or immunoglobulin, is produced in response to a foreign substance known as an **antigen**. B-cell deficiencies involve a lack of differentiation of B-cell precursors into mature B cells or a lack of differentiation of B cells into plasma cells. One example of a B-cell deficiency is X-linked agammaglobulinemia (XLA).

### X-Linked Agammaglobulinemia

#### Epidemiology

Agammaglobulinemia is an **X-linked recessive** inherited or congenital primary immune deficiency. It is the most common of the primary immune deficiencies and accounts for approximately 50% of cases. The term *X-linked recessive* means that the gene that causes this disease is located on the X chromosome. Humans have 46 pairs of chromosomes. One pairing identifies sex. Females have two X chromosomes; males have an X and a Y. X-linked agammaglobulinemia primarily affects males because it is unlikely that females will inherit two X chromosomes carrying the altered gene. Males get only one X chromosome. If their one X chromosome carries an altered or disease-carrying gene, they will have symptoms of the disease. Females may inherit one altered gene, which makes them a carrier of the disease. Figure 19.1 illustrates the genetic inheritance of XLA. An individual with a family history has the potential of

## X-Linked Recessive, Carrier Mother

**FIGURE 19.1** X-linked recessive genetic inheritance of disease. Males get only one X chromosome. The son who receives an altered gene on the X chromosome from his carrier mother will have symptoms of the disease. Females have two X chromosomes. The daughter who receives an altered gene on one X chromosome from her carrier mother will not manifest the disease but will be a carrier of the disease.

inheriting the disorder. It occurs at a frequency of about 1 in 250,000 male newborns. There is no ethnic predisposition. Prevalence is three to six per million males in all racial and ethnic groups. Symptoms do not appear until between 6 and 12 months of age because there is initial protection from the mother's antibodies. Many children die before their sixth birthday because of infection if the disorder is not identified and treated.

### Connection Check 19.1

The nurse is screening patients for the risk of developing agammaglobulinemia. The nurse should consider which patient at greatest risk?

- A 6-year-old female without any family history
- A 35-year-old female with a respiratory infection
- A 7-month-old male with recurrent infections
- A 40-year-old male with a family history

### Pathophysiology

X-linked agammaglobulinemia, also known as Bruton's agammaglobulinemia, is the result of a mutation of the *BTK* gene. The *BTK* gene is present on the long arm of the X chromosome, and its defect results in a deficiency of

Bruton's tyrosine kinase, which is essential for the development of the B lymphocyte. B cells are specialized white blood cells (WBCs) that, when mature, produce special proteins called antibodies or immunoglobulins. The BTK protein transmits chemicals that alert B cells to mature and produce antibodies. This type of B-cell deficiency is one in which immature B cells are present in normal numbers but are unable to mature. The inability to produce antibodies in response to the invasion of an antigen leaves the patient prone to severe bacterial infections.

### Clinical Manifestations

Clinical manifestations include infections of the ears, lungs, skin, conjunctiva, and central nervous system. The presence of recurrent bacterial infections of the respiratory tract in childhood is the first indicator of the possibility of this disease. Chronic respiratory infections such as sinus infections and pulmonary disease are common clinical manifestations. Serious infections can develop in the bloodstream and internal organs. Patients can have recurrent pneumonia, meningitis, and septicemia with organisms such as *Streptococcus pneumoniae* and *Haemophilus influenzae*. They may also develop autoimmune disease, leukemia, or lymphoma. Patients tend to cope well with most short-term viral infections but are very susceptible to chronic viral infections such as hepatitis, polio, and enterovirus viruses.

## Management

### Medical Management

#### Diagnosis

Obtaining a detailed family history and history of infections is an important first step in a patient suspected to have an abnormal immune response. Frequent infections such as otitis media, more severe infections requiring hospitalizations, or atypical infections can be indicators. Diagnostics include B-lymphocyte surface marker assays, which identify specific cells involved in the immune response. These are general tests that can aid in the diagnosis of primary immunodeficiency disorders. They diagnose disorders by identifying abnormal numbers and percentages of B lymphocytes and help to evaluate immunodeficiencies. In X-linked agammaglobulinemia (XLA), blood tests indicate a lack of circulating B cells as well as low levels of immunoglobulins. A Western blot test can be done to determine if the BTK protein is being expressed—determining if the effects of the gene are appropriately manifested in a person. BTK expression is reported as present, absent, partial deficiency, or mosaic. Mosaic BTK expression indicates a carrier. Genetic testing can confirm the diagnosis. Women with a family member with XLA should seek genetic counseling. Periodic radiographs of the chest or sinuses in a child at risk are utilized to detect any signs of infection in its early stages.

### Connection Check 19.2

The nurse monitors for which clinical manifestations in the patient diagnosed with XLA?

- Low temperature
- Recurrent respiratory infection
- Low blood pressure
- Diarrhea

#### Treatment

Treatment includes giving **IV immune globulin (IVIG)** to provide short-term passive immunity (see Geriatric/Gerontological Considerations). IV immune globulin is a sterilized solution made from human plasma. It contains the antibodies, mostly **immunoglobulin G (IgG)** or gamma globulin, to help protect against infection from various diseases. The dosage and the schedule are individualized, but typically IV immune globulin is given every 3 or 4 weeks. Gamma globulin can also be given by weekly subcutaneous injections. Both routes provide therapeutic concentrations of serum IgG.

Patients take a low dose of prophylactic antibiotics regularly, even when feeling well, if the episodes of infection are frequent. The aim of prophylactic antibiotics is to prevent an infection from starting. Aggressive treatment with specific antibiotics is initiated when the patient exhibits overt signs of infection. Patients should have an antibiotic

course at least twice as long as that used in normal, healthy individuals. Immunization with killed viral and bacterial vaccines is sometimes done to aid in the development of T-cell-mediated immune response, which may augment the protection that is obtained through immunoglobulin replacement. Vaccination with live viruses is contraindicated.

### Geriatric/Gerontological Considerations

Geriatric patients have an elevated risk of acute renal failure, arterial or venous thrombosis, hemolysis, and allergic/hypersensitivity reactions during IVIG treatment.

#### Complications

Children with this disorder are prone to many different complications. Approximately 60% of individuals with XLA develop a severe, life-threatening bacterial infection, such as pneumonia, empyema, meningitis, sepsis, cellulitis, or septic arthritis. They may also develop a chronic viral enterovirus. When IV gamma globulin became available in the mid-1980s, the incidence of chronic enteroviral infection markedly decreased in individuals with XLA. However, some patients still develop enteroviral encephalitis, and some have neurological deterioration of unknown etiology.

**Safety Alert** Of patients with X-linked agammaglobulinemia (XLA), 5% to 10% developed vaccine-associated polio after vaccination with the live attenuated oral polio vaccine. For that reason, children with XLA and their siblings should be given inactivated polio vaccine rather than oral polio vaccine.

### Nursing Management

#### Assessment and Analysis

Many of the clinical manifestations observed in the patient with XLA are directly related to infection of the respiratory tract, skin, conjunctiva, or ears. Common findings include:

#### General:

- Fever
- Changes in behavior (inconsolable crying), eating patterns, irritability, decreased activity

#### Respiratory:

- Increased respiratory rate
- Absent or decreased lung sounds

#### Skin:

- Rash
- Lesions

**Conjunctiva:**

- Redness or drainage

**Ear:**

- Pulling at the ears

**Nursing Diagnosis**

- **Risk for infection** related to compromised host defenses secondary to B-cell immunodeficiency

**Nursing Interventions****■ Assessments**

- Vital signs  
*Increased temperature may indicate the presence of infection; respiratory rate may increase with respiratory infections in an effort to increase oxygenation.*
- Assess lung sounds.  
*Decreased or absent breath sounds or adventitious breath sounds may be present, with excessive secretions being common with respiratory infections.*
- Inspect eyes and ears, skin and nails, rashes and lesions.  
*Red, inflamed ears indicate an ear infection. Recurrent ear infections are the most common infection prior to diagnosis. Red conjunctiva with drainage indicates conjunctivitis, a common manifestation. Skin rashes and infections are frequently seen.*
- Evaluate the infant or child's behavior and eating patterns.  
*Irritability, decreases in activity, and poor appetite are signs of infection and illness.*

**■ Actions**

- Administer IV gamma globulin as ordered.  
*IV immune globulin contains antibodies to protect against infection, providing short-term immunity.*
- Administer prophylactic antibiotic therapy as ordered.  
*Prophylactic antibiotics may prevent infections.*
- Anticipate prompt treatment with antibiotics when infection is present.  
*Aggressive organism-specific treatment with antibiotics should begin as quickly as possible to prevent the development of extensive and more severe infections.*

**■ Teaching**

- Teach parents of at-risk children about the 10 warning signs of primary immunodeficiency, and instruct them to speak to their provider if there are more than one of the conditions listed in Table 19.1.  
*Prompt detection of XLA is essential to manage infections and initiate proper treatment with IVIG to avoid life-threatening complications.*
- Institute precautions to prevent infection and minimize any source of infection in the environment at home related to foods (particularly raw foods) and water, domestic animals, or unsanitary conditions. Additionally, sites that accumulate stagnant water—such as sinks, toilets,

waste pipes, cleaning tools, and facecloths—readily support microbial growth and can become secondary reservoirs of infection.

*Potential sources of infection should be identified and controlled as much as possible.*

- Protect the patient from any direct contact with anyone with a contagious illness.  
*To prevent infection from others*
- Safe food handling and storage practices  
*Food-based microorganisms can be a source of infection.*
- Signs and symptoms of infection and when to seek medical attention, particularly any temperature of 100.5°F (38°C) or more  
*Infection requires immediate treatment, and the family should not wait to report fever or symptoms of infection in an immunocompromised infant or child.*
- Good hand washing  
*To prevent infection*
- Information regarding genetic disorders and community support groups  
*Support for the family regarding understanding of genetic disorders and peer support are useful to cope with the disorder and manage the care of the patient.*

**Evaluating Care Outcomes**

Appropriate antibiotic therapy and treatment with IVIG can help patients with XLA lead normal, active lives. The family and patient should be provided with information regarding the importance of preventing infection and when to contact their healthcare provider. Most patients have a good prognosis if they start the antibody replacement early.

**Other B-Cell Deficiencies****Common Variable Immune Deficiency**

Common variable immune deficiency (CVID) is the second category of B-cell deficiency. It is due to a lack of differentiation of B cells into plasma cells. This results in low levels of circulating antibodies. There are normal levels of B cells, but they fail to differentiate into antibody-secreting cells. The genetic basis is unknown, but it occurs in first-degree relatives of persons with IgA deficiency. It is similar to XLA in that it manifests with recurrent bacterial infections, but the infections tend to be less severe. This deficiency differs from XLA in that it appears in adolescents or in young adults between 15 and 35 years of age. It occurs equally in men and women. Patients with CVID have a tendency to develop autoimmune disorders, interstitial lung disease, hepatitis, non-Hodgkin's B-cell lymphoma, gastric cancer, hepatitis, and intestinal malabsorption. Treatment is similar to that of XLA.

**Selective Immunoglobulin A**

Selective IgA is the most common type of immunoglobulin deficiency. It affects 1 in 400 to 1 in 1,000 persons. The pattern of occurrence in families suggests an autosomal

inheritance, but there is variability in its expression. As another example of the second type of B-cell deficiency, the cause of this deficiency is likely due to a block in the pathway that provides for the final differentiation of mature B cells to IgA-secreting plasma cells. Two-thirds of persons have no symptoms because normal IgG and IgM levels compensate for the deficiency. Fifty percent of those affected overcome the deficiency by the age of 14. Persons with IgA deficiency may develop anaphylactic reactions when IgA immunoglobulin is administered because of antibodies against IgA. Thus, this treatment is not utilized routinely. If blood is necessary, specially washed erythrocytes or IgA-deficient donors are used.

### Immunoglobulin G Subclass Deficiency

Immunoglobulin G subclass deficiency affects one or more of the IgG subtypes but does not affect the overall levels of IgG. Because antibodies directed against carbohydrate and polysaccharide antigens are primarily IgG2, those with IgG2 deficiency are at greater risk for the development of sinusitis, otitis media, and pneumonia that is caused by polysaccharide-encapsulated microorganisms such as *S. pneumoniae*, *H. influenzae* type B, and *Neisseria meningitidis*. Those with mild forms can be treated with prophylactic antibiotics. Those with more severe symptoms can be treated with IVIG.

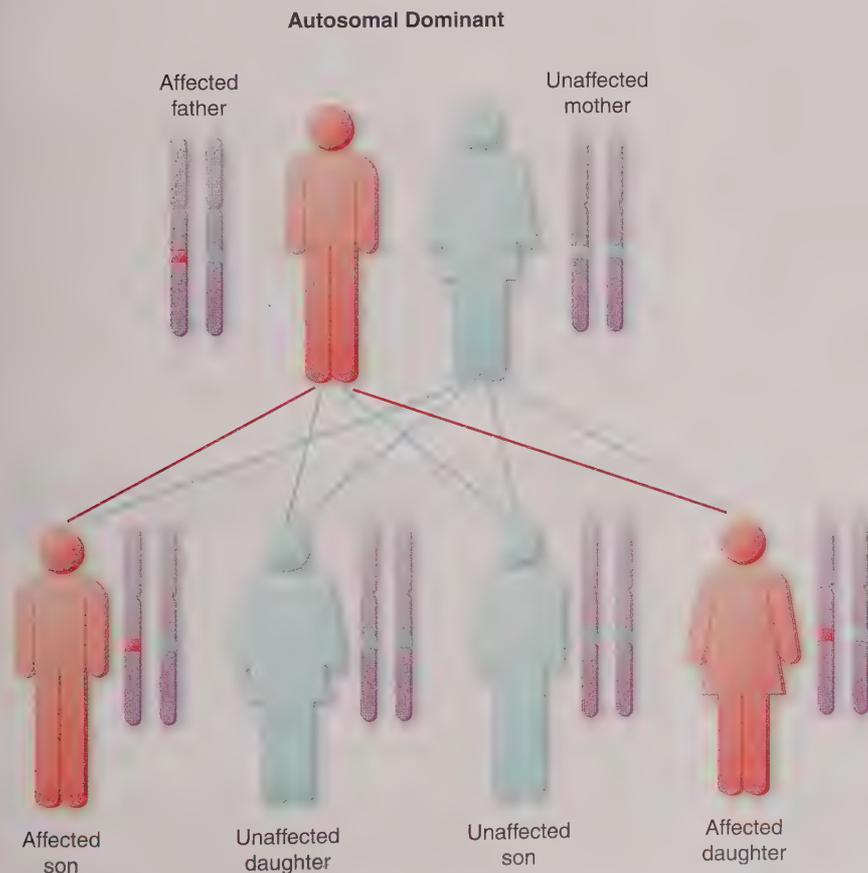

## PRIMARY IMMUNE DYSFUNCTION: T-CELL DEFICIENCIES

T lymphocytes include subtypes CD4 helper and CD8 cytotoxic T cells. They are responsible for the cell-mediated immune response that protects against fungal, protozoan, viral, and intracellular bacterial infections. They are also responsible for controlling malignant cell proliferation and coordination of the immune response. **T-cell deficiencies** lead to infections and other problems that are more severe than B-cell deficiencies. An example of a T-cell deficiency is DiGeorge's syndrome.

### DiGeorge's Syndrome

#### Epidemiology

DiGeorge's syndrome, or congenital thymic hypoplasia, is an **autosomal-dominant** genetic condition that arises from the 22nd chromosome. Autosomal dominant means that the presence of only one altered gene is required for the disease to be present. Figure 19.2 illustrates the genetic inheritance of DiGeorge's syndrome. This disorder arises spontaneously and is present at birth. It is hard to identify anyone at risk for this disorder, but gestational diabetes is implicated in increasing risk. A population-based study conducted by the Centers for Disease Control and Prevention (CDC) found a prevalence of

**FIGURE 19.2** Autosomal-dominant genetic inheritance of DiGeorge's syndrome. The child who receives the altered gene from an affected parent will manifest symptoms of the disease.

about 1 in 6,000 in whites, blacks, and Asians and 1 in 3,800 in Hispanics.

### Pathophysiology

DiGeorge's syndrome arises from a disturbance of the normal embryological development of the pharyngeal pouches occurring between the 6th and 10th weeks of gestation. Pharyngeal pouches are the embryonic precursors to specific organ systems in the head, neck, and chest. For example, the third and fourth pharyngeal pouches develop into the thymus, parathyroid gland, and aorta. The pulmonary artery arises from the sixth pharyngeal pouch. The effects of DiGeorge's syndrome are dependent on which pharyngeal pouch is affected but typically involve dysfunction of the **thymus gland** and parathyroid, facial deformities such as cleft palate, and heart anomalies.

The thymus gland is responsible for T-cell production and differentiation. Thymus dysfunction results in T-cell deficiencies. The deficiencies vary depending on the amount of thymus that is affected. Because T cells help B cells mature, the lack of T cells usually affects B-cell activity also. T-cell function may improve with age depending on the severity of involvement.

### Clinical Manifestations

Immune dysfunction caused by T-cell deficiencies results in recurrent infections. There are variations in the type and severity of dysfunction as a result of the extent of the body systems affected. If the patient has some limited thymic function, infections may be frequent but not necessarily severe. Infections include yeast, fungal, protozoan, and viral, such as chickenpox, measles, and rubella, which may be fatal. *Candida albicans* is almost always seen in patients with T-cell deficiencies. Frequent colds and ear infections are common. Other disorders are related to the specific body systems affected (Box 19.1). The acronym CATCH is formed by the first letter of each of these disorders. Because the disorder is caused by the deletion of a small piece of chromosome 22, the healthcare community sometimes refers to DiGeorge's syndrome as CATCH-22.

Other clinical manifestations include the following:

#### General

- Weakness or tiring easily
- Failure to thrive

### Box 19.1 DiGeorge's Syndrome

The acronym CATCH summarizes the possible clinical manifestations of DiGeorge's syndrome:

- Cardiac abnormality (especially tetralogy of Fallot)
- Abnormal faces
- Thymic aplasia
- Cleft palate
- Hypocalcemia–hypoparathyroidism (See Chapter 43 for details.)

- Failure to gain weight
- Difficulty feeding

### Respiratory

- Frequent infections
- Shortness of breath
- Bluish skin due to low oxygen-rich blood

### Other

- Twitching or spasms around the mouth, hands, arms, or throat
- Poor muscle tone
- Delayed development of infant milestones
- Delayed speech development
- Learning delays or difficulties, emotional and behavior problems
- Cleft palate or other problems with the palate
- Certain facial features, such as low-set ears, wide-set eyes, or a narrow groove in the upper lip

### Management

#### Medical Management

##### Diagnosis

Diagnosis of the disorder is primarily done by genetic testing. DiGeorge's syndrome is determined with a finding of submicroscopic deletion of chromosome 22 detected by fluorescence in situ hybridization. Fluorescence in situ hybridization uses fluorescence microscopy to find specific features in DNA.

##### Treatment

Treatment includes pharmacological therapy, such as calcium supplements to prevent tetany and seizures, which could be caused by hypocalcemia from hypoparathyroidism if the parathyroid gland is affected. T-cell immune deficiency may require aggressive treatment of infections. As with agammaglobulinemia, treatment includes giving IVIG to provide short-term passive immunity. It is given every 3 or 4 weeks, and the dosage and the schedule are individualized. Treatment also includes prophylactic antibiotics. Bone marrow transplantation may be indicated in severe cases (see Box 19.2 and Genetic Connections).

## Genetic Connections

### Primary Immunodeficiency Diseases (PIDs)

PID is caused by errors (mutations) in specific genes. The Human Genome Project has identified the specific genes involved in a majority of primary immunodeficiency diseases.

It has been demonstrated that it is possible to cure the disease by inserting a normal copy of the gene into the patient's hematopoietic stem cells (HSCs). Currently, viral vectors are tools utilized by molecular biologists to deliver

genetic material into cells through a process known as insertional mutagenesis. This process is associated with risks and adverse effects, such as the development of leukemia-like disorders. Overcoming risks and determining safer vectors for gene therapy will allow for this process to become a more common and successful treatment. Gene therapy is still regarded as an experimental therapy. New and improved self-inactivating retroviral and lentiviral vectors that incorporate additional safety features are now in clinical trials.

### Surgical Management

Surgery such as thymus tissue transplantation is an option if the thymus is absent. In that case, the child is extremely vulnerable to a number of severe infections. Ideally, the procedure is performed within 3 to 6 months of birth, prior to the onset of multiple infections. The tissue for this transplantation is obtained from infants having cardiac surgery. In cardiac surgery, in order to successfully visualize the heart, portions of the thymus gland are excised. With parental consent, that tissue can be saved for use in thymus transplantation for children with DiGeorge's syndrome. Surgery may also be an option to correct the cardiac defects of DiGeorge's syndrome, such as tetralogy of Fallot.

### Box 19.2 Hematopoietic Stem Cell Transplantation

The process of taking hematopoietic stem cells (HSCs) from one person and transfusing them into another is called hematopoietic stem cell transplantation, or HSCT. Transplantation of HSCs represents the main treatment for several severe forms of primary immunodeficiency diseases. Traditionally, HSCs were obtained from the bone marrow but can now be obtained from peripheral blood or blood taken from the placenta at birth (umbilical cord blood). Transplantation of HSCs has the potential to replace the deficient immune system of the patient with a normal immune system and, thereby, effect a cure. The primary immunodeficiency diseases for which HSCT is most commonly performed include severe combined immune deficiency (SCID), Wiskott–Aldrich syndrome (WAS), and many other severe primary immunodeficiency diseases. Current challenges in HSCT include:

- Identifying candidates before significant damage from infection occurs
- If damage has occurred, determining the extent of tissue and organ involvement
- Recruiting donors with a match to the patient

### Complications

DiGeorge's syndrome may cause problems with the development and function of the brain, resulting in learning, social, developmental, or behavioral problems. Delays in speech development and learning difficulties are common. Others develop disorders such as attention deficit-hyperactivity disorder, autism, or autism-related disorders. In later life, the patient is at increased risk of mental health problems, including depression, anxiety disorders, schizophrenia, and other psychiatric disorders.

Additionally, with a poor immune system due to the small thymus, patients may have an increased risk of autoimmune disorders, such as rheumatoid arthritis and Graves' disease. Patients with T-cell dysfunction are at risk for graft-versus-host disease. This is manifested when T cells in grafted tissue such as transfused blood attack and destroy the host's tissues.

### Connection Check 19.3

The nurse is caring for a patient with DiGeorge's syndrome. Precautions are taken for decreased levels of which of the following?

- A. B cells
- B. Thyroid hormone
- C. Serum calcium
- D. Serum iodine

### Nursing Management

#### Assessment and Analysis

The clinical manifestations of DiGeorge's syndrome are related to the disturbance of normal embryonic development of the pharyngeal pouches that leads to the eventual development of the thymus and parathyroid gland, facial structures, and cardiac structures. Table 19.2 summarizes the assessment data for DiGeorge's syndrome.

#### Nursing Diagnoses

- **Risk for complications** of opportunistic infections
- **Risk for infection** related to compromised host defenses secondary to T-cell immunodeficiency (inadequate function of B cells secondary to T-cell deficiencies)
- **High risk for ineffective airway clearance** related to laryngospasm secondary to hypocalcemia

#### Nursing Interventions

##### Assessments

- Vital signs  
*Increased temperature may indicate infection; respiratory rate may increase with respiratory infections in an effort to increase oxygenation.*
- Lung sounds  
*Decreased or adventitious breath sounds may be present with a respiratory infection.*
- Calcium levels  
*Calcium levels may be decreased because of hypoparathyroidism.*

**Table 19.2 Assessment Data for DiGeorge's Syndrome**

*The Portions of Chromosome 22 Deleted in DiGeorge's Syndrome Play a Role in the Development of a Number of Body Systems and Result in Several Errors During Fetal Development*

Assessment Data	Analysis/Explanation
<ul style="list-style-type: none"> <li>● Recurrent infections</li> <li>● Cardiac abnormality (especially tetralogy of Fallot) causes cyanosis, heart murmur, difficulty in feeding, failure to gain weight, retarded growth and physical development, dyspnea on exertion, clubbing of the fingers and toes, and polycythemia.</li> <li>● Abnormal faces and craniofacial findings include auricular abnormalities, nasal abnormalities, "hooded eyelids," increased distance between the eyes (ocular hypertelorism), cleft lip and palate, asymmetric crying faces, and premature fusing of the cranial sutures.</li> <li>● Cleft palate—velopharyngeal incompetence (VPI), which is the most common facial abnormality, may be a structural problem (short palate), a functional problem (hypotonia of the velopharyngeal musculature), or a combination of both.</li> <li>● Hypocalcemia</li> <li>● Assessment for possible feeding problems, such as significant gastroesophageal reflux; difficulty with sucking/swallowing, advancing feeds, addition of textured foods; and vomiting and constipation.</li> </ul>	<ul style="list-style-type: none"> <li>● Immunodeficiency occurs as a result of thymic hypoplasia, resulting in impaired T-cell production.</li> <li>● Cardiac anomalies such as tetralogy of Fallot are a result of a disturbance of normal embryological development of the pharyngeal pouches—embryonic precursors to specific organ systems in the head, neck, and chest.</li> <li>● Deletion of the portion of chromosome 22 leads to abnormal development of the structures of the face.</li> <li>● Because of the chromosome deletion, development of the palate is affected in utero. Sixty-nine percent of individuals with this syndrome have a palatal abnormality.</li> <li>● Due to decreased functioning of the parathyroid gland, hypocalcemia is present in 17%–60% of patients and is most serious in the neonatal period.</li> <li>● About 30% of children have feeding difficulties: severe dysphagia requiring nasogastric tube feedings and/or gastrostomy tube placement related to nasopharyngeal reflux; prominence of the cricopharyngeal muscle, abnormal cricopharyngeal closure, and/or diverticulum; dysmotility in the pharyngoesophageal area.</li> </ul>
<ul style="list-style-type: none"> <li>● Tetany <i>Lack of plasma calcium due to hypoparathyroidism leads to increased neuromuscular activity such as sustained contractions.</i></li> <li>● Monitor WBCs. <i>An increased WBC count is an indication of infection. - Information and emotional support from networking with other parents of children with similar problems  
*The family needs to have community resources to provide support with their child's diagnosis.*

### Connection Check 19.4

What is the desired therapeutic effect of calcium supplements for the patient with DiGeorge's syndrome?

- Improved muscular contractions
- Prevention of tetany
- Decreased heart rate
- Increased bowel sounds

### Evaluating Care Outcomes

The well-managed child has limited infections, no seizures, and growth and development within normal limits. This is accomplished through appropriate treatment with an interprofessional team, adequate monitoring for complications, and support for the caregivers of the child.

### Other T-Cell Immune Deficiencies

DiGeorge's syndrome provides one example of a T-cell deficiency. Other T-cell deficiencies include chronic mucocutaneous candidiasis and hyper-IgM (HIGM) syndrome.

#### Chronic Mucocutaneous Candidiasis

Chronic mucocutaneous candidiasis is a T-cell disorder that is autosomal recessive. It involves the thymus and other endocrine glands, resulting in an autoimmune disorder. There is a combination of endocrine failure and immunodeficiency. Problems include hypocalcemia and tetany due to hypofunction of the parathyroid glands. There are recurrent *Candida* infections of the skin, nails, and mucous membranes. Morbidity is high because of endocrine dysfunction. Hypofunction of the adrenal cortex is the major cause of death.

#### Hyper-IgM Syndrome

Hyper-IgM (HIGM) syndrome is an X-linked immunodeficiency with low IgG and IgA serum levels, normal or high IgM and IgD levels, and absent IgG-specific antibodies. This was previously designated as a B-cell defect but is now known to be a T-cell defect. In this disorder, T cells do not have the ability to signal B cells to undergo switching to IgG and IgA and can produce only IgM. Although it is identified by the levels of antibodies, its cause is a defect in cell-mediated immunity. The estimated prevalence of HIGM is 2:1,000,000 males in families of European, African, and Asian descent. The diagnosis of HIGM is based on a combination of clinical findings, family history, and molecular genetic testing of CD40LG,

the only gene known to be associated with HIGM. As with XLA, clinical manifestations in boys are seen in the first 2 years of life. Recurrent infections include sinusitis, otitis media, tonsillitis, and pneumonia. Patients are also susceptible to opportunistic infections, especially *Pneumocystis jiroveci*, because of the cell-mediated immunity defect. Complications include the development of an autoimmune disease of the blood, such as hemolytic anemia, thrombocytopenia, and neutropenia.

### Connection Check 19.5

The nurse correlates low levels of IgG with which disorder?

- Selective IgA deficiency
- CVID
- HIGM syndrome
- IgG subclass deficiency

## PRIMARY IMMUNE DEFICIENCY OF BOTH T CELLS AND B CELLS

Severe combined immune deficiency (SCID) is a potentially fatal primary immunodeficiency. This disease involves a combined absence of T-lymphocyte and B-lymphocyte function. There are at least 13 different genetic defects that can cause SCID.

David Vetter, who was born with SCID, was known as the boy in the bubble. When he was born in 1971, a bone marrow transplant from an exactly matched donor was the only cure, and no one in his family was a match. For 12 years, David lived in a protected, germ-free environment at Texas Children's Hospital. In 1984, after receiving a bone marrow transfusion, David died from lymphoma, a cancer that was introduced into his system by the Epstein-Barr virus.

Another primary immunodeficiency disorder is Wiskott-Aldrich syndrome, which results from a combined B- and T-cell defect; its characteristics include recurrent infection, eczema, and thrombocytopenia. The bleeding problems are unique to this primary immunodeficiency disorder and are the result of unusually small, dysfunctional platelets. The inheritance is X-linked recessive.

## Transitional Care

### Primary Immune Dysfunction (PID) Adolescent and Adult Care

Pediatric patients are usually treated from an early age by the same physicians, nurses, and healthcare providers. The transition from adolescence to adulthood involves managing changes related to physical, social, psychological, and educational aspects of life. A defined and coordinated pathway guiding them toward adult services is necessary to

avoid poor compliance with treatment, potential irreversible organ damage related to complications, reduced quality of life, and, very important, lower life expectancy as well as managing costs. A variety of disciplines related to PID services are required to coordinate adult care. They include:

- Access to essential providers:
  - Histopathologists familiar with lymphoid and infectious pathologies in PIDs
  - Respiratory medicine
  - Clinical hematology and hematological oncology
  - Gastroenterology (adult and pediatric)
  - Hepatology
  - Dermatology
  - Clinical genetics
- Access to:
  - Radiology services
  - Intensive care services
  - Other tertiary services may also be needed, for example, otorhinolaryngology (ENT), ophthalmology, neurology, and neurosurgery, as well as social services and psychiatric support

## SECONDARY IMMUNE DYSFUNCTION: THERAPY-INDUCED DEFICIENCIES

### Epidemiology

Secondary immune deficiencies are caused by a variety of factors, such as medication-induced **immunosuppression**, radiation, and surgery. The most common is medication-induced immunosuppression. Immunosuppressive therapy is prescribed to treat autoimmune disorders as well as to prevent transplant rejection. Immunosuppression is also a side effect of chemotherapy in the treatment of cancer. Chemotherapy can lead to leukopenia. This in turn results in decreased cell-mediated and humoral responses. Other medications that suppress the immune system are corticosteroids. Radiation therapy can also cause secondary immunodeficiency. Radiation destroys dividing and resting cells. With increased radiation, there is increased pancytopenia, which is a decreased number of all types of blood cells—red blood cells (RBCs), WBCs, and platelets. This causes a further suppression of the immune system function. Surgical removal of organs of the immune system, such as the lymph nodes, thymus, or spleen, also suppresses the immune response.

### Pathophysiology

Chemotherapeutic medications used to treat cancer are cytotoxic, which means they target rapidly dividing cancer cells. Cells of the immune system are also naturally rapidly

dividing and so are inadvertent targets of chemotherapeutic therapy. Cells such as WBCs, including lymphocytes and phagocytes, are destroyed by these medications. The result is a decrease in the number of circulating lymphocytes and phagocytes. Additionally, the medications cause general immunosuppression because remaining lymphocytes are unable to release antibodies and lymphokines, which are substances that bind to receptors on target cells, facilitating a directed immune response.

Immunosuppressive therapy, such as corticosteroid administration, is used to treat autoimmune disorders (discussed later in this chapter) or prevent transplant rejection by specifically targeting the immune system. The immunosuppressive medications interfere with cell-mediated immunity or the production of antibodies. Corticosteroids have anti-inflammatory effects in addition to immunosuppressive effects. The anti-inflammatory effects include stabilizing blood vessel membranes, decreasing permeability, and blocking the movements of neutrophils and monocytes. Immunosuppressive effects include decreased T cells because corticosteroids keep T cells in the bone marrow. This results in the suppression of cell-mediated immunity and lymphopenia as well as a decrease in the inflammatory response. There is also decreased IgG production and decreased antibody–antigen binding.

## Management

### Medical Management

Management of patients with secondary immune dysfunction is primarily preventive. Good hand washing is the first step. Avoiding contact with people who have obvious infections, such as a cough or cold, is recommended. Regular follow-up with the provider is necessary. Prompt action with any signs of infection, such as fever, chills, or cough, is essential. Any signs of urinary tract infection, such as difficulty with urination, bloody urine, or lower back pain, should be reported immediately.

### Nursing Management

#### Assessment and Analysis

The goal of managing secondary immune deficiency is to protect the patient from infection. The nurse assesses for signs of infection, such as a fever over 100°F (37.8°C), chills, or cloudy and foul-smelling urine.

#### Nursing Diagnoses

- **Risk for complications** of opportunistic infections
- **Risk for infection** related to compromised host defenses secondary to therapy-induced immunodeficiency

#### Nursing Interventions

##### ■ Assessments

- Vital signs  
*Increased temperature, hypotension, and tachycardia all indicate infection. The temperature increases in an attempt to kill organisms. Hypotension results because of*

*increased permeability causing fluid shifts and dehydration. Tachycardia occurs in an attempt to compensate for the hypotension.*

- Signs of infection:
  - Monitor WBC and differential.  
*Increased WBCs and leukocytes are part of the body's natural response to infection.*
  - Breath sounds  
*Decreased or adventitious breath sounds may be present with a respiratory infection.*
  - Urine  
*Cloudy or foul-smelling urine may indicate a urinary tract infection.*
  - Skin  
*Skin rashes or lesions indicate skin infections, which may occur with immunodeficiency.*

### ■ Actions

- Practice good hand washing.  
*Hand washing is the first step in preventing infections.*
- Treat infection with antibiotics or antivirals as ordered.  
*Antibiotics or antivirals specifically targeting the organism help control the infection.*
- Anticipate changing or discontinuing the immunosuppressive medication if possible.  
*With a change in medication, the cause of the secondary immune deficiency is removed. This is considered only if the infection is deemed a greater risk than the primary problem being treated with the immunosuppressive medications.*

### ■ Teaching

- Avoid crowds or large gatherings, and avoid exposure to anyone with an obvious illness.  
*To avoid exposure to infections*
- Do not change cat litter boxes.  
*Litter boxes expose the patient to toxoplasmosis.*
- Avoid turtles and reptiles as pets.  
*Turtles and reptiles carry diseases and bacteria such as Salmonella.*
- Eat a low-bacteria diet. Avoid salads; raw fruit and vegetables; and undercooked meat, fish, and eggs.  
*These foods can carry bacteria that can cause infection.*
- Report any of the following:
  - Temperature greater than 100°F (37.8°C)
  - Cough
  - Cloudy urine
  - Any drainage from a wound  
*Knowing the signs of infections and reporting them early to the healthcare provider can minimize infections and complications.*

### Evaluating Care Outcomes

A well-managed patient has a good understanding of the immune disorder and accompanying risks. This patient takes all appropriate precautions, practices good hand washing,

and knows when to contact the provider. If an infection does occur, it is treated promptly with the appropriate antibiotic or antiviral therapy.

## EXCESSIVE IMMUNE RESPONSE

In contrast to the immune deficiencies, when the immune system is initiated inappropriately or when it overreacts, autoimmunity and hypersensitivity disorders occur. **Autoimmunity** is when the body initiates an immune response against self; antibodies are formed that respond to normal healthy cells and tissue. The body fails to recognize these normal cells as self, which causes an immune reaction to occur against the perceived antigen, the healthy cell. The cause of autoimmune diseases is still not completely known. Theories of causation include the inheritance of susceptible genes that may contribute to the failure of self-tolerance. Much research is being conducted in this area. Even with a genetic predisposition, some trigger is required for the initiation of autoreactivity. This may include an infectious agent such as a virus. Medications and hormones may be a trigger as well.

Autoimmune diseases are often classified as systemic or organ specific, as listed in Table 19.3. Some of these diseases are discussed in other chapters of the book. For example, lupus, rheumatoid arthritis, and scleroderma are discussed in Chapter 20 with connective tissue disorders. Graves' disease and diabetes are discussed in Unit IX with endocrine disorders. Myasthenia gravis and Guillain-Barré are discussed in Chapter 38 with peripheral nervous system disorders. Hematological disorders are discussed in Chapter 34.

A **hypersensitivity reaction** is when the immune response is overreactive to a foreign antigen. An antigen is a foreign protein that stimulates an immune response in a susceptible individual. Hypersensitivity reactions can be damaging to the body, may cause discomfort, and may also be fatal, as in anaphylaxis.

There are several categories of hypersensitivity reactions. They can be divided into five types—type I, type II, type III, type IV, and type V—as illustrated in Table 19.4. These types are based on the specific mechanisms and mediators that are involved in the process, the source of the antigen, and the length of time for the reaction to occur. This chapter discusses all of these hypersensitivity reactions but focuses on type I and type IV.

Hypersensitivity reactions and autoimmunity overlap. Many autoimmune diseases have hypersensitivity as part of their pathogenesis. Graves' disease is an autoimmune disorder that is a result of a type V hypersensitivity reaction. Systemic lupus erythematosus (SLE) is the result of a type III hypersensitivity reaction. Goodpasture's syndrome is an example of a type II hypersensitivity reaction. Similarly, most but not all hypersensitivity reactions are manifested in autoimmune disorders, but one that does not manifest as autoimmune is a type I hypersensitivity reaction—a typical allergic reaction.

**Table 19.3** Examples of Known or Probable Autoimmune Diseases

Systemic Diseases or Non-Organ-Specific	Autoantigen	Organ-Specific Diseases	Autoantigen
<i>Systemic lupus erythematosus*</i>	DNA proteins	<b>Blood:</b> <i>Autoimmune hemolytic anemia</i> <i>Immune thrombocytopenic purpura</i>	Erythrocytes Platelets
<i>Rheumatoid arthritis*</i>	IgG, possibly cartilage	<b>Central nervous system:</b> <i>Multiple sclerosis</i> <i>Guillain-Barré syndrome</i>	Unknown but suspected: Myelin basic protein Antiganglioside antibodies
<i>Scleroderma (progressive systemic sclerosis)</i>	DNA proteins	<b>Muscle:</b> <i>Myasthenia gravis*</i>	Acetylcholine receptor, acetylcholine
<i>Mixed connective tissue disease</i>	DNA proteins	<b>Heart:</b> <i>Rheumatic fever</i>	Antibodies developed against group A streptococcus (GAS)
<i>Sjogren's syndrome</i>	Salivary gland cells, vaginal mucous cells, lacrimal gland cells	<b>Eye:</b> <i>Uveitis</i>	Uveal tract cells (eyes)
<i>Polymyositis-dermatomyositis</i>	Unknown	<b>Endocrine system:</b> <i>Addison's disease</i> <i>Thyroiditis</i> <i>Type 1 diabetes mellitus</i> <i>Graves' disease*</i>	Adrenal cell Thyroid cell-surface Islet cells, insulin, insulin receptor Thyroid-stimulating hormone receptor
		<b>Gastrointestinal system:</b> <i>Pernicious anemia</i> <i>Ulcerative colitis</i>	Intrinsic factor, parietal cell, B <sub>12</sub> complexes
		<b>Kidney:</b> <i>Goodpasture's syndrome*</i> <i>Glomerulonephritis</i>	Glomerular basement membranes, pulmonary basement membranes
		<b>Liver:</b> <i>Primary biliary cirrhosis</i> <i>Autoimmune hepatitis</i>	Unknown
		<b>Skin:</b> <i>Psoriasis</i>	Stratum corneum

\*Hypersensitivity reaction.

**Table 19.4** Types of Hypersensitivity Reactions

Type of Hypersensitivity	Mechanism	Antigen	Antibody Involved	Mediators of Injury	Example
<b>Type I: Immediate rapid allergic reaction</b>	Reaction of IgE antibody with antigen-releasing mediators especially histamine	Pollen, dust, food, medications	IgE	Histamine, mast cells, leukotrienes, prostaglandins	<ul style="list-style-type: none"> <li>● Allergic rhinitis</li> <li>● Asthma</li> <li>● Anaphylaxis</li> </ul>
<b>Type II: Cytotoxic reactions</b>	Reaction of IgG with host cell membrane or antigen absorbed by host cell membrane	Cell surface of RBCs	IgG, IgM	Complement lysis Macrophages in tissues	<ul style="list-style-type: none"> <li>● Transfusion reaction</li> <li>● Goodpasture's syndrome</li> <li>● Autoimmune thrombocytopenic purpura</li> <li>● Myasthenia gravis</li> </ul>
<b>Type III: Immune complex reactions</b>	Formation of immune complex of antigen and antibody that is deposited in walls of blood vessels, resulting in complement release and inflammation	Extracellular fungal, viral, bacterial	IgG, IgM	Neutrophils	<ul style="list-style-type: none"> <li>● Systemic lupus erythematosus</li> <li>● Rheumatoid arthritis</li> <li>● Serum sickness</li> </ul>
<b>Type IV: Delayed hypersensitivity reactions; T-cell mediated</b>	Reaction of sensitized T cells with antigen and release of lymphokines, which activate macrophages and cause inflammation	Intracellular or extracellular	None	Cytokines cytotoxic T cells, monocytes, macrophages, lysosomal enzymes	<ul style="list-style-type: none"> <li>● Contact dermatitis to poison ivy</li> <li>● Positive TB skin tests</li> <li>● Latex allergy</li> </ul>
<b>Type V: Stimulated</b>	Reaction of autoantibodies with normal cell surface receptors, which stimulates continual overreaction of the target cell			Autoantibodies	<ul style="list-style-type: none"> <li>● Graves' disease</li> <li>● B-cell gammopathies (increased levels of gamma globulins)</li> </ul>

Ig, Immunoglobulin; RBCs, red blood cells; TB, tuberculosis.

## Hypersensitivities

### Type I Hypersensitivity Reaction: Immediate Epidemiology

Type I hypersensitivity reaction is a rapid or immediate allergic reaction. There can be a local (**atopic**) reaction or a systemic reaction. The most common is allergic rhinitis or hay fever, a local reaction. The most severe form is anaphylaxis, a systemic reaction. A genetic predisposition exists for the development of allergic diseases. If both parents have allergies, there is an 80% chance the child will have allergies. If the mother is allergic, the child is likely to also have allergies. Approximately 20% of the population is atopic, which means having an inherited tendency to become sensitive to environmental **allergens**, the substances that cause an allergic response. Potential allergens include food, medications,

insect bites (e.g., bees, fire ants, hornets, yellow jackets, and wasps) and biting insects (e.g., mosquitoes), diagnostic testing substances (e.g., radiocontrast media), and blood.

In Western countries, between 10% and 25% of people annually are affected by allergic rhinitis. Allergic rhinitis affects 35.9 million individuals, which is about 11% of the population in the United States. It can be perennial or seasonal. Perennial rhinitis is caused by dust, molds, and animal dander. Seasonal rhinitis is caused by pollens from trees, weeds, or grasses. The person's immune system responds to the harmless material as though it were a real threat.

An accurate incidence of anaphylaxis is not known because of the differentiation between a full-blown anaphylactic response and milder cases. Milder forms are more common. There are up to 1,500 fatal cases of anaphylaxis annually. There are at least 40 deaths per year due to insect

venom, about 400 deaths due to penicillin anaphylaxis, approximately 220 cases of anaphylaxis and 3 deaths per year due to latex allergy, and an estimated 150 people die annually from anaphylaxis due to food allergy. A recent review concluded that the lifetime prevalence of anaphylaxis is 1% to 2% of the population as a whole. The incidence of anaphylaxis appears to be increasing, especially cases in children attributed to food allergy.

### Pathophysiology

The primary mediator of type I hypersensitivity reactions is **immunoglobulin E (IgE)**. The first time a patient is exposed to an allergen, IgE is produced. The IgE antibodies attach to mast cells. The next time the patient is exposed to that specific allergen, it binds to the IgE antibodies that are attached to the mast cells. This causes the mast cell to degranulate, releasing **histamine** and other chemicals such as leukotrienes and prostaglandins that cause smooth muscle contraction, vasodilation, increased vascular permeability, bronchoconstriction, and edema. This results in the symptoms associated with the allergy. The allergic reaction is illustrated in Figure 19.3.

Anaphylaxis is the most severe form of type I hypersensitivity reaction that exhibits the extremes of the symptoms. Table 19.5 indicates the specific mediator of a type I hypersensitivity reaction, its pathophysiological activity, and the symptoms it produces. Anaphylaxis can occur when these mediators are released systemically.

### Clinical Manifestations

The various clinical manifestations may be local or systemic. Clinical manifestations of allergic rhinitis include

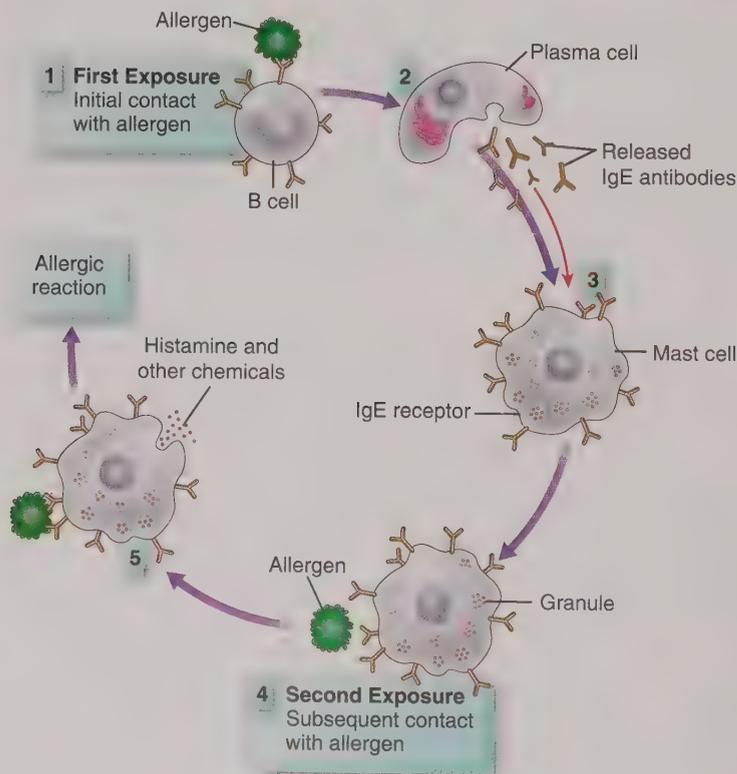

nasal discharge, sneezing, and pruritus of the upper airways. The patient may complain of headache or sinus pressure. Typically, the patient has itchy, watery eyes. In anaphylaxis, a systemic response, there is an immediate response to an allergen. The patient complains of dyspnea and shortness of breath. Audible wheezes and/or crackles are present. A skin reaction or rash may appear. Patients may experience nausea, vomiting, or diarrhea. They complain of anxiety and often state they feel a flush of heat. **Angioedema**, swelling just below the surface of the skin, typically around the mouth and eyes, may also be present.

In an extreme anaphylactic reaction, there is a severe and rapid onset of symptoms. They include bronchospasm with extreme dyspnea and shortness of breath and wheezing. The patient may have hoarseness and stridor, a high-pitched crowing sound, which indicates narrowing of the airways. Severe or untreated reactions result in anaphylactic shock with hypotension and tachycardia due to the vasodilation and capillary leak.

### Connection Check 19.6

The nurse monitors for which clinical manifestation in the patient diagnosed with a severe anaphylactic reaction?

- A. Hypotension
- B. Bradycardia
- C. Diuresis
- D. Hypertension

**FIGURE 19.3** Steps in an allergic reaction. The first exposure to the allergen results in the formation of IgE antibodies, which attach to mast cells. On the second exposure, the allergen binds to the IgE antibodies that are attached to the mast cells, causing degranulation and the release of histamine and other chemicals.

**Table 19.5 Mediators of Hypersensitivity Reactions, Pathophysiology, and Symptoms**

Mediator	Pathophysiological Activity	Symptoms Produced
<b>Histamine</b>	Increases vascular permeability, constricts smooth muscle, increases gastric acid secretion	Edema of the airways and larynx, bronchial constriction, urticaria, angioedema, pruritus, nausea, vomiting, diarrhea, shock
<b>Leukotrienes</b>	Enhance the effect of histamine on the smooth muscle, constrict smooth muscle of the bronchi, increase vascular permeability	Bronchial constriction: wheezing
<b>Platelet-activating factor</b>	Platelet aggregation, stimulates vasodilation	Systemic hypotension, increase in pulmonary artery pressure
<b>Kinins</b>	Stimulate mucus secretion, increase vascular permeability	Bronchial constriction: wheezing, angioedema with painful swelling
<b>Serotonin</b>	Increases vascular permeability, stimulates smooth muscle contraction	Mucosal edema, bronchial constriction: wheezing
<b>Prostaglandin</b>	Stimulates smooth muscle contraction, increases capillary permeability, stimulates the inflammatory response, increases platelet aggregation, increases gastric acid creations	Bronchial constriction: wheezing, edema, nausea, and vomiting
<b>Anaphylatoxins</b>	Stimulate histamine release	Edema of the airways and larynx, bronchial constriction, urticaria, angioedema, pruritus, nausea, vomiting, diarrhea, shock

## Management

### Medical Management

**Diagnosis.** Diagnostics include a WBC count and differential. This test reveals an increase in eosinophils, which indicates the presence of an allergic response. Eosinophils are the key inflammatory cells seen in allergic rhinitis. As eosinophils increase, the symptom severity increases. A normal count is 1% to 2%. Someone with severe seasonal allergic rhinitis may have an eosinophil count as high as 12%.

Skin testing is performed to determine the specific allergen. Various allergens are introduced via a scratch test to determine which produce a positive reaction that indicates an allergy. The results are used to determine the causes of allergic rhinitis, urticaria or hives, and asthma. A localized reaction or wheal indicates a positive result within 15 to 20 minutes. Glucocorticoids and antihistamines are discontinued 5 days prior to testing. NSAIDs may also be discontinued before allergy testing. The forearm and the back are used as sites for scratch testing.

### CASE STUDY: EPISODE 2

Mr. Smith's chest radiograph reveals pneumonia. He is placed on IV penicillin. The nurse returns to check on the patient and finds he is short of breath and extremely anxious about his symptoms and states that his skin is "itching" and he feels dizzy. Upon initial assessment, his pulse is rapid, his lips are blue tinged, a rash is

apparent on his chest and arms, and wheezing is heard on auscultation of his lungs. The patient expresses a sense of impending doom. Vital signs at this time are:

- Blood pressure—85/50 mm Hg
- Heart rate—130 bpm
- Pulse oximetry—89%...

**Treatment.** Treatment of type I hypersensitivity reactions depends on the severity. Allergy management includes the identification, treatment, and prevention of allergic responses.

Avoidance therapy can be successful when the allergies have been identified. If a reaction does occur but is mild, merely removing the offending agent may be the only necessary action. If symptoms persist, antihistamines and decongestants are utilized. Decongestants can be used to decrease edema and secretions, especially in allergic rhinitis. Diphenhydramine hydrochloride (Benadryl), an antihistamine, decreases edema and constriction of smooth muscle in the respiratory tract and blood vessels. Steroids may be indicated to decrease the inflammatory response and decrease mast-cell degradation. Beta-agonist bronchodilators may aid in easing respiratory distress by causing respiratory smooth muscle relaxation.

In severe cases of anaphylaxis, prompt recognition and treatment are necessary to avoid a potentially fatal result

(see Evidence-Based Practice). Emergency intervention and cardiopulmonary resuscitation may be necessary.

## Evidence-Based Practice

### Treatment of Anaphylaxis

Prompt recognition and treatment of an anaphylactic reaction are essential for a positive outcome. The most common clinical manifestations are skin reactions such as urticaria and angioedema, occurring in 90% of patients. Respiratory distress is seen in 50% of patients. First-line treatment includes the administration of intramuscular (IM) epinephrine. Epinephrine is effective as a respiratory smooth muscle relaxant and vasoactive medication to open airways to ease respiratory distress and constrict blood vessels to maintain the patient's blood pressure. It may be repeated every 5 to 15 minutes. Intravenous epinephrine is indicated in patients unresponsive to the IM doses. Glucagon is indicated in patients on beta blockers who are unresponsive to epinephrine. Second-line treatment includes antihistamines and corticosteroids, but importantly, they should not be given before or as first-line therapy.

Lee, S. E. (2017). Management of anaphylaxis. *Otolaryngologic Clinics of North America*, 50(6), 1175–1184.

### Connection Check 19.7

The nurse understands that which actions of epinephrine help alleviate symptoms of anaphylaxis?

- Dilates bronchioles, constricts blood vessels, improves cardiac contraction
- Dilates blood vessels, constricts bronchioles, and slows cardiac conduction
- Blocks histamine and decreases inflammation
- Inhibits mast cells and decreases inflammation

### Nursing Management

**Assessment and Analysis.** The clinical manifestations associated with a type I hypersensitivity reaction are caused by the release of histamine and other chemical mediators from mast cells upon exposure to the antigen. Typical results from histamine release include bronchoconstriction and increased capillary permeability. A runny nose, itching, red eyes, and rash are common. In extreme cases, the patient complains of shortness of breath and dyspnea. Wheezes are evident on auscultation.

### Nursing Diagnosis

- **Risk for complications** of allergic reaction: wheals, itching, light-headedness, hypotension, wheezing, dyspnea, chest tightness, decreased level of consciousness, respiratory distress, and shock

### Nursing Interventions

#### ■ Assessments

- Monitor respiratory rate, depth, and lung sounds; pulse oximetry; and arterial blood gases (ABGs). *Because of bronchoconstriction produced by the histamine release, the respiratory rate may be increased, and wheezing, dyspnea and chest tightness, and throat or palate tightness may be present. Because of decreased oxygenation, the SpO<sub>2</sub> is decreased and the ABGs demonstrate hypoxemia.*
- Blood pressure/pulse *If anaphylaxis occurs, hypotension may be present because of vasodilation and capillary leak. Tachycardia is present as a compensatory response to the hypotension. Irregular and increased pulse and decreased blood pressure are also due to leukotriene release, which constricts airways and coronary vessels.*
- General systems assessment *Initial symptoms caused by the histamine release may be a rash and itching followed by watery red eyes, runny nose, and sneezing. Angioedema may be present. The patient may complain of feeling faint and diaphoretic. Diarrhea, stomach cramps, and abdominal pain may be present because of increased acid production due to histamine release.*

#### ■ Actions

- Discontinue offending agent ASAP; if the offending agent is in an IV infusion, stop the IV medication, change the IV tubing, and hang normal saline. *The medication causing the allergic reaction needs to be stopped to prevent any further reaction. The tubing has to be changed to prevent any further medication being infused.*
- Administer oxygen as ordered via 100% nonrebreather. *The vasodilation, capillary leak, and other shock responses are interfering with oxygenation and tissue perfusion. Starting oxygen enhances oxygen delivery to the tissues, especially the brain cells and cardiac muscle cells.*
- Elevate the head of the bed as able; care is taken if hypotension is present. *To improve ventilation, elevate the head of the bed, but do not compromise blood pressure if low.*
- Medication administration as ordered
  - Administer diphenhydramine hydrochloride (Benadryl) as ordered. *Diphenhydramine hydrochloride (Benadryl) is a histamine-receptor blocker; histamine is the main mediator in type I hypersensitivity reaction.*
  - Administer corticosteroids as ordered. *To inhibit the inflammatory response exacerbating the allergic response*

- Administer bronchodilators as ordered.  
*Beta agonists or bronchodilators facilitating bronchial smooth muscle relaxation may be indicated to ease bronchoconstriction.*
- Anticipate order for STAT dose of intramuscular (IM) epinephrine if the reaction is severe.  
*Epinephrine is the medication of choice to counteract anaphylactic shock by causing blood vessel constriction, raising blood pressure, and improving cardiac output through inotropic and chronotropic activity. It also acts as a beta-2 agonist to promote bronchial smooth muscle relaxation.*
- Administer vasopressors as needed.  
*If anaphylaxis occurs, vasoactive medications may be indicated to constrict blood vessels and increase blood pressure.*
- Have emergency resuscitation equipment available (endotracheal intubation or tracheostomy) for possible progression to anaphylactic shock.  
*As anaphylaxis progresses, there may be complete circulatory and ventilatory collapse requiring resuscitation.*
- Stay with the patient and provide reassurance.  
*Provide support to the patient who is anxious and fearful.*

### ■ Teaching

- Educate patient regarding potential causes in the environment and ways to avoid exposure to the allergen.  
*Minimizing any potential allergen exposure can prevent any future allergic or anaphylactic reaction.*
- Educate the patient regarding the signs and symptoms of an initial reaction: rash and itching.  
*The patient should know the possible signs and symptoms of a reaction to be able to react in a timely manner and prevent a more serious reaction.*
- Educate the patient on the use of EpiPen.  
*The EpiPen can inject a small dose of epinephrine when the patient has been exposed to an allergen and is at risk for anaphylaxis.*
- Advise patient to obtain a Medic Alert bracelet or pendant and ensure that healthcare professionals are aware of any potential allergies.  
*A Medic Alert bracelet alerts others to a patient's allergies. Healthcare professionals should be aware of any potential reactions to guard against potentially dangerous food or medication exposure.*

### Evaluating Care Outcomes

A well-managed patient is free of symptoms of the allergic reaction and has a normal oxygen level. With the removal of the offending agent and appropriate treatment of the allergic reaction with diphenhydramine hydrochloride (Benadryl), steroids, bronchodilators, and epinephrine if necessary, there is no further evidence of a rash, itching, or difficulty breathing. The patient is discharged when respiratory and cardiovascular assessment criteria have returned to baseline. After a severe allergic reaction for which the cause is not known, a trigger should be identified if possible. An allergist/immunologist should perform an evaluation, which may include a detailed history, physical examination, skin testing, in vitro testing, and

challenges when indicated. Future avoidance of the identified triggers should prevent subsequent anaphylactic episodes.

### Connection Check 19.8

The nurse understands that information related to which of the following is a priority in the teaching plan about the management of an anaphylactic response to a bee sting?

- Avoiding allergens
- Wearing a Medic Alert bracelet
- The use of an EpiPen
- Immunotherapy through allergy shots

### Type II Hypersensitivity Reaction: Cytotoxic

Type II antibody-mediated hypersensitivity reactions include three subtypes:

1. Complement and antibody-mediated cell destruction
2. Complement and antibody receptor-mediated inflammation
3. Antibody-mediated cellular dysfunction

### Epidemiology

One example of a type II hypersensitivity reaction that causes cell destruction is erythroblastosis fetalis, which is due to Rh sensitization (Fig. 19.4). Rh sensitization occurs in approximately 1 in 1,000 births to Rh-negative women. The incidence of Rh-negative blood type is approximately 15% to 20% of Caucasians, 5% to 10% of African Americans, and less than 5% of individuals of Chinese and American Indian descent.

An example of type II hypersensitivity that causes inflammation is Goodpasture's syndrome, which is rare. It is more common in European populations, in which there is approximately one case present per million people per year. This syndrome is most common between ages 18 and 30 and again between 50 and 65. It is more common in males by a 6:1 ratio.

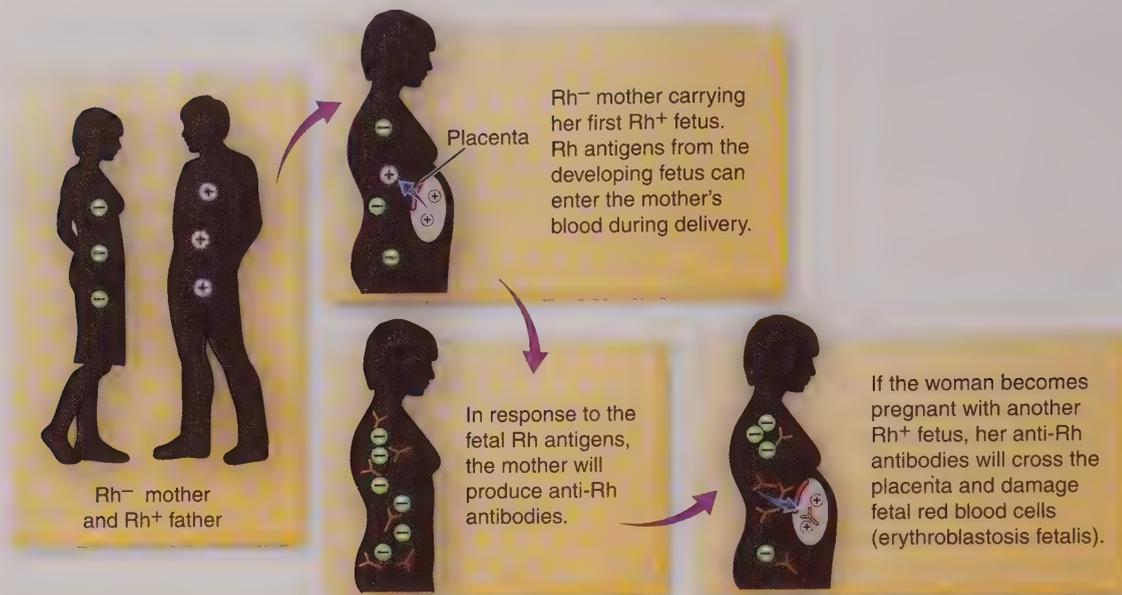

An example of type II hypersensitivity that causes cell dysfunction is myasthenia gravis. This disease affects approximately 2 out of 100,000 people. It can occur at any age but is most common in females 18 to 25 years of age and males 60 to 80 years of age.

### Pathophysiology and Clinical Manifestations

The pathophysiology for each of the three subtypes of type II hypersensitivity has a basic component of complement and antibody-mediated cell involvement.

#### Subtype 1: Complement- and Antibody-Mediated Cell Destruction Hypersensitivity

Complement and antibody-mediated cell destruction hypersensitivity reaction is cytotoxic and antibody dependent. **Complement** is a series of proteins that distinguishes the individual's own cells from foreign substances: self-tolerance or self-recognition. When this function is not working, the individual is susceptible to autoimmune diseases as a result of the hypersensitivity reaction. The antibodies

**FIGURE 19.4** Rh sensitization. The Rh-negative mother develops anti-Rh antibodies during her first pregnancy in response to fetal Rh antigens entering her bloodstream. When pregnant again, the anti-Rh antibodies cross the placenta and damage fetal red blood cells.

involved in this hypersensitivity reaction are **immunoglobulin M (IgM)** and immunoglobulin G (IgG).

In subtype 1, the targeting of cells for deletion by antibodies is mediated by the complement system or by antibody-dependent cell-mediated cytotoxicity (ADCC). Destruction of cells by the complement-mediated system involves opsonization of cells or coating them with molecules that attract the phagocytes. Antibody-dependent cell-mediated cytotoxicity does not require complement. With ADCC, cells are coated with IgG antibody and are killed by various effector cells that bind to their target by the receptors for IgG; cell lysis results without phagocytosis. Examples of subtype 1 are blood transfusion reactions that occur when incompatible blood is transfused (Fig. 19.5; see Safety Alert), hemolytic disease of the newborn due to blood type (ABO) or Rh incompatibility, and certain medication reactions. In the example of medication reactions, medications or metabolites of medications bind to the surface of either red or white blood cells. This action causes an antibody response that lyses the medication-coated cell.

To avoid potentially fatal blood reactions, patients should receive only matching blood types, but in an *emergency*, there are some options (Table 19.6). Type AB blood is called a *universal recipient* because it lacks both anti-A and anti-B antibodies. Type O blood is called the *universal donor* because it lacks antigens.

If a patient receives incompatible blood, the patient will complain of chills, fever, pain, and a heat sensation at the transfusion site. A rash may develop. Antibodies coat the foreign erythrocytes, causing agglutination or clumping. The clumping blocks small blood vessels, resulting in ischemia. Neutrophils and macrophages phagocytize the clumped cells, causing the release of hemoglobin into the urine and plasma. This reaction causes vascular spasms in the kidney that can cause blockage of the renal tubules. The result can be acute renal failure from the hemoglobinuria. Coagulation is stimulated, which depletes clotting factors, resulting in massive bleeding.

### **Safety Alert** Blood Transfusions and Hemolytic Transfusion Reactions

A person with type A blood has A antigens and anti-B antibodies.

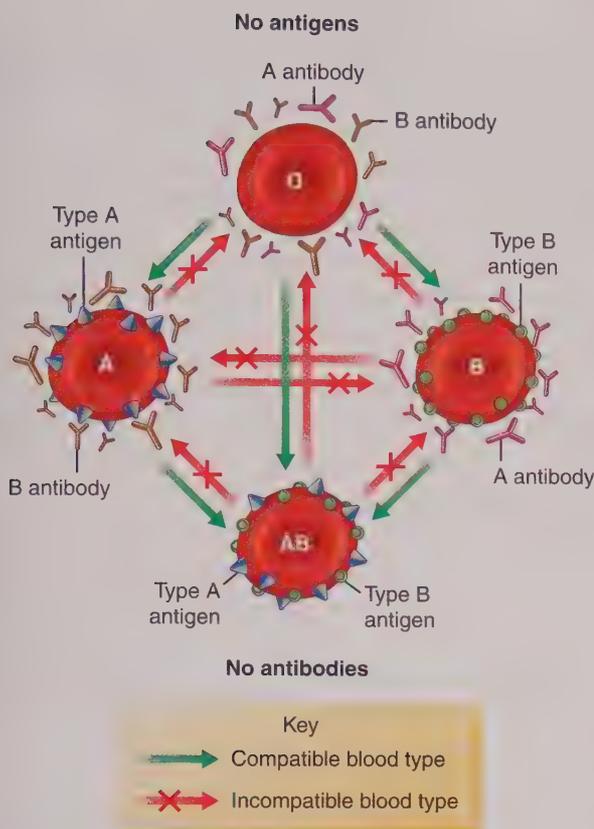

A person with type B blood has B antigens and anti-A antibodies.

A person with AB blood has both A and B antigens and no antibodies.

A person with type O has no antigens and both anti-A and anti-B antibodies.

### *Subtype 2: Complement- and Antibody-Mediated Inflammation*

Complement- and antibody-mediated inflammation causes inflammation rather than destruction. An example of this type is Goodpasture's syndrome, also known as antiglomerular basement antibody disease. Goodpasture's syndrome is an autoimmune disease triggered when the patient's immune system attacks the Goodpasture's antigen, an antigen in the glomerular basement membrane. The exact cause and trigger agent are not known. The antibody-mediated autoimmune reaction involves the glomerular and alveolar basement

**FIGURE 19.5** Compatibility of blood types. AB is the universal recipient because it carries no antibodies. Type O is the universal donor because it carries no antigens. In addition to type O, type B can receive type B blood but not type A or AB. In addition to type O, type A can receive type A blood, but not type B or AB. Type O patients can only receive type O blood.

**Table 19.6** Blood Types and Related Antigens

*It Is Imperative to Check Blood Prior to Administration to Avoid a Potentially Fatal Reaction*

Patient Blood Type	Antibodies	Antigens	Cannot Receive
<b>Type A</b>	Anti-B antibodies	A antigen	Type B or AB
<b>Type B</b>	Anti-A antibodies	B antigen	Type A or AB
<b>Type AB</b>	No antibodies	A and B antigens	Can have any blood type in an emergency
<b>Type O</b>	Anti-A and Anti-B	None	Type A, B, or AB

membranes. The antibodies combine with tissue antigen to activate complement. This causes deposits of IgG to form along the basement membranes of the lungs or kidneys. This disease is characterized by glomerulonephritis and hemorrhaging of the lungs and results in

damage to the kidney and lungs. This is a rapidly progressing disorder.

### Subtype 3: Antibody-Mediated Cellular Dysfunction

Antibody-mediated cellular dysfunction is a hypersensitivity reaction where the antibodies bind to cell-surface receptors. An example is myasthenia gravis. In myasthenia gravis, autoantibodies to acetylcholine receptors on the neuromuscular endplates are formed. The autoantibodies either block the action of acetylcholine or mediate the destruction of receptors. Either of these situations leads to decreased neuromuscular function and weakness. See Chapter 38 for more information on myasthenia gravis.

## Management

### Medical Management

As in type I hypersensitivity reactions, treatment of type II reactions requires removal of the medication or blood product that is causing the reaction. In addition, there are procedures to remove the offending blood components from the plasma. Plasmapheresis involves filtering the plasma to remove substances that precipitated the cytotoxic reaction. In this procedure, blood is removed via a catheter, RBCs and plasma are separated, and the RBCs are returned to the patient. In traditional plasmapheresis, the plasma is treated and returned to the patient. In plasma exchange, the patient's plasma is discarded and replaced by donor plasma. Plasmapheresis is covered in more detail in Chapter 20.

Goodpasture's syndrome is treated with corticosteroids and immunosuppressive medications in addition to plasmapheresis to slow the progression. Some patients require IVIG, a solution made from human plasma containing mostly IgG antibodies, to maintain antibody protection. Depending on the amount of renal involvement, dialysis may be necessary. Renal transplantation is an option for some patients.

**Complications.** Complications such as renal failure or hemolytic reaction may be life threatening. Renal function may be completely lost in a matter of days, a condition known as rapidly progressive glomerulonephritis. Lung damage, occurring as rapidly as the renal damage, may cause severe impairment of oxygenation requiring artificial ventilation. The patient may be anemic because of loss of blood through lung hemorrhaging over a long period. In Goodpasture's syndrome, lung hemorrhaging most often occurs in smokers and those with damage from lung infection or exposure to fumes. Medication reactions causing hemolytic reactions that cause cell lysis can produce transient anemia, leukopenia, or thrombocytopenia. Once the medication has been removed, these effects are corrected.

### Type III Hypersensitivity Reaction: Immune Complex

Type III hypersensitivity reactions are immune complex-mediated reactions. These immune complex allergic disorders are mediated by the formation of antigen-antibody complexes. Similar to type I hypersensitivity reactions, there are two categories of type III reactions: systemic and local immune complex reactions. Examples of systemic immune complex reactions are systemic lupus erythematosus (SLE),

rheumatoid arthritis, and serum sickness. A local immune complex reaction is Arthus reaction.

### Epidemiology

Systemic lupus erythematosus may be caused by genetic, environmental, or unknown factors. In the United States, the prevalence of SLE is estimated to be about 53 per 100,000. Systemic lupus erythematosus occurs more frequently and with greater severity among those of non-European descent and is higher in those of Afro-Caribbean descent. Systemic lupus erythematosus is more common in females than males, 9 to 1, which is similar to other autoimmune diseases. Rheumatoid arthritis affects all ethnic groups, and women are affected 2.5 times more often than men. Arthus reaction is considered to be rare, and no specific prevalence is known.

### Pathophysiology and Clinical Manifestations

A type III hypersensitivity reaction involves the formation of an antigen–antibody immune complex. Immunoglobulin G is the immunoglobulin involved. These immune complexes are large molecules of antibody combined with antigen and, due to their size, are difficult for the body to remove. Disease results when they are not removed but lodge in the tissues.

### Systemic Immune Complex Disorders

Manifestations of rheumatoid arthritis are caused by the immune complexes that are lodged in joint spaces. When there are too many immune complexes, too much complement is activated, and an acute inflammatory response develops. Complement attracts neutrophils to the area of inflammation and stimulates the release of lysosomal enzymes. This release causes tissue damage, especially in small blood vessels where the immune complexes tend to lodge and the lack of blood supply causes tissue necrosis. This is followed by destruction of tissue, scarring, and fibrous changes.

Systemic lupus erythematosus produces antibodies against virtually any organ or tissue in the body. It forms immune complexes that lodge in the vessels, causing vasculitis; in the glomeruli, causing nephritis; and in the joints, causing arthralgia (joint pain) and arthritis. It affects the connective tissues and multiple organs, resulting in cardiovascular, renal, or neurological complications.

Serum sickness is an immune system reaction to certain kinds of medications, most commonly penicillin and other antibiotics or injected proteins (antiserum) used to treat immune conditions. Antiserum is given to enhance immunity, most commonly after a snake bite. Serum sickness occurs when the body mistakenly identifies a protein from the antiserum or medication as harmful and activates the immune system to fight it off. This results in the collection of immune complexes in blood vessel walls of the skin, joints, and kidney. The deposited complexes activate complement. This then increases vascular permeability, and phagocytic cells are recruited to the area that cause tissue damage and edema.

It usually develops within 7 to 12 days after initial exposure but sometimes can take as long as 3 weeks. If the patient is exposed to the substance a second time, serum sickness

tends to develop faster (within 1 to 4 days), and a very small amount may cause an intense response. Serum sickness is less common currently because vaccines are made with human proteins rather than being animal based.

Clinical manifestations include fever, arthralgia, lymphadenopathy (swollen lymph nodes), malaise, and possibly polyarthritides (arthritis in multiple joints), nephritis (inflammation of the nephrons in the kidney), urticaria (hives), a patchy or generalized rash, or extensive edema involving the face (angioedema), neck, and joints. The symptoms may last only a few days, and damage is temporary, but if there is prolonged exposure, it may lead to irreversible damage. In extreme cases, serum sickness may be fatal.

### Local Immune Complex Reactions

Arthus reaction is a localized vasculitis due to the deposit of immune complexes in dermal vessels after intradermal or subcutaneous injections, typically vaccinations. Within 4 to 10 hours, a red raised lesion develops at the site of the injection. An ulcer forms in the center. This is due to the in situ formation of antigen–antibody complexes.

### Management

#### Medical Management

Removal of the offending agent is the first treatment. Symptom treatment for systemic immune complex reactions includes aspirin for joint pain and antihistamines for the pruritus. For the severe reactions, epinephrine or systemic corticosteroids may be utilized. Epinephrine is used for symptomatic relief of serum sickness, urticaria, and angioedema. Corticosteroids such as prednisone have been used to reduce the inflammation associated with serum sickness.

### Type IV Hypersensitivity Reactions

#### Epidemiology

Type IV is a delayed-type hypersensitivity. Examples are poison ivy, the Mantoux test for tuberculosis, and latex allergy. Some patients may experience a mixed type I and type IV reaction. Latex allergy may be an immediate, rapid type I hypersensitivity reaction or a type IV delayed hypersensitivity reaction. The prevalence of latex allergy in the general population is approximately 2%. People at high risk for developing a latex allergy include healthcare workers who are routinely exposed to latex; patients who have undergone multiple surgical procedures, especially spina bifida patients; people with a previous history of atopic dermatitis or pre-existing hand dermatitis; and females.

### Pathophysiology and Clinical Manifestations

Type IV cell-mediated/delayed-type hypersensitivity is also known as cell-mediated immune memory response or antibody independent. This reaction is different from the previous reactions in that it is mediated by cells rather than antibodies. This type of hypersensitivity reaction is delayed and is regulated by T lymphocytes that are

damaging to cells or cytotoxic. The reaction usually occurs 24 to 72 hours after exposure to the antigen. Sensitized T lymphocytes are the cells that attack the antigens and release cytokines and thus mediate the reaction. The macrophages and enzymes released by macrophages are responsible for most of the tissue destruction. In the delayed hypersensitivity reaction, it takes 24 to 48 hours for a response to occur.

Clinical manifestations of a local reaction typical of a positive TB test include a wheal and flare reaction. This reaction is a raised area containing edematous fluid surrounded by red flare. The clinical manifestations of a latex allergy may range from local contact dermatitis, rhinitis, and conjunctivitis to pharyngeal edema and severe systemic reaction such as anaphylactic shock. The following Medical and Nursing Management section focuses on latex allergy.

## Management

### Medical Management

As in other hypersensitivity reactions, treatment is based on prevention, such as avoiding products that contain latex. If exposure does occur, antihistamines may help with a less severe reaction. Skin creams containing steroids help with the contact dermatitis. More severe reactions that occur with repeated exposure may require a trip to the hospital to receive oxygen, epinephrine, and IV corticosteroids to reduce the inflammatory response.

### Nursing Management

**Assessment and Analysis.** The clinical manifestations seen with type IV hypersensitivity latex reaction are typically due to the tissue damage caused by the inflammatory response mediated by sensitized T cells. Mild reactions include:

- Local skin reactions, typically on the hands in relation to latex gloves
- Conjunctivitis
- Rhinitis

More severe reactions can include severe respiratory distress related to pharyngeal edema and anaphylactic shock as described previously under type I hypersensitivity reactions.

### Nursing Diagnoses

- **Risk for localized tissue damage** related to hypersensitivity reaction secondary to latex allergy
- **Risk for impaired oxygenation** related to pharyngeal edema secondary to hypersensitivity reaction

### Nursing Interventions

#### Assessments

- Assess vital signs.  
*A severe latex allergy reaction may produce clinical manifestations of anaphylaxis: respiratory distress with decreased oxygenation, hypotension, and tachycardia.*
- Assess the skin.  
*Mild reactions may include rashes, especially on the hands from latex gloves.*

- Assess for previous history of latex allergy.  
*A secondary exposure to latex after an allergic reaction may cause a more severe anaphylactic response because of already sensitized T cells.*
- Assess for allergies for any of the following: avocado, chestnut, mango, papaya, passion fruit, tomato, raw potato, peach, banana, kiwi.  
*Allergies to these substances may also indicate a sensitivity to latex.*
- Assess for history of repeated surgical procedures or adverse reaction or complication related to surgery.  
*Patients having repeated surgical procedures resulting in multiple exposures to latex are more likely to become sensitized and suffer an allergic response to latex.*

#### Actions

- Administer medications as ordered.  
*Steroid skin creams and/or IV corticosteroids may be necessary to decrease inflammation. IM epinephrine may be necessary to relieve respiratory distress and increase blood pressure in a severe reaction.*
- Eliminate exposure to latex products by using nonlatex alternatives: vinyl or neoprene gloves.  
*The best treatment is prevention. A secondary exposure may lead to anaphylaxis.*
- Protect patients from exposure to latex by:
  - Covering skin with cloth before applying the blood pressure cuff
  - Not allowing rubber stethoscope tubing to touch the patient
  - Not injecting through rubber ports on IV tubing  
*As stated, overexposure to latex can exacerbate the hypersensitivity reaction. Avoidance of exposure is the best treatment.*

#### Teaching

- Teach the patient to avoid exposure to products that are commonly made of latex:
  - Healthcare equipment: wheelchair cushions, tourniquets, airways, endotracheal tubes, masks for anesthesia, electrode pads
  - Office/household products: erasers, rubber balls, tires, shoe soles, rubber bands, hot water bottles, cycle grips, baby bottle nipples, carpeting  
*Any exposure can result in an anaphylactic reaction.*
- Instruct the patient to wear a Medic Alert bracelet and inform healthcare providers of allergy.  
*It is essential that the patient identify latex allergies to avoid exposure as much as possible and aid in the response should a reaction occur and the patient is unable to articulate the problem.*
- Instruct the patient on the use and necessity of an EpiPen.  
*The EpiPen delivers a small dose of epinephrine to counteract an allergic response, decreasing respiratory distress and increasing blood pressure.*

**Evaluating Care Outcomes.** Patients can avoid the complications related to latex allergy by maintaining a

heightened awareness of products in the environment that contain latex. Carrying an EpiPen and wearing a Medic Alert bracelet are necessary in the case of an inadvertent exposure to latex.

### Type V Hypersensitivity: Stimulated

The type V designation can be noted as a distinct subcategory but is sometimes included in type II hypersensitivity reactions. This is an antibody-mediated cellular dysfunction that leads to a change in cell function but does not lead to cell death as in type II hypersensitivity reactions. This reaction is also called a *stimulatory reaction*. There is an excessive stimulation of a normal cell-surface receptor by an autoantibody. This stimulation results in a continuous turned-on state for the cell. An example of this is Graves' disease, which is a form of hyperthyroidism. An autoantibody binds to the thyroid-stimulating hormone receptor sites on the thyroid gland. The action of the binding results in a continual stimulation of thyroid cells to produce thyroid hormone. The normal feedback system is no longer working to stop the overproduction of thyroid hormones. The thyroid gland is normal, but the manifestations that are exhibited are those of hyperthyroidism. Graves' disease is discussed in detail in Chapter 43.

## Making Connections

### CASE STUDY: WRAP-UP

On auscultation, audible wheezing with decreased breath sounds in the lower lobes is noted. Mr. Smith complains of severe dyspnea and shortness of breath. Hoarseness is evident. Itchy skin wheals or hives have spread over his body, forming large, red blotches. Angioedema of his lips and mouth is visible. The nurse immediately discontinues the IV penicillin. The IV tubing is changed, and normal saline is initiated. Epinephrine 0.5 mg is administered IM stat. Oxygen therapy is provided via a 100% high-flow nonrebreather face mask. Oxygen saturation is monitored via pulse oximetry.

Mr. Smith is placed on a cardiac monitor, which reveals a heart rate of 130 bpm with occasional premature ventricular contractions (PVCs). His blood pressure (BP) is 85/50 mm Hg. His oxygen saturation improves to 90% after the initiation of oxygen. Diphenhydramine 50 mg is administered via IV push, and IV fluids are initiated. Albuterol, a beta agonist, is administered via nebulizer to relieve the bronchospasm. Emergency equipment for endotracheal intubation and possible tracheotomy is readied.

Mr. Smith's condition begins to improve. His shortness of breath lessens, and pulse oximetry indicates improved oxygenation at 95%. Vital signs reveal:

Blood pressure—110/60

Heart rate—90

### Case Study Questions

- The nurse caring for Mr. Smith, who is having an anaphylactic response to penicillin, incorporates which nursing diagnosis into the plan of care?
  - Risk for ineffective gas exchange
  - Risk for hyperventilation related to anxiety
  - Pain related to bronchospasm
  - Knowledge deficit: Prevention and treatment of anaphylaxis
- Which is the priority nursing assessment for the nurse caring for Mr. Smith?
  - Assessing bowel sounds
  - A full head-to-toe assessment
  - Monitoring respiratory status
  - Assessing skin for a rash
- The nurse caring for Mr. Smith understands that which of the following is the priority intervention when noting he is having a reaction to the penicillin infusion?
  - Contact provider for orders.
  - Ready emergency medications.
  - Discontinue IV penicillin.
  - Discontinue IV completely.
- The nurse understands that Mr. Smith is having a potential allergic reaction by which of the following symptoms?
  - Generalized fatigue
  - Tachycardia and hypertension
  - Abdominal pain and nausea
  - Hypotension and tachycardia
- The nurse monitors for which complication in the patient with progressing anaphylaxis?
  - Circulatory failure
  - Seizures
  - Bradycardia
  - Hypertension

## CHAPTER SUMMARY

Primary immune dysfunction occurs in persons born with an immune system that is deficient or is limited in its ability to function. In this case, there is an intrinsic (inborn), congenital, or genetic cause. These primary immunodeficiencies result from defects in T lymphocytes, B lymphocytes, natural killer cells, phagocytic cells, or the complement system. The majority are diagnosed in childhood.

Secondary immune dysfunction, or acquired immune deficiency, arises secondary to some other disease process or exposure to medications or chemicals. Examples of secondary immune dysfunction include immune deficiency caused by HIV disease, irradiation, chemotherapy, malnutrition,

or burns. Secondary immune dysfunctions comprise the majority of deficiencies presented in the clinical setting.

X-linked agammaglobulinemia is an X-linked recessive inherited or congenital primary immune deficiency. Clinical manifestations include infections of the ears, lungs, skin, conjunctiva, and central nervous system. The presence of recurrent bacterial infections of the respiratory tract in childhood is the first indicator of the possibility of this disease. Diagnostics include blood tests that show a lack of circulating B cells as well as low levels of immunoglobulins (Igs). Treatment includes giving IV gamma globulin (IVIG) to provide short-term passive immunity and aggressive treatment with specific antibiotics if the patient exhibits overt signs of infection.

T-cell deficiencies lead to infections and other problems that are more severe than B-cell deficiencies. An example of a T-cell deficiency is DiGeorge's syndrome. It typically involves the thymus gland and parathyroid dysfunction, causing hypocalcemia, facial deformities such as cleft palate, and heart anomalies. Treatment includes calcium supplements to prevent tetany and seizures, aggressive treatment of infections, prophylactic antibiotics, IVIG therapy, or thymic transplantation. Bone marrow transplantation may be indicated in severe cases.

Secondary immune deficiencies are caused by a variety of factors, such as medication-induced immunosuppression and chemotherapy, radiation, and surgery. Management of patients with secondary immune dysfunction is primarily preventive. The focus of nursing care priorities is assessing for signs of infection and prevention of infection. Teaching priorities are primarily avoiding exposure to infections, such as avoiding large crowds.

Hypersensitivity reactions and autoimmunity are examples of excessive immune responses. Autoimmunity is when the body initiates an immune response against self; antibodies respond to normal, healthy cells and tissue. Hypersensitivity is when the immune system responds inappropriately or overresponds to the presence of an antigen.

Type I hypersensitivity reaction is a rapid or immediate allergic reaction. There can be a local (atopic) reaction or a systemic reaction. The most common is allergic rhinitis, or hay fever, a local reaction. The most severe form is anaphylaxis, a systemic reaction. The primary mediator of type I hypersensitivity reactions is IgE. IgE causes mast cells to degranulate, releasing histamine and other chemicals, such as leukotrienes and prostaglandins, that cause smooth muscle contraction, vasodilation, increased vascular permeability, bronchoconstriction, and edema. In anaphylaxis, the primary mediator is histamine. The patient complains

of extreme dyspnea and shortness of breath. Additional symptoms include hypotension, tachycardia, and in the extreme or untreated, anaphylactic shock. Treatment of type I hypersensitivity reactions depends on the severity. Nursing care priorities include discontinuing the offending agent as soon as possible, administering epinephrine IM, administering oxygen, and having emergency resuscitation equipment available. Other medications utilized include methylprednisolone, a glucocorticoid to decrease the inflammation, diphenhydramine, an antihistamine, and albuterol to help relieve respiratory distress. Patient teaching includes educating the patient regarding the signs and symptoms of an anaphylactic reaction and the use of an EpiPen.

Type II antibody-mediated hypersensitivity reactions include three subtypes: (1) complement and antibody-mediated cell destruction, (2) complement and antibody receptor-mediated inflammation, and (3) antibody-mediated cellular dysfunction. Subtype 1 involves cell destruction, subtype 2 involves inflammation, and subtype 3 involves cell dysfunction. One example of subtype 1 is the blood transfusion reaction that occurs when incompatible blood is transfused.

Type III hypersensitivity reactions are immune complex-mediated reactions. These immune complex allergic disorders are mediated by the formation of antigen-antibody complexes. Examples of systemic immune complex reactions are systemic lupus erythematosus, rheumatoid arthritis, and serum sickness.

Type IV cell-mediated/delayed-type hypersensitivity is also known as cell-mediated immune memory response or antibody independent. This reaction is different from the other reactions in that it is mediated by cells rather than antibodies. Examples are poison ivy, the Mantoux test for TB, and a latex allergy. Latex allergy may be an immediate, rapid type I hypersensitivity reaction or a type IV delayed hypersensitivity reaction. Nursing care priorities are to eliminate patient exposure to latex products by using nonlatex alternatives, such as vinyl or neoprene gloves. Teaching priorities include providing information about products commonly made of latex and emergency procedures if an immediate anaphylactic response should occur.

Type V hypersensitivity is an antibody-mediated cellular dysfunction that leads to a change in cell function. This reaction is also called a *stimulatory reaction*. There is an excessive stimulation of a normal cell-surface receptor by an autoantibody. This stimulation results in a continuous turned-on state for the cell. An example of this is Graves' disease, which is a form of hyperthyroidism.

## Coordinating Care for Patients With Connective Tissue Disorders

*Kathleen Ogle*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Describing the epidemiology of connective tissue disorders
2. Correlating clinical manifestations to pathophysiological processes of:
  - a. Osteoarthritis
  - b. Rheumatoid arthritis
  - c. Scleroderma
  - d. Lupus erythematosus
  - e. Gout
  - f. Fibromyalgia
3. Describing the diagnostic results used to confirm the diagnosis of connective tissue disorders
4. Discussing the medical management of:
  - a. Osteoarthritis
  - b. Rheumatoid arthritis
  - c. Scleroderma
  - d. Lupus erythematosus
  - e. Gout
  - f. Fibromyalgia
5. Developing a comprehensive plan of nursing care for patients with connective tissue disorders
6. Designing a teaching plan that includes pharmacological, dietary, and lifestyle considerations for patients with connective tissue disorders

### ESSENTIAL TERMS

Bouchard's node  
Cartilage  
Collagen  
Connective tissue  
Cytopenia  
Disease-modifying antirheumatic drugs (DMARDs)  
Effusion  
Episcleritis  
Heberden's node  
Osteopenia  
Osteophyte  
Pericarditis  
Pleural effusion  
Pleuritis  
Podagra  
Raynaud's phenomenon  
Rheumatoid nodule  
Scleritis  
Synovitis  
Synovium  
Tophi

### CONCEPTS

- Assessment
- Comfort
- Immunity
- Inflammation
- Medication
- Mobility

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Shannon Logan is a 32-year-old female patient who is referred to a rheumatology clinic by her primary care provider with complaints of multiple joint pain and swelling, fatigue, and morning stiffness. She is an elementary school teacher and has noticed that holding a marker has become progressively more difficult over the last 7 to 8 months. Because of morning stiffness lasting for more than 1 hour, she has to get up earlier to get ready for work. She complains of bilateral hand and wrist pain as well as pain and swelling in the second and third fingers bilaterally. By the end of the work day, she is extremely tired and is unable to carry on with her usual evening activities. She has a history of mild hypertension, which is treated with hydrochlorothiazide, but is otherwise in excellent health...

## INTRODUCTION

**Connective tissue**, the most widely distributed and abundant tissue in the body, is an extracellular matrix made up of ground substance (a clear viscous fluid that aids in cellular adhesion to the matrix and facilitates the movement of substances between capillaries and cells), **collagen**, and elastic and reticular fibers. Cells, principally fibroblasts, participate in the synthesis of the matrix. Connective tissue provides support, structure, insulation, and cushion to tissues and organs of the body as well as fills space. In connective tissue disease, the collagen and elastin are typically damaged through inflammation or immune system dysfunction. Bone, cartilage, tendons, ligaments, lymphatic tissue, and blood are all examples of connective tissue.

## OSTEOARTHRITIS

### Epidemiology

Osteoarthritis is the most common form of arthritis in the United States. Affecting almost 27 million people in the United States, it is the leading cause of chronic disability in the country. It involves weight-bearing joints such as the knees, hips, feet, and lumbar spine, but it also affects the cervical spine, proximal interphalangeal joints, and distal interphalangeal joints of the hands (Fig. 20.1). Osteoarthritic involvement of the shoulders and elbows usually occurs after trauma, inflammation, or overuse.

There are multiple risk factors associated with osteoarthritis, including age, female sex, obesity, occupations that involve repetitive motions, sports activities, previous injury, muscle weakness, genetics, history of inflammatory arthritis, and other bone and joint disorders. Obesity is the single most modifiable risk factor contributing to osteoarthritis.

Obesity correlates most closely to the development of knee osteoarthritis; however, it has also been shown to correlate with the development of hand osteoarthritis, indicating that obesity itself, not only increased stress on weight-bearing joints and decreased exercise, may contribute to osteoarthritis. There have been links made between certain occupations and osteoarthritis. Individuals whose job entails repetitive knee bending are prone to develop knee osteoarthritis, and individuals who perform physical labor are at an increased risk for developing hand and hip osteoarthritis.

Aging is one of the most prevalent risk factors for developing osteoarthritis; only 0.1% of those aged 25 to 34 years are affected compared with 80% of individuals over age 55; however, osteoarthritis is not considered a normal process of aging. In general, women are more commonly affected by osteoarthritis than men. Osteoarthritis of the knees is more common in African American women than in Caucasian women. Osteoarthritis of the hands is most prevalent in women.

### Connection Check 20.1

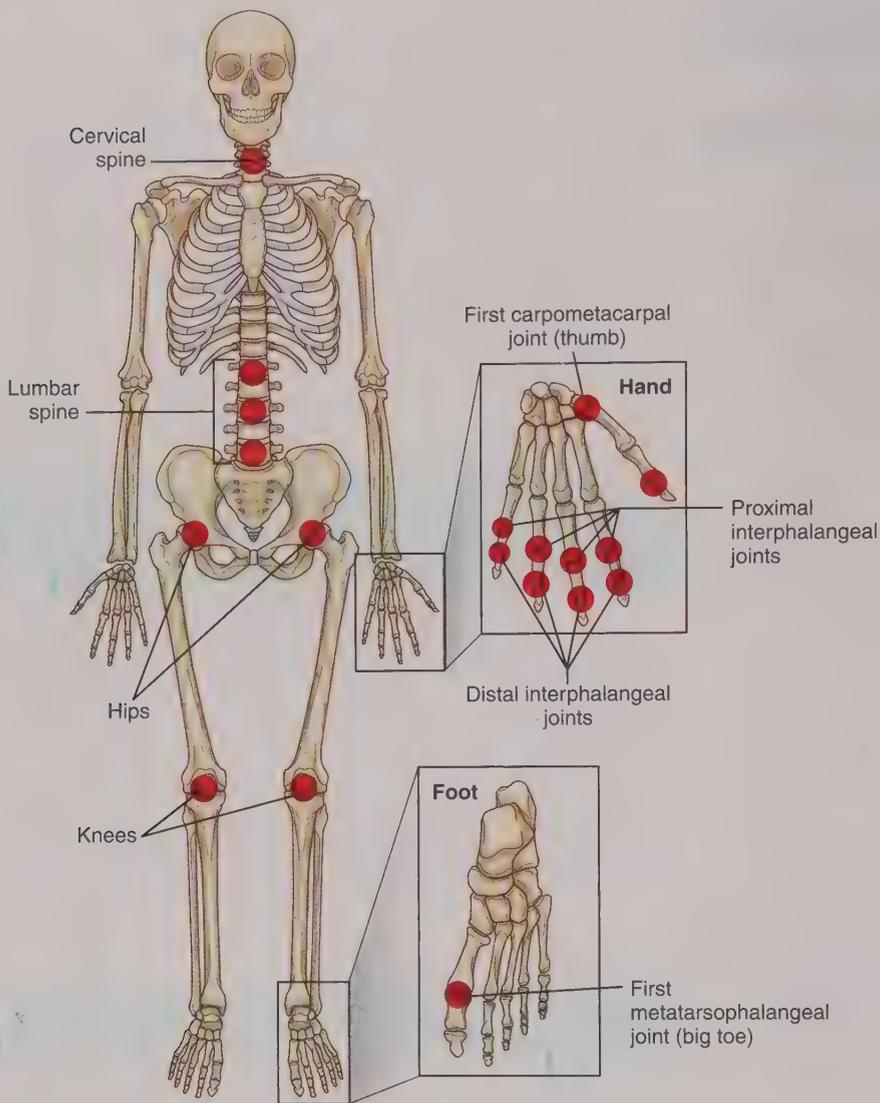

The nurse recognizes which patient to be at greatest risk for developing osteoarthritis?

- A. A 70-year-old African American male
- B. A 45-year-old Caucasian female
- C. A 65-year-old obese African American female
- D. A 30-year-old Caucasian male

### Pathophysiology

Osteoarthritis is a disease that affects the joint as a whole because of biological, chemical, and viscoelastic changes within the joint. Tendons and ligaments are viscoelastic, meaning they lengthen while under tension but return to normal shape at rest. Cartilage, synovium, subchondral bone, synovial fluid, ligaments, periarticular muscle, and sensory nerves are altered by osteoarthritis. **Cartilage** is a material made primarily of water, collagen, proteoglycans, and elastin. Cartilage serves to provide joint protection by providing a smooth surface on which bones glide and disperses loads across the joint. When the cartilage is damaged from major trauma or repetitive microtrauma, osteophytes are formed by the body in an attempt to repair the damage. **Osteophytes** are projections of new cartilage and bone growth that form along joint lines, contributing to pain in the joint and decreased range of motion. Osteophyte formations on the proximal interphalangeal joints and distal interphalangeal joints are referred to as **Bouchard's nodes** and **Heberden's nodes**, respectively (Figs. 20.2A and B). Some of the new bone growth may break off as bone spurs and contribute to further cartilage loss. Cartilage loss is a clinical feature of osteoarthritis, causing the bone to be unprotected, which leads to the deterioration of joint function.

The **synovium** is a membrane that lines the noncartilaginous surfaces of highly mobile joints. It produces synovial fluid, serving to lubricate the joints. In osteoarthritis, the synovial membrane may become thickened and overproduce synovial fluid, causing more pain and even greater

**FIGURE 20.1** Common joints affected by osteoarthritis.

restriction on joint movement. Chronic **effusions**, an overproduction of synovial fluid, may cause collateral ligaments to stretch, leading to joint laxity, or looseness, and mechanical instability, compounding joint damage. Muscles around the joints tend to atrophy as a consequence of decreased use of the joint. Radiographs may reveal sclerosis or cyst formation in the subchondral bone, which lies just below the cartilage. Ligaments, elastic band-type structures that connect bones to bones, may experience edema and fibrosis, also contributing to pain and decreased joint function (Fig. 20.3).

### Clinical Manifestations

Clinical manifestations of osteoarthritis include progressive pain over time, decreased range of motion, tenderness to touch over the joint line or around the joint, bony swelling, soft tissue swelling, deformity, and instability. Crepitus, a crackling, grating sound or feeling due to air or gas under the skin, may also be present. This is due to cartilage breakdown in the joint. Patients typically experience more pain with activity, which improves with rest.

### Connection Check 20.2

The nurse monitors for which clinical manifestations in the patient diagnosed with osteoarthritis? (*Select all that apply.*)

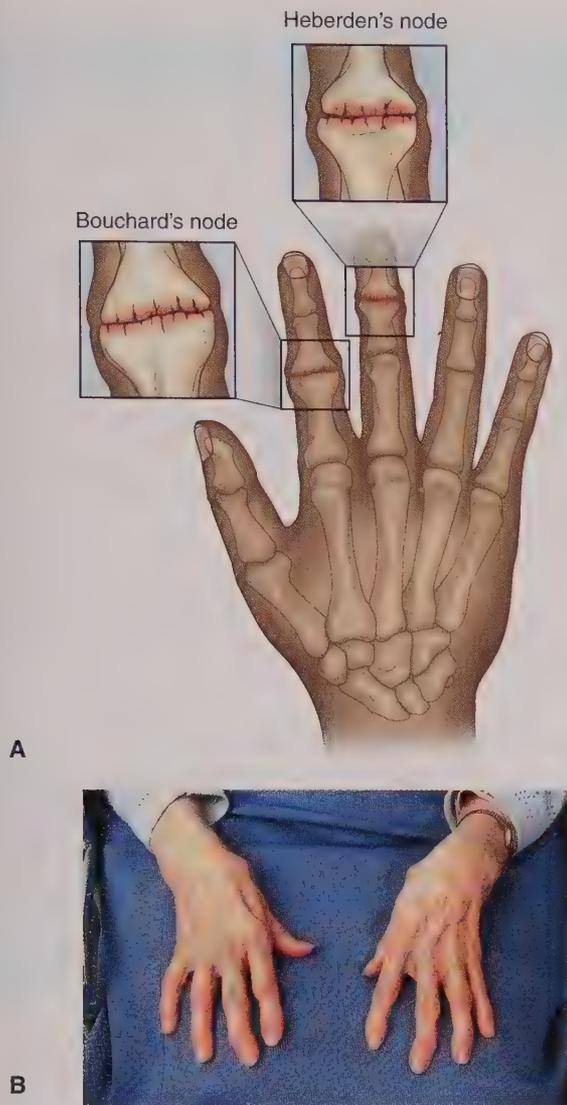

- A. Pain that improves with activity
- B. Joint pain
- C. Joint swelling
- D. Unsteady gait
- E. Increased temperature

### Management

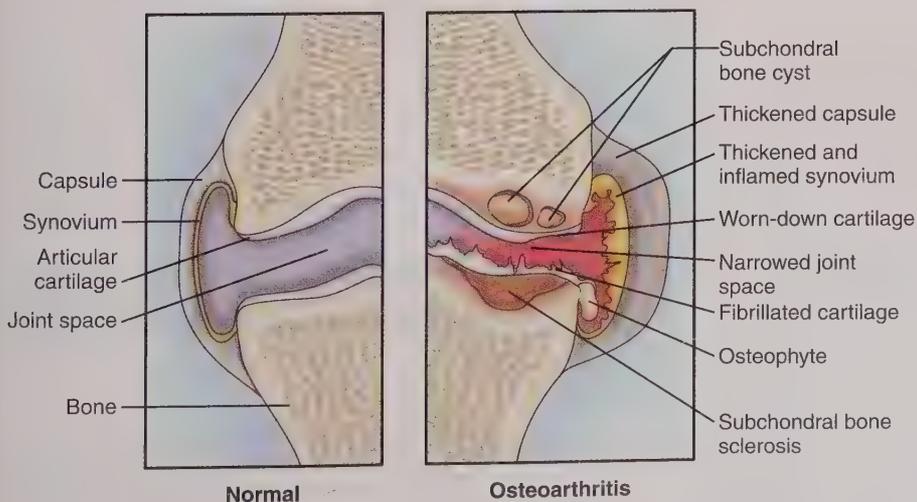

#### Medical Management

#### Diagnosis

Diagnosis can be made based on clinical manifestations without laboratory testing or radiographs when the patient is 45 or older and presents with persistent usage-related pain in several joints and morning stiffness that lasts less than 30 minutes. The American College of Rheumatology

**FIGURE 20.2** Osteoarthritis of the hand. *A*, Heberden's nodes and Bouchard's nodes. *B*, Clinical presentation of Heberden's and Bouchard's nodes.

**FIGURE 20.3** Osteoarthritis of the knee.

(ACR) developed criteria for the diagnosis of osteoarthritis of the hand, hip, and knee initially in 1986. They are still current today (Boxes 20.1, 20.2, and 20.3).

### Laboratory Testing

Laboratory testing may be performed to rule out other diagnoses, such as rheumatoid arthritis (RA). Laboratory testing should also be conducted as a part of the medical management of osteoarthritis in order to monitor for side effects related to medication use.

### Radiographs

Plain radiographs of the affected joints, such as the hands, hips, knees, and spine, along with a history and physical examination can be used to confirm the diagnosis of osteoarthritis. Evidence of osteoarthritis includes joint-space narrowing, subchondral sclerosis or cysts, and the presence of osteophytes. Plain radiographs, however, may not show evidence of osteoarthritis until the disease is well advanced.

### Treatment

Ideally, both pharmacological and nonpharmacological therapies should be utilized to treat osteoarthritis. Unfortunately, there is no therapy available to stop the progression of osteoarthritis. The goals of care include decreasing pain and improving or maintaining joint mobility while avoiding the toxic effects of pharmacological therapy.

### Nonpharmacological Therapies

Nonpharmacological therapies for osteoarthritis include the following: weight loss if indicated; heat and cold compress applications; aerobic exercise; physical therapy, including range of motion and muscle-strengthening exercises; the use of ambulatory assistive devices; appropriate footwear, such as lateral-wedged insoles; occupational therapy; joint protection; energy conservation; and assistive devices for activities of daily living. Also important is patient education about self-management programs and social support.

## Box 20.1 Classification Criteria for Osteoarthritis of the Hand

Hand pain, aching, or stiffness and three or four of the following features:

- Hard tissue enlargement of 2 or more of 10 selected joints
- Hard tissue enlargement of two or more distal interphalangeal (DIP) joints
- Fewer than three swollen metacarpophalangeal (MCP) joints
- Deformity of at least 1 of 10 selected joints

The 10 selected joints are the second and third DIP joints, the second and third proximal interphalangeal (PIP) joints, and the first carpometacarpal joints of both hands.

This classification method yields a sensitivity of 94% and a specificity of 87%. From Altman, R., Alarcón, G., Appelrouth, D., Bloch, D., Borenstein, D., Brandt, K., . . . Wolfe, F. (1990). The American College of Rheumatology criteria for the classification and reporting of osteoarthritis of the hand. *Arthritis & Rheumatism*, 33, 1601–1610.

## Box 20.2 Combined Clinical and Radiographical Classification Criteria for Osteoarthritis of the Hip

Hip pain and at least two of the following three features:

- Erythrocyte sedimentation rate less than 20 mm/hr
- Radiographical femoral or acetabular osteophytes
- Radiographical joint space narrowing

This classification method yields a sensitivity of 89% and a specificity of 91%. From Altman, R., Alarcón, G., Appelrouth, D., Bloch, D., Borenstein, D., Brandt, K., . . . Wolfe, F. (1991). The American College of Rheumatology criteria for the classification and reporting of osteoarthritis of the hip. *Arthritis & Rheumatism*, 34, 505–514.

## Box 20.3 Clinical Criteria for Classification of Idiopathic Osteoarthritis of the Knee

Knee pain plus three of the following criteria:

- Age greater than 50 years
- Stiffness less than 30 minutes
- Crepitus
- Bony tenderness
- Bony enlargement
- No palpable warmth

From Altman, R., Asch, E., Bloch, D., Bole, G., Borenstein, D., Brandt, K., . . . Wolfe, F. (1986). Development of criteria for the classification and reporting of osteoarthritis: Classification of osteoarthritis of the knee. *Arthritis & Rheumatism*, 29, 1039–1049.

## Pharmacological Therapy

Pharmacological therapy includes acetaminophen (Tylenol), which is used in patients with mild to moderate pain related to osteoarthritis. It is safe to use in doses not exceeding 4 g daily, but be sure to ask the patient about any history of liver disease. Acetaminophen works by inhibiting prostaglandin synthesis, a modulator of the inflammatory response, and blocking the generation of pain impulses. Patients with more severe pain or those who are refractory to acetaminophen are treated with NSAIDs, which nonselectively inhibit cyclooxygenase, an isoenzyme responsible for the production of the prostaglandins. Nonselective means inhibition of prostaglandin's role in inflammation and pain but also inhibition of the gastrointestinal (GI) protective function of prostaglandin, hence the adverse effect of GI bleeding and ulceration with NSAID use.

Osteoarthritis refractory to acetaminophen and NSAIDs may warrant treatment by using intra-articular injections of corticosteroids or hyaluronans. Intra-articular steroid injections strategically place the steroid into the joint space. The steroid inhibits the inflammatory process by suppressing the migration of polymorphonuclear leukocytes. Hyaluronans work inside the joint to provide lubrication to the articular surfaces. It is acceptable and safe to use acetaminophen, NSAIDs, and intra-articular medications in conjunction with each other; however, patients should not use more than one NSAID concomitantly because of increased risk of bleeding, development of gastric ulcers, and risk of renal damage (see Safety Alert and Geriatric/Gerontological Considerations). Opioid analgesics are an option but should be used sparingly because they may be habit forming. They bind to opioid receptors in the central and peripheral nervous systems, which decreases pain perception. See Table 20.1 for an overview of pharmacological treatment options.

### Safety NSAID Warning Alert

NSAIDs may cause an increased risk of serious cardiovascular thrombotic events, myocardial infarction, stroke, renal insufficiency (especially in a “stressed” kidney, e.g., a patient with pre-existing risk factors such as dehydration or a patient with already compromised renal function), and serious GI adverse events, including bleeding, ulceration, and perforation of the stomach. They are contraindicated for the treatment of perioperative pain in the setting of coronary artery bypass graft surgery and patients in renal failure.

## Geriatric/Gerontological Considerations

### Using NSAIDs

- Polypharmacy

Many geriatric patients may be on multiple medications, which can interact with NSAIDs. Be aware of the possible medication interactions.

- Multiple comorbidities

*Older patients may have multiple disorders. Confirm that NSAIDs are an appropriate treatment.*

- Possible renal insufficiency

*Use of NSAIDs carries an increased risk of renal complications and can exacerbate renal problems that are common in older patients.*

- Use of current antiplatelet or anticoagulant therapy

*NSAIDs can increase the risk of bleeding disorders and should not be used with antiplatelet or anticoagulant therapy.*

## Complications

Possible complications of osteoarthritis include chronic pain, decreased function, and toxic effects of medications.

Osteoarthritis can also negatively affect comorbid conditions such as diabetes and heart failure related to a decreased ability to exercise.

## Surgical Management

Surgical interventions may be necessary for some patients suffering from disability and severe pain related to osteoarthritis. These procedures include arthroscopic irrigation and/or débridement, arthroscopic synovectomy, surgical fusion, and total joint replacement. Arthroscopic irrigation and/or débridement is a procedure in which the joint is irrigated and expanded in order to visualize the joint and remove debris that could be promoting joint inflammation. Synovectomy is a surgical procedure used to remove excessive growth of the synovial membrane in order to reduce joint inflammation. Surgical fusion is a procedure performed to fuse together the joint surfaces to eliminate any movement of the joint. Total joint replacement involves surgically replacing the joint surface with a prosthesis.

**Table 20.1 Pharmacological Therapy for the Treatment of Osteoarthritis**

Oral, Systemic Medications	Uses	Possible Side Effects
<b>Acetaminophen</b>	Mild to moderate pain	<ul style="list-style-type: none"> <li>● Hepatic toxicity especially in those who use alcohol regularly</li> <li>● Potentiation of warfarin</li> </ul>
<b>NSAIDs</b>	Mild to moderate pain unresponsive to acetaminophen or severe pain	<ul style="list-style-type: none"> <li>● Nephrotic toxicity</li> <li>● Gastrointestinal bleeding</li> <li>● Anticoagulation</li> </ul>
<b>Nonacetylated salicylates</b>	Use as an alternative to NSAIDs for high-risk patients	<ul style="list-style-type: none"> <li>● Ototoxicity</li> </ul>
<b>Opioid analgesics</b>	Moderate to severe pain	<ul style="list-style-type: none"> <li>● Nausea</li> <li>● Constipation</li> <li>● Confusion</li> <li>● Drowsiness</li> <li>● Respiratory depression</li> <li>● Addiction</li> </ul>

<b>Intra-articular corticosteroids</b>	Use in conjunction with oral medications	<ul style="list-style-type: none"> <li>● Local discomfort</li> <li>● Temporary increase in blood glucose level</li> </ul>
<b>Intra-articular hyaluronans</b>	Use in conjunction with oral medications	<ul style="list-style-type: none"> <li>● Local discomfort</li> <li>● Temporary increase in synovitis</li> </ul>
<b>Topical NSAIDs</b>	Use as alternative to oral medications	<ul style="list-style-type: none"> <li>● Local skin irritation</li> </ul>
<b>Topical capsaicin</b>	Use as alternative to oral medications	<ul style="list-style-type: none"> <li>● Local skin irritation</li> </ul>

## Nursing Management

### Assessment and Analysis

Clinical manifestations of osteoarthritis are related to pain and decreased function of the affected joints. In addition, there may be clinical manifestations related to pharmacological therapy. The nurse may identify the following:

- Unsteady gait
- Bony enlargement or swelling of affected joints
- Fatigue
- Painful range of motion of affected joints
- Elevated serum creatinine secondary to NSAID use
- Elevated liver enzymes related to multiple medication use
- Constipation secondary to decreased physical activity and/or use of narcotic analgesics

### Nursing Diagnoses

- **Pain** related to the disease process
- **Ineffective sleep patterns** related to pain
- **Self-care deficit** related to decreased range of motion

### Nursing Interventions

#### ■ Assessments

- Vital signs  
*Hypertension may occur related to chronic NSAID therapy that alters renal function, reducing sodium excretion and enhancing fluid retention.*
- Weight  
*The use of NSAIDs may alter renal function as noted previously, leading to weight gain.*
- Skin integrity  
*Skin breakdown may occur in bony prominences because of decreased physical mobility.*
- Serum creatinine  
*The use of NSAIDs may lead to renal impairment by inadvertently blocking essential prostaglandins, which maintain blood flow to the kidneys, resulting in an increase in serum creatinine, while blocking the targeted prostaglandins, which are necessary for pain control.*

#### ■ Actions

- Administer analgesic and anti-inflammatory medications as ordered.  
*Acetaminophen and NSAIDs reduce pain by inhibiting prostaglandin production, thus blocking the generation of pain impulses and inhibiting the inflammatory response. Opioids alter the perception of pain.*
- Provide cold packs for painful joints.  
*Cold reduces inflammation.*
- Provide a heat pad for painful muscles.  
*Heat relaxes muscles and causes vasodilation, which improves blood flow and promotes healing.*

#### ■ Teaching

- Take medications only as prescribed.  
*Misuse or overuse of analgesics and anti-inflammatories may lead to side effects and can be dangerous; NSAID therapy may increase the risk of myocardial infarction (MI), GI bleeding, stomach ulcers, renal insufficiency, and abnormal platelet function. See Safety Alert.*
- Report chest pain, abdominal pain, abnormal bleeding, and blood in the stool or emesis.  
*Signs of NSAID toxicity or MI*
- Participate in regular physical activity.  
*Physical activity promotes good health, weight management, joint mobility, muscle strength, cardiac health, and self-efficacy. It also can reduce stress, anxiety, and depression.*
- Assist with referring the patient to occupational and physical activities.  
*Fitting for assistive devices, splints, and other assistive devices should be done by physical and occupational therapists. Physical and occupational therapies should be utilized to improve or maintain joint function.*
- Assist with referring the patient to orthopedic surgery when necessary.  
*Surgery may be necessary for end-stage osteoarthritis once other treatments have failed.*
- Assist with home healthcare referral.  
*Home care may be utilized for a number of reasons, including assessing patients' homes for safety hazards and teaching patients and their families about the management of osteoarthritis.*

### Evaluating Care Outcomes

It is important for patients with osteoarthritis to maintain function. A well-managed patient has pain under control and has good, unrestricted movement. This may be achieved by utilizing both pharmacological and nonpharmacological modalities. Patient compliance with therapy is best achieved when they and their support system are well educated and understand why therapies are prescribed and the possible negative outcomes related to nonadherence.

## RHEUMATOID ARTHRITIS

### Epidemiology

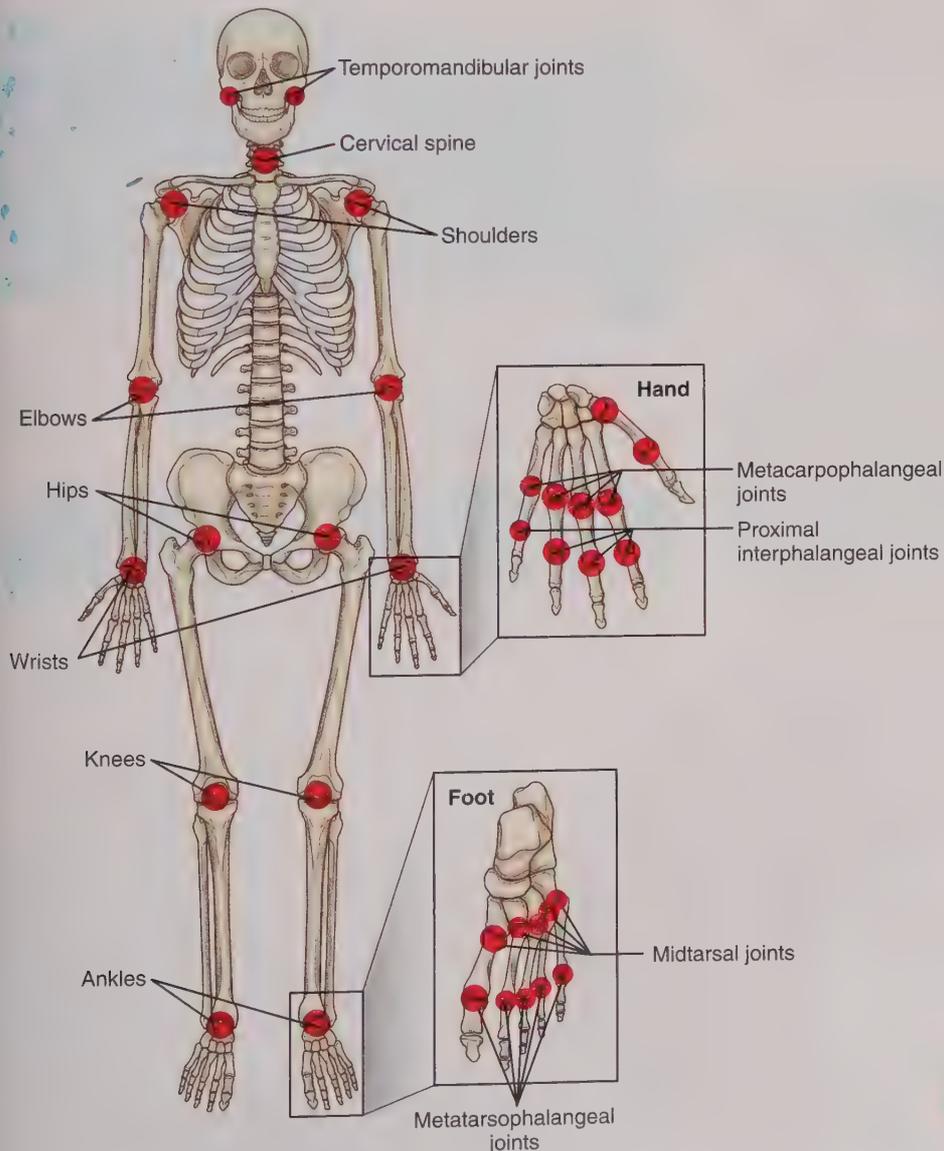

Rheumatoid arthritis (RA) affects approximately 1% of the population. Females are three times more likely to be affected than males, and it is more prevalent in certain ethnic groups, such as Pima and Chippewa Indians. The onset of RA may occur at any age but is most common in the third through fifth decades, and the incidence increases after the sixth decade. The exact etiology of RA is unclear; however, it is well understood that genetics and environmental factors play a key role in the development of the disease. First-degree relatives of patients with RA are at a 1.5-fold higher risk than the general population. Environmental factors such as cigarette smoke, bacteria, and viruses have been implicated as initiating factors for the development of RA

in the genetically predisposed population. Some patients initially diagnosed with RA may experience long-term remission within 1 year of onset. For those patients who do not enter remission, about 60% will be disabled within 10 years.

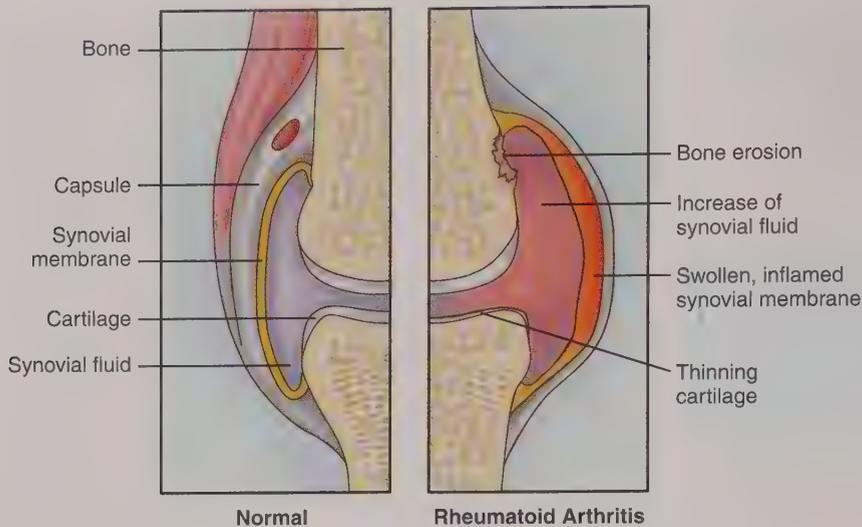

### Pathophysiology

Rheumatoid arthritis is a chronic, systemic, autoimmune inflammatory disease characterized by an inflammatory process that affects diarthrodial, or freely moving, joints, causing pain and swelling. The involved joints are usually distributed in a symmetrical fashion, meaning bilateral wrists, ankles, or knees (Fig. 20.4). Rheumatoid arthritis primarily targets the synovial membrane. The exact pathophysiology is unclear; however, it is known that an unknown antigen triggers an immune response, leading to synovial tissue damage. The immune system essentially fails to

distinguish “self” from “non-self” and causes destruction to the synovium of joints. Inflammation of the synovium may lead to a dramatic increase in synovial fluid, impairing movement and causing pain. The synovial membrane becomes thickened and promotes the destruction of the joint (Fig. 20.5). In this process, antigens (substances that trigger an immune response in order to rid the body of that substance) activate monocytes and T lymphocytes; then immunoglobulin antibodies form immune complexes with antigens. Phagocytosis of the immune complexes generates an inflammatory reaction. Leukotrienes and prostaglandins are produced as a result of phagocytosis. Leukotrienes attract additional white blood cells, and prostaglandins modify inflammation. Collagenase, an enzyme that breaks down collagen, is also produced by leukotrienes and prostaglandins, leading to edema, proliferation of synovial membrane and pannus formation (a layer of vascular fibrous tissue), destruction of cartilage, and erosion of bone.

**FIGURE 20.4** Common joints affected by rheumatoid arthritis.

**FIGURE 20.5** Rheumatoid arthritis of the hand.

Less commonly, there is inflammation in other organs, including the lungs, heart, skin, kidneys, blood vessels, salivary glands, bone marrow, and the nervous system, leading to vasculitis, lung fibrosis, neuropathy, and kidney disease, to name a few.

### Clinical Manifestations

Clinical manifestations include joint pain, joint swelling, erythema, morning stiffness, and fatigue. Onset is often insidious, with vague complaints of joint and muscle pain that evolves into joint pain with **synovitis**, inflammation of the synovial membrane, and can lead to joint destruction and deformity. Rheumatoid arthritis, if left untreated or inadequately treated, leads to irreversible joint damage and disability. Common joint deformities include swan-neck deformity caused by hyperextension of the proximal interphalangeal joints, boutonnière deformity caused by abnormal flexion of the proximal interphalangeal joints, and ulnar deviation caused by the lateral deviation of the phalanges

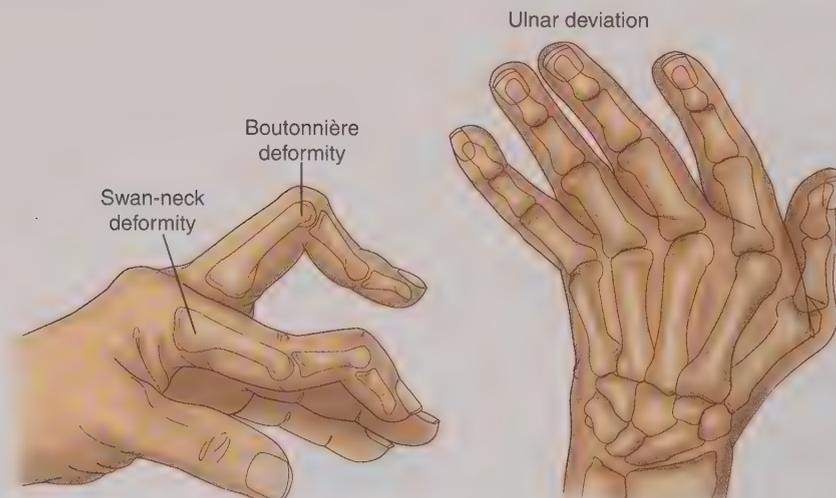

(Fig. 20.6). **Rheumatoid nodules** may be formed in subcutaneous tissue over bony prominences. The nodules are usually mobile and nontender. **Extra-articular** (outside of the joint) clinical manifestations of RA include **osteopenia** (decreased bone density), muscle weakness, **episcleritis** (red, painful inflammation of the episclera without discharge), **scleritis** (inflammation of the sclera, which produces deep ocular pain), **pleuritis** (inflammation of the lining surrounding the lungs), **pleural effusion** (excess fluid accumulation around the lungs), **pericarditis** (inflammation of the fibrous lining that surrounds the heart), an enlarged spleen, and anemia. For a comparison with osteoarthritis, see Table 20.2.

### Management

#### Medical Management

#### Diagnosis

Rheumatoid arthritis is diagnosed by combining clinical manifestations, laboratory values, and radiographs or ultrasound. The ACR and the European League Against

**FIGURE 20.6** Common joint deformities in rheumatoid arthritis: swan-neck deformity, boutonnière deformity, and ulnar deviation.

**Table 20.2 Comparing Osteoarthritis to Rheumatoid Arthritis**

	Osteoarthritis	Rheumatoid Arthritis
<b>Morning stiffness</b>	Less than 30 minutes	More than 30 minutes
<b>Immune mediated</b>	No	Yes
<b>Typical joint involvement</b>	<ul style="list-style-type: none"> <li>● Large weight-bearing joints such as hips and knees</li> <li>● PIPs</li> <li>● DIPs</li> <li>● CMC</li> <li>● First MTP</li> <li>● Previously injured joints</li> </ul>	<ul style="list-style-type: none"> <li>● MCPs</li> <li>● PIPs</li> <li>● MTPs</li> <li>● Wrists</li> <li>● Elbows</li> <li>● Ankles</li> <li>● Knees</li> </ul>
<b>Symmetrical joint involvement</b>	Not typical	Very typical
<b>Systemic organ involvement</b>	No	Yes

DIP, Distal interphalangeal; CMC, carpometacarpal; MTP, metatarsophalangeal; MCP, metacarpophalangeal; PIP, proximal interphalangeal

Rheumatism have worked together to update criteria for diagnosing RA in order to diagnose the disease at an early stage. The criteria assign point values to joint involvement, laboratory values, and duration of symptoms. When evaluating clinical manifestations, patients typically present with peripheral joint pain, which is usually symmetrical, and complain of morning stiffness lasting greater than 30 minutes. Symptoms persisting 6 weeks or longer are consistent with RA. Another important finding of RA is synovitis. Tenderness and synovitis are assessed by palpating each joint individually. Tenderness is subjective, whereas synovitis is objective. The clinician is usually able to detect the synovitis on examination via palpation or, if not detected by palpation, through ultrasonography.

### Connection Check 20.3

When comparing osteoarthritis to RA, the nurse recognizes which of the following statements to be true? (Select all that apply.)

- A. Osteoarthritic pain tends to get worse with activity, but RA gets better with activity.
- B. Both RA and osteoarthritis are autoimmune diseases.
- C. Patients with RA are at risk for developing extra-articular manifestations such as eye inflammation and lung disease, whereas osteoarthritis affects only joints and surrounding structures.
- D. Patients with osteoarthritis typically have morning stiffness lasting less than 30 minutes hour, whereas RA patients typically complain of morning stiffness lasting greater than 30 minutes
- E. Both RA and osteoarthritis affect joints in a symmetrical pattern.

### Laboratory Testing

Laboratory testing is not conclusive but is done to help with diagnosis and to monitor for side effects related to medication use. The presence of the antibodies, rheumatoid factor, and anticyclic citrullinated peptides may assist in the confirmation of the diagnosis, but the absence of these does not exclude the diagnosis because approximately 25% to 30% of patients are negative for antibodies. Also, a positive rheumatoid factor does not always indicate the presence of RA. Other autoimmune diseases may have a positive rheumatoid factor. Acute-phase reactants such as C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) may be used to detect inflammation but are not specific for RA. Elevated CRP and/or ESR is an indicator that can be useful in distinguishing inflammatory from noninflammatory arthritis.

Obtaining information regarding renal and hepatic functions is necessary before initiating therapy because many medications used to treat RA can be toxic to the kidneys and liver. Baseline complete blood counts are necessary because antirheumatic medications may cause **cytopenia**, a reduced amount of blood cells. Common cytopenias include thrombocytopenia, a reduced number of platelets; leukocytopenia, a reduced number of white blood cells; and anemia, a reduced number of red blood cells. An elevated platelet count may indicate the presence of inflammation. Before the initiation of most biological therapies, an option for treatment of RA, a tuberculin skin test and hepatitis testing should also be performed because some biological therapies have the potential to reactivate dormant infections.

### Radiographs

Conventional radiographs are used to assess for bony erosions and joint-space narrowing. Radiographs may be repeated during treatment to assess for disease progression and efficacy

of pharmacological therapy. Magnetic resonance imaging (MRI) may detect erosions not detected by conventional radiographs. Ultrasonography may also be used to assess for synovitis and erosions not detectable by plain radiographs, and is a good option for patients who decline MRI because of cost or claustrophobia.

## Treatment

### Nonpharmacological Therapy

Education is very important in the management of RA. Patients must understand their disease and the measures they can take to help manage the disease. Range-of-motion exercises promote joint mobility, reduce stiffness, and improve muscle strength. Aerobic exercise promotes cardiac health. Physical and occupational therapies may be necessary to teach patients appropriate exercises, teach patients how to protect their joints, evaluate the need for assistive devices, and teach proper use of the devices. Proper nutrition is important to maintain good health, prevent obesity, and decrease the risk of heart disease. It is important for patients to take rest periods to manage fatigue and joint pain.

### Pharmacological Therapy

The goal of pharmacological treatment is to control the inflammation that leads to joint and tissue destruction, decreasing joint pain, synovitis, and stiffness as well as maintaining joint function and preventing joint destruction. Treatment decisions are based on disease severity and response to medications. Initial treatments include analgesics, NSAIDs, and glucocorticoids. Analgesics, including acetaminophen and narcotic agents, provide only pain relief with no alteration in the disease process. Anti-inflammatory medications provide pain relief and some reduction in inflammation but do not alter the disease process. Glucocorticoids such as prednisone may be given orally, intramuscularly, intra-articularly, or IV and can actually suppress inflammation and alter the disease process but are not safe at high doses over long periods of time. Patients with RA whose disease does not respond very well to a combination of analgesics, anti-inflammatory agents, and low-dose prednisone are treated with **disease-modifying antirheumatic drugs (DMARDs)**.

Synthetic DMARDs include but are not limited to methotrexate (Rheumatrex), leflunomide (Arava), hydroxychloroquine (Plaquenil), sulfasalazine (Azulfidine), and tofacitinib (Xeljanz). Each alters the immune system in various ways, altering the inflammatory response to decrease inflammation and slow disease progression. These medications may be used alone as monotherapy or in conjunction with one another. Remember, before starting DMARD medications, patients should inform their healthcare provider of a history of or exposure to active tuberculosis. Fortunately, many patients respond well to methotrexate, which has been accepted as a first-line DMARD of choice to treat RA. Methotrexate is taken once weekly orally, subcutaneously, or intramuscularly (see Safety Alert). Traditionally, patients move on to additional or alternative medications if methotrexate alone does not control the disease (Table 20.3).

**Table 20.3 Disease-Modifying Antirheumatic Medication Therapy**

Medication	Mechanism of Action (MOA)
● Methotrexate (Rheumatrex)	● Exact MOA is unknown, but it is thought to affect immune function
● Sulfasalazine (Azulfidine)	● Systemically interferes with prostaglandin synthesis
● Hydroxychloroquine (Plaquenil)	● Impairs complement-dependent antigen-antibody reaction
● Leflunomide (Arava)	● Inhibits pyrimidine synthesis, resulting in antiproliferative and anti-inflammatory effects
● Tofacitinib (Xeljanz)	● Inhibits Janus kinase; an inflammation mediator

Over the last decade, several medications, known as *biologics*, genetically engineered medications made from living organisms and their products, such as proteins, have obtained approval by the U.S. Food and Drug Administration to treat RA. These medications have proven to be beneficial in slowing or even halting the progression of RA. To date, the approved biological therapies must be infused IV or injected subcutaneously. Biologics target specific entities of the inflammatory cascade, thus interrupting the immune response and decreasing inflammation. See Table 20.4 for an overview of biological therapy.

### Safety Methotrexate Safety Warning Alert

- Patients on methotrexate must be monitored closely for hepatic toxicity while the dose is being escalated and periodically while on a maintenance dose.
- Take folic acid daily to prevent side effects such as oral ulcers.
- Avoid alcohol while taking this medication because of the risk of hepatotoxicity.
- Counsel female patients on proper birth control methods because of significant risk of teratogenicity, the capability of producing fetal malformation.
- Patients with renal insufficiency require lower doses of methotrexate.

### Surgical Management

Surgical interventions including joint replacement or fusion may be necessary to help alleviate pain but may not actually improve function. Patients may choose to have surgical removal of rheumatoid nodules, but they may return over time.

**Table 20.4 Biological Therapy Approved to Treat Rheumatoid Arthritis**

Medication	Mechanism	Route
<b>Infliximab</b> ( <i>Remicade</i> )	Binds to TNF	Intravenous
<b>Etanercept</b> ( <i>Enbrel</i> )	Binds to TNF	Subcutaneous
<b>Adalimumab</b> ( <i>Humira</i> )	Binds to TNF	Subcutaneous
<b>Rituximab</b> ( <i>Rituxan</i> )	Targets B lymphocytes	Intravenous
<b>Certolizumab</b> ( <i>Cimzia</i> )	Binds to TNF	Subcutaneous
<b>Golimumab</b> ( <i>Simponi</i> )	Binds to TNF	Subcutaneous
<b>Tocilizumab</b> ( <i>Actemra</i> )	Binds to IL-6 receptors	Intravenous
<b>Abatacept</b> ( <i>Orencia</i> )	Modulates T-lymphocyte activation	Intravenous or subcutaneous

IL, Interleukin; TNF, tumor necrosis factor.

## Complications

Many complications may be associated with RA, which may be caused by uncontrolled disease or as a result of pharmacological therapy. Patients can develop decreased function of joints and permanent joint deformities, which may lead to permanent disability if the disease is not well controlled. Extra-articular complications include increased risk of infection and increased risk of developing cancer.

## Nursing Management

### Assessment and Analysis

As with osteoarthritis, clinical manifestations of RA are related to pain and decreased function of the affected joints. In addition, there may be clinical manifestations related to pharmacological therapy. The nurse may identify the following:

- Unsteady gait
- Bony enlargement or swelling of affected joints
- Warmth and redness of joints
- Painful range of motion of affected joints
- Increased incidence of infection
- Elevated serum creatinine secondary to NSAID use
- Elevated liver enzymes secondary to methotrexate or leflunomide
- Constipation secondary to decreased physical activity and/or use of narcotic analgesics
- Nausea and oral ulcers related to methotrexate use
- Cough and/or shortness of breath due to interstitial lung disease, which can be caused by RA or by methotrexate therapy

- Self-care deficit
- Fatigue

### Nursing Diagnoses

- **Pain** related to disease process
- **Ineffective sleep patterns** related to pain
- **Self-care deficit** related to decreased range of motion

### Nursing Interventions

#### Assessments

- **Joint pain and mobility**  
*Joint pain and mobility are indicators of treatment efficacy and disease progression.*
- **Temperature**  
*An increase in temperature is an indicator of infection.*
- **Laboratory testing**
  - **CRP and ESR**  
*Elevated values are indicative of inflammation.*
  - **Hemoglobin**  
*May be less than normal in patients with active RA, but a decreased value may also indicate a GI bleed, which can be caused by NSAID use.*
  - **Serum albumin**  
*Decreased value is correlated with increased disease severity because it is a negative acute-phase reactant and decreases in response to acute inflammation.*
  - **Platelet count**  
*May be elevated in very active disease because inflammation causes elevated platelet count.*
  - **Liver and renal function**  
*Elevated levels may be due to medications used to treat RA.*
- **Assess for pleural effusion, pericarditis, pleuritic, scleritis, episcleritis, and osteopenia.**  
*Extra-articular clinical manifestations of RA may be present due to the inflammatory changes outside of the joints.*

#### Actions

- Administer analgesics and anti-inflammatories as ordered.  
*Analgesics and anti-inflammatories provide pain relief by reducing inflammation but do not alter the disease process.*
- Administer glucocorticoids as ordered.  
*Glucocorticoids decrease pain by suppressing the inflammatory process and may alter the course of the disease.*
- Administer DMARD therapy as ordered.  
*DMARD therapy is very important in slowing disease progression by modulating the immune system and decreasing the inflammatory process.*
- Administer biologics as ordered.  
*Biologics have been shown to slow or halt the progression of RA through inhibition of tumor necrosis factor (TNF) or interleukins (ILs).*

#### Teaching

- Importance of adherence to treatment plan  
*It is essential to maintain the treatment plan to control disease progression.*

- Report signs and symptoms of infection.  
*Because of treatment with anti-inflammatories and immunosuppressive therapy, patients must be aware of signs and symptoms of infection and the importance of reporting these to their rheumatologist.*
- Immunosuppressive therapy should be discontinued while patients have an active infection.  
*Immunosuppressive therapy puts patients at a higher risk for developing infections and complications from infections.*
- Assist with referral to an infectious disease specialist for patients with chronic or atypical infections.  
*Patients with rheumatoid arthritis who are on immunosuppressive therapy are at risk for developing infections.*
- Keep current with vaccinations.  
*Patients with rheumatoid arthritis are at risk for infections due to treatment but should not receive live vaccines if on immunosuppressive therapy.*
- Refer to physical and occupational therapies as needed.  
*Therapy may preserve joint function and improve patients' quality of life.*

### Connection Check 20.4

The nurse knows that which of the following statements regarding laboratory values and RA are true? (Select all that apply.)

- Patients with a positive rheumatoid factor definitely have RA.
- An elevated CRP is indicative of inflammation but is not specific only for RA.
- Certain DMARD therapies may cause laboratory abnormalities such as elevated liver enzymes, thrombocytopenia, and leukocytopenia.
- Approximately 25% to 30% of patients who have RA do not have a positive rheumatoid factor.
- Patients with RA have elevated cardiac enzymes due to pharmacological therapy.

### Evaluating Care Outcomes

Important assessments of the efficacy of pharmacological therapy are the amount of joint tenderness and synovitis the patient is experiencing and the duration of morning stiffness.

It is possible to achieve remission by using effective medications. Having active patient involvement aids in that process (see Evidence-Based Practice). Teaching the importance of using antirheumatic medications properly and consistently is key in treating RA patients. Patients should understand that full efficacy cannot be achieved if the medication is not used consistently and that the medications can be dangerous if used more than directed. Ideally, the patient with well-controlled RA will have very few or no tender or swollen joints with minimal morning stiffness while experiencing little or no adverse effects from pharmacological therapy.

## Evidence-Based Practice

### PROMIS: Patient-Reported Outcomes Measurement Information System

The DREAM Remission Induction Cohort Study published in 2012 was designed to identify patients with early rheumatoid arthritis (RA) and evaluate the treatment strategies best able to achieve remission. The study developed the treat to target (T2T) strategy to guide care and determine treatment goals. Treat to target included the goal of clinical remission by adjusting medication therapy frequently and documenting the disease process frequently. The study suggested that clinical disease remission through use of effective medications is a realistic goal and should be the goal for every patient with RA. An important component of the success of the treatment program is active patient involvement. Standardizing and personalizing the T2T approach for RA using the Patient-Reported Outcomes Measurement Information System (PROMIS) was initiated as a way to increase patients' involvement in their plan of care. Patients were asked to complete a survey quarterly to identify the treatment domains most important to them. Options included pain management, fatigue, depression, physical function, and social function. The incorporation of the quarterly PROMIS questionnaires into clinic visits was found to be a viable process for incorporating patient preferences into a T2T approach to the management of RA.

Bacalao, E. J., Greene, G. J., Beaumont, J. L., Eisenstein, A., Muftic, A., Mandelin, A. M., . . . Ruderman, E. M. (2017). Standardizing and personalizing the treat to target (T2T) approach for rheumatoid arthritis using the Patient-Reported Outcomes Measurement Information System (PROMIS): Baseline findings on patient-centered treatment priorities. *Clinical Rheumatology*, 36(8), 1729–1736.

## CASE STUDY: EPISODE 2

Ms. Logan presents with bilateral hand and wrist pain and pain and swelling in the second and third fingers. She also describes morning stiffness lasting longer than 1 hour and increased fatigue, which are symptoms consistent with RA. Initial laboratory testing reveals elevated rheumatoid factor, ESR, CRP, and anticyclic citrullinated peptide levels. Ultrasound reveals synovitis located in each wrist and bilateral second and third proximal interphalangeal joints. . .

## SCLERODERMA

### Epidemiology

The incidence of scleroderma is estimated to be 9 to 19 cases per million per year. The usual age of onset is 30 to 50 years; however, the age of onset for women ranges

from 15 to 40 years, and the risk for developing scleroderma declines after menopause. The prevalence of scleroderma in women exceeds the prevalence in men by a ratio of 3:1 to 5:1. The disease affects all races, but African Americans are affected at a higher rate than Caucasians. African Americans tend to develop the disease earlier in life and are likely to have more diffuse disease with a worse prognosis. Scleroderma is not considered a hereditary disease, but patients who have a first-degree relative with scleroderma are more susceptible to developing the disease than the general population. It has also been suggested that, as in other autoimmune connective tissue diseases, environmental exposures such as infectious agents and occupational toxins may play a role in triggering the disease.

### Pathophysiology

Scleroderma is a very complex disease that not only affects the skin but also may involve internal organs. The exact cause of scleroderma is unknown, but it is believed to be an autoimmune disease caused by many external triggers. Small-vessel vasculopathy (disease affecting blood vessels), pathological accumulation of collagen, and autoimmunity cause the disease manifestations. Tissue damage occurs when mononuclear cells cluster in tissues such as the skin, blood vessels, and organs, stimulating lymphokines that stimulate procollagen, causing insoluble collagen formation in excess. The inflammatory response causes edema, which leads to fibrotic changes, causing loss of elasticity and movement. Eventually, the tissue degenerates and becomes nonfunctional.

### Clinical Manifestations

Scleroderma is divided into two main categories: localized and systemic. Localized scleroderma leads to morphea (isolated patches of hardened skin), linear scleroderma (lines of thickened skin affecting the tissues beneath), and scleroderma en coup de saber (thickened skin on the head). Localized scleroderma typically does not affect the internal organs. Systemic sclerosis is divided into the categories of diffuse and limited (Table 20.5).

Clinical manifestations of diffuse or limited systemic sclerosis may involve the skin, lungs, heart, kidneys, and musculoskeletal system. Skin manifestations include patches of thickened skin sometimes accompanied by itching, especially in the early stages. Patients with pulmonary involvement may experience dyspnea, nonproductive cough, and pulmonary fibrosis and have an increased risk of lung cancer. Conditions related to cardiac involvement include pericarditis, pericardial effusion, myocardial fibrosis, heart failure, and arrhythmia. Proteinuria and impaired renal function are common with renal involvement. Musculoskeletal complaints include swelling of the hands, joint pain, muscle pain, and fatigue. Three important manifestations of systemic sclerosis include Raynaud's phenomenon, scleroderma renal crisis, and pulmonary artery hypertension, all of which are due to abnormal vasoconstriction of

**Table 20.5 Systemic Scleroderma: Limited Versus Diffuse**

Limited	Diffuse
<ul style="list-style-type: none"> <li>● Insidious onset</li> </ul>	<ul style="list-style-type: none"> <li>● Rapid onset</li> </ul>
<ul style="list-style-type: none"> <li>● Involves the skin of extremities distal to the elbows and knees</li> </ul>	<ul style="list-style-type: none"> <li>● Involves skin of extremities and trunk</li> </ul>
<ul style="list-style-type: none"> <li>● Internal organ involvement less likely and with late onset</li> </ul>	<ul style="list-style-type: none"> <li>● Most likely affects internal organs, typically within 2 years of onset</li> </ul>
<ul style="list-style-type: none"> <li>● Raynaud's phenomenon may precede disease diagnosis by years</li> </ul>	<ul style="list-style-type: none"> <li>● Raynaud's phenomenon may occur concurrently or after diagnosis</li> </ul>

small vessels as a result of functional changes in the arteries. **Raynaud's phenomenon** results from vasospasm of the small vessels in the hands caused by exposure to cold. Vasospasm of the small vessels causes the fingers to blanch white, become blue from cyanosis, and then become red from reactive hyperemia. Raynaud's phenomenon is secondary to scleroderma and should not be confused with primary Raynaud's disease. Primary Raynaud's disease is common in the general population and does not result in permanent tissue damage, whereas Raynaud's phenomenon frequently causes permanent tissue damage and loss of digits due to chronic ischemia. Although mild renal dysfunction is common in scleroderma patients, scleroderma renal crisis occurs in approximately 10% to 20% of patients with diffuse systemic scleroderma but rarely in those with the limited cutaneous form. Scleroderma renal crisis is characterized by a sudden onset of severe hypertension, proteinuria, and progressive renal failure. Even with aggressive treatment, morbidity and mortality are high. Pulmonary artery hypertension symptoms develop insidiously, usually with a feeling of generalized weakness on exertion, then later dyspnea. Pulmonary disease is the leading cause of death in patients with systemic scleroderma. See Table 20.6 for clinical manifestations according to organ system.

### Connection Check 20.5

The nurse recognizes which patient with scleroderma to be at the highest risk for morbidity and mortality?

- An 18-year-old Caucasian female with linear skin lesions noted on her face
- A 20-year-old Hispanic male with patches of skin on the distal portions of his arms and legs
- A 32-year-old Caucasian female presenting with thickened skin on her trunk
- A 45-year-old African American male with Raynaud's disease

**Table 20.6 Common Clinical Manifestations of Systemic Scleroderma**

Organ System	Manifestations
<b>Skin</b>	<ul style="list-style-type: none"> <li>● Thickened skin</li> <li>● Digital ulcers</li> <li>● Puffy hands</li> <li>● Pruritus</li> <li>● Superficial skin tenderness</li> <li>● Diffuse hyperpigmentation</li> </ul>
<b>Gastrointestinal</b>	<ul style="list-style-type: none"> <li>● Frequent heartburn</li> <li>● Dysphagia</li> <li>● Esophageal stricture</li> <li>● Erosive esophagitis</li> <li>● Postprandial bloating</li> <li>● Constipation</li> <li>● Malabsorptive diarrhea</li> </ul>
<b>Pulmonary</b>	<ul style="list-style-type: none"> <li>● Generalized fatigue</li> <li>● Shortness of breath</li> <li>● Dry cough</li> <li>● Lung fibrosis</li> </ul>
<b>Cardiac</b>	<ul style="list-style-type: none"> <li>● Arrhythmias</li> <li>● Heart failure</li> <li>● Pericarditis</li> </ul>

## Management

### Medical Management

#### Diagnosis

The diagnosis of scleroderma is supported by the presence of clinical manifestations and serum antibodies. Laboratory testing may confirm a diagnosis of scleroderma but is not beneficial in excluding the diagnosis. Common laboratory tests include antinuclear antibody (ANA) screening, then testing for specific antibodies such as antitopoisomerase I (anti-scl-70), anticentromere, anti-RNA polymerase III, and anti-beta2-glycoprotein I. More than 95% of scleroderma patients have at least one of these antibodies present.

Radiographical testing may reveal subcutaneous calcification, distal esophageal hypomotility, and pulmonary fibrosis. Pulmonary function tests are important to assess

the vital lung capacity and lung compliance. Echocardiograms should be done routinely to assess for pulmonary artery hypertension and myocardial involvement. Before treatment is initiated, more invasive tests such as bronchoalveolar lavage and right heart catheterization may be required for a definitive diagnosis of interstitial lung disease and pulmonary hypertension, respectively. Kidney biopsies are required to accurately diagnose renal disease.

#### Treatment

There is no single treatment to manage scleroderma. Treatment is focused on specific organ involvement and clinical manifestations. Systemic steroids such as prednisone suppress the immune response by reducing the migration of leukocytes and reducing the activity of the lymphatic system. Immunosuppressants, such as methotrexate, work by modulating the immune response to decrease inflammation. Antihistamines, such as loratadine (Claritin) and cetirizine (Zyrtec), may alleviate pruritus by blocking H<sub>1</sub> receptors on effector cells. Topical ointments and moisturizers are used to help soften the skin and relieve itching. Vasodilators such as amlodipine (Norvasc) or nifedipine (Procardia) are used to improve circulation and treat Raynaud's phenomenon, pulmonary hypertension, and renal impairment. See Table 20.7 for an overview of treatment options.

#### Complications

There are many possible complications related to systemic diffuse scleroderma, including infection, renal failure, heart failure, pulmonary fibrosis, and death. Complications should be addressed by healthcare providers based on the system affected and the degree of involvement.

### Nursing Management

#### Assessment and Analysis

Clinical manifestations of scleroderma are related to multiple factors according to the extent of organ involvement as well as side effects of pharmacological therapy. The nurse may identify the following:

- Fatigue
- Thickened or hardened skin
- Digital ulcers
- Dyspnea
- Hypertension
- Decreased range of motion of joints
- Poor nutrition
- Frequent heartburn
- Dysphagia
- Cough

#### Nursing Diagnoses

- **Altered tissue perfusion** related to chronic ischemia
- **Fatigue** related to the disease process
- **Altered self-image** related to disfiguring skin lesions

**Table 20.7 Overview of Treatment Options for Scleroderma**

<b>Organ System Involved</b>	<b>Manifestations</b>	<b>Treatment</b>
<b>Skin</b>	<ul style="list-style-type: none"> <li>● Localized skin thickening such as morphea</li> <li>● Pruritus</li> <li>● Telangiectasia (vascular lesions formed near the surface of the skin)</li> <li>● Widespread skin involvement</li> </ul>	<ul style="list-style-type: none"> <li>● Phototherapy and topical glucocorticoids (prednisone)</li> <li>● Antihistamines and topical lubricants</li> <li>● Green-tinted foundation makeup to disguise lesions; laser therapy for large lesions</li> <li>● Immunosuppressive agents (methotrexate)</li> <li>● Physical therapy to limit contractures if skin involvement is over joints</li> </ul>
<b>Vascular</b>	<ul style="list-style-type: none"> <li>● Raynaud's phenomenon</li> <li>● Pulmonary artery hypertension</li> <li>● Scleroderma renal crisis</li> </ul>	<ul style="list-style-type: none"> <li>● Avoidance of cold temperatures, stress, nicotine, caffeine, and vasoconstrictive medications (such as cold medications containing pseudoephedrine); wearing gloves and dressing warmly</li> <li>● Antiplatelet therapy using low-dose aspirin should be considered in patients with digital ulcers in order to reduce the risk of blood clots.</li> <li>● Surgical amputation of affected digit may be necessary in severe cases.</li> <li>● Vasodilators such as calcium channel blockers (amlodipine [Norvasc])</li> <li>● Endothelin-receptor antagonist (bosentan [Tracleer]) that blocks endothelin receptors in smooth muscle in order to inhibit vasoconstriction</li> <li>● Phosphodiesterase-5 inhibitor (sildenafil [Revatio]) that inhibits phosphodiesterase type 5 in smooth muscle of pulmonary vasculature to promote vasculature relaxation</li> <li>● Angiotensin-converting enzyme inhibitors are used to help prevent and to treat scleroderma-related renal disease because they promote vasodilation of renal arteries, therefore improving blood flow through the kidneys.</li> </ul>
<b>Pulmonary</b>	<ul style="list-style-type: none"> <li>● Interstitial lung disease</li> </ul>	<ul style="list-style-type: none"> <li>● Immunosuppressive agents: cyclophosphamide is the primary immunosuppressive agent used to treat interstitial lung disease related to scleroderma.</li> <li>● Severe cases should be referred for lung transplantation.</li> </ul>
<b>Musculoskeletal</b>	<ul style="list-style-type: none"> <li>● Arthralgia and arthritis</li> <li>● Decreased joint mobility</li> </ul>	<ul style="list-style-type: none"> <li>● Analgesics (acetaminophen)</li> <li>● NSAIDs (ibuprofen)</li> <li>● Low-dose glucocorticoids (prednisone)</li> <li>● Physical therapy to prevent or limit contractures</li> </ul>
<b>Gastrointestinal</b>	<ul style="list-style-type: none"> <li>● Gastroesophageal reflux disease</li> <li>● Malabsorption and malnutrition</li> </ul>	<ul style="list-style-type: none"> <li>● Proton pump inhibitors (omeprazole) that suppress gastric acid secretion should be used even if patients are asymptomatic in order to prevent esophageal strictures.</li> <li>● Severe cases may require parenteral nutrition.</li> </ul>
<b>Cardiac</b>	<ul style="list-style-type: none"> <li>● Pericarditis</li> </ul>	<ul style="list-style-type: none"> <li>● NSAID therapy or glucocorticoids if NSAIDs are contraindicated</li> </ul>

## Nursing Interventions

### ■ Assessments

- Vital signs at every assessment: blood pressure, heart rate and rhythm, respiratory rate  
*Elevated blood pressure may be a sign of renal crisis. Elevated heart rate and ventricular arrhythmias may be present due to heart failure. Increased respiratory rate and effort may indicate interstitial lung disease, pulmonary vascular disease, or pulmonary artery hypertension.*
- Auscultate lung sounds.  
*The presence of crackles may be indicative of interstitial lung disease.*
- Assess skin integrity and document skin thickening.  
*Maintaining adequate records of skin involvement is important in monitoring disease progression.*
- Assess the musculoskeletal system.  
*Swelling of the hands, joint pain, muscle pain, and fatigue are common symptoms of scleroderma. Fibrosis around tendons and joint structures may lead to joint immobility.*
- Auscultate bowel sounds and gather information regarding gastroesophageal motility.  
*Chronic gastric reflux, difficulty swallowing, choking, cough, bloating, and alternating constipation and diarrhea are manifestations of GI involvement.*
- Monitor serum creatinine and blood urea nitrogen (BUN).  
*Monitor routinely to assess renal function and possible renal failure.*

### ■ Actions

- Administer medications as ordered: steroids, immunosuppressants, antihistamines, vasodilators, steroids, topical ointment.  
*Steroids reduce the inflammatory response; immunosuppressants modulate the immune response to decrease inflammation; antihistamines alleviate pruritus by blocking H<sub>1</sub> receptors on effector cells; vasodilators dilate arterial vessels, improving circulation; and ointments soften skin and relieve itching.*
- Perform range-of-motion exercises.  
*Range-of-motion exercises improve joint mobility and help prevent contractures.*
- Assist in referring the patient to pulmonologist, gastroenterologist, plastic surgeons, and physical therapy as needed.  
*Diffuse scleroderma may lead to decreased pulmonary function, GI dysfunction, disfiguring skin lesions, and decreased joint mobility.*
- Refer patients to counseling as needed.  
*Many patients suffer from depression as a result of the diagnosis and clinical manifestations.*

### ■ Teaching

- Scleroderma disease process.  
*Scleroderma is a very complicated disease that varies from one patient to another. Patients should understand and monitor for possible complications but realize that they may not experience all possible complications.*

- Protect skin from trauma.

*Patients are at higher risk for infection and prolonged healing time related to decreased tissue perfusion.*

## Connection Check 20.6

In assessing the patient with scleroderma for pending renal crisis, which findings require an intervention by the nurse? (Select all that apply.)

- A. Significant weight gain
- B. Blood pressure 174/100 mm Hg
- C. Creatinine 1.9 mg/dL
- D. Clear urine output
- E. BUN 15 mg/dL

## Evaluating Care Outcomes

Diffuse systemic sclerosis is a very complicated and serious condition that is very difficult to treat and usually results in disability and shortened life span; there is no cure. Maintaining stable cardiac, pulmonary, and renal functions is the goal of treatment. Care is focused on monitoring, preventing, and managing complications. The maintenance of skin integrity may help minimize tissue loss, infection, and contractures. A well-controlled scleroderma patient maintains skin integrity and pulmonary, cardiac, GI, and renal functions.

## LUPUS

### Epidemiology

Systemic lupus erythematosus (SLE) affects fewer than 25 people per 100,000 in North America, South America, Europe, and Asia. Prevalence rates vary depending on gender, ethnicity, geographic location, and age. The female-to-male ratio in children affected by SLE is 3:1 but is as high as 15:1 for women during childbearing years. Statistically, African American women are almost four times more likely to develop the disease than Caucasian Americans; however, SLE occurs infrequently in blacks in Africa, Asians, and African Caribbeans. Hispanic Americans have a higher prevalence rate when compared to Americans of European descent in the United States. The age of onset varies according to gender and ethnicity, but overall, 65% of patients are diagnosed between the ages of 16 and 55. Many factors play a role in disease outcome. African Americans and Mexican Hispanics have a poorer prognosis related to renal disease than do Caucasians. Less-educated patients and those with low socioeconomic status are also more likely to have poorer disease control. Men are more likely than women to have renal disease, skin manifestations, laboratory abnormalities, neurological involvement, thrombosis, cardiovascular disease, and vasculitis, whereas women are more likely to suffer from Raynaud's phenomenon, photosensitivity, and mucosal ulceration. People who have relatives with SLE are at a higher risk than the general

population for developing the disease. There have been genes identified that predispose humans to SLE.

### Connection Check 20.7

The nurse recognizes which patient to be at the highest risk for developing SLE?

- A. A 10-year-old Hispanic female
- B. An 18-year-old African American male
- C. A 30-year-old African American female
- D. A 50-year-old Caucasian male

### Pathophysiology

Systemic lupus erythematosus is a chronic inflammatory disease that can affect virtually any organ system. The exact etiology is unknown, as is the case with other autoimmune diseases, but the disease is triggered by multiple factors. Triggering factors include pregnancy, exposure to sunlight, illness, major surgery, silica dust, and medication allergies. Most clinical manifestations of SLE are attributed to antibodies and the creation of immune complexes that are deposited into tissues.

### Clinical Manifestations

Clinical manifestations of SLE are diverse, do not follow a clinical pattern, and vary greatly from one person to another. The clinical course of SLE usually involves periods of remission and acute disease flares. See Table 20.8 for a description of clinical manifestations according to organ system.

### Management

#### Medical Management

#### Diagnosis

Diagnosing lupus may be a complicated and frustrating process for most patients. There is no specific test used to diagnose SLE; rather, laboratory findings are used to support or confirm the diagnosis when combined with patient history and physical examination findings.

The ACR developed guidelines to help in the diagnosis of lupus. The Systemic Lupus International Collaborating Clinics revised and validated the classification criteria to aid in diagnosis. They identified 17 broad criteria that align with the clinical manifestations with specific definitions—some clinical, some immunologic. The clinical criteria include skin rashes such as the lupus malar rash, oral ulcers, thinning hair, joint tenderness, pleural or pericardial effusions, renal (urine protein) and neurological (seizures/confusion) disorders, and haematological disorders such as thrombocytopenia, leukopenia, or anemia. The immunological criteria include positive antinuclear antibody (ANA), low complement, positive anti-Sm, antiphospholipid antibodies, and positive anti-double-stranded DNA (anti-dsDNA). Four of the 17 criteria must present in order to support a

**Table 20.8 Clinical Manifestations of Systemic Lupus Erythematosus**

Organ System	Manifestations
<b>Constitutional</b>	<ul style="list-style-type: none"> <li>● Fatigue</li> <li>● Fever</li> <li>● Difficulty concentrating</li> </ul>
<b>Mucocutaneous</b>	<ul style="list-style-type: none"> <li>● Rash <ul style="list-style-type: none"> <li>● Malar, also known as “butterfly rash” across the cheeks</li> <li>● Discoid lesions, erythematous plaques covered by scale that typically appear on sun-exposed areas</li> </ul> </li> <li>● Photosensitivity</li> <li>● Alopecia</li> <li>● Urticaria, palpable purpura, erythematous papules of fingers and palms, splinter hemorrhages, and digital ulcers caused by vasculitis</li> <li>● Oral, nasal, and anogenital ulcers</li> </ul>
<b>Musculoskeletal</b>	<ul style="list-style-type: none"> <li>● Joint pain with or without synovitis</li> <li>● Muscle pain and weakness</li> </ul>
<b>Renal</b>	<ul style="list-style-type: none"> <li>● Lupus nephritis</li> <li>● Proteinuria</li> <li>● Hematuria</li> </ul>
<b>Neurological</b>	<ul style="list-style-type: none"> <li>● Stroke</li> <li>● Seizures</li> <li>● Neuropathy</li> <li>● Psychosis</li> <li>● Organic brain syndrome</li> <li>● Depression</li> <li>● Anxiety</li> </ul>
<b>Cardiovascular</b>	<ul style="list-style-type: none"> <li>● Pericarditis</li> <li>● Endocarditis</li> <li>● Increased risk of cardiovascular disease</li> </ul>
<b>Pulmonary</b>	<ul style="list-style-type: none"> <li>● Pleurisy</li> <li>● Pleural effusion</li> <li>● Pneumonitis</li> <li>● Interstitial lung disease</li> <li>● Pulmonary hypertension</li> </ul>
<b>Ocular</b>	<ul style="list-style-type: none"> <li>● Retinal lesions</li> <li>● Rarely scleritis or uveitis</li> <li>● Dry eyes</li> </ul>
<b>Hematological</b>	<ul style="list-style-type: none"> <li>● Leukopenia</li> <li>● Anemia of chronic disease</li> <li>● Thrombocytopenia</li> <li>● Thromboembolism</li> </ul>

diagnosis of SLE—at least one clinical and one immunologic. In clinical practice, however, patients may not have four criteria present to be diagnosed if there is sufficient evidence otherwise.

### Laboratory Testing

Laboratory testing is used to confirm some of the clinical and immunological criteria. First, testing is done to confirm the presence of autoantibodies. Patients with SLE produce antinuclear antibody (ANA), confirming the existence of an autoimmune disease. The presence of ANAs does not in itself confirm the diagnosis of SLE because approximately 2% of healthy individuals are positive. Anti-dsDNA and anti-Sm antibodies are most specific for SLE because these autoantibodies are rarely found in other conditions. Antiphospholipid antibodies should also be assessed because the presence of these antibodies may lead to the formation of blood clots. Laboratory values to evaluate the clinical criteria include a complete blood count (CBC) to check for leukopenia (decreased white blood cell count), thrombocytopenia (decreased platelet count), and anemia (decreased red blood cells). Urinalysis with random protein and creatinine along with serum creatinine and BUN should be evaluated and monitored closely in order to detect kidney disease early. C-reactive protein and ESR are markers used to identify inflammation but are not specific for SLE. C-reactive protein and ESR may be monitored to assess for level of disease activity and response to treatment.

### Radiographical Imaging

Radiographical imaging is beneficial to detect or assess some of the clinical criteria or to eliminate other causes of symptoms. See Table 20.9 for common radiographical diagnostic tools used to assess patients with SLE.

## Treatment

### Nonpharmacological Therapy

Nonpharmacological interventions include avoiding prolonged sun exposure and using sunscreen (SPF 50 or higher)

on a daily basis. A well-balanced diet is recommended for proper nutrition. Frequent rest periods and a regular sleep schedule help combat fatigue. Regular exercise improves strength and maintains range of motion as well as a healthy weight.

### Pharmacological Therapy

Pharmacological interventions for patients with SLE are typically based on disease manifestations. Antimalarial medications such as hydroxychloroquine (Plaquenil) are frequently used to treat patients with SLE. The exact mechanism of action of hydroxychloroquine is not fully understood; however, it is believed to impair complement-dependent antigen-antibody reactions. Hydroxychloroquine is also useful in treating constitutional symptoms such as fatigue as well as skin and joint manifestations. It also helps to prevent disease flares and serious organ disease such as lupus nephritis. The most common side effects related to hydroxychloroquine use are abdominal pain and nausea, which may improve over time (see Safety Alert).

Nonsteroidal anti-inflammatory medications such as ibuprofen are useful in treating arthralgias, myalgias, headaches, and fever. Glucocorticoids may be necessary to suppress inflammation in joints, kidneys, and other organ systems. Immunosuppressive agents such as methotrexate may be necessary to treat joint inflammation, which does not respond to NSAIDs or steroids. Glucocorticoids and immunosuppressive agents may be used in combination with hydroxychloroquine in order to treat more serious clinical manifestations. Belimumab (Benlysta) is a biological response modifier that was approved in 2011 for the treatment of SLE. It is the first new treatment to be approved for the treatment of SLE in more than 40 years. Belimumab is made of monoclonal antibodies that bind to proteins known as BLYS and interferes with the inflammatory cascade, decreasing the immune response that is responsible for causing clinical manifestations of SLE. See Table 20.10 for medications used to treat specific manifestations.

**Table 20.9 Common Diagnostic Tools for Complications of Systemic Lupus Erythematosus**

Diagnostic Tool	Implication
<b>Plain radiograph</b>	<ul style="list-style-type: none"> <li>● Painful, swollen joints—assess for joint damage.</li> <li>● Chest—assess for lung disease and cardiomegaly.</li> </ul>

<b>Biological response modifier</b> Belimumab (Benlysta)	<ul style="list-style-type: none"> <li>● Used in conjunction with traditional medications in SLE patients with serologically active disease</li> </ul>

SLE, Systemic lupus erythematosus.

### **Safety Alert** Common Lupus Medications **Alert** Plaquenil

Patients taking Plaquenil are required to have a baseline eye examination and then biannual or annual eye examinations to assess for retinal toxicity, which may be caused by long-term use.

#### **Nonsteroidal Anti-inflammatory Medications**

Nonsteroidal anti-inflammatory medications should be avoided in patients with renal impairment because of the inhibition of the prostaglandins responsible for preserving renal blood flow.

### **Surgical Management**

Surgical interventions may include renal transplant for patients with severe lupus nephritis and joint replacement for patients at risk for avascular necrosis of large joints.

### **Complications**

Lupus is a chronic disease with many possible complications, including renal failure, premature heart disease, interstitial

lung disease, hypercoagulation, stroke, avascular necrosis of joints, and increased risk for infection. Complications may also arise from toxicities related to pharmacological therapy.

### **Nursing Management**

#### **Assessment and Analysis**

There are many clinical manifestations related to SLE. The etiology is unknown, but it is thought to be attributed to antibodies and the creation of immune complexes, which are deposited into tissues. The nurse may identify the following:

- Fatigue
- Difficulty concentrating
- Joint pain
- Rash
- Photosensitivity
- Oral or nasal ulcers
- Dry eyes
- Dry mouth
- Hypertension
- Leukopenia
- Thrombocytopenia

- Alopecia
- Chest pain

### Nursing Diagnoses

- **Fatigue** related to chronic inflammation and altered immunity
- **Altered skin integrity** related to rash
- **Altered self-image** related to manifestations such as rash and alopecia

### Nursing Interventions

#### ■ Assessments

- Vital signs  
*Hypertension may occur as a renal or cardiac complication of SLE, fever may be present due to infection that is a complication of treatment with immunosuppressants, and decreased oxygen saturation may be present because of the complication of interstitial lung disease.*
- Past health history/head-to-toe physical assessment  
*The diagnosis of SLE is based on the presence of 4 of 17 clinical manifestations in the patient's history and physical assessment, such as butterfly rash, oral or nasal ulcers, alopecia, musculoskeletal complaints, joint swelling, weight loss, and blood abnormalities.*
- Monitor laboratory values: BUN and creatinine, urinalysis, CBC, CRP/ESR, coagulation studies.  
*Elevated BUN and creatinine along with the presence of proteinuria may indicate decreased renal function and is one of the clinical criteria for SLE. Decreased white blood cells, platelets, and red blood cells are common in patients with SLE and may require intervention. Elevated CRP and/or ESR indicates inflammation and may require intervention. Coagulopathies are a complication of SLE.*

#### ■ Actions

- Administer analgesics and anti-inflammatory medications as ordered.  
*Most patients require analgesics and anti-inflammatory medications to manage the pain caused by inflammation.*
- Administer medications as ordered to treat specific clinical manifestations.  
*Managing clinical manifestations is imperative in the treatment of patients with SLE to help prevent complications. See Table 20.10 for medications used to treat clinical manifestations.*

#### ■ Teaching

- Disease process  
*It is very important for patients to understand the disease process in order to manage the disease and help prevent complications.*
- Use sunscreen daily.  
*Photosensitivity is common. Daily use of sunscreen helps prevent rash related to photosensitivity.*
- Energy conservation and activity prioritization  
*Fatigue is a common complaint and can be better managed by ensuring frequent rest periods and prioritizing activities.*

- Keep up to date on immunizations, but avoid live vaccines.  
*Patients at risk for infections due to treatment should not receive live vaccines if on immunosuppressive therapy.*
- Avoid oral contraceptives in patients with SLE who have migraine headaches, Raynaud's phenomenon, a history of phlebitis, or antiphospholipid antibodies.  
*Patients with SLE, specifically patients with the manifestations noted, have an increased risk of hypercoagulability, which may be heightened by the use of oral contraceptives.*
- Assist in referrals to a pulmonologist, nephrologist, neurologist, cardiologist, and dermatologist as needed.  
*Complicated clinical manifestations require the care of specialists to provide optimal care.*

### Evaluating Care Outcomes

Systemic lupus erythematosus is a complicated disease that can be very difficult to manage. Medication compliance plays a major role in controlling the disease. Disease flares are not unexpected and may consist of increased fatigue, fever, rash, arthritis, and mucosal ulcers as well as other common clinical manifestations. Frequent evaluations should be performed on a regular basis by a rheumatologist who monitors disease progression and treats new clinical manifestations as they arise. Patients with well-controlled SLE are high-functioning individuals who are able to carry out the usual activities of daily living.

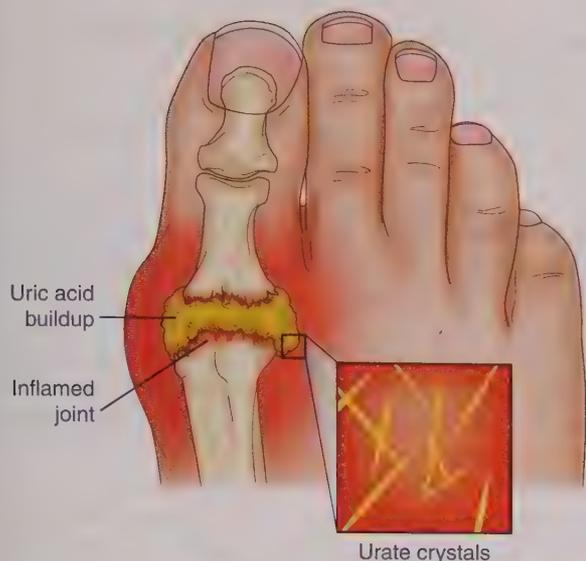

## GOUT

### Epidemiology

Gout affects approximately 2% of people in the United States and is most commonly found in men aged 40 to 60 years and women aged 55 to 70. Risk factors for developing gout include obesity, hypertension, eating large amounts of meat and seafood, using thiazide diuretics, and consuming large quantities of alcohol. When metabolized, purine-rich foods such as seafood, meat, and alcohol increase uric acid production. Thiazide diuretics, such as hydrochlorothiazide, increase the net urate reabsorption in the renal tubules, therefore increasing the serum uric acid level.

### Pathophysiology

Gout is a disease in which monosodium urate crystals are deposited in joints, bone, and soft tissues, accompanied by inflammation (Fig. 20.7). Hyperuricemia, an elevated uric acid level in the blood, must be present prior to the evolution of gout, but the presence of hyperuricemia is not indicative of gout. Hyperuricemia results from the overproduction of or diminished renal excretion of uric acid. Urate crystals are the result of an oversaturation of uric acid in the blood. The uric acid settles out of solution into soft tissues and joints. The body's attempt to rid itself of the crystal deposits results in an inflammatory process causing swelling, warmth, and intense pain in the affected joint. Gout attacks typically resolve after several days or weeks even if left untreated; however,

**FIGURE 20.7** Urate crystal buildup in the great toe, a common presentation of gout.

gout can become a chronic inflammatory destructive arthritis. There are three phases of gout, which are termed *acute*, *intercritical*, and *chronic*. Acute gout usually involves one joint and is characterized by acute onset of pain, redness, and swelling. Intercritical gout is the asymptomatic period between gout attacks. If gout is left untreated, the attacks may come more often, with a shortened intercritical period. Chronic tophaceous gout is characterized by repeated attacks of many years, leading to the production of **tophi** (uric acid deposits or nodules in the joint) and joint destruction. About 80% of patients present with the first attack of gout affecting a lower extremity joint, typically the first metatarsophalangeal (MTP) joint. **Podagra** is the term used to identify gout in the first MTP. The severity of the attack typically peaks at 12 to 24 hours after onset.

## Management

### Medical Management

#### Diagnosis

A presumptive diagnosis of gout may be achieved by combining objective, subjective, and laboratory data, but the definitive diagnosis can be made only by observing crystals

in synovial fluid or tophaceous material. Radiographical evidence is not necessary to diagnose gout; however, joint erosions and soft tissue nodules are radiographically consistent with chronic gouty arthritis. See Table 20.11 for the typical presentation of gout patients. Other diagnoses such as septic arthritis, trauma, and pseudogout should be ruled out. The presentation of septic arthritis and pseudogout may mimic acute gout and may not be differentiated by clinical examination alone. In some cases, it is necessary to examine joint fluid for uric acid crystals to make a definitive gout diagnosis.

### Connection Check 20.8

The nurse assesses for which *initial* clinical manifestation in the patient diagnosed with gout?

- Pain and inflammation in the shoulder
- Pain and inflammation in the wrist
- Pain and inflammation in the knee
- Pain and inflammation in the great toe

## Treatment

### Nonpharmacological Therapy

Nonpharmacological treatment consists of weight management because obesity is a modifiable risk factor for gout. Alcoholic beverages, specifically beer, should be avoided because they increase uric acid production. Splinting of the affected joint may also be useful in protecting the joint and alleviating pain.

### Pharmacological Therapy

Pharmacological treatment of gout depends on which stage the patient is in when requesting treatment. Acute gout management is focused on pain relief and reduction of inflammation. Common medications used include NSAIDs such as indomethacin (Indocin) and colchicine (Colcris), which decrease the buildup of uric acid crystals in the joint. Glucocorticoids are used to reduce inflammation and provide pain relief. Management of intercritical gout consists of the use of NSAIDs and colchicine, whereas managing chronic gout focuses on the use of uric acid-lowering agents.

**Table 20.11** Typical Presentation of Gout Patients

Subjective	Objective	Laboratory	Radiographical
<ul style="list-style-type: none"> <li>I have severe joint pain (usually great toe or knee).</li> <li>I think my joint is swollen.</li> <li>I cannot move my joint.</li> <li>My joint feels hot when I touch it.</li> </ul>	<ul style="list-style-type: none"> <li>Tenderness on palpation</li> <li>Soft tissue swelling on examination accompanied by warmth and redness</li> <li>Presence of tophi in the chronic gout patient</li> </ul>	<ul style="list-style-type: none"> <li>Elevated serum uric acid level</li> <li>Visualization of urate crystals found in synovial fluid on microscopic examination</li> </ul>	<ul style="list-style-type: none"> <li>Plain radiographical findings are usually normal in early gout.</li> <li>Erosions and soft tissue nodules may be present in chronic gout.</li> </ul>

Uric acid–lowering agents such as allopurinol (Zyloprim) or febuxostat (Uloric) reduce serum uric acid by inhibiting the production of uric acid. One very important fact to remember is that acute gout is never treated with uric acid–lowering agents such as allopurinol. For unknown reasons, a rapid change in serum uric acid levels may provoke or worsen a gout attack.

**Safety Alert** Although aspirin is an NSAID, it should be avoided in the treatment of gout because it can increase uric acid levels by causing retention of uric acid.

### Complications

Urate crystals can aggregate to form a stone, making gout patients more likely to experience kidney stones than the general population.

### Nursing Management

#### Assessment and Analysis

Clinical manifestations of gout are related to pain and decreased function due to the accumulation of urate crystals and tophi nodules in the affected joints. The nurse may identify the following:

- Intense joint pain
- Tenderness on palpation of affected joint
- Swelling of affected joint
- Redness of affected joint
- Warmth over affected joint
- Decreased range of motion
- Presence of tophi

#### Nursing Diagnoses

- **Pain** related to the disease process
- **Knowledge deficit** related to the disease process and treatment

#### Nursing Interventions

##### Assessments

- Monitor uric acid level.  
*Hyperuricemia promotes crystal formation.*
- Assess for presence of tophi—lumps or hard nodules under the skin around joints.  
*The presence of tophi is indicative of advanced gout.*
- Assess for red, swollen, and painful joints.  
*Red, swollen, and painful joints indicate an acute gout flare.*
- Assess pain levels.  
*Evaluating pain helps determine the occurrence of a flare and also evaluates the efficacy of treatment.*

##### Actions

- Administer uric acid–lowering agents as directed.  
*Uric acid–lowering agents are necessary to decrease serum uric acid and decrease the incidence of gout flares in chronic gout.*

- Administer analgesics and anti-inflammatory medications as ordered.  
*Anti-inflammatory agents and analgesics must be used to help control pain and decrease inflammation in acute or intercritical gout.*
- Administer glucocorticoid therapy as directed.  
*Systemic glucocorticoid therapy may be used in conjunction with or as an alternative to NSAID therapy to reduce inflammation in acute gout.*

##### Teaching

- Avoid alcoholic beverages, especially beer.  
*Alcohol is high in purines, which metabolize into uric acid, increasing serum uric acid levels.*
- Take uric acid–lowering agents as directed.  
*The use of uric acid–lowering agents is necessary to decrease serum uric acid levels and help prevent future attacks.*
- Report gout flares promptly.  
*Prompt treatment decreases the pain and the severity of gout flares.*
- Proper nutrition  
*Avoid high-purine foods, such as red meat, liver, and fish.*

### Connection Check 20.9

Which statement by the patient with gout indicates that further teaching is needed?

- “Losing weight will help to reduce further gout attacks.”
- “I should report my diagnosis of gout to my cardiologist because taking some forms of diuretics may increase gout flares.”
- “Avoiding foods containing purines, such as red meats, seafood, and alcoholic beverages, will help to reduce the incidence of gout flares.”
- “I can drink alcohol if I limit the number of beers I drink.”

### Evaluating Care Outcomes

The goal of treating gout patients is to eliminate gout flares and prevent joint destruction. This is done by controlling the uric acid level. A well-managed patient takes gout-lowering agents appropriately; avoids foods containing purines, such as seafood and red meat; and limits alcohol consumption.

## FIBROMYALGIA

### Epidemiology

Fibromyalgia is the most common cause of chronic musculoskeletal pain in women between the ages of 20 and 55. The disorder affects approximately 4% of the U.S. population, with a greater prevalence in women. Fibromyalgia is commonly found in patients with rheumatic conditions such as RA, SLE, and Sjogren’s syndrome. The onset of fibromyalgia usually occurs in middle adulthood but may occur in adolescence or later in life. Genetic factors may

play a role in predisposing patients to the development of fibromyalgia.

## Pathophysiology and Clinical Manifestations

Fibromyalgia is a chronic pain disorder of soft connective tissues that is characterized by widespread pain and other symptoms such as insomnia, fatigue, stiffness, and cognitive dysfunction (e.g., inability to focus or concentrate on tasks). The etiology and pathophysiology of this disorder are unclear, but current theories include the abnormal processing of stimuli by the central nervous system, causing normal pain signals to be amplified. The amplification of stimuli causes fibromyalgia patients to feel pain, whereas those without fibromyalgia would not feel pain. Fibromyalgia may be triggered by an infection or physical or emotional trauma. In females, the menstrual cycle can affect sensitivity to pain. Normal daily stress combined with common fibromyalgia symptoms can create a cycle that builds one on another (Fig. 20.8).

## Management

### Medical Management

#### Diagnosis

Laboratory testing is not necessary to diagnose fibromyalgia but may be necessary to rule out other diagnoses. History and physical assessment are used to diagnose fibromyalgia. Patients often report hurting all over or feeling as if they have the flu. Other complaints include fatigue, headaches, cognitive impairments, and abdominal pain. Physical examination of the patient is essentially normal, with no evidence of joint or muscle inflammation. In 1990, the ACR criteria for the diagnosis of fibromyalgia required that the patient experience pain at 11 or more of 18 specified locations (tender points) and have widespread pain. The assessment of

tender points is done by applying approximately 4 kg of pressure (this is comparable to the pressure it would take to blanch your nail bed) to specific points on the patient's body (Fig. 20.9). Widespread pain involves pain on both sides of the body and above and below the waist.

## Treatment

### Nonpharmacological Therapy

Nonpharmacological therapy includes physical therapy, strength training, aerobic exercise, cognitive behavioral therapy, education, and self-management. Physical therapy is helpful in maintaining strength and function. Cognitive-behavioral therapy may be used to help understand the illness and change patients' behavioral response to pain. Self-management skills include utilizing relaxation techniques to minimize stress, establishing regular sleep patterns, and exercising regularly.

### Pharmacological Therapy

Pharmacological therapy includes medications that alter chemicals in the brain, such as serotonin and norepinephrine, or block overactivity of nerve cells. Other medications that may prove useful are those that improve sleep and treat pain. The use of opioid analgesics is not recommended because they may be habit forming and usually are ineffective. Table 20.12 provides an overview of medications used for the treatment of fibromyalgia.

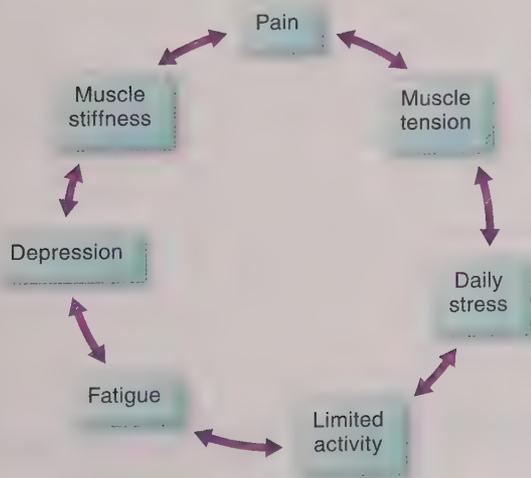

### Nursing Management

#### Assessment and Analysis

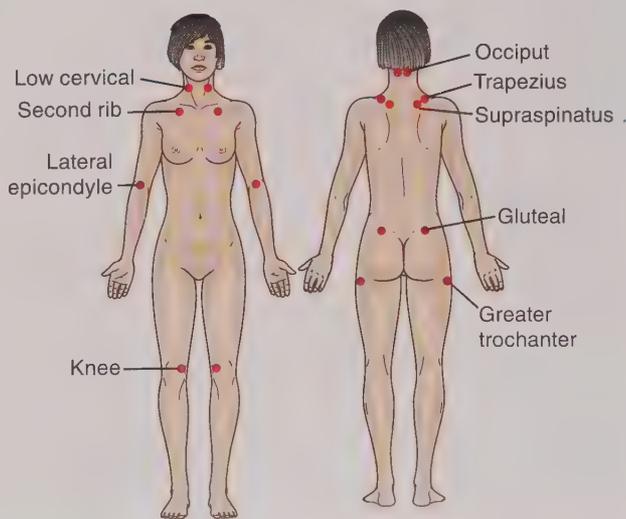

The nurse may identify the following clinical manifestations in fibromyalgia patients due to enhanced pain perception and stress related to that enhanced pain:

- Fatigue
- Arthralgia and myalgia
- Headache
- Abdominal pain

**Fibromyalgia Cycle**

**FIGURE 20.8** Fibromyalgia cycle.

**FIGURE 20.9** The 18 fibromyalgia tender points.

**Table 20.12 Pharmacological Treatments for Fibromyalgia**

	Medication	Action	Common Side Effects
<b>Antidepressants to help with pain and promote sleep</b>	Duloxetine (Cymbalta)	Inhibits norepinephrine and serotonin reuptake	Nausea Dry mouth Constipation Somnolence
	Milnacipran (Savella)	Inhibits norepinephrine and serotonin reuptake	Nausea Vomiting Constipation Insomnia
	Amitriptyline (Elavil)	Inhibits norepinephrine and serotonin reuptake	Drowsiness Dry mouth Dizziness Constipation
	Fluoxetine (Prozac)	Selectively inhibits serotonin reuptake	Nausea Headache Insomnia Nervousness
<b>Anti-seizure medications to reduce pain</b>	Pregabalin (Lyrica)	Binds alpha-2-delta subunit of calcium channels, reducing neurotransmitter release	Dizziness Weight gain

- Decreased desire to participate in activity
- Nonrestorative sleep
- Anxiety

### Nursing Diagnoses

- **Chronic pain** related to the disease process
- **Ineffective coping skills** related to chronic pain
- **Depressed mood** related to chronic pain
- **Ineffective sleep patterns** related to chronic pain

### Nursing Interventions

#### ■ Assessments

- Vital signs  
*Pain may alter vital signs (increased heart rate and blood pressure).*
- Affect  
*Depression may be an associated symptom because of chronic pain.*
- Pain  
*Fibromyalgia causes chronic pain. Increased levels indicate ineffective treatment strategies, whereas*

*decreased pain levels indicate effective treatment and self-management.*

#### ■ Actions

- Administer medications as ordered:  
Nonsteroidal anti-inflammatories  
Antidepressants  
Anti-seizure medications  
*Pain management is an integral part of managing patients with fibromyalgia. Nonsteroidal anti-inflammatories manage inflammation. Antidepressants manage depression, promote sleep, and help control pain through inhibition of the reuptake of neurotransmitters, which inhibit pain transmission in the brain. Anti-seizure medications work for unknown reasons but may modify the release of neurotransmitters through action on calcium channels.*
- Provide a heating pad for painful muscles and cold packs for painful joints.  
*Heat is used to relax muscles, increasing blood flow to the affected area; cold packs may soothe aching joints.*

### Teaching

- Take medications only as prescribed.  
*Improper use of medications can be very harmful. Proper use of medications is required in order to receive the desired effect.*
- Participate in regular physical activity.  
*Physical activity is necessary to maintain or improve strength and function.*
- Teach effective coping skills.  
*Effective coping skills are important to maintain a positive attitude and improve self-concept.*
- Assist with referring the patient for a sleep study.  
*Ineffective sleep may increase pain and fatigue.*
- Assist with referring the patient to a mental health facility if necessary.  
*Fibromyalgia patients may benefit from therapy to help deal with depression related to chronic pain.*
- Assist with referral to occupational and physical therapies as needed.  
*Occupational and physical therapists may formulate an exercise plan appropriate for the patient.*

### Evaluating Care Outcomes

Compliance with a healthy diet and exercise regimen and getting adequate rest are essential in managing fibromyalgia. Taking medications as prescribed helps to control the enhanced sensation of pain and the depression associated with the disease process. A well-managed patient has decreased pain and fatigue, healthy sleep patterns, and maintenance or improvement of strength and function (see Transitional Care).

## Transitional Care

### Connective Tissue Disorders

Considerations for all connective tissue diseases include:

- Evaluating the effects of medications due to declining renal function

*May require more frequent follow-up to monitor medication levels and renal function*

- Inadequate nutrition and exercise/ineffective or no support system

*May require home-care follow-up to ensure proper nutrition and exercise*

- Risk for falls

*May require home safety evaluation; potential installation of grab bars in bathroom and shower*

- Increased risk of depression

*May require psychosocial follow-up*

### Connection Check 20.10

Which statement by the patient with fibromyalgia indicates that teaching has been effective?

- “Because of my fibromyalgia, I may get inflammatory arthritis, which may lead to joint damage.”
- “I won’t know for sure about my diagnosis until I have diagnostic tests such as x-rays and blood tests done.”
- “My only option to treat my pain is narcotic analgesics.”
- “It’s frustrating, but I understand that fibromyalgia typically presents with a normal physical examination with no evidence of joint or muscle inflammation.”

## Making Connections

### CASE STUDY: WRAP-UP

On the basis of the laboratory results indicating elevated rheumatoid factor, elevated ESR and CRP, and anticyclic citrullinated peptide, as well as synovitis on ultrasound in the affected joints, RA is diagnosed. Ms. Logan is started on ibuprofen and short-term low-dose prednisone. The rheumatologist discusses treatment options that are available to help control disease progression. Ms. Logan will most likely begin to use methotrexate to decrease the disease progression. She will follow up with the rheumatologist frequently until her disease is well controlled.

#### Case Study Questions

- The nurse is reviewing the treatment plan for Ms. Logan. It is a priority for the nurse to follow up with the provider about which part of the plan?
  - Ibuprofen 600 mg PO tid
  - Prednisone 5 mg PO every day
  - Oxycodone 5 mg PO every 6 hours prn
  - Consider methotrexate if other options are unsuccessful in controlling pain
- Which statement made by Ms. Logan regarding methotrexate indicates that teaching has been effective?
  - “I guess I’ll have to cut back to drinking only one beer a day.”
  - “Since the doctor ordered me to take six methotrexate pills a week, I can take one a day Sunday through Friday and skip taking a pill on Saturday.”
  - “My husband and I will use two effective means of birth control to prevent pregnancy if I start methotrexate.”
  - “If my joint pain and swelling get worse, I’ll take more methotrexate then notify the doctor at my next appointment.”

3. The nurse caring for Ms. Logan incorporates which nursing diagnosis into the plan of care?
  - A. Impaired perfusion related to vasoconstriction secondary to RA
  - B. Impaired oxygenation related to decreased respiratory effort secondary to RA
  - C. Risk of injury related to unstable gait secondary to RA
  - D. Imbalanced nutrition related to dietary limitations secondary to treatment of RA
4. The nurse caring for Ms. Logan after the initiation of methotrexate therapy monitors for which clinical manifestation?
  - A. Weight gain
  - B. Elevated liver enzymes
  - C. Weight loss
  - D. Decreased ESR
5. The nurse providing care for Ms. Logan should include which lifestyle modifications into the plan of care? (*Select all that apply.*)
  - A. Limit range-of-motion exercise to reduce stress on joints.
  - B. Begin high-carbohydrate, low-protein diet.
  - C. Begin range-of-motion exercises to increase the flexibility of joints.
  - D. Limit aerobic exercise to reduce stress on joints.
  - E. Begin aerobic exercise for weight control.

## CHAPTER SUMMARY

Connective tissues are made of collagen, elastin, and reticular fibers. Examples of connective tissues include bone, bone marrow, cartilage, tendons, ligaments, vasculature, and lymphatic tissue. Connective tissue diseases may affect any of these connective tissues.

Osteoarthritis is primarily a noninflammatory type of arthritis that results from weight bearing, trauma, infection, and overuse. Damage occurs within the joint, which leads to the deterioration of joint function. Osteoarthritis presents as joint pain, swelling, possible decreased range of motion, and at times, unsteady gait due to joint damage. Morning stiffness typically lasts less than 30 minutes, and pain tends to become worse with movement. The diagnosis of osteoarthritis is commonly made on the basis of symptoms and conventional radiographs. There is no cure for osteoarthritis, and there are no medications to greatly inhibit disease progression. Pain is treated with nonsteroidal anti-inflammatory medications, and in some cases narcotic medications are necessary. Nursing management consists of assessing for pain, swelling, redness, range of motion, and effectiveness of pain medications, as well as assessing for side effects related to medication management.

Rheumatoid arthritis, scleroderma, and lupus are autoimmune diseases that may affect multiple organ systems. These diseases may be difficult to diagnose and are not diagnosed solely by using laboratory data. Elevated CRP and ESR rates indicate inflammation but are not specific for RA. Patients may or may not present with a positive RA factor. A complete history and physical examination are extremely important in making these diagnoses. All of these diseases are more prevalent in women.

Rheumatoid arthritis is completely different from osteoarthritis. It affects only about 1% of the population. Rheumatoid arthritis is an autoimmune inflammatory disease that not only affects joints but may also affect other organ systems. Inflammation within each organ system is what causes organ or tissue damage. Morning stiffness usually lasts for greater than 30 minutes, and pain generally gets better with movement. Joint involvement is typically symmetrical. Lung disease related to RA is a common clinical manifestation that may be present even in the absence of joint inflammation. There are many good treatment options available to treat patients with RA, and it is possible to achieve clinical remission by using DMARDs. Nursing management includes assessing for pain, redness, and decreased mobility as well as assessment for organ involvement outside the musculoskeletal system.

Scleroderma is an autoimmune connective tissue disease characterized by secondary Raynaud's phenomenon, thickened and hardened skin, and multiple other internal organ manifestations. Localized scleroderma affects the skin but does not affect the visceral organs, whereas systemic scleroderma is more likely to involve the internal organs. Limited systemic scleroderma has a slower onset and involves the skin of the extremities; internal involvement occurs late in the disease. Diffuse systemic scleroderma, which has a rapid onset, involves the skin of the trunk and involves internal organs early in the disease. Disease-modifying antirheumatic medication therapy is used to treat scleroderma, but specific medications must also be used to treat specific organ involvement (i.e., vasodilators to treat pulmonary hypertension). Nursing management includes assessing for the symptoms of scleroderma and other organ system involvement. It also includes teaching appropriate skin care, assessing skin integrity, and monitoring for digital ulcers.

Systemic lupus erythematosus is an autoimmune disease mostly characterized by fatigue, fever, rash, photosensitivity, oral and nasal ulcers, alopecia, arthralgia, and myalgia. More serious manifestations include pericarditis, endocarditis, arthritis, interstitial lung disease, and lupus nephritis. Lupus primarily affects women of childbearing age. Nursing management includes educating the patient about the disease, the treatments, and what to report to the rheumatologist.

Treatment for RA, scleroderma, and lupus must be individualized for each patient but typically includes anti-inflammatories, analgesics, DMARDs, and biological agents.

Gout is a disease in which a state of serum hyperuricemia causes monosodium urate crystals to deposit in and around

joints, which causes inflammation and leads to debilitating pain in the joint, with swelling and redness. It initially presents in a lower extremity joint, such as the great toe. Gout has three phases, acute, intercritical, and chronic, which are treated differently. Nursing management includes teaching about the disease, treatment options, and lifestyle modifications, including foods or drinks to avoid that increase in uric acid levels.

Fibromyalgia is a chronic pain syndrome characterized by widespread pain along with other symptoms, such as insomnia, fatigue, stiffness, and cognitive dysfunction. Patients typically present with a normal examination. Diagnosis is made through the evaluation of physical complaints. Nursing management focuses on the assessment of symptoms and includes teaching effective pain management and self-management.

# Chapter 21

## Coordinating Care for Patients With Multidrug-Resistant Organism Infectious Disorders

*Gladdi Tomlinson*

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Describing the epidemiology of multidrug-resistant organism infectious disorders
2. Correlating clinical manifestations to pathophysiological processes of:
  - a. Methicillin-resistant *Staphylococcus aureus*
  - b. Vancomycin-resistant *Enterococci*
  - c. *Clostridioides difficile*
  - d. *Acinetobacter baumannii*
  - e. Carbapenem-resistant Enterobacteriaceae
3. Describing the diagnostic results used to confirm the diagnosis of infectious disorders
4. Discussing the medical management of:
  - a. Methicillin-resistant *Staphylococcus aureus*
  - b. Vancomycin-resistant *Enterococci*
  - c. *Clostridioides difficile*
  - d. *Acinetobacter baumannii*
  - e. Carbapenem-resistant Enterobacteriaceae
5. Developing a comprehensive plan of nursing care for patients with multidrug-resistant-organism infectious disorders
6. Designing a teaching plan that includes pharmacological, dietary, and lifestyle considerations for patients with multidrug-resistant organism infectious disorders

### CONCEPTS

- Assessment
- Fluid and Electrolyte Balance
- Immunity
- Infection
- Medication
- Safety

### ESSENTIAL TERMS

*Acinetobacter baumannii*  
Airborne transmission  
Bactericidal  
Bacteriostatic  
Carbapenem-resistant Enterobacteriaceae (CRE)  
Coagulase-positive bacterium  
*Clostridioides difficile* (*C. diff*)  
Colonized  
Contact isolation  
Contact transmission  
Endogenous pathogen  
Exogenous  
Facultatively anaerobic  
Hand hygiene  
Methicillin-resistant *Staphylococcus aureus* (MRSA)  
Multidrug-resistant (MDR) organisms  
Nonsporulating  
Nosocomial infections  
Peak levels  
Probiotics  
Trough level  
Vancomycin-resistant *Enterococci* (VRE)  
Vector-borne transmission  
Vehicle transmission

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Joe Brown is a 76-year-old male who presents to his healthcare provider from his nursing home residence with a painful, red, swollen abdominal surgical wound that is warm to the touch and is draining pus. Joe had a cholecystectomy last week and is returning to his healthcare provider to get the staples removed. Joe has just finished his antibiotics. He takes metformin for his diabetes mellitus type 2 and is on Coumadin for atrial fibrillation...

## INTRODUCTION

Infectious diseases have been plaguing the world for centuries. They are caused by pathogens—microorganisms that are capable of causing disease. For a pathogen to cause a disease, a susceptible host and a mode of transmission are required. A susceptible host usually has a weakened immune system or has had a breakdown in the body's defense mechanism. For an infection to be transmitted, a transport mechanism is required. Routes of transmission are contact, airborne, vehicle, and vector borne. **Contact transmission** occurs when a person or object comes in contact with a pathogen. **Airborne transmission** occurs when pathogens are carried through the air. **Vehicle transmission** is an indirect mode of transmission that occurs when a disease-carrying agent touches a person's body or is ingested. Similarly, **vector-borne transmission** is also an indirect mode of transmission that occurs when a vector, an organism that transmits a pathogen, bites or infects a person.

Contact transmission is the most common mode of transmission. In this mode, pathogens are introduced into the body by direct or indirect contact. When an infectious disease is spread by direct contact, the microorganisms are transferred directly from person to person. In indirect-contact transmission, microorganisms are spread from a source to a susceptible host by passive transfer from an inanimate object or fomite, an object or substance capable of carrying an infectious organism. Often in healthcare settings, patients acquire infectious diseases through indirect contact via the unclean hands of healthcare workers, from contaminated equipment, or from the contaminated environment. Infections that are acquired in the hospital and were not present on admission are called **nosocomial infections**. In 2016, the Centers for Disease Control and Prevention (CDC) reported the findings from the 2014 Healthcare Associated Infection (HAI) progress report. The survey results concluded that 1 in 25 inpatients in U.S. acute care hospitals had at least one healthcare-associated infection. The survey also revealed a 50% decrease in central line-associated

bloodstream infections, a 17% decrease in surgical infections, an 8% decrease in *Clostridioides difficile* infections, a 13% decrease in methicillin-resistant *Staphylococcus aureus*, and no change in urinary tract infections. The Health and Human Services Department has implemented an *Action Plan to Prevent Healthcare-Associated Infections* goal of decreasing healthcare-associated infections by 25% by the year 2020.

**Multidrug-resistant (MDR) organisms** are common causes of nosocomial infections. **Methicillin-resistant *Staphylococcus aureus* (MRSA)**, **vancomycin-resistant *Enterococci* (VRE)**, ***Clostridioides difficile* (C. diff)**, ***Acinetobacter baumannii***, and **carbapenem-resistant *Enterobacteriaceae*** are all examples of MDR organisms that cause nosocomial infections.

## MULTIDRUG-RESISTANT ORGANISMS

### Methicillin-Resistant *Staphylococcus Aureus*

#### Epidemiology

*Staphylococcus aureus* (*S. aureus*) is a common asymptomatic pathogen and is considered normal bacterial flora of humans. Two in 100 carry it, and approximately 30% of healthy individuals are **colonized** (the host carries the bacteria without active infection) with this pathogen in the nose, throat, axillae, toe webs, or perineum. The most common site of colonization is the anterior nares. Although 30% of people are colonized with *S. aureus*, fewer than 2% are infected with it.

The first case of MRSA was described in 1961, and the first documented outbreak occurred in the United States in 1968. In 2007, the Association for Professionals in Infection Control and Epidemiology reported that an estimated 1.2 million hospitalized patients acquire MRSA each year in the United States. Today, it is estimated that approximately 80% of *S. aureus* isolates from clinical cultures are MRSA. Methicillin-resistant *S. aureus* is the result of decades of unnecessary antibiotic use and is currently resistant to all beta-lactam antibiotics, including penicillins, cephalosporins, and carbapenems. It is also the most commonly identified MDR pathogen in North America, South America, Europe, Asia, Africa, and the Middle East.

A CDC study found that healthcare-initiated MRSA declined 54% between 2005 and 2011 and was down 13% in 2014. The CDC goal was a decrease of 25% by 2011. Data from the CDC and Healthcare-Associated Infections Progress Report continue to show progress; from 2011 to 2013, there were an estimated 8% fewer hospital-onset MRSA infections. Also, it is reported that there were 9,000 fewer deaths from MRSA in hospital patients in 2011 versus 2005. The National Healthcare Safety Network reported that the incidence of MRSA central line-associated bloodstream infections decreased in recent years in most intensive care units (ICUs), except in pediatric units. The decline in MRSA infection rates is attributed to general infection control efforts such as the use of alcohol-based hand rubs, improved **hand hygiene**, efforts targeted at eliminating bloodstream infections, and enhanced antimicrobial stewardship programs.

Historically, MRSA has been associated with healthcare; however, recently, a newer strain has been identified. The first case of community-acquired MRSA (CAMRSA) was reported in the United States in 1980. Community-acquired MRSA has become the most frequent cause of skin and soft tissue infections presenting to emergency departments in the United States. Hospital-acquired MRSA (HAMRSA) tends to lead to more invasive diseases such as bloodstream infections, surgical-site infections, and pneumonia.

Epidemiologically, HAMRSA and CAMRSA have different molecular characteristics. Community-acquired MRSA strains are resistant to beta-lactam and macrolide antimicrobials; however, they remain susceptible to many non-beta-lactam antimicrobials. Hospital-acquired MRSA strains are resistant to many other classes of antibiotics in addition to beta-lactam and macrolide antibiotics. Recent studies suggest that HAMRSA and CAMRSA should be treated on the basis of the type of infection and antibiotic susceptibility rather than the strain of bacteria.

Risk factors for HAMRSA include hospitalization in the past 12 months, soft tissue infection on hospital admission, hospitalization in intensive care, and residing in a long-term care facility, thus increasing the risk of exposure; invasive procedures or medical devices such as urinary catheters or IV lines that create a portal for the entry, including hemodialysis; and recent or long-term broad-spectrum antibiotic therapy allowing bacteria to become resistant to a specific antibiotic. Other risk factors include people with an immature or weakened immune system, such as young children, older adults, or people with HIV or AIDS as well as other comorbid conditions such as diabetes, cancer, chronic obstructive pulmonary disease, congestive heart failure, and immunosuppression.

Risk factors for CAMRSA include children younger than 2 years of age, athletes, IV drug users, men who have sex with men, military personnel, and persons living in correctional facilities or shelters. These risk factors are associated with close skin-to-skin contact, crowded living conditions, and poor hygiene (Table 21.1).

### Pathophysiology

*Staphylococcus aureus* is an aerobic, gram-positive, non-sporulating (does not make spores capable of reproduction), coagulase-positive bacterium (produces the enzyme coagulase, which helps convert fibrinogen to fibrin). Because it is a coagulase bacterium, MRSA is coated with a fibrin wall that resists phagocytosis, making the bacterium more virulent, thus enabling it to protect itself from host defense mechanisms. Also, *S. aureus* has developed the ability to destroy the active lactam ring in the penicillin molecule by secreting an enzyme called beta-lactamase. This genetic mutation prevents the beta-lactam ring from binding to the bacterial cell; thus, the agent cannot exert its antimicrobial effects.

Methicillin-resistant *S. aureus* is not naturally found in the environment, but it is found on humans. *Staphylococcus aureus* and MRSA can live on surfaces and humans for days to weeks; it has a varying life span. When a person is colonized with MRSA, the endogenous pathogen (the

pathogen residing on the body) can easily be transferred to the skin and other body areas, increasing the risk for infection (Fig. 21.1). For example, if a person is colonized with MRSA in the nose and he or she wipes the nose with the hand and then touches an open wound, the bacteria can then be transferred to the wound and cause an infection.

Methicillin-resistant *S. aureus* infections are also caused by exogenous (meaning “outside the body”) sources. The mode of transmission from an exogenous source is contaminated surfaces. Methicillin-resistant *S. aureus* can be spread if an infected person touches the source of infection and then touches an object or surface. To prevent transmission from a contaminated surface, the CDC recommends covering cuts and open wounds with bandages and maintaining good hygiene, including bathing or showering regularly. The more common mode of transmission for MRSA is direct contact. Methicillin-resistant *S. aureus* is easily spread, especially in hospitals and healthcare settings, from patient to patient or from body part to body part on the unclean hands of healthcare personnel or through improperly cleaned equipment. Thus, proper hand hygiene is essential when caring for patients with MRSA. A study done by Duke University found that the most commonly transmitted pathogen was *S. aureus*, including MRSA and methicillin-susceptible *S. aureus*. Contamination was from side rails, beds, supply carts, nurses’ sleeves, and the pockets of nurses’ uniforms.

### Clinical Manifestations

Clinical manifestations of *S. aureus* commonly include minor skin infections, including pimples, abscesses, sties, and impetigo. Methicillin-resistant *S. aureus*, on the other hand, causes more serious infections, including pneumonia, skin and soft tissue infections, surgical-site infections, and bloodstream infections.

### Complications

Because MRSA is resistant to numerous antibiotics, infections can often be difficult to treat and can cause serious complications as well as widespread infection. Infections with MRSA are associated with increased morbidity and mortality rates. The MRSA mortality rate overall is 20% to 50%. The highest mortality rates of 55.6% were observed among patients with MRSA-related septic shock. Patients with MRSA pneumonia had the next highest mortality rate at 32.4%, followed by MRSA endocarditis at 19.3%. Methicillin-resistant *S. aureus* bacteremia has a mortality rate of 10.2%, and the mortality of MRSA cellulitis is 6.1%. Patients with MRSA bacteremia have significantly longer lengths of stay, averaging 9.1 days, and the average hospital cost is significantly higher. The costs of MRSA average \$20,000 per patient, with a total burden of \$2.5 billion yearly. Patients who develop MRSA surgical-site infections have a 3.4-times-higher risk of death than a non-MRSA patient, and hospital costs are twice as much as the average hospital stay. Patients colonized with MRSA from a previous hospital stay have a 29% greater risk for developing bacteremia, pneumonia, or soft tissue infection within 18 months of colonization. Methicillin-resistant

**Table 21.1 Risk Factors for Multidrug-Resistant (MDR) Organisms**

Hospital-Acquired MRSA	Community-Acquired MRSA	VRE	<i>Clostridioides Difficile</i>	<i>Acinetobacter Baumannii</i>	CRE
Current/recent hospitalization	Less than 2 years of age	Prolonged hospitalization	Recent antibiotic use	Recent surgery	Weakened immune system
Residing in long-term care facility	Athletes	Weakened immune system	Greater than 64 years old	Invasive procedures/medical devices	Disruption in the body's natural flora
Invasive procedures/medical devices	IV drug abusers	Prolonged antibiotic exposure	NGT or feeding tubes	Tracheostomy	Mechanical ventilation
Recent antibiotic use	Men who have sex with men	Invasive procedures/medical devices	Prolonged hospitalization	Mechanical ventilation	Enteral feedings
Weakened immune system	Military personnel	Comorbid conditions	Chemotherapy	Recent antibiotic use	Indwelling devices such as Foley catheters, central venous catheters, and feeding tubes
Comorbid conditions	Prison inmates		Gastrointestinal surgery	Prolonged hospitalization	Patients in hospitals and long-term care facilities
Dialysis devices	People living in shelters		Acid-suppressing medications	Intensive care unit admission	Older adults
Gastrointestinal disorders			Comorbid conditions	Prior hospitalization	Comorbid conditions: Heart disease Diabetes Renal disease
				Residing in long-term care facility	

CRE, Carbapenem-resistant Enterobacteriaceae; MRSA, methicillin-resistant *Staphylococcus aureus*; NGT, nasogastric tube; VRE, vancomycin-resistant *Enterococci*.

*S. aureus* infections can also lead to osteomyelitis and toxic shock syndrome, and ultimately, untreated infections can lead to multisystem organ failure and death.

## Vancomycin-Resistant *Enterococci*

### Epidemiology

*Enterococci* are bacteria that normally live in the gastrointestinal tract and the female genital tract and are also found in the environment in soil, water, and food.

They are the third most common organisms seen in nosocomial infections. Traditionally, *Enterococci* have been considered low-grade pathogens; however, in the 1990s, they surfaced as an increasingly important cause of nosocomial infections. *Enterococci* are **facultatively anaerobic** (organisms that use aerobic metabolism if oxygen is present but can switch to anaerobic metabolism if oxygen is absent) gram-positive cocci.

### Connection Check 21.1

Which are risk factors for MRSA infection? (Select all that apply.)

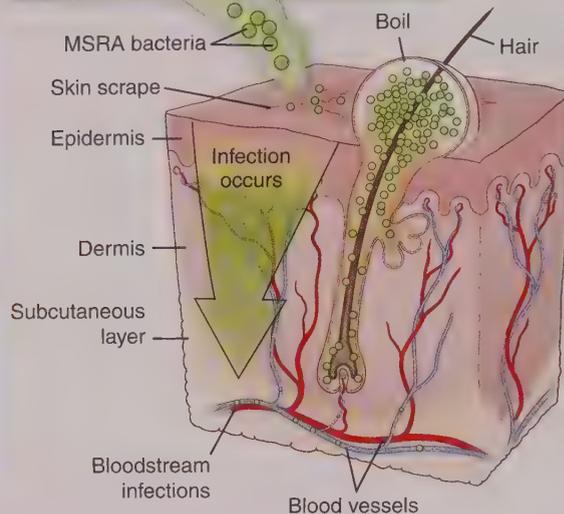

- Surgery
- Urinary catheters
- Antibiotic use
- Feeding tubes
- Recent hospitalization

MSRA can be transmitted easily to the skin and other body areas. It is transmitted by skin contact with a carrier and contact with contaminated items and surfaces.

MSRA bacteria infects the skin by entering minor scrapes or cuts. The infection looks like a boil, a pimple, or a spider bite. The wound is very contagious, filled with the bacteria.

#### Symptoms

- Swelling
- Pus/infection
- Painful
- Infection slow to heal

**FIGURE 21.1** Methicillin-resistant *Staphylococcus aureus* mode of infection; transmitted via skin contact with a carrier and entering through breaks in the skin.

In the late 1980s, the increasing prevalence of MRSA, as well as the discovery of antibiotic-associated diarrhea, resulted in an increased use of vancomycin and the emergence of VRE. Vancomycin-resistant *Enterococci* (VRE) were first reported in 1986 in Europe. The first case of VRE was reported in the United States in 1987. The exact origin of the vancomycin-resistant genes is unknown. Both *Enterococcus faecalis* and *Enterococcus faecium* are vancomycin-resistant species of *Enterococci*. *Enterococcus faecium* exhibits natural resistance to antimicrobial agents, including beta-lactams and aminoglycosides, and more than 95% of the VRE strains isolated in the United States are *E. faecium*. The majority of the remaining isolates are *E. faecalis*, which is a more pathogenic strain.

Since the emergence of VRE in the 1980s, the rates of VRE colonization and infection have risen steadily. In the United States, VRE infections mostly occur in hospitals and are not associated with community acquisition. They are associated with higher morbidity and mortality rates, higher healthcare costs, and prolonged lengths of hospital stay. The prevalence of VRE is highest among patients who are critically ill in ICUs. High VRE rates are also seen in hematology patients and organ-transplant recipients secondary to immunosuppression. Rates of VRE are significantly lower in western regions of the United States than in hospitals located in the eastern region. Larger hospitals or teaching centers also have significantly higher rates of VRE than smaller hospitals with fewer beds, secondary to increased severity of illness. Hand-hygiene compliance also affects the prevalence of VRE. Hospitals with observed hand-hygiene compliance rates at 59% or greater had significantly lower rates of VRE. Antibiotic stewardship is associated with lower rates of VRE. Efforts to reduce the use of vancomycin and cephalosporins have decreased the prevalence of VRE in the United States.

The risk factors for VRE are very similar to those for MRSA. They include prolonged hospital stays, people with weakened immune systems (such as patients in ICUs, transplant patients, and cancer patients, especially hematological malignancies), prolonged exposure to antibiotics (especially exposure to vancomycin and cephalosporins), and invasive procedures and devices. Severe comorbidities also are a risk factor for the acquisition of VRE (see Table 21.1).

#### Pathophysiology

Vancomycin-resistant *Enterococci* are hardy organisms and can remain viable on environmental surfaces for 7 days to 2 months. Patients can remain colonized with VRE for prolonged periods of time ranging from 7 weeks to 3 years. Although VRE are less virulent than MRSA, they can still cause many therapeutic problems because of their resistance to many antibiotics. They are spread by direct patient-to-patient contact or indirectly on the hands of healthcare personnel or on unclean patient care equipment. Colonization with VRE is associated with progression to VRE infection. Accordingly, there is a large emphasis on prevention because VRE outbreaks are very difficult to control owing to the fact that antibiotic use increases the microbial load of VRE and facilitates nosocomial transmission. They are also difficult to control because treatment options may be limited. A polypharmacological approach may be necessary.

#### Clinical Manifestations

*Enterococci* commonly cause urinary tract infections (UTIs), peritonitis (intra-abdominal and pelvic wound infections), and bacteremias; thus, clinical manifestations vary depending on the site of infection. Classic signs of UTI are back pain, pain on urination, the sensation of needing to urinate, and fever. Wound infections typically present as red and hot

and, at times, with purulent drainage. Bacteremias present with signs of sepsis: tachycardia, hypotension, and fever.

### Complications

One of the many complications of VRE is the growing list of resistance to antimicrobial agents as well as the emergence of vancomycin-resistant *S. aureus*. The vancomycin-resistant gene from VRE has been transferred to *S. aureus* isolates. This is quite disturbing because IV vancomycin is the medication of choice in the treatment of MRSA. Additional complications of VRE infections include prolonged hospital stays, prolonged antimicrobial therapy, higher attributable mortality rates, and increased cost of hospitalization. Vancomycin-resistant *Enterococci* bacteremia is associated with higher mortality rates than other *Enterococci* bacteremias because of antibiotic resistance. Another complication of VRE is endocarditis. *Enterococci* are the third most common cause of infective endocarditis. This is a problem because no agent has been approved by the U.S. Food and Drug Administration (FDA) for the treatment of VRE endocarditis.

### Connection Check 21.2

The nurse is screening patients for their risk of developing VRE.

The nurse should consider which patient at greatest risk?

- A. The patient cared for at home
- B. The patient with prolonged antibiotic exposure
- C. The patient in a small community hospital setting
- D. The patient hospitalized for an uncomplicated procedure

## Clostridioides Difficile

### Epidemiology

*Clostridioides difficile* (*C. diff*) was first detected in 1978. Increased use of antibiotics and the increased incidence of *S. aureus* infections are implicated in the emergence of *C. diff*. *Clostridioides difficile* is the most common cause of antibiotic-associated diarrhea in the United States, responsible for 12% of all hospital-acquired infections. The CDC identifies *C. diff* as one of the three most “urgent” threats to the public health system. In the mid-1990s, the incidence of *C. diff* in acute care hospitals was 30 to 40 cases per 100,000 patients. In 2001, the incidence had increased to almost 50 cases per 100,000 patients, and in 2005, it rose to 84 cases per 100,000. U.S. hospitals had a significant increase in *C. diff* infections between 2013 and 2014. Fifty percent or more of hospitalized patients are colonized with *C. diff* without showing symptoms of the disease. The risk of colonization increases steadily each day during hospitalization secondary to the daily risk of exposure to *C. diff* spores in a healthcare setting. The prevalence of *C. diff* in the stool of asymptomatic adults without recent hospitalizations is less than 2%. Ninety-six percent of patients infected with *C. diff* have received antimicrobial therapy

within the previous 3 months, and 85% of patients have received antimicrobials within 28 days prior to the onset of symptoms. The risk of recurrent *C. diff* infection increases in patients who have already had one infection. The rate increases from about 20% after the initial episode to about 40% after the first recurrence and to more than 60% after two or more recurrences. It is not known whether recurrence results from reinfection with a different strain or if it is the persistence of the strain responsible for the initial episode.

The risk factors for *C. diff* infections include the use of antimicrobials, particularly clindamycin, cephalosporins, and fluoroquinolones. Other risk factors include age greater than 64 years old; duration of hospitalization; immunocompromising conditions; chemotherapy; nasogastric (NG) tubes, including feeding tubes; gastrointestinal surgery; severe underlying illness; and the use of acid-suppressing medications such as histamine-2 ( $H_2$ ) blockers and proton-pump inhibitors. The use of antimicrobial agents is a risk factor for *C. diff* infections because antimicrobials suppress the normal bowel flora and create an environment for *C. diff* to flourish. The greater the number of antimicrobials, the greater the number of doses, and the greater the duration of administration, the higher the risk of a *C. diff* infection. The prevalence of *C. diff* infections increases with age. People more than 85 years old are two times more likely to become infected compared with people aged 65 to 84 years old. Ironically, newborns and children in the first year of life have some of the highest rates of colonization but not infection. The use of acid-suppressing medications is a risk factor because these medications prevent the protective effect of stomach acid, which usually kills *C. diff* bacteria. Nasogastric tubes and gastrointestinal surgery increase the risk for *C. diff* infections because NG tubes are usually inserted in patients who have had gastrointestinal surgery who then undergo prolonged periods of no oral caloric intake and who are prescribed prolonged courses of post-operative systemic antibiotics. These patients also suffer from impaired bowel motility, which increases the risk for *C. diff* infections (see Table 21.1).

### Pathophysiology

*Clostridioides difficile* is a spore-forming, gram-positive anaerobic bacillus. *Clostridioides difficile* spores are resistant to many types of disinfectants, heat, and dryness. They also can live for months on surfaces, in skin folds, and on the hands of healthcare workers. They are transmitted through the oral-fecal route. This occurs when a pathogen from feces is introduced into the oral cavity of a host. *Clostridioides difficile* is almost exclusively found in healthcare settings. The hands of healthcare workers are the primary source by which *C. diff* is spread during outbreaks. Environmental contamination is also a means by which the organism is spread secondary to its ability to survive in the environment for long periods of time. It can also be spread by direct person-to-person contact; thus, a patient with *C. diff* must be put on contact-isolation precautions.

Once a person becomes a susceptible host for *C. diff* by having one or more risk factors and has lost the protective normal flora in the colon secondary to antimicrobial therapy or decreased stomach acidity, its growth goes undetected and proliferates. The organism produces two toxins that cause the detrimental effects of the disease. One of the toxins produced is an enterotoxin, or toxin A, and the other toxin produced is a more potent cytotoxin, toxin B. Toxin A activates macrophages and mast cells, which release inflammatory mediators. The inflammatory mediators then cause disruption of the cell-wall junction, which results in increased permeability of the intestinal wall. Toxin B causes an increase in leukocytes and cytokines. Toxin B also causes degradation of the epithelial cells in the colon. Both toxins illicit a colonic inflammatory response that causes massive fluid secretions to move into the colon, resulting in diarrhea. As the *C. diff* infection worsens, purulent and necrotic debris accumulates and forms pseudomembranes (thin tissue layer covering the surface of the epithelium).

### Clinical Manifestations

People who develop *C. diff* infections test positive for *C. diff* toxins in their stool. Although patients may be asymptomatic, the most common clinical manifestation is mild to moderate diarrhea.

### Complications

*Clostridioides difficile* infections increase lengths of stay in healthcare facilities by 2.6 to 4.5 days, and costs nationally per infection range from \$6,000 to \$9,000. Unlike with MRSA and VRE, the attributable mortality of *C. diff* is low. The mortality rate has been reported as 6.9% at 30 days after diagnosis and 16.7% at 1 year. The rising incidence of the disease is causing higher mortality rates related to the increasing virulence of *C. diff* strains and the increasing host vulnerability. Severe *C. diff* infections lead to complications such as:

- Volume depletion (hypovolemia) and hypotension (low blood pressure)
- Renal insufficiency
- Electrolyte imbalances (hypo-/hyperkalemia, hypo-/hyponatremia)
- Hypoalbuminemia (low serum albumin levels)
- Peritonitis (inflammation of the peritoneum)
- Paralytic ileus (intestinal obstruction)
- Toxic megacolon (rapid dilation of the large intestines)
- Fulminant pseudomembranous colitis
- Sepsis
- Death

Complications are more common in patients with a white blood cell (WBC) count of  $15.0 \times 10^3/\text{mm}^3$  or higher, and catastrophic complications occur in patients with a WBC count of  $50.0 \times 10^3/\text{mm}^3$ . Patients who are severely ill may require a subtotal colectomy (part of the colon is removed) with preservation of the rectum or colectomy (removal of the entire colon) for treatments for severe *C. diff*

infections that progress to fulminant pseudomembranous colitis, paralytic ileus, toxic megacolon, or sepsis.

Skin breakdown is also a complication of the disease. Excessive moisture, alkaline pH, colonization with microorganisms, and friction contribute to skin breakdown in patients with *C. diff*. Proper perineal cleansing is imperative. Creams and ointments that serve as a moisture barrier should be applied after cleaning to prevent skin breakdown. Fecal management systems can also be used in stool-incontinent patients to maintain skin integrity.

## Acinetobacter Baumannii

### Epidemiology

*Acinetobacter* has emerged as an important healthcare-associated pathogen. It was first identified in 1911 and was named *Micrococcus calcoaceticus*. In the 1950s, it became known as *Acinetobacter*. *Acinetobacter* is identified as an MDR organism because it is resistant to more than three classes of antibiotics. The CDC reported that the rates of *A. baumannii* resistance against the class of carbapenems increased from 9% in 1995 to 40% in 2004. The emergence of MDR *Acinetobacter* is due to the use of broad-spectrum antimicrobials and the transmission of strains among patients. The incidence of hospital-acquired *Acinetobacter* infections is continually increasing. Studies demonstrate that 17% to 26% of patients colonized with *Acinetobacter* in one or more sites may develop a clinical infection. The prevalence and resistance of *Acinetobacter* are also increasing in the community. Research has shown that increasingly resistant strains of *Acinetobacter* are being introduced into nursing homes and long-term care facilities, which is concerning because there are fewer resources for infection surveillance and prevention in these settings.

*Acinetobacter baumannii* outbreaks have been experienced throughout the world. They rarely occur outside of healthcare settings, and healthy people rarely get serious infections from this organism; however, outbreaks have been reported among U.S. military personnel dating back as far as the Korean War in 1955. The incidence of *Acinetobacter* infections is highest in ICUs. Within the past two decades, *Acinetobacter* has been responsible for increasing infections in ICUs globally. It causes an increase in morbidity and mortality as well as an increased length of stay in that setting. Studies suggest that there is a very low prevalence of *Acinetobacter* in the non-critically ill medical-surgical patient population.

Risk factors for MDR *A. baumannii* infections and colonization include recent surgery, central venous catheters, tracheostomy, mechanical ventilation, enteral feedings, exposure to antimicrobial agents, and underlying severity of illness. Vascular catheters and the respiratory tract have been identified as the most frequent source of *Acinetobacter* bacteremia. Other risk factors include prolonged hospitalization, ICU admissions, prior hospitalizations, and nursing home residence (see Table 21.1).

### Pathophysiology

Multidrug-resistant *Acinetobacter* is a nonfermentative, aerobic, gram-negative coccobacillus that naturally inhabits water, soil, animals, and humans. It grows at varying temperatures and pH environments. More than 25 species within the *Acinetobacter* genus have been described. The most important species of this genus in human pathology is *A. baumannii*. It accounts for nearly 80% of *Acinetobacter* infections. It has been recovered from the skin, throat, and rectum of humans. It also colonizes the respiratory tract. This organism has the ability to survive for weeks to months on both dry and moist surfaces, which promotes transmission via contamination in hospital settings. Since 1974, higher rates of nosocomial *Acinetobacter* infections have been noted in the summer than in other seasons. Infection rates were approximately 50% higher from July to October than other times of the year. This is possibly due to the warmer, more humid air that favors the growth of *Acinetobacter* in its natural environment.

The mechanism by which the *Acinetobacter* species become resistant to antimicrobials is an impermeable outer membrane, antimicrobial-inactivating enzymes, reduced access to bacterial targets, and mutations that change targets or cellular function. This organism is spread by direct or indirect contact. Direct transmission occurs when *Acinetobacter* is transferred from patient to patient without a contaminated intermediate object or person. This usually occurs when an infected *Acinetobacter* patient and noninfected patient share the same room. Indirect transmission occurs when *Acinetobacter* is transferred through a contaminated object or person. The most common mode of transmission is through the unclean hands of healthcare workers who have cared for infected or colonized patients. Transmission commonly occurs through contaminated skin, body fluids, equipment, or the environment. Multidrug-resistant *Acinetobacter* outbreaks are often traced back to common-source contamination. Respiratory care equipment, wound care procedures, humidifiers, and patient care items have been named as sources of contamination in recent outbreaks.

### Clinical Manifestations

*Acinetobacter* can infect or colonize many body sites. Typical sites of colonization and infection are the respiratory tract, blood, pleural fluid, peritoneum, urinary tract, surgical wounds, central nervous system (CNS), skin, and eyes. The most frequent clinical manifestations of *A. baumannii* infections are ventilator-associated pneumonia and bloodstream infections.

### Complications

Many complications are associated with MDR *Acinetobacter* infections. They increase mortality, morbidity, length of hospitalization, and length of ventilator days. Patients with *Acinetobacter* bacteremia have a 5-day excess length of mechanical ventilation compared with patients without *Acinetobacter* infections. These infections also prolong an

ICU stay by 6 days, with the median duration of hospitalization being 18 days.

Although difficult to prove secondary to the patient's severe underlying illnesses, the associated crude mortality rates range from 26% to 68% for MDR *Acinetobacter* infections. Other sources estimate the attributable mortality at 21.8%.

## Carbapenem-Resistant Enterobacteriaceae (CRE)

### Epidemiology

In 2018 the CDC reported about 9,300 CRE healthcare-associated infections in the United States. The CDC also reported that 50% of hospital patients who develop bloodstream infections from CRE bacteria die from them. Due to this, the CDC has labeled CRE an "urgent" concern, the CDC's highest level of concern. Enterobacteriaceae can cause infections in people in both the hospital and community setting. Healthy people are typically not at risk. Risk factors are similar to those for other MDR organism. They include any disorder or treatment that disturbs the body's natural flora. There is an increased frequency in older individuals, patients in hospitals and long-term care facilities, and a slight increase in women. Common comorbidities include diabetes, heart disease, and renal disease. Indwelling devices such as Foley catheters, central venous catheters, and feeding tubes increase risk.

### Pathophysiology

Enterobacteriaceae include *Klebsiella* species and *Escherichia coli* (*E. coli*). These organisms are normally found in the intestines, where they are typically harmless if contained, but if spread outside the intestine, they can cause serious infections, such as UTIs, bloodstream infections, wound infections, and pneumonia. Infections with CRE are usually spread through direct contact with infected or colonized people, particularly contact with wounds or stool. The resistance of CRE to carbapenems is caused by two main mechanisms: (1) the activity of  $\beta$ -lactamase enzymes that results in resistance to  $\beta$ -lactam antibiotics and (2) the production of carbapenemases, enzymes that hydrolyze (break down compounds in a reaction with water) carbapenem antibiotics.

### Clinical Manifestations

Manifestations vary depending on the location of the infection—bloodstream, pneumonia, wound infections, or UTIs. Common manifestations include fever, chills, and signs of sepsis if the infection has not been successfully controlled.

### Complications

Carbapenem-resistant Enterobacteriaceae are strains of bacteria that are resistant to carbapenem, a class of antibiotics typically used as a last resort for treating severe infections when other antibiotics have failed. These organisms

are particularly dangerous and difficult because they have become resistant to nearly all available antibiotics. Because of this, mortality is high, especially in hospitalized patients.

### CASE STUDY: EPISODE 2

Mr. Brown's abdominal wound is cultured. It is determined that he has an MRSA infection. His vital signs are:

BP: 110/66

HR: 110; atrial fibrillation noted on ECG

RR: 18

T: 100.5°F (38°C)

Bedside blood glucose monitoring: 140

Complicated by his history of diabetes and the presence of atrial fibrillation, it is essential that Mr. Brown receives prompt attention for his wound infection to avoid a systemic infection. He is admitted to the hospital for a course of IV vancomycin to be given every 12 hours...

## MANAGEMENT OF MULTIDRUG-RESISTANT ORGANISMS

### Medical Management

#### Diagnosis

Diagnosis of MDR organisms begins with detection. In an effort to contain outbreaks of VRE and MRSA, hospitals have initiated surveillance programs. A recent study suggests that lower rates of MRSA were found in healthcare settings where surveillance for antimicrobial-resistant organisms occurred. There is an MRSA risk assessment tool that is used to identify baseline data on MRSA incidence, prevalence, and transmission. The risk assessment helps to identify patient populations that are likely to be colonized or infected with MRSA. The purpose of the MRSA risk assessment is to prevent transmission through the development of a plan that is based on facility data and conditions. Thus, MRSA patient screening or active surveillance testing (AST) is individualized for each institution. With AST, MRSA cultures are obtained from patient populations identified as being at risk through the MRSA risk assessment. The most commonly cultured site is the anterior nares. Other sites that are typically screened for MRSA are areas of skin breakdown and draining wounds.

Tracking VRE colonization is done through active surveillance in high-risk populations. Some institutions perform VRE screening on any patient admitted to the intensive care environment. The screening is done through the collection of perianal specimens. These specimens are obtained by swabbing back and forth across the perianal region using culture swabs; if stool is present, the culture swab should be immersed in the stool.

There is no current surveillance for *C. diff* or *Acinetobacter*. If a patient is suspected of having *C. diff* secondary to watery diarrhea, a stool sample should be obtained. It is not recommended to test the stool of asymptomatic patients because infection is not likely. Once collected, the stool sample must be promptly sent to the laboratory. The *C. diff* toxins are unstable at room temperature, and false-negative results may occur in samples that are not tested within 2 hours of collection. *Clostridioides difficile* can also be diagnosed through direct visualization of the pseudomembranes via sigmoidoscopy or colonoscopy because it is nearly the exclusive cause of pseudomembranous colitis.

Currently, there are no specific recommendations regarding best practice for surveillance cultures for *Acinetobacter* because of the lack of verified effectiveness of screening cultures. However, in an outbreak situation, screening cultures may be a part of an enhanced intervention when rates are increasing. Suggested body sites for screening cultures include the nose, throat, skin sites such as the axilla or groin, the rectum, open wounds, and endotracheal aspirates. When environmental contaminants are suspected of playing a role in an outbreak, environmental or equipment culturing may be used. At present, there is no active screening for CRE. Infections are typically identified through blood, wound, sputum, or urine cultures.

### Treatment

#### Hand Hygiene

The best treatment of MDR organisms begins with prevention—hand hygiene. The declining rates of some MDR infections have been attributed to the use of alcohol-based hand rubs and improved hand-hygiene programs. It is important to remember that alcohol-based hand rubs are not effective against *C. diff*.

#### Safety Alert *Clostridioides difficile* and Hand Washing

- Alcohol-based hand sanitizers do not kill *C. diff* but just displace the spores.
- Healthcare workers, patients, and visitors must use soap and water and mechanical hand washing to perform hand hygiene when coming in contact with a patient who has *C. diff*.

### Isolation

Patients in healthcare settings who are either colonized or infected with MDR organisms are placed on contact-isolation precautions (see Safety Alert: Isolation Precautions) to help reduce patient-to-patient spread of the organism within the hospital. Contact-isolation precautions include wearing gowns and gloves on entry to a patient's room, removing both the gown and gloves just prior to exiting, and performing proper hand hygiene before exiting. Past studies have shown that organisms remained on healthcare workers'

isolation gowns, gloves, and hands before hand washing after caring for an infected or colonized patient. As noted previously, proper hand hygiene is essential with all MDR organisms. Patients colonized or infected with MDR organisms are placed in private rooms when available or placed in a room with other patients colonized or infected with the same organism. Contact-isolation precautions are typically continued throughout the duration of the hospital stay or, as in the case of *C. diff*, until the diarrhea has stopped. Discontinuation of contact precautions for MRSA patients may occur when clearance of the organism has been documented with three or more surveillance tests. Retesting patients to document clearance is commonly done 3 to 4 months after the last positive test result. However, some institutions consider MRSA-colonized patients to be colonized indefinitely.

During large MDR *Acinetobacter* outbreaks, patients are usually placed in a specific area or unit. Sometimes, the closure of an entire ICU is warranted to halt transmission. Dedicated nursing and respiratory staff, as well as dedicated equipment, is used to prevent further transmission.

### Safety Isolation Precautions Alert

- Isolation precautions **MUST** be used for patients with MRSA, VRE, *C. diff*, *Acinetobacter*, and CRE.
- Hand hygiene **MUST** be performed before healthcare workers put on isolation gowns and gloves.
- Isolation gowns **MUST** be secured at the neck and waist to effectively prevent bacteria transmission.
- Isolation gowns and gloves **MUST** be removed before the healthcare worker leaves the isolation patient's room.
- Hand hygiene **MUST** be performed before the healthcare worker leaves the isolation patient's room.

## Medications

### Methicillin-Resistant *Staphylococcus Aureus*

The most commonly used medication for the treatment of infections caused by MRSA is vancomycin (Vancocin), administered either IV or orally. The **trough level** (blood sample drawn after a dose is given but immediately before the next dose) should be monitored at least weekly to avoid toxic doses and maintain therapeutic levels. If trough levels are too high, vancomycin can cause nephrotoxicity as well as ototoxicity. Weekly blood urea nitrogen (BUN) and serum creatinine tests are recommended to assess kidney function because of the nephrotoxicity. Linezolid (Zyvox) given IV or orally is another antibiotic commonly used to treat skin and soft tissue infections caused by MRSA. Linezolid is a synthetic antibiotic of the oxazolidinone class and is **bacteriostatic** (stops organism reproduction) against *Enterococci* and *Staphylococci*. Recent studies have demonstrated that linezolid is equally as effective as vancomycin (Vancocin) for patients with skin and soft tissue infections.

Linezolid is given for 7 to 21 days depending on the infection. If it is given for more than 10 days, the patient should be monitored through evaluation of a complete blood count for myelosuppression, including anemia, leukopenia, pancytopenia, and thrombocytopenia. Linezolid may also cause diarrhea, nausea, and vomiting. Serious CNS reactions can occur when Linezolid is used together with serotonergic psychiatric medications. Patients taking Linezolid should avoid foods with high tyramine content (such as aged cheeses, dried/processed meats, alcohol, soy sauce) and should report any vision changes to their healthcare provider.

IV daptomycin (Cubicin) and IV tigecycline (Tygacil) are used for the treatment of complicated skin and soft tissue infections caused by MRSA. Daptomycin is a cyclic lipopeptide that has an antimicrobial spectrum similar to that of linezolid and exhibits **bactericidal** activity (kills the organism) against gram-positive organisms. Patients receiving daptomycin should be monitored for muscle pain and weakness and should have weekly creatine phosphokinase (CPK) levels drawn to assess for rhabdomyolysis (the breakdown of muscle tissue—releasing proteins into the blood). Patients with renal insufficiency need to have more frequent CPK level monitoring. Tigecycline is in the glycylcycline antibiotic class that has extended-spectrum activity against gram-positive, gram-negative, and anaerobic microorganisms. Tigecycline may cause diarrhea, nausea, and vomiting. It also decreases the effectiveness of oral contraceptives, so female patients should be instructed to use an alternative method of contraception while receiving this therapy.

Clindamycin (Cleocin) given IV or orally is one of the more commonly used antibiotics used to treat CAMRSA infections. Clindamycin has activity against aerobic and anaerobic gram-positive organisms including MRSA. The most common side effects of Clindamycin are diarrhea, and it can cause *C. diff*.

Sulfamethoxazole-trimethoprim (Bactrim) given IV or orally is also used to treat CAMRSA skin and soft tissue infections. Dosing must be adjusted for patients with impaired renal function. The most common side effects are gastrointestinal (nausea, vomiting, loss of appetite). Sulfamethoxazole-trimethoprim can cause sun sensitivity, so instruct patients to use sunscreen when going out into the sun. Patients should also report signs of jaundice, somnolence, and confusion to their healthcare provider because sulfamethoxazole-trimethoprim can cause fulminant hepatic necrosis. It is also important to instruct patients to stay hydrated to prevent the formation of renal stones while taking this medication.

Because MRSA has started to become resistant to many antibiotics, antibiotic stewardship must be practiced when prescribing medications. The CDC suggests that minor to moderate skin infections be treated with incision and drainage of abscesses without the use of antibiotics.

Currently, there are no recommendations to treat MRSA colonization; however, some institutions provide decolonization therapy. Decolonization therapy is the administration

of local antimicrobial or antiseptic agents alone or in conjunction with antimicrobial therapy (Table 21.2). A typical therapy used to decolonize patients is 2% mupirocin (Bactroban) ointment administered intranasally; mupirocin ointment is often used along with chlorhexidine bathing to complete the decolonization process. Mupirocin ointment should not be used with other intranasal products, and contact with mupirocin ointment should be avoided with open wounds, burns, and eyes. It can also cause headaches, pharyngitis, and rhinitis.

#### Vancomycin-Resistant Enterococci

Vancomycin-resistant *Enterococci* infections are often difficult to treat and may require multiple antibiotics for treatment because most VRE isolates are resistant to penicillin and ampicillin. Susceptibility testing is recommended to verify the activity of the antimicrobial agent being used. Quinupristin-dalfopristin (Synercid) given via IV was the first antimicrobial agent available to treat VRE infections caused by *E. faecium*. Quinupristin-dalfopristin is a streptogramin and targets bacterial ribosomes, thereby inhibiting protein synthesis. This medication can be caustic to veins; thus, peripherally inserted central catheter (PICC) placement is recommended if long-term use is required. Dosages may need to be adjusted in patients with liver insufficiency or cirrhosis. The length of therapy depends on the type of infection. Common side effects of quinupristin-dalfopristin are joint pain, mild diarrhea, nausea and vomiting, and muscle pain.

Linezolid, daptomycin, and tigecycline are also used to treat VRE infections. Linezolid has activity against both *E. faecium* and non-*E. faecium* species. It is the only oral agent approved by the FDA for the treatment of infections caused by VRE. Daptomycin has been reported to be effective against more than 99.5% of VRE isolates. Tigecycline has in vitro activity against VRE, but clinical data are lacking for the treatment of VRE infections. Treatment for VRE colonization is not recommended because there is currently no antimicrobial agent available to eradicate VRE colonization. See Table 21.2 for a list of antibiotics used in the treatment of VRE.

#### *Clostridioides Difficile*

Before treatment for *C. diff* can begin, the suspected causative antibiotic must be stopped. In about 20% of patients, *C. diff* infection will resolve within 2 to 3 days of discontinuing the antibiotic to which the patient was previously exposed. Additionally, the use of antiperistaltic agents should be avoided because they may delay clearance of toxins from the colon and exacerbate toxin-induced colonic injury or precipitate ileus (an intestinal obstruction that results in the failure of intestinal contents to pass through) and toxic megacolon (a life-threatening complication of inflammatory bowel disease that causes rapid dilation of the large intestines, which results in septic shock).

Oral vancomycin is considered the first-line agent for the treatment of an initial episode of severe *C. diff* because

**Table 21.2 Antibiotic Treatments for Infections With Multidrug-Resistant (MDR) Organisms**

MRSA	VRE	<i>Clostridioides Difficile</i>	<i>Acinetobacter</i>	CRE
Vancomycin	Quinupristin-dalfopristin	Vancomycin	Ampicillin-sulbactam	Ceftazidime-avibactam
Linezolid	Linezolid	Fidaxomicin	Imipenem/Cilastatin	Meropenem-vaborbactam
Daptomycin	Daptomycin	Metronidazole	Meropenem	Polymyxin-based, combination such as polymyxin (colistin or polymyxin B) and meropenem
Tigecycline	Tigecycline		Tobramycin	Plazomicin
Clindamycin			Amikacin	
Sulfamethoxazole-trimethoprim			Tigecycline	
			Polymyxin B	
			Polymyxin E	
			Colistin	
			Minocycline	
			Doxycycline	

CRE, Carbapenem-resistant Enterobacteriaceae; MRSA, methicillin-resistant *Staphylococcus aureus*; VRE, vancomycin-resistant *Enterococci*.

it causes prompt symptom resolution and there is a significantly lower risk of treatment failure. It is effective because it is not absorbed in the intestines and kills the bacteria at the site of the infection in the colon. When oral vancomycin is not appropriate for the treatment of severe *C. diff* because of a coexisting ileus or toxic megacolon, IV metronidazole is used.

Fidaxomicin (Dificid) is also used to treat *C. diff* infections. It is a bactericidal agent against *C. diff* that inhibits RNA synthesis by RNA polymerases. Common side effects include vomiting and other gastrointestinal disorders. This medication is reserved for patients who have recurrent infections and probable vancomycin resistance. Oral metronidazole, once the treatment of choice, is an alternative if vancomycin or fidaxomicin is not available.

Recurrence of *C. diff* infections is seen in 20% to 30% of cases. Recurrence typically occurs 4 weeks after therapy has been completed. The recurrence rate for patients treated with metronidazole is 20.2%, and the recurrence rate for patients treated with vancomycin is 18.4%. Subsequent occurrences should be treated with vancomycin using a tapered regimen. In 2016, the FDA approved bezlotoxumab (Zinplava). It is indicated in the reduction of the recurrence of *C. diff* in patients who are receiving antibacterial medication treatment for *C. diff* infection and are at high risk for *C. diff* recurrence. Bezlotoxumab is a monoclonal antibody that binds to *C. diff* toxin B and neutralizes its effects. It is given as a single dose of 10 mg/kg and is administered by IV intermittent infusion over 60 minutes. The half-life is 10 days. Bezlotoxumab does not replace antibacterial treatment. See Table 21.2 for a list of antibiotics used in the treatment of *C. diff*.

**Probiotics** (live bacteria and yeasts) are another treatment that is used supplementally. Probiotics have effectively reduced the incidence of simple antibiotic-associated diarrhea and are sometimes used to treat recurrent *C. diff*; however, their efficacy is inconsistent. Another potential treatment option for recurrent *C. diff* is immunoglobulin therapy, but there is limited evidence supporting the efficacy of its use. Because of the inadequacies of current therapies as reflected by the high recurrence rate, the search is on for new antibiotics that inhibit vegetative cells of *C. diff* while preserving colonic flora during treatment.

Emerging as a treatment for recurring *C. diff* is fecal microbiota transplantation (FMT). The success rate of FMT in *C. diff* symptom resolution has been reported to be 81% to 94% in patients with recurrent disease. Fecal microbiota transplantation may restore the gut microbiota to create an environment resistant to *C. diff*. The treatment of FMT is indicated for patients who have had three or more occurrences of *C. diff* or who have had unsuccessful treatment with 6 to 8 weeks of vancomycin. Relatives who share similar microbiota are thought to be the most effective donors. The donor is screened for ova and parasites; HIV; and hepatitis A, B, and C. A stool culture and sensitivity

may also be done. The fecal sample from the donor is combined with normal saline or water. Methods of administering the sample to the patient are nasogastric (25–50 mL) or colonoscopic (250–500 mL). Although frozen FMT oral capsules appear to be a viable delivery method, their clinical availability is limited, and their cost-effectiveness is still to be determined.

### Connection Check 21.3

The nurse is reviewing orders for a newly admitted patient with *C. diff*. The nurse will follow up with the provider about which order?

- A. PO Flagyl
- B. Probiotics
- C. Encouraging fluid intake
- D. Imodium

### *Acinetobacter*

Many different antimicrobial classes are used to treat MDR *Acinetobacter*; however, before treatment begins, susceptibility testing must occur because antibiotic resistance has increased over the last decade. Beta-lactamase inhibitors, especially sulbactams, possess the greatest intrinsic bactericidal activity against *A. baumannii*. Sulbactams, which in the United States are combined with ampicillin-sulbactam (Unasyn) given intravenously or intramuscularly, can be used for mild to severe cases of *A. baumannii* infections; however, the cure rate is only 67%. Better patient outcomes are associated with lower severity of illness. Ampicillin-sulbactam commonly causes diarrhea or a rash. It also decreases the effectiveness of oral contraceptives, so female patients should be instructed to use another form of contraception. Carbapenems given intravenously, such as imipenem/cilastatin (Primaxin IM) and meropenem (Merrem I.V.), are some of the most important therapeutic options for serious infections caused by MDR *Acinetobacter*. They have excellent bactericidal activity; however, the increasing carbapenem resistance is creating therapeutic challenges. It still remains the treatment of choice if the isolates retain susceptibility. Dosages need to be adjusted for patients with renal impairment. Carbapenems commonly cause nausea and headaches. They are also implicated in the development of Stevens-Johnson syndrome, a very rare toxic epidermal necrosis that causes the epidermis to separate from the dermis, typically because of a severe medication sensitivity.

Aminoglycoside agents such as IV tobramycin and IV amikacin are options for MDR isolates that retain susceptibility. Tobramycin maintains the highest susceptibility rates, and amikacin susceptibility has been reported at 53%. Tobramycin **peak levels** (medication levels obtained 30 minutes after administration) and trough levels should

be obtained every 3 to 4 days to maintain a therapeutic dose. Amikacin may cause nephrotoxicity and ototoxicity; thus, peak and trough levels should also be monitored to maintain a therapeutic dose. Tigecycline, a glycycline agent, also has bacteriostatic activity against MDR *Acinetobacter*. However, the development of resistance to tigecycline has been reported recently.

Polymyxin agents are the most active agents in vitro against MDR *Acinetobacter*. They are cationic detergents that disrupt bacterial cell membranes, causing leakage of the cell contents, thus increasing permeability and leading to cell death. Polymyxin agents include Polymyxin B and Polymyxin E, which is also known as colistimethate sodium (Colistin). This class of medication has demonstrated its effectiveness as a treatment for highly drug-resistant gram-negative bacteria. The efficacy ranges from approximately 55% to more than 80%. Cure or improvement rates with colistin are 57% to 77% among severely ill patients. Resistance rates of MDR *Acinetobacter* for polymyxin agents are currently low. Polymyxin agents can be administered orally, intravenously, ophthalmically, intrathecally, or by inhalation. In the past, polymyxin agents could be administered intramuscularly, but the route was discontinued when Aminoglycosides became available. Polymyxins are poorly absorbed in the gastrointestinal tract, and gastrointestinal side effects are rarely reported with oral agents. Renal dose adjustment is required for patients with renal impairment.

Tetracycline agents, such as minocycline (Dynacin) and doxycycline (Doryx), are also used to treat MDR *Acinetobacter* infections. These agents can be given both intravenously and orally. Dosage and length of therapy vary depending on the type and severity of the infection. These agents decrease the effectiveness of oral contraceptives, so female patients should be instructed to use an alternative form of contraception. Tetracyclines also cause sun sensitivity, and patients should be instructed to use sunscreen when out in the sun for prolonged periods of time. It is recommended that tetracycline agents be taken, if prescribed orally, 1 hour before meals or 2 hours after meals to help with absorption. Adequate fluid hydration is also recommended to prevent esophageal irritation or ulcer. They may also cause gastrointestinal disturbances. Complete blood count (CBC) and liver and kidney function tests should be monitored if the patient is receiving chronic tetracycline therapy. See Table 21.2 for a list of medications used to treat *Acinetobacter* infections.

### Connection Check 21.4

The nurse is screening patients for their risk of developing *Acinetobacter* infections. The nurse should consider which patient(s) at greatest risk? (Select all that apply.)

- A. The patient on mechanical ventilation
- B. The patient with a high-acuity illness
- C. The patient recovering in the ICU overnight after surgery
- D. The patient with prolonged antibiotic exposure
- E. The patient with a wound infection

### Carbapenem-Resistant Enterobacteriaceae

Treatment options are limited because no one antibiotic regimen has been shown to be better than another. As with other infections, treatment is based on the susceptibility of the organism. What follows is an overview because treatment is tailored to meet individual needs based on type of infection, comorbidities, and possible medication interactions. For serious infections caused by *Klebsiella*, ceftazidime-avibactam and meropenem-vaborbactam are acceptable options. These medications are given intravenously. They both work through the inhibition of bacterial cell-wall synthesis. They have reliable dosing and greater susceptibility, but data are limited. Options when neither of these is used are polymyxin-based combinations such as polymyxin (colistin or polymyxin B) and meropenem. These medications are also given intravenously and work through the disruption of the organism's outer cell membrane. These medications are associated with renal toxicity and neurotoxicity. Renal function should be carefully monitored, and the patient should be assessed for signs of neurological dysfunction. Some signs are mild, such as dizziness, diplopia, and weakness, but some adverse effects can be very serious, such as ataxia, dysphagia, dysphonia, psychosis, coma, and neuromuscular blockade leading to apnea. Polymyxin-based combinations and plazomicin are also options for other types of CRE. Plazomicin is given intravenously. It is associated with nephrotoxicity and ototoxicity, including hearing loss, tinnitus, and vertigo. Neuromuscular blockade is also associated with plazomicin.

### Nursing Management

#### Assessment and Analysis

The clinical manifestations seen with MDR-organism infections are consistent with typical signs of infection: fever, tachycardia, tachypnea, and hypovolemia. Diarrhea is the prominent manifestation of *C. diff*, and MRSA wound infections can be red and warm with purulent drainage.

#### Nursing Diagnoses

- **Risk for deficient fluid volume** related to *C. diff* infection
- **Ineffective airway clearance** related to MDR pneumonia
- **Alteration in comfort** related to diarrhea and abdominal pain
- **Risk for perineal skin breakdown** related to frequent stools
- **Impaired tissue integrity** related to MDR wound infection
- **Impaired urinary elimination:** frequency related to urinary tract infection secondary to an MDR organism
- **Acute pain** related to wound infection secondary to an MDR organism

## Nursing Interventions

### ■ Assessments

- Vital signs  
*Increased body temperature is an immune response to an infection. A person's body temperature rises to try to kill the bacteria or virus that is causing the infection. Increased heart rate can occur due to fever and metabolic rate increases or hypovolemia. Tachypnea can occur secondary to pneumonia from infection with an MDR organism. Tachypnea is also caused secondary to a fever, which increases the metabolic rate, which then increases the work of breathing. Low blood pressure may indicate vasodilation due to systemic infection and hypovolemia. Hypovolemia can also occur secondary to fluid loss as a result of C. diff diarrhea.*
- Oxygen saturation  
*Monitor the patient's oxygen saturation. Decreased oxygen saturation can be a symptom of pneumonia caused by an MDR organism.*
- Pain  
*Pain is the fifth vital sign. Monitor patients for increased pain. Increased pain can be a sign of infection caused by an MDR organism; pain may also result from a fever.*
- Skin turgor and mucous membranes  
*Decreased skin turgor and dry mucous membranes can result from dehydration secondary to a C. diff infection.*
- Urine output  
*Decreased urine output is a sign of dehydration and can occur secondary to C. diff diarrhea or may indicate the presence of a systemic infection with an MDR organism. It can also occur as an adverse side effect of antibiotics used to treat the infection.*
- Wound or surgical sites  
*An infected wound or surgical site caused by an MDR organism may be red, swollen, painful, and warm to the touch and may have purulent drainage.*
- Bowel movement frequency and consistency  
*Increased bowel movement frequency can result in dehydration. When a person has a C. diff infection, the bacteria proliferate and cause the release of toxins, resulting in an inflammatory response in the colon, which causes fluid to be secreted into the colon, resulting in diarrhea.*
- Skin integrity  
*Monitor skin integrity to assess for skin breakdown or incontinence-associated dermatitis (IAD) secondary to C. diff diarrhea.*
- Laboratory tests
  - White blood cell (WBC) count  
*An increased WBC count is seen as part of the immune response; a large increase in WBCs may occur in C. diff infections.*
  - Serum creatinine level  
*Increased creatinine levels can occur when a patient is dehydrated or has an adverse reaction to antibiotic treatment, signaling decreased renal function.*
  - Electrolyte and albumin levels  
*Electrolyte and albumin levels may be decreased or increased secondary to dehydration from a C. diff infection or any MDR-organism infection.*

### ■ Actions

- Hand hygiene  
*To prevent the spread of MDR organisms: (1) alcohol-based cleansers are effective against nearly all MDR organisms, except C. diff; (2) physical hand washing with soap and water is necessary to remove C. diff.*
- Place the patient on contact-isolation precautions.  
*To prevent the spread of MDR organisms*
- Administer medications as ordered:
  - Administer antibiotics.  
*To treat infection of an MDR organism*
  - Administer fever reducers.  
*To decrease fever and complications associated with increased metabolic rate; also increases comfort*
  - Administer pain medications.  
*To decrease pain from wound or surgical-site infection*
- Administer IV fluids or encourage the patient to drink fluids.  
*To rehydrate from loss of fluid secondary to diarrhea from C. diff infection or from infections with MDR organisms*
- Administer supplemental oxygen.  
*To increase oxygen saturation secondary to MDR pneumonia*
- Administer chest physiotherapy.  
*To mobilize secretions in patients with MDR pneumonia and to increase oxygen saturation*
- Encourage early mobilization.  
*To decrease the risk of atelectasis secondary to MDR pneumonia and promote overall patient conditioning*
- Stop administration of causative antimicrobial agent with a C. diff infection.  
*To stop/decrease C. diff-associated diarrhea*
- Perform wound care as ordered.  
*To treat wound or surgical-site infection and promote wound healing*
- Cleanse perineum and apply moisture barriers.  
*To prevent skin breakdown or IAD secondary to C. diff-associated diarrhea*
- Use fecal diversion or containment systems in the stool-incontinent patient.  
*To prevent skin breakdown and increase comfort in C. diff patients*
- Encourage family visits and the use of the telephone and television.  
*To prevent depression in a patient in isolation with an MDR-organism infection*

### ■ Teaching

- Contact-isolation precautions and hand washing (see Evidence-Based Practice)  
*Teach patient and visitors the importance of wearing gowns and gloves when entering the room and removing the gowns and gloves when exiting the patient's room; also teach them the importance of performing hand hygiene after removing the gown and gloves.*
- Take antibiotics as prescribed.  
*Antibiotics should be taken as prescribed, and the patient should finish the course of antibiotics to prevent the reoccurrence of MDR infections.*

- Clinical manifestations of infection  
*It is important that the patient and family are able to recognize the signs and symptoms of infection.*
- Sun protection  
*Be aware of antibiotics such as tetracyclines that create sun sensitivities. Avoid prolonged sun exposure, wear sunscreen and appropriate covering clothing*

## Evidence-Based Practice

### BUGG Study

A clinical trial was conducted to investigate the benefits of universal gowning and gloving (BUGG) in reducing the acquisition of methicillin-resistant *Staphylococcus aureus* (MRSA). The BUGG Study was sponsored by the Yale New Haven Health System Center for Healthcare Solutions in collaboration with the Agency for Healthcare Research and Quality (AHRQ), Centers for Disease Control and Prevention, University of Maryland, University of Iowa, and The Joint Commission. This observational study tested if doctors, nurses, and others wearing gloves and a gown while caring for all patients in an intensive care unit (ICU) would:

- Decrease the chance of patients getting an infection while in the hospital
- Decrease the chance of patients picking up bacteria as a result of being in the hospital
- Decrease the time a patient spends in the ICU or in the hospital
- Decrease the frequency of adverse events

A study by Harris et al. examined the results of that study. They found the following percentage decreases in MRSA acquisition:

- A reduction of 44% was due to universal gown and glove use.
- A reduction of 38% was due to improved hand hygiene.
- A reduction of 14.5% was due to decreased contact between healthcare workers and patients.

For more information on this clinical trial, go to the Web site [ClinicalTrials.gov](http://ClinicalTrials.gov); the ClinicalTrials.gov Identifier is NCT01318213.

U.S. National Institutes of Health. (2015). *Benefits of universal glove and gowning* (BUGG). Retrieved from <http://clinicaltrials.gov/ct2/show/NCT01318213>

Harris, A. D., Morgan, D. J., Pineles, L., Perencevich, E. N., & Barnes, S. L. (2017). Deconstructing the relative benefits of a universal glove and gown intervention on MRSA acquisition. *Journal of Hospital Infection*, 96(1), 49–53.

## Evaluating Care Outcomes

Infections due to MDR organisms can usually be successfully treated with antimicrobial therapy. Once the infection has been treated, the patient's vital signs and laboratory values should return to within normal limits. Patients should know the importance of finishing their antibiotic regimen to prevent the reoccurrence of infection. Patients and families should also know the clinical manifestations of a reoccurring infection in order to know when to seek health-care advice.

## Connection Check 21.5

What is the priority intervention to prevent the spread of MDR organisms?

- Hand washing
- Diagnostic cultures
- Isolation precautions
- Antibiotic administration

## Making Connections

### CASE STUDY: WRAP-UP

Upon his admission to the hospital, Mr. Brown's abdominal sutures are removed. The wound is irrigated; a sterile dressing is applied. The wound is left unsutured to facilitate drainage and allow for wound care. After 2 days and four doses of 1 g of IV vancomycin administration, Mr. Brown's wound infection is clearing. He remains in the hospital for 1 more day and two more doses of IV vancomycin. A vital sign check reveals:

BP: 130/80

HR: 80; atrial fibrillation still present

RR: 18

T: 98°F (37°C)

Bedside glucose monitoring: 98

At discharge, Mr. Brown receives instructions that include how to monitor his wound and change the dressing. Follow-up with the nursing home staff is arranged to help with dressing-change management. A follow-up appointment with his provider is set up for 2 weeks post-discharge. Mr. Brown is counseled to report any changes in the wound to his health-care provider.

### Case Study Questions

- The nurse understands that Mr. Brown is at increased risk for a MRSA infection because of which factor(s)? (Select all that apply.)
  - His recent hospitalization
  - His history of atrial fibrillation
  - His recent surgical procedure
  - His residence in a long-term care facility
  - His current use of the medication Coumadin
- The nurse monitors for which clinical manifestations of MRSA in Mr. Brown's wound infection?
  - Hyperglycemia
  - Tachycardia
  - Tachypnea
  - Red, edematous, draining wound
- The nurse should intervene immediately if Mr. Brown is noted to have which of the following symptoms?
  - Depression
  - Oliguria
  - Decreased appetite
  - Pain at the incision site
- Which statement by Mr. Brown indicates the need for further teaching?
  - "I need to be careful about the antibiotics I take."
  - "I'll stop taking my antibiotics when I'm feeling better."
  - "I never want to go to the hospital again."
  - "I'll call my doctor if my blood sugar goes up."
- Important transitional care plans for Mr. Brown include which of the following? (Select all that apply.)
  - Follow-up with a home-care nurse
  - Follow-up with a physical therapist
  - Follow-up with his healthcare provider
  - Follow-up with the emergency department
  - Follow-up with a nutritionist

Proper hand hygiene is essential when caring for all patients and is especially vital for patients with MDR organisms. Alcohol-based hand rubs can be used for hand hygiene in patients with MRSA, VRE, and *Acinetobacter*, as well as hand washing with soap and water. However, hand washing with soap and water must be used to disinfect hands after contact with a patient with *C. diff*. Patients who are colonized or infected with MDR organisms are placed on contact-isolation precautions. Contact-isolation precautions are used to prevent the spread of the organisms in the healthcare setting. If private rooms are not available for patients with MDR organisms, they should be roomed with patients who are either colonized or infected with the same organism.

Methicillin-resistant *S. aureus* is the most well-known MDR organism, and it is the only MDR organism discussed in this chapter that is readily seen in the community as well as the healthcare setting. The most common MRSA infections seen in the community are skin and soft tissue infections. Vancomycin-resistant *Enterococci*, *C. diff*, and *Acinetobacter* infections are not seen in the community and are almost exclusively found in healthcare settings, particularly in the ICUs. Of the MDR organisms discussed in this chapter, *A. baumannii* is transmitted the most easily and is the most virulent. Carbapenem-resistant Enterobacteriaceae is an emerging "urgent" crisis because it is so difficult to treat.

All of the MDR organisms discussed in this chapter can both colonize and cause active infections in patients. Methicillin-resistant *S. aureus* causes common bacterial infections, including pneumonia, skin and soft tissue infections, surgical-site infections, and bacteremias. Vancomycin-resistant *Enterococci* commonly cause UTIs, peritonitis, and bacteremias. *Clostridioides difficile* is the cause of most antibiotic-associated diarrhea and can also cause pseudomembranous colitis, toxic megacolon, perforation of the colon, and sepsis. *Acinetobacter* causes bacteremias, pneumonia, meningitis, UTIs, and wound infections. Additionally, *Acinetobacter* is typically found in the more acute care setting or ICUs with intubated patients because of their increased susceptibility.

The risk factors associated with all of these MDR organisms are very similar. Hospitalizations, antibiotic use, invasive procedures, and residing in a long-term care facility are all common risk factors among MRSA, VRE, *C. diff*, *Acinetobacter*, and CRE. Similarly, they also have common complications. These MDR organisms all cause increased morbidity, mortality, and length of hospital stay. The use of proton-pump inhibitors or H<sub>2</sub> blockers is an additional risk factor for *C. diff* because they decrease the stomach's acid concentration, which helps destroy the organism.

Each MDR organism discussed in this chapter is extremely difficult to treat and has a set of specific antibiotic

## CHAPTER SUMMARY

Methicillin-resistant *S. aureus*, VRE, *C. diff*, *Acinetobacter*, and carbapenem-resistant Enterobacteriaceae are MDR organisms that plague healthcare settings because of their resistance to antimicrobial therapies. All of these organisms are easily spread within the healthcare setting by direct or indirect contact. Unclean hands of healthcare workers are one of the major causes of transmission of these organisms.

therapies. Antibiotic stewardship must be practiced when prescribing antimicrobial therapies for MDR organisms to prevent increased antibiotic resistance and the emergence of new MDR organisms. Additionally, once a patient has been diagnosed with *C. diff*, antiperistaltic agents should be avoided because they may delay the clearance of toxins from the colon.

Nursing implications when caring for patients with MDR-organism infections include impeccable hand hygiene, maintenance of isolation, administration of antibiotics as ordered, continual monitoring for resolution of infection or signs of systemic infection, and patient teaching. The single most important implication for nursing and the whole healthcare team is hand hygiene.

# Chapter 22

## Coordinating Care for Patients With HIV

Thomasine Guberski

### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Describing the etiology of human immunodeficiency virus (HIV) disorders
2. Discussing the epidemiology of HIV
3. Comparing and contrasting clinical presentations of the disease spectrum of HIV
4. Describing diagnostic results used to confirm the diagnosis of HIV

### Finding Connections

#### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Margo Castillo is a 45-year-old woman who presents to the emergency department with mild difficulty breathing for the past 2 days when walking a city block. She has had increasing fatigue for the past week. Prior to this, she had been relatively well except for several outbreaks of genital herpes in the past 6 months. The last outbreak was 2 months ago. She is currently on no medications. Her husband died of a blood infection 4 years ago...

### ESSENTIAL TERMS

Acquired immune deficiency syndrome (AIDS)  
AIDS-defining condition  
Antiretroviral therapy (ART)  
CD4+ lymphocyte count  
Human immunodeficiency virus (HIV)  
Immune reconstruction  
inflammatory syndrome (IRIS)  
Opportunistic infection (OI)  
*Pneumocystis carinii* pneumonia (PCP)  
Seroconversion  
Serodiscordant  
Viral load  
Viral set point

### OVERVIEW OF THE HIV/AIDS CONTINUUM

Like many chronic illnesses, HIV disease, caused by the **human immunodeficiency virus (HIV)**, is comprised of several stages, ranging from acute infection to death. In an HIV-infected individual who does not receive treatment, the length of time from infection to death is approximately 12 years. In resource-limited countries, the time from infection to death is approximately 5 years. Malnutrition, tuberculosis (TB), and malaria are comorbidities that shorten the time the untreated patient survives.

June 2016 marked the 35th anniversary of the first reported cases of **acquired immune deficiency syndrome (AIDS)** in the United States. In June 1981, the Centers for Disease Control and Prevention (CDC) reported confirmed cases of *Pneumocystis carinii* pneumonia (PCP) in five

previously healthy gay men. Because this disease occurs only in individuals with severely compromised immune systems, their new illness was called *acquired immune deficiency syndrome*. In 1985, when the antibody test for the HIV virus first became available, positive antibody tests confirming the presence of HIV antibodies were found in individuals who did not have signs or symptoms of AIDS. As a result of these findings, in 1986 the CDC published a disease classification system for individuals with a positive HIV test. Individuals were categorized into one of four mutually exclusive hierarchical groups on the basis of the presence or absence of signs or symptoms commonly associated with AIDS. This was the first recognition of the continuum of HIV/AIDS as a disease that progresses through stages, from acute HIV infection, asymptomatic HIV infection, and symptomatic HIV infection to the most advanced stage, AIDS.

Currently, anyone infected with HIV, regardless of the stage of his or her disease, is considered to have an HIV infection. In adults, the illness is then categorized into one of three different stages on the basis of the individual's CD4+ lymphocyte count, CD4+ percentage of total lymphocytes, or the presence or absence of certain infections commonly found in individuals with compromised immune systems, an AIDS-defining condition. If the person has an AIDS-defining condition, that person is considered to have AIDS regardless of CD4+ count (Table 22.1). Criteria for the stages of HIV infection in infants and children under the age of 13 are different from those for adults. Disease progression is from less severe to more severe. Once individuals are classified in a more severe stage, they cannot be reclassified into a less severe surveillance stage.

Outside the United States, a classification of HIV infection in adults and children developed by the World Health Organization (WHO) is used. The stages of HIV infection and criteria for classification are slightly different from those of the CDC classification. In addition, the WHO has a classification system for HIV based on response to treatment that allows individuals to move from severe to less severe stages.

According to the Joint United Nations Program on HIV/AIDS (UNAIDS), in 2010 approximately 33.3 million adults and children were living with HIV. Unlike many other infectious diseases, a vaccine to prevent the illness is

not available. The constant change in the structure of the virus makes the development of a vaccine challenging. Until a vaccine is available, eliminating risky behaviors such as unprotected sex and IV drug use provides the major intervention to reduce transmission.

## HUMAN IMMUNODEFICIENCY VIRUS (HIV)

### Epidemiology

In 2016 UNAIDS estimated that approximately 1.8 million people were newly infected with HIV. This reflects a slow decline since the peak in 1997 due to an emphasis on prevention. With increased access to care and treatment for HIV, UNAIDS stated that in 2016 there was a decrease in the number of deaths to 1 million and an increase in the number of people living with HIV.

The picture in the United States is similar to that in the rest of the world. In 2016, the CDC estimated that since the beginning of the epidemic in the United States, approximately 2 million adults and children had been infected, and 600,000 had died. Currently, approximately 1.1 million individuals are living with HIV in the United States, and 15% are unaware of their infection. The latest statistics from the CDC indicate that in 2016, the new infection rate among gay men was 67% of new HIV infections, the highest of any group. This is a change from the early 2000s, when the highest new infection rates were via IV drug use and heterosexual transmission. African Americans are the racial and ethnic group most affected by HIV. The CDC states that in 2016, the highest rate of new infections among different racial and ethnic groups was in African American men, especially men who were having sex with men. HIV affects different populations in different ways. The highest incidence of HIV infections in the United States is found in Georgia, Louisiana, and Nevada, whereas the lowest is in Vermont.

HIV disease is most commonly a sexually transmitted disease, although a significant number of individuals contract the disease via IV drug use. Blood containing the HIV virus is injected into the bloodstream of an uninfected individual from an infected individual when needles or syringes are shared. A very small number of individuals are still infected with blood transfusions; the CDC notes one

**Table 22.1 Classification of HIV Infection in Adults**

Classification	CD4+ Count	CD4+ Percentage of Total Lymphocytes	AIDS-Defining Condition
HIV infection, stage 1	At least 500 cells/ $\mu$ L	At least 29%	None
HIV infection, stage 2	200–499 cells/ $\mu$ L	14%–28%	None
HIV infection, stage 3 (AIDS)	Less than 200 cells/ $\mu$ L	Less than 14%	Yes

Source: Centers for Disease Control and Prevention. (2008). Revised surveillance case definitions for HIV infection among adults, adolescents, and children aged <18 months and for HIV infection and AIDS among children aged 18 months to <13 years—United States, 2008. *MMWR*, 57(RR10), 1–8. Retrieved from <http://www.cdc.gov/mmwr/preview/mmwrhtml/rr5710a1.htm>

reported case since 2002. A smaller number of people, 0.36%, have gotten HIV through occupational exposure. Pregnant women or breastfeeding women infected with HIV can transmit the disease to their child. The latest figures available in the United States indicate that 99 children were born with HIV infection in 2016.

### Connection Check 22.1

A nurse is screening patients for their risk of developing HIV. The nurse should consider which patient at greatest risk?

- A. African American man
- B. Asian woman
- C. Caucasian man
- D. Latino woman

### Pathophysiology

The immune system protects the body by recognizing and destroying:

- Infectious agents such as bacteria, viruses, and parasites
- Abnormal cells
- Foreign objects—anything from splinters to transplanted organs

When an individual becomes infected with HIV, immune system functions are compromised, and the individual becomes more susceptible to a variety of infections. There is a chronic, persistent destruction of infection-fighting cells, the CD4+ cells, by the replication of HIV. The CD4+ cell is a type of T lymphocyte with CD4+ receptors on the cell surface, also called a *T helper cell*. Normally, when stimulated by a recognized antigen from a virus-infected cell, the CD4+ cell releases cytokines. This in turn activates B lymphocytes and killer T lymphocytes in an effort to destroy the invading organism. The HIV targets the CD4+ cell. The infected individual manifests various stages of HIV disease over the course of time. If the HIV infection is untreated, the individual eventually dies, usually from an **opportunistic infection (OI)**.

### Viral Transmission, Acute Viral Infection, and Seroconversion

When a person is first infected with HIV, the virus causes an inflammatory reaction, bringing white blood cells and macrophages to the site of the inoculation with the virus. A virus particle attaches to specific receptors on the CD4+ cell, CD4+ receptors and co-receptors, and enters the cell. Once inside the cell, viral RNA is changed to viral DNA using the enzyme reverse transcriptase. The viral DNA is then integrated with the CD4+ lymphocyte cellular DNA in the nucleus of the lymphocyte. The HIV DNA is now in charge of cell reproduction and produces new viral proteins.

The viral proteins are assembled, and new HIV viruses are released, able to infect other CD4+ lymphocytes. The CD4+ lymphocyte is destroyed as the result of new viruses being produced (Fig. 22.1).

The result is a rapid decrease in the CD4+ lymphocyte count and a rapid increase in the **viral load**, the amount of HIV virus in the blood. During this time of acute viral infection, the individual may manifest symptoms of a flu-like viral illness: low-grade fever, generalized aches and pains, swollen lymph nodes, and generally feeling ill. After several weeks, the person's immune system develops antibodies to HIV, **seroconversion** occurs (the interval when HIV antibodies are first produced and rise to detectable levels), and the person tests positive for HIV.

### Asymptomatic Chronic Infection

The immune system begins to exert control but is not able to eliminate viral replication. The CD4+ count increases to near normal, and the viral load drops to a set-point level. The **viral set point** occurs when viral replication is still taking place but the immune system is able to destroy the virus in equal amounts as is being produced. Over the years, the CD4+ count slowly falls, with the individual losing approximately 50 to 100 CD4+ cells per year, and the viral load slowly increases. This may take as long as 10 years.

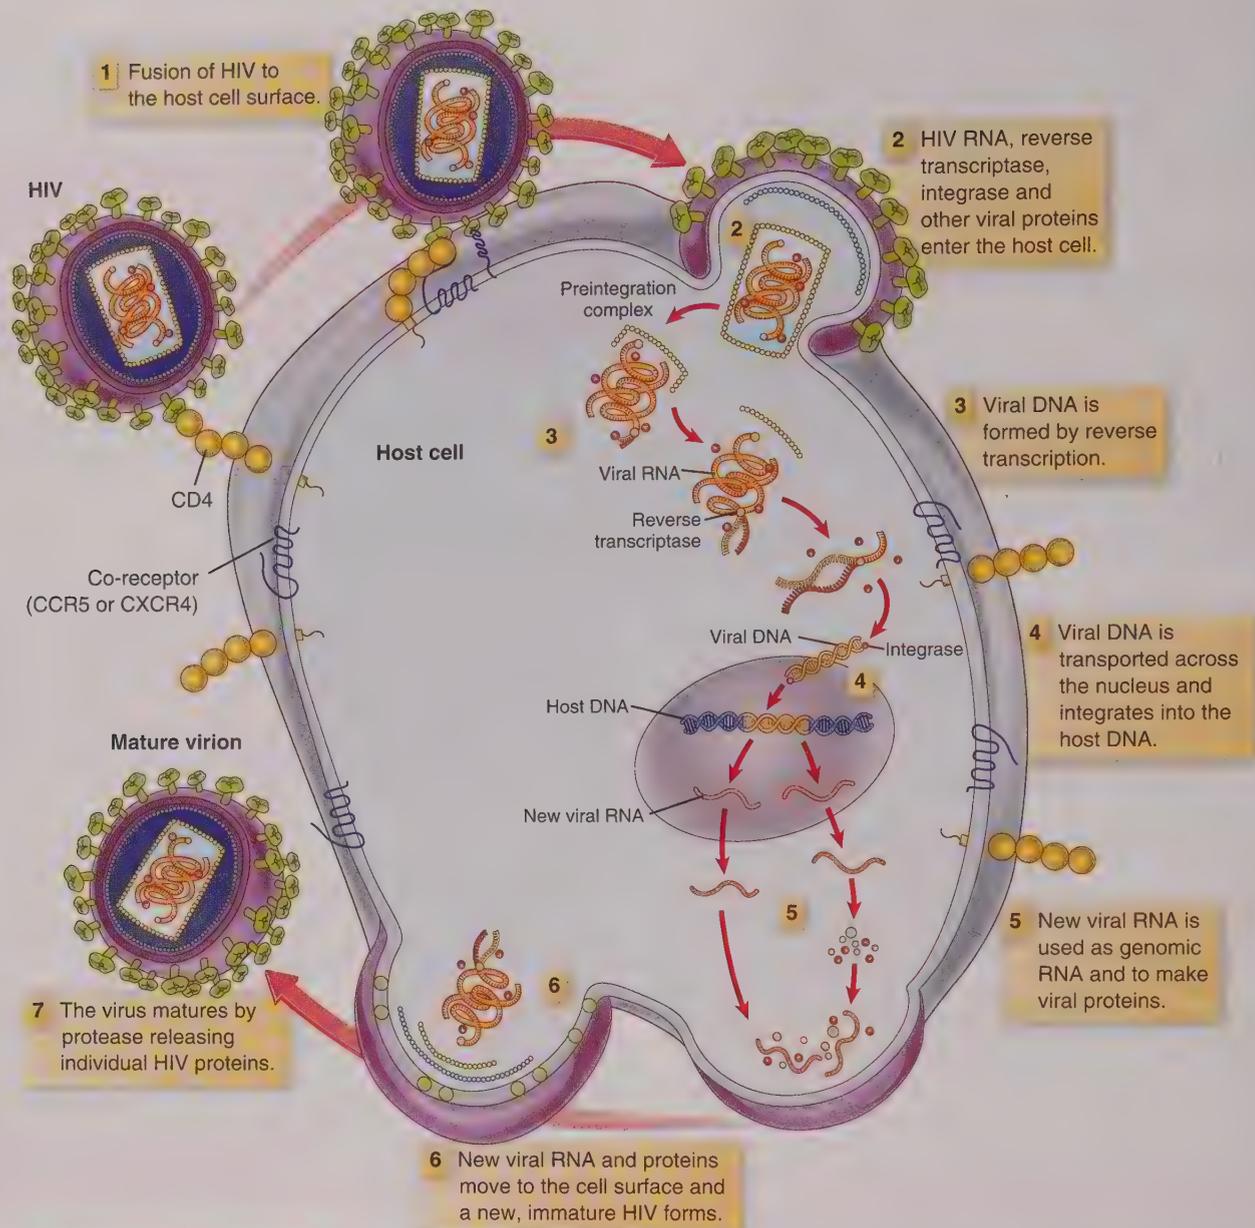

### Symptomatic Chronic Infection

As the HIV-infected individual's CD4+ count continues to fall, control over viral replication is slowly lost. The immune system becomes less able to fight off infections. Individuals begin to develop nonspecific symptoms, such as more frequent respiratory tract infections, skin problems, lymphadenopathy (enlarged lymph nodes), and weight loss. The CD4+ count falls more rapidly, and there is a rapid increase in viral replication. **Once a person becomes symptomatic, the average time to the development of AIDS is 2 years.**

### Acquired Immune Deficiency Syndrome (AIDS)

As the CD4+ count continues to fall, the immune system is less and less able to fight off infections. Infections can use the "opportunity" of a nonfunctioning immune system to infect the body, or the immune system loses the ability to control infections that are in a dormant phase, allowing the infection to become reactivated. **An HIV-infected individual has AIDS when the CD4+ count is less than 200 cells/ $\mu$ L or when he or she is diagnosed with one or more AIDS-defining illnesses.**

Commonly occurring AIDS-defining illnesses in the United States are *Pneumocystis (carinii) jiroveci* pneumonia, *Mycobacterium avium* complex, toxoplasmosis, esophageal candidiasis, and recurrent bacterial pneumonia. Target organs for damage secondary to HIV are the kidneys, the peripheral and central nervous systems, and the cardiovascular system. The progression from viral transmission to AIDS is summarized in Box 22.1.

**FIGURE 22.1** HIV replication.

### Box 22.1 Progression Through HIV/AIDS Stages

- Viral transmission
- Acute viral infection, 1 to 2 weeks
- Seroconversion
- Asymptomatic chronic infection, average = 3 to 10 years
- Symptomatic/AIDS, average = 2 years
- Death

### Connection Check 22.2

Which of the following statements regarding viral replication is correct?

- A. Endotoxin and/or exotoxin is required for viral proliferation.
- B. The virus must use host white blood cells for viral proliferation.
- C. Pathogenic replication is facilitated by the administration of antivirals.
- D. The virus replicates by preventing phagocytosis by white blood cells.

## Clinical Manifestations

Clinical manifestations observed in the patient with HIV/AIDS are most often related to impaired immune function and are typically a reflection of the OIs that occur as a result of HIV disease. The common signs and symptoms are:

- Fever
- Cough
- Weakness
- Nausea/vomiting
- Diarrhea
- Dysphagia, or difficulty swallowing
- Forgetfulness
- Skin lesions (Fig. 22.2)
- Shortness of breath, or dyspnea, on exertion
- Headache
- Vision changes
- Pain
- Night sweats
- Lymphadenopathy

Clinical manifestations indicating a deterioration in status requiring immediate attention by a healthcare provider are:

- New cough
- Increased fatigue
- Fever less than 97°F (36°C) or greater than 102°F (39°C)
- Night sweats
- New onset of headache
- New onset of visual blurring
- Recent change in mental status
- New skin lesions
- New onset of diarrhea
- Weight loss greater than 10% of previously recorded weight

See Table 22.2 for a list of the common clinical manifestations and their probable causes.

**FIGURE 22.2** Kaposi's sarcoma lesions.

**Table 22.2** Clinical Manifestations of HIV and Probable Cause

Clinical Manifestation	Probable Cause
Weight loss	Worsening disease
Fever	Infection
Night sweats	Mycobacterial infection
Cough	Pneumonia, tuberculosis
Dyspnea on exertion but not at rest	<i>Pneumocystis carinii</i> pneumonia
Unable to do usual activities	Neurological infections, anemia
Severe headache	Meningitis
Pain when swallowing	Oral or esophageal candidiasis, aphthous ulcers
Mental status changes	Central nervous system infection/tumor
Fatigue	Anemia, infection

## CASE STUDY: EPISODE 2

Vital signs for Ms. Castillo are:

Temperature: 98°F (36.8°C)

Pulse: 104 bpm

Blood pressure: 100/50 mm Hg

Respirations: 28

Pulse oximetry: 92% on room air

She is put on 2 liters of oxygen via a nasal cannula. A peripheral IV is started, blood is drawn for a complete blood count and metabolic profile, and she is started on 0.9 normal saline 100 mL/hr...

## Management

### Medical Management

#### Diagnostic Testing

Diagnostic or screening tests assess for antibodies to the HIV virus. Rapid tests or point-of-care tests utilizing blood or oral fluids can be used in settings where a quick answer for the presence or absence of HIV antibodies is required, such as in health screening, occupational exposure, or labor and delivery. Rapid tests do not require a laboratory to perform the test. The results from the rapid tests are available in 5 to 30 minutes depending on the test used. Point-of-care positive tests are confirmed by an HIV-1/2 antibody assay performed by a laboratory.

A negative screening test does not require confirmation but should be repeated in 3 to 6 months, allowing time for antibodies to develop and be detected if they are present. HIV infection can also be confirmed by the presence of the HIV virus in the blood, the viral load. Although not contraindicated in adults, the viral load is most often used to confirm the presence of HIV infection in infants less than 12 months of age.

Although common comorbidities are not diagnostic of HIV, newly diagnosed HIV+ individuals are screened for these conditions. The common comorbidities are chronic hepatitis B and/or C. If there is a decrease in CD4+ count to less than 200 cells/ $\mu$ L, individuals testing positive for HIV are also screened for the presence of antibodies that could indicate a higher risk of developing certain OIs. These OIs include toxoplasmosis, TB, and syphilis. In addition, testing is done for anemia, kidney disease, liver disease, diabetes mellitus, and cholesterol. HIV+ women are screened for cervical cancer.

At the time of diagnosis, the patient's viral load and CD4+ count are obtained. The CD4+ count is obtained routinely every 3 to 6 months for the first 2 years on therapy and then every year. The viral load is also obtained every 3 months for the first 2 years on therapy for adherent patients, then is obtained every 6 to 12 months. Viral load is used as the primary indicator of treatment success or failure, but it is not recommended as an indicator for hospitalized patients. The viral load can be affected by other viral illnesses, resulting in a falsely high level. In U.S. cities with a high prevalence of HIV infection, newly infected individuals may be infected with a medication-resistant virus. A genotype assay, which determines changes in the viral gene sequence that make the virus resistant to antiretroviral therapy (ART) medications, is part of the initial evaluation. A genotype assay of viral tropism, a test to determine if there is a CCR5 coreceptor on the CD4+ cells, may also be done to help determine the cause of treatment failure and assist in the selection of ART.

Ongoing screening for TB should be routinely done every 6 months. In a person with a history of a positive purified protein derivative (PPD), an interferon gamma release assay (IGRA) such as the blood test QuantiFERON-TB Gold can be used to screen for TB. A positive test requires further evaluation for a current TB infection.

### Connection Check 22.3

A nurse is caring for a patient in the emergency department. The patient asks for an HIV test. The nurse explains that a screening test can provide quick results and determine whether more testing is necessary. That test is a(n)

- CD4+ count.
- ELISA.
- rapid test.
- viral load.

## Medications

### Prophylaxis

If an HIV+ individual has a CD4+ count of 200 cells/ $\mu$ L or less, prophylaxis to reduce the risk of OIs, such as toxoplasmosis and PCP, is initiated prior to starting antiretrovirals. Individuals with a CD4+ count of 50 cells/ $\mu$ L or less are at risk for *M. avium* complex, a disseminated infection affecting multiple organs. As the immune system reconstitutes, patients will have a lower risk of developing opportunistic infections, and prophylaxis can be discontinued. Specifically, prophylaxis for toxoplasmosis and PCP can be discontinued in individuals when their CD4+ count has been greater than 200 cells/ $\mu$ L for at least 3 months. Prophylaxis for *M. avium* complex can be discontinued when the CD4+ count is greater than 100 cells/ $\mu$ L for 3 months.

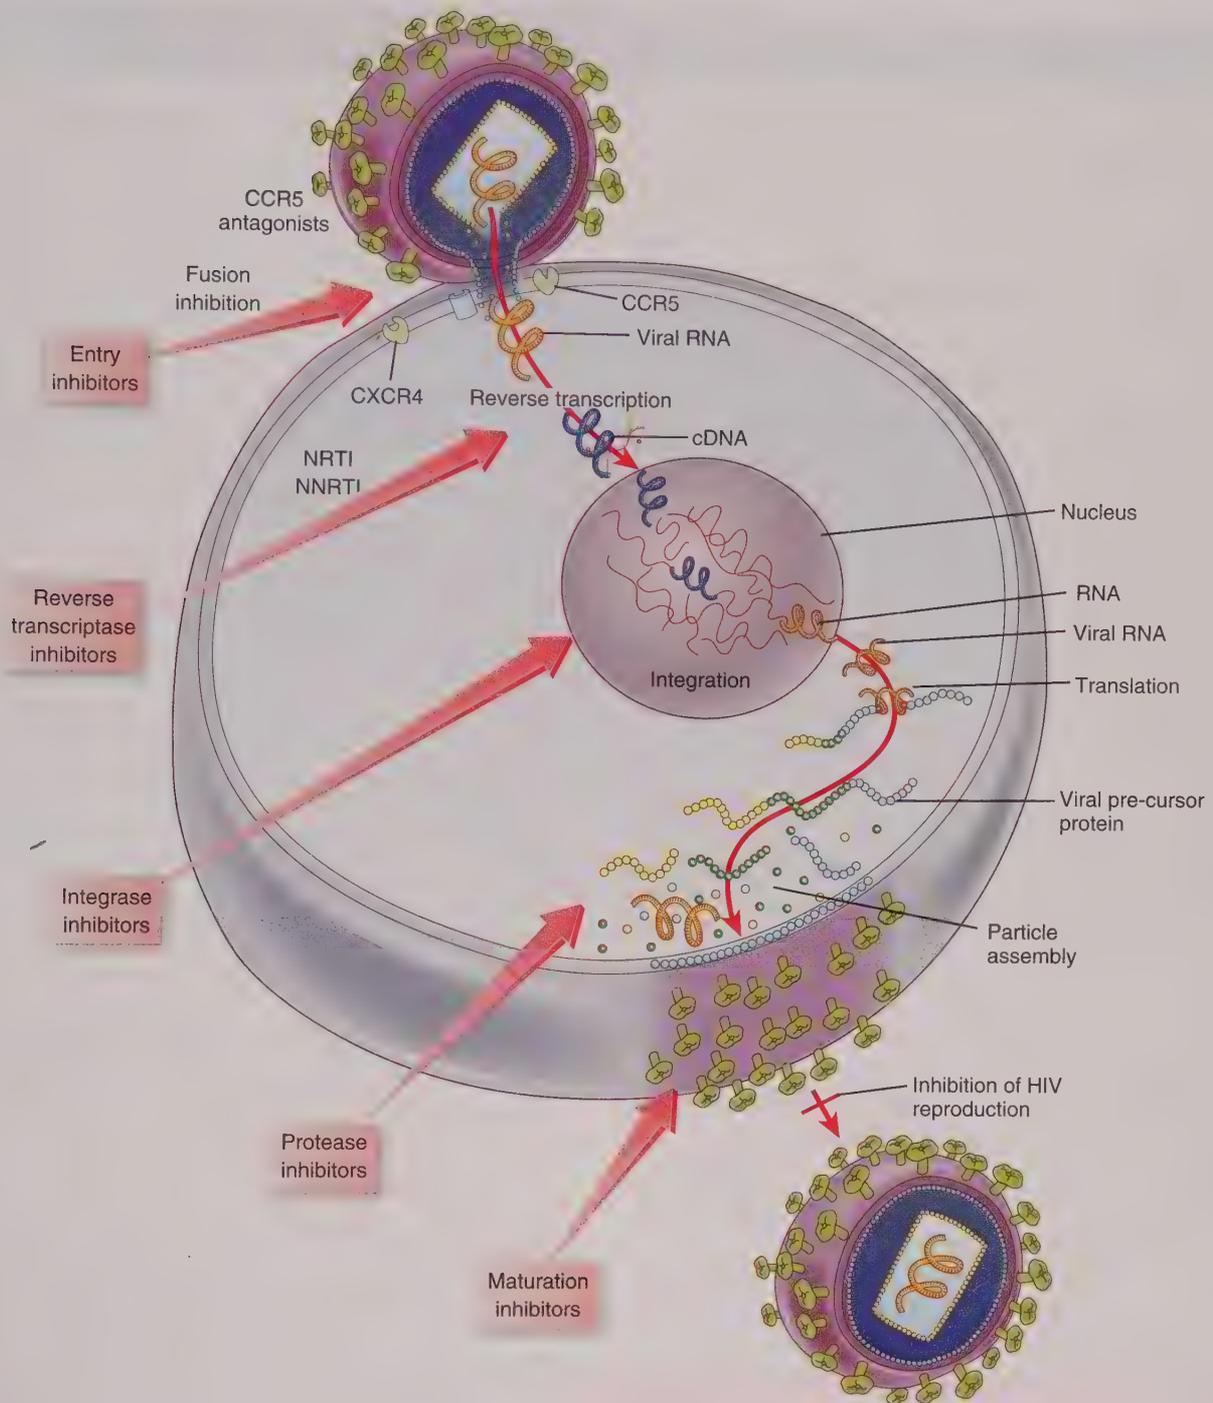

**Safety Alert** Individuals who have an allergic reaction to the sulfa component in Bactrim, a medication that is used for prophylaxis, may have a delayed manifestation of their allergy. The rash associated with an allergic reaction to Bactrim may not occur for 7 to 14 days after starting the medication. When assessing the patient who presents with a new rash, the nurse should ask about starting Bactrim within the past 2 weeks.

The sudden onset of anemia in an individual who has recently started Bactrim may be a sign of another serious manifestation of an adverse reaction to the sulfa component. Hemolytic anemia caused by glucose-6-phosphate dehydrogenase (G6PD) deficiency (an enzyme that supports the functions of red blood cells) can be precipitated by an allergic reaction to sulfa. This is more common in African Americans.

### Antiretroviral Therapy (ART)

Current Department of Health and Human Services (DHHS) 2017 recommendations for initiating antiretroviral therapy (ART) state that it should be recommended to all HIV+ individuals. Antiretrovirals interfere with the ability of HIV to reproduce itself (Fig. 22.3). Six classes of medications are currently available in the United States. Individuals are prescribed a minimum of three medications from at least two different classes. Most individuals are able to take a combination medication, one pill that contains three medications. The classes and their mechanism of action are described in Table 22.3.

Prior to the initiation of ART, hepatic and renal functions are evaluated. Significant physiological abnormalities influence the medication choice because medication metabolism takes place in the liver and kidneys. Once ART is begun, the CD4+ count will increase, and the HIV viral load will decrease to nondetectable levels. This is generally achieved in 6 to 8 weeks. The CD4+ counts and viral loads

**FIGURE 22.3** Targets for antiretroviral therapy (ART).

are followed at regular intervals, as recommended in the DHHS guidelines. For stable patients, the viral load may be obtained every 6 months and the CD4+ count yearly. Adherence to therapy is evaluated at each encounter to maintain a 95% adherence rate. One of the earliest signs of treatment failure is missing doses of medication or missing scheduled appointments.

Starting antiretrovirals is rarely an emergency. Critical to starting is a commitment to 100% adherence to therapy for a lifetime to reduce the possibility of viral resistance developing to therapy. Treatment preparation prior to starting

therapy is critical to success. Treatment preparation includes explaining:

- The advantages and disadvantages of therapy
- That taking ART is a lifetime commitment
- Why a certain medication combination was selected for that individual
- How and when to take the medications
- Side effects of the medications
- How to reduce potential side effects
- The effect of the medications on the immune system

**Table 22.3** Classes of Retroviral Medications

Class of Medication and Example of Medication in Class	Mechanism of Action	Adverse Effects
<b>Nucleoside reverse transcriptase inhibitors (NRTI)</b> <i>Tenofovir</i> <i>Abacavir</i>	Prevent viral RNA from becoming viral DNA by inhibiting the enzyme reverse transcriptase	Lactic acidosis Decrease in bone density
<b>Non-nucleoside reverse transcriptase inhibitor (NNRTI)</b> <i>Etravirine</i>	Prevents viral RNA from becoming viral DNA by altering the enzyme reverse transcriptase	Lipodystrophy (abnormal fat redistribution)
<b>Protease inhibitors</b> <i>Darunavir</i>	Prevent functional viral proteins from assembling into a new virus	Diabetes mellitus Hyperlipidemia
<b>Fusion inhibitors</b> <i>Enfuvirtide</i>	Prevent the HIV virus from entering target cells	Injection-site reaction
<b>CCR5 antagonists</b> <i>Maraviroc</i>	Prevent HIV from entering target cells by blocking receptors	Hepatitis
<b>Integrase inhibitors</b> <i>Raltegravir</i> <i>Dolutegravir</i>	Prevent integration of viral DNA into the T cell's DNA	Elevated amylase or liver function tests  Dolutegravir may increase the incidence of neural tube defects in the fetus.
<b>Post-attachment inhibitors</b> <i>Ibalizumab</i>	Blocks CD4+ receptors on certain immune cells	Diarrhea Rash

 **Safety Alert** Several cases of neural tube birth defects, including spina bifida, have been reported in babies born to women with HIV in Botswana being treated with dolutegravir. The Food and Drug Administration (FDA) recommends that clinicians should consider alternative regimens for women of childbearing age.

### Immunizations

Maintaining up-to-date immunizations is essential because HIV+ individuals are more at risk for infections owing to their compromised immune systems. HIV+ patients with a CD4+ count of 200 cells/ $\mu$ L or greater should receive Pneumovax every 5 years to reduce the risk of pneumococcal pneumonia. PCV13 (Prevnar) should be given once. The influenza vaccine should be offered yearly, and patients are encouraged to receive it early in the season so that they can develop antibodies. The diphtheria, pertussis, and tetanus vaccine should be given every 10 years. The herpes zoster live-attenuated vaccine (ZVL) is recommended at age 60 for individuals with a CD4+ count of greater than 200.

Live-virus vaccines are generally contraindicated in HIV-infected individuals with a CD4+ count of less than 200 and in household members.

 **Safety Alert** Occupational exposure to blood or bodily fluids should be reported immediately. If the patient's HIV status is unknown, permission may be requested to do the appropriate screening. If there is visible blood or fluids, washing the area under running water is recommended. Do not squeeze the injured area because that may increase the possibility of infection. An HIV test to ascertain seropositivity is offered. If positive, a referral for care is initiated. If negative, antiretroviral medications are prescribed. The exact medications depend on the risk of the exposure and the patient's HIV treatment status if HIV+. Generally, two or three medications are prescribed to be taken for 28 days. HIV testing is done at 6 weeks, 12 weeks, and 4 to 6 months after exposure. Nursing mothers are encouraged to stop breastfeeding.

## Connection Check 22.4

The nurse understands that which of the following are correct statements about HIV disease? (*Select all that apply.*)

- A. HIV disease progresses in stages; HIV disease is diagnosed by determining viral load.
- B. A CD4+ count of 500 cells/ $\mu$ L or more indicates HIV, not AIDS.
- C. The Western blot test is diagnostic for HIV disease.
- D. A CD4+ count of 200 cells/ $\mu$ L or less increases the chances for opportunistic infections.
- E. ART is started immediately after diagnosis if the CD4+ count is less than 200 cells/ $\mu$ L.

## Prevention

**Prevention is a critical component of HIV care.** Inadequate testing and compliance with the treatment plan or remaining in care remain barriers to the prevention of the initial HIV infection or progression through the continuum to AIDS. The HIV care continuum, or cascade of care, is used to estimate the percentage of HIV-infected individuals in each step of care from the acquisition of an HIV infection through engagement in care, including receiving ART and achievement of complete viral suppression. Approximately 85% of HIV+ individuals know their status, and only about 25% of HIV-infected individuals have a nondetectable viral load, potentially indicating patients not remaining in care.

A critical part of prevention is testing for HIV. Current recommendations state that all providers should offer routine opt-out screening for all individuals between the ages of 15 and 65. In HIV-negative individuals, yearly testing is recommended for those at high risk. *High risk* is defined as being in a community with an HIV prevalence of greater than 1%. Examples of high-risk communities include sexually transmitted infection clinic attendees and incarcerated individuals.

Antiretroviral therapy for HIV+ individuals is a cornerstone of prevention of the spread of the disease. When HIV+ individuals have a nondetectable HIV viral load, the risk of transmitting HIV to an HIV-negative partner is less than 3%. Another cornerstone of prevention is Truvada, a combination of the medications tenofovir and emtricitabine, also referred to as *preexposure prophylaxis* (PrEP). This medication has been approved for daily use to reduce the risk of acquiring HIV. Guidelines from the U.S. Public Health Service recommend its use by HIV-negative individuals who are part of an HIV **serodiscordant** couple (one partner is HIV positive, and one partner is HIV negative) and by those who engage in risky behaviors. Follow-up with a health-care provider every 3 months to assess medication adherence and provide reinforcement for additional risk-reduction behaviors is highly recommended. Prior to initiation of PrEP, acute and chronic hepatitis B must be ruled out (see Evidence-Based Practice).

## Evidence-Based Practice

### Preexposure Prophylaxis

Preexposure prophylaxis (PrEP) with Truvada is taken prior to exposure to reduce the likelihood of infection with HIV from an HIV+ partner. Except for the HIV-negative partner in long-term serodiscordant couples, PrEP is controversial because of the lifestyles associated with the practice of high-risk behaviors. It is well documented that exposure to blood and body fluids is the mode of transmission for HIV and that the risk of transmission is related to the viral load of the HIV+ individual. When taken with greater than 95% adherence, antiretroviral therapy reduces the HIV viral load to nondetectable levels in most persons. This reduces the risk of transmission to HIV-negative partners. However, only 25% of individuals infected with HIV in the United States have a nondetectable viral load.

A Cochrane Database systematic review of six clinical trials in both the United States and sub-Saharan Africa found that both the HIV-negative partner in serodiscordant couples and those individuals who practiced high-risk behaviors (such as commercial sex workers, sexually active young adults engaging in casual sex, men who have sex with men, and IV drug users) who were treated with daily Truvada showed significantly fewer new infections with HIV than those in the placebo groups. Efficacy ranged from 44% to 75% and was related to adherence in taking the medication. In one study of heterosexual women in sub-Saharan Africa, there was no significant difference in new HIV infections between the placebo and control groups. Adherence to the medication was low.

The availability of PrEP is not well known outside of individuals who have participated in clinical trials. When the availability and efficacy of treatment were made known to individuals practicing high-risk behaviors, more than 50% were interested in participating, provided the medication could be obtained at low or no cost.

Public health concerns include the cost of PrEP for a large number of individuals and the possibility of decreasing adherence over time. Another concern is the probability of the individual developing medication resistance to Truvada if he or she contracts HIV because Truvada alone has not been shown to suppress viral load.

Individuals who are at risk for HIV and are interested in taking PrEP need accessible and acceptable therapy. They need to understand the medical and social benefits of PrEP in order to make an informed decision. Other

risk-reduction behaviors, such as the use of condoms in all sexual encounters, must be incorporated into the individual's treatment plan.

## Connection Check 22.5

A patient states that she has recently been treated for gonorrhea. Her last HIV test was 18 months ago. When you review the orders, you notice that an HIV test has been ordered. What do you do?

- Explain that the test has been ordered and that she can opt out.
- No discussion is necessary; just do the test.
- Obtain her written consent for the test.
- Provide pretest counseling before getting consent.

## Complications

Complications of HIV disease are related to the decrease in immune function and consist of opportunistic infections and malignancies. When the CD4+ count is greater than 500 cells/μL, the individual often has no signs or symptoms related to HIV infection, although women may have an increased incidence of vaginal candidiasis unrelated to antibiotic use or diabetes. When the CD4+ count is between 500 and 350 cells/μL, individuals may have increased respiratory illnesses or dermatological manifestations such as herpes zoster. As the CD4+ count falls to between 350 and 200 cells/μL, the individual may notice an increase in infections mediated by the adaptive immune system and may develop symptoms of fever, fatigue, or severe bacterial infections. As the CD4+ cells continue to fall to below 200 cells/μL, the individual is considered to have AIDS. Individuals with AIDS are likely to develop specific OIs that are new infections or reactivations of dormant infections.

Examples of OIs associated with AIDS are PCP, cryptococcal meningitis, cryptosporidiosis, *Candida* esophagitis, toxoplasmosis, cytomegalovirus (CMV), *M. avium-intracellulare* (MAC), and progressive multifocal leukoencephalopathy (PML) infections (Fig. 22.4).

Another complication of HIV disease is **immune reconstruction inflammatory syndrome (IRIS)**. This syndrome occurs as the CD4+ count increases and the immune system is able to respond to the presence of previously acquired OIs, such as cryptococcal meningitis. Paradoxically, the response is an overwhelming inflammatory response, making the symptoms of the infection worse.

## Nursing Management

### Assessment and Analysis

As stated earlier, clinical manifestations are most often a reflection of the OIs associated with HIV, such as frequent respiratory illnesses, pneumonia, meningitis, or *Candida* esophagitis. Common signs and symptoms are:

- Fever
- Cough
- Weakness
- Nausea/vomiting
- Diarrhea
- Dysphagia, or difficulty swallowing
- Forgetfulness
- Skin lesions
- Shortness of breath, or dyspnea, on exertion
- Headache
- Vision changes
- Pain
- Night sweats
- Lymphadenopathy

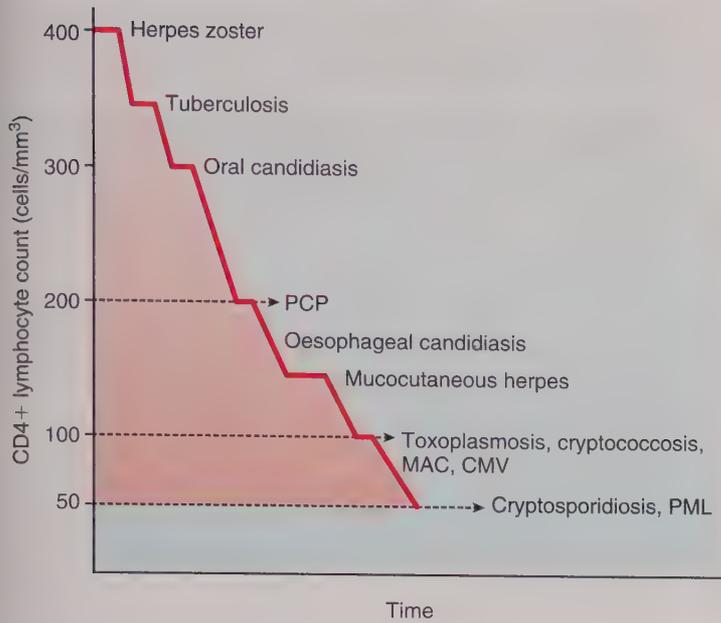

### Nursing Diagnoses

- **Risk for infection** related to decreased immune function
- **Imbalanced nutrition**; less than body requirements
- **Risk for fluid volume deficit** related to gastrointestinal manifestations
- **Anxiety** related to disease diagnosis or progression of the disease
- **Knowledge deficit** related to self-care and the disease process

### Nursing Interventions

#### ■ Assessments

- Temperature, pulse, respirations, oxygen saturation  
*Fever is often the first indicator of an infection. In individuals with low CD4+ lymphocytes, there is an inability to release pyrogens, resulting in a low-grade fever even in the face of a significant infection. A drop in body temperature in the presence of infection is a sign of compensatory failure. An indirect measure of fever is an increase in the pulse rate above baseline. The respiratory rate may also increase in an effort to reduce the core body temperature.*

**FIGURE 22.4** Association between opportunistic infections and CD4+ count.

*Hypoxemia, or decreased oxygen-carrying capacity, may occur as a result of a decreased number of functional alveoli secondary to a respiratory infection such as PCP or from anemia secondary to a side effect of medication or pancytopenia from the invasion of the bone marrow by HIV.*

- **Weight trends**

*Weight loss results from caloric expenditure exceeding caloric intake and can affect cellular metabolism. Weight loss of 10% or more can indicate worsening disease, treatment failure if the patient is on ART, or depression. It can lead to decreased albumin levels, impairing medication transport and utilization.*

- **CD4+ count**

*There is a correlation between CD4+ count and the risk of developing certain OIs. The lower the CD4+ count, the more suppressed the individual's immune system is. Individuals with a low CD4+ count are more likely to have serious complications of HIV and non-HIV-related infections and a potentially blunted response to therapy.*

- **Viral load**

*The viral load reflects the amount of viral replication. Viral load is an indicator of disease progression; the higher the viral load, the more quickly the disease progresses from HIV infection to AIDS.*

- **Adherence to ART**

*An adherence rate of 95% or greater is essential to achieve viral suppression and prevent the development of resistance to one or more ART medications. If an individual misses one dose of even one medication during a day, the adherence rate for that day is 0%.*

- **TB status**

*Although the incidence of TB has decreased overall, there has been an increase in TB in HIV-infected individuals, probably related to reactivation of a prior exposure.*

- **Immunization status**

*Immunocompromised individuals should maintain up-to-date immunization status. They should not receive live-virus vaccines because of the risk of developing the disease. Immunizations in individuals with a CD4+ count less than 200 cells/ $\mu$ L may not be as effective because of the compromised ability to produce antibodies in response to the immunization.*

- **Depression**

*HIV is often a stigmatizing illness requiring the infected individual, family members, and friends to confront behaviors or lifestyles that put the infected individual at risk for contracting the disease. Stigma may put distance between the HIV-infected individual and his or her support system.*

- **Actions**

- **Utilize universal precautions consistently.**

*Universal precautions are designed to prevent the spread of infections between individuals. In addition to HAND WASHING for a minimum of 15 to 30 seconds, which is the MOST IMPORTANT precaution, personal protective equipment may be required. The selection of personal protective equipment, such as gloves, goggles, and gowns, is related to the risk of exposure.*

- **Administer ART as prescribed and on time.**

*Maintaining medication levels is critical to preventing medication resistance. Several medications that are commonly used have low resistance thresholds when subtherapeutic levels are present. Administering doses more than 1 or 2 hours after the usual time can increase the risk of the development of viral resistance.*

- **Provide nutritionally dense foods and small, frequent meals.**

*Anorexia, nausea, and vomiting are commonly seen in individuals with HIV/AIDS as a result of medications or HIV infection. Persistent anorexia, nausea, or vomiting*

can lead to dehydration, weight loss, and electrolyte imbalances. Small, frequent meals/snacks, incorporating foods such as nuts or nutritional supplements, will increase caloric intake and provide protein and essential micronutrients.

- Provide emotional support.  
*Complex emotional issues, such as sexuality, shame, and anger, may be associated with HIV/AIDS. Listening and being nonjudgmental can assist the patient in developing effective coping behaviors. Referral to a mental health professional may be needed. The focus is on living with HIV, not dying with HIV.*
- Refer for social services evaluation.  
*Many patients need assistance with the cost of HIV medications, which can cost more than \$12,000 a year and up. Individuals may be eligible for other programs and support services available through community organizations and the local, state, or federal government.*

### Teaching

- Avoidance of high-risk behaviors that increase the risk of transmission  
*Consistent use of condoms with every sexual encounter and avoiding the use of street drugs or alcohol or other situations that might impair judgment reduce the risk of transmitting HIV. These behaviors also reduce the risk of reinfection with a medication-resistant or more virulent strain of HIV.*
- Adherence to treatment regimen  
*Adherence is essential in managing the progression of the disease. Taking medications as ordered and at the same time each day (plan administration times around activities of daily living) helps maintain therapeutic medication levels and decreases the risk of viral resistance developing. Understanding the name, purpose, and dosage of the medication and how to take the medication, potential side effects, and how to manage them contribute to maintaining greater than 95% adherence.*
- Implementing infection-control precautions at home  
*Fear of transmission to other household members is a cause of stigma. Discussing specific methods of infection control will result in less stigma and enhance the protection of others from infection. Blood spills should be cleaned with a bleach solution. Avoid raw or undercooked eggs, meat, poultry, or fish to reduce the risk of diarrheal illnesses. Animal excrement should be taken care of by a non-HIV-infected, nonpregnant individual to avoid exposure to toxoplasmosis and other animal-borne illnesses.*
- Signs and symptoms to report to the healthcare provider urgently  
*Early evaluation and intervention can reduce the morbidity and mortality associated with opportunistic infections or side effects of medications. Explain how to utilize a self-care symptom management manual.*

- Health maintenance needs  
*Individuals with HIV are at higher risk of developing opportunistic infections and malignancies, which can be identified early with routine screenings such as mammograms, gynecological examinations, dental examinations, eye examinations, and colonoscopies following clinical preventive services guidelines.*

### Evaluating Care Outcomes

Individuals with HIV can live a normal life span when they are adherent to therapy. Strict compliance with the medical regimen is necessary to achieve viral suppression and prevent the development of resistance. The patient and caregivers must know how to reduce the risk of transmission by practicing infection control practices at home and eliminating risky behaviors. In addition, patients and caregivers need to know what signs and symptoms require urgent evaluation by a healthcare provider. The response to ART is determined by measuring the CD4+ count and the viral load. Within 6 to 8 weeks of therapy initiation, there is an increase in the CD4+ count and a decrease in the viral load. Over several months following the initiation of therapy, the viral load should reach nondetectable levels.

### Transitional Care

HIV/AIDS has evolved into a chronic condition, with individuals experiencing symptoms related to aging, treatment side effects, and the disease process associated with HIV. In addition, those patients who are diagnosed late in the disease process may not recover immune function and are more likely to have disease-related symptoms, even with treatment. There is a need for palliative care for better symptom management. This should be incorporated into patient care from the time of diagnosis to death. Introducing the concept of palliative care as one intervention to improve quality of life is critical and, over time, may lead to other discussions, such as advanced directives and the need for hospice care.

### Connection Check 22.6

A patient newly diagnosed with HIV asks about community support groups. What should the nurse do?

- Contact psychiatry for an evaluation for depression.
- Provide a list of groups in a neighboring community.
- Request a referral to the social work department.
- Suggest the patient contact the physician.

## Finding Connections

### CASE STUDY: WRAP-UP

Initial diagnostic results for Ms. Castillo are “confirmed HIV+”: low white blood cell count, CD4+ count of 125 cells/ $\mu$ L, mild anemia, and normal renal and liver functions. She is experiencing symptoms of PCP. The common symptoms are a dry, persistent cough and mild shortness of breath with activity that occurs over several weeks. Patients often experience weight loss, fatigue, a low-grade fever, and hypoxia. Her healthcare provider orders PML *Cryptosporidiosis* antibiotic prophylaxis to treat her PCP. Consideration is given to preparing her to start ART.

#### Case Study Questions

- Ms. Castillo is briefly admitted to the hospital for an evaluation. The charge nurse is reviewing her orders. It is a priority for the charge nurse to follow up with the provider about which order?
  - Stopping antibiotic prophylaxis
  - CD4+ count in the morning
  - Applying PPD
  - Dietary referral
- The nurse caring for Ms. Castillo incorporates which nursing diagnosis into the plan of care?
  - Imbalanced nutrition; more than body requirements
  - Ineffective denial related to refusal to acknowledge diagnosis
  - Risk for infection
  - Risk for other-directed violence
- When the nurse teaches Ms. Castillo about the ART she will soon start, which of the following will be helpful in increasing patient adherence?
  - Centering medication taking on a daily activity
  - Direct observation for negative side effects
  - Increased frequency of medication administration
  - Using multiple medications whenever possible
- Which of the following would you include in your teaching plan for Ms. Castillo?
  - Decreasing risky behaviors
  - Emphasizing exploration of experimental treatments
  - Implementing universal precautions at home
  - Evaluating measures to decrease exposure to others
- Which statement by Ms. Castillo indicates that teaching has been effective?
  - “Anyone who touches me needs to wear gloves.”
  - “I can use alcohol in moderation with my medications.”
  - “I can take my medications late if I am out for the day.”
  - “I need to use condoms with every sexual encounter.”

## CHAPTER SUMMARY

When an individual becomes infected with HIV, immune system functions are compromised, and the individual becomes more susceptible to a variety of infections because of the chronic, persistent destruction of infection-fighting cells, the CD4+ cells, by the replication of HIV. The CD4+ cell is a type of T lymphocyte with a CD4+ receptor on the cell surface: a T helper cell. When stimulated by a recognized antigen from a virus-infected cell, cytokines are released. This in turn activates B lymphocytes and killer T lymphocytes. The HIV virus targets the CD4+ cell.

Approximately 1.7 million people are newly infected with HIV yearly. HIV disease is most commonly a sexually transmitted disease, although a significant number of individuals contract the disease via IV drug use. African Americans now have the highest new infection rate (45%), followed by Latinos (17%).

The individual manifests various stages of HIV disease over the course of time. If the HIV infection is untreated, the individual eventually dies, usually from an opportunistic infection (OI). Individuals infected with HIV are categorized into one of four mutually exclusive, hierarchical groups according to the presence or absence of signs or symptoms commonly associated with AIDS. This is the first recognition of the continuum of HIV/AIDS as a disease that progresses through stages from acute HIV infection, asymptomatic HIV infection, and symptomatic HIV infection to the most advanced stage, AIDS. Clinical manifestations are typically a reflection of the OIs that occur as a result of HIV disease. *P. carinii* pneumonia is the most common OI seen in HIV+ individuals.

Diagnostic or screening tests assess for antibodies to the HIV virus. Rapid tests utilizing blood or oral fluids can be used in settings where a quick answer for the presence or absence of HIV antibodies is necessary. A negative screening test does not require confirmation. A positive screening test requires confirmation by additional laboratory testing.

Medication therapy for an HIV+ individual who has a CD4+ count of 200 cells/ $\mu$ L or less starts with prophylaxis to reduce the risk of OIs and is initiated prior to starting antiretroviral therapy (ART). Antiretrovirals interfere with the ability of HIV to reproduce itself. Everyone infected with HIV should start ART as soon as possible after diagnosis.

Nursing management includes comprehensive assessment to assess response to therapy and the presence of OIs. Teaching is extremely important to help the patient understand the necessity of compliance with the medication regimen and the importance of avoidance of risky behaviors.

## Promoting Health in Patients With Oxygenation Disorders

### Chapter 23

## Assessment of Respiratory Function

*Megan Lynn*

#### LEARNING OUTCOMES

Content in this chapter is designed to assist in:

1. Identifying key anatomical components of the respiratory system
2. Discussing the function of the respiratory system
3. Describing the procedure for completing a history and physical assessment of respiratory function
4. Correlating relevant diagnostic examinations to respiratory function
5. Explaining nursing considerations for diagnostic studies relevant to respiratory function
6. Discussing changes in respiratory function associated with aging

#### CONCEPTS

- Assessment
- Infection
- Oxygenation
- pH Regulation
- Safety

#### ESSENTIAL TERMS

Alveolar dead space  
Alveoli  
Anatomical dead space  
Apnea

## Finding Connections

### CASE STUDY: EPISODE 1

Follow this patient throughout the chapter.

Mr. Larry Thomas is a 66-year-old male complaining of shortness of breath for the past 2 weeks. He has come to his provider's office for evaluation of his symptoms.

#### History of Present Illness:

Mr. Thomas reports chest pain that increases with coughing. He reports thick green/yellow sputum for the past week. His current weight is stable at 100 kg from his previous visit 6 months ago. He admits to occasionally smoking cigarettes...

## INTRODUCTION

The respiratory system is a complex system that is divided into the upper and lower respiratory tracts. Air enters the respiratory system through the nose or mouth and travels to the lungs, where **respiration**; the exchange of oxygen and carbon dioxide between the outside air and the lungs occurs at the alveoli level. The major function of the respiratory system is to supply oxygen to and remove carbon dioxide from the body. Because of the complexity of the respiratory system, a thorough assessment should be completed by the nurse, including inspection, auscultation, percussion, and palpation to identify dysfunction. This chapter discusses the anatomy, physiology, assessment steps, and diagnostic tests specific to the respiratory system.

## OVERVIEW OF ANATOMY AND PHYSIOLOGY

### Functions of the Respiratory System

The major functions of the respiratory system are to perform the functions of **ventilation** and respiration. Ventilation occurs as air moves into and out of the respiratory system through the process of inspiration and exhalation. During ventilation, the structures of the respiratory system filter and humidify the air entering the system. The process of respiration occurs as oxygen and carbon dioxide are exchanged at the level of the alveoli. After respiration occurs, the circulatory system is responsible for transporting the oxygenated blood to the tissues of the body. This movement of oxygenated blood into the tissues is known as *perfusion*. The circulatory system provides the body with oxygenated blood and then returns deoxygenated blood back to the lungs to allow for re-oxygenation through the process of respiration. In addition to the processes of

respiration and ventilation, the respiratory system is responsible for the following:

- **Acid-base balance:** The exchange of carbon dioxide for oxygen in the lungs and the renal secretion of bicarbonate maintain the body's pH between 7.35 and 7.45. If carbon dioxide levels rise within the body, this results in a decrease in the pH level: **acidosis**. If carbon dioxide levels decrease, this results in an **increase** in the pH level: **alkalosis**.
- **Speech:** The movement of air through the **vocal cords** allows vocalization of words.
- **Sense of smell:** The movement of air through the nose allows an individual to **smell odors** in the environment.
- **Fluid balance:** Water is excreted as water vapor through the **exhalation process**. This helps to maintain the body's fluid balance.

## Connection Check 23.1

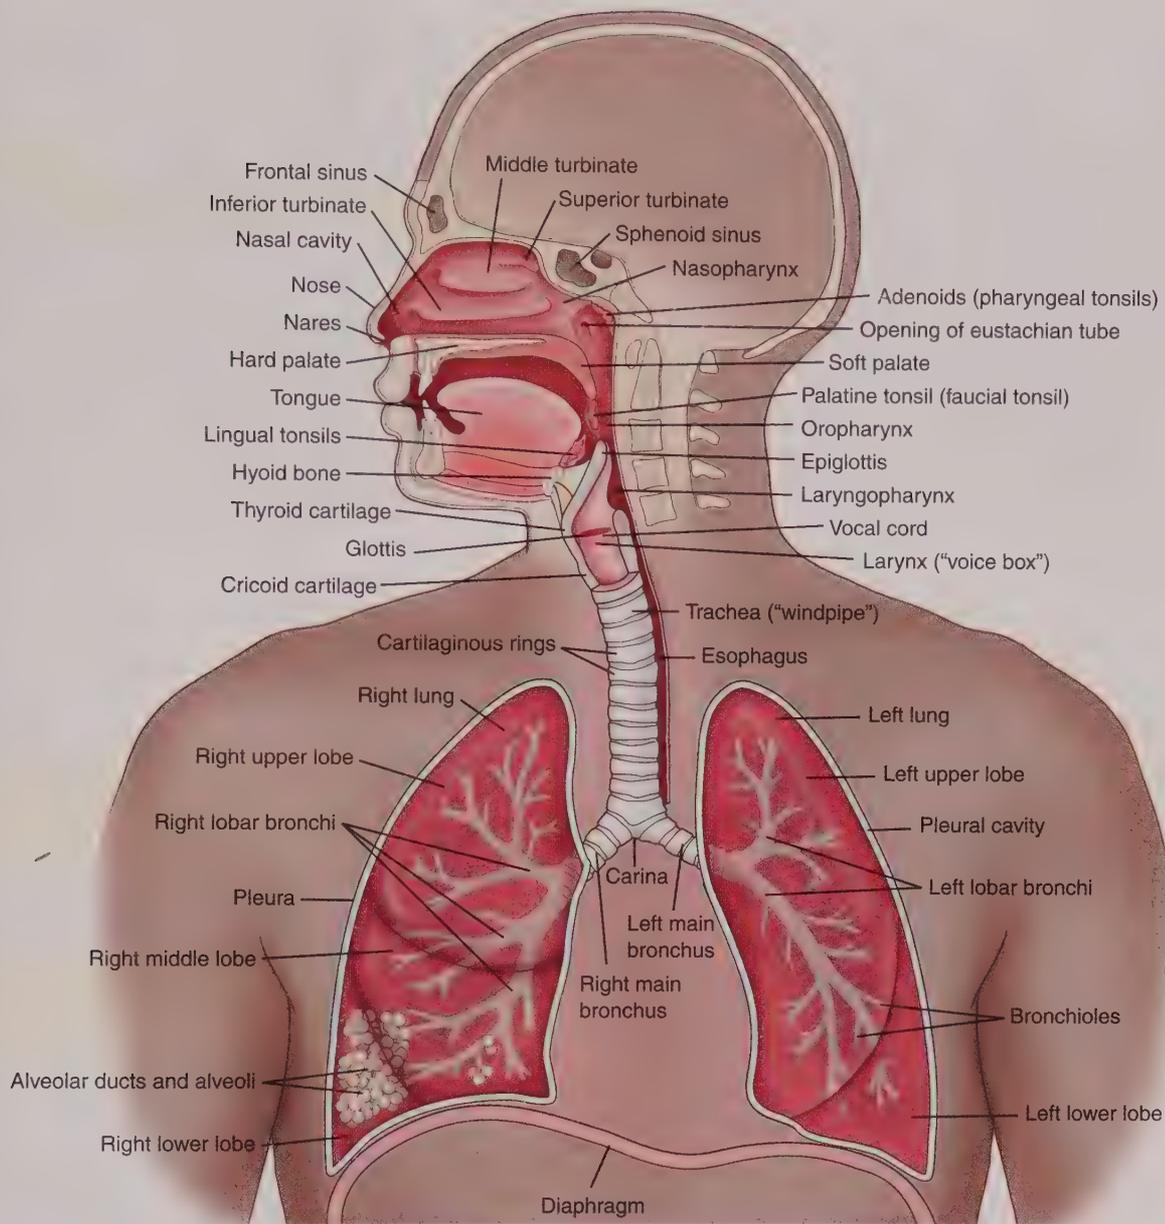

Which of the following is *not* a function of the respiratory system?

- Acid-base balance
- Temperature regulation
- Fluid balance
- Tissue perfusion

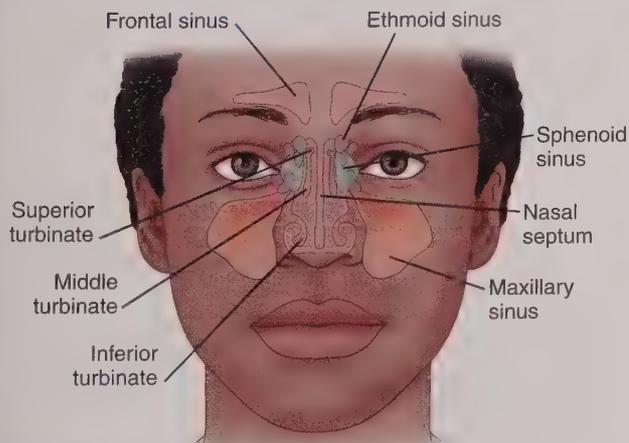

## Anatomy of the Respiratory System

The easiest way to understand the structures of the respiratory system is to follow the path of air through the system. Air travels through the upper respiratory system to the lower respiratory system. The upper respiratory system consists of the nose, mouth, sinuses, pharynx (throat), and larynx. The lower respiratory system consists of the trachea and lungs. Figure 23.1 displays the major structures of the respiratory system.

Oxygen enters the respiratory system through the nose or mouth. The nose consists of two nares that are separated by a septum. The interior of each naris is lined with hair, which acts as a filter to prevent the entrance of microorganisms and/or foreign particulates into the respiratory system. Once oxygen passes through the nares, it encounters the three turbinates located within the nasal cavity. The turbinates are made of bone and are covered with cilia. Turbinates filter the air, and any foreign matter is filtered out through the cilia. In addition to filtering the air entering the nostril, turbinates are responsible for humidifying and warming the air. Around the nose are the paranasal sinuses—the ethmoid, frontal, sphenoid, and maxillary sinuses, named for the bones in which they are located. The sinuses are empty, air-filled cavities that humidify and warm inspired air; absorb shock, providing protection from facial trauma; provide voice resonance; and decrease the weight of the skull (Fig. 23.2).

**FIGURE 23.1** Major structures of the upper and lower respiratory system.

**FIGURE 23.2** Frontal, ethmoid, and sphenoid sinuses: superior, middle, and inferior turbinates.

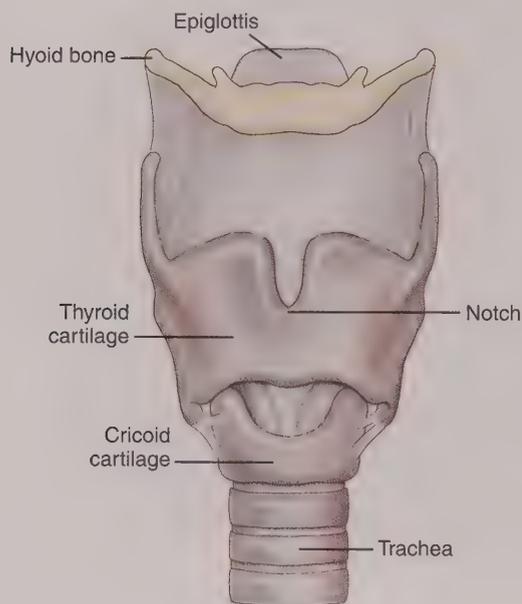

Once the air passes through the turbinates, it enters the pharynx. The pharynx is divided into the nasopharynx, oropharynx, and laryngopharynx. The area behind the nose is a mucous membrane called the *nasopharynx*. The ends of the eustachian tubes are located in the nasopharynx and connect the nasopharynx to the middle ear. Below the eustachian tubes are the adenoids. The adenoids filter out any foreign objects or microorganisms.

Once air passes the soft palate at the back of the mouth, it enters the oropharynx. The oropharynx is the mucous membrane located directly behind the mouth. Within the oropharynx are the palatine tonsils. The palatine tonsils, like the adenoids, are responsible for filtering out any foreign objects or microorganisms. Once the air moves past the oropharynx, it moves into the laryngopharynx. The laryngopharynx starts at the base of the tongue and continues to the larynx.

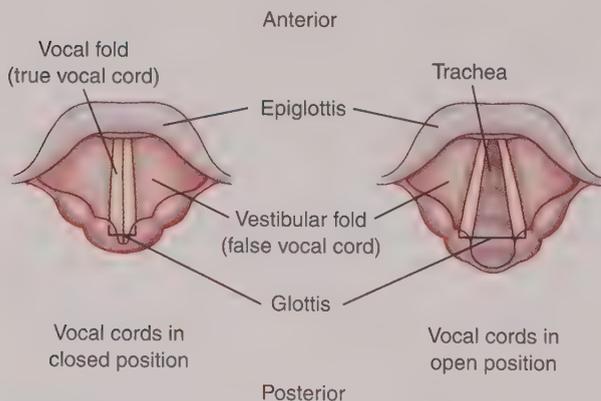

The larynx is composed of different types of cartilage: thyroid and cricoid cartilage. The thyroid cartilage protrudes from the neck and forms what is commonly known as the “Adam’s apple.” The cricoid cartilage is just below the thyroid cartilage (Fig. 23.3).

At the top of the larynx is the epiglottis. The epiglottis is a leaf-shaped flap that covers the opening of the larynx and provides a tight seal over the larynx when an individual is swallowing food or liquids to prevent aspiration. As air moves past the epiglottis, it enters the vocal cords, located in the larynx. The vocal cords consist of the true and false vocal cords (Fig. 23.4). Speech occurs when air passes through the glottis (located between the true vocal cords).

Once air leaves the larynx, it enters the lower respiratory system (see Fig. 23.1) via the trachea. The trachea is composed of C-shaped rings of cartilage, and the posterior portion of the trachea is composed of smooth muscle. The

**FIGURE 23.3** Thyroid and cricoid cartilages of the larynx.

**FIGURE 23.4** True and false vocal cords; sound is produced as air moves past the open true vocal cords.

smooth muscle of the posterior portion of the trachea is shared with the esophagus, but they are two separate structures. The trachea divides into the right and left main bronchi just above where they enter the lungs. The point of trachea bifurcation is known as the *carina*. The right lung consists of three lobes, and the left lung consists of two lobes (Fig. 23.5). The main bronchi are composed primarily of cartilage. The right bronchus is wider and shorter than the left, which increases the chance of aspiration of foreign material into the right bronchus versus the left. Once air enters the right or left main bronchus, it travels to the lobar bronchi. The lobar bronchi are composed of cartilage, and the interior is lined with cilia. The cilia assist the lungs with mucous expectoration. The mucous, produced by epithelial goblet cells or mucous glands, functions as a barrier to infection by trapping bacteria or microorganisms. The mucous is moved up the **mucociliary elevator** by the beating motion of the cilia (Fig. 23.6).

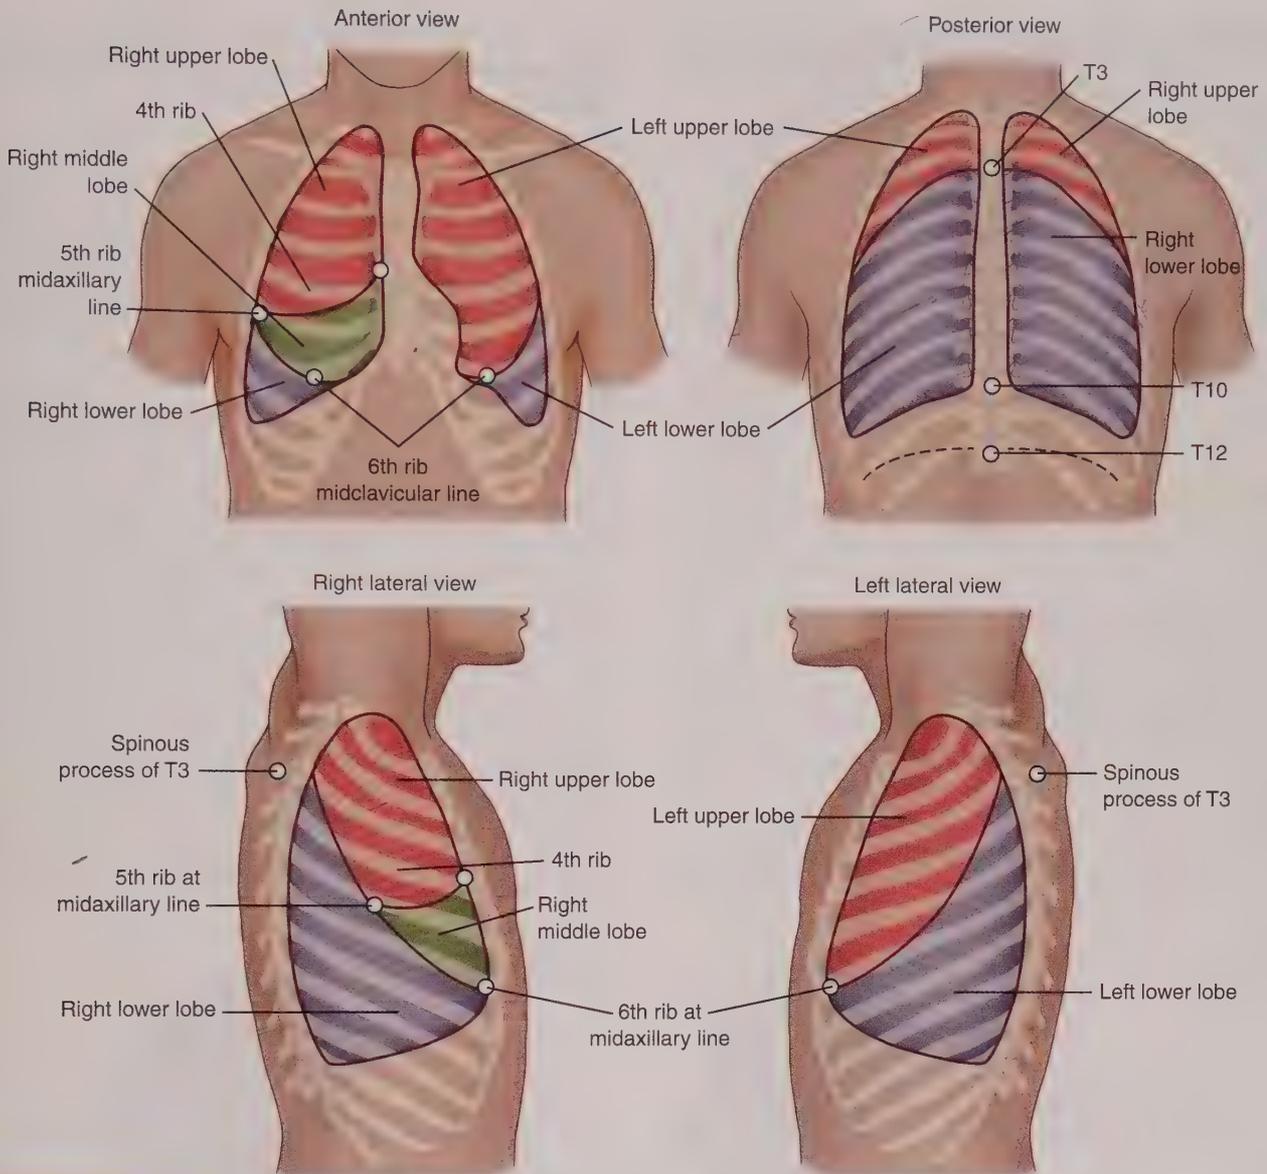

Once air travels through the lobar bronchi, it enters the bronchioles. The bronchioles are not made of cartilage and thus rely on the elastic recoil of the lungs to remain open. The bronchioles divide into terminal bronchioles, and each terminal bronchiole branches to form two or more respiratory bronchioles. Air travels through the respiratory bronchioles to the alveolar ducts, both of which are lined with **alveoli**, to the alveolar sacs, which are clusters of alveoli. Gas exchange occurs from the respiratory bronchioles down (Fig. 23.7). The alveolar membrane is very thin, which enhances the transfer of oxygen and carbon dioxide across the alveolar membrane. Alveoli secrete a substance called **surfactant** that prevents collapse, or atelectasis, from occurring. If atelectasis occurs, the alveoli are unable to participate in gas exchange, thus limiting the gas-exchange capacity of the lungs.

The lungs are covered in a thin membrane called the **visceral pleura**. The inside of the chest cavity is covered in a membrane called the **parietal pleura**. The space between the parietal and visceral pleurae is called the **pleural space**. Pleural fluid, secreted by the pleural cells, is secreted between the two layers and acts as a lubricant. This allows the lungs to move freely during inspiration and expiration (Fig. 23.8).

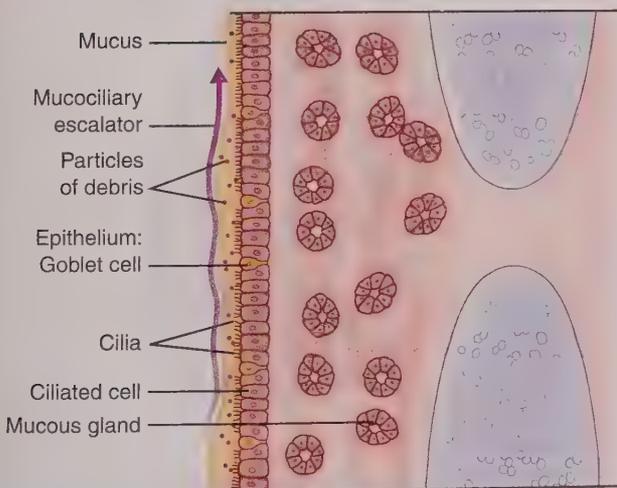

## Physiology of the Respiratory System

### Inspiration

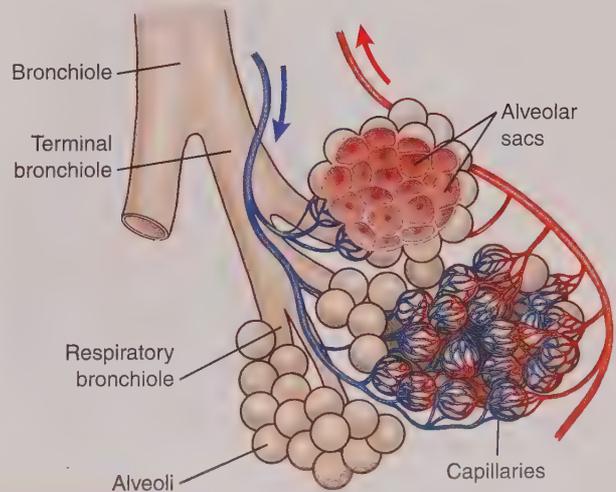

In order for ventilation to occur, there has to be movement of the diaphragm. The diaphragm resides below the lungs in the thoracic cavity. Inspiration occurs when there is stimulation of the phrenic nerve. The phrenic nerve is responsible for the movement and contraction of the diaphragm. Contraction causes the diaphragm to lower, compressing the abdominal contents and pulling the parietal pleura down to allow for expansion of the chest cavity. The expansion of the chest cavity increases the volume capacity of the lungs and decreases the pressure within the lungs to below atmospheric pressure. The decrease in

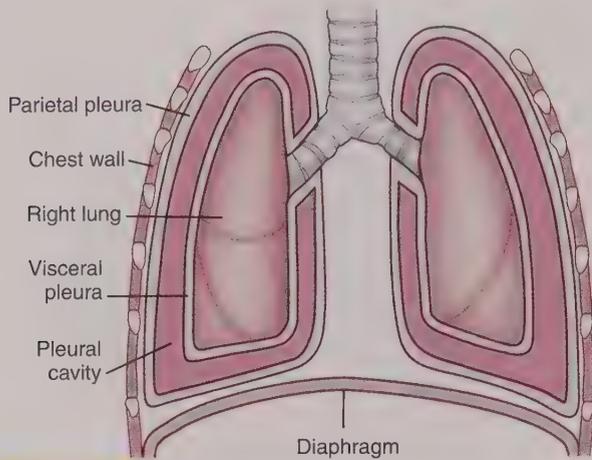

**FIGURE 23.5** Lobes of the lungs: upper, middle lower on the right; upper and lower on the left.

**FIGURE 23.6** The movement of mucus and bacteria or debris up the mucociliary evaluator via the movement of the cilia.

**FIGURE 23.7** Terminal airways; gas exchange takes place from the respiratory bronchiole down to the alveolar sac.

**FIGURE 23.8** Membranes covering the lung and chest cavity, the parietal and visceral pleurae, and the space in between, the pleural space.

pressure of the lungs to below atmospheric pressure causes air to rush in because air moves from areas of high pressure to areas of low pressure.

During periods when there is increased demand for oxygen, such as periods of exercise, the body engages the muscles responsible for inspiration. They consist of the external intercostals, sternocleidomastoid, serratus anterior, and scalene muscles, which lift the rib cage during inspiration. The lifting of the rib cage combined with contraction

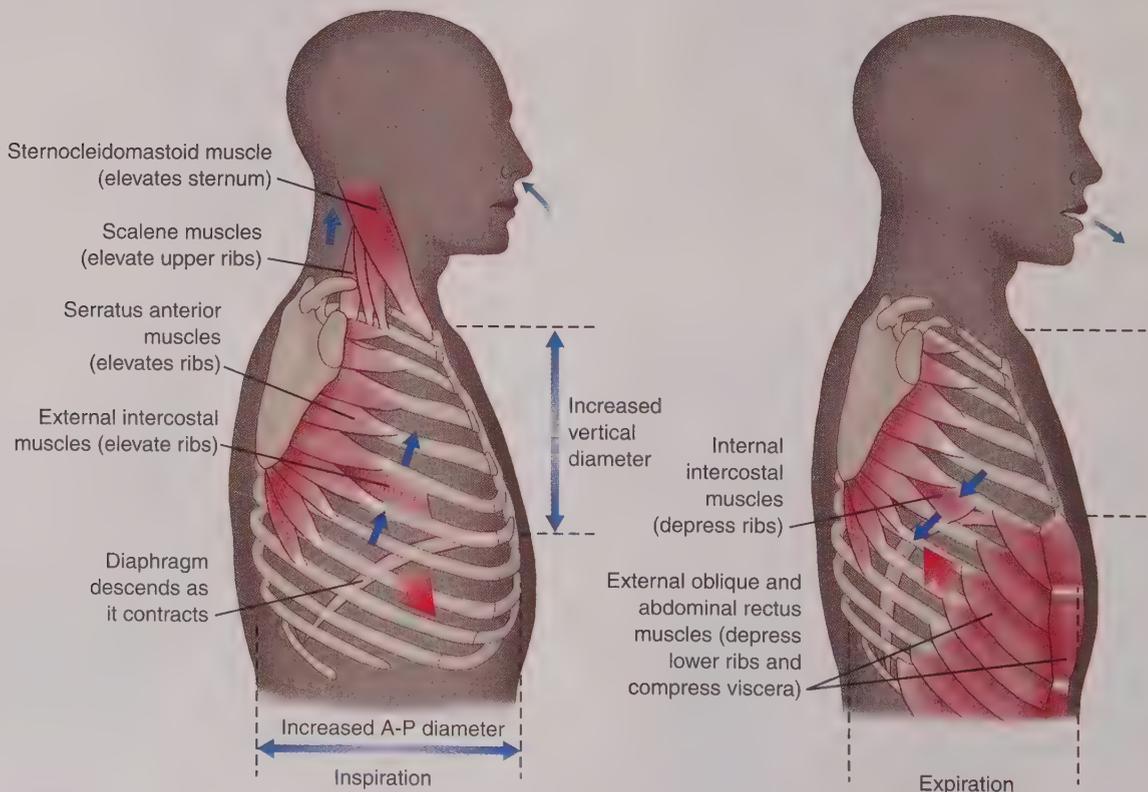

of the diaphragm increases the anteroposterior diameter of the chest by 20%, thus increasing the amount of air inhaled during inhalation (Fig. 23.9).

### Expiration

Expiration is a passive process that occurs as the diaphragm relaxes. As the diaphragm relaxes, pressure is exerted on the lungs by the chest and abdominal cavity. The decrease in the size of the thoracic cavity causes an increase in pressure within the lungs that exceeds atmospheric pressure, causing air to passively leave the lungs through expiration.

### Respiration

Respiration is the exchange of oxygen and carbon dioxide at the alveolar level. The respiratory bronchioles, alveolar ducts, and alveolar sacs contain or are lined with alveoli and thus participate in respiration. Each alveolus is covered in a capillary membrane. These capillaries carry deoxygenated blood returning from systemic circulation. The deoxygenated blood flows through microscopic capillary beds to allow the red blood cells to come into contact with the capillary wall. The area of contact is known as the **respiratory membrane**. This membrane allows for the diffusion of oxygen into the red blood cells and carbon dioxide into the alveoli. The diffusion of these gases occurs because of a difference in the concentrations and thus pressures exerted by these gases between the red blood cell and alveoli. The concentration of oxygen is higher within the alveoli, causing

**FIGURE 23.9** The muscles of respiration. The movement of the diaphragm and muscles of respiration during inspiration decrease the pressure within the lungs to below atmospheric pressure, allowing an influx of air. On expiration, the diaphragm relaxes and ascends, increasing pressure within the lungs and allowing air to passively exhale.

oxygen to diffuse across the respiratory membrane into the red blood cell. The concentration of carbon dioxide is higher within the red blood cell, causing the diffusion of carbon dioxide into the alveoli.

### Dead Space/Shunt

Areas of the tracheobronchial tree that do not participate in gas exchange or respiration are referred to as **dead space**. There are two types of dead space within the respiratory system, anatomical and alveolar. All of the structures from the nose or mouth to the level of the respiratory bronchioles are filled with air but do not participate in gas exchange, so they are considered **anatomical dead space**. **Alveolar dead space** occurs when there is impaired or absent respiration at the level of the alveoli. This can occur when there is a lack of perfusion of the alveoli by the pulmonary capillaries. **Physiological dead space** is the sum of both anatomical and alveolar dead space. In patients with normal or healthy respiratory function, physiological dead space is typically equal to anatomical dead space.

Whereas dead space refers to alveoli that do not participate in gas exchange, **shunt** refers to blood that does not participate in gas exchange, or blood that returns to the left heart without being oxygenated. The two types of shunts are anatomical and physiological. Anatomical shunt refers to blood moving from the right to the left heart without traveling through the lungs. This can be caused by congenital heart defects. Physiological shunt occurs when alveoli are not functioning even though there is perfusion by the pulmonary capillaries. As a result, a portion of the blood returns to the left side of the heart deoxygenated. A shunt unit can occur as a result of atelectasis or collapse of the alveoli.

### Ventilation–Perfusion Mismatch

Both dead space and shunt may result in a **ventilation–perfusion (V/Q) mismatch**. As noted previously, when there is no perfusion of functioning alveoli by the pulmonary capillaries (dead space) because of an obstruction of blood flow through the pulmonary capillaries, there is a high ventilation–perfusion mismatch, or adequate ventilation with poor perfusion. This can occur when there is a pulmonary embolism obstructing flow through the pulmonary artery. When there is adequate perfusion through poorly functioning alveoli (shunt), there is a low ventilation–perfusion mismatch, or poor ventilation with adequate perfusion (Fig. 23.10). A low V/Q mismatch can occur when a patient has pneumonia.

## Connection Check 23.2

Which of the following structures actively participates in gas exchange?

- Bronchi
- Visceral pleura
- Respiratory bronchioles
- Terminal bronchioles

## CASE STUDY: EPISODE 2

The evaluation of Mr. Thomas's complaint of shortness of breath continues with a medical history.

**Past medical history:** chronic obstructive pulmonary disease (COPD) and hypertension. He is unsure of his immunization status and does not remember receiving a PPD, or purified protein derivative skin test (most commonly a Mantoux test) to assess for TB, and he denies receiving a flu shot.

**Past surgical history:** Denies

**Allergies:** No known medication, food, or environmental allergies

**Medications:**

Amlodipine (Norvasc), 10 mg PO daily

Hydrochlorothiazide (HydroDIURIL), 25 mg PO bid

Salmeterol (Serevent), 50 mcg inhaled bid

Budesonide powder (Pulmicort), 90 mcg inhaled bid

Albuterol (Proventil), 2 puffs inhaled prn

Multivitamin, 1 tablet PO daily...

## ASSESSMENT

### History

History of present illness (HPI) is an important component of the assessment process. Information that should be obtained during the HPI includes:

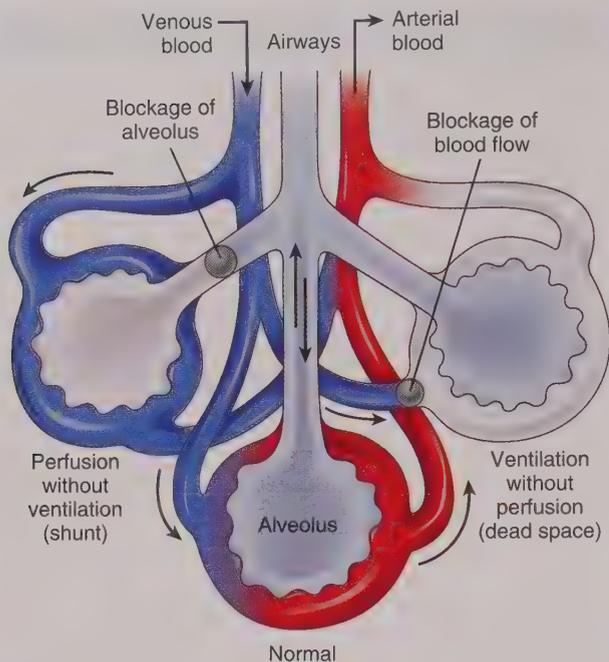

- Factors that exacerbate or improve symptoms
- Pain
- Cough
- Change in weight
- Dyspnea

### Factors That Exacerbate or Improve Symptoms

Factors that exacerbate or improve symptoms should be assessed to help determine the cause and degree of the illness. Factors such as walking, climbing stairs, or remaining at rest can indicate the level of strain on the respiratory and cardiac systems. If symptoms do not improve at rest, it may indicate a greater degree of dysfunction than for a patient whose symptoms are present only with activity but improve at rest.

### Pain

Pain assessments should include quality, location, radiation, severity, and precipitating factors. Patients reporting pain in the thorax may have dysfunction of the cardiac, gastrointestinal, and/or respiratory system. Patients with a respiratory disease process may not experience any symptoms of pain because of the lack of sensory nerves in the lungs and visceral pleura. Conversely, the parietal pleura is able to generate a pain response. The parietal pleura may become inflamed (pleurisy) and cause pain that can be described as

**FIGURE 23.10** Ventilation-perfusion mismatch. On the left, perfusion without ventilation = shunt. On the right, ventilation without perfusion = dead space.

rubbing, sharp, or stabbing. It occurs because of the movement of the pleura during ventilation. In addition, pain caused by the respiratory system is normally increased with inspiration, deep breathing, and coughing because all of these cause movement of the parietal pleura.

### Cough

Patients with a cough may have a productive or nonproductive cough. The frequency, duration, and presence of sputum production should be noted. The nurse should assess the color, volume, odor, consistency, and characteristics of the sputum. The assessment of the sputum will be helpful in understanding the possible causes of the cough. For example, pneumonia causes the production of thick sputum. A dry cough may be from asthma, a viral infection, or seasonal allergies.

#### Safety Alert

Patients reporting a productive cough with the following symptoms should be screened for tuberculosis (TB):

- Hemoptysis (bloody sputum)
- Low-grade fevers
- Weight loss
- Night sweats

Tuberculosis is a highly contagious illness that is transmitted via the air. Any patients with the previously listed symptoms should be placed in respiratory isolation until TB is ruled out to ensure the safety of the patient and providers.

### Changes in Weight

Patients with recent weight changes need to be evaluated to determine if the changes in weight occurred with the onset of respiratory symptoms. Patients who have had recent weight gains and respiratory complaints will have an increased risk for sleep apnea or pauses in breathing during sleep. For patients with weight loss, the nurse needs to assess if the loss is due to lack of food intake. Many patients with respiratory complaints may have weight loss due to fatigue and shortness of breath with eating. Weight loss is common in chronic respiratory conditions such as COPD. A 24-hour food recall is a helpful tool to assess the dietary intake of a patient. The food recall will help the nurse understand the amount and the nutritional value of the patient's diet, providing insight into weight loss or gain.

### Dyspnea

During assessment, **dyspnea**, the patient's perception of being short of breath, should be assessed for patients with respiratory complaints. It is important to note that dyspnea is based on the patient's perception; therefore, it is a subjective finding. Because dyspnea is a subjective finding, objective data are needed to identify the cause; dyspnea may be caused by nonrespiratory disease processes such as anxiety.

### Health History

Once the nurse has evaluated the HPI, a detailed health history should be obtained. The nurse needs to assess the patient's current medications; allergies; past medical history; previous surgeries; family history; occupation/area of residence; and smoking, social, and recent travel histories.

### Current Medications

Prescribed medications, herbal supplements, vitamins, and over-the-counter medications need to be documented. Patients with chronic respiratory disease processes should be asked about recent changes in medications, dosage, and/or frequency of administration. Changes in medication may account for the noted change in a patient's respiratory status. For example, a patient who starts a new respiratory medication but discontinues his or her previous therapy may experience improvement, worsening, or no change in symptoms. If the patient experiences a worsening in symptoms, it may indicate that the new medication regimen is not sufficient. In addition, many nonrespiratory medications have respiratory side effects. For example, angiotensin-converting enzyme (ACE) inhibitors used to treat hypertension may cause patients to develop a dry, nonproductive cough.

### Allergies

The environment, food, and medications can all cause allergies. Environmental allergens may be found within or outside the home. Examples include fumes, chemicals, pollen, pets, and dust. Food allergies may be from food preservatives/additives or may be due to actual food items. Any allergy may cause shortness of breath, wheezing, or cough.

### Past Medical History

Past medical history includes any previous acute illness, previous respiratory infections, and chronic disease processes. The current status of chronic disease processes should be noted (improving, worsening, or no change). The patient's immunization status should be evaluated, with particular attention to pertussis, pneumonia, and flu (novel and seasonal) vaccinations. In addition, patients should be asked for previous PPD results. Patients with a positive PPD need to have the date of the last chest x-ray documented.

### Previous Surgeries
